Let the sets of user-set v which contains the user k is $\mathcal{I}_k$ and the sets of user-set in which the transmissions of user k are successful is $\mathcal{I}_k^s \subset \mathcal{I}_k$. Thus, the throughput of user k is given as

$$\lambda_k = C_k \sum_{v \in \mathcal{I}_k^s} \pi(v). \tag{4}$$

where, C_k is the data rate of user k. This model can be used for the both MIMO schemes and hence, the difference will be in the set $\mathcal{I}_k^s$ and data rate C_k. The main complexity in computing the throughput of a user k is to enumerate all the successful user-sets $\mathcal{I}_k^s$. Under the exhaustive search method, for the both MIMO schemes, one has to check the condition of successful transmission of data stream(s) of a user for $\sum_{i=N'}^{U-1} \binom{U-1}{i}$ user-sets using the condition in Section II-C, where N' is number of data streams transmitted by user k depending on the used MIMO scheme. The value of C_k is given by $N'c_k$; where, c_k is the data rate of a data stream of user k. The value of c_k can be determined according to Section II-E. Thus, the complexity of computing the throughput of a user in a WLAN increases exponentially with the number of users.

C. Energy Model

Two modes are considered for a node: IDLE and TRANSMIT. In the IDLE mode, a node senses the carrier in each mini-slot and in the TRANSMIT mode, a node transmits data stream(s). Let $\frac{P_t}{\alpha}$ be the power consumption when a node is in the IDLE mode, where α is ratio of the energy consumptions in the TRANSMIT and IDLE modes. It is assumed that the energy consumption does not depend on data transmission rate. Further, the energy required for processing signal of a data stream at transmitter and receiver is neglected. The energy consumption per second for the transmissions by a user-set v is given as

$$E_v = \left(|v| P_t + (U - |v|) \frac{P_t}{\alpha} \right) \pi(v). \tag{5}$$

The total energy consumption per second is then given as

$$E = \sum_{v \in \mathcal{I}} E_v = \sum_{v \in \mathcal{I}} \left(|v| P_t + (U - |v|) \frac{P_t}{\alpha} \right) \pi(v). \tag{6}$$

Approximating $(\alpha - 1) \approx \alpha$, (6) can be written as

$$E \approx \frac{U P_t}{\alpha} + P_t \sum_{v \in \mathcal{I}} |v| \pi(v). \tag{7}$$

The number of user-sets in $\mathcal{I}$ is 2^U and hence, the computation complexity of energy computation increases exponentially with the number of users. For a given transmission probability, $\pi(v)$ is the same for the SU-MIMO and MU-MIMO schemes for a user-set v, thus the total energy consumption is the same for the both MIMO schemes for a given MAC parameter and it is independent of the number of MIMO communication antennas.

IV. Numerical Results

A. Networks and Parameters

Five WLAN scenarios each consisting of 19 users and an AP are considered. The AP is located at the centre surrounded by the users. The positions of the users are determined by a uniform random distribution. One of the WLAN scenario (WLAN-1) is shown in Fig 1, where the AP is labelled as a rectangular box. It is assumed that for a data stream a user can use one of the 10 modulation and coding schemes in an 80 MHz channel depending on the SNR of the data stream at the AP. The data rates and the SNR thresholds for the different modulation and coding schemes are illustrated in Table I. The transmission power and the noise power are considered to be 10 dBm and -100 dBm, respectively. Considering the indoor WLAN environment, the path loss exponent and the far field cross-over distance are assumed to be 4 and 1 m, respectively. The transmission time of each packet is taken to be 200 mini-slots.

TABLE I
DATA RATES AND THE CORRESPONDING SNR THRESHOLDS.

Data Rate (Mbps)	Modulation	Coding Rate	SNR Threshold (dB)
15	BPSK	1/2	8
30	QPSK	1/2	11
45	QPSK	3/4	13
60	16-QAM	1/2	16
90	16-QAM	3/4	20
120	64-QAM	2/3	24
135	64-QAM	3/4	25
150	64-QAM	5/6	26
180	256-QAM	3/4	30
200	256-QAM	5/6	32

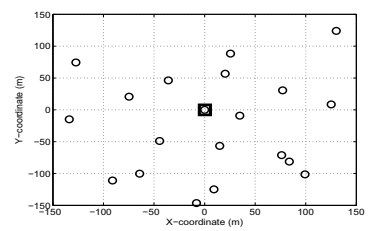

Fig. 1. Positions of the nodes in WLAN-1.

B. Comparison of Total Throughput

For each of the WLAN scenarios, the total throughputs are computed for different transmission probabilities by using the throughput model under the two MIMO schemes. The total throughput of each WLAN scenario is shown in Fig. 2, where the same marker is used for a WLAN scenario for different MIMO schemes and different number of MIMO communication antennas. It is observed that the SU-MIMO scheme provides better throughput than the MU-MIMO scheme when the number of MIMO communication antennas is 4. However, the optimal throughput of the MU-MIMO scheme is higher than that of the SU-MIMO scheme when the number of MIMO

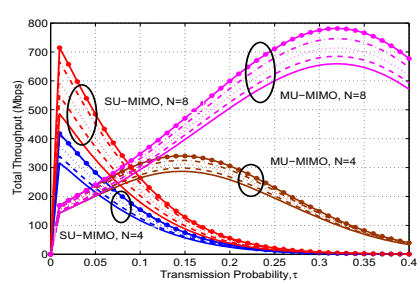

Fig. 2. Comparison of total throughput of the SU-MIMO and MU-MIMO schemes.

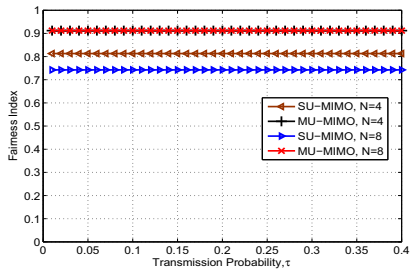

Fig. 3. Comparison of fairness index of the SU-MIMO and MU-MIMO schemes for WLAN-1.

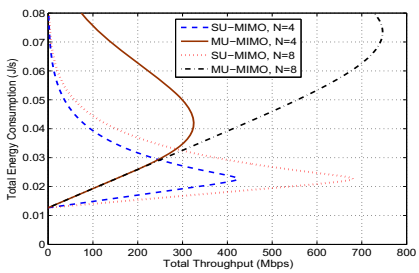

Fig. 4. Total energy consumption in the SU-MIMO and MU-MIMO schemes for WLAN-1.

communication antennas is increased to 8. The throughput optimal transmission probability of the MU-MIMO scheme is higher than that of the SU-MIMO scheme which increases significantly for the MU-MIMO scheme with increasing the number of MIMO communication antennas. This is due to the fact that a higher number of antennas at the AP allows it to receive a higher number of data streams simultaneously from a higher number of users and hence, a higher transmission probability causes to transmit a higher number of users at the same time.

C. Comparison of Fairness

To investigate the fairness among the users, for the both MIMO schemes, the throughput of each user of the WLAN-1 is computed and then the Jain's fairness index (FI) [12] is calculated as $FI = \frac{\left(\sum_{k\in\mathcal{U}} \lambda_k\right)^2}{U \sum_{k\in\mathcal{U}} \lambda_k^2}$. The FI of WLAN-1 with transmission probability is depicted in Fig. 3. It is observed that the FI of the WLAN does not change with transmission probability for the both MIMO schemes. This is due to the fact that physical layer capture is absent in the WLAN for using a large number of data rates. Further, the FI of the MU-MIMO scheme is higher than that of the SU-MIMO scheme. This is due to the fact that, in the SU-MIMO scheme, the users located close to the AP obtain the highest data rate and contribute mostly in the total throughput. On the other hand, in the MU-MIMO scheme, the contribution of each user in total throughput is more or less very close in value since multiple users can transmit their data streams successfully at the same time. Similar fairness results are also generated for the other 4 WLAN scenarios and found the similar insights.

D. Comparison of Energy Consumption

The total energy consumption of the WLAN-1 is computed for different values of transmission probability under the both SU-MIMO and MU-MIMO schemes. The value of α is assumed to be 15 in computation of energy. Since for a given transmission probability, the energy consumption is the same for the both MIMO schemes and the total throughput is different, the energy consumptions of the both MIMO schemes to achieve the same throughput are calculated for the WLAN-1 and plotted in Fig. 4. From the plots it can be observed that the SU-MIMO scheme is more energy efficient than the MU-MIMO scheme. We attribute this to the fact that the same throughput is achieved by the MU-MIMO scheme at a higher value of transmission probability (See Fig. 2) and the energy consumption increases with increasing the value of transmission probability for increasing the attempt rate of the users. Similar results are also generated for the other 4 WLAN scenarios and found the similar conclusions.

V. Conclusion

In this paper, the total throughput, fairness and energy consumption performances are studied in CSMA/CA based uplink WLAN under SU-MIMO and MU-MIMO techniques. Analytical models are provided to compute the throughput of each user and the total energy consumption of a WLAN. Through numerical results of several WLAN scenarios, it is demonstrated that the MU-MIMO technique is more beneficial than the SU-MIMO technique in term of throughput only when the number of MIMO communication antennas is high and the MAC parameters of the users are chosen properly. However, the energy consumption increases significantly for achieving the higher throughput with the MU-MIMO technique.The MU-MIMO technique provides better fairness over the SU-MIMO technique.

HETNET Neighbour Handover Cell List Optimization Based On Cognitive Programmed Threshold Response

Sanyat Hoque, Shovon Pal, and Atiqur Rahman

Department of Electrical and Computer Engineering
North South University, Dhaka, Bangladesh

sanyat.hoque@gmail.com, shovon.pal.bd@ieee.org, atiqur@northsouth.edu

Abstract—- **The growth of mobile broadband has unleashed the necessity of advance mobile network structure. Heterogeneous Network (HetNet) technology is designed to be highly adaptable in subscribers' homes to provide high data rate communications with good quality of service. Femtocells are the indoor nodes of HetNet. Efficient handover of calls is the priority for successful femtocell/macrocell joint transmission. Handoff of femtocell-to-femtocell handover is the most visible challenge for dense deployment of nodes. This particular handover needs minimum as well appropriate neighbouring cell list which is needed for its successful operation. In this paper, we proposed an algorithm for dense femtocells deployment, i.e., an algorithm to create an optimized neighbour cell list with minimum number of femtocells (including the reduction of interfering femtocells and finding hidden ones). An appropriate and optimal neighbour femtocell list is mandatory for the much needed dense femtocellular network deployment in the near future. Therefore, reducing the size of the neighbour femtocell and making the list more efficient results in minimizing the amount of scanning and signal flow of mobile station during handover.**

Keywords: Handoff, HetNet, Femtocell, SON.

I. INTRODUCTION

The demand for high data rate for wireless communication is increasing in exponential growth [1]. Existing mobile data communication systems faces various challenges [2] to support high wide band data access. Both the coverage area and the capacity of existing cellular network systems are not sufficient to meet the expected demand of multimedia traffics. Closer transmitter and receiver of a wireless system cause increase in capacity of a wireless link and creates dual benefits of higher quality links and more spatial reuse. So among many approaches femtocell approach is one of the best approach to diverse the load from the cellular networks as well as to reduce the operating and capital expenditure costs for operators. In Heterogeneous network environment of the mobile communication network design, femtocells are taken as a home base station solution of the data offloading problem and coping up with the OPEX problem.

The HETNET Scenario comprises with macrocell along with the small cell nodes like femtocell, picocells, etc. The femtocells are enabled with SON capability [3]. Their special care with respect to SON(Self-Organizing Networks) shall be taken for mass deployment scenarios like in the case of Home eNodeB, i.e. for In and Outbound Mobility for Home eNodeB and problems caused by incorrect behaviour of Home eNodeBs. With the deployment of the Home eNodeB, the handover between femtocell and 3GPP macrocell networks is becoming more and more important, mostly in the LTE based networks. Thousands of femtocells within a macrocell area will create a large neighbour cell list and interference problem where the modifications of handover procedures for existing networks are needed.

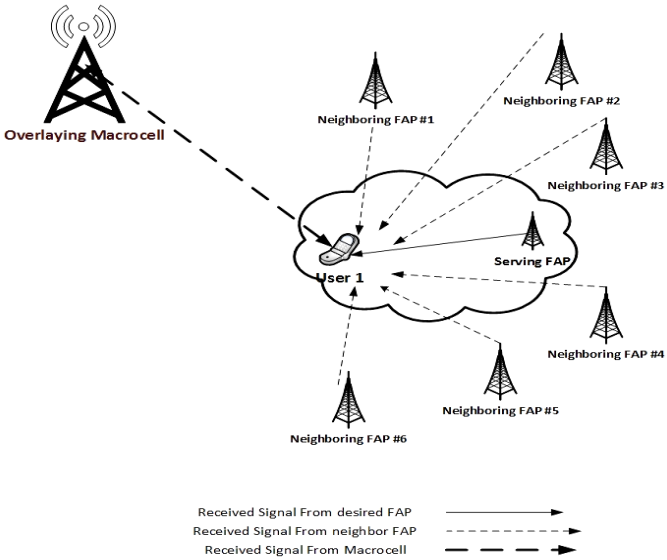

Fig. 1. Dense deployment scenario of eNodeB

In figure 1, the dense deployment scenario has been illustrated of dense deployment of small cell femtocell (eNodeB) in an under-laid macrocell environment. With the received signal indicator, the problem of unplanned deployment has been shown with a perspective view of one user. With the interference problem [4], the Handoff problem emerges as well. With the localization change of the user the neighbour cell list expands correspondingly and the efficiency of handoff decays-so the QoS of network experiences bad data signal from the adjacent femto access points (FAPs). The remainder of this paper is organized as follows: The related works are discussed in Section II. We present the system model and analyse the proposed scheme in Section III. In Section IV, cell association and handover management algorithms are proposed. The performance evaluation and analysis is shown in Section V. Section VI concludes this paper.

II. RELATED WORK

Deployment of femtocells at a large scale is the final objective of this technology. Zhang et al. [5] presented a handover optimization algorithm based on the UE's mobility state. Soldani and Ore report results on self-optimization of NCR lists for UTRA FDD networks using DSR measurements [6]. Traditional schemes (e.g., [6,7]) based on the received signal strength indicator (RSSI) are used for the existing cellular system. But none of them provided a clear definition of optimized neighbour cell list for HeNodeB to HeNodeB handover. The neighbour eNodeB list based on only the RSSI will contain a large number of femtocells in the list. Features like self-organizing network (SON) capability and FAP management system should be added to the HetNet for improved performance.

III. SYSTEM MODEL

The existing macrocellular networks utilize centralized RNC to control their associated macro base stations (BSs). One RNC is in charge of radio resource management of approximately 100 macro BSs. Femtocells are deployed within a macrocell coverage area or within a separate zone. The recent change in the network optimization, ie. small cells like femtocells, being overlaid within the macrocell network for the purpose of data offloading and serving the cell edge users with a better data quality. This change is named as Heterogeneous network or the HETNET. In figure 1, there is an illustration of the HETENT network with a reference user in the network mode-under the couple of unplanned FAP (Femto access points) under laid in the macrocell. Initially the user is in the region of FAP#1 but as long as the user is not static it will experience the interference from the adjacent FAPS and strong interfering signal from the macro cell as well. This interference issue is not the leading topic in the research. Along with the interference the Hand off issue arises in a big questionable fact.

In a dense HETNET deployment, a lot of femtocells are deployed within small coverage area. Therefore, there may be huge interference effects. Whenever a mobile station (MS) realizes that the receive signal from the serving femto AP (FAP) is going down, the MS receive many signals from the several neighbour FAPs for the handover. The hidden FAP problem arises when a neighbour FAP is very close to the MS but the MS cannot receive the proper amplitude of signal it is supposed to due to a barrier between the MS and that FAP. So, that particular hidden FAP will be out of neighbour femtocell list if the neighbour femtocell list is designed based on the receive signals only as in the case of traditional schemes. In the case of the use of same frequency by surrounding T-FAPs and S-FAP, the corresponding T-FAPs should be avoided to avoid interference. Femtocells that uses the same frequency that matches with S-FAP should only be used that is located far enough apart. In a more recent scheme [8], two threshold levels are used in order to determine the NCL. The first threshold (S_{T0}) is a pilot signal at -90 dBm that is used to detect FAPs in the surrounding area. The second threshold, S_{T1} is higher (-75 dBm) than the first threshold which is responsible for adding the corresponding T-FAPs in the NCL. Use of stationary thresholds in these schemes prevent many potentially important FAPs to be included in the final NCL.

IV. OPTIMIZED NEIGHBOUR FEMTOCELL LIST

In my proposed algorithm, value of upper threshold depends on the density of femtocells keeping -90 dBm as the minimum signal for femtocell detection in coverage area. Therefore, by increasing the value of S_{T1} with the increasing density of femtocells (S_{T2}), the number of femtocells in the neighbor cell list can be reduced yet optimized. Chowdhury et al.[8,12] proposed a scheme of neighbor cell list based on reduction of femtocells using the same frequency as the serving FAP to reduce Co channel interferences along with the inclusion of hidden FAP detection based on the increased threshold compared to the threshold of Traditional Scheme.
In my proposed scheme, the approach starts with the RSSI level indicator from the neighbouring FAPs. The FAPs that are initially listed as the neighbour femtocell list based on the received RSSI level can be expressed as set N_1:

$$N_1 = |\{...FAPi(RSSIi),...:1 \leqslant i, RSSI_i \geqslant S_{T2}\}| \quad ; \quad (1)$$

where, FAPi(RSSIi) represents that *i-th* neighbour FAPs from where the received RSSI level is greater than or equal to S_{T2}. During the deployment of dense femtocellular network, neighbouring FAPs using the same frequency as the S-FAP should be cut off from NCL to prevent frequency interference. So from the neighbor femtocell list we deduct those femtocells which use same frequency as the serving femtocell. The femtocells those can be categorized in this group can be expressed as set N_2:

$$N_2 = |\{...FAPk(f_k),...:1 \leqslant k, N_2 \subseteq N_1, RSSI_k \geqslant S_{T2}\}| \quad ; \quad (2)$$

where, FAPk (f_k) is the *k-th* neighbor femtocell that uses the same frequency as S-FAP. Hidden FAPs are femtocells that are very close to Serving Femtocell but cannot be detected due to an obstacle. The hidden FAP problem is tackled using SON based coordination between S-FAP and its surrounding neighbouring FAPs to find out location of the hidden FAPs. Hidden femtocells are chosen where the received RSSI level is less than S_{T2}, or femtocells using the same frequency as the serving femtocell. Since the serving FAP can coordinate with nearest FAPs, those femtocells can inform the location of some hidden FAPs. Therefore, the hidden femtocell nodes within a specific range of distance can be included in the neighbour femtocell list. The femtocells those can be categorized in this group can be expressed as set M:

$$M = |\{...FAPm(RSSI_m, f_m, d_m),...:1 \leqslant m, ((RSSI_m < S_{T2}) \vee (fs \cup fm = fs)) \wedge (d_m \leq d_{max})\}| \quad ; \quad (3)$$

where, d_{max} is the predefined maximum distance between MS and mth FAP that is set by Mobile Operator depending on propagation environment.

Based on the new proposed cognitive algorithm depending on femtocell density in a coverage area, proposed neighbour femtocell list is as follows:

$$N_f = N_1 - N_2 + M \quad ; \quad (4)$$

Similarly, the corresponding exponential polynomial function is given below:

$$S_{T2} = \{-41.5 \times exp(-0.019n)\} - T_{\max} \quad ; \quad (5)$$

where,

n = Number of Femtocells in its coverage vicinity,
T_{max} = Maximum Threshold Mobile Operator can allow (-50 dBm is taken to be the maximum in this model scenario).

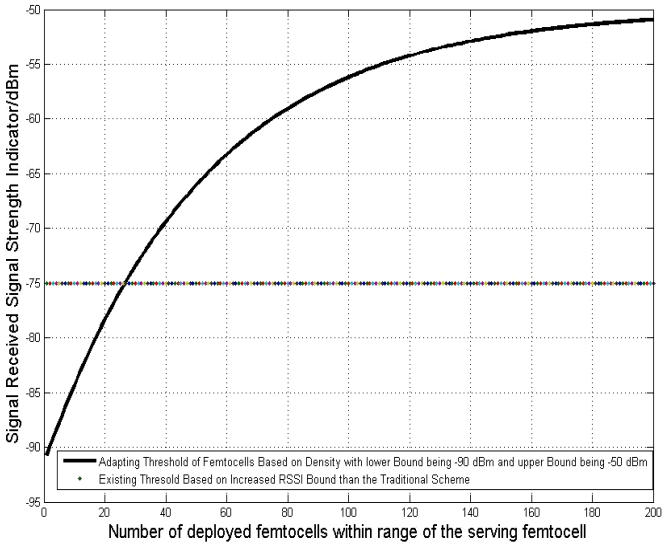

Fig. 2. Maximum and Minimum Threshold of RSSI that MS would accept.

The algorithm is illustrated in Table. 1 below:

Table. 1. Optimized Cell list algorithm

1. **Start**
2. Detection of downwards signal from S-FAP
3. While Checking signal level of #N femtocells
   if $N_f = N_f - 1$ exclusion for set N1, added on M set
   else Frequency of potential T-FAP is checked whether it is the same as S-FAP.
   else if $N_f = N_f$ Kth FAP included in N1 list
4. Checking # neighbor Femtocells of RSSI level ≤ ST2
   if d ≤ dmax, include the FAP in Set M
5. Add Set M with N_f $(N_1 - N_2)$, $N_f = N_f + M$
6. **end**

This cognitive programmed threshold density-based response function (S_{T2}) as shown in figure 2 is an exponential polynomial function that gives the final upper bound to –50 dBm (T_{max} or any value set by the operator) and makes the lower bound to be –90 dBm depending on femtocell detection in its coverage vicinity. The variable threshold rapidly rises from very low threshold of RSSI to accommodate closer femtocells with greater signal power and then passes the mark of –75 dBm rapidly after acquiring fairly adequate number of femtocells in its cell list while keeping the RSSI for femto detection constant at –90 dBm. Only after acquiring a decent number of T-FAPs in its neighbour femtocell list, threshold rises and eventually stops at –50 dBm. This is done so that new femtocells can be added by the mobile operator through increasing the transmission power of any particular T-FAP to more than –50 dBm. If increasing the desired T-FAP's propagation power and thus its RSSI level to S-FAP becomes more than –50 dBm, then that T-FAP would still be included in the neighbour femtocell list despite having significant number of femtocells that has been already added to neighbour cell list.

V. THE PERFORMANCE EVALUATION AND ANALYSIS

For simulation model, four carrier frequency were used (0.7 GHz, 1.8 GHz, 2.1 GHz, 3 GHz) which were distributed randomly along with the Poisson distribution of femtocells around the simulation area of 1000 m. Call arriving processes are assumed as Poisson. Also, a random distribution of hidden femtocells is assumed.
The indoor propagation path loss prediction model for ITU model in dBm [9], [10], [11] is:

$$PL = 20 \log_{10}(f) + N \log_{10}(d) + L_f(n) - 28 \text{ dB} \quad ; \quad (6)$$

Distance power loss coefficient, N is the quantity that expresses the loss of signal power with distance. Floor penetration loss, L_f (n), where n ranges from 1-3.

Table. 2. Parameters used for simulation

- Radius of femtocell coverage area 10 m
- Carrier frequency for S-FAP 1.8 GHz
- Maximum transmit power by a FAP 10mW
- Number of deployed femtocells in scenario 200
- Standard deviation for lognormal shadowing loss 4
- Penetration loss 20 dB
- Power Loss Coefficient Values, N 30
- Coverage Area 1000 m

Referring to coefficient values, the path loss propagation of an indoor environment is being simulated and shown in figure 3. Based on this propagation model, we extend our result for the proposed algorithm for optimized cell list.

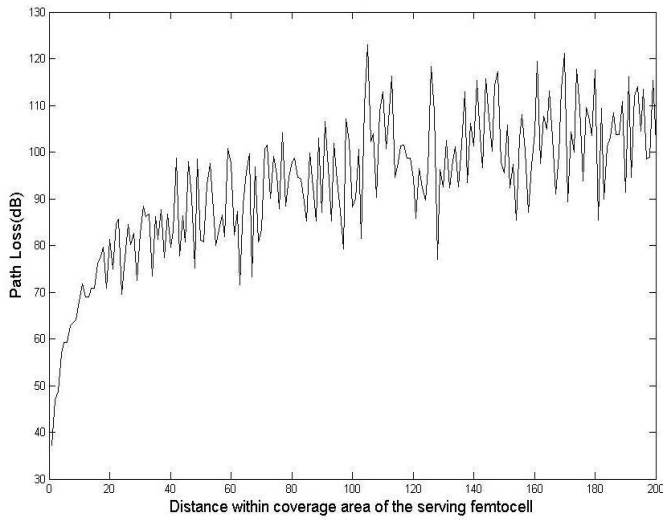

Fig. 3. Path loss with respect to distance between S-FAP and T-FAPs.

In the simulation in figure 4, we compare the performance of the traditional neighbour cell list management scheme [6,7] and the existing one [8,12] versus the proposed scheme. The result shows that neighbour femtocell list based on the proposed scheme contains only a limited number of femtocells during the handovers despite increasing number of FAPs in coverage area. The new algorithm completely optimizes the neighbour cell list. However, reducing number of femtocells in the neighbour femtocell list does not hamper handover efficiency. The new scheme rapidly adds a satisfactory number of femtocells but excludes most of the

unnecessary FAPs through: improved reduction of Co-channel interference femtocells and improved algorithm of finding Hidden FAPs, based on coverage area's density. This makes the algorithm more efficient and effective for handoff.

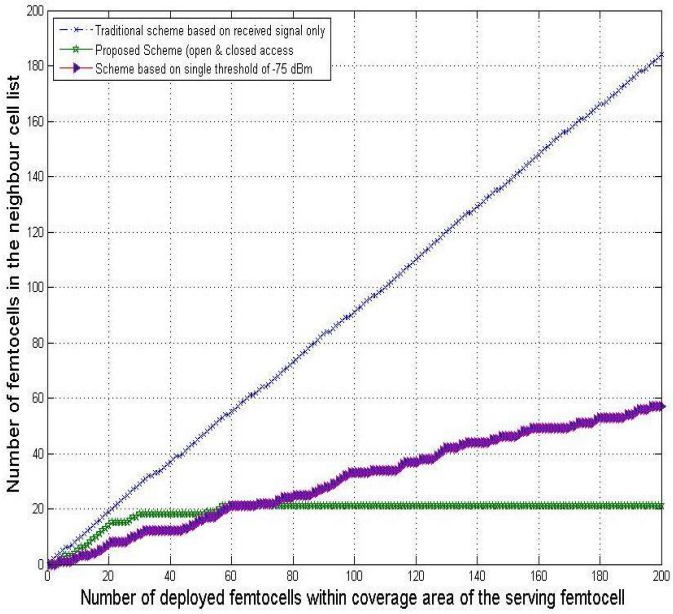

Fig. 4. Neighbour femtocell listing comparison.

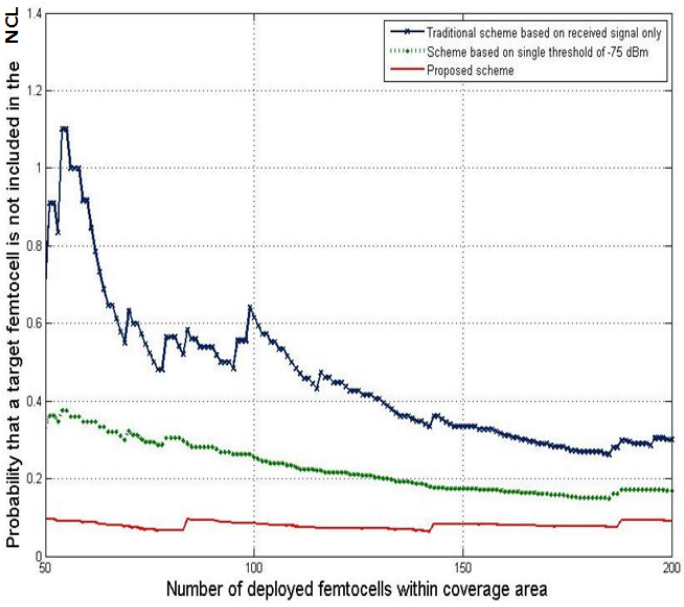

Fig. 5. Probability comparison that a target femtocell is not in its NCL.

Also, expected probability of missing target femtocell from neighbour femtocell list in traditional scheme is higher than the algorithm proposed by Chowdhury and Jang [8,12]. The proposed scheme improves the reduction of missing target femtocell probability by tackling and improving the co-channel interference problem and the Hidden FAP issue. The problem of hidden FAP is tackled in proposed scheme by checking for signals that are less than S_{T2} (i.e., less than -90 dBm initially as shown in fig. 2) at a threshold of a very small distance (10 m for this simulation model where maximum power loss occurs).

VI. Conclusions

In this paper, we proposed a novel approach to solve the mobility management concern for HETNET with dense deployment of small cells. The proposed SON-based algorithm is capable of handling large numbers of FAPs inside its coverage. On top of that, our proposed algorithm helps in improving to overcome the hidden FAP problem. The reduced neighbour cell list results in reduced power loss as well as reduced MAC overhead. The proposed handover neighbour cell list can be very effective to implement for handover processes in dense HETNET deployment.

Results found in this paper adequately show the advantage of our proposed schemes.

Abstract— **In recent days intense research is taking place on energy efficiency (EE) of a multi-user wireless network. In this paper we propose a model to detect EE based on limited user traffic model. We observe the variation of EE against the number of users and energy signal to noise ratio engaged by the user. The impact of enhancement of subcarriers on EE and channel capacity is also analyzed to reach an optimum condition of network performance. Finally satisfaction index (SI) is plotted against signal-to-noise-ratio (SNR) for different bandwidth of subcarriers.**

Index Terms— **Energy efficiency, OFDMA, satisfaction index, Markov chain, Engset traffic.**

I. Introduction

Mobile and wireless communication system has flourished over the last few years as a result of the increasing demands for high data rates and for supporting large number of users with guaranteed quality of service (QoS). With the aim to provide higher data rates and to optimize radio resource management, next generation wireless communication systems such as Wimax and 3GPP LTE has emerged recently. The LTE system has been designed based on the orthogonal frequency division multiple access (OFDMA) where the channel bandwidth is divided into large number of orthogonal subcarriers for multi-access purposes and effective reduction of the inter-symbol interference (ISI) and inter-carrier interference (ICI). Energy consumption is one of the substantial problems for the LTE system. A number of techniques have been studied so far to reduce the energy consumption and to design an efficient power model for LTE systems [1 - 3].

However, the performance of the OFDMA systems can be greatly improved through energy efficiency which has become the fundamental issue in recent wireless technology. The influence of subcarrier numbers, modulation techniques and resource allocation techniques in OFDMA systems has been studied in [4, 5]. To be able to operate a network in an efficient manner is a very difficult and complex task. At times, optimizing energy consumption in the one part of the network can enlarge power consumption and can degrade the performance on the other side of the network. For network optimization there should be trade-off among QoS, efficiency in capacity, coverage, etc. If we can adopt an intelligent power management which can monitor the traffic and power consumption of different components of the base station, it can identify idle components and can decrease the carriers in a time slot to provide energy efficiency. The power-efficient radio resource control mechanism can also be applied to achieve energy efficiency in multi-antenna packet radio system [6]. Different aspects of energy efficiency in modern and future telecommunication networks have been outlined in [7].

Some of the earlier researches on OFDMA systems considered energy efficient link adaptation technique to maximize energy efficiency [8]. Recent research focuses on energy efficient radio resource scheduling techniques. In [9], authors have proposed QoS aware energy efficient resource scheduling for multi-user OFDMA systems based on Lagrangian model. To address this issue, we have proposed a model to determine the energy efficiency using Engset traffic model. To observe the impact of varying the number of subcarriers on energy efficiency and channel capacity, we have done analysis in terms of number of users and signal to noise ratio (SNR) level. In addition to energy efficiency, to meet the expectation of the customers the main concern of modern marketing is to build a strong customer relationship. Customer satisfaction index (SI) is one of the key parameters by which companies can estimate the customer's satisfaction level [10, 11]. In this paper, we have examined the SI for our proposed model based on the relationship among SI, bandwidth, and SNR.

This paper is structured as follows. The system model is illustrated in section II. The numerical results for the proposed model are described in section III and finally, the paper is concluded in section IV.

II. System Model

Let us consider a central base station (BS) with M mobile users and N orthogonal subcarriers in an OFDMA cell. The SNR of the system can be defined as

$$\gamma = \frac{P_m^n \left| h_m^n \right|^2}{\sigma^2}, \tag{1}$$

where P_m^n is the transmission power for user m with allocated subcarrier n and h_m^n is the multi-path fading coefficient between the transmitter and receiver which is also known as

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

the complex fading experienced by user m and subcarrier n. σ^2 is the variance of the additive white Gaussian noise (AWGN) channel on each subcarrier.

The instantaneous transmission capacity can be denoted as

$$C_m^n = B\log_2(1+\gamma), \tag{2}$$

where B is the channel bandwidth. From equations (1) and (2), we get

$$C_m^n = B\log_2\left(1+\frac{P_m^n\left|h_m^n\right|^2}{\sigma^2}\right). \tag{3}$$

Let us now consider a binary variable $X_m^n \in \{0,1\}$. It indicates the assignment of subcarrier in a multi-user system, where $X_m^n = 1$ indicates n^{th} subcarrier is used by the mth user and $X_m^n = 0$ indicates n^{th} subcarrier is not used by the mth user.

The QoS requirement of a user m can be defined as

$$\sum_{n=1}^{N} C_m^n X_m^n \geq \overline{C}_m, \tag{4}$$

where $\overline{C}_m$ is the maximum rate required for user m.

The power consumed by a base transceiver station (BTS) can be defined as

$$P_{BTS} = \in_0 P_{tx} + \overline{P}_o, \tag{5}$$

where $\in_0$ is a coefficient, that is scaled with radiation power P_{tx}, such as feeder loss, amplifier efficiency etc., $\overline{P}_o$ is the power offset derived from signal processing, battery backup etc. and independent with radiation power.

Now, the maximized energy efficiency can be defined as [12]:

$$EE = \frac{\sum_{n=1}^{N}\sum_{m=1}^{M} C_m^n X_m^n}{\in_0 \sum_{n=1}^{N}\sum_{m=1}^{M} P_m^n X_m^n + \overline{P}_o}. \tag{6}$$

Again, let us consider a limited user network with M number of users. Fig. 1 shows the network model by a Markov chain where λ is the call arrival rate per user and μ is the call termination rate. Here P_0, P_1, P_2 … etc are the probability of arrival of no call, one call, two calls and so on. Basic assumption of Markov chain is that probability of arrival of next step depends on present state but not on previous states. Any new call arrival rate λ will make transition of a probability state P_i to P_{i+1}; similarly, any call termination rate μ will make transition from P_i to P_{i-1}.

Applying cut equations [12] in Fig. 1, we get

$$P_1 = P_0 M\left(\frac{\lambda}{\mu}\right), \tag{7}$$

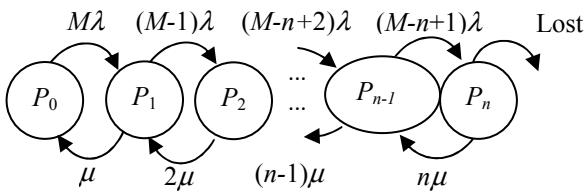

Fig. 1. State transition chain of limited user.

$$P_2 = P_0\left({}^M C_2\right)\left(\frac{\lambda}{\mu}\right)^2, \tag{8}$$

$$P_3 = P_0\left({}^M C_3\right)\left(\frac{\lambda}{\mu}\right)^3, \tag{9}$$

… … … … … … …

and so on. The probability state in general form can be written as

$$P_x = P_0\left({}^M C_x\right)\left(\frac{\lambda}{\mu}\right)^x. \tag{10}$$

In case of the entire sampling space, the following normalization condition must be satisfied:

$$P_0 + P_1 + P_2 + P_3 + \ldots\ldots\ldots + P_n = 1. \tag{11}$$

From the above equations (7-11), the probability of arriving no call P_0 can be derived as

$$P_0 = \frac{1}{\sum_{i=0}^{n} {}^M C_i\left(\frac{\lambda}{\mu}\right)^i}. \tag{12}$$

Now, substituting equation (12) into equation (10), we get

$$P_x = \frac{{}^M C_x a^x}{\sum_{i=0}^{n} {}^M C_i a^i}, \tag{13}$$

where the offered traffic per user is $a = \lambda/\mu$.

The expected number of subcarriers used in a cell is

$$\overline{n} = \sum_{x=0}^{N} x P_x \tag{14}$$

and expected number of deprived user is

$$\overline{m} = \sum_{x=N}^{M-1} x P_x. \tag{15}$$

Hence, the energy efficiency of a multi-user wireless network can be defined as

$$\eta = \frac{\overline{n}C}{\overline{n}P_m^n + \overline{m}\overline{P}_o} = \frac{B\log_2\left(1+\frac{P_m^n\left|h_m^n\right|^2}{\sigma^2}\right)\times\left(\sum_{x=0}^{N} x P_x\right)}{P_m^n\left(\sum_{x=0}^{N} x P_x\right) + \overline{P}_o\left(\sum_{x=N}^{M-1} x P_x\right)}, \tag{16}$$

where $\overline{P}_o$ is the power of the paging signal.

The satisfaction index of the system is defined as

$$SI = \frac{1}{M}\sum_{m=1}^{M}\frac{C_m}{\overline{C}_m} = \frac{B}{\overline{C}_m}\log_2\left(1+\overline{\gamma}_m\right), \tag{17}$$

where $\gamma_1 = \gamma_2 = \ldots\ldots\ldots\ldots = \gamma_m = \overline{\gamma}_m$.

III. Results

We consider an OFDMA cell where the channel bandwidth is 4kHz, transmission power is 45W, $\overline{P}_o$ =12W multipath fading coefficient is 0.78 and variance is chosen as 0.89. Fig. 2 shows the variation of energy efficiency against different number of users considering the number of subcarriers N = 5, 10, 15, and 20. It is visualized from the Fig. 2 that energy efficiency decreases as the number of users increases. Again

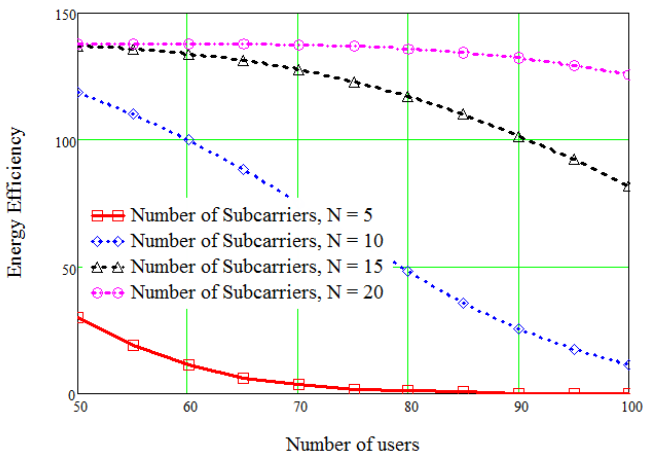

Fig. 2. Variation of energy efficiency against number of users.

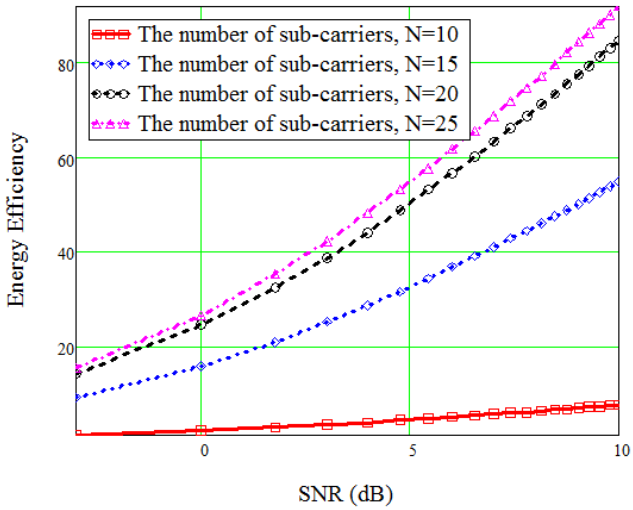

Fig. 3. Variation of energy efficiency against SNR (dB).

energy efficiency increases with increasing number of subcarriers that is the case of enhancement of licensed bandwidth.

From equation (6) it is noticed that energy efficiency is proportional to SNR, taking other parameters constant. It indicates that if the value of SNR increases, the value of energy efficiency also increases. Fig. 3 shows the exact scenario as we have discussed; that is, energy efficiency increases with the increase of the SNR, considering $M = 100$ and $N = 10$, 15, 20, and 25. Instead of using complex algorithm based on Lagrangian model, similar trend found in [9] can be achieved by using our simple state transition model for limited user traffic model.

Fig. 4 illustrates the relation between SI and SNR. It shows that, SI increases as SNR increases for data rate 150kbps, 130kbps, and 120kbps. By showing the relationship between SI and SNR we tried to indicate the user groups whose SI responds with users' data rate with fixed channel capacity.

IV. Conclusions

Previously, energy efficiency in cellular network was analyzed with Lagrangian model where as this paper we have calculated the energy efficiency of a network using limited user traffic model. In particular, we have used Engset traffic model with Markov chain. We have plotted energy efficiency against number of users and SNR taking the number of subcarriers as a parameter. Our results resemble to the conventional Lagrangian model. This implies that using the

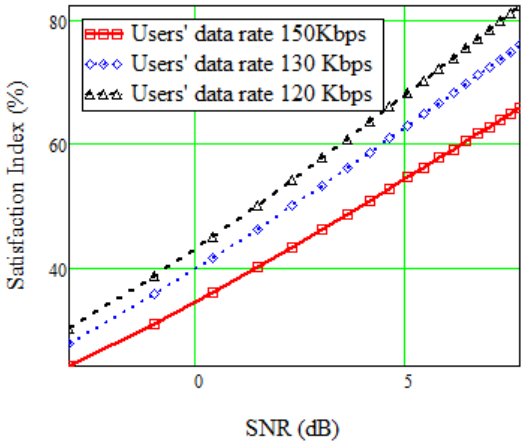

Fig. 4. Variation of satisfaction index against SNR(dB).

simple state transition model, the energy efficiency can be greatly improved for multi-user wireless network. The entire work can be extended incorporating an intelligent network management system to measure the energy efficiency over a period to take necessary measures to allow or block certain users group.

Abstract—**An analytical approach is presented to evaluate the impact of timing jitter on the bit error rate performance of optical M-ary pulse position modulation (M-PPM) free space optical (FSO) link under the influence of atmospheric turbulence modelled by Log-normal distribution. The expression of the conditional bit error rate (BER) for a given timing jitter is developed and the average BER is found by averaging the conditional BER over the probability density function of the timing jitter which is considered to be zero mean Gaussian. The results are evaluated at a bit rate of 2.4 Gbps over weak turbulence with Avalanche Photodiode (APD) receiver for different order of M-PPM modulation. It is found that there is significant deterioration in BER performance with increase in timing jitter variance and results in BER floor at higher value of jitter variance for a given M-PPM order and APD gain. Further, it is noticed that higher order M-PPM system suffer less than lower order PPM system at a given system BER. The analysis can also be useful for evaluating the impact of slot timing jitter for M-PPM FSO system with strong turbulence.**

Index Terms*— *Bit Error Rate (BER), Free-Space Optical (FSO), Pointing Error, Timing Jitter, M-PPM, Log-Normal Distribution, Gamma-Gamma Distribution, Hermite Polynomial etc.

I. INTRODUCTION

Free Space Optical (FSO) communications have gain sufficient interests in recent years as a serious alternative to radio frequency (RF) links due to the fact that FSO equipment are small, less costly, and easy to deploy [1-3]. Further FSO have enormous bandwidth compared to RF communication systems. However, the performance of terrestrial FSO links are highly affected by the atmospheric effect caused by refractive index fluctuations due to temperature change which results in atmospheric turbulence classified into weak and strong turbulence [1-2]. Several statistical models are considered such as log-normal distribution, Gamma-gamma distribution and negative exponential distribution to evaluate analytically the degradation caused by atmospheric turbulence on terrestrial FSO links with intensity modulation and direct detection (IM/DD) [2-5].

Numerous woks on optical M-ary pulse position modulation (M-PPM) are also carried out to investigate the effectiveness of M-PPM in FSO links as M-PPM is an energy efficient modulation format compared to on-off keying (OOK) and other modulation schemes [6-10]. The effects of atmospheric turbulence and pointing error on the bit error rate performance of a PPM FSO link is reported in [6]. In [7] the authors have investigated the BER performance of M-PPM over FSO link with log-normal and negative exponential distribution with error correction coding and without coding. The performance of optical PPM for deep space communication is also reported recently [8] with multi-pulse position modulation with channel fading. The performance of Avalanche Photodiode (APD) based M-PPM receiver over atmospheric turbulence is also carried out considering different APD gain [9]. More recently, the effect of strong turbulence on the shot noise limited and thermal noise limited operations of M-PPM receivers for a FSO link is investigated with strong turbulence condition [10]. However, all the previous works on M-PPM FSO links are based on perfect synchronization although the performance of an optical M-PPM receiver is highly sensitive to slot synchronization error [11]. Several slot synchronizers are also reported earlier for optical M-PPM system [11-12] and the effect of imperfect slot synchronization on the performance of optical M-PPM receiver are reported earlier [11-13] without and with error correction coding.

In this paper we provide an analytical approach to evaluate the impact of imperfect slot synchronization on optical M-PPM FSO system in presence of atmospheric turbulence. Analysis is carried out for M-PPM FSO links to find the effect of timing error on the BER performance with log-normal fading considering weak and strong scintillation indices.

II. SYSTEM MODEL

The block diagram of the free-space optical (FSO) M-ary PPM link is shown in fig. 1. Input binary bits are given input to M-ary PPM modulator to generate the M-PPM symbols. The M-PPM symbols are transmitted by a laser transmitter using a collimator lens.

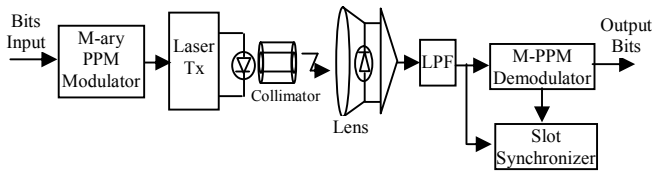

Fig. 1. Block diagram of M-PPM transmitter and photon counting receiver for a FSO link

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

At the receiver the optical beam is received by a photo-detector followed by a preamplifier and a low pass filter (LPF). The slot synchronizer generates the clock using the received M-PPM signal. The generated clock is used by the M-PPM demodulator to determine the slot count over the M-PPM slots. Based on the slot count the demodulator take decision of the transmitted M-PPM symbol and generates the output bit stream.

III. SYSTEM ANALYSIS

We consider an M-PPM slot of duration T_s and slot count over k^{th} time slot with perfect synchronization is m_k. We define the normalized timing error as $\varepsilon = \Delta T/T_s$. In presence of timing error ε, the slot count over a signal slot is given by:

$$m_k(\varepsilon) = m_k\left(\frac{T_S - \Delta T}{T_S}\right) = m_k(1-\varepsilon) \tag{1}$$

The slot duration T_s of M-PPM with the modulation order M, data rate R_b and bit duration T_b is given by:

$$T_s = (T_b \log_2 M)/M = \frac{\log_2 M}{M} R_b \tag{2}$$

In presence of log-normal distribution, the average photon per PPM slot $E[K_s]$ are function of the mean $m_k(\varepsilon)$ and variance of the log-normal channel σ_k^2 and can be represented as:

$$E[K_s] = \exp\left[\frac{\sigma_k^2}{2} + m_k\right] \tag{3}$$

where, E means expectation and σ_k^2 is a function of the scintillation index σ_{si}^2 as:

$$\sigma_K^2 = \ln\left(\sigma_{si}^2 + 1\right) \tag{4}$$

The total noise photons per PPM slot $K_n(\varepsilon)$which results from background noise, thermal noise and timing error induced signal count as:

$$K_n(\varepsilon) = \frac{2\sigma_n^2}{Gq^2} + 2F(K_b + \varepsilon . m_k) \tag{5}$$

where, K_b is the average background noise photons per PPM slot, G is the mean gain of APD and q is the electronic charge and F is the APD excess noise factor defined by:

$$F = 2 + \zeta G \tag{6}$$

where, ζ is the ionization factor for APD.

The variance σ_n^2 of the thermal noise in a PPM slot is defined as:

$$\sigma_n^2 = \frac{2KT_r T_S}{R_L} \tag{7}$$

where, T_r is the effective absolute temperature of the APD receiver, K is the Boltzmann's constant, R_L is the APD receiver load resistance.

The conditional it error rate (BER) conditioned on a given timing error ε, of an M-ary PPM over log-normal channel can be represented as [8]:

$$P_b(\varepsilon) \le \frac{M}{2\sqrt{\pi}} \sum_{\substack{i=-N \\ i\neq 0}}^{N} w_i Q\left[\frac{\exp\left\{2(\sqrt{2}\sigma_k x_i + m_k(\varepsilon))\right\}}{F\exp(\sqrt{2}\sigma_k x_i + m_k(\varepsilon) + K_n(\varepsilon))}\right] \tag{8}$$

where, M is the PPM order, w_i and x_i are the weight and zeroes of Hermite Polynomial [7]. Considering $\varepsilon = \frac{\Delta T}{T_s}$ being Gaussian distributed with zero mean and variance σ_ε^2, the pdf of ε is given by[13]:

$$p(\varepsilon) = \frac{1}{\sqrt{2\pi\sigma_\varepsilon^2}} e^{-\varepsilon^2/2\sigma_\varepsilon^2} \tag{9}$$

The average BER can now be evaluated as:

$$\text{BER} = \int_{-\infty}^{\infty} P_b(\varepsilon)\, P(\varepsilon)\, d\varepsilon \tag{10}$$

IV. RESULTS AND DISCUSSIONS

Following the analytical approach in section III we evaluate the conditional bit error rate $P_b(\varepsilon)$ conditioned on a given value of normalized timing error ε and the average bit error rate (BER) for M-PPM FSO link with APD gain of 150 at a bit rate of 2.4 Gbps with weak turbulence with scintillation index of 0.3.

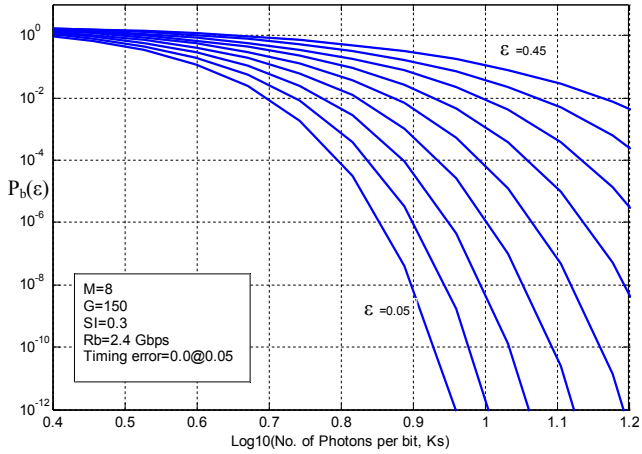

Fig. 2. Plots of conditional BER $P_b(\varepsilon)$ conditioned on a given value of normalized timing error ε versus number of photon per bit of 8-PPM FSO link with turbulence of scintillation index 0.3 at a bit rate of 2.4 Gbps and APD Gain 150.

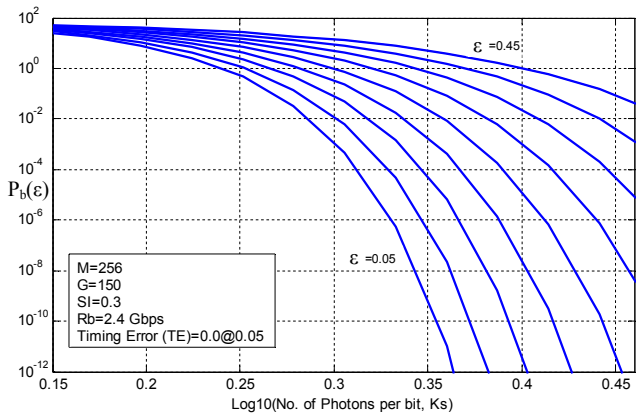

Fig. 3. Pots of conditional BER $P_b(\varepsilon)$ conditioned on a given value of normalized timing error ε versus number of photon per bit of 256-PPM FSO link with turbulence of scintillation index 0.3 at a bit rate of 2.4 Gbps and APD Gain 150.

The plots of $P_b(\varepsilon)$ as a function of number of photons per bit K_s are depicted in fig. 2 and fig. 3 for M=8 and M=256 respectively with ε as a parameter. It is noticed that M-PPM FSO System suffers due to timing error ε, which is significant at high value of ε.

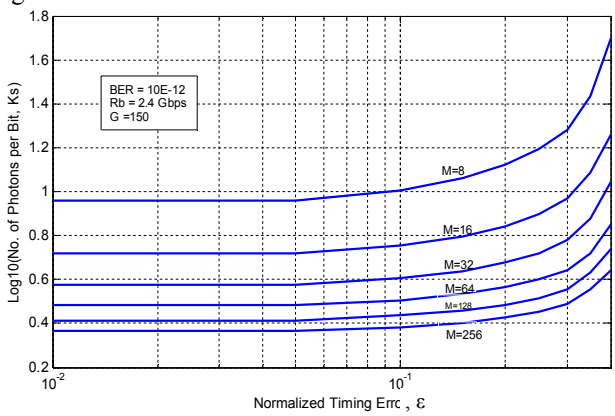

Fig. 4. Plots of receiver sensitivity in terms of number of photons per bit for a conditional BER of 10^{-12} as a function of fixed timing error ε for different M-PPM order.

The plots of receiver sensitivity in number of photons per bit due to timing error at a given $P_b(\varepsilon)$ of 10^{-12} are shown in fig. 4 for M=8, 16, 32, 64, 128 and 256. It is noticed that penalty is significant at higher timing error and is less for high PPM order.

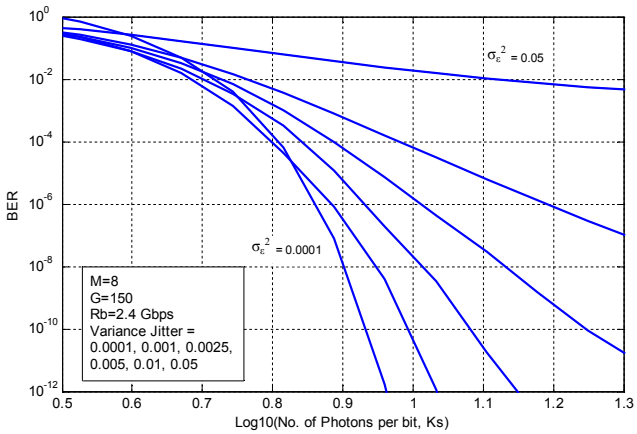

Fig. 5. Pots of average BER versus number of photon per bit of 8-PPM FSO link for different values of timing variance σ_ε^2 with turbulence of scintillation index 0.3 at a bit rate of 2.4 Gbps and APD Gain 150.

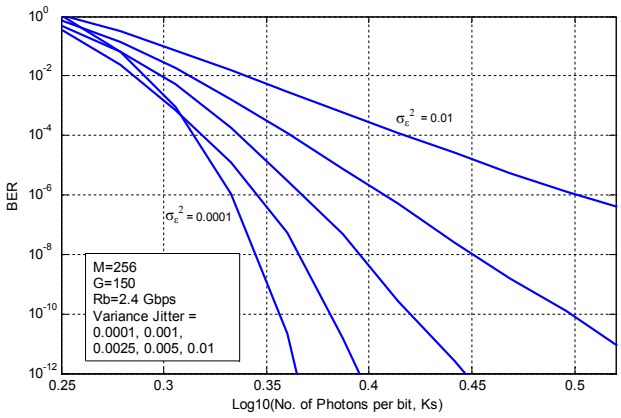

Fig. 6. Pots of average BER versus number of photon per bit of 256-PPM FSO link for different values of timing variance σ_ε^2 with turbulence of scintillation index 0.3 at a bit rate of 2.4 Gbps and APD Gain 150.

The plots of average BER as a function of number of photons per bit K_s are depicted in fig. 5 and fig. 6 for M=8 and M=256 respectively with Jitter Variance σ_ε^2 as a parameter. It is also noticed that M-PPM FSO System suffers due to Jitter Variance, which is significant at high value of σ_ε^2.

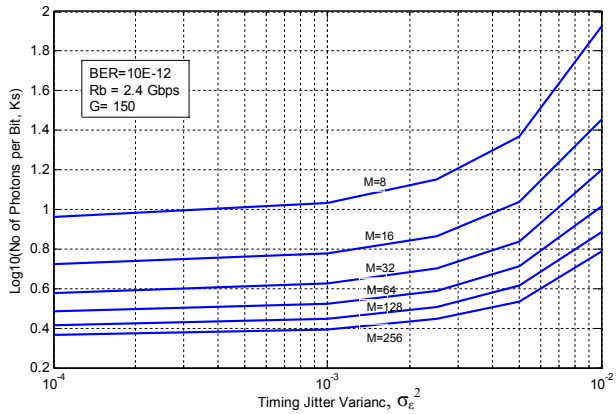

Fig. 7. Plots of receiver sensitivity in terms of number of photons per bit for an average BER of 10^{-12} as a function of variable timing jitter variance σ_ε^2 for different M-PPM order.

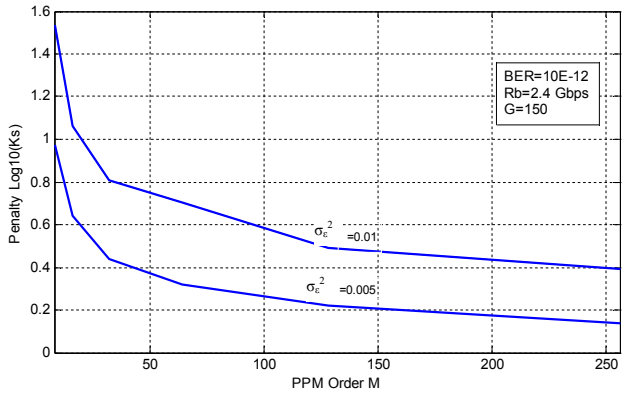

Fig. 7. Plots of penalty log10 (Ks) in terms of number of photons per bit for an average BER of 10^{-12} as a function of different M-PPM order for different timing error variance σ_ε^2 .

The plots of receiver sensitivity in number of photons per bit due to variable timing error at a given BER of 10^{-12} are shown in fig. 6 for M=8, 16, 32, 64, 128 and 256. It is noticed that penalty is significant at higher Jitter Variance σ_ε^2 and is less for high PPM order.

The plots of power penalty in number of photons per bit due to Jitter Variance and PPM modulation order at an average BER of 10^{-12} are shown in fig. 7. It is noticed that penalty is significant at higher jitter variance and is less for high PPM order.

CONCLUSIONS

An analytical development is carried out to obtain the BER of an M-PPM FSO communication system under the influence of atmospheric turbulence with log-normal distribution. Results are evaluated at a bit rate of 2.4 Gbps with weak turbulence and APD receiver. It is found that the system suffers significant power penalty due to timing jitter and BER floor occurs at higher value of jitter variance. The analysis will find application in design of high data rate M-PPM FSO system with APD based receiver.

Abstract—**Due to the harshness of underwater environment, size estimation of underwater network is difficult using conventional protocol techniques. A statistical signal processing approach of size estimation is proposed for this purpose using cross-correlation of Gaussian signals, which is effective for any environment networks. Limited bandwidth of underwater communications channel poses constraint on using Gaussian signal, which has infinite bandwidth. The aim of this paper is to investigate the effect of this limited bandwidth in cross-correlation based underwater network size estimation using Gaussian signals with finite bandwidth.**

Index Terms—**Cross-correlation function (CCF); effect of bandwidth; size estimation; underwater acoustic channels; underwater wireless communication network (UWCN).**

I. Introduction

UWCNs using acoustic waves, which are referred to as underwater acoustic sensor networks (UASN), have several applications, such as monitoring daily ocean life, climatic data collection, disaster alleviation [1], deep-sea archaeology, seawater data collection [2]. To successfully achieve these goals, network size information plays an important role, which ensures proper functionality of the network as well as effective data collection. So, network size is a crucial factor, which is equal to the number of operational nodes in the network and needed to estimate it accurately.

Number of tag ID estimation in radio frequency identification (RFID) systems is equivalent to size estimation of terrestrial wireless network, where different protocols [3]–[5] are used for tag estimation. For dynamic anonymous networks, consensus based size estimation methods have been proposed in [6]–[8]. Another size estimation technique has been investigated by Evans et al. [9] for Peer-to-Peer (P2P) network. Size of a network can also be estimated using distributed orthogonalization [10]. These methods are designed for RFID as well as terrestrial network and not applicable to underwater network due to large propagation latency, non-negligible capture effect, high path loss and limited bandwidth of underwater environment [11]. For underwater wireless network, a dynamic network structure estimation technique has been proposed by Blouin [12] based on intermission between the nodes. ALOHA based node estimation techniques have been investigated by Howlader et al. [13]–[15] for underwater network considering long propagation delay and capture effect. As these size estimation techniques ([12]–[15]) utilize some aspect of communications protocol(s), they suffer from protocol complexity in underwater environment.

An alternative approach of underwater network size estimation with reduced protocol complexity has been proposed by Anower et al. [16], [17] through the cross-correlation of Gaussian signals received at two sensors. A similar node estimation technique using three sensors has been investigated by Chowdhury et al. [18], [19]. In those literatures, Gaussian signals of infinite bandwidth are used for estimation and bandwidth effect is not considered. In this paper, finite band Gaussian signals are used to analyze the effect of limited bandwidth of underwater acoustic channel in cross-correlation based size estimation technique.

II. Size Estimation Procedure

To obtain insight into the cross-correlation based size estimation technique, a review of the estimation process with two sensors [16], [17] is discussed in this section. In this process, a 3D spherical region is considered as network where N nodes are uniformly distributed as shown in Fig. 1. Two sensors are placed at the middle of that spherical region to estimate the network size as shown in Fig. 1, which send probe request. In this approach, acoustic wave is considered as the underwater communication carrier for signal propagation.

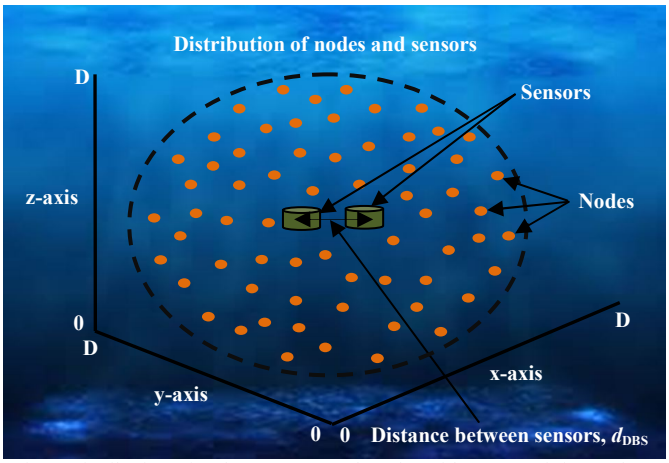

Fig. 1 Distribution of underwater network nodes with N transmitting nodes.

After receiving probe request, it is assumed that, nodes can transmit Gaussian signal using acoustic wave as the carrier. Gaussian signal has a certain property that, cross-correlation of two Gaussian signals results a delta function, which is the basic idea of this estimation approach and also the reason of using Gaussian signals as transmitted signals. Simultaneously transmitted Gaussian signals from N nodes are received by the sensors at different delay differences and summed at each

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

sensor location forming composite Gaussian signals. These two composite signals are then cross-correlated to formulate cross-correlation function (CCF), which results a series of delta functions [17]. One such CCF obtained with N (=1000) nodes is shown in Fig. 2.

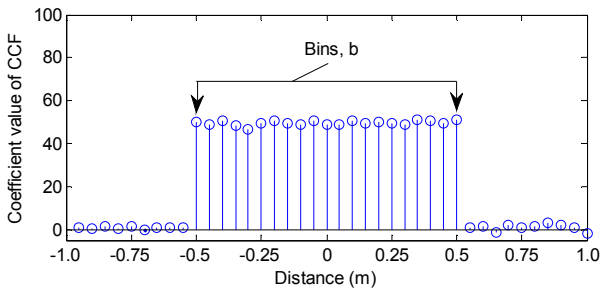

Fig. 2 Bins, b in the cross-correlation function.

Bins, b in the CCF (as shown in Fig. 2) is defined as a place occupied by a delta inside a space of a width twice the distance between sensors and that place is determined by the delay difference of the signal coming to the sensors [20]. The deltas of equal delay differences are placed in that particular bin. Number of bins, b is twice the number of samples between the sensors (NSBS), m, minus one [16] and can be expressed as [20]:

$$b = \frac{2 \times d_{DBS} \times S_R}{S_P} - 1 \tag{1}$$

where, d_{DBS} is the distance between the sensors, S_{R} is the sampling rate and S_{P} is the speed of acoustic wave propagation.

Ratio of standard deviation (σ) to the mean (μ), R of the CCF is chosen as the estimation parameter, which requires no prior knowledge of signal strength [20]. Direct calculation of this estimation parameter using statistical expression is very complex. For this reason, cross-correlation problem is reframed to a probability problem using the well known occupancy problem which follows the binomial probability distribution, where the parameters are N and $1/b$ [17]. After reframing, ratio of standard deviation to the mean, R of CCF can be expressed as [16]:

$$R = \frac{\sigma}{\mu} = \sqrt{\frac{b-1}{N}} \tag{2}$$

Form (2) network size, N is obtained as follows:

$$N = \frac{b-1}{R^2} \tag{3}$$

Using this equation we can estimate N, as we know b and R can be calculated from the CCF.

III. Effect of Bandwidth

An underwater acoustic channel is effectively considered as bandwidth limited due to the frequency dependency of absorption loss, as absorption coefficient, α is an increasing function of frequency [21]. So, absorption loss becomes more significant with the increase of bandwidth, which limits the transmission range. Typical bandwidths of underwater acoustic channel for different ranges are shown in Table I [22]. Channel bandwidth restricts the signal bandwidth which might affect the estimation performance.

TABLE I

Available Bandwidth for Different Ranges in Underwater Acoustic Channel

	Range [km]	Bandwidth [kHz]
Very long	1000	< 1
Long	10 – 100	2 – 5
Medium	1 – 10	≈ 10
Short	0.1 – 1	20 – 50
Very short	< 0.1	> 100

To analyze the effect of bandwidth, a 10kHz Gaussian signal is used in the simulation instead of infinite band signal using a low-pass filter to avoid unwanted high frequency attenuation of underwater environment. The ratio of standard deviation to the mean of CCF for finite and infinite bandwidth case is denoted as R_{finiteBW} and $R_{\mathrm{infiniteBW}}$, respectively. Now ratio of R_{finiteBW} and $R_{\mathrm{infiniteBW}}$ is plotted against N in Fig. 3 for $b = 29$. It can be seen in the figure that, R_{finiteBW} is almost the constant multiple of $R_{\mathrm{infiniteBW}}$ and the mean of those constants are 0.8093 for this case. This scaling factor (0.8093) can be used to match the results of finite (10kHz) bandwidth cases with infinite bandwidth cases.

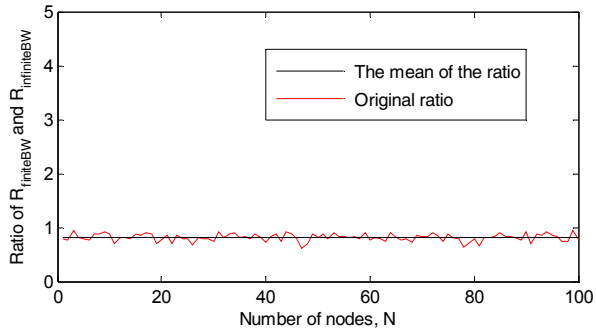

Fig. 3 Ratio of R_{finiteBW} and $R_{\mathrm{infiniteBW}}$ for 10kHz bandwidth.

Now, theoretical approximation of R_{finiteBW} can be obtained by multiplying this scaling factor with theoretical $R_{\mathrm{infiniteBW}}$. So, R_{finiteBW} can be expressed as:

$$R_{\mathrm{finiteBW}} = 0.8093 \times R_{\mathrm{infiniteBW}} \tag{4}$$

As infinite band Gaussian signals are considered in section II, R of CCF expressed in (2) is similar to $R_{\mathrm{infiniteBW}}$. Then using (2) we can write:

$$R_{\mathrm{finiteBW}} = 0.8093 \times \sqrt{\frac{b-1}{N}} \tag{5}$$

For finite (10 kHz) bandwidth case, network size, N can be estimated using the following equation:

$$N = \left(\frac{0.8093}{R_{\mathrm{finiteBW}}}\right)^2 \times (b-1) \tag{6}$$

IV. Results and Discussion

Matlab is used as the programming tool. Theoretical and simulated results of R_{finiteBW} and $R_{\mathrm{infiniteBW}}$ are shown in Fig. 4 with respect to N for $b = 29$ ($d_{\mathrm{DBS}} = 0.5$m and $S_{\mathrm{R}} = 45$kSa/s). It is obvious from Fig. 4 that, R_{finiteBW} is always less than $R_{\mathrm{infiniteBW}}$, but maintains the same shape. Due to the limited bandwidth, cross-correlation of Gaussian signals results sinc functions [23] instead of delta functions, which corrupts the CCF as well as R_{finiteBW}.

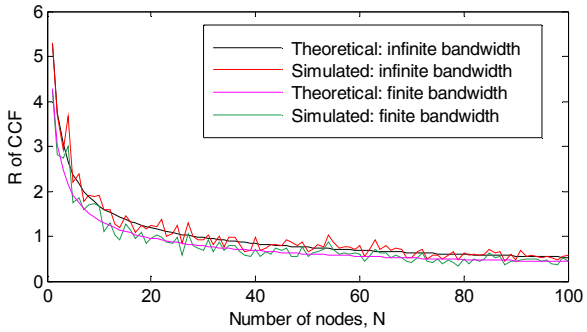

Fig. 4 R_{finiteBW} and $R_{\text{infiniteBW}}$ versus N for finite (10kHz) and infinite bandwidth cases with $b = 29$ ($d_{\text{DBS}} = 0.5$m and $S_{\text{R}} = 45$kSa/s).

For better understanding, results of $R_{\text{infiniteBW}}$ and R_{finiteBW} for $b = 29$ ($d_{\text{DBS}} = 0.5$m and $S_{\text{R}} = 45$kSa/s) are plotted against N in Fig. 5 with less points. Simulated results agree with the theoretical results in Fig. 5, which verify the effectiveness of the scaling factor. With this R_{finiteBW} and the scaling factor (0.8093), number of nodes, N can be estimated using (6).

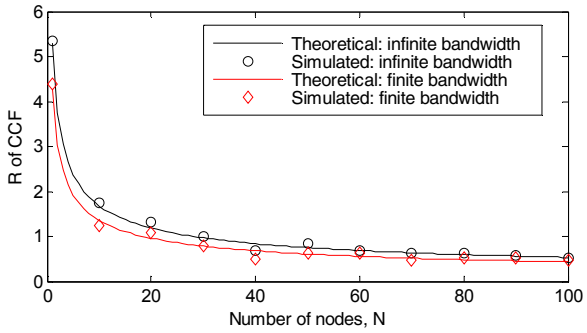

Fig. 5 R_{finiteBW} and $R_{\text{infiniteBW}}$ versus N for finite (10kHz) and infinite bandwidth cases with $b = 29$ ($d_{\text{DBS}} = 0.5$m and $S_{\text{R}} = 45$kSa/s). (with less points)

To test the validity of the scaling factor obtained in section III for different number of bins, b, theoretical results of R_{finiteBW} and $R_{\text{infiniteBW}}$ are compared with the corresponding simulated results in Fig. 6 and 7 for $b = 49$ ($d_{\text{DBS}} = 0.5$m and $S_{\text{R}} = 75$kSa/s) and 69 ($d_{\text{DBS}} = 1.0$m and $S_{\text{R}} = 52.5$kSa/s), respectively. Matching theoretical and simulated results of R_{finiteBW} in Fig. 6 and 7 signify that, for 10kHz bandwidth case, this scaling factor (0.8093) will hold for all b. All of these results are obtained based on an assumption that, received power from each node is equal, which can be achieved using probing technique. The other parameters used in the simulations are: dimension of the sphere, $D = 2000$m; $S_{\text{P}} = 1500$m/s; signal length, $N_{\text{s}} = 10^6$ samples.

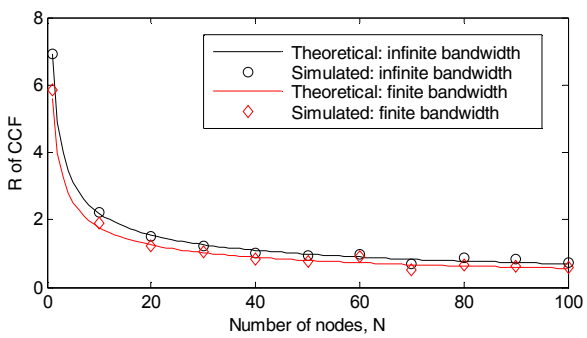

Fig. 6 R_{finiteBW} and $R_{\text{infiniteBW}}$ versus N for finite (10kHz) and infinite bandwidth cases with $b = 49$ ($d_{\text{DBS}} = 0.5$m and $S_{\text{R}} = 75$kSa/s).

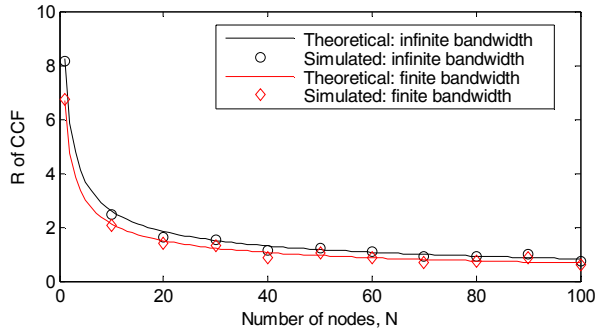

Fig. 7 R_{finiteBW} and $R_{\text{infiniteBW}}$ versus N for finite (10kHz) and infinite bandwidth cases with $b = 69$ ($d_{\text{DBS}} = 1.0$m and $S_{\text{R}} = 52.5$kSa/s).

V. Conclusions

Limited underwater acoustic channel bandwidth makes it impractical to utilize infinite band Gaussian signals in cross-correlation based size estimation technique. Effect of cross-correlating band limited Gaussian signals on estimation parameter, R of CCF is investigated in this paper using 10kHz Gaussian signals. It is shown that, scaling factor can be derived for this band limited condition to develop the corresponding theoretical results. Using this scaling factor network size can be estimated accurately with finite band (10kHz) Gaussian signals. Further investigations are required for the bandwidth less than 10kHz. It is also shown that, this scaling factor is independent of b.

***Abstract*—In this paper the optimal allocation of fiber Bragg grating (FBG) as a dispersion compensator in the presence of group velocity dispersion (GVD) and third-order dispersion (TOD) has been examined. The optimization is performed by varying the compensator arrangements and span length. Four different arrangements are considered–pre-configuration, post-configuration, mid-configuration and bi-end configuration. Span length is varied from 30 to 120 km. At the receiver, Q-factor and bit error rate (BER) have been systematically compared for standard single mode fiber (SSMF) and non-zero dispersion-shifted fiber (NZDSF). The results show that NZDSF based long-haul lightwave communication system with mid compensated scheme provides better performance at 160-Gb/s.**

***Index Terms*—FBG, coupled-mode theory, dispersion compensation, BER, Q-factor.**

I. Introduction

Recent growth in telecommunication services and upcoming technologies like video conferencing, HD video streaming, interactive multimedia and a tremendous increase in the number of the end users have set a limit to the current capacity of optical fiber communication system. To meet the ever increasing demand data rate must also be increased to a higher level. With the increase in data rate the detrimental effects of chromatic dispersion has also become more prominent. Studies on dispersion compensation is thus a matter of acute importance for next generation of optical fiber communication.

Several techniques such as fiber Bragg grating (FBG) [1], dispersion compensating fibers (DCF) [2], optical phase conjugator (OPC) [3] and electronic compensation [4] have been employed to lessen dispersion at high-speed links. The conventional DCF provides high loss and increased Kerr nonlinearity as a result of its attempt to reduce core size to achieve the required negative dispersion. OPC might be a good alternative to DCF but due to the mitigation of attenuation by periodic amplification using Erbium doped fiber amplifier (EDFA), asymmetric signal power evolves in the fiber with respect to the phase conjugator position, which degrades the system performance [3]. Although today's signal processing ensures total compensation of chromatic dispersion in electronic domain, its clumsy and time consuming property increases the possibility of data packet loss.

At ultra-high speed system performance is degraded not only by group velocity dispersion (GVD) but also by third-order dispersion (TOD). Among the other competing dispersion compensators FBG is proven to be an efficient means to compensate dispersion both for GVD and TOD [1], [5]–[8]. The comparison of FBG based system with the popular dispersion compensating fiber is presented in [9]–[11]. Due to the accessibility of low loss high performance FBG in optical fiber communication system, the dispersion management technique has gone through significant improvement during the past decade. The dispersion value from −495.5 ps/nm to −1406 ps/nm and dispersion slope of −43.3 ps/nm^2 is already reported [6], [8].

Although a number of research work is found unveiling the opportunities of FBG as both GVD and TOD compensator, there is hardly any optimization routine at ultra high-speed. The optimization at 10-Gb/s was previously investigated in [7]. However the authors considered GVD compensation only for NRZ data format. The current work presents an optimization of the appropriate location of FBG in the transmission line so that GVD and TOD will be compensated substantially. A number of compensator arrangements in the presence of self-phase modulation, chromatic dispersion and polarization mode dispersion are explored. In this paper four different orientations namely, pre-configuration, post-configuration, mid-configuration and bi-end configuration are investigated thoroughly. In addition to that, repeater span length is varied to find the best performance for a given configuration.

II. Theoretical Modeling

A. Mathematical Analysis

The optical pulse propagation through the fiber is simulated using non-linear Schrödinger equation. However, the transfer function of chirped FBG is modeled by solving coupled-mode equations. FBG is used in reflective mode to achieve the required negative dispersion. For reflection of a particular wavelength λ_B, it needs to satisfy the Bragg condition $\lambda_B = 2n_{eff}\Lambda_B$, where n_{eff} and Λ_B are the effective refractive index of the core and chirping period for the wavelength λ_B. Various appodization function and chirping are used to modulate the refractive index.The refractive index of apodized and linearly chirped FBG can be described as,

$$n(x,y,z) = n_{co}(x,y) + \delta n_{dc}(x,y,z) + \delta n_{ac} A(z) f(\Lambda(z)/\cos(\theta), z) \quad (1)$$

$$\delta n_{ac}(z) = \delta n_{ac} A(z) f(\Lambda(z)/\cos(\theta), z) \quad (2)$$

TABLE I
PROPOSED SCHEMES

Model	Fiber				Dispersion Compensator Orientation
	Type	Attenuation (dB/km)	Dispersion (ps/nm/km)	Dispersion Slope (ps/nm^2/km)	
Scheme I	SSMF / NZDSF	0.2	17 / 4	0.07	Pre-configuration
Scheme II	SSMF / NZDSF	0.2	17 / 4	0.07	Post-configuration
Scheme III	SSMF / NZDSF	0.2	17 / 4	0.07	Mid-configuration
Scheme IV	SSMF / NZDSF	0.2	17 / 4	0.07	Bi-end configuration

where, n_{co} is the refractive index of unperturbed core, $\delta n(z)$ is the peak to peak index modulation amplitude and it includes the effect of direct index change δn_{dc}, index change due to apodization δn_{ac} and refractive index variation due to appodization and chirping. f, $A(z)$ and $\Lambda(z)$ are shape function, apodization and period chirp function respectively. The chirping function can be expressed as

$$\phi(z) = \frac{8\pi n_{co}^2 L_g^2}{\lambda_B^2 c D_f L_f} \times \frac{z^2}{2L_g^2}, \tag{3}$$

where, L_g, λ_B, D_f, L_f are length of the grating, Bragg wavelength, dispersion of the fiber and length of the fiber respectively. Coupled-mode equations are used to describe the pulse propagation along the FBG. If U and V are forward and backward propagating wave in a periodic structure it can be expressed as,

$$\frac{\partial U}{\partial z} = i\sigma U + i\kappa V \tag{4}$$

$$\frac{\partial V}{\partial z} = -i\sigma V - i\kappa U. \tag{5}$$

where,

$$\kappa = \frac{\pi \delta n_{ac}(z)}{\lambda}, \ \psi = \frac{\pi \delta n_{dc}(z)}{\lambda} \tag{6}$$

$$\delta = \frac{2n_{eff}}{c}\left(\frac{2\pi c}{\lambda} - \frac{2\pi c}{\lambda_B}\right) \tag{7}$$

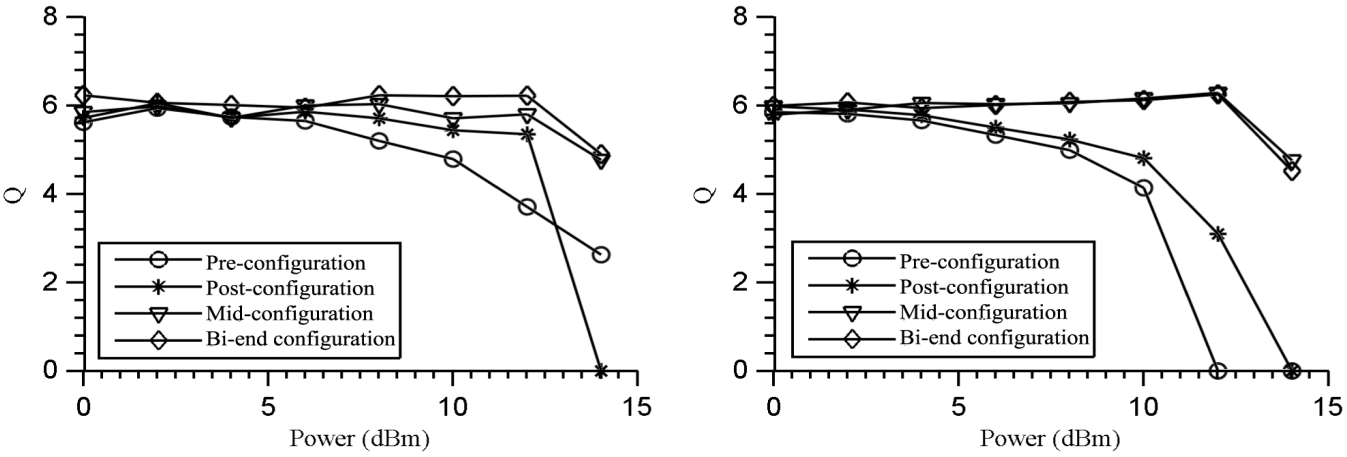
$$\sigma = \delta + \psi - \frac{1}{2}\frac{d\phi}{dz}. \tag{8}$$

The parameter κ and δ are called the alternate coupling coefficient and the detuning of the grating. The coupled-mode equations are solved using transfer-matrix method to find the transmitted and reflected wave, delay and dispersion of the FBG.

B. Description of the System

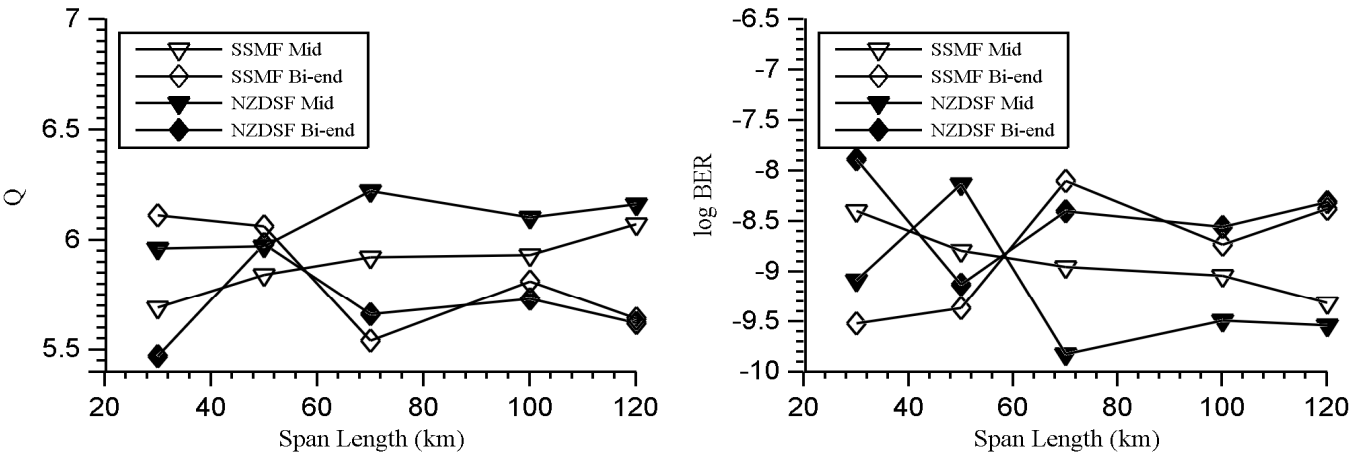
The different models considered for optimization is summarized in Table I. Four different configurations are used and named according to the location of FBG dispersion compensator in the transmission line. Scheme I is called pre-configuration where dispersion is compensated prior to transmitting the signal to the fiber using FBG. Post-configuration in Scheme II does exactly the opposite of Scheme I, it compensates dispersion after the signal go through the transmission line. Mid-configuration in Scheme III uses FBG to compensate dispersion at the mid of the line. Scheme IV refers to biend-configuration that compensate dispersion at both starting and terminating end.

The transmission model basically consists of three parts: transmitter, transmission line (that includes the fiber, dispersion compensator and amplifier) and receiver as shown in Fig. 1. The transmitter section is composed of a bit sequence generator, an electric pulse generator, an optical source (CW laser) and an optical modulator (Mach-Zehnder (MZ) modulator). Following the bit sequence generator, which generates



(a) SSMF (b) NZDSF

Fig. 2. Q-factor as a function of input power for two different types of fiber.



(a) (b)

Fig. 3. (a) Q-factor as a function of repeater span. (b) BER as a function of repeater span.

a PRBS of 2^7–1, the electric pulse generator generates binary sequence of data which is used to modulate the optical signal from CW laser at MZ modulator. Transmitter section produces RZ Gaussian pulses of 50% duty cycle at center emission wavelength of 1550 nm at 160 Gb/s.

Two different models of single channel single-mode fiber, namely standard single mode fiber (SSMF) and non-zero dispersion shifted fiber (NZDSF) have been considered in our work. Both of these fibers are individually checked with each of the configurations described in Table I. SSMF has an effective core area of $70\,\mu\text{m}^2$ and nonlinear index coefficient of 2.6×10^{-20} m^2/W whereas NZDSF an effective core area of $80\,\mu\text{m}^2$ and nonlinear index coefficient of 2.6×10^{-20} m^2/W. PMD coefficient of 0.5 ps/$\sqrt{\text{km}}$ is used in this paper. The specification of the fiber parameters are summarized in Table I. GVD, TOD and SPM are included inside the fiber. For dispersion compensation FBG is used. FBG offers low loss and negligible nonlinearity in practice, so for simulation purpose both of these effects are neglected in FBG. An EDFA is used to compensate for the attenuation due to fiber loss at the end of each repeater span. However EDFA noise is not considered. The whole length of 2000 km is covered by a recirculting loop at the repeater span.

At the receiver end the optical signal is detected by a PIN detector followed by a fourth order Bessel type low pass electrical filter with cutoff frequency 0.75×bit rate. The PIN has a responsivity of 1 A/W and a dark current of 10 nA.

III. Optimization

To begin with the optimization we first decide the best scheme from Table I. For this purpose we have tested the Q-factor of the system both for SSMF and NZDSF type of fiber. The variation is observed with the increase in input power.

Fig. 2 shows the input power versus Q-factor curve for the four proposed schemes. Fig. 2(a) shows the variation for SSMF fiber and the Fig. 2(b) shows the variation for NZDSF fiber. In case of SSMF fiber Q-factor degrades with the increase in input power. Bi-end configuration performs best among the four schemes. The Q-factor is 5.61, 5.71, 5.84 and 6.22 for the four configurations respectively at 0 dBm of input power which degrades to 2.62, 0, 4.76 and 4.89 at 14 dBm of input power. In reference to Fig. 2(b), both mid and bi-end compensations work well. At 0 dBm the Q-factor is 5.84, 5.78, 5.97 and 5.98 for pre-, post-, mid- and bi-end configuration which degrades to 0, 0, 4.75 and 4.71 respectively for the four models.

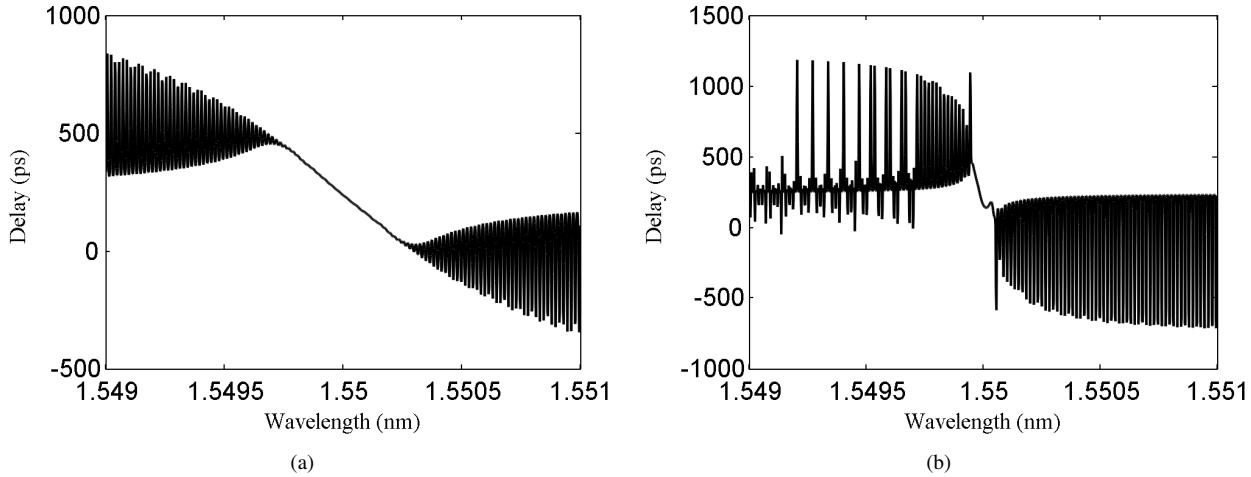


Fig. 4. (a) Group delay ripple in delay line for lower GVD. (b) Group delay ripple in delay line for higher GVD.

In comparison among the four models, mid- and bi-end configuration performs better than pre- and post-configuration. So in the next simulation of varying the repeater span we consider only the mid- and bi-end configuration. The Q-factor and BER is monitored. The results of varying the repeater span are included in Fig. 3. The repeater span is varied from 30 to 120 km with an increment of 20 km and tested for Q-factor and BER both for SSMF and NZDSF fiber. From the figures above it can be concluded that SSMF fiber gives the best performance at repeater span of 50 km (Q-factor=6.06, BER=4.25×10^{-10}) and NZDSF fiber at 70 km (Q-factor=6.22, BER=1.49×10^{-10}). It can also be concluded that mid-configuration with NZDSF fiber works slightly better than bi-end configuration with SSMF fiber.

The physical reason underlying the above conclusion can be explained with Fig. 4. In Fig. 4(a) we can see the delay line with negligible ripple inside the passband. But with the same device when we try to increase the delay to meet the required higher level of accumulated dispersion by the fiber, an enormous amount of ripple show off as shown in Fig. 4(b). We call this the group delay ripple (GDR) and this degrades the system performance of FBG as a consequence. FBG can operate good within certain amount of negative GVD. Beyond this certain limit it's performance is limited by the GDR. Mid-configuration with NZDSF fiber and bi-end configuration with SSMF fiber meet FBG within this specific limit and as a result performs better than other configurations.

IV. Conclusion

In this paper we present an optimization routine to compensate GVD and TOD using FBG at 160 Gb/s long haul optical fiber transmission. We find that received signal gets degraded with the increase in input optical power due to the increased nonlinear effects. Apparently bi-end and mid-configurations offer better performance than that of pre and post configurations. Bi-end configuration works better with SSMF fiber whereas mid-configuration with NZDSF fiber. While changing repeater span, SSMF based model performs excellent at 50 km of repeater span whereas NZDSF based model with 70 km of repeater span. The overall best performance is achieved for NZDSF based model with repeater span 70 km among the all combinations.

Abstract— **The Bit Error Rate(BER) and theoretical channel capacity of OCDMA transmission has been analyzed in this paper for M-ary chip symbol. A comparison has also been made between uniform and non-uniform signalling and the result shows that channel capacity is increased for the same number of active users if the modulation level or bits per OCDMA symbol is increased for non-uniform. Finally SNR and BER simulation result has been shown for both uniform and non-uniform M-ary OCDMA transmission system in presence of Self Phase Modulation and dispersion. The simulation result shows that unlike conventional OCDMA system better performance can be achieved using M-ary Chip Symbol.**

Index Terms—**M ary Chip Symbol, Gold Sequence, Channel Capacity, Self Phase Modulation.**

I. Introduction

Optical Code Division Multiple Access (OCDMA) can provide numerous smart features such as asynchronous, flexible and decentralized networks, potential of high data throughputs, inherent data security, potential of total bandwidth utilization by all network users and many more[1]-[9]Since users in OCDMA networks are non-orthogonal and asynchronous, severe multi-user interference (MUI) has been a crucial factor which is responsible for limiting the performance of OCDMA channel transmission [4]. Besides the effect of the non-linearity such as self-phase modulation, cross phase modulation, Stimulated Brilloiun Scattering, Stimulated Raman Scattering, Four Wave mixing and various kinds of dispersion such as chromatic dispersion, Polarization Mode Dispersion, Modal Dispersion are also responsible for degrading the performance of an OCDMA transmission system[5]-[7].

This paper illustrates the results that the instead of the traditional binary OCDMA, utilizing M-ary OCDMA system; where symbol is constructed by several bits a higher spectral efficiency can be achieved [8]-[9]. The mathematical modelling and simulation has been carried out considering the effect of the dispersion and noise. We present relevant channel capacity results and simulated bit error rate (BER) performance of a coded M-ary OCDMA system to show that as much as the modulation level is increased, the data rate is also increased consequently when compared to binary OCDMA systems. As in most prior literature, single-user demodulation and decoding (SUD) has been focused in this research due to practical implementation complexity constraints and signal processing speed requirements.

The rest of this paper is organized as follows: the next section includes system models including Self Phase Modulation(SPM), noises and MUI, Section III presents numerical capacity results illustrating the achieved capacity considering M-ary OCDMA transmission, BER performance for different modulation level and in addition to SNR for different modulation level has also been analysed. Section IV concludes this paper and presents directions of future work.

II. Proposed System Model

Figure 1 illustrates M-ary OCDMA transmission architecture with single-user demodulation at the receiver where K independent users send information data simultaneously over a fiber-optic channel. In the transmitter, a user's binary data is converted to symbol by bit to symbol converter. During the modulation, transmission and demodulation processes, the optical signals are assumed to add up incoherently without beatings and optical intensity direct detection is used at the receiver. In the receiver, a particular user data symbol is recovered by the correlation operation using an optical correlator receiver. The decoded signal is incident on the avalanche photo detector. a level detector is used to determine the output signal magnitude and then the output symbol is recovered.

In our paper it is assumed that the data signal and the chip signal has no relative delay although the signals from various users may have a certain amount of delay. This delay is not shown in the simulator. But its effect on BER is calculated. The product signals depicted in the block diagram of the simulator is the multiplication of data sequence and chipping sequence of each user. The product signal for k-th user can be represented by

$$S_k(t-\tau_k) = V\alpha_k(t-\tau_k)b_k(t-\tau_k)\mu_k(t-\tau_k) \quad (1)$$

Here $b_k(t)$ is the data sequence for user k, $\alpha_k(t)$ is the spreading sequence (chip) sequence for user k, $\tau_k$is the delay of user k relative to some user reference user 0, V is the amplitude of the signal and $\mu_k(t)$ is the Gaussian function. Both $\alpha_k(t)$ and $b_k(t)$ are binary sequence with values -1 and +1 . In this simulator, it is assumed that the total chipping sequence is repeated for each bit period. The chip sequence $\alpha_k(t)$ is of the form

$$\alpha_k(t) = \sum_{j=-\infty}^{\infty}\sum_{i=0}^{N-1}\alpha_{k,i}\prod\left(\frac{t-(i+jN)T_c}{T_c}\right) \quad (2)$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

N is the spreading factor of the number of the chips ber bit, T_c is the chip period, NT_c is the repetition period of the chipping sequence = Bit period of the users (T_B).

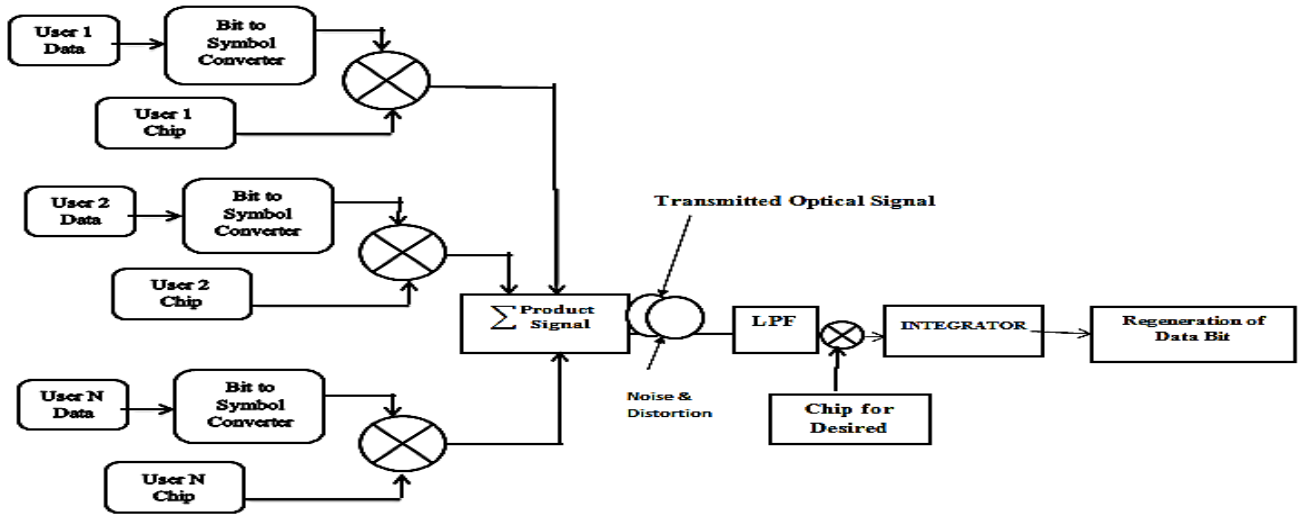

Fig 1 Block Diagram of the System Model.

$\prod(t)$ represents the unit impulse function and i is an index to donate the particular chip within a PN chip sequence

$$\prod = \begin{cases} 1 & 0 < t < 1 \\ 0 & otherwise \end{cases} \quad (3)$$

The user data sequence $b_k$is given by

$$b_k(t) = \sum_{j=-\infty}^{\infty} \sum_{i=0}^{N-1} b_{k,i} \prod \left(\frac{t-(i+jT_b)}{T_b}\right) \quad (4)$$

The Gaussian function $\mu_k(t)$ is given by

$$\mu_k(t) = \exp\left(-\frac{1-i\alpha}{2} \cdot \left(\frac{t}{t_0}\right)^{2m}\right) \quad (5)$$

If the total number of users is k then the compound signal that is to be transmitted through the optical fiber is:

$$r(t) = \sum_{k}^{K-1} S_k(t-\tau_k) \quad (6)$$

Now if the transfer function of the optical fiber be$H(f)$, then the Fourier transform of the fiber output signal becomes:

$$G(f) = r(f)H(f) \quad (7)$$

Therefore the fiber output signal is

$$g_{out}(t) = F^{-1}(G(f)) \quad (8)$$

To observe the effect of noise in a digital communication system in this simulator there is a provision for adding a particular amount of noise. Now the noisy signal becomes

$$g_{noisy(t)} = g_{out}(t) + g_{noise}(t) \quad (9)$$

Where g_{noise} is considered as a summation of thermal noise, shot noise, bulk current noise, dark current noise. Now if the Fourier transform of the noisy signal $g_{noisy}(t)$ to be $G_{noisy}(f)$ and the transform function of the low pass filter $H_{filter}(f)$, then inverse Fourier Transform of the output of the fiber will be

$$r_{out}(t) = F^{-1}[G_{noisy}(f).H_{filter}(f)] \quad (10)$$

If the output of the low pass filter be $r_{out}(t)$ then the decision statistic for k'th user is

$$Z_0 = \int_{jT_B}^{(j+1)T_B} r_{out}(t)\,\alpha_k(t) \quad (11)$$

The output symbol magnitude of k-th user is

$$Z_0 = |y_{out}(t)| \quad (12)$$

III. Simulation Result And Analysis

A. Channel Capacity for OCDMA Transmission

As one seeks ways of improving the throughput of an OCDMA system, it is important to know the absolute maximum throughput. This gives insight in handling a suitable channel coding strategy to allow reliable communication. The concepts in information theory .can be applied to any channel model to determine the maximum rate at which data can be sent across a channel with error probability approaching zero as the block length is made arbitrary large. Fundamentally, the channel capacity is given by the source probability that maximizes the mutual information of the channel. For a discrete-memory less channel, the channel capacity C in bits per channel use is given by

$$C = maxI(X;Y) = \max[H(Y) - H(Y|X)] = max[H(X) - H(X|Y)] \quad (13)$$

To evaluate the performance of channel model under the condition of interface the following near-optimal channel input Probability Mass Function (PMF) is used :

$$\rho_0 = 1 - \frac{1}{K} and\ \rho 1 = \rho 2 = \cdots = \rho M - 1 = \frac{1}{K(M-1)} \quad (14)$$

It I observed form Fig. 2 that, when uniform signaling is used i.e all M-ary inputs are used with equal probability and the number of users K increases, the OCDMA spectral efficiency limit converges to 0.72 bits per OCDMA chip, despite the fact of the modulation levels M increases from M = 2 to M = 4,8

or even 16. Another important factor that should be noticed from the figure is that when non-uniform signaling is considered for analysis, as the modulation level increases the OCDMA Network throughput i.e bits/OCDMA chip also increases. Whereas capacity remains around 0.87 bits/OCDMA chip for M=2, it becomes 2.1 bits/OCDMA chip when modulation level M=16 is used which means that the capacity is increased near about 2.5 times.

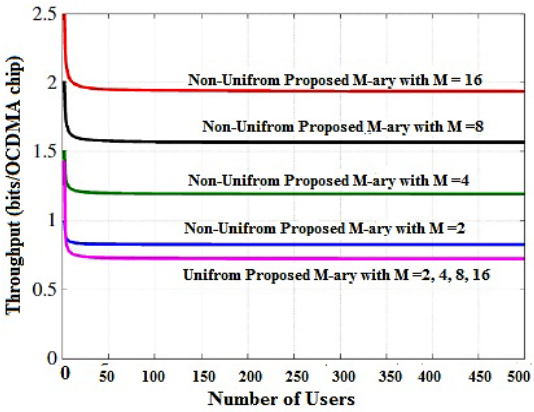

Fig. 2 Theoretically achievable rates for an OCDMA network transmission both for uniform and nonunifrom signal.

Another key factor which limits the performance is the Multi User Interference (MUI).It is expected that increasing the number of modulation levels is expected to increase the amount of MUI, but the use of the non-uniform input PMF from Eq. (14) keeps the MUI reduced. Figure 3illustrates the reduced MUI obtained with non-uniform channel input PMF and compares it to the much larger amount of MUI resulting from uniform channel input signaling. This reduction of the MUI through non-uniform signaling allows increase of the theoretically achievable spectral efficiency to almost 2.1 bits per chip for M =16.

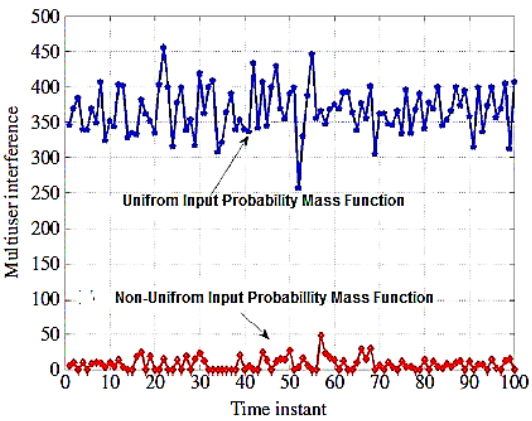

Fig. 3 Comparison of the amount of OCDMA MUI in the cases of uniform and non-uniform channel input PMF.

Another key observation is that the MUI, when using the non-uniform channel input PMF from Eq. (14), turns out to be strongly reduced and *non-Gaussian*in nature, as illustrated in fig. 4 for an OCDMA network transmission.

The diagram has shown for modulation level M=16 obtained from equation (14). On the contrary, conventional OCDMA network transmission with single-user decoding using uniform chip symbols, and the MUI converges in distribution to a Gaussian random variable. The reason behind this is the effect central limit theorem. In such a case, the transmitted data end up being severely corrupted by the MUI, which is also shown for illustration purposes in Fig. 4.

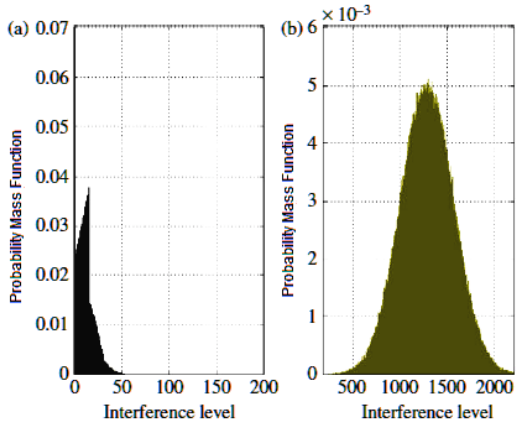

Fig. 4 Histogram of MUI for 16-ary (M = 16) OCDMA transmission (a) Non-Gaussian MUI for non-uniform signalling (b) Gaussian interference with uniform PMF

From this observation we can conclude that, since non-uniform channel input signaling leads to a reduced MUI and larger achievable transmission rates, we will consider OCDMA transmission with non-uniform channel input.

B. Performance Analysis in terms of BER and SNR

Bit error rate is defined as the rate at which errors occur in a transmission system. This can be directly translated into the number of errors that occur in a string of a stated number of bits. The definition of bit error rate can be translated into a simple formula:

$$Bit\ Eror\ Rate\ BER = \frac{Numbers\ of\ Error}{Total\ Numbers\ of\ bit\ Sent}$$

In practice, the bit error rate of a system for optical data transmission (e.g. a fiber-optic link) can be increased by noise influences (particularly in the receiver, but also in the transmitter and in amplifiers), by optical losses, and chromatic and other types of dispersion. On the other hand, Signal to noise ratio (SNR) is a measure of the amount of good signal divided by the amount of noise being received.

The Bit Error Rate (BER) or Probability of Error is the probability to occur an error during the transmission of a bit. It is the sum of the probabilities of all the ways that an error can occur. BER for transmission of binary digits in presence of a Gaussian distributed noise having a noise variance σ^2 is

$$P_{B=}Q\left(\frac{\alpha_1-\alpha_2}{2\sigma_0}\right) \quad (15)$$

Where $Q(x)$ is the complementary error function or co-error function and $\alpha_1$and $\alpha_2$be the voltage levels for two bits.

Again Signal to Noise Ratio (SNR) $=(\frac{S}{N})_T=\left(\frac{\alpha_1-\alpha_2}{\sigma_0}\right)^2$ (16)

Therefore $$P_B = Q\left(\frac{\sqrt{(\frac{S}{N})_T}}{2}\right) \quad (17)$$

For Matched Filter $$(\frac{S}{N})_T=(\frac{S}{N})_{T,max} = \frac{2E_d}{N_o} \quad (18)$$

Where E_d = Average Differential Energy for filter input. Differential energy is taken to include the effect of bipolar signals in consideration. Therefore,

$$P_B = Q\left(\frac{\frac{2E_d}{N_o}}{2}\right) = Q\left(\sqrt{\frac{E_d}{2N_o}}\right) \quad (19)$$

But $$Q(x) = \frac{1}{2}\, erfc\left(\frac{x}{\sqrt{2}}\right) \quad (20)$$

Therefore $$P_B = \frac{1}{2}\, erfc\left(\frac{\left(\sqrt{\frac{E_d}{N_o}}\right)}{2}\right) \quad (21)$$

For convection Filters,

$$\left(\frac{S}{N}\right)_T = \frac{\alpha_i^2}{\sigma_0^2} \quad (22)$$

Where signal output $\alpha_i = F^{-1}$ (Filter Transfer Function * F (input of Filter Signal)) = Output signal of Filter. To include also the effect of $\alpha_i$is taken as follows

$$\alpha_i = mean\big(abs(s_1 - s_2)\big) \quad (23)$$

Where s_1 and $s_2$be the voltage levels of two bits. Therefore,

$$\left(\frac{S}{N}\right)_T = \frac{\left[mean\big(abs(s_1 - s_2)\big)\right]^2}{\sigma_0^2} \quad (24)$$

$$P_B = Q\left(\frac{mean\big(abs(s_1 - s_2)\big)}{2\sigma_0}\right) \quad (25)$$

$$= \frac{1}{2}\, erfc\left(\frac{mean\big(abs(s_1 - s_2)\big)}{2\sqrt{2}\sigma_0}\right) \quad (26)$$

Figure 5 illustrates the BER performance versus Received Optical Received Power(ORP) for up to M=64 modulation level. We observe again that BER decreases when the ORP and the number of users is increased.

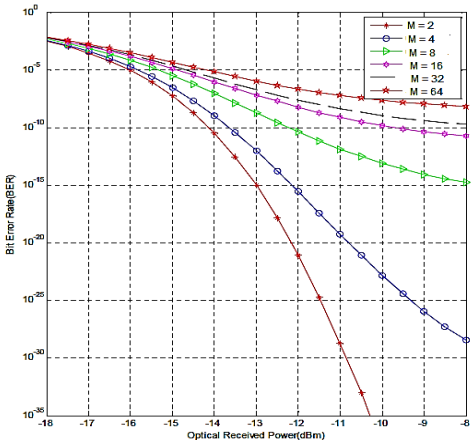

Fig. 5 Performance Comparison – BER vs. Received Optical Power

For instance, when we consider a 10-5 BER, the ROP is -14.8 dBm for M=32 modulation level while for M=64, this becomes -14.2 dBm.

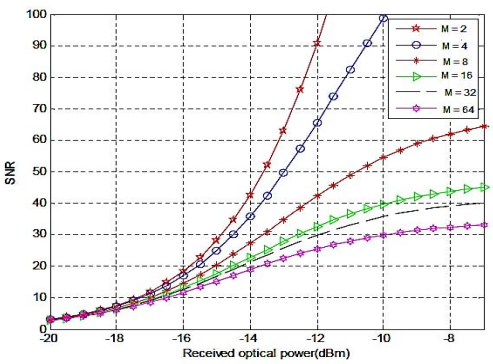

Fig. 6. Performance Comparison – SNR Vs. Received Optical Power

Similarly, Signal to Noise Ratio influences the receiver section of the OCDMA system. If SNR is increased, it will increase the performance of the system. In our paper performance of our proposed M-ary system has been analyzed in terms of SNR. Figure 7 presents the SNR versus ROP of the OCDMA system for up to 64 modulation level.

For instance, it is observed, that when the SNR is 30 dB, the ROP is -12 and -10 dBm for M-=32 and M=64 modulation level respectively.

IV. Conclusions

In this paper, the channel capacity limits on optical CDMA transmission is evaluated, when single-user detections used at the receiver. It has been seen that the *M*-ary modulation for OCDMA systems can be used to increase the capacity limitations of the conventional binary optical CDMA. It is illustrated that the channel capacity is increased with the increase of the modulation level and increases up to 2.1 bits/OCDMA chip for M=16.Furthermore, the proposed scheme is robust against several impairments which limit the performance such as Self Phase Modulation, MUI, Poisson shot noise and AWGN thermal noise.

It is attention-grabbing to note that the considered non-uniform M-ary OCDMA transmission scheme achieved a spectral efficiency which is significantly better compared to the best uniform M-ary OCDMA. Finally with the analysis of performance based on BER and SNR, it can concluded that the improved performance achieved by the designed M-ary OCDMA system..

Abstract— **System–on-a-chip (SoC) is now a trend in digital design because it gives a lot of advantages over discrete electronic based product such as higher speed, lower power consumption, smaller size, lower cost etc. Reconfigurable platforms such as FPGA, CPLD, and PLD are now being used for designing and implementing SoC due to their low cost, high capacity and tremendous speed. In this project single chip Orthogonal Frequency Division Multiplexing (OFDM) transmitter and receiver have been designed using Verilog HDL. OFDM is a multi carrier modulation technique used in the various digital communication systems like 3G GSM, WiMAX and LTE etc. The main advantage of this transmission technique is its robustness to channel fading in wireless communication environment. There are many applications of OFDM in communication such as digital audio broadcasting, Asynchronous Digital Subscriber Line (ADSL) and High bit-rate Digital Subscriber Line (HDSL) systems. In OFDM, two algorithms digital signal processing algorithm Fast Fourier transform (FFT) and Inverse Fast Fourier Transform (IFFT) are mainly involved. The 8-point IFFT/FFT Decimation-In-Frequency (DIF) with radix-2 algorithm has been analyzed and incorporated in the design. The design has been simulated on the FPGA platform with Altera's Quartus II simulator. Simulation results show that each of the modules of the proposed OFDM is working as desired. The test output achieved from the simulation result of the OFDM has been verified with that of the MATLAB output.**

Keywords—OFDM, FFT, IFFT, FPGA, Verilog HDL

I. INTRODUCTION

Reconfigurable computing is a computer architecture, which combines software with the high performance hardware by very flexible high speed computing fabrics like field-programmable gate arrays (FPGAs).This reconfigurable platform is now being used for designing and implementing SoC due to its low cost and high capacity and tremendous speed [1].

Designing various modern communication standards require digital signal processing throughput. Modeling theses standards on general purpose CPUs can be extremely slow with traditional software. Besides this, for some real time applications the test time can become even longer when noise or real time disturbances are considered.

By transferring the processing technique to FPGAs, test time can be reduced significantly and real time application could be implemented. By using large amount of parallel processing, FPGAs can be targeted and reconfigured to test any communication system like OFDM scheme. In present, the application of FPGAs to speed up computation tasks has been researched widely. Some of these researches have focused on the benefits of using FPGAs for communications processing [2-5]. We have implemented an optimized 8-point FFT or IFFT processor for OFDM system in the FPGA platform using Verilog HDL.

A. *OFDM System Overview*

The Orthogonal Frequency Division Multiplexing (OFDM) is developed to support high data rate and can handle multi carrier signals. Its specialty is that, it can minimize the Inter Symbol Interference (ISI) much more compared to other multiplexing schemes [6]. It is more likely improved Frequency Division Multiplexing (FDM) as FDM uses guard band to minimize interference between different frequencies which wastes a lot of bandwidth. But OFDM does not contain inter-carrier guard band which can handle the interference more efficiently than FDM. So, this is the perfect choice for WiMAX as it can help to satisfy the requirements of efficient use of spectrum and minimize the transmission cost [10]. The Discrete Fourier Transform (DFT) is the novel technique to transmit the FDM signal [9]. In OFDM, two digital signal processing algorithm Fast Fourier transform (FFT) and Inverse Fast Fourier Transform (IFFT) are mainly involved. However, the main constraints nowadays for FFT processors used in wireless communication systems for OFDM are execution time and lower power consumption [11]. The main issue in FFT/IFFT processors is complex multiplication, which is the most prominent arithmetic operation used in FFT/IFFT blocks. By using The Cooley–Tukey FFT algorithm, the complexity can be reduced to O ($N.\log_2 N$) [13].

The main objective of this work is to design an OFDM Transmitter and Receiver using FPGA. FFT or IFFT are the main building blocks of OFDM, which operates on finite sequences. The OFDM signal is generated by implementing the Inverse Fast Fourier Transform (IFFT) at the transmitter and Fast Fourier Transform (FFT) at the receiver side. Firstly we derive an algorithm for the IFFT and FFT. A variable may correspond to a wire or a register depending on its application and sometimes an operator can be mapped to hardware like adder, latches, multiplexers etc.

The mathematical model of OFDM symbol defined by Inverse Discrete Fourier Transform IDFT which would be transmitted as given bellow:

$$x(n) = \frac{1}{N}\sum_{k=0}^{N-1} X(K) e^{\frac{j2\pi k}{N}} \quad (1)$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

x(n) represents the IDFT time domain output at the *n-th* spectral point where n ranges from *0 to N-1*. The *N* represents the number of sample points in the IDFT data frame. The quantity *X(k)*represents the *k-th* time sample, where *k* also ranges from *0 to N-1*.And the corresponding Discrete Fourier Transform (DFT) operates on sample time domain signal which is periodic. The sequence x(n) gives a sequence X(k) defined only on the interval from *0 to N-1* .The equation for DFT is:

$$X(k)=\sum_{n=0}^{N-1} x(n)e^{-\frac{j2\pi k}{N}} \tag{2}$$

The computation of each point of DFT requires (N-1) complex multiplication and (N-1) complex addition. Thus to compute N points in DFT require N(N-1) complex multiplication and N(N-1) complex addition. The DFT equation (2) can be divided into two equal halves and after that the two equations were formed, one is for even signal terms and another for odd signal terms. DFT can be subdivided until only two points are left in each DFT. Since the outputs were subdivided to obtain this algorithm, it is referred to as decimation-in-frequency (DIF) FFT algorithm.

B. *FPGA Processing*

Modern FPGAs have a tremendous amount of parallel processing power. The latest family of FPGAs released by Xilinx (Vertex Ultra Scale) has up to 4,407,480 logic cells and 4,268 GMACs of DSP processing throughput. This processing power exceeds the latest Multi-Core Multi-Gigahertz processor. In addition to processing power, FPGAs are highly reconfigurable. The user can simply recompile and download a new design and they have a new custom piece of digital processing hardware.

C. *Contributions*

We make the following contributions in this work:

- Demonstration of FPGA as a communication design platform
- Design and Implementation of OFDM transmitter and receiver on the FPGA device
- A comparison of Verilog HDL and MATLAB simulation

Section V: Conclusion

II. Implementation of An 8-Point FFT/IFFT Processor

The implementation of IFFT and FFT is simple as compared to DFT and its 8-point DIF output is derived from the input directly. Multiplication of the twiddle factor is skipped to avoid redundancy and reduce computation time. Thus, IFFT and FFT implementation is optimized.

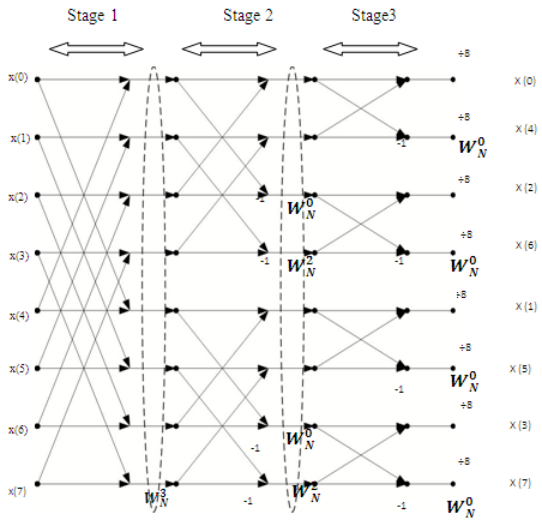

Fig.1 Stage 3 Computation Flow Chart of an 8-point IFFT Computation

The Fig. 1 shows the 8-point IFFT computation. There are three stages. In stage 1 the input data is accepted directly. The outputs of Stage 1 are feed as the inputs of the Stage 2. In stage 2 computations take place and this process repeats at the final stage 3. The complexity of the output equations increases as the Stage number increases because twiddle factor computations are involved. It includes multiplication and additions operations.

Fig. 2 shows an 8-point IFFT block diagram and their interconnections. This module passes the inputs to the sub-modules that process the IFFT computations.

The Pass module consists of 8 D type flip-flop registers. The function of Path 0 and Path 4 is to compute and display the result of these computations.

The arithmetic operation for Xout(0) is summation. The Xout(4) involves summation, subtraction and division. The arithmetic operation for Xout(2) and Xout(6) involves real and imaginary operation. They are performed separately. The twiddle factor for this output is either j or –j which contributes to the imaginary components for this path.

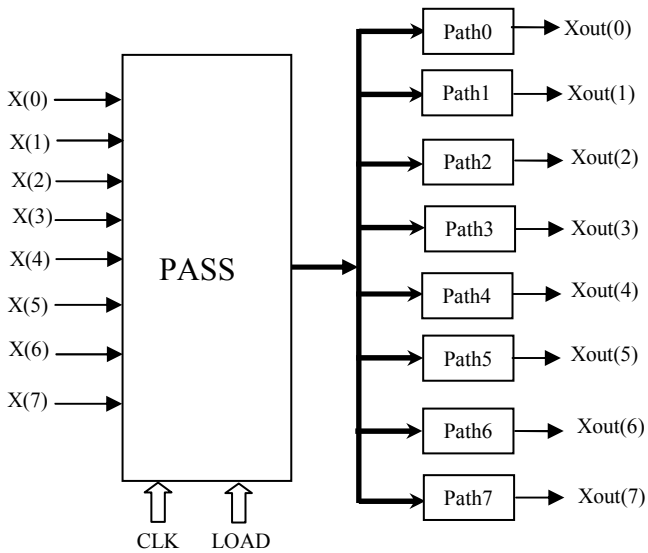

Fig. 2 Block diagram of an 8 point IFFT processor

Same arithmetic operations are involved for Xout(1), Xout(3), Xout(5) and Xout(7) modules including real and imaginary calculation. They are performed separately. The output of the twiddle factor is approximated to 0.70703125 or in binary 0.110110101, including a most significant bit (MSB) to indicate the twiddle factor is a positive number. Any decimal value after summation is approximate to integer '1'.

A. *Expanding Direct Method of an 8-point IFFT*

Using direct method, the equations of every module have been optimized for an efficient implementation. The twiddle factors are represented by 8 bit binary number. There will be slight error percentage in this design due to the approximation of the twiddle factor values. By using Verilog HDL the final equations are implemented to make an 8-point IFFT processor which is shown in below.

TABLE I
THE FINAL EQUATIONS FOR AN 8-POINT IFFT PROCESSOR

X(0) = x(0)+ x(4)+ x(2)+ x(6)+ x(1)+ x(5)+ x(3)+ x(7)
X(4) = x(0)+ x(4)+ x(2)+ x(6)- x(1)- x(5)- x(3)- x(7)
X(2) = x(0)+ x(4)- x(2)- x(6)+ jx(1)+ jx(5)- jx(3)- jx(7)
X(6) = x(0)+ x(4)- x(2)- x(6)- jx(1)- jx(5)+ jx(3)+ jx(7)
X(1) = x(0)- x(4)+ jx(2)- jx(6)+ 0.7071x(1)+ j0.7071x(1) - 0.7071x(5)- j0.7071x(5) - 0.7071x(3)- j0.7071x(3) + 0.7071x(7) + j0.7071x(7)
X(5) = x(0)- x(4)+ jx(2)- jx(6)- 0.7071x(1)- j0.7071x(1) + 0.7071x(5)+ j0.7071x(5) + 0.7071x (3) + j0.7071x (3) - 0.7071x(7) - j0.7071x(7)
X(3) = x(0)- x(4)- jx(2)- jx(6)- 0.7071x(1)+ j0.7071x(1) + 0.7071x(5)- j0.7071x(5) + 0.7071x(3)- j0.7071x(3) - 0.7071x(7)+ j0.7071x(7)
X(7) =x(0)- x(4)- jx(2)- jx(6)+ 0.7071x(1)- j0.7071x(1) - 0.7071x(5)+ j0.7071x(5) - 0.7071x(3)+ j0.7071x(3)+ 0.7071x(7)- j0.7071x(7)

The equations for FFT are similar to IFFT equations except for the negative sign in the twiddle factor and the scaling factor. Thus, the algorithm developed for the IFFT in the previous section can be used for FFT algorithm development with minor modification.

B. *IFFT and FFT Algorithm*

Both the processors IFFT and FFT are divided into subsequent modules. These are pass module, Path0, Path1, Path2, Path3, Path4, Path5, Path6 and Path7 modules. In pass module the input data is passed at the positive edge of the clock to the different modules of FFT processor. In that condition, the load signal is active high. It requires only one clock signal to pass the data.

The implementations of Path0 and Path4 are almost identical except the mathematical operators. There is no imaginary component present at the output. But Path2 and Path6 modules have imaginary component. Thus, they have more complex mathematical expressions.

Path1, Path3, Path5 and Path7 are the most complicated modules among all the modules in the FFT processors because they involve number of mathematical operations, such as addition, subtraction, and multiplication. The outputs contain real and imaginary components. The imaginary components resulted from the twiddle factor which involves sin 45 degree and cosine 45 degree. This value is approximated to 0.70703125 which is equivalent to 0.10110101 in binary form. The IFFT processor has more complex mathematical operations because it has a scaling factor (1/N). In the digital domain, this translates a division operation. The working of all the modules of IFFT is same as in the FFT processor.

III. SIMULATION RESULTS FOR IFFT AND FFT PROCESSOR

The results of IFFT and FFT Processors are obtained from the Quartus-II simulation with random input samples. Each of the input samples contains 8 bits of input. The accuracy of the output is also verified to the output from MATLAB simulation. The result is divided into 2 different sections, for FFT processor and IFFT processor. The output from each of the modules is shown and followed to the overall output.

A. *Resources Used*

The design of the FFT and IFFT processor are compiled and simulated separately using Altera Quartus-II simulator software. The following resources used in the compilation and simulation process are shown in the Table II.

TABLE II
RESOURCE USED IN CYCLONE II FAMILY

Resource	**Usage**
Device Family:	Cyclone II
Device:	EP2C35U484C8
Total Logic elements:	745 (out of 33216) for FFT and 1146 for IFFT
Total combinational function:	641 (out of 33216) for FFT and 967 for IFFT
Dedicated log registers:	349 for FFT and 632 for IFFT
Total registers:	349 and 632 for IFFT
Total Pin:	178 (out of 362) for FFT and 179 for IFFT
Total memory bits:	0
Embedded Multiplier 9 -bit elements	3

Fig. 3 shows the final simulation of the 8-point FFT processor where we see that when we give data through the eight input point it will give eight output data respectively. These simulations also show that Path0 and Path4 give only real output and rest of paths give both real and imaginary value. So, this simulation results is very close to the mathematical calculation and further we will compare these data with MATLAB simulation.

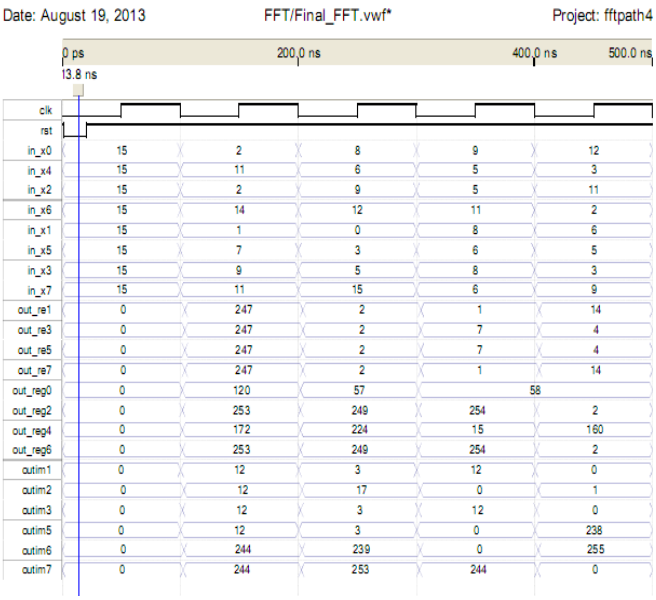

Fig. 3 FFT processor output

IV. Verification Of Verilog HDL Simulation Output With Matlab

In this section, the result of Verilog HDL has been verified. The Verilog HDL output and the MATLAB simulation output using same arbitrary input number are compared to measure the accuracy of the result. In Table III, the accuracy of the Verilog HDL simulation output has been rounded to the nearest integer because only 8 bit is used to represent the output value.

TABLE III
Comparison Between Quartus-II Vs Matlab Output For 8-point FFT

Sl No	Input	Quartus II Out put		MATLAB Out put	
-	---	Real	Imaginary	Real	Imaginary
1	2	60	0	60	0
2	1	247	12	246	19
3	2	253	15	253	15
4	9	247	12	248	252
5	11	224	0	254	0
6	7	247	12	248	4.22
7	14	253	241	253	241
8	14	247	244	246	237

V. Conclusion

In this modern era, OFDM (Orthogonal Frequency Division Multiplexing) is one of the best technologies which support the 3G and 4G standards of wireless communication. OFDM is mainly used in the WiMAX, LTE, WLAN etc. and providing tremendous speed.

The core processing blocks of an OFDM system i.e. the FFT and the IFFT processors have been designed and implemented successfully using common pass module and multiple path modules. Direct mathematical method was adopted as it was found to be an efficient and optimized method implementation which is based on butterfly operation instead of the structural. At the end functional simulation was performed from Altera Quartus II to generate the design net list file and to translate the design into the target Altera FPGA device. The output of the functional simulation matched the data calculated from pre- synthesis MATLAB simulations.

***Abstract*—Orthogonal Frequency Division Multiplexing (OFDM) is an excellent choice of high speed data transmission systems. Since a large number of subcarriers uses in most of the broadband data communications standards, high PAPR is also a great drawbacks. On the other hand, subcarriers orthogonality is very sensitive to carrier frequency offset (CFO) in between transmitter and receiver oscillators. Golay complementary sequences (Coset Representatives) with Reed-Muller code gives maximum $3\ dB$ PMEPR [20] and reduces ICI, due to the CFO, significantly [1]. In this work, our contributions are two-fold: 1) we obtain all, total 1024, possible coset representatives for 32 subcarriesrs BPSK modulated Coded-OFDM (COFDM), 2) we simulated maximum Peak Envelope Power (PEP) and Inter-carrier Interference (ICI) over each coset representatives.**

***Index Terms*—PEP, ICI, Coset Representatives, Coded-OFDM.**

I. Introduction

A. Motivation

Orthogonal frequency division multiplexing (OFDM) systems are characterized by large number of closely spaced orthogonal subcarriers that carry data from a single source. OFDM systems, hence, have high spectral efficiency and excellent ability to cope with various channel condition e.g. narrow-band interference and frequency selective fading cause of multipath environment [3]. That's the reason for considering the OFDM as air-interface by many high-data-rate wireless transmission systems. OFDM systems can however experienced two major drawbacks: high peak-to-mean envelope power ratio (PMEPR) due to summing up of large number of subcarriers data together and inter-carrier interference (ICI) because the orthogonal properties are easily broken down by carrier frequency offset (CFO) errors caused by inaccuracies between transmitter and receiver oscillators, Doppler effects, etc.

B. Basic COFDM Architecture

A basic COFDM systems architecture is represented in Fig.1. As the blocks show that information data, output of a source-encoder, are passed through a channel-encoder which adds redundancy bits for error control due to severe channel conditions. In the modulation phase, the bits are mapped into a symbol, and they are phase shift keying (PSK) modulated so as to maintain simplicity and constant amplitude patterns. The data is then converted into parallel from serial followed by inverse discrete fourier transform (IDFT) process. IDFT transmutes the domain of data to frequency from time and coherently sums up to get OFDM symbol. Following some required manipulation, the OFDM symbol is transmitted through the AWGN channel. At the receiver end inverse operations of the transmitter end takes place.

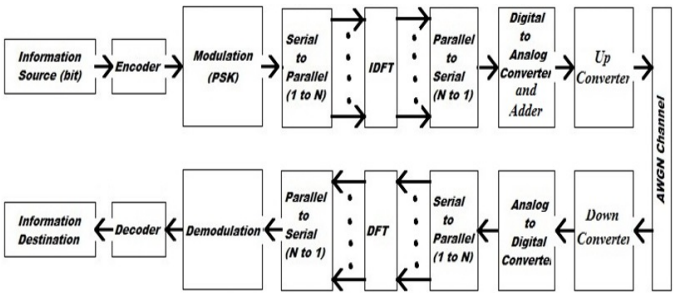

Fig. 1. A basic architecture of Coded-OFDM systems.

C. Related Works

It is clear from the OFDM architecture given in the Fig.1, to create an OFDM symbol, all subcarriers signals are added together after IDFT has been done. The process results high fluctuations in signals power levels and the detrimental aspects well known as peak-to-mean envelope power ratio (PMEPR). Also recognizing as peak to average power ratio (PAPR), some techniques have been proposed in literature to reduce the effect. The PAPR reduction methods are categorized as follows: Selected mapping (SLM) and partial transmit sequences (PTS) [14], [15], [16], [17], Clipping and filtering techniques [13] and coding [20]. SLM and PTS approaches reduce the probability of generating a signal with large PMEPR, by generating multiple statistically independent OFDM symbols for a given data frame and transmitting the symbol with the lowest peak power.

In Clipping and filtering techniques, a pseudo-maximum amplitude has been determined to cut-off the peaks of the OFDM time domain signals followed by the filtering process for minimizing the out of band radiation, generated by clipping. Last approach is to use coding to reduce PMEPR. The theoretical aspects of the relation between the code rate, minimum Euclidean distance of the code and its block length is provided in [18] as two fundamental theorems. The first one proves a lower bound for PAPR based on the three aforementioned parameters.

To get the advantage of spectrum efficiency, the orthogonality between sub-carriers must be maintained. In the literature, two types of approaches have been proposed to mitigate the frequency-offset problem. The first approach focuses on estimating and then eradicating the frequency offset [4]. The second approach focuses on reducing the sensitivity to CFO with no need to precisely estimate the CFO.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

The first approach is beyond the scope of this paper. We assume here that a coarse-offset estimation that estimates the part of frequency offset that is multiple of the subcarrier spacing is carried on successfully.

The second approach employs a combination of signal processing and coding to reduce the sensitivity to the residual frequency offset [5]. An effective method, named ICI self-cancelation, proposed by Zhao and Haggman in [6] and later extended in [7], [8], [9], uses polynomial coding in the frequency domain. The self-cancellation method modulates copies of the same data symbol on r adjacent sub-carriers using optimized weights. The method reduces the ICI significantly but it lowers the transmission rate by a factor r. Some forward-error correction codes are also proposed, to remove the errors caused by the ICI, in [10]. The correlative-coding, proposed in [11], is another way of reducing the sensitivity of the ICI. More recently, Smida proposed in [12] to choose a well understood code and to rotate each coordinate of the code by a fixed phase shift to reduce ICI.

All of the above methods are useful for reducing PAPR and ICI separatetly. Very few research work has been done for remedy both the problems of OFDM systems. The most few important exceptions are Golay complementary repetition code [2] and Selective Coset (SLC)[1] which alleviate both PAPR and ICI.

D. Our Contributions

In this paper, we simulate maximum PEP and ICI over all possible coset representatives for 32 subcarriers, where 1024 Golay complementary sequences are possible. The results are important because both Golay complementary repetition codes and Selective Coset (SLC) methods use the Golay complementary sequences, well known as coset representatives.

II. Mathematical Terms and Definitions

A. Preliminaries

We consider a OFDM systems with N subcarriers where modulated time domain signals of all subchannels are added together to form an OFDM signals within a OFDM time period of T_s after IDFT operation. The transmitted signal at time t may be represented as the real part of the complex envelope,

$$S_{\mathbf{c}}(t) = \sum_{n=0}^{N-1} c_n \exp(j2\pi(f_0 + nf_s)t) \quad \text{for} \quad 0 \le t \le T_s, \quad (1)$$

where $j = \sqrt{-1}$, f_0 is the beginning frequency and f_s is the bandwidth of each subcarrier. The OFDM-symbol duration T_s is equal to $\frac{1}{f_s}$ to ensure the orthogonality among the subcarriers. The vector $\mathbf{c} = [c_0, c_1, \ldots, c_{N-1}]$ of length N is the modulating data sequence. We refer to $\mathbf{c}$ as codeword of code $\mathcal{C}$ that maps blocks of k input bits into blocks of N symbols. The data-coefficients c_n are typically taken from a constellation $\mathcal{Q}$ with 2^h elements, where h is the number of bits being mapped on each symbol.

The *peak envelop power*(PEP) of the transmitted signal is

$$\text{PEP}(\mathbf{c}) = \max_{0 \le t \le T_s} |S_{\mathbf{c}}(t)|^2, \quad (2)$$

So according to the definition, the *peak-to-mean envelope power ratio* (PMEPR) is as follows,

$$\text{PMEPR}(\mathbf{c}) = \max_{0 \le t \le T_s} \frac{|S_{\mathbf{c}}(t)|^2}{\| \mathbf{c} \|^2}. \quad (3)$$

Where, $\| \mathbf{c} \|^2$ is known as *mean* or *average* power of the OFDM signal over T_s. In case of *phase shift keying*, the magnitude of $\| \mathbf{c} \|^2$ is equal to N.

We use an additive white Gaussian noise (AWGN) environment to represent the channel and $S_{\mathbf{c}}(t)$ is transmitted through it. The receiver performs inverse of IDFT after receiving the signal $\Re(S_{\mathbf{c}}(t))$ which is the perturbed version, due to noise, of transmitted signal and estimates of $\mathbf{c}$. Then at the receiver, a useful error-correction algorithm is used to extracts the block of input codes. The received signal sample for the kth subcarrier after DFT can be written as

$$y_k = c_k b_0 + \sum_{l=0, l \ne k}^{N-1} b_{l-k} c_l + n_k = c_k b_0 + I_k + n_k, \quad (4)$$

for $k = 0, 1, \ldots, N-1$, where n_k is a complex Gaussian noise sample. The first term in the right-hand side of (4) represents the desired signal. The ICI term, attributable to the CFO, on the kth subcarrier is expressed by I_k. The ICI coefficients b_k is given by

$$b_k = \frac{\sin \pi(k+\varepsilon)}{N \sin \frac{\pi}{N}(k+\varepsilon)} \exp\left[j\pi(1 - \frac{1}{N})(k+\varepsilon) \right], \quad (5)$$

where ε is the normalized frequency offset defined as a ratio between the frequency offset (which remains constant over each symbol period) and the subcarrier spacing. Note that I_k is a function of both $\mathbf{c}$ and ε.

Sathanannthan and Tellambura [2] defined the *peak interference-to-carrier ratio* PICR as

$$\text{PICR}(\mathbf{c}, \varepsilon) = \max_{0 \le k \le N-1} \frac{|I_k|^2}{|b_0 c_k|^2}. \quad (6)$$

PICR is *maximum interference-to-signal ratio* for any kth subcarrier, where $|b_0 c_k|^2$ is the signal power of kth subcarrier. It specifies the worst-case ICI on any subcarrier. Large I_k values cause high bit errors in subcarriers. To make the PICR compatible with PMEPR, we called it the *peak interference-to-carrier power ratio (PICPR)*.

To measure the detrimental effect of ICI, we have introduced the *peak interference power* (PIP) as

$$\text{PIP}(\mathbf{c}, \varepsilon) = \max_{0 \le k \le N-1} |I_k|^2, \quad (7)$$

which is fuction of both $\mathbf{c}$ and ε, too. To reduce ICI effects, PIP should be minimized.

To improve the performance of OFDM systems both PMEPR in (3) and PICPR in (6) should be minimized.

B. Golay Complementary Sequences and Reed-Muller Codes

In [20], authors present a coding technique that connects Golay sequeces and first order binary Reed-Muller codes. The Golay sequeces transpire as cosets of first order Reed-Muller codes in the second order Reed-Muller codes. The following theorems justify the preference of the Golay complementary sequences.

Theorem 1: For unit power constellations, the PMEPR of any complementary Golay sequence is bounded by 2.

Theorem 2: For any permutation ϕ of the set $\{1, 2, \ldots, m\}$, and for any $c_k, c \in \mathbb{Z}_{2^h}$. The sequence generated by

$$u(\mathbf{x}) = 2^{h-1} \sum_{k=1}^{m-1} x_{\phi(k)} x_{\phi(k+1)} + \sum_{k=1}^{m} c_k x_{\phi(k)} + c,$$

is Golay complementary over $\mathbb{Z}_{2^h}$ of length 2^m.

For H-*phase shift keying*, where $H = 2^h$ and $h \geq 1$, each OFDM symbol period contains exactly h code bit. In the case of $H = 2, 4,$or 8 the code is called binary,quaternary and octary respectively.

Popovic proved Theorem 1 in [19] which inspired the use of Golay sequences for OFDM systems to mitigate PAPR problem. Theorem 2 explicitly describes connection between the Golay complementary sequences and RM codes [20]. The RM code over $\mathbb{Z}_{2^h}$ of order r and length 2^m, denoted by $\mathrm{RM}_{2^h}(r, m)$, consists of all linear combinations of vectors associated with the monomials of degree at most r in m variables. The Boolean monomial of m variables is defined as $f_x = x_0^{r_0} x_1^{r_1} ... x_{m-1}^{r_{m-1}}$ where $(x_0, x_1, \ldots, x_{m-1})$ is an m-tuple binary vector. Henceforth, each of $\frac{m!}{2}$ cosets of $\mathrm{RM}_{2^h}(1, m)$ in $\mathrm{RM}_{2^h}(2, m)$ having a coset representative of the form $\sum_{k=1}^{m-1} x_{\phi(k)} x_{\phi(k+1)}$ comprises $2^{h(m+1)}$ Golay sequences over $\mathbb{Z}_{2^h}$ of length 2^m. Thus, we conclude that costs of Reed-Muller codes over $\mathbb{Z}_{2^h}$, provide codewords with PMEPR that does not exceed 3 dB [20].

For example, if we consider $r = 1$ and $m = 5$ then $\mathrm{RM}_{2^h}(1, 5)$ has the generator matrix, G, given below as

$$\begin{bmatrix} 1 \\ x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{bmatrix} = \begin{bmatrix} 11111111111111111111111111111111 \\ 00000000000000001111111111111111 \\ 00000000111111110000000011111111 \\ 00001111000011110000111100001111 \\ 00110011001100110011001100110011 \\ 01010101010101010101010101010101 \end{bmatrix}$$

Therefore, the Reed Muller codeword, $\mathbf{c} = [c_0, c_1, \ldots, c_{31}]$, of length 2^5 is the linear combination of the generator matrix G and $\mathbf{u} = [u_0, u_1, u_2, u_3, u_4, u_5]$ as $\mathbf{c} = \mathbf{u} .* G$, where $\mathbf{u}$ is information bits. The sign, $.*$, represents matrix multiplication. Hence the Reed Muller Golay Codeword, $\mathbf{c}' = \mathbf{c} + u(\mathbf{x})$.

III. Coset Representatives for 32 subcarriers

It has been shown in [2] that both PAPR and ICI can be reduced by using Golay complementary repetition code. It is a simple combination of Golay complementary sequences (to reduce PAPR) and repetition code (to reduce PICR). Based on the previous theorems, a more efficient code to reduce PAPR and ICI has been proposed in [1]. The main idea is to choose a subset of coset representatives. Therefore coset representatives are most important factor for both techniques.

There are $2^{m(m-1)/2} = 2^{5(5-1)/2} = 1024$ cosets for 32 subcarriers. The coset values are calculated from the matrix multiplication of a certain combination. From table I the term $x_1 x_5$ is found by array multiplication. The values of x_1 and x_5 are obtained from the generator matrix above. The binary rows of x_1 and x_5 are multiplied in order to get a coset value of a particular sequence. Therefore, $x_1 x_5 = x_1 . * x_5 =$ 00000000000000000101010101010101 is a Golay sequence. In this way all the coset values of 1024 sequences are found and in the table I all coset representatives those are having maximum PMEPR at most 2 or 3 dB have been shown.

IV. Simulation Results

The simulation results, shown in table II, obtained considering BPSK modulation, AWGN channel environment and frequency offset $\epsilon = 0.1$. The number of subcarriers for an OFDM systems has been chosen as $N = 32$, for simulatating PEP, PMEPR, PIP as well as PICPR of Golay Complementary sequences. The coset representatives those give maximum PMEPR 3 dB has been chosen to be represented in the tables.

In second table the coset representatives having maximum PMEPR 3 have been rearranged according to their PICPR values. They can be categorized in 3 types. First the values which lies within the range from -8.73 to -8.05 dB give the cosets that are best for transmission, then the range -7.97

$x_1x_4 + x_1x_5 + x_2x_3 + x_3x_4$	64	3.01	213.18	-6.67

to $-7.05\ dB$ gives the cosets which are second best for our purpose. And the cosets with PICPR values within -6.96 to $-6.67\ dB$ are having high sensitivity with CFO.

V. CONCLUSION

In this paper, we repesents the cosets those are better for error correction through the simulation proces. We consider only PMEPR and PICPR to categorize the cosets. So there are 9 cosets out of 1024 those are having maximum 3 dB PMEPR and maximum $-8.05\ dB$.

Abstract—**Performance degradation due to nonlinear Kerr effects in return-to-zero differential phase-shift keying (RZ-DPSK) and carrier suppressed returned-to-zero (CSRZ) DPSK dense wavelength division multiplexed (DWDM) systems have been investigated. The quality factor *Q* is measured at the receiving end of the transmission line. Dispersion as well as Kerr effects are mitigated. Post mitigation performance for these two systems are evaluated and compared. RZ-DPSK outperforms CSRZ-DPSK largely.**

***Index Terms*— Cross-phase modulation, CSRZ, DPSK, dispersion management, DWDM, four-wave mixing, RZ**

I. INTRODUCTION

Over the last decade traffic on Internet has increased very rapidly and various telecommunication and multimedia applications are continuously increasing the data rate and implementing suitable modulation formats to meet the demands of ever growing Internet traffic. Differential phase-shift keyed (DPSK) format, which carries the information by optical phase changing between bits, has been attracted huge research attention for optical communication systems because of its 3 dB receiver sensitivity improvement compared to on-off keying (OOK) format. It also shows more resilience to nonlinear effects and chromatic dispersion than OOK. On the other hand, return-to-zero (RZ) optical signals possess advantages in operating with high input powers, small inter-symbol interference and high receiver sensitivity compared to non-return-to-zero (NRZ). RZ-DPSK has many advantages over NRZ-DPSK with higher noise tolerance and resistance to nonlinear effects [1]. Carrier-suppressed RZ (CSRZ) signal, which is a variation of the RZ format, provides higher efficiency in spectrum utilization, more tolerance to filtering and chromatic dispersion because of its narrow spectrum [2]. Among other modulation formats which provide higher spectral efficiency like DQPSK, 8-DSPK recent works show that DPSK is more attractive than DQPSK and 8-DPSK in many cases like higher tolerance to chromatic dispersion and nonlinearity and it can handle higher bit rate and transmission reach [3]. It becomes well-known that DPSK would be the next modulation format for fiber-optic communication, however, RZ and CSRZ have been found to be the two key potential contenders as line coding.

For narrow spectrum, CSRZ could be better option for DWDM application, however, some recent works show that RZ-DPSK offers better performance than CSRZ-DPSK with dispersion-slope compensation at 40 Gb/s [4]. In presence of limited amplifier noise, RZ-DPSK has shown the best performance among NRZ/RZ/CSRZ DPSK WDM systems [5]. Combination of RZ/CSRZ and DPSK can enhance system quality [6, 7]. Our current work shows the nonlinear performance analysis of RZ/CSRZ DPSK DWDM systems at ultra-high bit rate and reveals the better option for DWDM application after mitigation of dispersion and nonlinearity.

In this work, the channel count is varied upto 33-ch for DWDM. The *Q*-factor is measured at the receiver placed at the end of dispersion-managed (DM) transmission line and different parameters like transmission reach, launch power, channel spacing, residual dispersion and bit rate are varied to observe performance. OPTISYSTEM simulation tool is used to model the system and estimate the *Q*.

II. THEORETICAL MODELING

The optical signal propagating in fiber is governed by the nonlinear Schrödinger equation (NLSE) which is solved numerically using OPTISYSTEM 12 simulation tool. The NLSE for a propagating channel can be written as

$$i\frac{\partial U}{\partial Z}+\frac{D(Z)}{2}\frac{\partial^2 U}{\partial T^2}+\gamma(Z)\left|U\right|^2 U=-i\alpha(Z)U+ig(Z)U \qquad (1)$$

where U is the slowly varying envelope of the optical pulse, Z is transmission distance, $D(Z)$, $\gamma(Z)$, $\alpha(Z)$ and $g(Z)$ represent fiber chromatic dispersion, nonlinearity, fiber loss and amplifier gain respectively. The signals for RZ-DPSK and CSRZ-DPSK are generated using one Mach-Zehnder modulator (MZM) [7].

The center channel is placed at 1552.524 nm or 193.1 THz following 100 GHz ITU grid, with the consecutive channels each having same channel spacing from the previous one. For the RZ-DPSK system, an RZ signal is achieved from the differentially encoded bit sequence by modulating the phase of carrier from laser source using MZM and a pulse carver. The CSRZ signal is achieved in a similar process but using different encoder. The DM map consists of 50 km standard single mode fiber (SSMF) followed by dispersion compensated fiber (DCF). All modulated channels are multiplexed and transmitted through the DM line. The fiber and system parameters are given in Table I. The amplifier gain is adjusted to compensate for the loss for each span. Noise figure of EDFA is 6 dB. The polarization state of all channels is assumed identical.

TABLE I: FIBER AND SYSTEM PARAMETERS

Parameter	SSMF	DCF
Attenuation, α [dB/km]	0.2	0.5
Dispersion, D [ps/nm/km]	16.75	−83.25
Fiber length, [km]	50	10
Nonlinearity coefficient, γ [1/W/km]	1.32	4.78
Effective area of core, A_{eff} [μm^2]	80	22
PMD Coefficient, [ps/√km]	0.5	0.5
Center wavelength, λ [nm]	1552.524	
Typical data rate per ch, [Gb/s]	40	

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

The 3 dB bandwidth of MUX/DEMUX filter is optimized in order to obtain highest receiver sensitivity and spectral efficiency of 0.66 b/s/Hz has been achieved.

Eye-pattern is achieved numerically at the receiver-end and Q-factor of the received signal is measured. The Q-factor is defined by,

$$Q = \frac{|m_0 - m_1|}{\sigma_0 + \sigma_1} \tag{2}$$

where, m_o and m_1 are the mean and σ_o and σ_1 are the standard deviation of the received signal measured for binary data "0" and "1", respectively. The whole system is shown in Fig. 1.

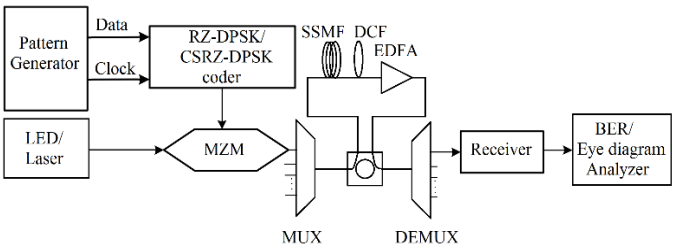

Fig. 1: System model for RZ-DPSK and CSRZ-DPSK DWDM system.

III. PERFORMANCE ANALYSES

The duty cycle for RZ-DPSK DWDM systems is 66% and typical channel spacing is taken as 100 GHz. In all cases, the worst channel is observed for measuring Q-factor using (2). In the first simulation Q-factor is evaluated by increasing the number of channels from 1 to 33. The total transmission reach is 360 km and launch power is 3mW. From Fig. 2(a) for RZ-DPSK and Fig. 2(b) for CSRZ-DPSK DWDM systems, we observe that Q-factor decreases with number of channel for uncompensated system. As we increase the number of channel, optical signal to noise ratio (OSNR) decreases due to adverse nonlinear effect i.e. addition of cross-phase modulation (XPM) and four-wave mixing (FWM). From the figure we see that Q-factor is equal to and above 6 dB (BER = 10^{-9} for Q = 6) up to 24 channels for RZ-DPSK DWDM system. For CSRZ-DPSK DWDM system it is 21 channels. After that Q goes below that margin. Nonlinear effects, mainly XPM and FWM increase with increase of number of channel, however, SPM effect might remain same as it affects single channel only. Pre-compensated, post-compensated and pre & post- compensated values for these two systems are also plotted in Fig. 2. The increase in values for Q shows that the performance degradation due to nonlinear effects are somewhat mitigated. We also find that Q values are higher (mostly in compensated cases) in RZ-DPSK than that of CSRZ-DPSK DWDM system.

Fig. 3 shows Q-factor as a function of transmission reach. For both DWDM systems, Q is equal to and above 6 dB upto 600 km for 12 channels. However, for compensated cases Q is higher in RZ-DPSK DWDM systems for short transmission reach, Q values are comparable at longer distances. In the next simulation we show the plot of Q against launch power for 24-ch DPSK DWDM system in Fig. 4. Transmission reach is taken as 360 km. Here without mitigation, Q reaches below 6 dB after 10 mW for RZ-DPSK and after 5 mW for CSRZ-DPSK. Compensated values by pre-compensation, post-compensation and pre & post- compensation are also plotted with uncompensated values. It is found that Q is above 6 dB for RZ-DPSK upto 12 mW whereas it goes below that margin for CSRZ model.

Fig. 5 shows the plot of Q vs. channel spacing for 600 km long 7-ch DWDM system. We vary the channel spacing from50 GHz to 200 GHz. At lower channel spacing like 50 GHz, Q is below 6 dB for all except RZ-DPSK with pre & post-compensation. With the increase in channel spacing, Q increases as both XPM and FWM crosstalk reduce with larger spacing.

In order to observe the effect of residual dispersion on system performance, the Q-factor is plotted as a function of residual dispersion for 21-ch DPSK DWDM system in Fig. 6. So far residual dispersion at the central channel has been kept zero. We now vary residual dispersion at central channel for both positive and negative values. At lower values of residual dispersion, RZ-DPSK DWDM system outperforms CSRZ-DPSK DWDM system. At higher residual dispersion above 30 ps/nm, CSRZ DPSK performs better. Pre & post–compensation is the best among the three mitigation techniques.

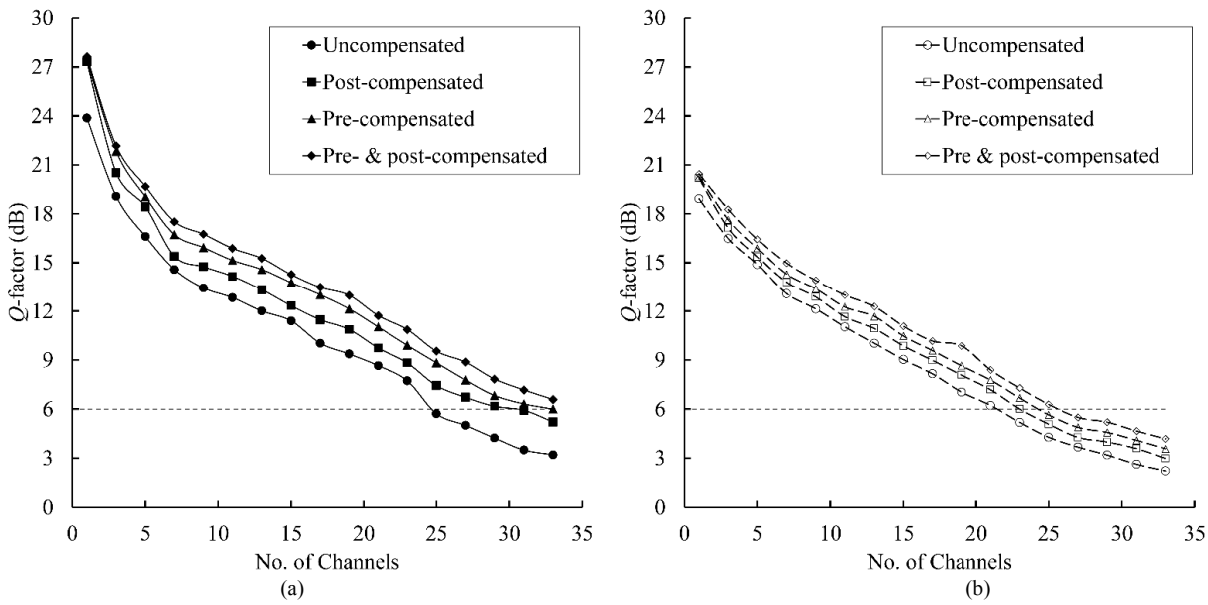

Fig. 2: Q vs. number of channels, (a) RZ-DPSK DWDM system, (b) CSRZ-DPSK DWDM system.

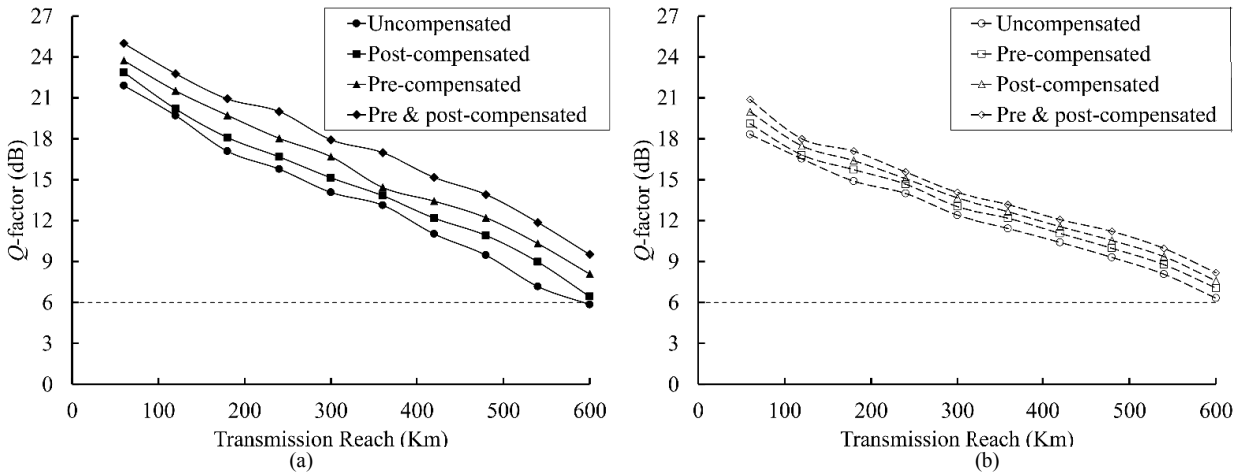

Fig. 3: Q vs transmission reach, (a) RZ-DPSK DWDM system, (b) CSRZ-DPSK DWDM system.

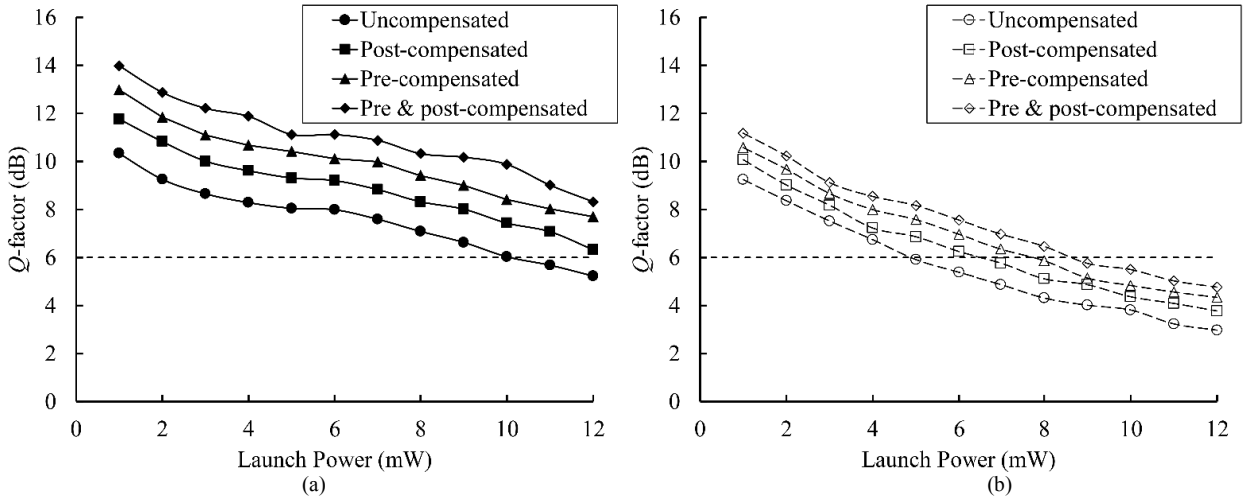

Fig. 4: Q vs. launch power, (a) RZ-DPSK DWDM system, (b) CSRZ-DPSK DWDM system.

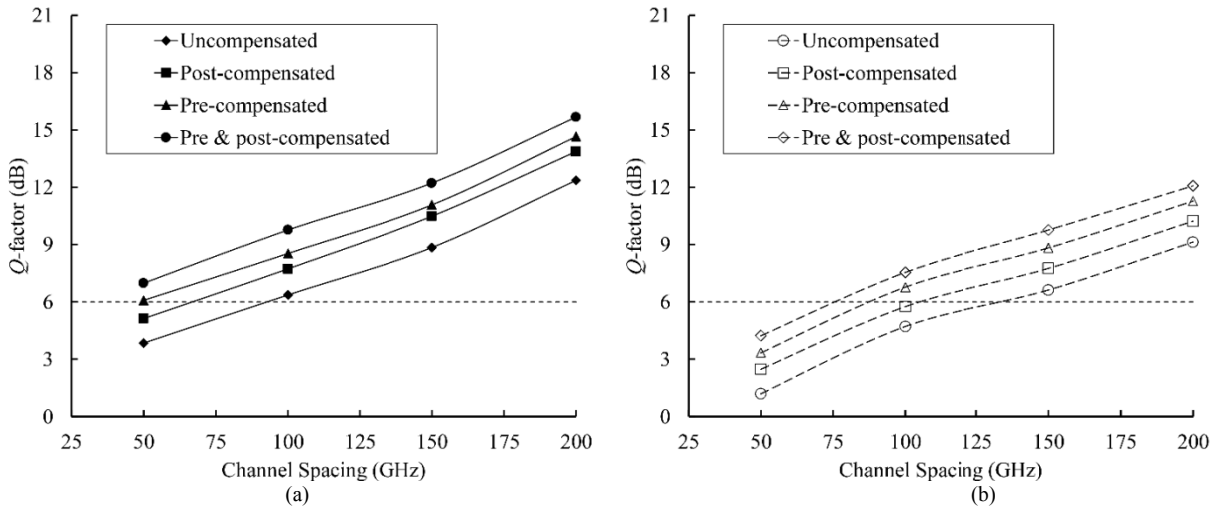

Fig. 5: Q vs. channel spacing, (a) RZ-DPSK DWDM system, (b) CSRZ-DPSK DWDM system.

The last simulation result is obtained by varying bit rate for 17-ch DPSK DWDM system. We vary bit rate per channel from 10 Gb/s to 160 Gb/s and plot the value of Q against it in Fig. 7. At lower bit rate system performance is satisfactory but degrades with increase in bit rate. The compensated values are also plotted which show that mitigation by pre & post-compensation excels the other two mitigation techniques. It is obvious that RZ-DPSK yields much improved performance compared to CSRZ-DPSK for any bit rate.

These investigations show that all the three compensation techniques reduce fiber nonlinear effects and among the three methods, pre & post-compensation is found to be the best choice for both RZ and CSRZ DPSK DWDM systems. The numerical simulation results also prove that RZ-DPSK excels CSRZ-DPSK in all cases except at higher residual dispersion. Spectrum spreads in RZ-DPSK which reduces nonlinearities and might cause the performance improvement. On the other hand, CSRZ-DPSK possesses more compact spectrum.

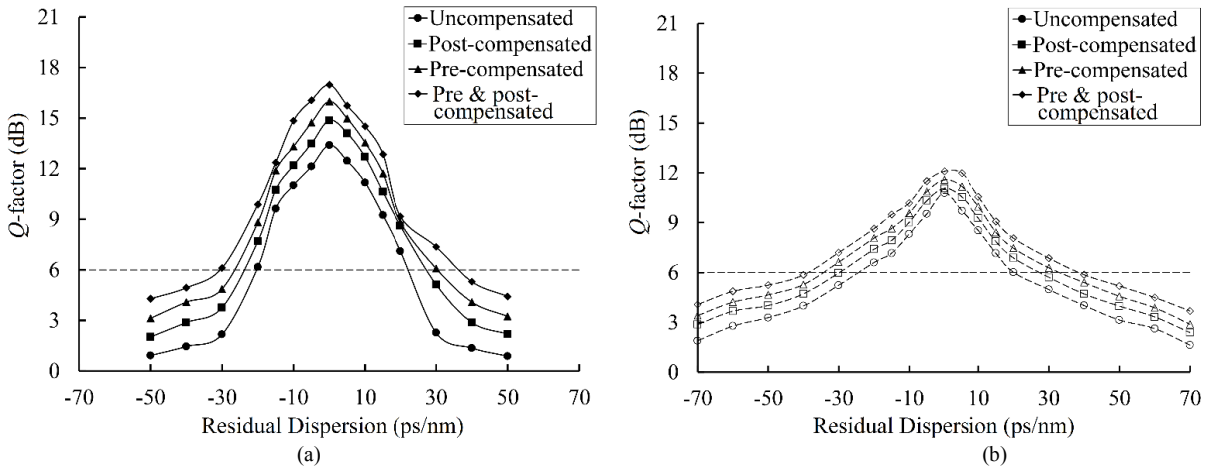

Fig. 6: Q vs. residual dispersion, (a) RZ-DPSK DWDM system, (b) CSRZ-DPSK DWDM system.

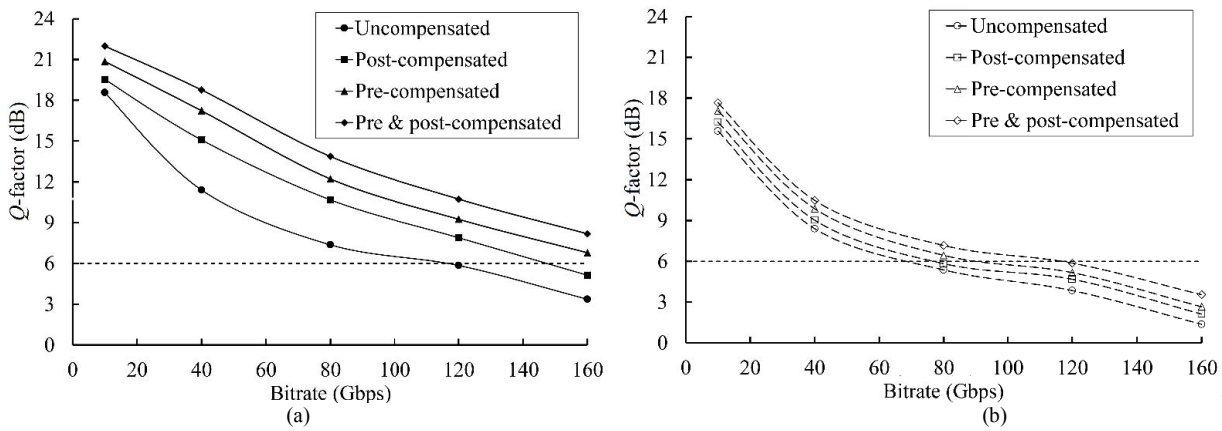

Fig. 7: Q vs. number of channels, (a) RZ-DPSK DWDM system, (b) CSRZ-DPSK DWDM system.

IV. CONCLUSIONS

In this paper, the nonlinear performance is evaluated by varying number of channels, transmission reach, launch power, residual dispersion and bit rate for RZ-DPSK and CSRZ-DPSK DWDM systems. The numerical simulation is done by solving NLSE. As far as real environment is considered, RZ-DPSK DWDM system is found to be superior to CSRZ-DPSK DWDM system in all cases except at higher values of residual dispersion. For all cases in RZ-DPSK and CSRZ-DPSK DWDM systems, pre & post-compensation mitigation technique gives the best performance improvement followed by pre-compensation and post-compensation respectively.

Future work may include experimental investigation. Intra-channel nonlinear effects and amplifier noise can be taken into account. Other dispersion and nonlinearity mitigation techniques may also be studied for DPSK DWDM systems.

***Abstract* - Content Management System (CMS) is one of the recent upcoming concepts due to its efficient and explicit use in the real world applications. The demand for growth in its diversity has been documented by many researchers. Due to the limitation of traditional database management system (DBMS), which enforces limits on the type of data items need to be stored, CMS becomes the cost-effective alternative in the scope of information management. In this ever increasing data scenario we need a framework for managing and publishing all types of data with appropriate data analytics and natural language processing. Nowadays the information, especially in the Internet, consists of structured, semi-structured and unstructured data. Therefore it is unwise to think only about the use of DBMS, rather its alternative framework must be used, keeping the objectives same. The main reason for proposing a new architectural model for a content management system is that there are several important characteristics that CMSs should have to provide opportunity to specific optimizations [1]. Our "Next Generation CMS model" includes functionalities like multi-language, copyright, multichannel publishing, natural language processing, garbage collection management which are not included in the traditional ones.**

Keywords: Fragmentation Management, Language Management, Copyright Management, Multichannel Publishing, Garbage Collection, Data Analytics(DA), Natural Language Processing(NLP)

I. INTRODUCTION

CMS is a basic framework, usually manage heterogeneous data, along with considering the security and privacy (wherever the application demands) in highly concurrent multi-user environments. CMSs are often used to run websites containing blogs, news, and shopping. Many corporate and marketing websites use CMSs. CMSs typically aim to avoid the need for hand coding, but may support it for specific requirements.

The term "content management" has several different meanings in today's marketplace. Basically, a content management system is one that stores digital content for search, browsing, access and retrieval by users in a workgroup or enterprise. The most prevalent types of content management systems are: [3]

Enterprise Content Management (ECM): systems that facilitate management of corporate documents and other types of information for use internally as well as externally with a company's business partners, customers, regulators and the general public.

Digital Asset Management (DAM): systems that manage rich media assets, often including digital audio and video clips, for retrieval and repurposing in media production environments. These systems are sometimes also called Media Asset Management (MAM).

Web Content Management (WCM): it provides page template design, editorial workflow and publishing environments specifically for Web sites and other forms of Internet content delivery.

A Document Management System (DMS) is an electronic filing system for capturing, storing and tracking document images. Access to content in a DMS should be quick and secured. Retention and Traceability should also be parts of DMS.

A Component Content Management System (CCMS) deals with content or component at a granular level rather than finished document. Each component can be represented as a topic, with a concept and a potential set of tasks defined. A component can be a chapter or a single word within a chapter. Further each component can have its own lifecycle and be tracked individually or as part of the whole document. CCMS can also be integrated with ECMs, WCMs or DMS.

Today, businesses and educational institutions are using CMS to help them for delivering targeted information for its stakeholders. Many software packages are available; however selecting a CMS is sometimes difficult because trend and evaluation data does not always coexist in the same contexts. Developing a new CMS represent great challenges especially if it copes with the organization needs. Using a process that incorporates trend analysis conducted by independent researchers and feature analysis conducted by open source organizations can often facilitate decision making. The developed CMS in KAU achieved the major requirements and needs of all customers, employee, academic members who deals with KAU either in research track or other university jobs. A lot of benefits of the developed MARZ system include: fast production and deployment of courses, reduce production and deployment cost, supporting innovation of web technology, security and privacy of contents, increased return on investment, increased security and privacy and more time and focus to learning.

Considering the different forms of CMS, we are proposing an architectural model of next generation content management system with all desirable features. The model describes the functionalities of Data Analytics (DA) module, NLP module,

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Content Repository (CR) module along with the others in brief. We have also highlighted the measurable performance criterions of the proposed model.

The rest of the paper is structured as follows: Section II details out the architecture of the proposed model with its functional details and a brief overview of implementation part. Section III describes the performance of the model and Section IV concludes the paper with next level of development.

II. PROPOSED ARCHITECTURAL MODEL

Traditional CMS do not provide appreciable data quality. This includes timely service, quality of information and data accuracy. Nowadays all the information are either semi-structured or unstructured [2]; so there is the need for metadata [3] creation. Therefore the metadata stored in the CMS becomes the bottleneck for searching the content. But metadata based searching can be an efficient alternative. All the naive users needed technical skills for using the framework.

There are large numbers of challenges required to fulfill for maximum utilization of any CMS. CMS model must be secured from unauthorized access. A CMS must keep up -to - date strategies and maintain statistical records (required for data mining). A link from a hypertext to another location, typically activated by clicking on a highlighted word or icon att a particular location on the screen is referred as web linking. We need to avoid such switching and keep the required updated content in the CMS itself. Nowadays copyright has become an important issue in most of the real world applications. To make our CMS's performance better it would be beneficial to swipe out obsolete content. Garbage refers to the obsolete data, whose importance becomes negligible after a certain period. For example, the individual votes in polling, for selecting CEO of an organization become obsolete after the declaration of result. So we need a module to store obsolete or unused data of the CMS. Content or data security is an important issue in any CMS to protect it from intruders. One can view a single content in different formats; for example one user may need the graphical (or pictorial) format, another user may need the text (or numerical) format. Further different portion of the content must have different permission [1] for proper handling of the CMS. The possible permissions allowed can be read only, read and write only, publish only. Non-technical personnel – like marketing staff – must actively participate in managing, updating and reusing content without having to rely on technical experts.

A. ARCHITECTURE

Our CMS architectural model includes all the required functionalities discussed in section II. It is referred to as "Next Generation CMS model" because of the new modules (such as Copyright Management, Security Management, and Multichannel Publishing Management) incorporated in it. In Fig.1, pictorial representation of our architecture is shown. Two primary blocks are- Input Interface and Content Management System.

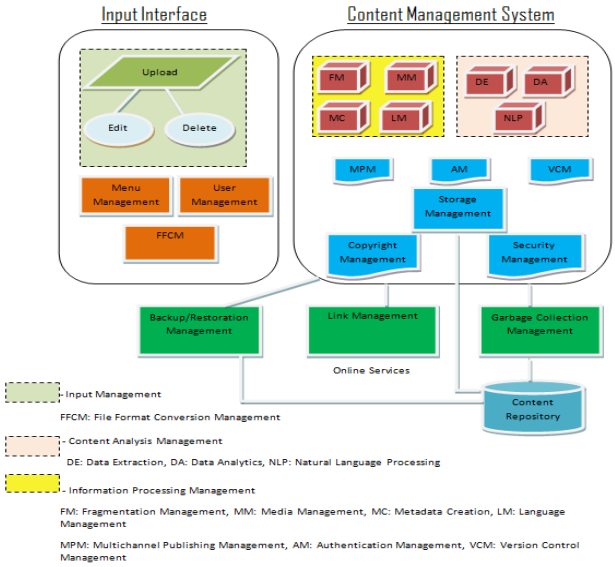

Fig.-1: Architecture of CMS

A content repository (CR) is a store of digital content with an associated set of data management, search and access methods (allowing application-independent access to the content). A CR (functions as the logical storage facility for content) thus typically forms the technical underpinning of CMS; therefore it is included in our model. With reference to any website, with every visit, visitors or customers allow you to study their browsing patterns; we can also monitor traffic, transactions, usability and even aspects like server performance. Web analytics help collect, compile and review all this data, thus providing Web managers with a crucial tool to ensure the effectiveness of the enterprise Web site and monitor conversions almost continuously. Web-based analytics typically consist of standardized analytic tool boxes through which users' can generate and view reports through a desktop or web browser. The data generated can be analyzed, graphically displayed and delivered to product development, manufacturing and senior executives who can make adjustments in real time as appropriate. Therefore Data Analytics (DA) becomes an important sub-module of Content Analysis Management. The essential attributes linked with Data Extraction (DE) are- accuracy, comprehensiveness, relevance and timeliness. It can be best explained with respect to Web CMS.

Natural Language Processing (NLP) is the ability of a computer program to understand human speech as it is spoken. The development of NLP applications is challenging because computers traditionally require humans to speak to them in a programming language that is precise, unambiguous and highly structured or, perhaps through a limited number of clearly-enunciated voice commands. NLP tasks in software programs today include: sentence segmentation, part-of-speech tagging, parsing, deep analytics, named entity extraction and co-reference resolution. "Authentication Check" is required during registration process. Each registered user will be provided a unique id for future log-in; accordingly they will be given access rights for different contents. Fragmentation Management sub-module will partition (or identify) the content of individual files into disjoint fragments of different types (audio, video, text etc.) and assign accessing pointers to them. An efficient indexing

technique will be used to index these fragments pointers. All pointers are separately stored so that the reference to content would be easier. Media Management functionality includes compression of large size files (such as a high definition image), within a fixed tolerance limit. Offline or online conversion within a stipulated time is a desirable feature of media management module. In multi-linguistic nations it is necessary to make the content available in different languages. Therefore the Language Management module will convert the content in few popular languages with the help of web link management module. The basic patent semantic for translation into different languages makes use of the Unicode. The 'moral' reasons for following copyright rules are-(1) copyright protection is essential to ensure that authors and publishers receive appropriate appreciations for their work. With Multichannel Publishing Management module, one can view a single content in different formats (for example numerical or pictorial). Garbage Collection Management module will store obsolete or unused data of the CMS. To make our CMS's performance better it would be beneficial to swipe out obsolete content. Moreover the metadata will contain a link to recover the obsolete data whenever required. Different types of garbage collection are-

Transaction-based: After termination of a project (or deal), most of the transactions related to it becomes obsolete.
Time-based: Fixed time schedule
Policy-based: Some prefixed policy will determine whether a data will be obsolete.
Poll-based (opinion poll based): Not predefined.
Context-based: Whenever a particular context goes out of scope its products become obsolete.

To protect our CMS from intruders we have two different schemes-

User level security: Uses password mechanism, each time the user logged-in.

Document level security: It can be further sub-divided into three categories:

Cryptography - Uses encryption and decryption techniques.

Trust (Reputation or Direct) - Trust towards users can be build up by satisfying few criteria over a time period (Reputation). At the initial stage we can assign trust to different users (Direct).

Policy based - Uses access control list for security specification purpose.

B. STORAGE STRUCTURE

The content, now available for the general user groups and in commercial organizations, is mostly a mixture of video, audio, text etc. So we need different structure or framework to store them. In Fig.2, A, B, C, .. are various sub domain of contents linked together; for example in an organization we will have information about personal details of employees, financial details of company(for audit purpose), customer details, etc. Within each such sub domain we will further have thousands of different files (for serving different purposes). In our problem domain, for individual file we will fragment (as shown in Fig.2) the content, so that we have mutually disjoint fragments of similar and different types. Assuming (A1,A2,A3,A4,A5), (V1,V2,V3,V4), and (T1,T2,T3,T4,T5) are the fragments pointers containing pointers to audio, video and text content respectively (in different files). Now these fragments pointers can be chained together with the help of indexing, as shown in Fig.2, and stored in the storage for efficient retrieval and access. Since buffering of different data format requires different time, systems which have different data processors (with different speed) can be utilized. For example, high speed processors can be used to access video files and low speed processors for accessing text files. Thus in a cost effective way we can have better performance.

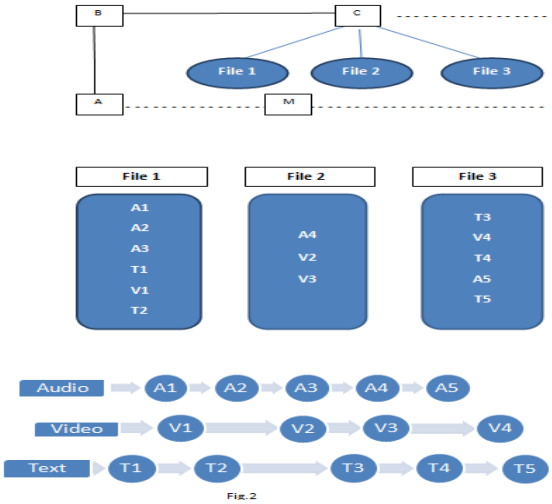

Fig.2- Storge Structure

At the initial stage we will have a readily available file format conversion engine (in FFCM); to convert different files formats (in different format) to a compatible format so that the new CMS can work on it. Autonomous and controlled CMS [1] are the two versions which will be available in our model. This will make our CMS user friendly. Since Autonomous CMS has the merits of self descriptive, scalable and self healing property, whereas the other one has reduced workload and prospective content manager's supervision (for better performance); therefore whatever an application will demand we can choose the appropriate one.

The basic operations (subject to specified access) which should be available for accessing the content in CMS are-update (insert/delete), read, publish, content's access right update, language translation, data extraction and write. When we are allowing a user to read (or update) a part of content then the user must provide few parameters. The parameters will not vary for content to content. For simplicity, the parameters would be the content name, what (keyword specific) data he wants to read or update and for how long. Internally, mapping will be done between content name and index (redirected by fragments pointers) to fetch the appropriate data. For updating, which can be either insert or delete, the user must be authenticated via some existing well defined authentication protocol. However not every content can be updated, to maintain system integrity or due to administrative constraints.

III. PERFORMANCE CRITERIA OF CMS MODEL

The proposed model should have the following performance criteria to maintain the sustainability of the system.

Validity: Content needs to get validated after a certain period of time during its life cycle. For example, digital signature needs to get renewed after a fixed interval of time. With respect to market condition or external world, some content gets stale. So we need to validate them within a predefined time. This helps in maintainability. In CMS we can group this in three categories-associated validity, time validity and context validity. In CMS we have multiple numbers of contents; if one becomes invalid, the others become invalid too, this is referred as associated validity. Time validity refers to validity change with respect to time. Whenever we predict something and the results are declared, the prediction estimate becomes obsolete after result declaration. This is referred as context validity.

Scalability: Scalability is the ability of a system to handle a growing amount of work in a capable manner or its ability to be enlarged to accommodate that growth. In CMS with increased resource, the performance must remain same (must not deteriorate aggressively).

Modularity: An efficient infrastructure must be build up to provide all the required services. Modules concept give better maintainability and proper scalability option, for accessing the content.

Upgradability: Nowadays most of the applications get upgraded to newer version. So we need each module to get upgraded to newer version, with the slightest change incorporated. For example, new file formats are introduced and put to use in a short span.

Response Time: Response time is the time a system or functional unit takes to react to a given input. In CMS it can be measured with respect to user satisfaction time. For example a particular content can be accessed in 10msecs at the first access, and it can take 20msecs in the second access. Therefore the user will be more satisfied in the first access than in the second. It can also be extended with respect to the growth of the content and rationality of the user.

Discover: Different aspects of content in CMS can be stored and combination of few aspects can become another aspect.

Flexibility: It is the ability of a system to respond to potential internal or external changes affecting its value delivery, in a timely and cost-effective manner. Universal readability (For example use of xml, awl, etc. in metadata creation) can be a key factor in CMS affecting the flexibility.

Reliability: Multiple copies (or replication) of content must be kept for making the system reliable, in case of failure (generally, of sub-components). With increased number of users and content, the performance of the CMS should not get affected. Different archival policy need to be used.

Availability: Irrespective of condition of the system, requisite information is available. MTBF (Mean Time Between Failure), MTTR (Mean Time To Repair), MTTF (Mean Time To Failure) and FIT (Failure In Time) are ways of providing a numeric value based on a compilation of data to quantify a failure rate and the resulting time of expected performance.

Fault Tolerance: Within a definite time interval some maintenance must be done to recover from a failure (here it is with respect to access ability). Failure can be with respect to-Network failure (which occurs due to site failure), User-related (when an authenticated user is not permitted to access a content; solution: Training message showing the user do not have access right, so that other users are not delayed) and Context-related (there is a one to one mapping between user group and individual content access ability; if any one changes failure occurs. Read failure occurs whenever the buffer overflows. So flow control is required. Write failure can be overcome by maintaining log files.

IV. CONCLUSIOS

In this paper we presented an architectural model for next generation Content Management System. We have proposed the extended functionalities of the desired CMS. In our future work we will extend the same to extract the semantic aspects of the related information, stored in CMS and the respective engines of different modules and sub-modules as service delivery points of the CMS. The CMS needs to be associated with its own and third party crawlers to extract the relevant updated information from the external repositories into the CMS under consideration

Abstract—**As technology is evolving as a driving force in our society, the need for computer programming is arising. However, since most of the computer programming languages are English-based, they can act as barriers for learning computer programming for people who are not adequate in English. In this paper we present a Non-English based educational programming system which was build with the goal to help Bengali speaking people learn and write computer programs in Bengali. We have also discussed how the system was build and why it will be useful for Bengali students to use as a platform to learn computer programming.**

Index Terms—**Non-English Based Programming Language, Educational Programming Language, ECMAScript, Jison, JavaScript, Learning Programming;**

I. Introduction

According to HOPL [8] online database of languages there are about over 8500 programming languages which are recorded and more than one third of them are build with English keywords. The prevalence use of English keywords in programming language is mainly because it is the most common language in the world. However, people who are not properly exposed to English Language may face challenges in learning and practicing computer programming using programming languages where English keywords are in use.

It is imminent that in order to understand and practice computer programming in greater depth students need to use the most common programming languages. Hence, Non-English based educational programming language will act like a bridge that will introduce users to the world of logic by solving existing problems they have probably solved in math classes or similar problem solving classes. Once the concept of logic is clear, the transition towards a full-fledged programming language would be easier.

In this paper we are presenting a Bengali educational programming language called ChaScript[1]. ChaScript was build in order to create a platform for Bengali speaking people learn computer programming without the need for English Language. To understand the need of Bengali programming language first we need to know about Social Cognitive Theory[4][6]. Social Cognitive Theory states that, learning from other people by means of observing them is an effective way of gaining knowledge and altering behaviour. In case of common programming languages it is a tough task. Not only does these programming languages have very complicated structures but their documentations are also a huge barrier for people with limited knowledge of English. This is where ChaScript[1] comes in handy. It gives a gateway for new programmers to start coding and getting the hang of it through observation and do it so without any particular need of supervision. Another aspect of Social Cognitive Theory states that a learner improves his newly learned knowledge or behaviour by putting it into practice. In common programming language cases, this might not always be easy because learners find it hard to apply them in real life scenarios. ChaScript, on the other hand, is designed in a way that allows students to use it easily for solving computational and mathematical problems.

In order to build the programming system, the grammar of the scripting language ECMAScript[9] was used and the grammar was parsed using a JavaScript parser generator, Jison. Since ChaScript contains modified parser syntax and it can be considered as a translated version of ECMAScript.

The paper is organized as follows, in section II, we present related works, section III presents implementation of the programming system, syntax of the programming system is illustrated in section IV followed by the user experiment results on section V and then the conclusion.

II. Related Works

In order to demonstrate the need for a Non-English based educational programming language, we are going to show other programming languages of similar nature as well as we explored and also explore the domains beyond the realm of computer science. We are going to present some works where it is discussed how language plays an important role in the efficiency of learning of students.

Hindawi[11] is a free, open-source, complete non-English based systems programming platform that supports all paradigms of programming languages such as assembly language, logic programming and functional programming. It takes away language barrier allowing non-English literates to take up computer sciences and learn computer programming in their mother tongue.

Mallet[10] has discussed about how a course like mathematics can be difficult to understand in a lecture conveyed in certain language that the students are not as familiar with. Mallet has also emphasized how a person who cannot understand the spoken form of the language of instruction quickly, will have difficulty understanding what is being taught without the facility of additional learning support. Novak and Langerova[2] have considered the problems arising when teaching mathematics with the aid of tools such as computer algebra systems that are not available in the students' native language. This is a problem encountered in the Czech Republic-based classroom. The authors suggested the use of a multilingual dictionary of mathematical terminology which will help overcome such issues to an extent. Bretag et al.[3] has addressed the problem of the consistent lower-than-average achievement of international students from non-English speaking

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

backgrounds in information systems courses in South Australia through an action research project aimed at facilitating improved learning outcomes for these students. Cuevas[7] had discussed that learning of mathematics needs a variety of linguistic skills of the language with which lessons are conveyed. Students who are not habituated with the language may take considerably more time to master it.

RoboMind[12] is a programming environment with its own integrated scripting language which is available in seven different language. The goal of this system is to help people learn programming without much hurdle and regardless of language and without much hurdle.

DoLittle[5] is a Japanese based educational programming language developed by Kanemune et al. This programming language fully supports Objects Oriented Paradigm. Moreover, easy syntax are provided for Japanese people to learn programming smoothly.

III. Implementation of the Programming System

We chose ECMAScript as our intermediate language to interpret and we used Jison, a JavaScript parser generator to parse the ECMAScript grammar. We used Jison to generate a JavaScript file from the ECMAScript grammar. That JavaScript file was used to parse the intermediate language. The file was used as a parser and the intermediate file was given to it as input. During the parsing, an Abstract Syntax Tree was generated. The Abstract Syntax Tree was used to maintain the semantic information of the program properly. If the parser successfully parses the file, an ECMAScript program generated from the semantic information found in the Abstract Syntax Tree is given as output which is then evaluated by the JavaScript interpreter. If the parsing procedure cannot successfully parse the file, it raises an exception and gives detail information about the parsing error and the line number where the error has occurred.

Interpreting a language gives implementations some additional flexibility over compiled implementations. Features that are often easier to implement in interpreters than in compilers include: Platform independence: ECMAScript not only gives us platform independence, but also certain level of portability. You can run an ECMAScript (as well as our code) from any platform as long as you have a web browser in it. Reflection and reflective use of the evaluator: ECMAScript has a first order eval function which lets us compile and run the code on client side without needing a backend support. Dynamic typing: Another advantage of ChaScript is we don't need to define a variable data type thanks to dynamic typing of ECMAScript. Dynamic scoping: When a symbol is referenced, the ChaScript will walk up the symbol-table stack to find the correct instance of the variable to use. This is extremely helpful for inexperienced users.

When designing the interpretation process we wanted to make the system as modular as possible so that future addition and development to the language can be easily facilitated. We also tried to maintain a certain level of standardization because we want this software to be available for future open source development.

We start by declaring 4 string arrays. These arrays contain,

- Bengali Keywords: The Bengali keywords of our programming language. E.g. যদি, নাহলে
- English Keywords: Contains the corresponding JavaScript keyword. E.g. If, Else
- Bengali Numbers: Contains Bengali Numerals(০-৯)
- Symbols: All general symbols used in ChaScript.

We take the whole code in a string and start processing. We start the interpretation process by replacing all the Bengali numerals. We do it simply by searching for each Bengali numeral and replacing it with the array index of that number. Then we look for the general symbols in the code and add whitespace to each of the symbols for tokenization purposes. We start with an empty string as our final JavaScript code. Step by step we interpret ChaScript[1] and parse it to the JavaScript code. The Interpretation process can be divided into 6 main steps. They are

a) String Handling: For string handling we keep a string stack. Than we split each line of code into string arrays based on quotation mark (“). Theoretically, every even number element of that array should be a string. We replace that string with the keyword “str” and push the string into the string stack. This is done to avoid complication in the keyword and variable handling process. After the variable handling process, we search for the keyword “str” and every time it's found, we pop an element from the string stack and parse it to the JavaScript code. The process is shown in Figure 1.

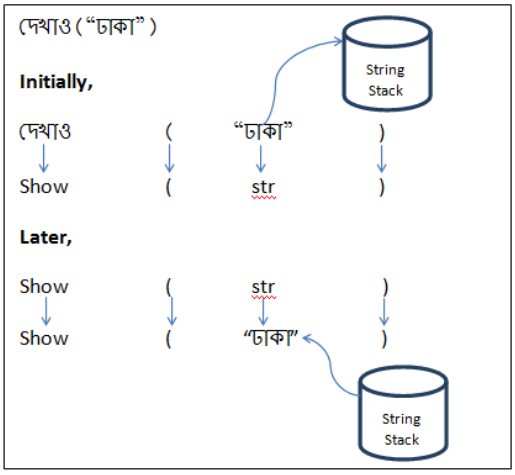

Fig. 1 String Handling Method

b) Tokenization: In this stage we simply split the whole code into several strings based on line breaks. Then each of those strings again broken down into tokens based on whitespaces. Each token is then analyzed and handled accordingly.

c) Number Handling: For number Handling we simply take each token and check all the characters within that token are a number and then parse the number to our code. If not, we go to the next stage.

d) Keyword Handling: The token later gets searched in the Bengali Keyword array, and if found the corresponding JavaScript keyword is parsed into the code. If not found in the Keyword array we go to variable handling.

e) Variable Handling: For variable handling keep two stacks. The first one keeps all the Bengali variables and the second one keeps track of their English counterpart. Whenever we find a token which is neither a keyword nor a number. We look for the token in the Bengali variable stack and if found we simply parse its corresponding English variable to our code. If not found we push the new variable to our Bengali

Variables stack. Then we randomly generate an English variable and push that in the English variable stack. Parsing that variable ends the process. The whole variable handling process is illustrated in Figure 2.

f) Input/output Handling: After the code is generated we check which platform and browser the code is running on. And implement proper JavaScript input/output function for that platform.

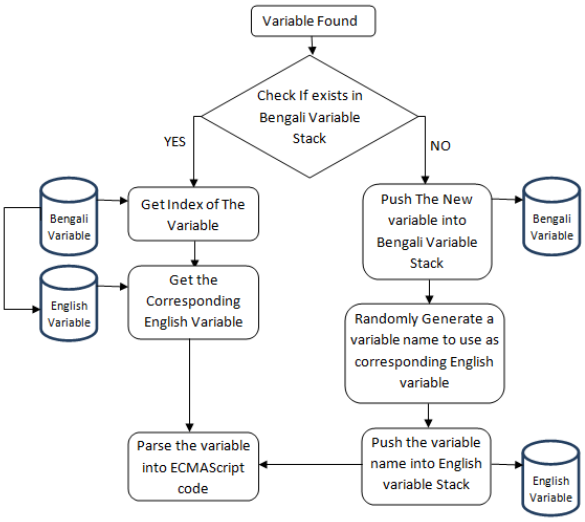

Fig 2. Variable Handling System

IV. Syntax of the Programming System

Designing ChaScript syntax our prime focus was to make the language as easy and accessible as possible. We also wanted to have maximum amount of output with minimum amount of syntax. And of course consisting with common tongue so that people new to programming language will not have much problem understanding it. If we look at the core components of our programming language we can see how easy it is compared to a generic C language .Let us start with a simple "Hello World" program which is shown in Table I.

TABLE I. Hello World Program

ChaScript	C

দেখাও ("হ্যালো ওয়ার্ল্ড")	#include"stdio.h"
	int main(){
	
	printf("Hello World");
	
	return 0;
	}

Easy variable declaration is a feature of ChaScript. There is no need for variable type declaration since type declaration is implicitly handled. If we look at the figure we can see how easily we can manipulate variables. If we tried to write the same code in C or Java, it would take a much larger set of codes and a lot of supervision. The conditional statements are almost the same as any other C-alike programming languages. However, when designing loop statement we wanted to make the concept of loop accessible to new programmers. So, instead of using conditional loop we simply run a loop and want the users to stop it manually. Although this may make the program vulnerable to infinite loop, designing the loop structure in primitive fashion will help the students to learn the logic of loop structures.

TABLE II. Fibonacci Number Generator

Using Recursion	Using Loop

ফাংশন ফিবোনাচি(ক)
{
যদি(ক == ০)

উত্তর (ফিবোনাচি(ক - ১) +
ফিবোনাচি(ক -২))
}
 	
দেখাও(ফিবোনাচি(৩))
	ফাংশন ফিবোনাচি(ম){
	ক = ০
	খ = ১
	প=০
	গ=০
	চলবে{
	যদি (প <= ১){গ = প}
	নাহলে{
	গ = ক + খ
	ক = খ
	খ = গ
	}
	প=প+১
	যদি(প==ম){
	থামো
	}
	}
	উত্তর গ
	}
	
	দেখাও(ফিবোনাচি(৩))

In the Table II, we are representing a recursive and a loop based approach to write a Fibonacci Number generation program in ChaScript. This example highlights the syntax of this programming language where we can notice the difference in loop structure with other conventional programming languages.

V. Experiment on Non Programmers

We commenced an online survey as well as a paper based survey with approximately 110 participants. Most of these participants have not been properly exposed to computer programming before. We tested them with two simple programming problems written in ChaScript and asked them to select the right answers. Our goal was to test whether the participants can understand the programs written in ChaScript.

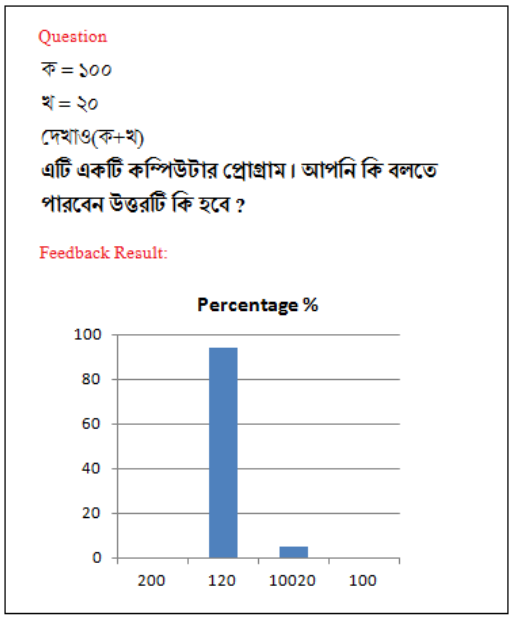

Fig. 3 User feedback on the programming question

Figure 3 shows the question that is being asked to the participants. Under the questions, a graph is presented showing the participant's responses to the multiple choice question in terms of percentages. It is evident from the graph that almost 95% of the participants chose the correct answer.

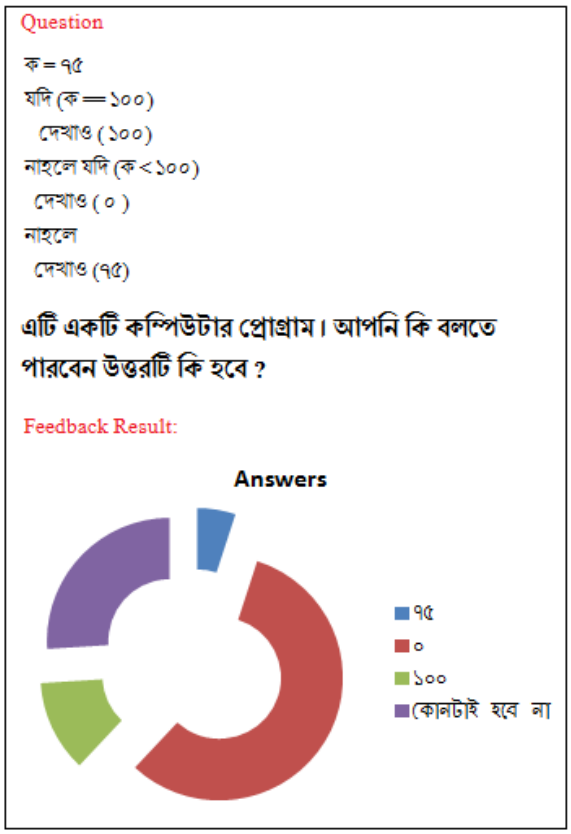

Fig 4. User feedback on another programming question

We asked the participants to answer another programming problem (Figure 4) which is slightly more difficult in nature compared to the first question. This program was also written in ChaScript and is based on conditional statements. As we can notice from the figure 4, almost 60% of the participants managed answer correctly, given that the correct answer was 0. Provided that the experiment was conducted mostly on non-programmers, getting a higher percentage of correct answers indicates that this platform can be used effectively to teach students how to program.

We would like to cordially thank the participants who agreed to take part in our survey.

VI. Conclusions

In this paper, we have introduced a programming language based on a native language that may break the initial barrier of learning the concept of programming. We have developed a full-fledged running version of this language and made it available through a web portal and the language has received positive responses from many native speakers.

As our description of ChaScript is restricted to only four pages we could not provide with full details. Although ChaScript is a well translated programming language, a lot more work is required to make it more refined and , hence, amiable to Bengali speaking individuals who are curious to learn programming but are confined because of their lack of knowledge in English language.

Ontology Matching by Applying Parallelization and Distribution of Matching Task within Clustering Environment

Tanni Mittra[1,*] and Muhammad Masroor Ali[1]
[1]Department of Computer Science and Engineering, Bangladesh University of Engineering and Technology
Dhaka, Bangladesh
*mittra.cse.buet12@gmail.com

***Abstract*—Recent advances of information and communication technology provides huge amount of heterogeneous information available for us. But integration of information semantically and provide machine understandable meaning to information is still a great challenge in current web technology. To overcome the challenges, ontology matching plays a vital role, which is introduced by semantic web technology. In this paper, we propose a new method of ontology matching using parallelization and distribution technique. To apply parallelism, we develop a partitioning algorithm by using property-by-class and subclass of relationship, which partitions the ontology into smaller cluster. Then the clusters from different ontology are matched based on terminological and structural similarity with semantic verification. These entire tasks of matching are handled in a parallel way and all the tasks are distributed over the computational resources. Thus, we significantly reduce the time complexity and space complexity of large scale matching task. Our proposed method reduces misaligned pairs while increasing correct aligned concepts. Validity of our claims have been substantiated through different experiments on small and large ontologies.**

***Index Terms*—Semantic web, Ontology matching, Data integration, Semantic heterogeneity**

I. Introduction

Semantic web [1], [2] is an advanced concept that has made revolutionary changes in current web technology of World Wide Web. It is the extension of current web and is built on top of it. One common reason behind the concept of semantic web is, to introduce a smart data integration agent. In current web technology, data integration is not smartly handled. For example, if we search some restaurant for particular kind of food in the web, first, we have to find out some restaurant which serves that food and then search in Google map to find out the location. We do this kind of information or data integration on the web on a daily basis, but now we are hoping that a machine will do the task for us. Another common problem of current web is that, the machine cannot understand what it represents. To solve these problems semantic web provides machine-understandable meaning and a standard way of data integration to the current web. This task of semantic web is done by constructing a vocabulary that has meaning coded inside its term.

A web page in the semantic web markup the vocabulary and thus it will get the meaning of the terms used in the vocabulary. This vocabulary is called ontology [3], [4] and it is domain specific which may be a specific subject or area such that agriculture, anatomy, education, food etc.

Since the domains have their own data vocabulary, the growth of disparate domain knowledge may cause data redundancy. To reduce data redundancy we have to manage semantic heterogeneity among them. Among the various solutions of heterogeneity problem, ontology matching [4], [5] has taken a critical place. Ontology alignment or matching is the process of determining correspondences between concepts that are semantically equivalent. It is an important operation in many traditional applications e.g. ontology merging, query answering, data translation, data warehouses etc. [4].

The evaluation in the recent years indicates that ontology matching has made a measurable improvement [4]. Considerable work has been done on automating the process of ontology alignment. System for matching and merging biomedical ontologies [6], automatic divide-and-conquer approach [7], clustering-based approach for large-scale ontology matching [8], dynamic multi-strategic matching [9], inter-matcher and intra-matcher techniques for matching [10], a session based approach for aligning large ontologies [11] and anchor wise ontology matching [12] are some of the automated processes for ontology alignment. But there are still some challenges to improve the performance of ontology matching. Among them, increasing the efficiency of matching task is still a great challenge. Because, once quality is achieved, increasing the efficiency of matching task is of prime importance. To our best knowledge, current matching tools are not optimized for resource consumption and efficiency handling. So in overall, the challenge is to come up with scalable ontology matching reference solutions. To overcome this challenge our proposed method has two major criterion. Firstly, it reduces execution time by performing the matching task by applying parallelization and distribution techniques in a clustering environment. Secondly, it performs wider automation in acquisition of reference alignments of large scale data among several ontologies. The approach presented in this paper uses cluster computing mechanism to introduce parallelization and distribution of matching tasks with available computational resources. It uses property-class relationship with subclassof relations to cluster ontology. As a result, all the cardinality relationships and instances are preserved. The issue of pairwise comparison complexity is reduced by applying only a simple version of the linguistic and structure based strategy with semantic verification. In the experimental section we compare our approach with some well established methods.

The remainder of the paper is organized as follows. Section II describes the proposed method and how it is applied in ontology matching, section III describes analytical and experimental comparison of the proposed method with some state of the art methods of matching. Finally, section IV

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

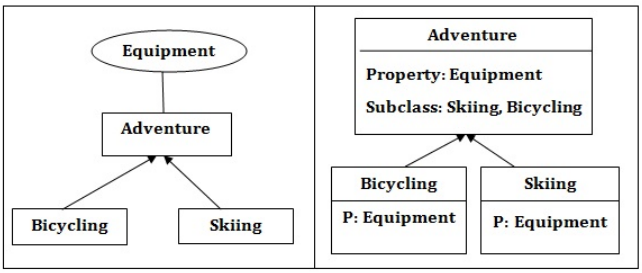

Fig. 1. Helper object model of Russia1 ontology.

provides the conclusions and future challenges of the proposed method.

II. Ontology Matching with Parallelization and Distributed Matching Task

The proposed method of ontology matching is subdivided into three basic steps. These are, 1) ontology clustering, 2) similarity matching, 3) entity alignment determination. Each of the steps sequentially produces a set of aligned concepts between two ontologies O_1 and O_2. Following subsections contain detailed description of the proposed method.

A. Ontology Clustering

Ontology may be of different sizes and from different domains. Based on this, our proposed method can take both large or small ontologies as input. One of the features of our method is that, clustering is performed for large ontologies. For small ontologies, clustering is ignored because clustering of smaller ontologies with up to three hundred classes could be a wastage of time. Classes, properties, individuals and relationships are the most common components of ontology. The first step of clustering is to create a helper object model by extracting all these necessary components and preserving the relationship that exists among them. Fig. 1 represents a small part of Russia1 ontology mentioned in [7] and a helper object model of the ontology. This ontology describes the content of a travel web site about Russia.

The helper model is used to calculate structural similarity among internal classes of ontology by using property-class and subclassof relationship, which are further elaborated hereafter. From the design principle of large ontology we come to know that an ontology is designed based on classification and modularization principle. These two issues can be easily solved by property-class relationship because the property of an ontology can provide the subclassof relationship. Suppose location is a class of an ontology and hasplace is a common property of location class. As a subclass of location class region and space get the property of hasplace. Again, ontology property ties an individual to a class and preserves cardinality relationship among entities. To handle ontologies without property declaration we use hierarchical relation among classes i.e. subclassof relationship to find structural similarity. The process of calculating structural similarity using these relationships is elaborated below.

1) Entity Vector: To calculate the similarity value the first step is, to build a property by class matrix. The key formula of building property by class matrix is property-class relationship. Assume an ontology O with $|C|$ classes and $|P|$ properties where C represents set of classes and instances and P represents set of properties. The property by class matrix is defined as (R_{ij}) and determined by using the following equation,

$$R_{ij} = \begin{cases} 1 & \text{if } C \subseteq P \\ 0 & \text{otherwise.} \end{cases} \tag{1}$$

From this property by class matrix, entity vector is calculated. Here, entity vector means vector of the classes of the ontology. As each column of the matrix represents class and each row represents property so, the entity vectors are stored in the column space of the matrix.

2) Internal Structural Similarity Calculation: After finding out the entity vector, the similarity between two entities is determined by dividing the total number of common properties by the total number of uncommon properties between them. According to this rule, two entities are similar if they share more common properties between them. This is done by using Jaccard coefficient [13], [14] which is a measurement of asymmetric information on binary variables. Our entity vector is a binary vector with 1 or 0 representation. By using entity vectors r_i and r_j we get the following equation to calculate structural similarity.

$$\mathrm{Sim}(r_i, r_j) = \frac{\#(r_i = r_j = 1)}{\#(r_i = 1) + \#(r_j = 1) - \#(r_i = r_j = 1)} \tag{2}$$

3) Partitioning Ontology: Clustering of the ontologies starts with the determination of the seed nodes by computing shared number of properties between classes. Initially all the classes are the member of seed node set. If two classes share the same properties then we remove one class from the seed node set. Otherwise, we check hierarchical relations between them. If they are connected hierarchically then we again remove one class from the seed node set. We repeat the whole process until each of the classes is checked and thus we get a seed note set.

For partitioning classes we begin our work with the remaining classes of ontology except seed classes. First, the $|S|$ seed classes are individually assigned to the $|S|$ clusters as their initial members. Here, each seed node acts as the starting point for each cluster in the cluster set S. Then we calculate the internal structural similarity value of the remaining class members with each of the classes in the cluster set. We choose the maximum value among them and assign the classes to the appropriate cluster set for which the similarity value is higher. Thus, by repeating this process, each class is assigned to a particular cluster.

B. Similarity Matching between Entities

Integration of ontology is not as simple as just mapping classes in one ontology to corresponding classes in another ontology. Finding matching by maintaining the actual meanings of classes is a great challenge for ontology matcher. So by keeping this in mind we have organized our matching task by computing structural similarity and terminological similarity with semantic verification. Description of the matching task is preseted below.

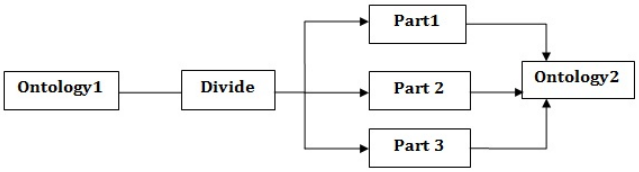

Fig. 2. Parallel matching task.

1) Terminological Similarity Calculation: The terminological similarity is calculated in two steps. At first step, it is checked that if two strings are identical or not. Here the term identical string means two strings having the same semantic significance. Again, for dissimilar strings a limit parameter is selected. If the difference between two strings are less than the limit value then we select those strings for the next step of terminological similarity calculation. The next step is to computed string similarity using WordNet lexical database [15].

But, if two entities are terminologically equal then it is not mandatory that each entity represents the same meaning in the ontologies. To ensure that each similar entity contains approximately same meaning we find out semantic similarity or proximity between them. To find out semantic proximity between each terminologically similar entity we first calculate their distance from the common super node in the class hierarchy. Distance means the depth of class in the class hierarchy. In our proposed method, if the depth of both classes is equal then they are treated as semantically equal. Then, finally we will treat them as aligned concepts. Thus, using this strategy we have found that, it improves the matching results with the inclusion of the correct matches.

2) Structural Similarity Calculation: If two entities are terminologically similar then we collect all the neighbouring entities of the aligned concept. Then we check the terminological similarity between the neighbouring concepts and find out the structurally aligned concepts. We repeat this process until each neighbour is compared.

3) Parallelization and Distribution of Matching Task: The similarity matching process described above is handled by parallel and distributed matching technique [16]. The main motivation behind this task is that, ontology matching requires a robust and scalable solution that ensures the maximal efficiency of matching operations. This is the main reason for which ontology is partitioned into small clusters. For each of the clusters, similarity matching task is performed in parallel and distributed over the computing resources. Fig. 2 describes how to divide the priority ontology and match the concepts of each part in parallel with the concepts of a selected ontology.

III. Experiments and Evaluation

We have implemented the proposed approach in Apache Jena [17], a free and open source Java framework for building semantic web and linked data applications. We have applied our proposed method on variety of datasets, including small ontologies such as Bibliography, Russia12, TourismAB and large ontologies such as Anatomical and Food ontology. For better comparison, our experimental study has been performed on data sets, considered in [7]. In this section, we discuss the result attained in our experiments in terms of scalability, memory consumption and time efficiency.

A. Evaluation Dataset

In our experiment, as mentioned above, we have used two ontologies Russia12 and TourismAB which have been mentioned in [7]. Among them, Russia1 contains 151 classes, Russia2 contains 162 classes and TourismA contains 340 classes, TourismB contains 474 classes. We have also used the Anatomy and Food ontologies[1]. Anatomy includes two ontologies, whereas Human contains 3304 entities and Mouse contains 2743 entities. Again, Food ontology contains two ontologies, whereas AGROVOC contains 28,439 entities and NALT contains 42,326 entities.

B. Experimental Methodology

We have conducted three types of experiments in order to ascertain, 1) quality of clustering, 2) correctness of alignment, and 3) compute the scalability, memory consumption, time complexity of finding alignment between ontologies.

The first experiment is done to determine the clustering quality. Because, clustering quality reflects the effectiveness of the clustering algorithm and good clustering quality indicates the possibility of discovering correct alignments. To determine clustering quality, we manually partitioned the ontology into clusters using close human intervention. After that, we again partitioned them with our proposed clustering approach. Then we compared the resultant clusters with the manual clustering result and determined the correctness of clustering.

Our second experiment is to determine the mapping quality (correctness) of the proposed method. For this reason, we evaluated our method with a popular ontology matcher, FALKON [7]. Because that matcher worked with large ontologies and used clustering method to determine alignment between entities. Moreover, in our third experiment, we experimented to observe the time efficiency, effects on memory consumption and to evaluate scalability of our proposed method.

C. Experimental Result

Experimental results, as elaborated below, of our proposed method can be judged based on the aspects which have been mentioned previously.

1) Clustering Quality: According to our first experiment of determining clustering quality the result produced by close human intervention rather than applying proposed clustering method, we found 5 clusters for Russia1; 6 for Russia2; 6 for TourismA and 7 for TourismB. On the other hand, our proposed clustering algorithm has produced almost the same number of clusters for Russia12 ontology. But Tourism AB has produced few more clusters than the number of clusters produced by human intervention. Table I shows the number of clusters that have been produced from different ontologies. In our method the clusters are not partitioned into smallest blocks like FALKON [7]. Because we build clusters automatically from ontologies by maintaining internal structural proximities and neighboring relationship between classes. Again, we kept the number of clusters smaller to reduce the computation cost of similarity mapping. Thus, our proposed approach is quite different from the previously mentioned method.

[1]http://oaei.ontologymatching.org

TABLE I
TABLE TO REPRESENT CLUSTER NUMBER

Ontology	Class Number	Property Number	Cluster Number
Russia1	151	76	6
Russia2	162	81	6
TourismA	340	97	8
TourismB	474	100	8
Mouse	2743	2	52
Human	3304	1	63

2) Time efficiency: If we consider the runtime spent by our method and FALKON during partitioning of ontologies and matching entities, we find that our method is more efficient than FALKON. Based on the current implementation, our method takes around 2 seconds to complete the comparison between Russia12 and 5 seconds for TourismAB, while FALKON spends nearly 5 seconds and 8 seconds correspondingly. Again, we also performed other different experiments over large ontologies for testing performance, which are shown in Table II. It may be argued that the machines used and hence the processing powers are different for the aforementioned methods. Still, as we have used parallelism and distribution technique for alignment measurement so our algorithm should take less time to produce alignment between entities.

3) Correctness of Alignments: The average number of comparison to find alignment between classes of our proposed method is smaller. Because, once we found alignment between two classes, then according to the nature of the cluster, alignment easily found between their neighbouring classes by collecting and comparing them with each other. Thus the average number of comparisons per aligned pair of our algorithm is approximately determined by total number of class/average number of children. The main motivation of our proposed method is to calculate one-to-many alignment between classes. As we compared the correctness of our aligned concepts with FALKON, the comparison results showed that, our method produced 45 alignment for Russia12 and 52 for TourismAB while FALKON constructs 39 mappings for Russia12 and 33 ones for TourismAB. We found that, the potential computational cost of our proposed method on discovering alignments is smaller than that of FALKON and the number of block mappings is higher than FALKON. The comparison results for other large ontologies are exhibited in Table II.

4) Memory Efficiency: We have experimented with both large and small sized ontologies. Table II contains the name of ontologies, memory consumption to store ontology model in memory. We have stored classes, properties and relationship of ontologies in a managed and structured way to minimize the memory consumption. We experimented for retrieving alignments across several pairs of ontologies and we hardly found out of memory exception. As we have used parallelization technique so each of the process is distributed within computational resources and increase memory efficiency.

TABLE II
MEMORY CONSUMPTION AND ELAPSED TIME OF COMPARISONS PER ALIGNED PAIR.

Ontology1	Ontology2	Memory(MB)	Time(s)	Aligned Pair
Russia1	Russia2	7	2	45
TourismA	TourismB	10	5	51
Mouse	Human	205	60	1091

IV. CONCLUSIONS

In this paper, we described our proposed method that can align ontologies of arbitrary size effectively, that helps our method to achieve high performance and scalability over previous alignment algorithms. Our proposed method automatically performed clustering on large ontologies and ignores clustering for smaller ones. For each ontology we created our own persistent storage with classes, properties and relations. We used both subclassof relationship and property-to-class relationship to perform clustering between entities. After clustering, we performed alignment operation in parallel for each of the entities of clusters, which reduced run time and out of memory exception. In similarity matching part, we used WordNet and string matching algorithm in our own way. We calculated both terminological and structural similarity with semantic verification between entities. We experimented our proposed method with popular ontology matchers and found that our proposed method outperformed in some aspects to other alignment systems.

In future, we will work on ontology matching that can find out similarity between ontologies of different languages. our future target includes, increasing the alignment strength by finding $m : m$ alignment between entities of ontology and implementing a tool for web interface that can find alignment between entities dynamically to work with semantic web services.

Towards Privacy-aware Photo Sharing using Mobile Phones

Sadia Shamma and Md. Yusuf Sarwar Uddin
Computer Science and Engineering Department, BUET
shamma167@gmail.com, yusufsarwar@cse.buet.ac.bd

***Abstract*—Mobile phones are used these days to capture photos almost everyday everywhere. When photos are taken and shared among peers through social network sites or photo sharing portals, sometimes they pose threats to personal privacy of persons who appear in those photos, particularly when the person being photographed has reservation about sharing the same. In general, photos containing detectable human faces would be handled with care. In this paper, we propose techniques and develop a mobile app that can be used as an assistant tool in order to make people aware of their photo content. The app, integrated as a part of phone's builtin Camera app, categorically detects faces in an image preview and notify the user about detected faces (if any). The user then uses his/her rightful discretion to share or store the captured picture being respectful that no one's privacy is violated through this capture. Two possible techniques for detecting faces, namely cloud based and in-phone processing based, are proposed and a few experimental results with the app have been reported.**

***Index Terms*—Mobile Phone App, Camera, Privacy, Photo sharing**

I. Introduction

This paper proposes and develops a working solution towards privacy-aware photo sharing using mobile phones. As multimedia phones are very much available now a days, people can capture photos anywhere and everywhere. Photo sharing has become a regular phenomenon these days. Online users share photos through social network websites, such as facebook, or through photo sharing portals, such as Flickr. Due to wide penetration of Internet-enabled smart phones equipped with high resolution camera, people using those phones can easily capture images of people or scenic sites and can upload them immediately to web 2.0 portals either through standard websites or specialized apps, such as Instagram. It has been reported that facebook alone stores nearly 260 billion images and users upload around one billion new photos every week [2]. While photos are intended to capture moments of life very vividly, they also pose significant threats of personal privacy. A person can take a photo of another person where the later one may not necessarily opt in for the take. The photo can be even captured stealthily without letting the subject knowing that his/her photo is taken. Usually face reveals a person's identity quite certainly, which makes the presence of detectable faces in a photo an important issue that deserves to be treated with care. The issue becomes even more sensible in some cultures when the photo contains face of a woman whose consent was not sought while taking the photo.

In this paper, we propose techniques and develop a mobile App that can be used as an assistant tool in order to make people aware of their photo content. The app, integrated as a part of phone's builtin Camera app, categorically detects faces in an image preview and notify the user about detected faces (if any). The app can also detect the gender of the faces, specially whether there is any female face. The user then uses his/her rightful discretion to share or store the captured picture being respectful that no one's privacy is violated through this capture. We propose two possible techniques for detecting faces, one using a cloud service and another one with in-phone processing. Experimental results with the app are reported.

It is note that the app does not really solve the big problem of photo privacy. The key issue is with lack of strong enforcement. The problem is privacy breach (if at all) occurs with the person whose photo is taken, but not with the person who is taking the photo and who is actually holding the camera. This can be called *subject mismatch*. We argue that our proposed solution is mostly an advisory tool that assumes responsible and sensible attitudes to human subject guided with proper judgment. The app helps in avoiding accidental sharing, particularly for automated uploading of photos as they are shoot.

II. Related Work

Many researchers worked in different platform to protect photo privacy in web services and camera devices. Sergej Zerr, Stefan Siersdorfer and Jonathon Hare have developed a search engine for privacy oriented image PicAlert! [7] It automatically identifies potentially sensitive images in the result set and separates them from the remaining pictures. But PicAlert does not support any additional features for pictures taken with mobile phones where we expect a larger proportion of private images. Roberto Yus *et. al.* have worked on Faceblock service [6]. It takes regular pictures taken by smart phones or Google Glass as input and converts them into privacy-aware pictures. Photographer and the person who is being photographed both of them need to be Faceblock user. He Wang *et. al/* proposes techniques on Insight project which recognizes human without face recognition [5].

The closest match with our work is [3] where authors propose a system architecture for privacy-aware photo sharing over social network websites. The system allows users to set privacy preferences in their personal profiles hosted in their respective social network sites. These preferences ascertain certain policies, such as whether other people upload his/her photos without his/her consent as well as whether to notify user when someone's else upload his/her photo in any portal where the user has account in. While the work addresses privacy issues, it does so in an offline manner. In contrast, our proposed scheme is rather online in the sense that we address the privacy issue right on the spot, at the very instance when the users capture photos, not in a later time when they actually

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

upload them. This happens to be possible because we develop our scheme on mobile phones.

III. Privacy-aware Photo Sharing

We propose a service to prevent people to be photographed by camera unwillingly. If someone attempts to capture a photo, it detects if there is any face in camera preview. If any face is detected, then it notifies the user with a message that he/she is going to capture a photo with a face in it. If it is unintentional, then the user can choose his rightful actions. Face detection is computationally expensive that requires advanced vision algorithms. We use existing available services to detect faces. We apply two approaches for face detection: one is to use a cloud base service for face detection and the other one is to detect face locally in phone using available vision library, such as openCV (www.opencv.org). It is noteworthy that we do not 'recognize' individual person in photos, rather 'detect' the presence of human faces, which is apparently less expensive than recognition in terms of computation, which makes it suitable for in-phone processing. Unlike recognition, it also does not require large training dataset to learn faces.

A. Cloud based Face Detection

One of our approaches is to use cloud base service for face detection. We select a photo and send it to a Web service through REST API to check whether it contains a face. If so, the user is notified with a message. We use REST APIs from SkyBiometry for our demo application.

An advantage of using cloud base face detection is that computational overhead is transferred to cloud. Cloud itself processes the image, analyzes it and provides us the result. Our application notifies user according to that provided result. Accuracy of face detection is very satisfactory in this service as it has large data set, training set and continuous learning algorithm is applied here.

Disadvantage of using cloud base face detection is privacy issue. We need to upload image to cloud server for result. If privacy issue is highly significant, then uploading image to server violates privacy policy. We need to ensure secured transport layer for image uploading and result transferring. Moreover, we need to trust the service that it does not have any image leakage. In case of strong privacy issue user may not like this cloud base face detection system. Another disadvantage of this cloud base service is service latency. It takes some time to process in cloud and show the result according to image size. And last but not bot least, it requires a persistent (and fat) data connection which may not be so viable for all.

B. In-phone processing for Face Detection

Another approach we describe is detecting faces in phone locally. It is recommended for cases where user wants to ensure strong privacy policy. In that, users do not need to upload photo to server as it detects photo locally in phone. We apply a classifier using computer vision algorithm that detects faces locally.

Advantage of in phone local face detection is that it does not hamper privacy issues. As it processes the image in phone, there is no risk of image leaking or privacy violation. Another benefit could be quick processing as it does not involving sending the photo file over Internet and receiving response back. Disadvantage of using local face detector is, however, low accuracy. Since local face detector is tested and trained on small data set, it often fails to detect face accurately. Processing capability of phone varies according to phone configuration. So, processing time and performance may vary according to the configuration of phone.

IV. Implementation

We implemented privacy-aware photo sharing as an Android app. The app uses builtin camera application to capture photos and then analyzes to check whether the photo contains any human faces in it. If so, it prompts the users for his/her explicit consent for the actions to follow. in current implementation, the app runs as a standalone app. That means, the user can easily bypass this app to take photos with phone's builtin camera which does not have, as we know, any privacy enforcement. The app can indeed be wired into camera application so that enforcement can be activated. We do not, however, consider this option in this work.

One important aspect of the app is to detect human faces when a photo is taken by the camera. As we mentioned, for detecting faces we use two techniques. First one is to use a cloud base service and second one is to detect face locally in phone. In the following, we describe these two techniques.

A. Cloud based implementation

In our implementation, we used SkyBiometry REST API for face detection [1]. SkyBiometry is a cloud-based face detection and recognition API. It uses computer vision algorithms for face detection and recognition. This API provides facial attributes like gender, glasses, eyes state, lips state, and mode. Face detection and recognition API currently supports methods, such as faces/detect, faces/recognize, faces/train. The API uses REST interface, which means API methods are called over the Internet, using standard HTTP methods like GET and POST to api.skybiometry.com/fc/. Depending on the HTTP request parameters, server can generate response in either JSON or XML format. It also supports JSONP callbacks to simplify the application development in JavaScript and callbacks for asynchronous invoking of lengthy operations. According to the result provided by service a face detection message is shown. As this service supports gender detection, so female faces can be especially marked for additional attention.

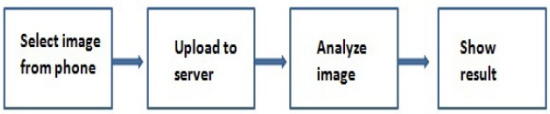

Fig. 1. Steps in cloud based face detection

B. In-phone processing

We use openCV library ported into Android for an in-phone processing of face detection. OpenCV's face detector uses a method that Paul Viola and Michael Jones published in 2001 [4]. This approach of detecting objects in images combines four key concepts: simple rectangular features, called Haar features, an integral image for rapid feature detection, the AdaBoost machine-learning method, and a cascaded classifier

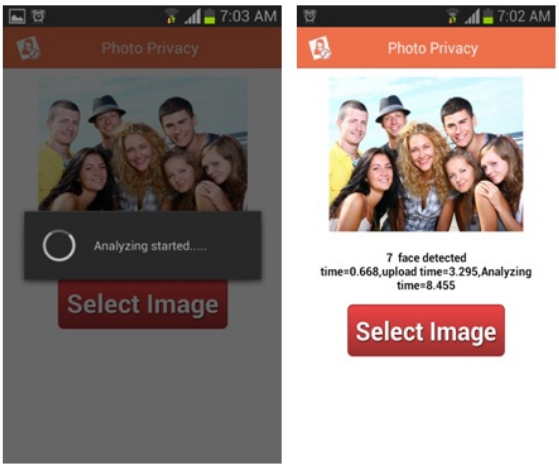

Fig. 2. Detecting face in cloud based service

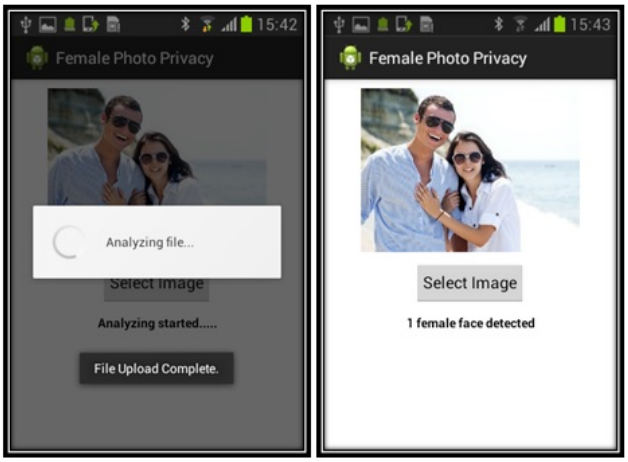

Fig. 3. Detecting female face in the cloud based service

to combine many features efficiently. It is a machine learning based approach where a cascade function is trained from a lot of positive and negative images. It is then used to detect objects in other images. OpenCV already contains many pre-trained classifiers for face, eyes, smile etc. Those XML files are stored in specific directories in openCV installation. We use openCV's face detection algorithm in our app. It detects face in camera preview and notifies user with a message when a face is detected. It then asks for user's permission to capture the photo with face. If the user wants to proceed in capturing photo with face, then it saves the image in phone memory. Otherwise, it discards the photo.

Fig. 4. In phone local face detection

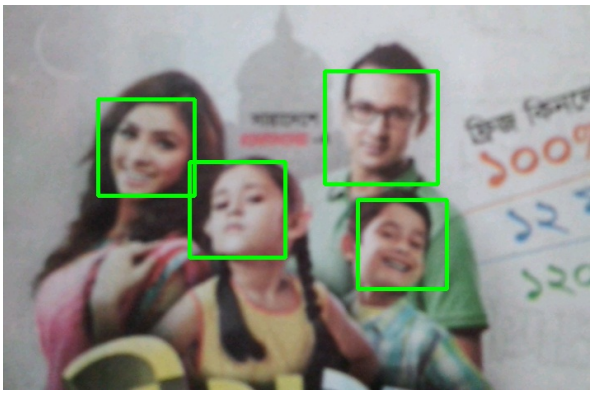

Fig. 5. In phone processing face detection

V. Experiments and Evaluation

We make experiments on our developed app with a small dataset. Firstly, we show results for the cloud based implementation. We measure the processing time for detecting faces for each photo set. We experiment with different resolution of photos as resolution affects processing time significantly. It is shown in Figure 7 that photos with higher resolution need more processing time than lower resolution. Cloud based service usually requires larger processing time as it needs transfer of image data to the server, which may constitute a large portion of processing time. We can in fact express processing time as a sum of its several components, as follows:

$$p(t) = pp(t) + u(t) + a(t)$$

where,
$p(t)$ = Processing time;
$pp(t)$ = Pre-processing time;
$u(t)$ = Data upload time (transfer image data);
$a(t)$ = Analyzing time (detecting faces);

Fig. 6. Accuracy for cloud based face detection

We also measure accuracy of our app in detecting faces. Accuracy is calculated with the following equation:

$$\text{accuracy} = \frac{\text{no of true positive + no of true negative}}{\text{total number of photos}} \quad (1)$$

Where, true position refers to cases when detection technique indeed detect faces, whereas true negative does not find

any face when there is indeed no face in the photo. False cases are those where things happen in contrary: detecting faces when there is actually none or misses a few faces to be detected. We show accuracy results in Figure 6. We see that photos with lower resolution have lower accuracy compared to photos with higher resolution. Since cloud base service uses more complex and efficient algorithm, it has better accuracy than in phone local face detector.

We also show detail accuracy results for openCV based in-phone face detection for a set of captured photos in Table I. We conclude that accuracy for cloud based service is almost 100 percent, while in-phone processing accuracy is 73 percent.

DETAIL ACCURACY CALCULATION OF IN-PHONE PROCESSING OF FACE DETECTION

VI. CONCLUSION AND FUTURE WORK

This problem of privacy breaches arising due to photo capture and sharing using mobile phones is taking much attention in recent years. This paper puts positive efforts towards privacy-aware photo sharing using mobile phones. Particularly, we propose instrumenting phones with a suitable app so that such breaches can be contained and passed to user attention immediately right after they shoot pictures of people. At this stage, the app is an independent standalone application, but it can be wired into built-in camera of devices.

Face recognition and other features can be added as an easy extension of this work. One possible thought can be as follows. Individual user can have some tagged photos of his friends/ relatives, which means these persons can be in photos without any objection. When the user attempts to capture faces other than those, the app detects a privacy breach and asks for confirmation. As a consequence, the user may avoid taking that photo or may take photo in which that unknown face is blurred. As the face area of image is detected, that area can be blurred with an appropriate measure.

Another extended version of this application can be adding features to prevent unwanted photo sharing over Internet. Photos containing unknown faces can be blocked from uploading to network. This can be integrated with gallery application of camera.

Sometime, photos in photos are automatically uploaded in some site where the user account is synced with the device. In that case, user will be asked for confirmation if image contains face before it uploads it to the respective server. If confirmation is unavailable, those photos will be kept in queue. Sometimes, phones are set of party mode, where all photos taken a particular time span are automatically shared in user's online social networks. Unwanted photos can be blocked if our scheme is activated in those cases.

mrhuq@ewubd.edu

Abstract— **A social networking service is a platform to build relations among people who share interests, activities, backgrounds or real-life connections. Communities in a social network are the gathering places for the people with common interest. Social network analysis is in high demand now a days for the increasing number of users. They involve themselves into different communities. They share post, their views, what they like etc. in communities. So it is important for them to find suitable communities where they have common factors like friends, followers and their activities etc. In this paper, we propose a technique for recommending a community in social network like Facebook, Twitter etc. Finding strong friends from a user's friend list and using clique and quasi-clique concepts introduced in graph mining, we recommend suitable communities for a user in a social network.**

Index Terms— **social network analysis and mining, data mining, strong friends, social media, clique, quasi-clique.**

I. Introduction

The rapid growth and exponential use of social digital media has led to an increase in popularity of social networks and the emergence of social computing [1]. In general social networks are structures made of social entities that are linked by some specific types of interdependency (e.g. kinship, friendship, common interest, beliefs, or financial exchange).

Recommendation system like social graph generation & forecasting using social network mining [1], finding strong groups of friends [3], finding popular friends [4] in social network are well known. In this paper we develop a recommendation system for user's communities. Day by day community is increasing with the rapid growth of social users. Nowadays we see the vast activity of social life. All those community can't be suitable for a particular social users. So our recommendation system will find suitable community for a user. For example, a social user has created a new profile in social network service. He or she has some common interests with some strangers or his/her friend. So they can create a community where being friend is not important but sharing the common interest is important. Suppose a cricketer always like to join in such groups which is involved with cricket. He must have some friends in his friend list who are interested in playing cricket. We then find those friends who are connected with some community associated with cricket. Our recommendation system will then recommend the user a suitable community based on detecting his strong friends and quasi-clique techniques.

II. Problem Definition

In this section, we present the problem formulation and basic definitions for mining set of friends having higher strength and set of communities which is associated with them.

Let us consider a sample database shown in Table-I that captures some users in a social network. The table consists of the friend lists of seven users. For example, Jack has some fiends in his friend list. They are Harry, Pet, James, Oliver, Kan and Tom. The list also shows the interaction strength (e.g. connectivity of each friend of Jack). For example, "James (15)" in the list may record that the interaction between them is 15. These interactions may be of various types like posting message on wall, chatting, giving likes to photos or status for any social network like Facebook, twitter etc.

Now in Table-II, we have listed those set of communities that is associated with each user in a social community. For example, Jack is a member of C3, C4 and C5 communities.

TABLE I
Friend Database (F_{DB}) of USER (u_i) in a Social Network

User(u_i)	List of friends(f_{ui}) with interaction strength
Jack	Harry(35), Pet(25), James(15), Oliver(10), Kan(10), Tom(5)
Harry	Jack(15), Pet(5), Oliver(25)
Pet	Jack(15), Harry(10), James(5)
James	Olive(20), Pet(10), Jack(15)
Oliver	Harry(5), Jack(15), Kan(20)
Kan	Harry(5), Jack(15), Tom(20), Oliver(20)
Tom	Kan(15), Jack(20), Pet(20)

Based on this connectivity information, we recommend a suitable community for a particular user. For example, if we see Table -II, Jack is connected with community C3, C4 and C5 but he is not connected with C1, C2 and C6. But his friends, Harry, Kan, James, Oliver and Tom are connected with both C1 and C2. Pet is connected with C1. Based on the interaction with his friends we first differentiate his strong and weak friends. Then applying our algorithm we recommend a community between C1 and C2 for Jack.

In the remainder of this section, we provide formal definitions and notations required to mine friend groups and communities from a social media database.

Definition 1**:** User (u_i), we define a set U= {u1, u2… u_n} who are the users of a social network site with some friends (f_i). Example 1: from Table -I, Jack is a user in a social network. Harry, Pet, James, Oliver, Kan, Tom are Jack's friends.

Definition 2: Community (c_{ui}), a community is a group of people with a common interest among them. We define a set C= {C1, C2… C_n} that are the communities in a social network. Example 2: Pet is connected with C1, C3 communities.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Definition 3**:** Normalized interaction strength ($nis_{ui,fj}$), interaction strength is the value or weight that defines the interaction of a user (u_i) with one of his friends (u_j) and we normalize these values based on the total number of interactions of the user (u_i). Example 3: Jack = {Harry (35), Pet (25), James (15), Oliver (10), Kan (10), Tom (5)}. Here Harry and Jack are friends and the interaction value for them is 35 and the normalized interaction strength ($nis_{ui,fj}$) is 0.35.

Definition 4: Minimum strength (min_{str}), minimum strength value (min_{str}) is the threshold or base value for recognizing strong and weak friends. In our case we set the value for min_{str} is 0.7.

Definition 5: Strong Friends (s_{ui}), we define S_{ui}= {s_1, s_2… s_n} as a set in descending order based on $nis_{ui,fj}$. When the cumulative normalized interaction strength ($nis_{ui,fj}$) exceeds the minimum strength value (min_{str}) we consider up to those friends as a strong friend set. The set indicates that the user (u_i) is most likely going to interact with these friends.

TABLE III
COMMUNITY (C_{DB}) DATABASE FOR EACH USER (u_I)

User(u_i)	Communities(c_i)
Jack	C3, C4,C5
Harry	C1, C2, C4
Pet	C1, C3
James	C1, C2,C4
Kan	C1, C2, C3, C5
Oliver	C1,C2,C3
Tom	C1,C2

Definition 6: Weak Friends (w_{ui}), we define W_i= {w1, w2… w_n} as a set of weak friends who are left in the friend list after selecting strong friends group S_{ui}. Moreover, they are such friends to which the user hardly contacts.

Definition 7: Clique, a set of vertices S is called a clique if the sub graph G(S) induced by S is complete and there is an edge between any two vertices in G(S). [7]

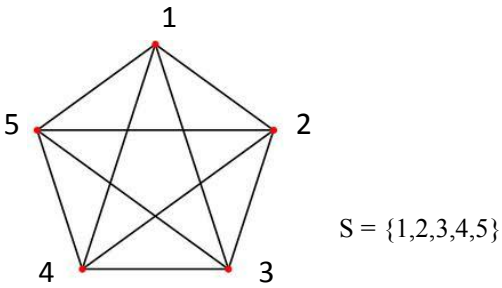

Fig. 1 Example of a clique

Definition 8: γ-quasi clique, a graph G = (V , E) is a γ -quasi-clique (0 ≤γ ≤ 1) if $\bar{G}$ is connected , and for every vertex v ∈ V , deg G(v) ≥ [γ.(|V |−1)]. [7]

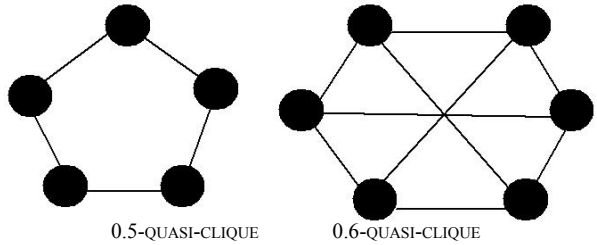

Fig. 2: Example of γ-quasi clique

III. CONSTRUCTION AND MINING.

Our proposed approach for recommending a community is based on several steps. We use clique and quasi-clique method to compare among various communities. Our algorithm first scan the friend database (Table-I) and then the community database (Table-II). After scanning, then follow some steps which are described below

STEP 1 :(Normalization) First we normalize the value of interaction strength. We calculate the normalization value of interactive strength for every friend by dividing the interaction strength with the total number of interaction to his all friends. The total value of normalized interaction strength should be equal to 1. Example: For Jack in table 1 the normalized values for his friend set (f_i) = {Harry (0.35), Pet (0.25), James (0.15), Oliver (0.10), Kan (0.10) and Tom (0.05)}. Then we arrange these normalized values in a descending order. The order of normalized interaction strength ($nis_{ui,\ uj}$) for our input dataset is given below.

TABLE IIIII
NORMALIZATION AND MIN_{STR} = 0.7

Friends of Jack	Normalized interaction strength	Cumulative normalized interaction strength
Harry	0.35	0.35
Pet	0.25	0.60
James	0.15	0.75
Oliver	0.10	0.85
Kan	0.10	0.95
Tom	0.05	1.00

STEP 2: (Recognizing s_{ui} and w_{ui}) Here we divide the friend dataset for a particular user (u_i) into two sets. One is strong friend set s_{ui} and other one is weak friend set w_{ui}. According to Table-III the result for strong friend set (s_{ui}) and weak friend set (w_{ui}) is given below.

Set of strong friends S_{ui}= {Harry (0.35), Pet (0.25), James (0.15)}

Set of weak friends W_{ui}= {Kan (0.10), Oliver (0.10), Tom (0.05)}.

STEP 3: (Creating Dense Sub graph) Here we create the dense sub graph for differentiating strong and weak group of friends. The strong friends of a user (u_i) create a sub graph and weak friend's group w_{ui} creates another. Then we calculate the γ -quasi-clique value for each sub graph. The friends of a user

who are also friend with one another from the friend database should be connected with one another. Suppose for our input data set Pet and Harry are also friends. So they should be connected.

STEP 4: (Community Recommendation algorithm):

1. The user should not be connected with the communities which will be compared for recommendation.
2. Take two communities from the list of communities of the user's friends.
3. Only consider those friends with that particular community.
4. Find the γ -quasi-clique value for each sub graph for each community and then apply our comparison algorithm for recommending a community.
5. The selected community (c_i) is then compared with another community (c_i) from the list of communities. Thus we recommend a suitable community (c_i) for and use (u_i).

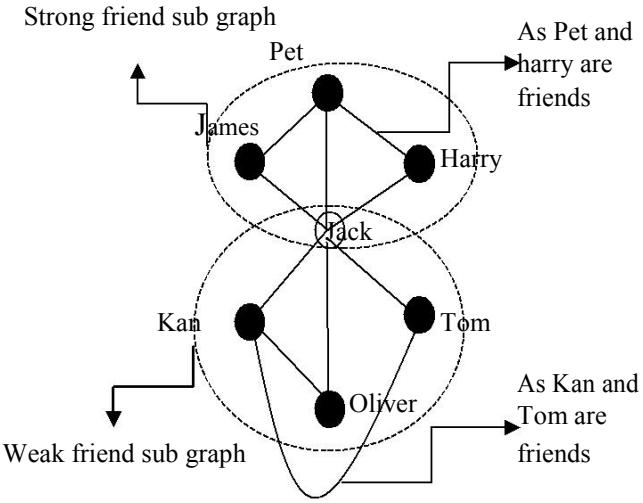

Fig. 3 Creating dense Sub graph

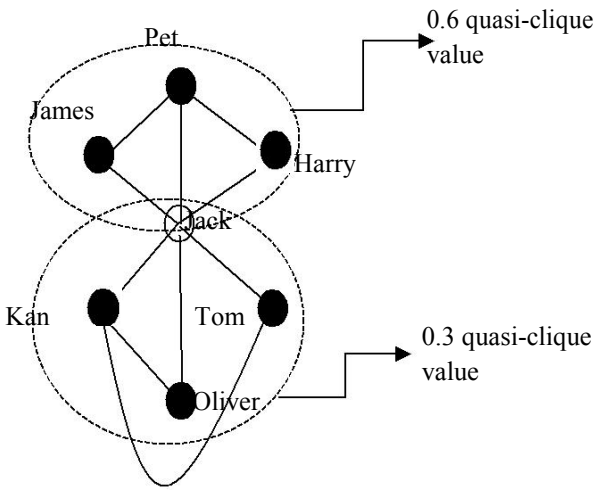

Fig. 4 γ -quasi-clique value for each sub graph of Community C1

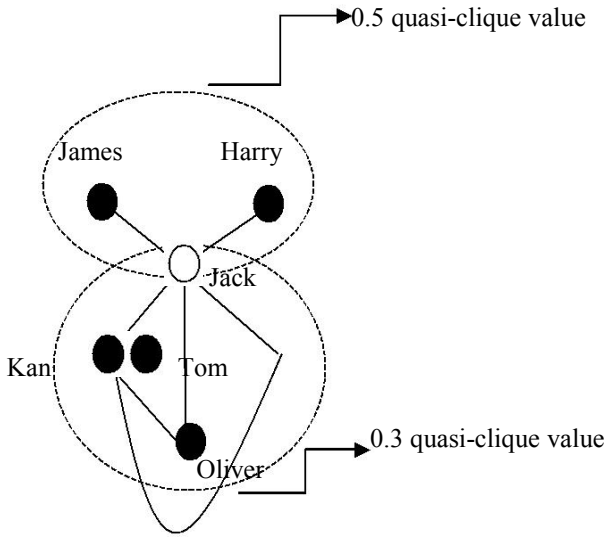

Fig. 5 γ -quasi-clique value for each sub graph of Community C2

Here q_i $[s_{ui}]$ denotes the γ -quasi-clique value for strong friends sub graph for i^{tn} community and q_i $[w_{ui}]$ denotes the γ -quasi-clique value for weak friends sub graph for i^{th} community. n_i denotes the number of nodes for each sub graph and g_i denotes the corresponding subgraph.

Community recommendation algorithm (CRA):

Input: (i) Friend database (F_{DB}), (ii) user specified minimum strength value (min_{str}), (iii) Community database (C_{DB}) Output: A recommended community (c_i)

1. If no friends are connected with the community then $q_i = 0$
2. Else if q_i $[s_{ui}] > q_{i+1}$ $[s_{ui}]$ and $n_i[s_{ui}] > n_{i+1}$ $[s_{ui}]$
3. Then $c_i =$ Recommended
4. Else if $n_i[s_{ui}] < n_{i+1}$ $[s_{ui}]$ and g_i $[s_{ui}]$ g_{i+1} $[s_{ui}]$
5. Then Recommended $c_{i+1} =$
6. Else if q_{i+1} $[s_{ui}] > q_i$ $[s_{ui}]$ and $n_{i+1}[s_{ui}] > n_i$ $[s_{ui}]$
7. Then c_{i+1} = Recommended
8. Else if $n_{i+1}[s_{ui}] < n_i$ $[s_{ui}]$ and g_{i+1} $[s_{ui}]$ g_i $[s_{ui}]$
9. Then c_i = Recommended
10. Else if q_i $[s_{ui}] = q_{i+1}$ $[s_{ui}]$ then
11. If $q_i[w_{ui}] > q_{i+1}[w_{ui}]$ and $n_i[w_{ui}] > n_{i+1}$ $[w_{ui}]$
12. Then c_i = Recommended
13. Else if $n_i[w_{ui}] < n_{i+1}$ $[w_{ui}]$ and $g_i[w_{ui}] \subset g_{i+1}$ $[w_{ui}]$
14. Then c_{i+1} = Recommended
15. Else if q_{i+1} $[w_{ui}] > q_i$ $[w_{ui}]$ and $n_{i+1}[w_{ui}] > n_i$ $[w_{ui}]$
16. Then c_{i+1} = Recommended
17. Else if $n_{i+1}[w_{ui}] < n_i$ $[w_{ui}]$ and $g_{i+1}[w_{ui}] \subset g_i$ $[w_{ui}]$
18. Then c_i = Recommended
19. Else if q_i $[s_{ui}] = q_{i+1}$ $[s_{ui}]$ and q_i $[w_{ui}] = q_{i+1}$ $[w_{ui}]$ and $n_i = n_{i+1}$

Then calculate the $\sum nis_{ui,fj}$ for each c_i

IF for strong friend sub graph,

c_i [$\sum nis_{ui,fi}$] > c_{i+1} [$\sum nis_{ui,fi}$]

Then c_i = Recommended

Else If c_{i+1} [$\sum nis_{ui,fi}$] > c_i [$\sum nis_{ui,fi}$]

Then c_{i+1} = Recommended

Else If c_i [$\sum nis_{ui,fi}$] = c_{i+1} [$\sum nis_{ui,fi}$]

Then for weak friend sub graph

If c_i[$\sum nis_{ui,fi}$] > c_{i+1}[$\sum nis_{ui,fi}$]

Then c_i = Recommended

Else if c_{i+1} [$\sum nis_{ui,fi}$] > c_i [$\sum nis_{ui,fi}$]

Then c_{i+1} =Recommended

Else both c_i and c_{i+1} recommended.

According to our CRA algorithm for community C1 in Figure-IV the γ -quasi-clique value for strong friend sub graph is 0.6 and the number of nodes is 4 and in Figure-V for community C2 the γ -quasi-clique value is 0.5 and the number of nodes is 3. And it full fills CRA's first condition. So C1 is the selected community for the user.

IV. Experimental Results

For experiments we have used a sample dataset which is given in Table-1 and Table-2 and works on various scenarios according to our survey on many users of Facebook. We have found some interesting situations like Fig. 6.

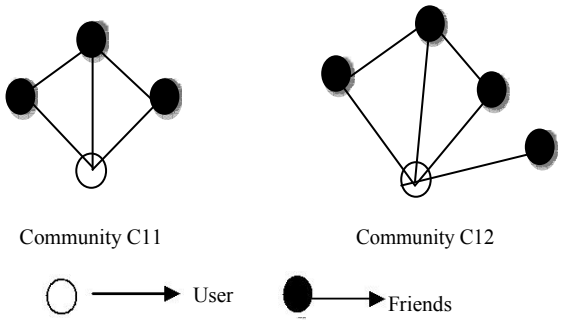

Fig. 6 Comparing communities

For community C11 the value of γ -quasi-clique is 0.6 but for community C12 the value of γ -quasi-clique is 0.25. If we only consider the γ -quasi-clique value then the resultant community is C11. But it seems that C12 is more connected. To solve this problem in our algorithm, we introduce comparing sub graph. When the γ -quasi-clique value of one sub graph is greater than the sub graph of other community, we count the number of nodes of that sub graph and compare with the other ones nodes. If the sub graph which has higher γ -quasi-clique value and has more nodes than the other one, it is recommended. But if the number of nodes is less than the other one, we check whether it's a sub graph of other one or not. If it is, then we recommend the community which has lower quasi-clique value. Here C12 is a super graph of C11 though having lower γ -quasi-clique value. So we will recommend C12 for the user. As we work on a survey of the users of Facebook, we have found our algorithm more accurate.

V. Related Work

As we work on recommending a community for an user in a social network, there are some existing works on it [1], [2]. One of those is social graph generation & forecasting using social network mining [1]. Here they used one way communication between the users and his corresponding friends. They assigned a strength value for each of the friends. And based on those values they came to an decision according their rule to recommend a community as well as the second one graph based forecasting for social networking site, communication [2], where the difference is the second one used two way directed graph to assign the strength values for defining the interactions between the users and his corresponding friends. Here we have used some basic graph techniques that is clique and quasi-clique [7] and based on those techniques we divide all the friends of an user into two groups, strong and weak, and for these we can access a portion of his friends at a time. For finding strong friends [3] or popular friends [4] the existing researches worked on finding a group of friends not on finding a single friend who is strong or weak for a particular user. But we need to detect a particular friend who is weak or strong for a particular user.

VI. Conclusion

In this paper we work through two main processes. Those are selecting strong friends and then applying quasi-clique technique to recommend a suitable community for a particular user. Usually when we work on some huge database it will take more time to check as well as to compare. But if we represent the database in a graph and work on that graph then it will be time consuming and easily understandable. As in our calculation a portion of a user's friends is accessed at a time so it is faster and we can visualize easily. Our future plan is to simplify our algorithm and add experimental results on real social network data.

Abstract— **In this paper, a new approach for detection of inter-turn short in the stator winding of an induction motor is presented. Discrete Wavelet Transform using DB4 is performed on the envelopes of the windowed steady-state current signatures. The envelopes are determined by applying Hilbert Transform. Low frequency oscillations below 50 Hz were extracted from the reconstructed details at higher wavelet levels. As the envelope works on narrow band frequencies or mono-component signal, it was analyzed using higher wavelet levels which belong to the narrow band harmonics. The RMS and Mean values of the reconstructed details and Power Detail Energy defined as PDE were used as fault parameters to detect the faulty motor from the healthy one. It has been observed that the faulty motor produces higher fault parameters than the healthy one. Laboratory test results confirm the validity of the proposed method.**

Index Terms— **inter-turn short, induction motor, Discrete wavelet transform, Hilbert Transform, envelope, RMS, Mean, Power Detail Energy.**

I. INTRODUCTION

In the present day industries, induction motor plays an important role as main drive. To reduce unscheduled downtime losses, to minimise occurrence of accidents, health monitoring of three phase induction motor has become very important. According to the survey, it has been observed that almost 40% of stator winding failures start as undetected turn to turn faults in a single phase due to destruction of insulation which finally grow and terminate in major faults [1]. In technical literature, several methods have been reported based on motor current signature analysis known as MCSA due to its easy availability and non-invasive nature. Motor current was analysed to search for characteristic (spatial) harmonics in the stator current to detect fault in the winding [2-3]. Apart from masking of the harmonics due to power frequency spectral leakage, similar types of harmonics may appear due to eccentricity related faults, supply unbalance, constructional imperfection [4]. Stator winding inter-turn fault has also been diagnosed by Negative sequence current [5] and negative sequence voltage[6], but they are not immune to unbalance of supply and inherent asymmetry of the motor. To overcome these difficulties, the negative sequence impedance has been used as fault indicator [7]. Park's vector's approach are also being applied for diagnosis of stator winding fault [8]. Advanced signal processing technique, wavelet transform are also producing very promising results for identifying motor faults [9].

The present paper proposed a novel approach for diagnosis of stator inter-turn short circuit fault of the induction motor through envelope analysis of windowed steady-state motor current. The proposed algorithm relies on efficient application of Hilbert Transform (HT) and Discrete Wavelet Transform (DWT). Windowing minimizes the edge effects that result in spectral leakage in the spectrum due to truncation of the selected portion of the signals. Selection of mother wavelet is not an easy task, if not proper, serious error may occur in the results which have been overcome by application of Hilbert Transform. Low frequency oscillations below 50 Hz were extracted from the reconstructed details at higher wavelet level of the envelope. As the envelope works on narrow band signals based on instantaneous frequencies, the reconstructed details at higher wavelet level were considerd. The method works with higher resolution and higher detectability due to simultaneous application of Hilbert transform and Wavelet transform.

II. THEORETICAL OVERVIEW

A. Stator Current envelope of an Induction Motor at the presence of inter-turn short of stator winding

In the investigation of *inter-turn short*, the stator current has been generally used. The faults affect the current according to motor slip

$$f_{stator} = \left\{ \frac{n}{p}(1-s) \pm k \right\} f \qquad (1)$$

where f is the supply frequency , p is the no. of pole pairs, s is the slip, n =1, 2, 3, --, k=1,3,5,----------, respectively.

The effects cause fluctuations on the current. The modulation of the stator current is the so-called envelope and that is cyclically repeated.

B. Hilbert Transform and Envelope Detection:

Hilbert Transform works on instantaneous frequency which is phase variability given by $f_i = (1/2\Pi)\, d\Phi/dt$

The Hilbert transform is defined as [10]

$$H\left[s(t)\right] = \frac{1}{\pi}\int_{-\infty}^{\infty} \frac{s(\tau)}{(t-\tau)} d\tau \qquad (2)$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Using the mean value theorem, we can evaluate

$$H\left[s(t)\right] = \frac{1}{\pi t} \otimes s(t) \qquad (3)$$

Therefore, H[s(t)] is obtained from the convolution of the function 1/(Πt) with the original function s(t). By Hilbert transform, negative frequencies are eliminated where as positive frequencies are phase shifted by Π /2 and their amplitudes are being doubled

Envelope Detection: The envelope of the signal, s(t) is defined as modulus of analytic signal z(t), given by

$$E(t) = \left|s(t) + jH\left[s(t)\right]\right| \qquad (4)$$

where $$z(t) = \left|s(t) + jH\left[s(t)\right]\right| \qquad (5)$$

It is a new dimension in the area of fault detection from the spectrum analysis of envelope which is almost free from 50 Hz frequency.

C. Discrete Wavelet Transform:

Discrete wavelet transform (DWT) decomposes a signal by successively passing it through high pass and low pass filter producing detailed (d_n) and approximate coefficients (a_n) using multi resolution analysis known as MRA [11].
Fig. 1 shows two level wavelet decomposition. Each level of decomposition corresponds to certain spectral bands given in Table I. The decomposed signal can be reconstructed as shown in Fig. 2.

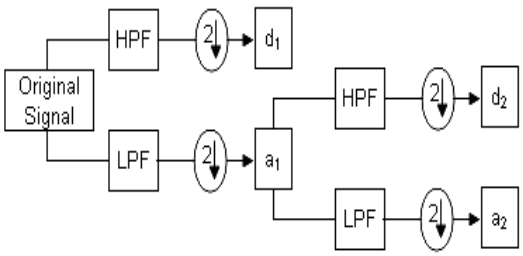

Fig. 1 Two Level multiresolution DWT decomposition

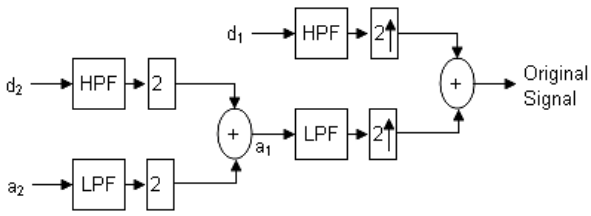

Fig. 2 Two Level multiresolution DWT reconstruction

Table 1 Spectral frequency bands at different decomposition levels

Decomposition Details	Frequency Bands(Hz)
Detail Level 1	512 - 1024
Detail Level 2	256 - 512
Detail Level 3	128 - 256
Detail Level 4	64 – 128
Detail Level 5	32 – 64
Detail Level 6	16 – 32
Detail Level 7	8 – 16
Detail Level 8	4 - 8

III. PROPOSED SCHEME

This paper presents a novel approach for detection of Induction motor stator inter-turn short circuit fault at no-load condition .The algorithm steps are summarised below:

Step 1: Use suitable window function to obtain specific size data vector from stator current of the Induction Motor. Window function is utilized to reduce the effect of transients.

Step 2: Perform Discrete Wavelet Transform in such a fashion that the reconstructed detailed coefficients at higher levels correspond to narrow band frequencies below 50 Hz.

Step 3: Compute fault parameters – RMS values, Mean values and Power Detailed Energy (PDE) of higher level wavelet coefficients. PDE is defined as

$$PDE = \sum_{1}^{N} (d_j \times d_j) \qquad (6)$$

where level of decomposition *j*, containing *N* number of samples .

Step 4: Compare the statistical parameters of the faulty motor with respect to the healthy one to obtain the information about the health of the Induction Motor.

Step 5: Go to Step 1.

This paper selects Hamming window of length 2048 (one sec. duration) samples. Then Discrete Wavelet Transform was performed using db4 mother wavelet which have the most compact support for a given number of vanishing moments, thus allowing the lowest computational loads. The spectral frequency bands at different decomposition levels are presented in Table1 for the sampling frequency 2048samples/sec.

IV. EXPERIMENTAL SET UP

Experiment was carried out on a test-rig built by Spectra Quest, USA, incorporated with a high speed data acquisition system (OROS OR35, 8 channels, 100 mbps). One induction motor with 3ph, 1HP, 415V, 50Hz, 1460 rpm with provisions for shorting from outside tapping was selected. The same motor can be used as healthy and inter-turn short (5% and 10%) in stator winding as faulty .The motors were run by direct-on-line supply at 330V, 50Hz through variac. Current signatures were captured using Hall Probe (LEM PR30 ACV 600V CATIII 30Ampac / 3Vac). The experimental set up and its schematic block diagram are shown in Fig. 3 and Fig. 4 respectively.

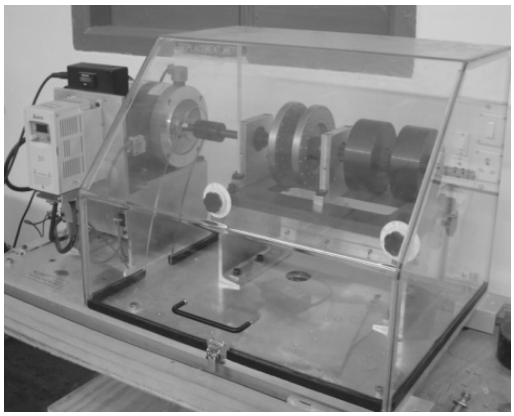

Fig. 3 Experimental setup

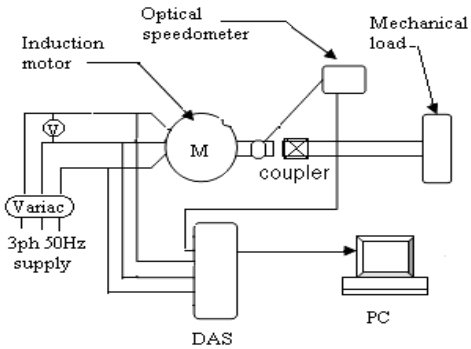

Fig. 4 Schematic block diagram of the experiment

V. Result Analysis

Discrete Wavelet Transform using db4 are performed on the the envelopes of windowed steady state signals (Sample size of duration of one sec.i.e.2048) at no-load. The signals and the envelopes for healthy, 5% and 10% inter-turn short conditions are shown in Fig. 5. Reconstructed details for the motor with the healthy and faulty conditions corresponding to 6th, 7th and 8th level below 50 Hz shown in Fig. 6, Fig.7and Fig. 8 are analysed. It is observed from the Table II that RMS, Mean values and PDE at all the three levels indicate considerable higher values for the motor with faulty condition than those for the motor with healthy condition. The most significant increases of these values are noticed at 8th level except the mean value at 7th level for 5%inter-turn short which is higher than the value at 8th level. The RMS values are 1.74 times and 6.61 times for 5% and 10% shorted turns with respect to the values for healthy condition whereas the rises in the Mean values are 1.57 and 6.22 times for 5% and 10% shorted turns. In the energy level analysis at 8th level, the increases in PDE are 3.10 and 42.84 times for 5% and 10% shorted turns with respect to the values for healthy condition.

Hence 8th level is considered most suitable for detection of stator inter-turn short.

The main advantages in this method are - the envelope analysis which makes diagnosis easier and cleaner as the power frequency is eliminated and the spectral leakage is minimized and the application of DWT on the steady state current which overcomes the difficulty of FFT analysis.

The main drawback is that once sampling frequency is selected, some ranges of frequencies remain unexplored. In the present analysis, it is (32 Hz - 50 Hz).

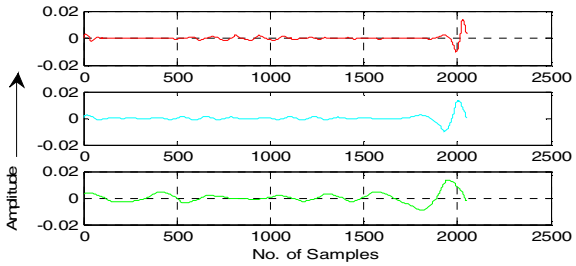

Fig. 7 The detailed coefficients corresponding) 8th ,9th and 10th level of envelope for motor at 10% at no load

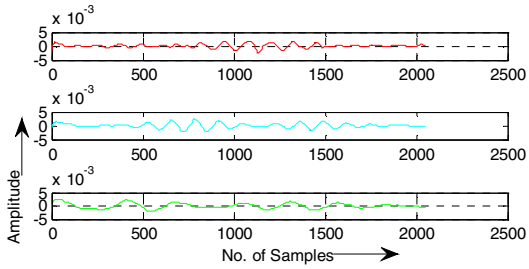

Fig. 8 The detailed coefficients corresponding to 6th ,7 th and 8th level of envelope for motor at 5% inter-turn short at no load

Table II Fault Parameters of the detailed coefficients of the Envelopes

Motor Condition	Wavelet Level	RMS value	Mean value	Power Detail Energy in joules
Healthy	6	.000496	.0000141	.000501
5% short		.000680	.0000211	.000947
10% short		.0019	.0000812	.0070
Healthy	7	.000687	.0000265	.000965
5% short		.000828	.0000378	.0014
10% short		.0024	..000148	.0115
Healthy	8	.000575	.0000409	.000677
5% short		.0010	.0000643	.0021
10% short		.0038	.0002545	.0290

VI. Conclusions

The present approach reveals that this method can successfully be employed for detection of stator winding inter-turn short. The method works with higher detectability and higher resolution due to DWT and Hilbert transform. The method is faster, less power consumption and hence less costly which makes it ideally suitable for industry

***Abstract*—Kalman filter and its variants are well known for the static and dynamic state estimation of power systems because of their accuracies. These adaptive filters generally employed for estimation purposes require high computational power when it comes to real time estimation. Therefore, in this paper we propose a computationally light yet effective estimation algorithm based on state space model which have not yet been applied to the problem of power system estimation. We propose the use of state space least mean square algorithms for the purpose of state estimation considering the problem of a two phase permanent magnet synchronous motor. The algorithms have been employed successfully in this paper in the state estimation of the highly non linear synchronous motor. We investigate the problem in the presence of Gaussian noise to show the novelty of the algorithms. Moreover, these algorithms are compared with the state estimation performance of the non linear Extended Kalman filter.**

***Index Terms*—SSLMS, SSNLMS, State Space Least Mean Square, State Space Normalized Least Mean Square, Power System Estimation, Synchronous Motor State Estimation**

I. Introduction

Adaptive filters are now widespread due to advancements in computational speed, complexity and power efficiency of digital processors. An adaptive filter adapts by self adjusting filter parameters according to the optimization algorithm utilized ([1],[2]). Two of the most widely used adaptive filtering algorithms are the least mean squares (LMS) algorithm ([1],[2],[3]) and the recursive least squares (RLS) algorithm ([1],[2],[3]). The state space (SS) version of these algorithms have been developed and presented by Malik et al. ([4],[5],[6],[7]) along with different analyses.

One of the important uses of adaptive filtering algorithms is in the area of power systems. State estimation has become an essential part of power system ([8],[9],[10],etc.) which requires the use of adaptive filtering algorithms like the Kalman filter, its variants and other algorithms ([11],[12],[13],etc.). However, these model based non linear adaptive filtering algorithms are highly computationally complex and requires more number of computations per iterations. Moreover, they don't always have the upper hand as will be presented in this paper. In this paper we deal with the state estimation of a permanent magnet synchronous motor. For effective control of the motor it is essential to know as best representation as possible of the true states of the motor. Which demands effective and efficient estimation algorithms giving us the cost benefit of having sensors. The synchronous motor is a highly non linear system and it is common practise to use non linear Kalman filtering algorithms like Extended Kalman filter (EKF), Unscented Kalman filter (UKF) ([12],[13],[14],etc.). The proposed state space least mean square (SSLMS) and the state space normalized least mean square (SSNLMS) by Malik et al. ([4],[5]) have only been applied to linear time varying systems. In this paper we propose and implement these algorithms for non linear synchronous motor state estimation and compare their performances with EKF. The proposed algorithms are superior due to the fact that they require lesser computations per iteration compared to the existing non linear model based algorithms. The performance of the algorithms in presence of Gaussian noise is investigated.

The paper is organized as such, Section II of the paper introduces the SS model along with the two phase permanent magnet synchronous magnet model. Then in Section III the overview of the existing SSLMS and SSLNMS is presented following Section IV presenting simulation results and discussion of the comparison of and proposed algorithms. And finally we conclude the paper in Section V.

II. State-Space Model

We begin by defining the general state-space model of a linear time varying system.

$$\mathbf{x}[k+1] = \mathbf{A}[k]\mathbf{x}[k] + \mathbf{B}[k]\mathbf{u}[k] + \mathbf{w}[k], \tag{1a}$$
$$\mathbf{y}[k] = \mathbf{C}[k]\mathbf{x}[k] + \mathbf{D}[k]\mathbf{u}[k] + \mathbf{v}[k] \tag{1b}$$

where $\mathbf{x} \in \Re^n$ are the process states, $\mathbf{y} \in \Re^m$ are the measured outputs such that $m \leq n$. $\mathbf{A}[k]$ is the state transition matrix, $\mathbf{B}[k]$ is the input matrix, $\mathbf{u}[k]$ is the input vector where $\mathbf{u} \in \Re^p$, $\mathbf{w} \in \Re^n$ is the process noise vector and $\mathbf{v} \in \Re^m$ is the measurement noise vector. The matrix $\mathbf{C}[k]$ is the output matrix where $\mathbf{dim}[\mathbf{C}[k]] = m \times n$, $\mathbf{D}[k]$ is the feed through matrix with $\mathbf{dim}[\mathbf{D}[k]] = m \times p$. It is assumed that the above system is observable. A special case is the unforced (autonomous) linear time varying system, represented as

$$\mathbf{x}[k+1] = \mathbf{A}[k]\mathbf{x}[k] + \mathbf{w}[k], \tag{2a}$$
$$\mathbf{y}[k] = \mathbf{C}[k]\mathbf{x}[k] + \mathbf{v}[k] \tag{2b}$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

The state space representation for a non linear continuous time system is

$$\dot{\mathbf{x}} = f(\mathbf{x}, \mathbf{u}, \mathbf{w}), \tag{3a}$$
$$\mathbf{y} = h(\mathbf{x}, \mathbf{u}, \mathbf{v}) \tag{3b}$$

where f and h are non linear functions and the parameters are as defined before. The two phase permanent magnet synchronous motor can be represented as ([14],[15])

$$\dot{i}_a = \frac{-R}{L} i_a + \frac{\omega\lambda}{L}\sin\theta + \frac{u_a}{L} \tag{4a}$$
$$\dot{i}_b = \frac{-R}{L} i_b + \frac{\omega\lambda}{L}\cos\theta + \frac{u_b}{L} \tag{4b}$$
$$\dot{\omega} = \frac{-3\lambda}{2J} i_a + \frac{3\lambda}{2J} i_b \cos\theta - \frac{F}{J}\omega - \frac{T_L}{J} \tag{4c}$$
$$\dot{\theta} = \omega \tag{4d}$$

where i_a and i_b are the current through the windings, R is the motor winding resistance, L is the motor winding inductance. θ is the angular position of the rotor, λ is the flux constant of the rotor, and ω is the angular velocity of the rotor. u_a and u_b are the voltages applied across the two windings, F is the viscous friction of the rotor, J is the moment of inertia of the rotor shaft and its load, and T_L is the load torque.[1]

III. Overview of the SSNLMS and SSLMS

Considering the system described by equation (2). A model based adaptive estimation process can be divided into the following two steps. Step 1, the time update which is given by

$$\bar{\mathbf{x}}[k] = \mathbf{A}[k-1]\hat{\mathbf{x}}[k-1] \tag{5}$$

Step 2, the measurement update which is given by

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] + \mathbf{K}[k]\varepsilon[k] \tag{6}$$

where

$$\varepsilon[k] = \mathbf{y}[k] - \bar{\mathbf{y}}[k] \tag{7}$$

here $\mathbf{y}[k]$ is as mentioned in (2), **K**[k] is the gain matrix and

$$\bar{\mathbf{y}}[k] = \mathbf{C}[k]\bar{\mathbf{x}}[k] \tag{8}$$

This is basically the structure employed in all Kalman Filtering techniques ([16],[17],[18],[19], etc.). In the case of SSNLMS [4] the gain matrix $\mathbf{K}[k]$ is derived as follows

$$\mathbf{e}[k] = \mathbf{y}[k] - \hat{\mathbf{y}}[k] = \varepsilon[k] - \mathbf{C}[k]\delta[k] \tag{9}$$

where

$$\delta[k] = \hat{\mathbf{x}}[k] - \bar{\mathbf{x}}[k] \tag{10}$$

Assuming $\mathbf{C}[k]$ is full rank, $\hat{\mathbf{x}}[k]$ is chosen such that $\mathbf{e}[k] = 0$ which implies the following

$$\varepsilon[k] = \mathbf{C}[k]\delta[k] \tag{11}$$

[1]The system has been discretized and linearized for the simulation and implementation of the estimation algorithms which can be referred to in the appendix.

$\delta[k]$ is chosen as the minimum norm solution of the above equation which results in

$$\delta[k] = \mathbf{C}^T[k](\mathbf{C}[k]\mathbf{C}^T[k])^{-1}\varepsilon[k] \tag{12}$$

here

$$\mathbf{K}[k] = \mathbf{C}^T[k](\mathbf{C}[k]\mathbf{C}^T[k])^{-1} \tag{13}$$

The estimator equation from (10) and (12) is hence derived as

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] + \mathbf{C}^T[k](\mathbf{C}[k]\mathbf{C}^T[k])^{-1}\varepsilon[k] \tag{14}$$

This is termed in ([4],[5]) as the SSNLMS algorithm. However, to avoid the non invertible scenario of $(\mathbf{C}[k]\mathbf{C}^T[k])^{-1}$, a small value γ might be added to the term and hence the estimator can be represented as

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] + \mathbf{C}^T[k](\gamma + \mathbf{C}[k]\mathbf{C}^T[k])^{-1}\varepsilon[k] \tag{15}$$

This is termed in [4] as the SSNLMS algorithm. However, the above estimator may be unstable and there are no known conditions for stability and hence convergence is not guaranteed. For this reason a $\mathbf{G}$ matrix has been introduced in [4] to overcome this problem. In [4], it is claimed that the choice of this matrix $\mathbf{G}$ depends on the nature of the problem and one simple approach is to take $\mathbf{G}$ to be all zeros except for the first column to have non zero entries. In our investigation, we will consider the SSNLMS and also the SSLMS algorithm [4] defined as

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] + \mu\mathbf{G}\mathbf{C}^T[k]\varepsilon[k] \tag{16}$$

here

$$\mathbf{K}[k] = \mu\mathbf{G}\mathbf{C}^T[k] \tag{17}$$

IV. Simulation Results & Discussion

Simulation results are presented here to validate the performance of the algorithms. We perform the estimation of the state parameters of the synchronous motor in the presence of Gaussian noise. For the EKF, the process and observation error covariance matrices were chosen to be similar to the noise covariances. An overview of the root mean square error (RMSE) of the states and the observations can be referred to in Table I. SSNLMS, SSLMS, and EKF were compared. The actual system is discretized at a sampling rate of 0.0002s but the algorithms sample at 0.001s to mimic the effect of real time scenario where sensors are limited by sampling rate. μ for SSLMS and SSNLMS were chosen as 0.2 and 0.4 respectively. The observation was subject to Gaussian noise of covariance $\sigma^2 = 0.01^2$ and the process noise was considered to be of covariance $\sigma^2 = 0.001^2$. The actual initial system states were considered to be $\mathbf{x}[0] = [1\ 3\ 0.5\ 2]^T$, and the initial estimate for the algorithms were chosen to be $\hat{\mathbf{x}}[0] = [0\ 0\ 0\ 0]^T$. The synchronous machine parameters can be referred to in [14] The plot of the states and observations are presented in Figure 1 and Figure 2 respectively. The square of the observation error is presented in Figure 3. It can be observed from Figure 1 that the EKF has lower error in the beginning, however, as time proceeds the SSLMS and SSNLMS converges faster than the EKF while the error of

the EKF remains higher.Moreover, the EKF performance is not acceptable when position and velocity plots are observed. A clear picture regarding the performance of the algorithms can be observed from the observation error square plots in Figure 3. It can be clearly seen that both the SSLMS and the SSNLMS converges faster and hence performs better in synchronous motor state estimation.

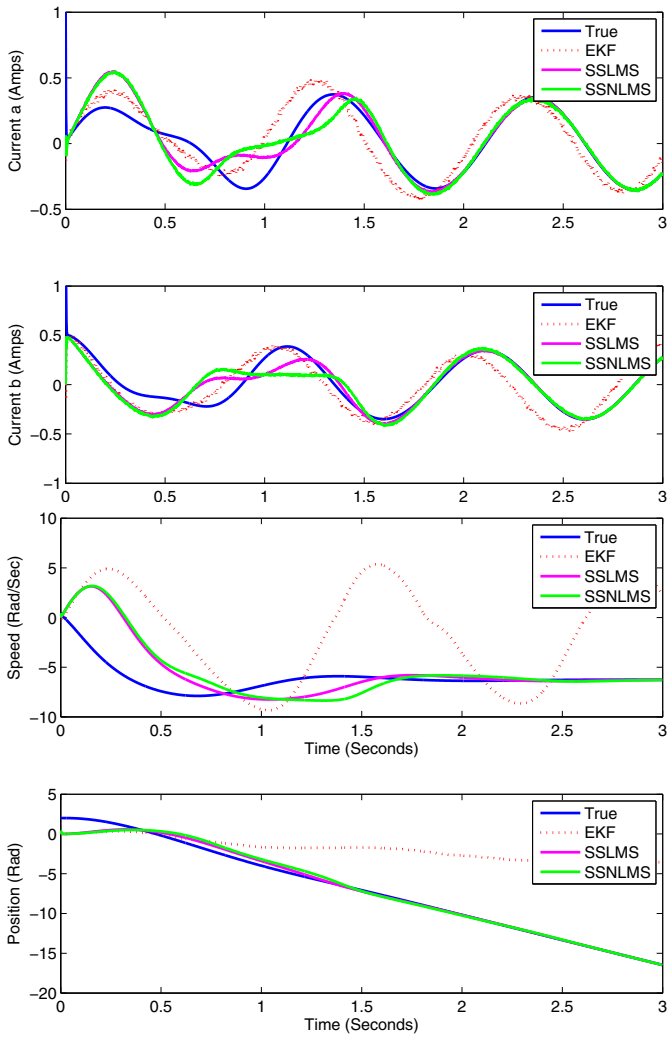

Fig. 1: State $x_1[k]$, $x_2[k]$, $x_3[k]$, and $x_4[k]$

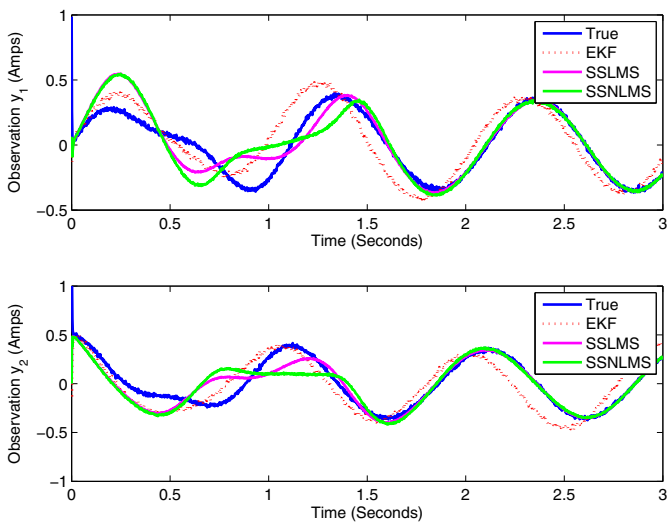

Fig. 2: Observation $y_1[k]$ and $y_2[k]$

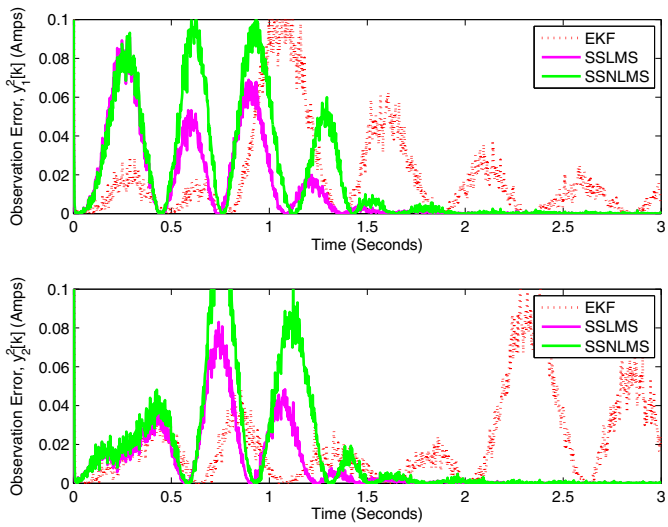

Fig. 3: Observation Error, $y_1^2[k]$ and $y_2^2[k]$

The Table presented below gives a much clearer representation of the performance of the algorithms. The root mean square error of both of the proposed algorithms remain much lower compared to the EKF and therefore these algorithms can very well be implemented and considered as novel state estimation algorithms in power system considering the fact that they have extremely low computational load.

TABLE I: Root Mean Square Error

	Root Mean Square Error		
	EKF	***SSLMS***	***SSNLMS***
State x_1	0.1389	0.1134	0.1392
State x_2	0.1644	0.1261	0.1506
State x_3	6.6513	2.2112	2.4001
State x_4	6.7208	0.5750	0.6740
Observation y_1	0.1391	0.1139	0.1397
Observation y_2	0.1644	0.1265	0.1509

V. Conclusion

In this paper the SSLMS and the SSNLMS algorithms have been implemented for the state estimation of a non linear synchronous motor. More recently, a lot of model based non linear Kalman filtering algorithms have been proposed for such estimation problems. However, it is very well known that these algorithms are complex and require high computational power in real time estimation. Therefore, we have suggested and implemented two state space least mean square algorithms which we have found to be effective by a very good margin. It is of much importance that the algorithms be computationally light which these algorithms are and therefore we claim them to be novel algorithms for non linear power system state estimation problems. We have investigated the performance of these two algorithms and compared them with EKF and found great results which is demonstrated by the root mean square error. A two phase permanent magnet synchronous motor has been investigated here in the presence of Gaussian noise. For further studies different variants of the SSLMS and SSNLMS can be developed and implemented for investigation along with time varying step size parameters for yet better results.

VI. Appendix

For the simulation of the system model, it is essential that the system be discretized. Considering the synchronous motor system described by the set of equations (4), the system is discretized as

$$\mathbf{x}[k+1] = f(\mathbf{x}[k], \mathbf{u}[k], \mathbf{w}[k]) = \mathbf{x}[k] + \begin{bmatrix} \frac{-R}{L}x(1) + \frac{\lambda}{L}x(3)\sin x(4) + \frac{u_a}{L} \\ \frac{-R}{L}x(2) + \frac{\lambda}{L}x(3)\cos x(4) + \frac{u_b}{L} \\ \frac{-3\lambda}{2J}x(1) + \frac{3\lambda}{2J}x(2)\cos x(4) - \frac{F}{J}x(3) - \frac{T_L}{J} \\ x(3) \end{bmatrix} \Delta t + \mathbf{w}[k] \tag{18}$$

$$\begin{aligned} \mathbf{y}[k] &= h(\mathbf{x}[k], \mathbf{u}[k], \mathbf{v}[k]) \\ &= \begin{bmatrix} x(1) \\ x(2) \end{bmatrix} \Delta t + \mathbf{v}[k] \end{aligned} \tag{19}$$

For the implementation of the algorithms the system was linearized which resulted in

$$\mathbf{A}[k] = f'(\hat{\mathbf{x}}[k], \mathbf{u}[k]) = \begin{bmatrix} -\frac{R}{L} & 0 & \frac{\lambda \sin \hat{x}(4)}{L} & \frac{\hat{x}(3)\lambda \cos \hat{x}(4)}{L} \\ 0 & -\frac{R}{L} & -\frac{\lambda \cos \hat{x}(4)}{L} & \frac{\hat{x}(3)\lambda \sin \hat{x}(4)}{L} \\ -\frac{3\lambda \sin \hat{x}(4)}{2J} & \frac{3\lambda \cos \hat{x}(4)}{2J} & -\frac{F}{J} & -\frac{3\lambda[\hat{x}(1)\cos \hat{x}(4) + \hat{x}(2)\sin \hat{x}(4)]}{2J} \\ 0 & 0 & 1 & 0 \end{bmatrix} \tag{20}$$

$$\begin{aligned} \mathbf{C}[k] &= h'(\hat{\mathbf{x}}[k]) \\ &= \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix} \end{aligned} \tag{21}$$

Maximum Power Delivery Capability of a Three-Phase Self-Excited Induction Generator

M. H. Haque
School of Engineering, University of South Australia, Australia
Mohammed.Haque@unisa.edu.au

Abstract—**Self-excited induction generators (SEIG) are increasingly being used in remote areas to energize isolated communities. The maximum power delivery capability of a SEIG depends on various factors, such as excitation capacitance, generator parameters, operating speed and load power factor. This paper proposes a simple method of determining the maximum power that can be delivered by a three-phase SEIG for various operating conditions. The maximum power of the generator is carefully formulated as a multi-variable constrained optimization problem. The problem is then solved using a numerical based routine "*fmincon*" given in the optimization toolbox of MATLAB. The effectiveness of the proposed method is then evaluated on a 1.5-kW, 220-V induction machine operated as a SEIG. The simulation results obtained by the proposed method are also compared with the corresponding experimental values.**

***Index Terms*--excitation capacitance, induction generator, maximum power, rural electrification, self-excited induction generator, stand-alone operation.**

I. Introduction

About one-fifth of world populations do not have access to grid electricity because they live in remote areas where extension of the grid is not economically viable. However, vast amount of renewable energy sources is usually available in remote areas. One of the possibilities of energizing remote communities is by using small-scale stand-alone generating systems based on renewable energy sources or in combination of renewable and fossil fuel sources.

Induction generators are increasing being used in small power plants driven by renewable energy sources, such as wind and mini-hydro. An induction generator has many advantageous features over its counterpart synchronous generator such as lower cost, maintenance and operational simplicity, brushless and rugged construction, lack of dc excitation, etc. [1-2]. Unlike a synchronous generator, a squirrel-cage induction generator cannot deliver reactive power. In fact, it absorbs reactive power for excitation. For stand-alone operation of an induction generator, the reactive power requirement of the generator as well as the load must be supplied by local capacitances. Such a generator is called self-excited induction generator (SEIG). The characteristics of a SEIG are highly dependent on the value of the capacitance used [3-6].

The per-phase steady-state equivalent circuit of a SEIG is usually used to determine its performance characteristics [2]. The circuit is normally analyzed either by loop impedance approach or nodal admittance approach [3-9]. References [10-13] determined the minimum capacitance required to build-up voltage in a SEIG under no-load condition. However, a SEIG has very poor voltage regulation and thus its voltage decreases rapidly with load [2, 14]. References [8, 15] determined the capacitance required in a SEIG under load conditions. In order to maintain a constant terminal voltage, the capacitance needs to be adjusted continuously with load [16, 17]. Alternatively, the terminal voltage can be regulated within a pre-specified upper and lower limit using discrete capacitances [18, 19].

For a given capacitance, the load characteristic (terminal voltage versus power) of a SEIG is very similar to the well-known *P-V* curve of a load bus in a power system [20]. In other words, there is a maximum power that can be delivered by the generator. The maximum power point is also called the critical point and it depends on the value of the capacitance used [3]. Reference [21] determined the capacitance as well as the maximum power point of a wind driven three-phase SEIG. The method mainly determined the maximum power of the wind turbine but not the generator. Mahato et al [22] determined the capacitance required to obtain the maximum output power for single-phase operation of a three-phase induction generator. In general, the terminal voltage at the critical point is much lower than the nominal value. In order to guarantee a minimum pre-specified terminal voltage, the generator should be operated away from the critical point. Thus, it is very important to determine the critical power as well as the maximum power that can be delivered while maintaining a pre-specified minimum terminal voltage for successful operation of the generator.

This paper proposes a method of determining the maximum power point of a SEIG for various operating conditions. An optimization problem is formulated to determine the maximum power point while satisfying the fundamental equations of the generator as well as a pre-specified minimum voltage criterion. The effectiveness of the proposed method is then tested on a 1.5-kW induction machine operated as a SEIG. The simulation results obtained by the proposed method are also compared with the corresponding actual values found through an experimental setup.

II. Generator Model and Characteristics

The per-phase steady-state equivalent circuit of a SEIG including its excitation capacitance and load impedance is shown in Fig. 1. The stator resistance, stator leakage reactance, rotor resistance, rotor leakage reactance, core loss resistance and magnetizing reactance of the generator are represented by R_1, X_1, R_2, X_2, R_c and X_m, respectively. The load impedance and the excitation capacitance reactance are represented by $\overline{Z}_L = Z_L\angle\theta$ (= $R_L + jX_L$) and X_C, respectively. The per unit (pu) generator speed and frequency are represented by v and F, respectively. All reactances are specified at the base frequency. Note that a SEIG may not generate voltage at rated frequency and thus the circuit of Fig. 1 is normalized to the base

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

frequency by dividing all parameters and voltages by the pu frequency F [2].

All parameters of the generator, except the magnetizing reactance X_m, are considered as constant. The value of X_m depends on magnetic saturation and hence air-gap voltage to frequency ratio (V_g/F). There are several ways of expressing V_g/F in terms of X_m [2, 8, 16, 21]. In this study, V_g/F is expressed by the following third-order polynomial of X_m and is used in some previous studies [3, 18]

$$\frac{V_g}{F} = k_1 + k_2 X_m + k_3 X_m^2 + k_4 X_m^3 \tag{1}$$

The coefficients k's of the polynomial can be determined from synchronous speed test data [3].

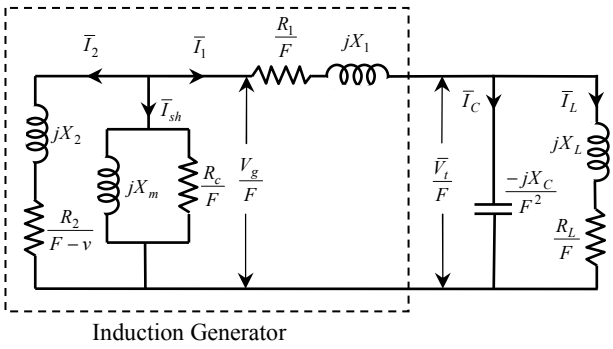

Fig. 1 Per-phase steady-state equivalent circuit of a SEIG

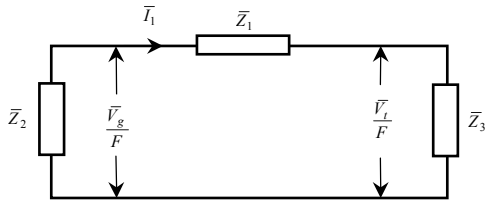

Fig. 2 Simplified representation of Fig. 1

The circuit of Fig. 1 can be represented by three series impedances ($\bar{Z}_1$, $\bar{Z}_2$ and $\bar{Z}_3$) as shown in Fig. 2. The impedances are given by

$$\bar{Z}_1 = (R_1 / F + jX_1) \tag{2.1}$$

$$\bar{Z}_2 = \left(\frac{1}{R_c / F} + \frac{1}{jX_m} + \frac{1}{R_2 /(F - v) + jX_2} \right)^{-1} \tag{2.2}$$

$$\bar{Z}_3 = \left(\frac{1}{-jX_C / F^2} + \frac{1}{R_L / F + jX_L} \right)^{-1} \tag{2.3}$$

The loop equation in Fig. 2 can be written as

$$\bar{I}_1 \left(\bar{Z}_1 + \bar{Z}_2 + \bar{Z}_3 \right) = 0 \tag{3}$$

Under normal operating condition, the stator current $\bar{I}_1$ is not zero and thus the sum of impedances must be zero.

$$\bar{Z}_1 + \bar{Z}_2 + \bar{Z}_3 = 0 \tag{4}$$

By separating the real and imaginary parts, the above phasor equation can be split into two scalar equations as follows

$$g_1 = real(\bar{Z}_1 + \bar{Z}_2 + \bar{Z}_3) = 0 \tag{5}$$

$$g_2 = imag(\bar{Z}_1 + \bar{Z}_2 + \bar{Z}_3) = 0 \tag{6}$$

Equations (5) and (6) represent the fundamental equations of a SEIG and must be satisfied for all operating conditions. Note that, for a given load power factor, the circuit of Fig. 1 has five unknowns (X_m, F, v, X_C and Z_L) but only two independent equations can be formulated [3]. Equations (5) and (6) are usually solved through a suitable iterative technique to find the values of two unknowns (X_m and F) for some assumed values of rest three unknowns (v, X_C and Z_L). By knowing the values of X_m and F, the air-gap voltage V_g can be evaluated through (1). Once V_g is known, the voltage, current and power in various parts of the circuit of Fig. 1 can easily be evaluated using standard circuit theories.

The voltage versus power curve of a SEIG can be obtained by repeatedly solving (5) and (6) in conjunction with (1) for various values of load impedance and assumed values of excitation capacitance and speed. A typical power characteristic of a SEIG is shown in Fig. 3. At no-load (when Z_L = infinity), P = 0 and the corresponding voltage is called the no-load voltage V_{NL}. When the load impedance is decreased from infinity, power increases and voltage decreases as can be seen in Fig. 3 (black line) and it represents the normal or stable operation of the generator. The above process continues until the maximum power point (marked by 'o') is reached. Further reduction of load impedance decreases both power and voltage as can be seen in Fig. 3 (red line). This is an abnormal operation and is called unstable operation. The maximum power point (marked by 'o') is also called the critical point. The power and the voltage at the critical point are represented by P_{cr} and V_{cr}, respectively.

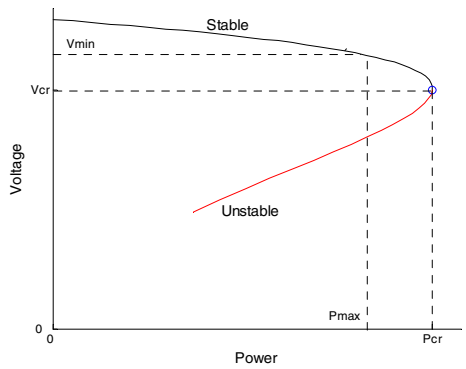

Fig. 3 A typical power characteristic of a SEIG

At the critical point, the load voltage may be far below the nominal value. When a minimum pre-specified voltage of V_{min} is maintained, the generator can deliver a maximum power of P_{max} (instead of P_{cr}) as can be seen in Fig. 3. The difference between P_{cr} and P_{max} can be considered as a power margin and is an indication of how far the operating point P_{max} is form the critical point.

III. Problem Formulation

As mentioned, the air-gap voltage V_g can be determined by solving (5) and (6) in conjunction with (1). Once V_g is known, the terminal voltage V_t in Fig. 2 can be written as

$$\bar{V}_t = \bar{V}_g \times \frac{\bar{Z}_3}{\bar{Z}_1 + \bar{Z}_3} \tag{7}$$

In order to guarantee a minimum terminal voltage of V_{min}, the following criterion must be satisfied

$$V_{\min} - \left| \bar{V}_g \times \frac{\bar{Z}_3}{\bar{Z}_1 + \bar{Z}_3} \right| \le 0 \tag{8}$$

The load current $\bar{I}_L$ in Fig. 1 can be written as

$$\bar{I}_L = \frac{\bar{V}_t}{R_L + jFX_L} = \bar{Y}_L \bar{V}_t \tag{9}$$

Here $\overline{Y}_L = 1/(R_L + jFX_L)$ is the load admittance. The active power P supplied by the generator can be written as

$$P = 3\left|\overline{I}_L\right|^2 R_L = 3\left|\overline{V}_g \times \frac{\overline{Z}_3}{\overline{Z}_1 + \overline{Z}_3} \times \overline{Y}_L\right|^2 R_L \qquad (10)$$

Determination of critical power P_{cr} involves the optimization of (10) while satisfying the fundamental equations (5) and (6). This can be achieved by varying the load impedance Z_L (or admittance Y_L) in the optimization process. In order to obtain the maximum power P_{max} while maintaining a minimum voltage of V_{min} (> V_{cr}), the inequality constraint (8) should also be included in the optimization process. Thus, for given excitation capacitance and speed, the optimization problem can be formulated as

Minimize $$f(\mathbf{X}) = -3\left|\overline{V}_g \times \frac{\overline{Z}_3}{\overline{Z}_1 + \overline{Z}_3} \times \overline{Y}_L\right|^2 R_L \qquad (11)$$

Subject to $$real(\overline{Z}_1 + \overline{Z}_2 + \overline{Z}_3) = 0 \qquad (12.1)$$

$$imag(\overline{Z}_1 + \overline{Z}_2 + \overline{Z}_3) = 0 \qquad (12.2)$$

$$V_{\min} - \left|\overline{V}_g \times \frac{\overline{Z}_3}{\overline{Z}_1 + \overline{Z}_3}\right| \le 0 \qquad (12.3)$$

Here $\mathbf{X} = [X_m \;\; F \;\; Y_L]^T$. The above problem can be solved using a numerical based optimization routine "*fmincon*" given in the optimization toolbox of MATLAB [24]. It may be mentioned here that when V_{min} in (12.3) is set to a lower value (< V_{cr}), the optimization process would provide the critical power P_{cr} (as described in Fig. 3). However, when V_{min} in (12.3) is set to a higher value (in between V_{NL} and V_{cr}), the optimization process would provide the maximum power P_{max} that occurs at V_{min} (as described in Fig. 3).

IV. Results and Discussions

The proposed method of determining the maximum power point of a SEIG was tested on a 1.5-kW, 220-V, 50-Hz, 4-pole, three-phase induction machine operated as a generator. The parameters of the generator are given in [3]. In the laboratory, the machine was driven at a constant speed of 1.0 pu by a synchronous motor. That is, the induced voltage under load condition would be slightly less than 50 Hz. The results found in the above machine are briefly described in the following.

First, the critical power (P_{cr}) at unity power factor are determined through (11) and (12) for various values of excitation capacitance. The results found through the optimization routine are shown in Fig. 4 by a solid line. The experimental results recorded in the laboratory are also shown in the figure by a symbol 'o'. It can be noticed in Fig. 4 that the critical power P_{cr} increases with the increase in capacitance. For C = 30 μF, the critical power is found as only 409 W (27.3% of rated value) and it increased to the rated value of 1500 W for a capacitance of about 50 μF.

The maximum power P_{max} that can be delivered by the generator while maintaining the rated voltage of 220 V is also determined through (11) and (12) by setting V_{min} = 220 V in (12.3). The results obtained in this case are shown in Fig. 5 and it indicates that the maximum power increases with the increase in capacitance but its value is lower than that found at the critical point (see Fig. 4) for the same value of capacitance.

In practice, the load voltage may not be kept constant at the rated value. The voltage may be allowed to drop to an acceptable minimum value (say 95% or 90% of rated value). With this in mind, the maximum power P_{max} that can be delivered by the generator while maintaining a minimum load voltage of 209 V (95% of rated value) or 196 V (90% of rated value) is also determined through (11) and (12) and the results found are shown in Fig. 6. For comparison purpose, the critical power is also shown in the figure. It can be noticed in Fig. 6 that the maximum power P_{max} increases with the increase in capacitance for all cases, as expected. For a given capacitance, the maximum power decreases as the specified load voltage is increased because the generator operates further away from the critical point.

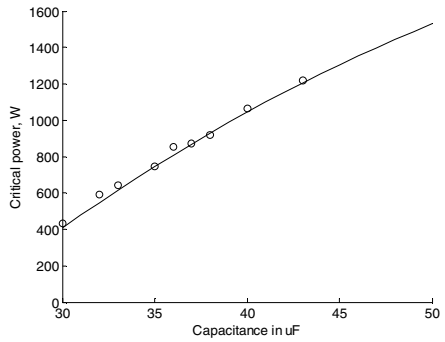

Fig. 4 Variation of critical power against capacitance.
'—' simulation results; 'o' experimental results

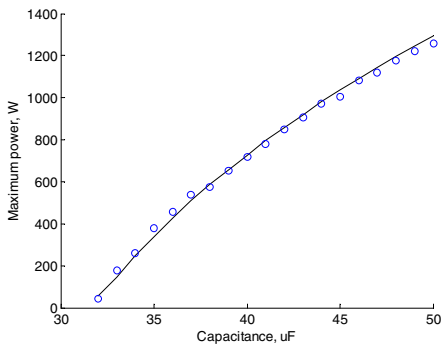

Fig. 5 Variation of P_{max} against capacitance at rated voltage (220V).
'—' simulation results; 'o' experimental results

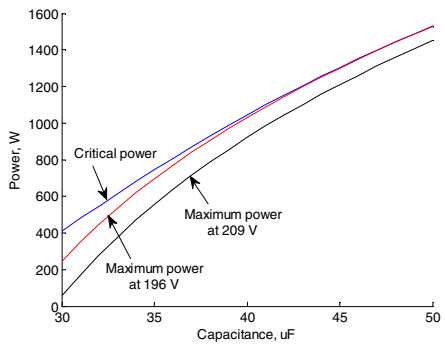

Fig. 6 Variation of critical power and maximum against capacitance.

Figure 7 shows the variation of critical power P_{cr} against capacitance for various load power factors. As mentioned, the capacitance in a SEIG supplies reactive power to both the generator and the load. For a lagging power factor, less reactive power is available for the generator excitation because of the load demand and thus the critical power decreases when compared with the unity power factor case. Finally, the variation of critical power against capacitance, for various operating speeds, is shown in Fig. 8 and it indicates that the critical power increases with the increase of speed.

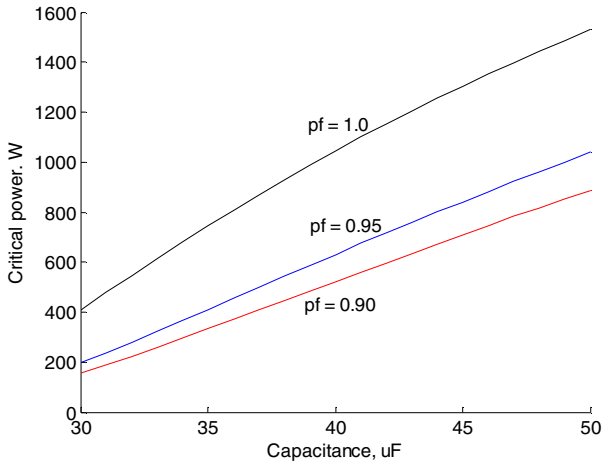

Fig. 7 Variation of P_{cr} against capacitance for various power factors.

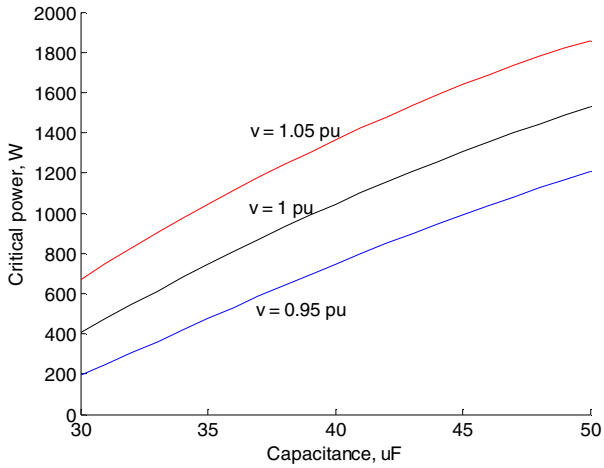

Fig. 8 Variation of critical power against capacitance for various speeds.

V. Conclusions

A simple method of determining the maximum power of a three-phase self-excited induction generator (SEIG) has been proposed in this paper. A constrained optimization problem has been formulated to find the maximum power point while satisfying the fundamental equations of the generator and a terminal voltage constraint. The formulated problem is solved using a standard numerical based routine given in MATLAB. By properly selecting the value of the minimum specified voltage, the same optimization problem can be used to determine the critical power as well as the maximum power that can be delivered while maintaining the minimum voltage. The effectiveness of the proposed method is then evaluated on a 1.5-kW, 220-V SEIG and the results found are compared with the corresponding actual values obtained through an experimental setup in a laboratory and are observed to be in very good agreement. It is found that the maximum power that can be delivered by the generator while maintaining a reasonable terminal voltage is lower than that at the critical point. It is also found that the maximum power of the generator depends not only on the value of the capacitance used but also on the load power factor and the generator speed.

Abstract—**In this paper, a two-phase induction motor is developed in the core of a single-phase induction motor to run with a two-phase supply. Modification is done by changing the auxiliary winding of the single-phase motor thus giving a constant 90 degree phase difference between main and auxiliary windings being fed through a two-phase voltage source. The two-phase supply is obtained from the conventional three-phase supply by a Scott-T transformer. Scott-T transformer is made of two single-phase transformers with different tapping ratios. Then these two transformers are connected in such a manner which gives two-phase supplies from a three-phase source. The motor is operated in both single-phase and two-phase modes varying the loads in the motor. An electromagnetic dynamometer brake is used for loading purpose in the motor shaft. Load is increased with increasing the DC excitation voltage of the dynamometer and necessary data are collected. The performance of the two-phase mode is analysed and then compared with that of a conventional single-phase mode of induction motor. The developed two-phase mode of operation gives the single-phase induction motor to gain the advantage of starting torque, higher efficiency, less torque harmonics, higher rated power and lower copper loss.**

***Keywords*—two phase, two-phase motor, two-phase supply, scott-t transformer.**

I. Introduction

Single-phase induction motors are widely used in many commercial and domestic applications. But their performance is inferior compared to the poly-phase induction motors due to zero starting torque, low rated power, high torque harmonics and low efficiency.

As single-phase induction motors have no starting torque, they require external electrical equipment for starting. Conventional methods for starting a single-phase induction motor are quite expensive. Besides, they need mechanical switches which are the most troublesome parts of the motor. They frequently suffer from mechanical wear that affects the performance of the motor. In this regard, two-phase operation of single-phase induction motor can serve a promising way for energy saving which requires no external starting equipment.

In this paper, a practical experiment is carried out to develop a two-phase motor in the same frame and core of a single-phase induction motor. There are several ways to drive a two-phase motor. Two-phase supply can be obtained from both conventional single-phase and three-phase supplies. In [3] an inverter circuit is proposed to drive a two-phase induction motor using 8 power transistors. Here, square fed delta modulation technique is used. In [4] a conventional method using three-phase inverter is proposed to drive two-phase induction motor. There are 6 power transistors used here and this method is only proposed for driving asymmetrical two-phase motors. In [5] a technique is proposed where the main winding of a two-phase motor is supplied from the conventional single-phase supply and auxiliary winding is fed through a variable voltage magnitude and variable phase-angle voltage source. For variable frequency motor operation a matrix converter methodology is used in [6] to drive the two-phase induction motor. Another example of driving single-phase induction motor as two-phase motor using two-phase inverter is presented in [7]. Here, additional harmonics are produced by solid state inverters. As a result, an extra circuitry is required to eliminate these harmonics.

The motivation of the experiment presented here is to develop a two-phase mode of operation in the core of a single-phase motor to analyze the improved performance caused by two-phase drive. To do so, an easier and simple method is proposed here to achieve two-phase supply from conventional three-phase supply using Scott-T transformer. Through this mode of operation advantages of poly-phase induction motor such as starting torque, higher efficiency, higher rated power, lower copper losses, reduced vibration and noise become available in single-phase induction motor.

II. Design of Two-Phase Induction Motor

Conventional capacitor-start single-phase induction motor has two windings, the main winding and the auxiliary winding. A capacitor is placed in series with the auxiliary winding, thus a 90 degree phase difference in current is obtained. Consequently, a torque is developed and motor becomes a self-starting motor. After the motor starts, the auxiliary winding is disconnected usually by means of centrifugal switch that operate at about 75 percent of synchronous speed. Finally the motor runs because of the main winding. Since this is being single-phase, some level of humming noise is associated with motor during running.

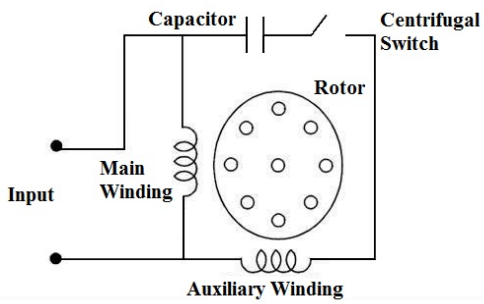

Fig. 1 Schematic diagram of capacitor start single-phase induction motor.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

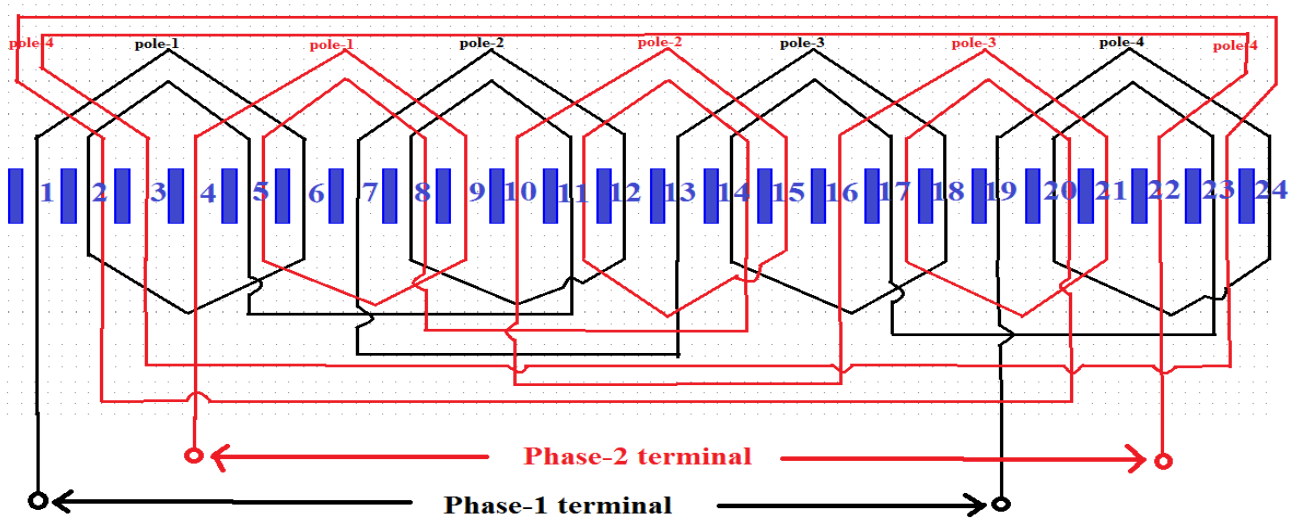

Fig. 2 winding configuration of two-phase induction motor.

To run this single-phase induction motor with two-phase supply modification is done. Capacitor and centrifugal switch is cut off first. The auxiliary winding is made of thin wire compared to that of main winding which has thick copper wire. It is because in single-phase operation auxiliary winding is connected to the supply only for a few times during staring. So, transformation is made to the auxiliary winding to have the same thick copper wire and number of turns as that of the main coil.

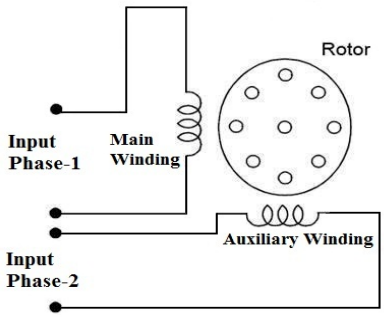

Fig. 3 Schematic diagram of two-phase induction motor.

In the developed two-phase induction motor there are 24 slots in the core of stator. Main and auxiliary coils are wound to develop a 4-pole motor shown in Fig. 2. Synchronous speed of the motor is thus 1500 rpm as supply frequency is 50 Hz.

III. TWO-PHASE SUPPLY

In order to successfully operate a single-phase induction motor as two-phase motor, two-phase power supply is required. This is done from three-phase supply using Scott-T transformer [1],[2].

The Scott-T transformer requires a three-phase power input and provides two equal single-phase outputs called Main and Teaser. The Main and Teaser outputs are 90 degrees out of phase. Scott-T transformer is made of two single phase transformers of equal power rating.

This connection consists of a centre-tapped 1:1 ratio Main transformer, T1, and an 86.6% ($0.5\sqrt{3}$) ratio Teaser transformer, T2. The centre-tapped side of T1 is connected between two of the phases on the three-phase side. Its centre tap then connects to one end of the higher turn count side of T2, the other end connects to the remaining phase. The other sides of the transformers (T1 & T2) then connect directly to the two pairs of the two-phase four wire induction motor.

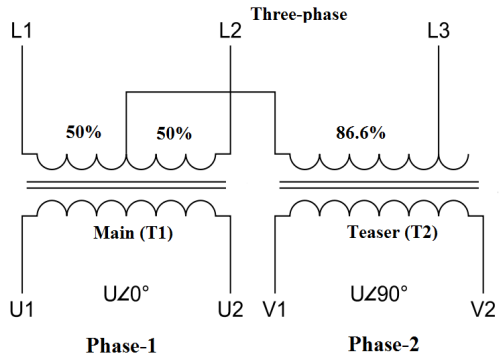

Fig. 4 Schematic diagram of Scott-T connection.

The complete system is then connected for operation and data collection. Modified induction motor, Scott-T transformer and electromagnetic dynamometer brake are assembled for final purpose of measurement in the picture of Fig. 5.

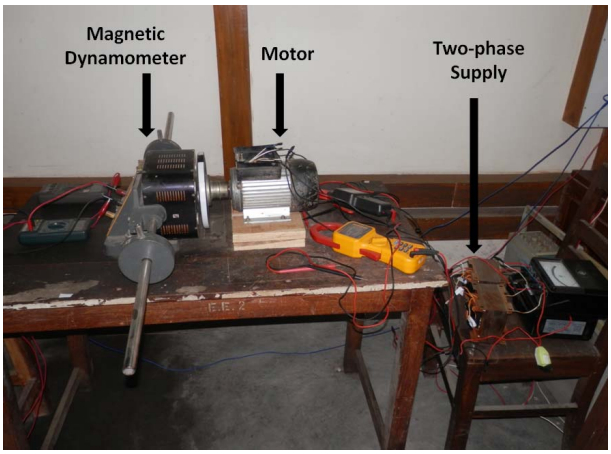

Fig. 5 Complete system with electromagnetic dynamometer.

IV. DATA COLLECTION PHASE

The modified motor is used to analyze the performance of the induction motor under single-phase and two-phase modes of operation. An electromagnetic dynamometer brake is used

to measure generated torque and power by the motor at various loads. With increasing the DC excitation voltage of the dynamometer the motor shaft is loaded. For various loads input power, output power, output torque and rotor speed are measured for both single-phase and two-phase operations.

A. Single-phase operation

In single-phase mode of operation a sinusoidal voltage of 220V is applied in one phase terminal of the modified motor. Varying the load of the shaft various data are collected.

TABLE I
DATA COLLECTION WITH SINGLE-PHASE

Input power (Watt)	Output power (Watt)	Developed torque (Nm)	Rotor speed (rpm)
38	0	0	1498
40	6.1	0.04	1495
46	9.1	0.06	1488
56	15	0.1	1477
70	26.8	0.17	1464
93	43.6	0.3	1428
123	59	0.4	1383
146	68.6	0.49	1350

B. Two-phase operation

In two-phase mode of operation two sinusoidal voltages, each being 220V, from the main and teaser windings of the Scott-T transformer are applied in both the terminals of each phase of the same motor. Here corresponding data are also collected varying the electromagnetic load.

TABLE II
DATA COLLECTION WITH TWO-PHASE

Input power (Watt)	Output power (watt)	Developed torque (Nm)	Rotor speed (rpm)
30	0	0	1500
33	4.6	0.03	1498
40	15.2	0.1	1494
52	19.7	0.13	1490
63	30	0.2	1472
83	47.7	0.31	1465
100	59	0.39	1452
134	89.5	0.6	1420
162	119.7	0.82	1401
205	137.5	0.97	1352
242	161.3	1.17	1322

V. COMPARATIVE ANALYSIS

With no load, both single-phase and two-phase modes have similar speed. In both cases, rotational losses are also similar when there is no load. When load is increased, developed torque and output power of the two-phase mode go higher than that of the single-phase mode. These two attributes of two-phase mode are compared with the single-phase mode in Fig. 6 and Fig. 7 respectively.

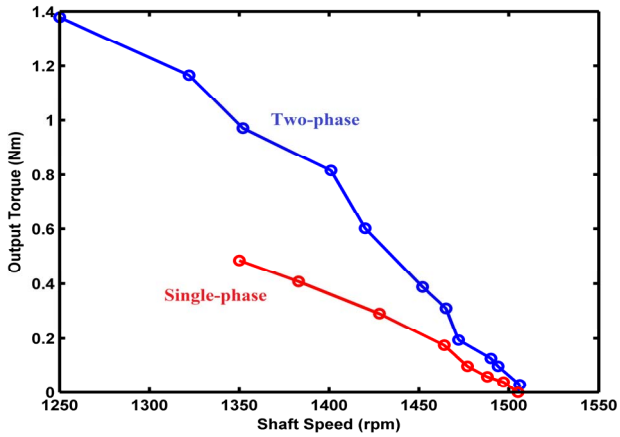

Fig. 6 Developed torque comparison.

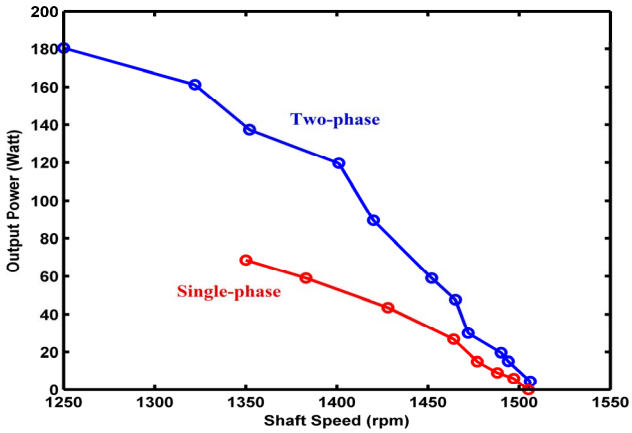

Fig. 7 Output power comparison.

It is prominent from the above figures that two-phase motor produces higher torque, which means more power for the same frame size of the motor. Table III shows that a 83% increase in torque is obtained at a 5% slip. Therefore, higher rated torque is achieved in two-phase operation.

TABLE III
POWER GAIN IN TWO-PHASE

	Single-phase		Two-phase	
Slip	2.7%	5%	2.7%	5%
Developed Torque (Nm)	0.17	0.3	0.31	0.55
Torque Gain	-	-	82.35%	83.33%

Besides, stator copper loss is also calculated for both modes of operation and their comparative analysis with increasing the load is shown in Fig. 8. Stator copper loss is increased for both modes with increasing load as it draws more currents through the stator winding. Copper loss is calculated using the input stator currents and stator resistance measured from the DC test of induction motor.

If we assume a motor slip of 5%, then copper losses in single-phase and two-phase are as follows:

$$P_{copper,\sin gle-phase} = 20.78\ \mathrm{W}$$

$$P_{copper,two-phase} = 16.5\ \mathrm{W}$$

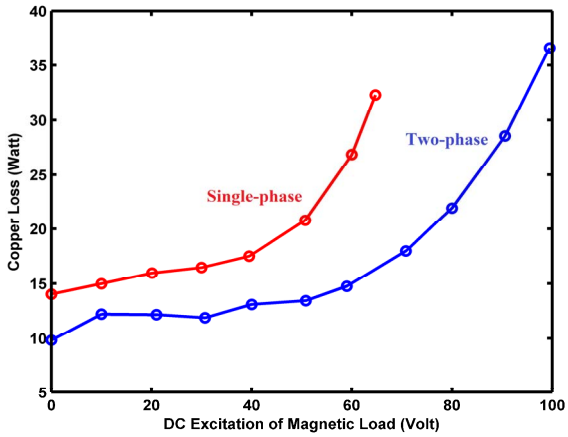

Fig. 8 Stator copper loss comparison.

Greater efficiency is also observed while motor is running in two-phase mode. Efficiency comparison between these two modes is illustrated in Fig. 9 with respect to shaft speed.

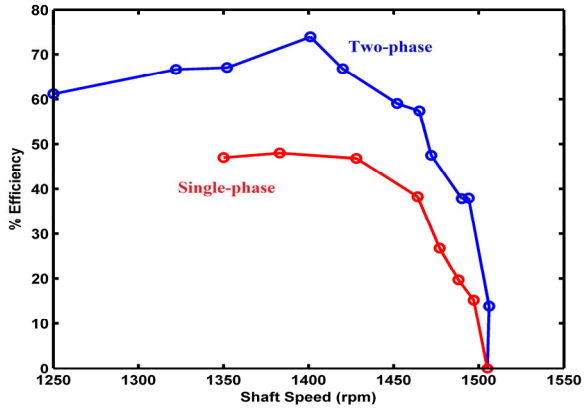

Fig. 9 Efficiency comparison with respect to shaft speed.

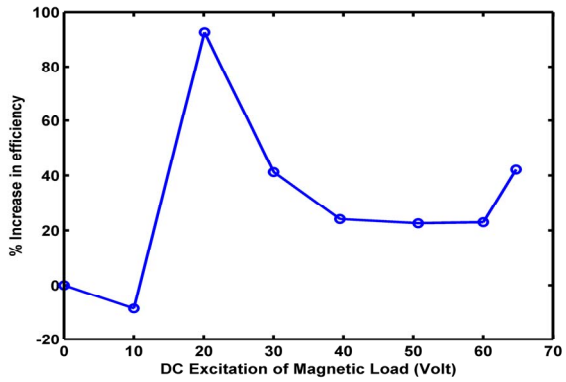

Fig. 10 Efficiency increment in two-phase mode.

It can be seen that with smaller load both single and two-phase modes gives similar efficiency. But with the increase of load, efficiency goes higher for two-phase operation the increment of which is in the range of 22.6% to at most 92.4% with an average of 29.6%. This increase in efficiency is shown in Fig. 10.

These results show that the two-phase operation increases the output power and reduces the copper losses, which means higher efficiency. This is due to the fact that, with the contribution of the two windings, a higher output can be obtained even with less current in each individual winding.

In this experiment, a single-phase induction motor is used to convert it into a two-phase induction motor driven with a two-phase supply. If we have a look at total the initial cost of both single-phase and two-phase motor, then it can be clearly seen that total conversion from single-phase to two-phase induction motor requires only less than 30 $ including cost of Scott-T transformer for getting two-phase supply.

TABLE IV
CONVERSION COST ANALYSIS

Single-phase		Two-phase	
Motor core, frame and rotor	17 $	**Motor core, frame and rotor**	17 $
Winding cost	13 $	**Winding cost**	15.5 $
Starting capacitor	1.5 $	**Scott-T transformer**	32 $
Centrifugal switch	4 $	-	-
Total cost	35.5 $	**Total cost**	64.5 $

Apart from these advantages, two-phase induction motor has benefits such as higher starting torque that is required to operate with high-starting-torque loads. Moreover, unlike single-phase motor, no humming noise and less vibration are associated with two-phase motor which is also essential for silent operation of motors.

VI. CONCLUSION

Single-phase induction motors are widely used for pumping purpose in households, irrigations and industries as well. A big portion of electricity bill is carried out by these motor pumps in a developing country like Bangladesh where energy crisis is a significant issue. If we replace them by more efficient two-phase motors with a minimal cost proposed here, then we can achieve starting torque with a higher rated power which means supplying water at a higher level is possible in a more efficient way. Moreover if we drive this motor by solar powered DC voltage through a two-phase inverter then it can reduce the load of our national grid power system to a great extent.

The results obtained, has confirmed that two-phase mode of operation gives better performance. Increased rated torque indicates more power in the same frame size thus less initial cost. Besides, improved efficiency translates into less running cost of motor. These savings justify the additional cost for motor conversion and two-phase supply circuits.

***Abstract*—The operation and efficiency of HEV (hybrid electrical vehicle) greatly depends on its charging system. The HEV uses grid power to charge the battery. The traction circuit components are not normally engaged during the charging time, so there is a possibility to use them in the charger circuit to have an on-board integrated charger. Most charges are non isolated type having low charging power capacity. Therefore on board isolated high power charger is required for PHEV (plug in hybrid electrical vehicle) which may improve the charging efficiency of the battery. The size and price are important considerations for such integrated charger. In this paper, an integrated on board charger is proposed which provides high charging power and unity power factor operation. In the proposed design, asynchronous machine and bi directional converter are used so that the machine can act as motor during traction and isolated transformer during charging. The boost converter topology is used for the bidirectional converter which can be used as inverter during traction. The proper operation of integrated charger greatly depends on grid synchronization and controlling mechanism of converter and asynchronous machine. The Park transformation is used for mathematical electromechanical model of the asynchronous machine. A controller scheme is designed by using the concepts of conventional controlling scheme of IPM (induction permanent magnet) motor/generator set and decoupled current control method of boost converter. The whole system is simulated in Matlab/Simulink based model in order to verify the system operation of the proposed charger. The simulation results show good performance of the charger leading to machine speed stability and smooth grid synchronization.**

***Index Terms*—Bidirectional converter, boost converter topology, integrated charger, PHEV.**

I. Introduction

The performance of battery modules in HEV depends on the charger. Generally there are two types of battery chargers which are on-board type and stand-alone (off-board) type [1], [2]. The on-board type of charger always should be carried by the vehicle which increases the weight of the system. With respect to weight, space and cost, it is difficult to install high power capacity on-board chargers in HEV. The assurance of galvanic isolation for battery charger is also an import issue [3].The integrated charger has electric machine, converter/inverter and charger circuit which reduces the system weight, space and cost [4]. It can be a suitable option for both onboard and off-board charger. Several different types of integrated chargers are proposed for vehicle application where the electric machine is used as inductor or isolated transformer and the vehicle remains standstill during charging[2],[5].For non-isolated integrated chargers, extensive protection and shielding are used [5]. However for isolated charger, a wound rotor induction machine is used as an isolated transformer which causes low system efficiency due to high magnetization current. So far no integrated chargers which are proposed by manufactures and academicians combine both galvanic isolation and high efficiency features. Though the isolated integrated chargers provide isolation but most of them are of low power capacity [3].In this paper, an approach is made for design and analysis of high power isolated integrated charger. In this design, asynchronous motor is used as isolated transformer during charging of the battery from grid whereas in traction mode, it is used as electric motor for the vehicle. The boost converter topology is incorporated in the proposed design so that the asynchronous machine remains stationary during charging [4]. In order to implement boost converter topology, the conventional squirrel cage or phase wound configuration of the asynchronous machine is modified to split wound configuration. The bidirectional converter is used for this design which acts as converter during charging and acts as inverter during traction. The proposed on board integrated charger provides both galvanic isolation and high efficiency. The determination of controlling topology for the integrated charger is the major concern of this design.

II. Proposed Isolated Integrated Charger

In the proposed design, the windings of the asynchronous electric machine are reconfigured which can be used as a grid isolated transformer. In traction mode the machine acts as motor whereas in charging mode its windings are arranged by switching device so that it can act as an isolated transformer [6]. The rotor of the three phase asynchronous machine is made of PM (permanent magnet) rather than electromagnet for simplification of machine construction so that it can start from initial stationary state without any extra starting arrangement [7]. This rotary three-phase machine constitutes a three-phase bidirectional converter which can be used as inverter as well. The figure 1 shows the schematic diagram of the proposed integrated charger for a PHEV. The charging power of the battery is controlled by bidirectional converter and therefore high power charging is possible in this configuration. During charging, the inverter is synchronized with the grid voltage through stator windings of the electric

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

machine. In order to keep synchronism, the gate pluses of switching devices of the bidirectional converter are synchronized with the grid voltage by using PWM technique [5], [8]. The stator windings act as an isolated three-phase transformer and the converter can control the dc voltage and current at the battery side [7]. The torque of the electric machine is kept zero during synchronization with the grid. For proper operation of the bidirectional converter, the dc bus voltage needs to be more than the peak ac line voltage which also ensures unity power factor operation [9]. This is attained by using Y −Δ connection of the stator windings of the machine.

The arrangement of stator and rotor windings of the two pole asynchronous machine is an important consideration for bidirectional operation of the machine [10]. The three phase stator winding is divided into six windings which are shifted 30^0 electrical degrees around the stator periphery [4]. These six windings can be considered as two sets of three-phase windings. The figure 2 shows the cross section of the machine where the direct axis components of the stator windings are a_1, b_1, c_1 for the first set and a_2, b_2, c_2 for the second set which are shifted 30^0 electrical degrees on the stator periphery. Similarly the quadrature axis components are a'_1, b'_1, c'_1 for the first set and a'_2, b'_2, c'_2 for the second set.

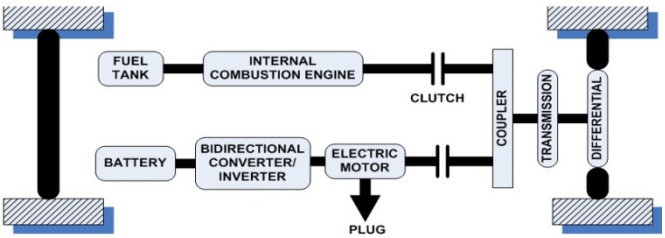

Fig. 1 Asynchronous motor based proposed integrated charger

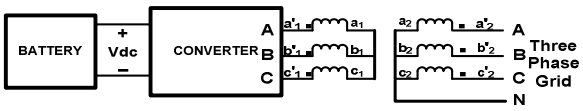

Fig. 4 System operation in charging mode

A. Mathematical Model of Six Stator Windings

A mathematical model of the machine is developed based on the assumption that all stator windings and magnetomotive forces of rotor magnets are sinusoidally distributed. This machine has six stator windings. A special abc to dq transformation is used which is based on the extended version of Park transformation for six variables instead of three [11], [12]. The system equations in the dq frame are reduced to a six order system while all sin and cosine terms are eliminated from the equations [12]. The voltage equations for six windings can be derived as follows [10], [12],

$$v_{a1} = r_s i_{a1} + \frac{d}{dx}\varphi_{a1} \quad \text{(1)}$$

$$v_{b1} = r_s i_{b1} + \frac{d}{dx}\varphi_{b1} \quad \text{(2)}$$

$$v_{c1} = r_s i_{c1} + \frac{d}{dx}\varphi_{c1} \quad \text{(3)}$$

$$v_{a2} = r_s i_{a2} + \frac{d}{dx}\varphi_{a2} \quad \text{(4)}$$

$$v_{b2} = r_s i_{b2} + \frac{d}{dx}\varphi_{b2} \quad \text{(5)}$$

$$v_{c2} = r_s i_{c2} + \frac{d}{dx}\varphi_{c2} \quad \text{(6)}$$

where v_{a1}, v_{b1}, v_{c1}, v_{a21} , v_{b2} , v_{c2} , i_{a1} , i_{b1} , i_{c1} , i_{a2}, i_{b2} , i_{c2}, φ_{a1}, φ_{b1}, φ_{c1}, φ_{a2}, φ_{b2}, φ_{c2} and r_s are windings voltages, currents, flux linkages and resistance respectively. The stator current i_s and voltage v_s can be derived by the following equations [9],

$$i_s = [\, i_{a1} \quad i_{b1} \quad i_{c1} \quad i_{a2} \quad i_{b2} \quad i_{c2} \,]^T \quad \text{(7)}$$

$$v_s = [\, v_{a1} \quad v_{b1} \quad v_{c1} \quad v_{a2} \quad v_{b2} \quad v_{c2} \,]^T \quad \text{(8)}$$

The developed electromagnetic torque in the machine can be calculated as follows [8],

$$T_e = \frac{P}{2}\left(\frac{1}{2}\, i_s T \frac{\partial L_s}{\partial \theta_r} i_s + i_s\, T \frac{\partial \varphi_{pm}}{\partial \theta_r}\right) \quad \text{(9)}$$

where, P is the number of poles, Ψ_{pm} is the stator winding fluxes due to rotor magnets and θ_r is the angular displacement of rotor.

B. Operation during Traction and Charging

The proposed integrated charging system has two modes of operation which are traction and charging. In traction mode, two set of stator windings are connected to each other in series to constitute a three-phase winding set. These three windings can be connected in Δ or Y to form a classical three phase machine. In traction mode, the machine acts as a motor which is powered by the battery through the inverter. The figure 3 shows the system diagram in traction mode. For charging mode, the two set of stator windings are separated from each other and windings a_2, b_2 and c_2 are connected to the grid for battery charging via converter. The system is reconfigured according to the scheme shown in the figure 4. In charging mode, the machine is kept standstill and it acts as an isolated transformer for transferring power from grid to the converter. The converter uses this isolated voltage source to charge the battery by means of machine leakage inductances (yielding a three phase boost converter).

C. Grid Synchronizing and Controlling Topology

In order to keep synchronization with the grid, it is necessary to determine the controlling topology of the proposed integrated charger [13]. When the battery is connected to the grid during charging, the dc voltage, stator current and rotor speed of the asynchronous machine need to be measured for controlling of the system [11]. For proper synchronization, both the magnitude and angle of grid side stator winding voltage and grid voltage need to be same [14]. Since the magnitude of voltage of the asynchronous machine

is a function of the speed and flux so by controlling the flux the voltage can be controlled. In a classical electrical machine usually the reference value for the direct component of the machine voltage is considered zero but in this integrated charger this value is used as a control parameter to change the induced voltage magnitude in machine [12],[15]. In order to match the voltage angles of the grid side stator windings and grid voltage, a PI controller is used to adjust the speed reference of the machine with the angle error signal [16]. The direct component of the voltage is close to zero so the angle error is replaced by the voltage direct components error in the PI controller for phase synchronization [15]. The figure 5 shows the schematic diagram of the charge control system of the proposed charger. When both voltage magnitude and angle error signals are within the predefined bands, the asynchronous machine is synchronized with the grid and the system is ready for the charge operation [17].

The direct and quadrature current control and feed forward compensation are used for this decoupled control scheme. The controller output sets the reference value for the direct component of the current that controls the power [15]. Two independent PI controllers are used to generate reference values u_α and u_β for the converter. The feed forward terms are added to reference values of the decoupled system in direct and quadrature axis to improve the system performance [13]. In the control system of the proposed design, currents are replaced by the difference of the primary and secondary winding currents. The control scheme of figure 5 is an extension of the classical boost converter control with some modifications. Two sets of three-phase machine currents and rotor position are measured and used in the controller. The grid voltage is also measured and used in the controller for proper operation (feed-forward compensation) [18]. The rotor speed error (the difference between the reference speed and true speed) is added to the controller by the means of a proportional controller to reduce these oscillations [2], [18]. By changing the set point of the direct and quadrature component of the current, the bidirectional flow of real and reactive power within the system can be controlled [19].

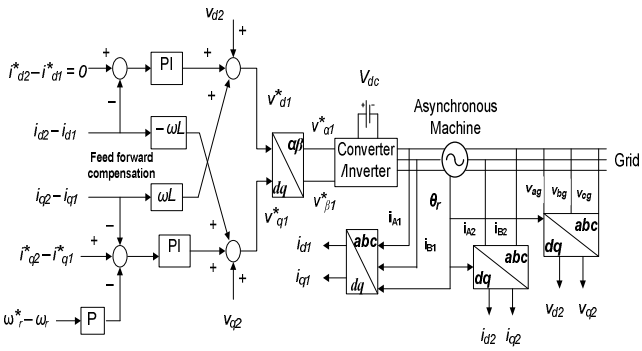

Fig. 5 Block diagram for charge control of proposed integrated charger

III. Simulated Model and Simulation Results

A 4 pole permanent magnet 3 phase asynchronous machine of 20 kW is considered for PEV vehicle. The base speed and maximum speed of the machine are 1500 and 6500 rpm respectively. During traction mode two set of stator windings are connected in delta whereas in charging mode the stator windings are disconnected from each other so that the machine can act as a transformer. The battery is considered of capacity of 200 Vdc. The charge power is limited to 12.5 kW due to the machine thermal limit. The bidirectional converter is synchronized to grid by using pulse width modulation technique. During charging, the voltage level of the grid side stator winding is adjusted by controlling the motor flux (the direct component of the current). The voltage angle is adjusted by speed control of the motor by means of the quadrature component of current [19]. The simulated model of the integrated charger for traction and charging mode is designed by using Matlab/Simulink.

A. Traction Mode

The figure 6 shows the simulated model of the proposed integrated charger during traction mode. A three-phase asynchronous machine of rated 2.24 kW, 220 V, 1725 rpm is fed by a sinusoidal PWM inverter. The base frequencies of the sinusoidal reference wave and triangular carrier wave are 60 Hz and 1980 Hz respectively for pulse width modulation. The inverter takes input from the battery and stator windings of the asynchronous machine are connected to the output side of the inverter. The load torque applied to the machine's shaft is constant which is set to its nominal value of 11.9 N.m. The machine attains its maximum speed which is considered 1 p.u. within 10 microseconds. Due to high switching frequency (1980 Hz) for PWM, the maximum time step has been limited to 10 microseconds and noise is introduced to rotor and stator currents which can be observed from the simulated results. The noise introduced by the PWM inverter is also observed in the torque waveform. However, the motor's inertia prevents this noise from appearing in the motor's speed waveform. The presence of ripple in torque waveform is about 1% of the rated torque. The figure 7 represents the waveforms for rotor speed and torque during traction mode.

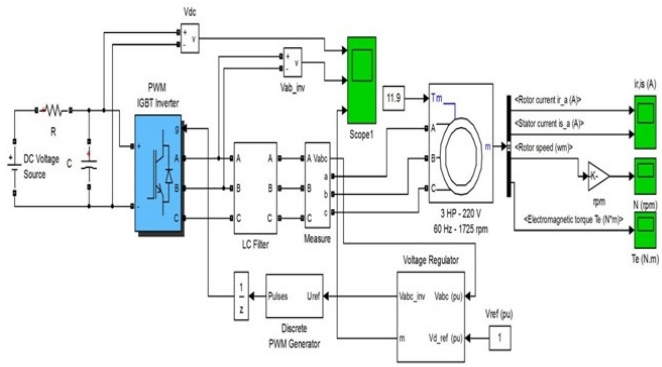

Fig. 6 Simulated model of the integrated charger during traction

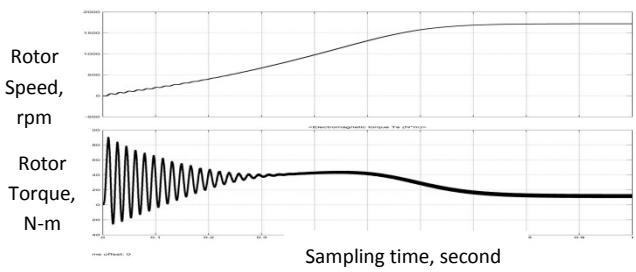

Fig. 7 Rotor speed and torque during traction

B. Charging Mode

The battery is discharged for rotation of asynchronous machine. When the SOC (state of charge) drops below 40%, the battery is charged by the bidirectional converter from the

grid when the asynchronous machine acts as a transformer. The SOC is calculated as,

$$SOC = 100(1 - \frac{1}{Q} \int_0^t i(t)dt\ ) \text{ ..... } (16)$$

The simulated model of the proposed charger during charging is shown in figure 8. The waveforms for charging voltage and SOC of battery are shown in the figure 9. It can be inferred from the waveforms of battery voltage and SOC that step charging occurs because of smooth synchronization of the charger with grid.

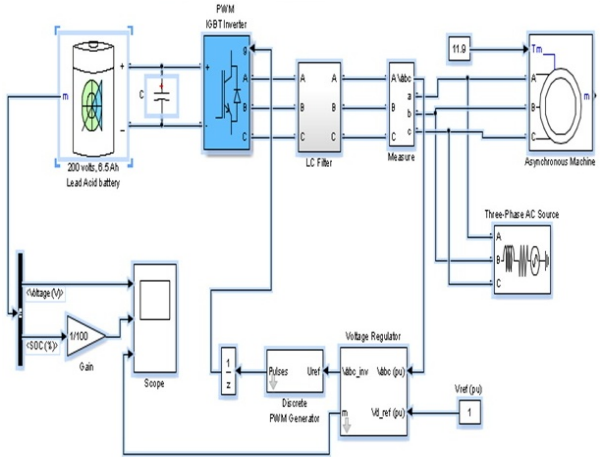

Fig. 8 Simulated model of the integrated charger during charging

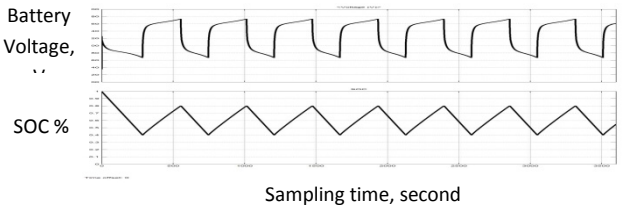

Fig. 9 Battery voltage and SOC during charging

IV. CONCLUSIONS

The proposed integrated battery charger for PHEV is cost effective and compact which has unit power factor capability. The controlling topology of the bi-directional converter is determined carefully so that it can act as converter during charging and inverter during traction. Though the use of high frequency carrier for PWM of bidirectional converter, the stator and rotor currents of the asynchronous machine become asymmetrical and distorted due to addition of noise signals from converter but the speed and torque wave shapes are less affected by noise signals due to proper synchronization of the machine with grid. The ripples in speed and torque wave shapes are less than 1% of rated speed and torque of the machine. The waveforms of battery voltage and SOC also represent smooth grid synchronization and better performance during charging. Further development in the proposed design is possible by using different winding configuration and other types of machine. The lower system efficiency during charging can be improved by using new techniques and control parameters in control scheme of the proposed design. Microcontroller based controlling of bidirectional converter can be used for better operation of the overall system. The losses and effects of magnetizing current for machine are not considered in this design. The controlling of the reactive power during the charging can affect the charging performance and therefore reactive power compensation needs to be considered in improved design of the integrated charger.

***Abstract*—Effective compensation of mechanical resonant modes is one of the design challenges in read/write head-positioning servomechanism of hard disk drive (HDD) servo. Resonant modes create oscillation in the system response and may lead to instability if not compensated properly. This paper presents a resonant controller designed in a simple and yet efficient way to suppress the effects of resonant modes of Voice Coil Motor (VCM) actuator used in HDD. The design is based on a mixed passivity and small gain approach to an unstable plant model. Since the original theorem is for stable systems, therefore a stabilizable controller is used for the design. Experimental results substantiate the effectiveness of the controller.**

***Keywords*—VCM, Lead-lag, Passivity, Small-gain**

I. Introduction

In hard disk drives (HDD), information bits are recorded in concentric data tracks on rotating disks. The write-head used for recording and the read-head for retrieving recorded bits are fabricated on a single piece of slider which is positioned on the tracks by a head-positioning servomechanism. In single-stage servo, a voice-coil-motor (VCM) actuator is used to move several sliders over several magnetic media coated disks spun by a spindle motor. Nowadays, HDD servomechanism uses dual-stage actuation with VCM providing coarse motion and piezoelectric secondary actuator for fine positioning. But the work presented here addresses the resonance issues in a single-stage actuator. The HDD servo-system has two modes of operation - track seeking and track following. In seeking mode, the head is moved from one track to another in minimum possible of time. In track-following mode, the head is maintained as close as possible to the center of the track.

The HDD industry has experienced tremendous growth in recording density over the years and presently the density is around 1 Tbits/in^2. It is projected to exceed the 10 Tbits/in^2 barrier in the near future. This will require increase in both density of tracks (*track density*) and density of bits on a track (*bit density*). Increased track density means smaller track width and thus, improved accuracy in positioning the read/write head in spite of various disturbances. The high track density needs a servo controller with high bandwidth for eliminating the effects external disturbances. But resonant modes of the actuator prohibit bandwidth to be pushed to higher frequencies and may even lead to closed loop instability.

A popular method of suppressing the mechanical resonances in high precision micro and nano positioning systems follows the open loop design approach by cascading notch filters with the plant [1]-[4]. These modes, however, have a wide range of perturbation in their characteristic parameters, e.g., resonant frequency and damping coefficient, especially in mass produced systems like HDD, which are mainly caused by batch-to-batch variation. Even in the same batch, resonant modes may vary due to ambient temperature changes, mechanical wear, excessive shock and disk rotation. This requires the magnitude plot of the notch filters to be wide and deep enough to accommodate all possible variations. Moreover, in a system with constrained sampling frequency, if a resonant mode exits near the Nyquist frequency, the digital realization of the notch filter fails to effectively suppress that mode. Multi-rate realization of the notch filter offers a possible solution [5], but it requires an accurate model of the plant and again robustness is compromised. Many feedback controllers have been proposed to damp the resonant mode of the actuator. Positive position feedback (PPF) control is a popular method which is designed using root locus technique where unknown parameters have to be determined for a second order controller and PPF suffers from the problem of low gain and phase margins [6]. An adaptive notch filter is proposed in [7], comprising of a tunable finite-duration impulse response (FIR) filter. The tuner is designed to identify the resonance frequency of the actuator rapidly and automatically adjust the center frequency. A similar method is used in [8], in which the center frequency follows the change in resonant frequency based on the balance of two types of frequency weighted variances of the control input signal. But adaptive methods are often complex and computationally expensive.

A resonant controller to damp the first resonant mode of the VCM actuator is proposed in this paper. The method is simple and easy to implement. A mixed passivity and small gain approach is followed to achieve large damping of the resonant mode with robust finite gain stability. Since the theorem is applicable for interconnection of two stable systems and VCM actuator is essentially a double-integrator, the plant is first stabilized by a stabilizing controller.

Small-gain approach is a possible solution to guarantee finite gain (FG) stability of the interconnection between the stabilized VCM and resonant controller. The small-gain theorem states that the feedback interconnection between two stable linear systems is stable if the loop-gain of the two systems is strictly less than one [9]-[10]. As the gain of the VCM actuator is large near resonance frequency, the small-gain approach requires that the gain of controller be low to make the loop-gain less than one.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

The rest of the paper is organized as follows. Mixed passivity and small gain theorem is discussed in section 2. Experimental setup used for this work is described in Section 3. The frequency response of the VCM actuator and response of the identified model are also given in the same section. Design of the controller is explained in Section 4 and experimental results are shown in Section 5. Conclusion of our findings and scope of future works are given in Section 7.

II. Mixed Passivity and Small Gain

Let $\mathcal{R}$ be the set of all real rational transfer function matrices and $\mathcal{RH}_\infty$ be the set of all real rational stable transfer functions. The largest and smallest singular values of a matrix A will be denoted by $\overline{\sigma}(A)$ and $\underline{\sigma}(A)$.

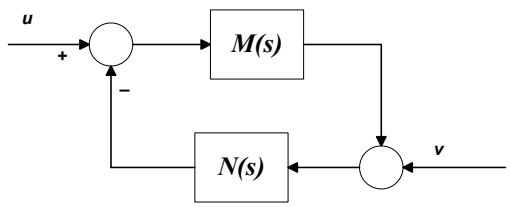

Fig. 1: Interconnection of systems with negative feedback

Consider the negative feedback interconnection between $M(s)$and $N(s)$ as shown in Fig. 1, where $M(s)$ and $N(s)$ are systems with "mixed" passivity and finite-gain properties. $M(s)$ and $N(s)$ are respectively bounded by gain k_1 and k_2 on different frequency intervals. According to [11] and [12], the theorem for mixed passivity and small gain properties of two interconnected system is as follows:

Theorem 1: Let $M(s) \in \mathcal{RH}_\infty$ and $N(s) \in \mathcal{RH}_\infty$ be two strictly proper, causal and linear time invariant systems which are connected as shown in Figure 1 where $M(s)$ is mixed passive and finite-gain system bounded by a gain $k_1 > \overline{\sigma}(M(0))$ and $N(s)$ is mixed passive and finite gain system bounded by a gain $k_2 > \overline{\sigma}(N(0))$. The interconnection of Figure 1 is finite-gain stable if (i) $k_1 k_2 < 1$, (ii) there exists two sets frequency bands: (a) a set of frequency intervals over which $M(s)$ and $N(s)$ both are passive or negative passive (b) a set of frequency intervals over which both $M(s)$ and $N(s)$ are respectively bounded by gain k_1 and k_2.

III. Experimental Setup

The setup for identification experiment (Fig. 2(b)) consists of a dynamic signal analyzer (DSA), a driver for the VCM actuator and the Laser Doppler Vibrometer (LDV) OFV 5001. The sweep sine excitation signal generated by the DSA is applied to the driver which provides required voltage-to-current conversion to drive the VCM actuator. The displacement of the actuator tip is measured using the LDV. The resolution of the LDV is set to 50 nm/V. The VCM actuator used for this work is obtained from a commercially available HDD (Western Digital's Caviar Black). With the help of the setup described above, the frequency response of the actuator is measured using sweep sine excitation signal generated by frequency response analyzer coded in LabVIEW. The analyzer produces the frequency response data and the result is saved for further processing. A linear model of the VCM actuator is identified from the frequency response. Experimental frequency response and the Bode plot of the identified model are shown in Fig. 3. Only the two most prominent resonances are considered in the identification.

For real-time implementation of controller, the setup is modified by replacing the DSA with a real-time controller card (dSPACE SD1104) (Fig. 2(c)). The sampling interval is set to 25 μs.

Remark: The two signals used in frequency response measurement are in volts. So the identified transfer function is unit-free. The output signal can be converted into displacement simply by multiplying by the scaling factor of 50 nm/V.

IV. Controller Design

A. Stabilizing Controller

Since the rigid body dynamics of the actuator is a double integrator, a lead compensator is used to stabilize it. We also design a lag compensator to increase the low-frequency slope of the Bode (magnitude) plot which is required for better tracking in low frequency range. The compensator is designed according to the bode-stability criteria [1] and is expressed by,

$$C(s) = K_d \frac{\left(\frac{s}{\omega_2}+1\right)\left(\frac{s}{\omega_3}+1\right)}{\left(\frac{s}{\omega_1}+1\right)\left(\frac{s}{\omega_4}+1\right)}, \qquad (1)$$

where $\omega_1, \omega_2, \omega_3, \omega_4$ are the corner frequencies of the lag and lead sections. The gain K_d is chosen to satisfy the condition

$$\left|\frac{1}{C(j\omega)P(j\omega)}\right|_{\omega=j2\pi f_v} = 1 .$$

f_v is the gain crossover frequency.

B. Resonant Controller

Now, the transfer function $M(s)$ in Figure 1 is the closed loop transfer function of VCM with lag-lead controller. Next we design a resonant controller $N(s)$ and the general transfer function for the resonant controller is as follows:

$$N(s) = -K_r \frac{s^2 + 2\xi_r \omega_r s}{s^2 + 2\xi_r \omega_r s + {\omega_r}^2}, \qquad (2)$$

where $K_r > 0$ is the gain of the controller, $\xi_r > 0$ and $\omega_r > 0$ are the damping constant and the frequency at which resonant mode needs to be damped. In our design we choose ω_r= frequency of the first resonant mode, desired damping ratio ξ_r=0.6 and then choose $K_r > 0$ in such a way that theorem 1 is satisfied.

V. Simulation Results

With the identified plant model and designed controller, some simulation analysis is done. Fig. 4(a) shows the frequency responses of the stabilized VCM model and frequency response of the interconnected system with resonant controller where sufficient damping can be observed for the first major resonant

mode. Simulated step responses (Fig. 4(b)) also proves the effectiveness of the proposed controller where less oscillation is observed for designed interconnected system with resonant controller.

V. Experimental Results

The performance of the proposed controller is evaluated experimentally using three types of reference signals. Firstly, a step input of 2 Volt is applied. The displacements measured with and without resonant controller are shown in Fig. 5(a) and Fig. 5(b), respectively. Secondly, triangular waveform of 50 Hz is used as reference input and corresponding outputs is shown in Fig. 5(c), Fig. 5(d). Finally, a sum of sinusoids $r(t) = \sin(2\pi \times 100t) + 0.8\sin(2\pi \times 200t) + 0.5\sin(2\pi \times 300t)$ is used as the reference input. Fig. 5(e) and Fig. 5(f) show the corresponding output with and without resonant controller, respectively. It is clearly evident from the results that oscillation in output becomes smaller for all cases when the resonant controller is used. Although the controller is designed to increase the damping of the first resonant mode, it is found that damping is increased for other higher frequency modes as well. Therefore it can be concluded that the proposed controller is able to suppress the effects of resonant modes.

VI. Conclusion

A simple and yet effective method of designing resonant controller is presented. The unstable plant is first stabilized and then a resonant controller is designed using a mixed passivity and small gain approach. Experimental results prove that the proposed method is effective. Although a VCM actuator of HDD is used as the experimental platform, this method can be useful in a wide range of applications. We are further investigating the applicability of this approach for designing a multi-mode resonant controller and also apply it in a dual-stage HDD servo system.

Abstract—**This paper presents photonic crystal fibers (PCF)based on hexagonal and rectangular structures designed to be operated in a range of wavelength 1.3 to 1.7μm and effects of various parameters on bending loss of the different structured index guiding PCFs have been investigated. According to simulation, bending loss is reduced down to 10^{-12}dB/km from 10^{-5}dB/km by changing bending radius and core diameters.Due to having low bending loss, these PCF structures can be used in applicationsof optical technologies including telecommunication and sensing applications.**

Index Terms—**Photonic crystal fiber (PCF), Bending loss, Bending radius, Core diameter, Wavelength.**

I. Introduction

Photonic crystal fiber has drawn emerging attention due to its attractive features such as wideband dispersion flattened characteristics, high birefringence, and low confinement loss and bending loss in transmission. Bend losses are a frequently encountered problem in fiber optics: optical fibers exhibit additional propagation losses when they are bent. Typically, these losses rise very quickly once a certain critical bend radius is reached. This critical radius can be very small (a few millimeters) for fibers with robust guiding characteristics (high numerical aperture), whereas it is much larger (often tens of centimeters) for single-mode fibers with large mode areas.Generally, bend losses increase strongly for longer wavelengths, although the wavelength dependence is often strongly oscillatory due tointerference with light reflected at the cladding/coating boundary, and/or at the outer coating surface. The increasing bend losses at longer wavelengths often limit the usable wavelength range of a single-mode fiber.Photonic crystal fibers can have very low bend losses even far beyond the single-mode cut-off wavelength. For estimating the magnitude of bend loss, the equivalent index method [1] can be used. The basic idea behind this technique is to calculate the mode distributions for an effective index which contains a term accounting the modified path lengths at different transverse positions. This is convenient and usually a good approximation, provided that there is no light reflected e.g. from the outer cladding surface back to the fiber core.The magnitude of bend losses has some dependence on the polarization[2-3].Bending not only introduces losses, but can also reduce the effective mode area. This is particularly true for large mode area step-index fibers. Also bending induces birefringence [4-5].

We, in this paper, propose two PCF structures with low bend loss ranges between in the order of 10^{-12} dB/km to the order of 10^{-5} dB/km. A simple five-ring Hexagonal PCF (H-PCF) is investigated and found to have comparatively higher bend-sensitivity in terms of bend loss dependent on wavelength(1.3-1.7μm), bend radius(1-7mm) and core diameter(1-8μm) firstly. Moreover, The Rectangular PCF (R-PCF) with five rings are developed and its propagation loss properties due to curvature are assessed using Finite Element Method (FEM) and a less sensitive structure is found in terms of bending effects on different guiding properties.The comparison job among the proposed structures was carried out in terms of bend loss and the effects on different parameters on it to find a bend-insensitive, low loss photonic crystal fiber.

II. Design Methodology

A. Hexagonal Structure

Fig.1 shows the simple geometry of the H-PCF with air-hole diameter, *d* and pitch, Λ between the adjacent air-hole rings. Pitch, Λ is the spacing between air hole centers on the adjacent rings and the spacing between air holes centers on the same ring is Λ_1. Pitch Λ_1 is related to Λ by the relation $\Lambda_1 \approx 0.866\Lambda$. Hexagonal PCF structure has isosceles triangular unit lattices [1] with vertex angle of 60^0. Owing to isosceles triangular unit lattices, it contains more air-holes in the cladding region for the same number of rings compared to conventional PCFs. The number of air-holes of an octagonal structure for rings 1, 2, 3, 4, 5 is, respectively, 6, 12, 18, 24, and 30. This results in a higher air-filling ratio and a lower refractive index around the core, thereby providing strong light confinement ability.

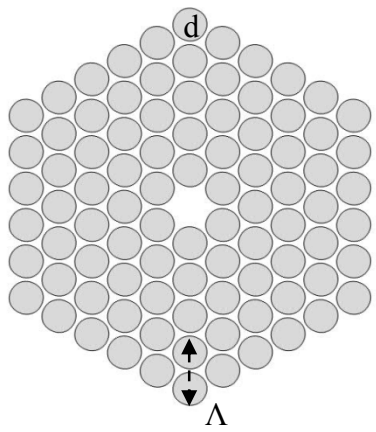

Fig. 1. Geometry of the proposed five-ring H-PCF with air-hole diameter *d*,, air-hole pitch Λ and number of ring, $N_r = 5$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

The core diameter is A, where 'A' equals 2(Λ-*d*/2). The air-holes of diameter d are located at each corner of the isosceles triangle resulting lower refractive index due to higher air-filling fractions (AFFs) around the core.

B. *Rectangular Structure*

Fig. 2 shows the simple geometry of the Rectangular-PCF with air-hole diameter, *d* and pitch, Λ between the adjacent air-hole rings. Pitch, Λ is the spacing between air hole centers on the adjacent rings and the spacing between air holes centers on the same ring is Λ_1. Pitch Λ_1 is related to Λ by the relation $\Lambda_1 \approx 0.866\Lambda$.The number of air-holes of an rectangular structure for rings 1, 2, 3, 4, 5 is, respectively, 12, 20, 28,36 and 44. This results in a higher air-filling ratio and a lower refractive index around the core, thereby providing strong light confinement ability. The core diameter is 2*a*, where '*a*' equals Λ-*d*/2. The air-holes of diameter d are located at each corner of the isosceles triangle resulting lower refractive index due to higher air-filling fractions (AFFs) around the core.

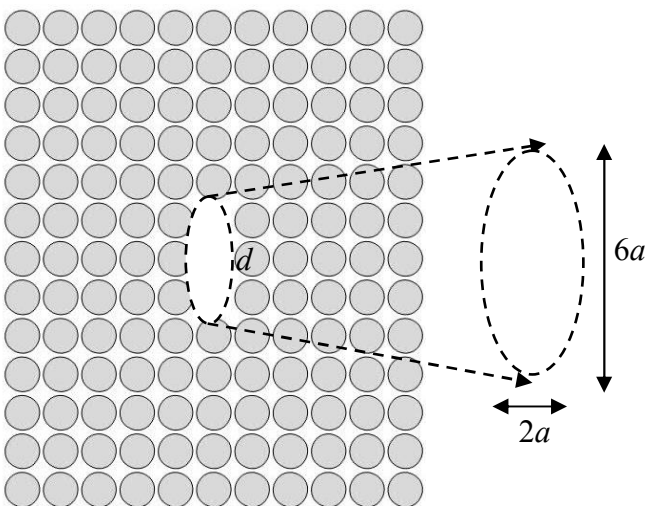

Fig. 2. Geometry of the proposed five-ring Rectangular-PCF with air-hole diameter *d*, air-hole pitch Λ .

III. Numerical Methodology

The COMSOL software 4.2 version is used as a simulationtool.Finite element method (FEM) with perfectly matched layers (PML) boundary condition is used to calculate the chromatic dispersion, effective area and confinement loss of the proposed PCFs.The FEM directly solves the Maxwell equations to best approximate the value of the effective refractive index. Various theoretical methods exist to predict curvature (bending) loss in optical fibers.The usual approach is to use a simplified formula introduced by Marcuse [1], applicable to weakly guided fibers,for sufficiently large radii of curvature. This formula agrees well with experiment of single mode fiber, after adjustments are made for bend-induced stress. Bent fiber simulations were performed using a finite difference approach, the beam propagtion method (BPM) , in conjuction with conformal mapping technique. The first step in the process was to transform the circularly curved fiber to an equivalent, straight fiber by the process of conformal mapping [6]. This process is schematically in Fig. 3. Co-ordinate transformation allowed the bent fiber to be represented by an equivalent, straight fiber, with modified refractive index disribution, $n'(x, y)$

$$n'(x, y) = n(x, y) \exp\left(\frac{x}{R}\right) \quad (1)$$

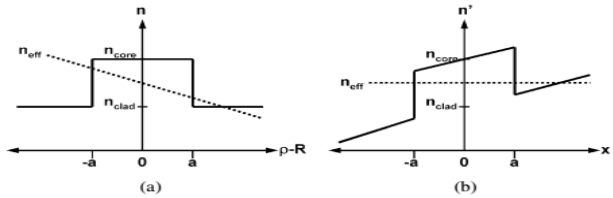

Fig. 3. Refractive index distribution of an unstressed,bent fiber and (b)that of its equivalent, straight fiber after conformal mapping.

Once the modal effective refractive index, n_{eff} is obtained by solving an eigen value problem drawn from Maxwell equations using the COMSOL software 4.2,The bend loss L_c is obtained from the imaginary part ofn_{eff} as follows [7]

$$Lc = 8.686 \times k_0 \mathrm{Im}[n'(x, y)] \quad (2)$$

Where, $\mathrm{Im}[n_{eff}]$ is the imaginary part of the refractive index, $k_0 = 2\pi/\lambda$is the wave number in the free space.

IV. Simulation Results and Discussion

A. Bending Radius Effects on Bend Loss

When fiber is bent, a propagation loss takes place due to the bend in optical fiber. The smaller the bending radius, the greater is the bending loss [8]. Fig. 4 shows the bending loss characteristics of x polarization for optimum design parameters with d/Λ=0.86 and pitch Λ=1μm. In the figure ,the bending loss is calculated by varying the bending radius from 1mm to 7mm.The amount of loss significantly decreases for the radius change from 1mm to 2mm and then the rate of fall slows down for further increase in bending radius [9].

B. Core Diameter Influence on Bending Loss

The bending loss is seen to stabilize with the increasing core diameter. As the core diameter hence Mode Field Diameter (MFD) increases, the loss due to bending seems to be decreased to a lower value and gets a stable value onwards. Fig. 5 illustrates the bending loss characteristics of x polarization for optimum design parameters with d/Λ=0.86 and bending radius 2mm and wavelength 1.55 μm. The above figure describes the bend induced loss change with the change in pitch Λ from 1μm to 4 μm.

C. Wavelength Dependence of Bending Loss

The bending loss increases considerably with the increase in wavelength of the propagating light through the fiber. In the telecom window, the losses are small, but increasing wavelength causes greater losses in H-PCF. The above figure depicts the bending loss characteristics of x polarization for optimum design parameters with d/Λ=0.86 and bending radius 2mm and pitch Λ=1μm. The bending loss or curvature loss rises with the rise in wavelength from 1.3μm to 1.7μm.

D.The Effects of Various Parameters on Bend Lossin H-PCF:

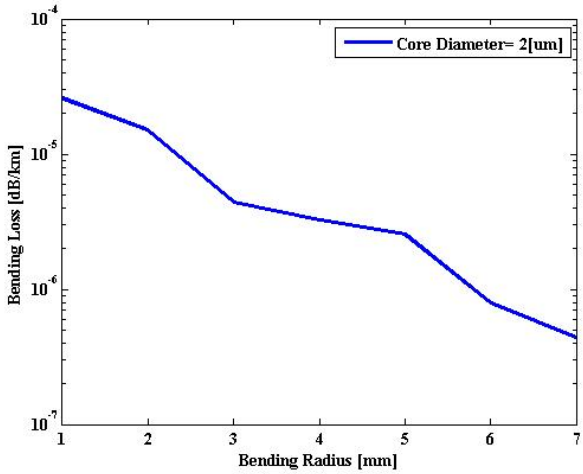

Fig. 4. Bending radius dependent bending loss curve in H-PCF.

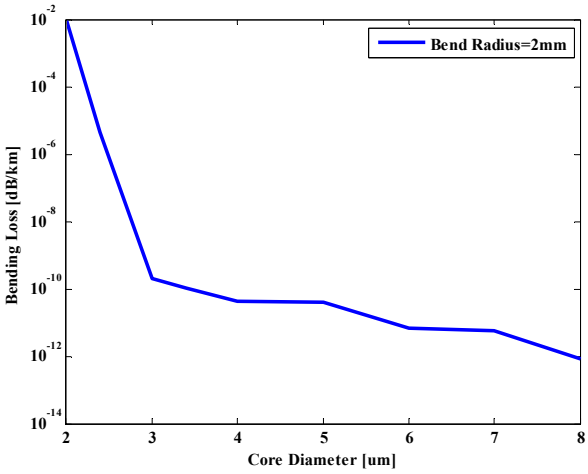

Fig. 5. Effect of Core diameter extension on Bending Loss in H-PCF.

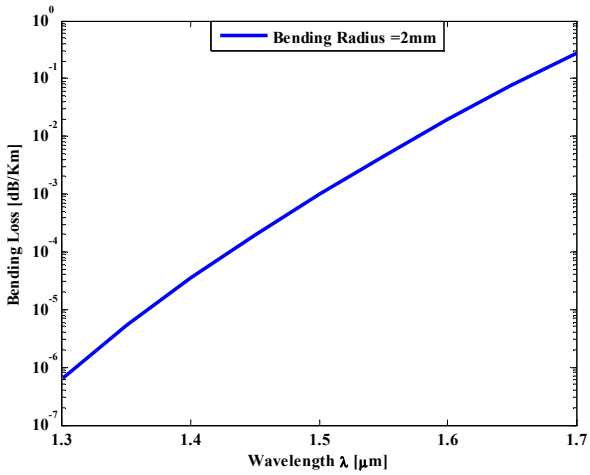

Fig. 6. Wavelength dependence of Bending loss in H-PCF.

E. The Effects of Various Parameters on Bend Loss in R-PCF:

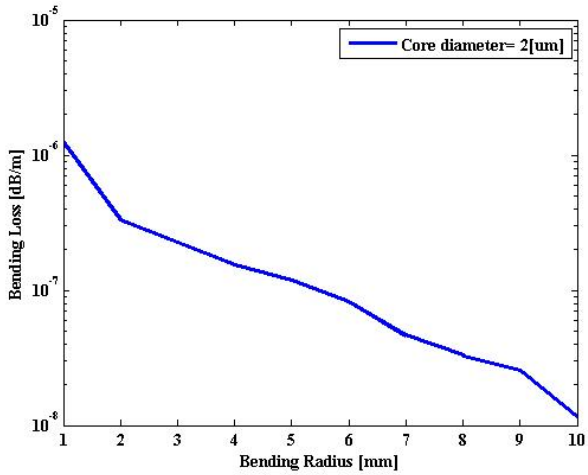

Fig. 7. Bending radius dependent bending loss curve in R-PCF.

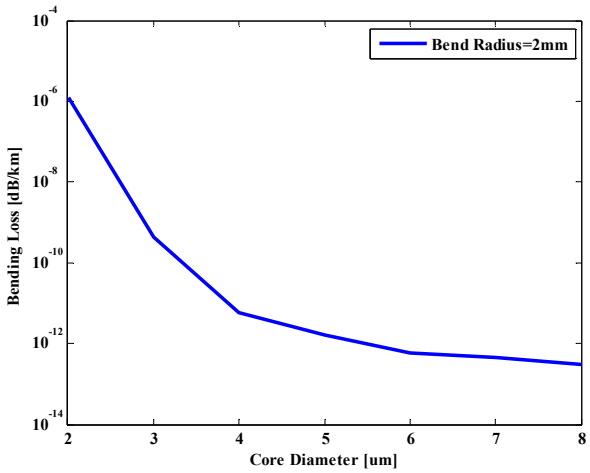

Fig. 8. Effect of Core diameter extension on Bending Loss in H-PCF.

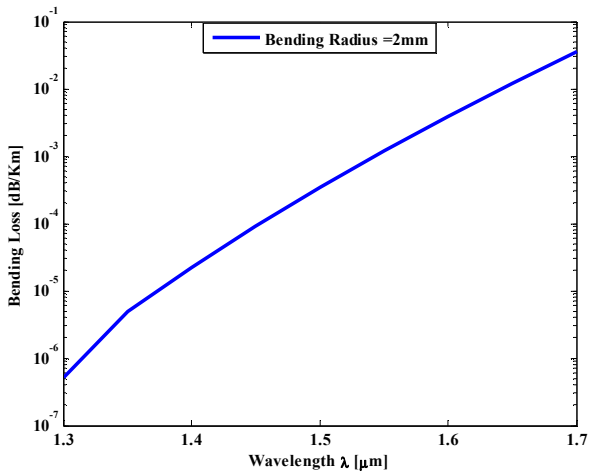

Fig. 9. Wavelength dependence of Bending loss in R-PCF.

Fig. 10 illustrates the curvatureloss characteristics of proposed photonic crystal fibers with design parameters as d/Λ=0.86 and pitch Λ=1μm and wavelength 1.55 μm. The bending radius is varied from 1mm to 7mm and corresponding responses of different proposed PCF structures were plotted on the curve.The H-PCF and the Rectangular PCF shows almost a flat loss response through the entire range of bending radius under consideration. The bend loss in H-PCF is higher than that of the Rectangular PCF all through.Fig. 11 presents the core diameter effects on bending loss of various photonic crystal fibers having design parameters d/Λ=0.86 and bending radius R=2mm.The bend loss in H-PCF is the largest and the lowest loss is obtained from the Rectangular structure shows a consistent inverse exponential loss curve with the increase in core diameter. It is observed that bend loss associated with the lowest core diameter is the highest and more than 1dB/km for H-PCF and it decreases to the order of 10^{-6} in H-PCF. Fig. 12 depicts the bending loss behaviour of different photonic crystal fibers with optimum design parameters with d/Λ=0.86 and pitch Λ=1μm and bending radius R=2mm.The bend loss in H-PCF is the largest among the proposed structures and the lowest loss is obtained from the Rectangular structure.. It is observed that bend loss associated with the lowest wavelength is the lowest and of 10^{-6} order and it increases up to 0.1dB/km for H-PCF which is the highest at wavelength 1.7 μm while lowest loss at this point is associated with Rectangular PCF and is of 10^{-2} order.

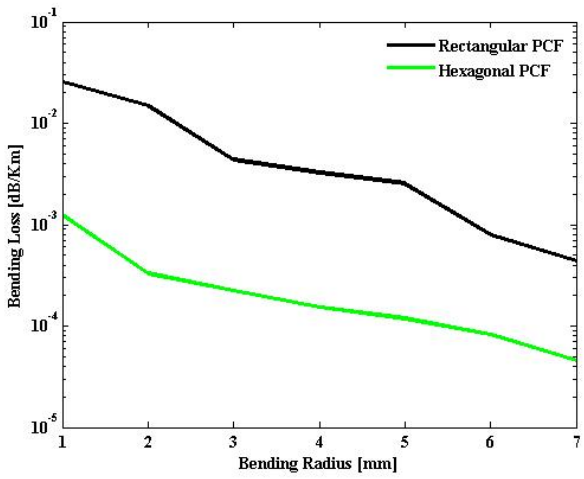

Fig. 10. Comparison of different PCF structures in terms of bending loss induced by a certain range of bend radius of the fibers.

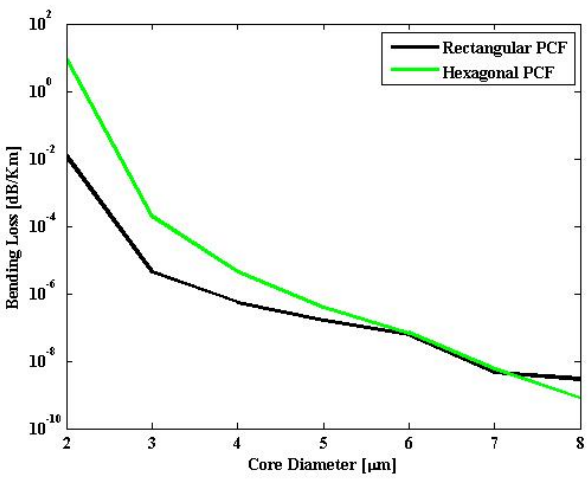

Fig. 11. Comparison of bending loss of proposed PCF structures influenced by core diameter effects on fibers.

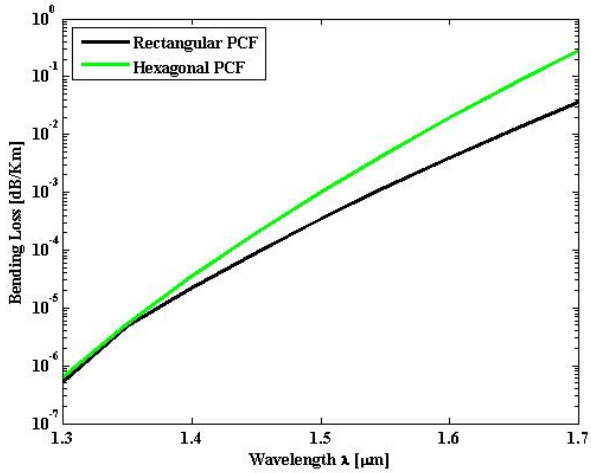

Fig. 12. Comparison of various PCF structures considering the effects of wavelength on bend loss .

V. Conclusion

In summary, we have proposed that afivering Hexagonal PCF (H-PCF) is found to have comparatively higher bend-sensitivity in terms of bend loss of the order 10^{-5} dB/km which is dependent on wavelength, bend radius and core diameter. The Rectangular PCF (R-PCF) with five rings are developed and its propagation loss properties due to curvature are assessed and observed to be a less sensitive structure in terms of bending effects on different guiding features with bend losses of the order 10^{-12} dB/km.

Abstract— **In this paper, we propose a highly birefringent modified circular photonic crystal fiber (M-CPCF). The proposed structure is found extremely suitable for chromatic dispersion compensation of standard single mode fiber (SMF) over E+S+C+L wavelength bands. Finite element method (FEM) with perfectly matched layer boundary condition has been applied to explore its guiding properties. Simulation results confirm the possibility of large negative dispersion coefficient and relative dispersion slope (RDS) of -650 ps/(nm.km) and 0.0036 nm^{-1} respectively at 1550 nm wavelength and effective dispersion coefficient of about ± 0.5 ps/(nm.km) from 1360 to 1640 nm wavelength. The proposed fiber also demonstrates a high birefringence of order 2.1×10-2 that allows the fiber to maintain a single polarization. The proposed fiber can be a promising candidate in high speed transmission system for broadband dispersion compensation and sensing applications as well.**

Index Terms—**Chromatic dispersion, Birefringence, Effective dispersion, Dispersion compensation, Photonic crystal fiber, Finite element method.**

I. INTRODUCTION

Photonic crystal fiber (PCF) consists of microscopic array of air channels running down their length that make a low index cladding around the undoped silica core [1]. It is possible to control the optical properties of PCF with this type of structure which is not achievable with conventional fiber structure [2]. Thus, PCF offers great flexibility in tuning dispersion [3]-[4] which is significant in designing dispersion compensating fiber. Recently wavelength division multiplexing (WDM) technique is being adopted to handle higher bit rate transmission system of more than 40 Gbps. However, the performance of optical WDM system is affected by the transmission impairment caused by dispersion in standard transmission fiber. This necessitates dispersion compensation to improve the quality of WDM system. Presently, dispersion compensating fibers (DCFs) is widely used and commercially available for dispersion compensation [5]-[7]. DCFs should have large negative dispersion to compensate the accumulated dispersion encountered into the single mode fiber (SMF) used for WDM transmission systems. At the same time, the RDS of DCF must be equal to SMF which is 0.0036 nm^{-1} at the operating frequency of 1550 nm. Hence, compensation of accumulated dispersion and dispersion slope of conventional fibers are simultaneously required for broadband applications. To reduce the cost and minimize the confinement loss, the DCF should be as short as possible. However, it is quite difficult to obtain high negative dispersion over a wide band of wavelength using conventional DCFs. In addition, conventional DCFs have some limitations related to their structure, for instance, materials of different thermal expansion coefficients (i.e., germanium-doped core and silica cladding regions) [8]. So, the key issue is to design a DCF which simultaneously ensures large negative dispersion over a wide band. Therefore, in designing DCFs, it is also important to consider other properties like dispersion slope, RDS, confinement loss, and birefringence [8]. On the other hand, high negative dispersion and high birefringence is very essential for a PCF to be applicable in broadband dispersion compensation and sensing application as well. PCF is first proposed in [9] for broadband dispersion compensation. However, the design experiences a small effective area and raises complexity in coupling light into the fiber. A dual core PCF with highly doped internal core is proposed in [10] for dispersion compensation which achieves a large dispersion peak of about □59,000 ps/(nm.km) and hence the available bandwidth for dispersion compensation becomes narrow. In addition, doping the internal core increases confinement loss and makes the fabrication process more difficult. M-OPCF designed with six air hole rings is proposed in [11] which obtains a negative dispersion of −239.5 ps/(nm.km) at 1550 nm but the RDS does not match accurately with the RDS of single mode fiber. In recent times, several PCF designs are proposed for addressing the issue of broadband dispersion compensation and sensing simultaneously. For example, square lattice photonic crystal fiber is proposed in [12] which provides unmatched RDS of 0.0034 nm^{-1} and insufficient negative dispersion of only −204.4 ps/(nm.km) requiring longer fiber to compensate the accumulated dispersion. A highly birefringent broadband dispersion compensating octagonal PCF is proposed in [8] shows a better negative dispersion coefficient of −400 to −725 ps/(nm km) over S to L-bands with perfect slope matching and a birefringence of 1.8×10^{-2}. Furthermore, a spiral microstructure optical fiber is proposed in [13] which successfully achieves negative dispersion coefficient of about −327 ps/(nm.km) at 1550 nm wavelength with high birefringence of about 1.79×10^{-2}.

In this work, we propose highly birefringent M-CPCF for dispersion management over E+S+C+L wavelength bands. The proposed M-CPCF structure shows a high negative

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

dispersion over the wavelength ranging from 1360 to 1640 nm and particularly −650 ps/(nm.km) with RDS of 0.0036 nm^{-1} at 1550 nm wavelength. The effective dispersion is obtained within ± 0.5 ps/(nm.km) over E+S+C+L wavelength bands. Moreover, the proposed M-CPCF shows a high birefringence of about 2.1×10^{-2} which is also suitable for sensing applications. Confinement loss is also found 0.012315 dB/m at 1550 nm wavelength. It is highly expected that the proposed M-CPCF should be greatly applicable in WDM communication system and polarization maintaining application like sensing applications.

II. Design Guidelines of the Proposed M-CPCF

Fig. 1 depicts the transverse cross section of the proposed HyC-CPCF that has five air-hole rings. The cladding is formed in combination with the circular and elliptical air holes. The symmetry of the core is intentionally broken by removing two circular air-holes while replacing those with elliptical air-holes. However, some extra elliptical air-holes are added into the cladding region to have better dispersion properties and fiber nonlinearity. This design is said to be modified circular in the sense that it consists of air-holes those comes from different shape i.e. circular and elliptical in this design. The material of the proposed structure is pure silica. The total number of air-holes for 1st, 2nd, 3rd, 4th, and 5th rings are respectively 6, 8, 12, 24 and 48. To achieve this number of air-holes, the air-holes on the first ring are rotated at an angle 60^0 while air-holes on the 2nd to 5th rings are rotated at an angle 45^0, 30^0, 15^0, and 7.5^0 respectively. The air-hole diameter of 1st, 3rd and 4th ring is d_1 while air-hole diameter of the 2nd and 5th ring is selected as d_2 and d_3 respectively. d_s and d_f are the minor axis and major axis lengths of the elliptical air-holes respectively. The proposed M-CPCF structure produces a higher degree of freedom regarding the total number of geometrical design parameters namely, pitch, □, air-hole diameters ($d_1$to d_3) and ellipticity, η. With the precise control of these design parameters, optimal fiber transmission properties such as high negative dispersion coefficient, low confinement loss, and high birefringence is possible to achieve simultaneously in particular frequency regimes.

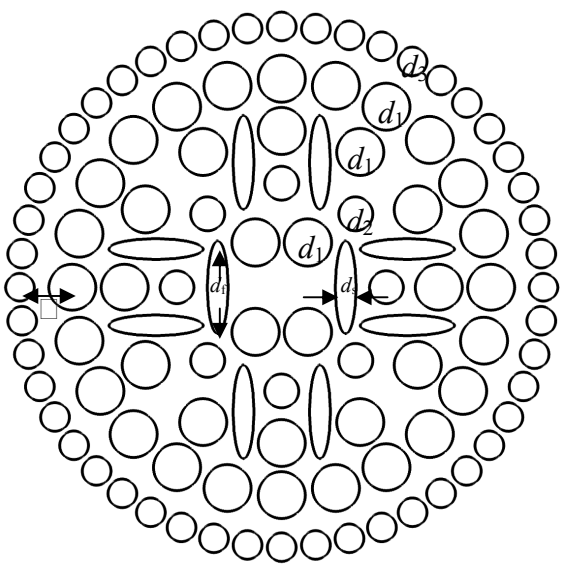

Fig. 1 Transverse cross section of the proposed HyC-CFCF structure showing pitch, □, air-hole channel with diameters, d_1, d_2 and d_3 and ellipse with dimension d_s and d_f.

III. Numerical Method

The finite element method (FEM) perfectly matched layer boundary condition is applied for numerical simulation to explore the guiding properties of proposed HyC-CPCF structure. Commercial full vector finite element software (COMSOL) with first order triangular vector edge elements is used to evaluate the value of modal effective refractive index n_{eff} . The wavelength dependent refractive index of optical material (silica) is calculated using three-term Sellmeier equation and directly included in the simulation. Once the modal effective index n_{eff} is obtained, dispersion $D(\lambda)$, effective dispersion D_e , confinement losses L_c , birefringence B and effective area, A_{eff} can be determined by the using the following equations (1) − (4) [13]-[15].

$$D(\lambda) = -\frac{\lambda}{c}\frac{d^2\,\mathrm{Re}[n_{eff}]}{d\lambda^2} \quad \text{ps/(nm.km)} \tag{1}$$

$$L_c = 8.686\times\frac{2\pi}{\lambda}\times\mathrm{Im}[n_{eff}] \quad \text{dB/m} \tag{2}$$

$$B = \left|n_x - n_y\right| \tag{3}$$

$$A_{eff} = \frac{\left(\iint |E|^2 dxdy\right)^2}{\iint |E|^4 dxdy} \quad \mu\text{m}^2 \tag{4}$$

Eq. (1) represents the total chromatic dispersion since material dispersion is directly included in the FEM calculation process with the help of Sellmeier equation.

IV. Numerical Results and Discussion

The designed M-CPCF offers design flexibility in tailoring the chromatic dispersion, birefringence, nonlinearity and confinement loss which is required to achieve application specific properties from the fiber. At first, the wavelength dependence nature of chromatic dispersion for optimized parameters □=1.0 µm, d_1=0.95 µm, d_2=70 µm, d_3=60 µm, η=0.22 µm is investigated and shown for both x and y polarized optical fields in Fig. 2. A negative dispersion coefficient of -224 and -650 ps/(nm.km) at operating wavelength of 1550 nm are observed for x and y polarization mode respectively. The y-polarized mode is about three times higher in magnitude than x polarized mode which represents fast axis mode.

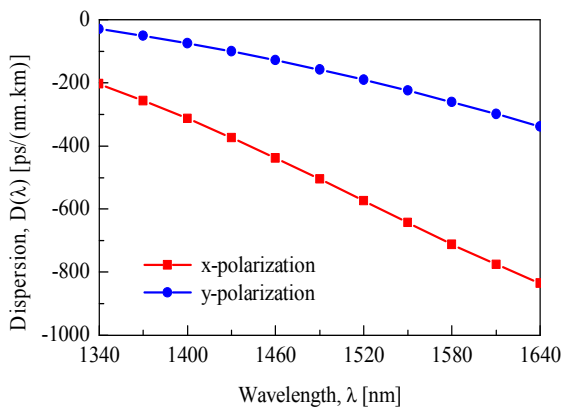

Fig. 2 Chromatic dispersion of the proposed HyC-CPCF as a function of wavelength, λ for x- and y-polarization.

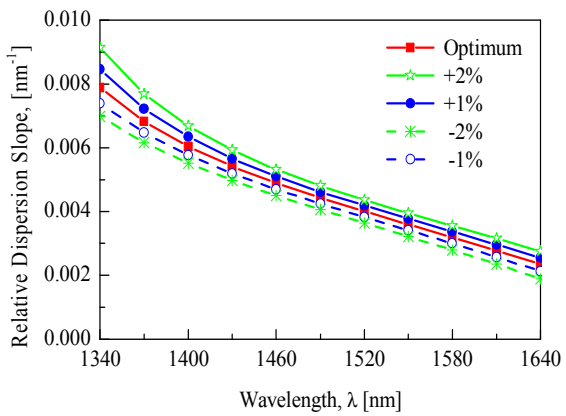

Fig. 3 RDS of the proposed HyC-CPCF for optimum design parameters and variation of pitch, □.

Hence y-polarized mode is considered to calculate other wavelength dependent parameters that include residual dispersion, residual dispersion slope (RDS), and confinement loss. However, the designed fiber shows a very high negative dispersion coefficient of about -204 to -836 ps/(nm.km) over 1340 to 1640 nm wavelength band for optimal design parameters. The high negative dispersion coefficient for the proposed M-CPCF particularly at 1550 nm wavelength is about -650 ps/(nm.km) which is higher than [8]. High negative dispersion is a key parameter in designing the fiber that should be as large as possible especially to reduce the length of dispersion compensation fiber. At the same time, the RDS profile of the designed fiber should be properly matched with the SMF for dispersion compensation application that requires a RDS of 0.0036 nm^{-1} at 1550 nm wavelength. Therefore, it is important to take into consideration the dispersion and dispersion slope simultaneously in designing PCF for dispersion compensation and also for parameter optimization [16].

RDS is shown in Fig. 3 for optimum design parameters as a function of wavelength and also by tuning the pitch, □. The RDS is exactly found 0.0036 nm-1 at 1550 nm for optimum design parameters. However, no sudden change in RDS profile is noticed over the entire band of interest.

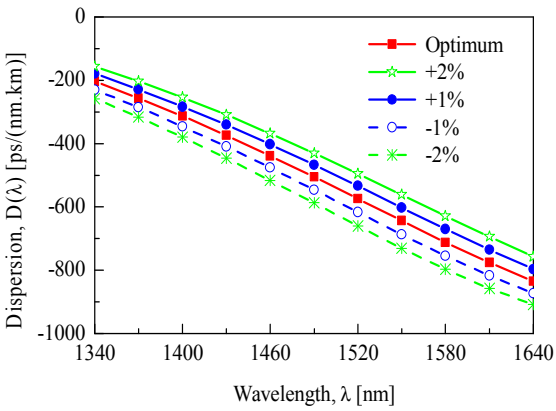

Fig. 4 Dispersion curve of the proposed HyC-CPCF for optimum design parameters and fiber's global diameter variation of order ±2%.

In a standard fiber draw, 2% variation in fiber's global diameter may occur during the fabrication process which may affect the dispersion accuracy [16]. After shaping the optimum dispersion curve and RDS profile, global diameter is varied up to 2% to check the dispersion accuracy about the optimum parameters. Fig. 4 illustrates the dispersion curve for optimum design parameters and due to fiber's global diameter variation. The optimum dispersion figure at operating wavelength of 1550 nm is -650 ps/(nm.km). The dispersion accuracy of the fiber up to ±2% variation in fiber's global diameter is found to be ±86 ps/(nm.km) which is less than [16]. So our proposed design can ensure the better dispersion accuracy.

Fig. 5 illustrates the effective dispersion curve of an optimized 1.04 km long M-CPCF as a function of wavelength after compensating the accumulated dispersion of 40 km long standard SMF used as a transmission fiber. To compensate dispersion for a high bit rate transmission system, for example 40Gbps system, the effective dispersion should not be higher than ±0.8 ps/nm/km [8]. Fig. 5 clearly shows that the effective dispersion is lower than ±0.8 ps/(nm.km) over E +S+C+L wavelength bands which gives an indication that our proposed design is enough capable to compensate accumulated dispersion of transmission fiber over the E to L wavelength bands. The most important feature of the proposed M-CPCF is that it provides two zero dispersion at 1430 and 1550 nm wavelength respectively. It also offers more bandwidth for dispersion compensation than [8] and the required length is smaller than [16]. The design is thus suitable for high bit rates transmission system.

We have then carefully investigated the birefringence property for optimum parameters in the wavelength range 1340-1640 nm. According to simulation, the birefringence of the proposed fiber seems to follow almost linear shape that increases with increase in wavelength as shown in Fig. 6.

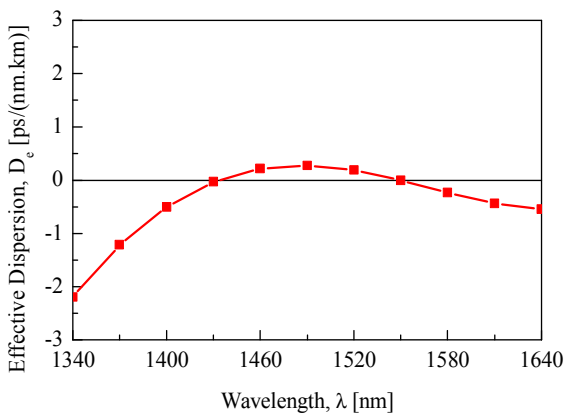

Fig. 5 Effective dispersion curve of the proposed HyC-CPCF for optimum design parameters against wavelength.

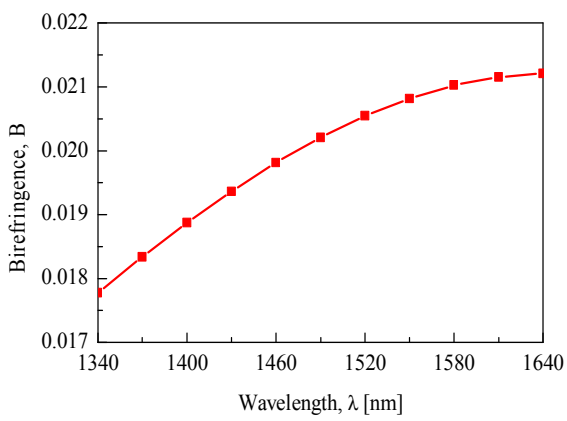

Fig. 6 Birefringence property of the proposed M-CPCF for the optimum design parameters.

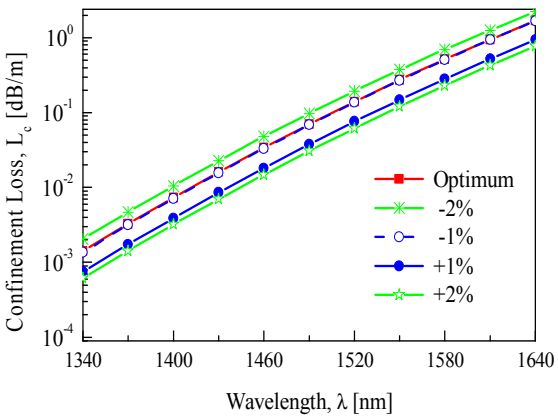

Fig. 7 Confinement loss of the proposed M-CPCF for the optimum design parameters.

Particularly, the birefringence is 0.021 at operating wavelength of 1550 nm which is 42 times higher than that of the conventional PM optical fiber. This indicates that the proposed M-CPCF can provide high birefringence which is very important and highly essential to eliminate the effect of PMD in optical transmission system. In addition to this, high birefringence is desirable in many other applications such as sensing application. For example, highly birefringent fibers are extensively used in fiber loop mirrors as a major component for optical fiber sensing applications. The high birefringence with high negative dispersion of the proposed M-CPCF would be attractive for optical fiber sensor design, optical amplification system and long distance data transmission systems as well.

Finally, we have studied the confinement loss against wavelength for optimum design parameters and also for fiber's global diameter variation. Fig. 7 shows the confinement loss of the proposed M-CPCF. It is clearly seen that the confinement loss is increased with wavelength and particularly found 0.012315 dB/m at 1550 nm wavelength.

V. Conclusion

This paper has presented M-CPCF based on FEM to concurrently ensure high negative dispersion, high birefringence those are crucial for PCF to be applicable in broadband dispersion compensation and sensing applications. The proposed M-CPCF gives a high negative dispersion of -650 ps/(nm.km) with a perfect RDS of 0.0036 nm-1 at 1550 nm wavelength and also provides an effective dispersion of about ± 0.5 ps/(nm.km) from 1360 to 1640 nm wavelength. This feature makes the designed M-CPCF appropriate for broadband dispersion compensation applications. In addition, the designed M-CPCF has shown high birefringence in the order of 2.1×10-2 at 1550 nm wavelength and thus has the potential to be suitable for PMD compensation and sensing applications.

Abstract—**In this paper, we report the formation of periodic array of micro/nano-scale holes/voids on the surface of and inside Al_2O_3-coated boro-aluminosilicate glass by means of single pulse femtosecond laser irradiation. The lowest diameter of the nano-holes printed on the Al_2O_3 coating reaches down to 700 nm, whereas the lowest diameter of the voids inside the glass was 1.1 μm. The fabricated micro/nano-metric holes and voids show uniformity in size and shape throughout the sample area. We also investigate the surface property of the nanovoids' evolved glass surface. We don't observe any structure on the sample surface, when the voids have been evolved inside the glass sample. In addition, we investigate the formation mechanism of the micro/nano-holes or voids in our double-layer samples. We strongly believe that, the periodic micro/nano-voids array will be useful in fabricating various photonic/optical devices, especially, in spreading light.**

Index Terms—**Femtosecond Laser, Al_2O_3-coated boro-aluminosilicate glass, micro-holes/voids, nano-holes/voids.**

I. Introduction

During the last several decades, the demand of forming micro/nano-metric structures in a large variety of materials has increased significantly due to their applications in a diverse field of science and technology. High precision, easy processing steps, and processing time are the important parameters for selecting the patterning technology. Currently, there are several established patterning technologies for micro/nano-structuring of materials: nanoimprint lithography [1], electron beam lithography [2], ion beam lithography [3], photo lithography [4], X-ray lithography [5], physical vapour deposition [6], chemical vapour deposition [7], and laser processing technologies [8–18]. Compared to other patterning technologies, laser sources have shown greater promise for micro/nano-patterning of materials due to their simplicity, high precision, and high throughput. Among various laser sources, femtosecond lasers are widely accepted by the researchers as well as the micro/nano-machining industry because of their non-linear properties and debris free patterning that influence the precise formation of micro/nano-scale structures in various materials [10–19].

Depending on the application area, researchers have proposed the formation of a large variety of micro/nano-structures on the surface of and inside both the transparent and non-transparent materials [11–19]. Formation of micro/nano-holes or voids in transparent materials including glasses has attracted many researchers due to their wide range application area [14–18]. However, it is still challenging to fabricate uniform holes/voids' array with size down to several micrometer to several hundred nanometers precisely in transparent materials. Although it is easy to pattern micro/nano-scale holes/voids on the surface of a single transparent material, it is quite difficult to pattern holes/voids inside double-layer materials without damaging the top layer. Besides, the threshold energy and holes/voids characteristics are solely dependent on the material properties, which vary significantly for different materials. Thus, it is significant to investigate the formation of micro/nano-holes or voids in various transparent materials.

In this paper, we demonstrate for the first time the fabrication of periodic micro/nano-holes or voids' array on the surface of and inside the Al_2O_3-coated boro-aluminosilicate glass samples. Nano-holes' array with diameter down to 700 nm have been observed on Al_2O_3 surface, whereas micro-voids with diameter down to 1.1 μm has been reported inside the glass. More importantly, these micro/nano-holes or voids show excellent uniformity throughout the sample area. Furthermore, we analyze the characteristics of the micro/nano-metric holes/voids, printed on the surface of and inside the Al_2O_3 coated boro-aluminosilicate glass samples. Our experimental result shows that, it is possible to fabricate voids array inside the boro-aluminosilicate glass without damaging the top Al_2O_3 layer. In addition, we examine the influence of numerical aperture and magnification of objective lens on the formation of holes/voids in our samples. Furthermore, we analyzed the formation mechanism of the holes/voids in Al_2O_3-coated boro-aluminosilicate glass samples. We believe that, this holes' array in the double-layer structure will be valuable to design various optical devices in spreading light such as LEDs.

II. Experimental Details

We carried out our experiments using a Ti:sapphire femtosecond laser beam of Gaussian shape that operates at the central wavelength of 786 nm. The pulse width and the pulse repetition rate of the laser pulses were 183 fs and 1 kHz. We applied p-polarized laser beam to pattern the samples. The femtosecond laser beam was guided by means of several mirrors and an achromatic objective lens (50× or 100×) onto the samples, placed on the translation stage. The numerical aperture of the 50× and 100× lenses are 0.42 and 0.7. Fig. 1(a) illustrates the schematic diagram of the experimental setup.

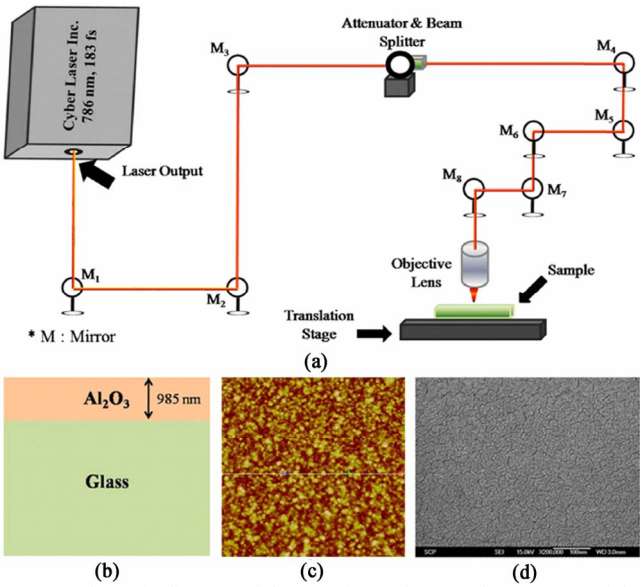

Fig. 1 (a) Schematic diagram of the experimental setup; (b) Structure of the Al_2O_3-coated boro-aluminosilicate glass sample; (c) AFM image of the Al_2O_3 bare surface; (d) SEM image of the boro-aluminosilicate glass surface before Al_2O_3 coating.

During our experiments, we used specially designed Al_2O_3-coated boro-aluminosilicate glass samples (Al_2O_3 thickness: ~ 985 nm; glass thickness: ~ 650 µm). The sample consists of two layers, where the Al_2O_3 layer was coated on the boroaluminosilicate glass surface, which is shown in Fig. 1(b). The atomic force microscope (AFM) image of the Al_2O_3 bare surface is depicted in Fig. 1(c). Using AFM image, we obtain the roughness (R_a) information of the Al_2O_3 bare surface, which is ~ 1.3 nm. To pattern the Al_2O_3-coated glass samples, we mounted them on top of a 3-axis translation stage, where the resolution of the translation stage in the x, y, and z directions were 100 nm. To examine the surface morphology of the material surface, we used a field emission scanning electron microscope (FE-SEM). Before SEM examination, the samples were cleaned in ultrasonic bath in de-ionized water for 30 minutes. The samples were sputter coated with a thin layer (~ 30 nm) of gold coating to provide conductivity for SEM examination. The SEM image of the boro-aluminosilicaate glass surface without the Al_2O_3 coating is shown in Fig. 1(d).

The laser beam was passed through an integrated circular attenuator & beam splitter, where the function of the attenuator was to control the power of the laser beam. The splitter splits the beam into s-polarized and p-polarized laser beams, passes the p-polarized laser beam and reflects the s-polarized laser beam in the perpendicular direction (this beam is blocked). We utilized the p-polarized laser beam to pattern periodic micro/nano-holes or voids' array on the surface of Al_2O_3 or inside boro-aluminosilicate glass. The micro/nano-patterned samples were investigated under an optical microscope. Before microscope examination, the samples were cleaned in ultrasonic bath in de-ionized water for 30 minutes. By controlling the irradiation conditions of the laser beam, we formed periodic holes/voids in our samples.

III. Results and Discussion

A. *Formation of Micro/nano-metric Holes' Array Using 50× Objective Lens*

By illuminating single laser pulse in each spot, we fabricated periodic micro-holes' array on Al_2O_3 surface. The laser beam was focused on the sample surface and scanned at a scanning speed (v) of 2 mm/s with vertical scanning step (a) of 2 µm. At a pulse repetition rate of 1 kHz and a scanning speed of 2 mm/s, the horizontal distance among the holes was 2 µm. On the other hand, the vertical distance among the holes was also 2 µm. For fabricating micro-holes with diameter of 1.7 µm, 1.3 µm, and 900 nm, the energy of the laser beam (E) was 500 nJ, 305 nJ, and 152 nJ, respectively. Figs. 2(a–c) represent the micro/nano-holes fabricated on the Al_2O_3 surfaces using 50× objective lens.

In order to produce nano-voids 3 µm inside the Al_2O_3-coated glass sample, we focused the laser beam inside the glass sample. Nano-voids with diameter down to 800 nm have been evolved inside the glass sample at a laser energy of 250 nJ, which is represented in Fig. 2(d). Because of the energy loss in the Al_2O_3 coating and the boro-aluminosilicate glass, more energy is required when the voids are formed inside the glass sample. If we closely look at the optical microscope images of Fig. 2, we find that the fabricated micro/nano-holes and voids show great consistency in size and shape throughout the sample area.

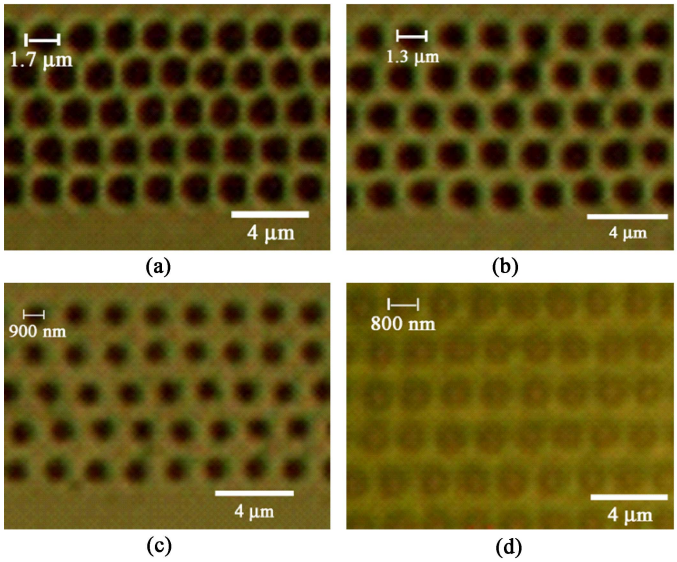

Fig. 2 Micro/nano-holes' array on the Al_2O_3 surfaces using 50× achromatic objective lens at a scanning speed of 2 mm/s and vertical scanning step of 2 µm. (a) E = 500 nJ; (b) E = 305 nJ; (c) E = 152 nJ; and (d) E = 250 nJ.

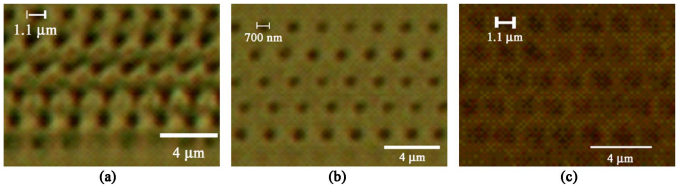
B. *Formation of Micro/nano-metric Holes/voids' Array Using 100× Objective Lens*

We also printed periodic micro/nano-holes or voids' array on the surface of Al_2O_3 and inside Al_2O_3-coated boro-aluminosilicate glass using 100× achromatic objective lens. To fabricate periodic micro-holes array on the Al_2O_3 surfaces, we focused the laser beam on the Al_2O_3 surface with laser energy of 607 nJ for 1.1 µm diameter holes and 430 nJ for 700 nm diameter holes. Figs. 3(a) and (b) illustrate the optical microscope images of the micro-holes' array on the Al_2O_3 surfaces.

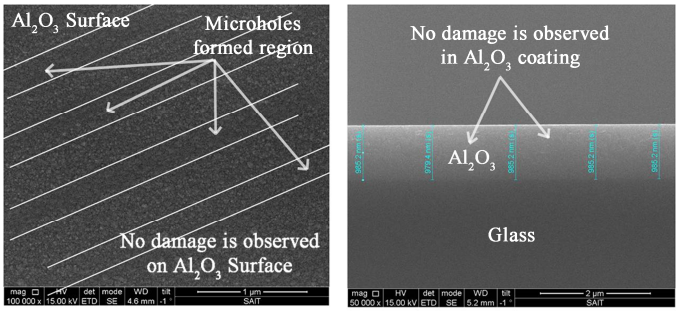
In order to fabricate micro-voids inside Al_2O_3-coated glass, we focused the laser beam 3 µm inside the glass by decreasing the laser energy down to 280 nJ. As a result, micro-voids' array with diameter of 1.1 µm are evolved inside the glass, which is shown in Fig. 3(c). The micro-voids developed inside the glass samples without damaging the top Al_2O_3 layer.



(a) (b) (c)

Fig. 3 Micro/nano-scale holes/voids' array on Al_2O_3 surface and inside Al_2O_3-coated boro-aluminosilicate glass using 100× achromatic objective lens at a scanning speed of 2 mm/s and vertical scanning step of 2 µm. (a) Micro-holes on the Al_2O_3 surface at E = 607 nJ; (b) nano-holes on the Al_2O_3 surface at E = 430 nJ; (c) micro-holes inside the boro-aluminosilicate glass at E = 280 nJ.

We also investigated the micro-voids evolved Al_2O_3 surface under SEM. Fig. 4(a) illustrates the SEM image (top view) of the micro-voids induced sample surface of Fig. 3(c), whereas Fig. 4(b) depicts the SEM image (side view) of the Al_2O_3-coated glass sample. If we closely look at the Al_2O_3 surface of Fig. 4(a), we don't observe any holes on the Al_2O_3 surface. The side view of Fig. 4(b) also confirms the absence of any holes on the top or inside the top layer (Al_2O_3 layer) of the sample. These results indicate that, femtosecond laser can fabricate voids inside the bottom layer without damaging the top layer, which is achieved due to the non-linear properties of the femtosecond laser beam.



(a) (b)

C. Formation Mechanism of the Micro/nano-scale Holes/voids in Transparent Materials

In transparent materials, when we apply single pulse in a spot, holes/voids are evolved in the material depending on the focus point of the laser beam. We can expect filamentation effect of the laser beam in transparent materials. High intensity femtosecond laser beam can create electron plasma filaments in transparent materials that cause the extension of the focal length of the laser beam. Alternate self-focusing and defocusing of electron plasma guides a femtosecond laser beam through a prolonged narrow channel, known as filamentation. The critical power (P_c) of self-focusing is obtained by the following equation [18]:

$$P_c = \frac{3.77\lambda^2}{8\pi n n_2} \tag{1}$$

where λ is the wavelength of the incident laser beam, n is the linear and n_2 is the non-linear terms of refractive index of the medium.

As mentioned before, we utilized Gaussian shape laser beam during our experiments. For a Gaussian laser beam, we can determine the radius of the focal spot size using the following equation [19].

$$w \approx \frac{\lambda f}{\pi w_0} \tag{2}$$

where λ is the wavelength of the incident light, f is the focal length and w_0 is the 1/e Gaussian beam radius. With the decrease in laser energy, the intensity of the Gaussian laser beam decreases in every part of the focal spot. As a result, only the central part of the Gaussian laser beam can cross the threshold energy of a material. As a result, by decreasing the laser energy we can reduce the diameter of the micro/nano-holes or voids. However, when the laser energy of the central part of the Gaussian laser beam is below the threshold energy of a material, we cannot produce holes or voids in that material. Thus, the lowest diameter of the nano-holes/voids depends on the threshold energy of that material and the lowest possible energy of the central part of the laser beam. These parameters are dependent on the material and the optical equipments. In order to fabricate holes/voids in any material, the flatness of the translation stage is very important. Slight variation in the stage flatness may vary the position of the holes/voids in the material.

IV. Conclusions

In summary, we reported the fabrication of periodic micro-nano-metric holes/voids on the surface of and inside Al_2O_3-coated boro-aluminosilicate glass. The lowest diameter of the fabricated nano-holes, printed on Al_2O_3 coating, was measured as ~ 700 nm. The nano-voids of 1.1 µm diameter have been developed inside the glass sample without damaging the top layer of Al_2O_3. Furthermore, we investigated the formation mechanism of the nano-holes and nano-voids in the Al_2O_3-coated glass samples. It is well known that, micro/nano-holes and micro/nano-voids can cause scattering of incident light. Thus, the proposed micro/nano-metric holes/voids' array will be suitable for spreading light, which property can be utilized to fabricate various optical/photonic devices.

Acknowledgment

We are very much thankful to R&D Centre, Samsung Corning Precision Materials, Republic of Korea for their Al_2O_3-coated boro-aluminosilicate glass samples and technical & financial support.

Abstract— **We proposed and demonstrated an efficient method to split electromagnetic wave in two dimensional photonic crystal by using a T-shaped splitter. By measuring normalized electromagnetic field, it is shown that the equal outputs of splitter can be limited and controlled by using a control rod which position can be varied. It is also showed that the output of two ports can be unequal and it can be controlled by varying the position of control rod.**

Index Terms— **photonic crystal, splitter, control rod.**

I. Introduction

"Photonic Crystals" (PC) are dielectric structures with periodic modulation of the refractive index on the scale of the wavelength of the light [1], [2]. Due to this periodic modulation of refractive index, a photonic bandgap (PBG) is generated and propagation of electromagnetic wave is forbidden for wave vectors within this bandgap. Over the past several years, various important scientific and engineering applications of the control of light emission and propagation and the trapping of photons have been realized such as line defect waveguide [3],[4],planar waveguide [5],[6], coupled cavity waveguide [7],[8]. The optical power splitter or divider is an indispensable component in photonic integrated circuits which is used in fiber optic networks. Basic structure of the splitter is divided into two parts, an input and an output port. Ideally, input power is equally divided into the output ports without any significant reflection and radiation loss.

In a PC, a simple Line defect waveguide is created by removing a row of rods along one of its main crystalline directions. Sharp bend of light wave was done in 90º by Attila Mekis, J. C. Chen, I. Kurland, Shanhui Fan, Pierre R. Villeneuve, and J. D. Joannopoulos [9]. We can enhance the model by removing the rods in both directions which can work as a T-shaped power splitter [10].

We have shown the control mechanism of the T-shaped power splitter by placing a control rod in between the paths. We can control the output power at the ports by changing the placement of the control rod.

II. Structure and Design

In experimental environment we used a 2D photonic crystal. The crystal consists of silicone rods having a refractive index of 3.48. We took a square block having the sides of 5.5µm. The center to center distance of the rods is chosen to be 500nm. This is a frequency tunable model. These parameters can be changed to select a different frequency. Our model is tuned to 200 THz for the simulation. To create the line defects silicone rods are removed in a style that it creates a path of 11µm and have the periodicity to the next rod in line of □ = 500nm.

For photonic conduction there are two requirements (1) strong localization of the individual defect modes, (2) weak interaction between these localized modes. Under these conditions the transmission of photons in a crystal can be achieved regardless of changing the direction. We have experimented with a T-shaped beam splitter with different configurations.

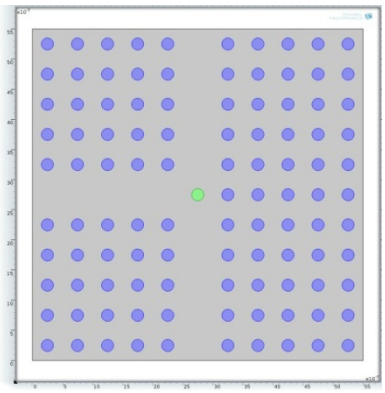

Figure - 1: Silicone rod based T-shaped photonic crystal beam splitter with □=500nm f=200THz. The control rod is marked in green. The output power at each port can be controlled by varying the position of the control rod.

III. Experiments

We first experimented with incident electromagnetic wave to the line defect. This experiment shows the result that the wave power is spilt into the top and bottom channel equally. The system is frequency selective. So the comparison of response at different frequency is not a concern in this case. We measured the distribution of field in the channel. This is quite a sinusoidal shape and shows a loss that tends to zero. The total power is conserved at the outputs.

Electric field in the output channels can be controlled with introduction of a control rod at the center. The position of the center rod controls the field (Fig-3). We can either introduce an amount of attenuation to the flow of the wave or we can drive the flow to a specific channel if we want.

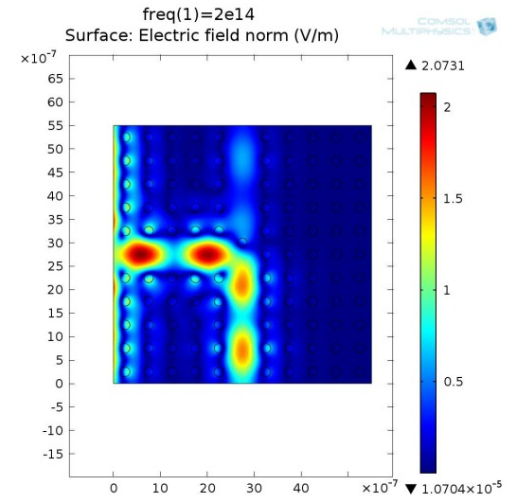
Fig-4: Output power with control rod moved towards positive x direction

Fig-5: control mechanism of the control rod. (a) More power at the bottom channel, (b) More power at the top channel.

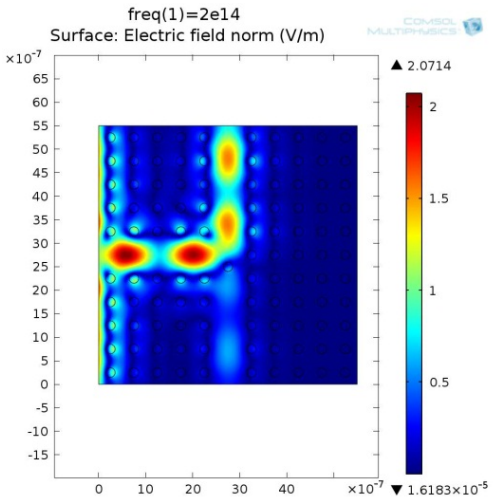
IV. Result analysis & discussion:

In the first experiment, we did not use the control rod. This gives us equal power split into both channels with a very low attenuation. Fig-2 shows the output power at the channels. We used 2v/m and got 0.99V/m at each channels. Then we introduced the control rod between the channels at central position. This gives also gives us an equal distribution of power at both channels but has a large amount of attenuation (Fig-3). Fig-3(a) shows the attenuated flow of the wave in the output channels. Fig-3(b) is a line graph for the field distribution in the output channels. The peak at the centre is for the absorption property of the control rod. We can see a large amount of power is absorbed by the centre rod. As earlier we used 2 V/m (peak) as the input and the graph is showing about 0.45 V/m at the output channels.

If we move the control rod horizontally towards the wall of silicone rods, more waves can pass through the gap between the input channel and the output channels. In fig-4 there is more power flowing in the output channels in comparison with the previous setup in fig-3(a). The opposite can be done by moving the control rod towards the input channels. This will decrease the output power at both channels. In all the cases the field distribution in both the output channels are equal. The change in the position of the control rod in horizontal fashion does provide same attenuation for both channels.



(a)



(b)

Fig-5: control mechanism of the control rod. (a) More power at the bottom channel, (b) More power at the top channel.

The field applied to the input can be driven to a specific channel out of the two by moving the control rod vertically. When the control rod is moved in the vertical direction, it provides more attenuation to one of the paths and thus driving the power flow to the other channel. The distribution of the power in the channels can be controlled by the position by the control rod position. If it is placed in line with the side wall of any one output channel, the other channel will carry most of the power. In fig-5(a), the control rod is placed in a fashion that 70% of power can flow in the bottom channel and the rest 30% in the top channel. As we are using 2V/m as input, we get peak of 1.42v/m in the bottom channel and 0.58v/m at the top channel (fig-5(a)). The same setup is repeated with the control rod placed at the mirror position of the previous setup (fig-5(b)). This gives the exact same result except that the maximum power is flowing in the top channel.

This model is a frequency tuneable system. The pitch and the radius of the rods are tuned to a specific frequency. In our experiments we have chosen 200 THz as the resonant frequency. In other frequencies the model does not provide a satisfactory result as a waveguide or a conducting path for the wave. At 200 THz the model works fine.

V. Conclusion

This paper has discussed about power splitter in optical frequency region based on photonic crystal. A T-shaped power splitter has been proposed to achieve an equal distribution over the channels. It is also scrutinized to establish a control mechanism for the splitter. A novel controlling method is also proposed by using a control rod. A flexible control is achieved with the control rod technique. The technique is studied extensively and investigated with different length and other conditions.

The results presented here indicated that this type of optical power splitter can be used in optical circuits. This can also be used to feed two or more output channels with the same signal.

Abstract— **Thermal stress which is unavoidably generated in the fabrication process alters the optical property of the waveguide materials and thus hinders the realization of polarization insensitive devices. This work reports the detailed numerical investigation of stress-induced birefringence in polymer strip waveguide. A more realistic model is used in the finite element analysis to estimate the stresses induced over the entire sequential fabrication process. It is observed that the birefringence in the strip channel is non-uniform which is maximum near the lower cladding and decreases to zero towards the top of the channel. The variation in birefringence is also influenced by the waveguide geometries. Such birefringence characteristics are obtained and discussed in a generalized form, allowing for their applicability with various polymer materials. Thus, the generalized characteristics can be used to determine the stress-birefringence of a polymer strip waveguide with air cladding only by knowing the stress-birefringence in its planar film. This will eliminate the necessity of extensive numerical analysis for the prediction of thermal stress in polymer waveguides and will be more accurate than analytical solutions.**

Index Terms—**Optical waveguide, Thermal stress, Polymer waveguides, Birefringence.**

I. Introduction

Stress, which is unavoidably generated in the fabrication process, has long been a key issue for the yield improvement of many optical waveguide devices [1]–[4]. The stress is generated in the waveguide materials mainly due to the thermal expansion mismatch among the constituent materials. In polymer based optical waveguides, the stress can also be generated due to the polymerization shrinkage even at room temperature when cured under UV light [5]. Due to the photo-elastic effect, this stress may cause anisotropic changes in the material refractive index (i.e., material birefringence), which then makes the device polarization dependent [4]. The problem is more severe in case of polymer based optical waveguides, since the polymer film has large thermal expansion coefficient and hence experience large thermal mismatch with inorganic substrate. To reduce such stress-induced effects, therefore, an accurate estimation of stresses and their influence on the optical properties of the waveguide materials are important. Polymer materials are very attractive in the fabrication of optical waveguide devices due to their low cost, ease of processing, simplicity of integration onto desired surfaces, and energy-saving property (e.g., large thermo-optic coefficient) [3], [6].

A large number of works have been devoted to study the stress-induced material birefringence in optical waveguides [3], [4], [7]. Most of these works used either analytical [3] or numerical methods [4] for the stress analysis, since the measurement of stress is difficult in tiny waveguides or inside the components. Available analytical methods are simple but insufficient to capture the complex behavior of polymer materials and thus to estimate the stresses accurately in polymer waveguides [7]. Numerical analysis based on finite element (FE) method is, therefore, often employed for the analysis of stress-birefringence in optical waveguides. Recently, we have proposed a more realistic FE model to accurately estimate the stresses in polymer waveguides [7]. A successful application of this model has also been demonstrated by the efficient design of polarization insensitive devices considering the stress-induced effects [8]. However, such accurate prediction of stresses requires extensive material properties (e.g., elasto-plastic and viscoelastic behaviour, chemical kinetics for cure reaction, etc) which are usually unavailable in literature for many optical polymers and also difficult to characterize in thin films.

This work presents a generalized characteristic of stress-birefringence in polymer strip waveguide based on the detail numerical investigation of thermal stress in various waveguide structures using the realistic FE model. The obtained characteristic is expressed by an empirical formula which then can be used to determine the stress-birefringence in an air-clad polymer strip waveguide avoiding the requirements of extensive numerical analysis. Since the strip waveguide has been widely used in fabricating various optical devices [2], the presented results will be useful for the treatment of stress-induced problems in many of those optical devices.

II. FE Modeling and Photo-elastic Theory

A. Finite Element Modeling

Fig. 1 shows the cross section of a strip waveguide (width, w; and height, h). As the material chosen, the waveguide is comprised of benzocyclobutene (BCB) for the core layer and epoxy (OPTOCAST 3507) for the lower cladding layer. In the fabrication process [2], epoxy was spin-coated on silicon (Si) wafer first, cured under UV light at room temperature (24 °C) and post-cured at 120 °C. Then the benzocyclobutene (BCB) was spin coated on the epoxy and cured at 250 °C. Finally, the strip was patterned by conventional photolithography and dry etching process. Although the quantitative values are derived for the BCB waveguide, the stress-birefringence characteristics would be applicable for other polymers as well.

To accurately predict the stresses, we employed our developed FE model [7] in MSC Marc software. Comparing to the conventional models, this model is more realistic for the

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

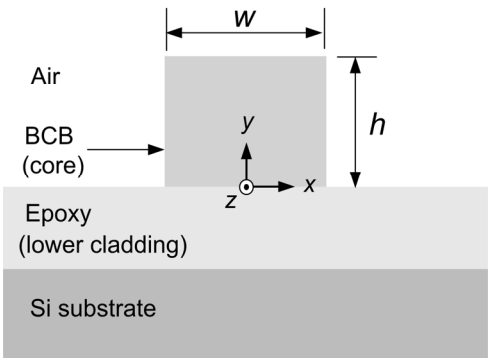

Fig. 1 Cross-section of a strip channel waveguide. The strip width and height are denoted by w and h respectively. The aspect ratio R is defined as w/h.

thermo-mechanical analysis of polymer optical waveguides over the entire sequential fabrication process. In the simulation, the geometry of the final structure was modeled at the very beginning and only the substrate was considered stress free at room temperature. The BCB layer was deactivated (i.e. exhibits no stiffness) till the end of the curing of epoxy. Thereafter, it was activated in a "strain-free" manner. Stress induced by the curing shrinkage was considered in our model by using coupled cure-thermal-mechanical approach. Creep model was used to simulate the stress relaxation process. The etching process was simulated by removal of the selected material elements which demonstrate zero stresses and strains on the post elements.

The strip waveguide analyzed in this work is of various heights around 3.0 µm (2.25 µm – 4.5 µm) and has a lower cladding thickness of 10 µm on 500 µm thick Si substrate. For the stress calculation, the waveguide geometry having dimension of 5 mm × 513 µm × 5 mm is used in the FE model which consists of over 8000 hex elements and 10000 nodes with required thermal and mechanical boundary conditions.

B. Photo-elastic Theory

In the elastic range of material, the stress dependence of the material refractive index is expressed by the Neumann-Maxwell equation [9]:

$$n_x = n_0 - C_1\sigma_x - C_2(\sigma_y + \sigma_z),$$
$$n_y = n_0 - C_1\sigma_y - C_2(\sigma_x + \sigma_z), \quad (1)$$

where n_x and n_y are the principal refractive indices in the in-plane (parallel to x-axis in Fig. 1) and out-of-plane (parallel to y-axis) direction, respectively, n_0 is the refractive index without stress, σ_x, σ_y and σ_z are components of principal stresses in the x, y and z direction, and C_1 and C_2 are the stress-optic coefficients. If the waveguide is invariant along the direction of light propagation (z-direction), the material birefringence can be calculated as $n_x - n_y = (C_2 - C_1)(\sigma_x - \sigma_y)$.

III. Results and Discussions

A. Stress Distributions

From the simulation model, the principal stresses (σ_x, σ_y, and σ_z) are noted at room temperature for two process steps: before etching and after etching. Before etching, the stresses in the planar BCB film (core layer) are obtained as $\sigma_{x,film} = \sigma_{z,film} = 44.1$ MPa and $\sigma_{y,film} = 0.657$ MPa for the in-plane and out-of-plane directions, respectively. Being a planar structure before etching, these stresses are uniform all over the BCB layer. A summary of the properties of fully cured materials used in the FE simulation are shown in Table I. Although not explicitly given in the table, a cure and temperature dependence for the CTE and elastic modulus is considered. The film stress can be verified easily in this stage by measuring the warpage of the structure [8]. In this work, the warpage and thus the stress was measured using Ambios XP-2 stylus profiler. The corresponding measured in-plane stress (45 ± 3 MPa) is in good agreement with the simulated result (44.1 MPa).

TABLE I
Material properties used in the FE analysis

Materials	Temperature (°C)	Elastic Modulus (GPa)	CTE (ppm/°C)	Poisson's ratio
Silicon	-	130	2.6	0.27
Epoxy T_g = 145 °C	Below T_g	2.5	65	0.34
	Above T_g	0.25	200	
BCB T_g = 350 °C	Below T_g	2.9	56.7	0.34

When the slab structure was etched to pattern strip waveguide, the stresses were relaxed and became non-uniform. However, it is very difficult, sometimes impractical, to measure that stress in the tiny channel waveguides. Fig. 2(a) and (b) shows the simulated in-plane (σ_x) and out-of-plane (σ_y) stress distributions in the strip channel (after etching) of width w = 3.0 µm and height h = 2.0 µm. The stress values are normalized by the in-plane stress retained in the film ($\sigma_{x,film} = \sigma_{z,film} = \sigma_{film}$) before etching. Unlike the planar (slab) waveguide, the stress distributions in the channel waveguide are highly non-uniform.

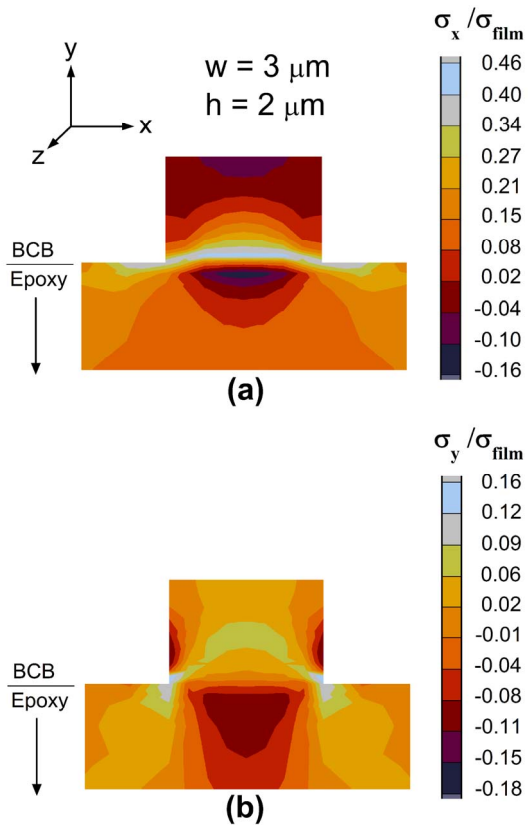

Fig. 2 a) In-plane, σ_x and b) out-of-plane, σ_y stress distributions in the strip waveguide consisting width, w = 3.0 µm and height, h = 3.0 µm. The stresses are normalized by the corresponding film (i.e., before etching) stress.

Fig. 2(a) reveals that the in-plane stresses (σ_x) in the strip channel are greatly relieved. The remaining maximum in-plane stress is about 50% of the film stress, but only in an extremely narrow area adjacent to the lower cladding or substrate. This is due to the absence of constraining force in the free standing part of strip structure compare to the bottom [10]. As shown in Fig. 2(b), a significant amount of out-of-plane stress (σ_y) also exist in the channel which is now comparable to the in-plane stress. Herein, positive stress is defined as tensile, whereas the negative stress is compressive.

To examine the influence of strip geometries on the evolution of stresses, numerical analysis is performed for a broad range of strip dimensions (2.25–4.5 μm in width and 2.0–4.0 μm in height). A more detail of such geometric influence will be discussed in the next section through its influence on the material birefringence. As mentioned earlier, the prediction of the stress-birefringence characteristics is of our primary interest.

B. Stress-Birefringence Characteristics

Once the stress distributions are obtained, combining them with photo-elastic coefficients using (1), the stress-induced birefringence (Δn) are determined for the waveguide material as $\Delta n = n_x - n_y = (C_1 - C_2)(\sigma_x - \sigma_y)$. For a BCB thin film, C_1 and C_2 are 99×10^{-12} Pa^{-1} and 31×10^{-12} Pa^{-1}, respectively at an optical wavelength of 1550 nm, whereas these are zero for epoxy [11]. Before etching, the birefringence calculated for the BCB film is 0.003, which is uniform all over the film layer. In this case, it was a slab waveguide and the material index of BCB can be measured easily by prism coupler. The measured birefringence was 0.0034 for BCB at 1550 nm wavelength [2], which is comparable to the calculated result of 0.003. Due to the zero values of photo-elastic coefficients, no birefringence is calculated here for the epoxy layer.

The birefringence retained in the BCB waveguide after etching is shown in Fig. 3 as a function of the position (y) along the height for various waveguide geometries. Similar to the waveguide stress, birefringence is also normalized by the value that retained in the planar (before etching) film. Such normalization will help us understand the general feature of the birefringence characteristics in channel waveguides. Fig. 3 shows that the birefringence is higher near the lower cladding or substrate, with its maximum value of about 50% of the birefringence remained in the film before etching. The birefringence decreases exponentially to the zero value as it approaches the top of the channel. As explained earlier, the material birefringence in the planar waveguide is induced mainly by the in-plane stress. In the etching process, however, the in-plane stress relaxes remarkably, while more of the out-of-plane stress is induced in the strip region. This is the reason why the material birefringence decreases sharply as it approaches the top of the channel.

Fig. 3 reveals that the significant birefringence remains only up to the height of about 2 μm regardless of the dimensions of the strip. For a given width, the birefringence retaining in the strip waveguide is constant, irrespective of the channel height. This is appeared in Fig. 3(a) with the essentially identical lines for w = 3 μm, and h = 2, 3 and 4 μm. However, Fig. 3(b) shows that the birefringence at a particular height slightly increases with the increase in strip width. The birefringence does not vary significantly along the width of the strip channel.

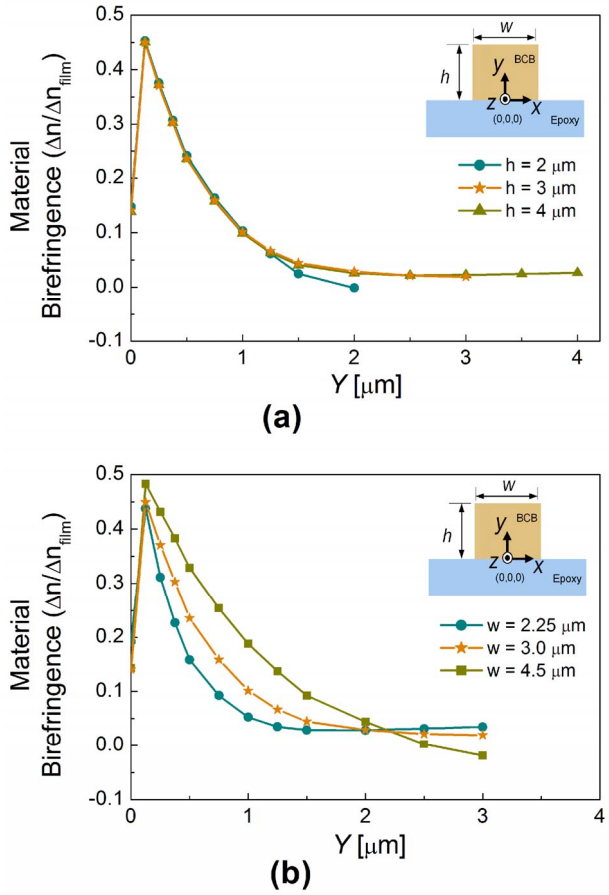

Fig. 3 Calculated normal birefringence ($\Delta n / \Delta n_{film}$), normalized by the corresponding value before etching, along the height of a strip channel (a) for different height (h = 2– 4μm), width w = 3.0 μm and (b) for different width (w = 2.25– 4.5 μm), height h = 3 μm.

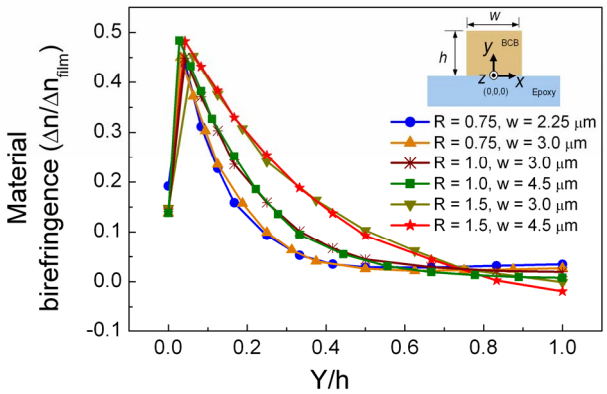

Fig. 4 Generalized characteristics of the stress-birefringence in strip channel waveguide. The birefringence is normalized by the value of that remains in the film before etching and the position along height is normalized by the maximum height of the corresponding strip channel.

Based on the aforementioned observations, a generalized stress-birefringence characteristic can be obtained by plotting the normal birefringence against the position (y/h) normalized by the corresponding maximum height. Fig. 4 shows the re-illustrated curves of Fig. 3, in which the x-axis is replaced by the normal position (normalized by the maximum height of the corresponding waveguide) instead of the actual position along the height. As can be observed, the stress-induced birefringence remaining in the strip waveguide is now simply related to the birefringence in planar film (Δn_{film}) and the aspect ratio ($R = w/h$) of the strip channel.

Using the curve fitting technique, the obtained generalized characteristics can be expressed by the following empirical relation:

$$\Delta n / \Delta n_{film} = 0.56\exp(-k_1 y_n) + k_2 (y_n / h)^2 \qquad (2)$$

where y_n is the normalized position (y/h), and k_1 and k_2 are the fitting constants. The values of these constants depend on the aspect ratio R of the waveguide and can be obtained as:

$$k_1 = 5.55 + 0.45(1-R), \quad k_2 = 0.16 + 0.7(1-R). \qquad (3)$$

Thus, by knowing the stress-induced birefringence before etching (Δn_{film}), which can be easily measured, the birefringence remaining in a polymer strip waveguide can be determined using (2) and (3).

Fig. 5 shows the estimated material birefringence in strip channel using the FE method and the developed empirical relation (2). The formulated birefringence for two different waveguides having same aspect ratio (R = 1.5) agree very well with those obtained using the FE method.

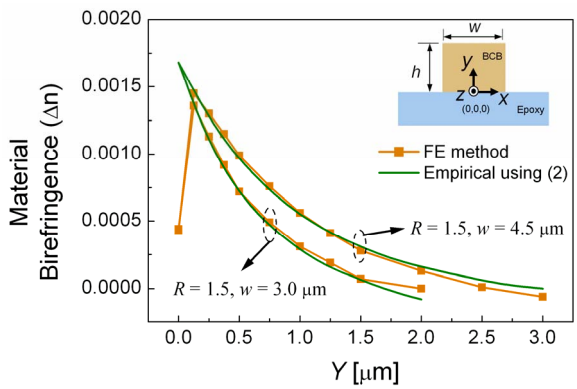

Fig. 5 Material birefringence (Δn) along the height of a strip channel obtained through the FE method (line with markers) and the developed empirical relation (2) (smoothed line). The birefringence is derived for the BCB film with birefringence (Δn_{film}) of 0.003.

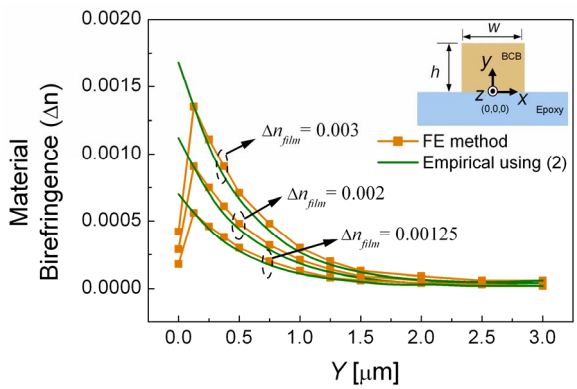

Fig. 6 Comparison between the material birefringence (Δn) estimated using the FE method (line with markers) and the empirical relation (smoothed line) in a strip channel for different film birefringence (Δn_{film}) of 0.003, 0.002 and 0.00125. The birefringence is derived for the strip waveguide with aspect ratio of unity (R = 1).

For different polymers, the value of Δn_{film} can be different due to different levels of induced stresses or different values of stress-optic coefficients, or both. Fig. 6 illustrates the birefringence (Δn) in a strip channel for different film birefringence of (Δn_{film}) of 0.003, 0.002 and 0.00125. A good agreement is found between the birefringence estimated using the FE method and the empirical relation given in (2) and (3). This indicates that the normalized channel birefringence for a given aspect ratio will get the same characteristics irrespective of the different levels of film birefringence (Δn_{film}). This is because the stress relaxes in the etching process mostly due to the elastic properties of the material. On the other hand, the birefringence varies linearly with the stress-optic coefficient. Thus, the obtained stress-birefringence characteristics for the strip channel will remain valid for the typical dimensions of optical waveguide comprising any other isotropic polymers. Such estimation of non-uniform birefringence will also be more accurate than the analytical methods which result only a uniform value [8].

IV. Conclusions

This work presents a detailed numerical investigation of stress-induced material birefringence in an optical strip waveguide composed of polymer materials. The stresses in the waveguide material are determined first through numerical solutions of the thermo-mechanical problem of different waveguide structures. Then, by combining them with the stress-optic coefficients, the material birefringence is obtained. It is found to be non-uniform in the strip channel. In the core layer, the maximum birefringence is observed near the lower cladding, which decreases to zero towards the top of the channel. This birefringence slightly increases with the increase in strip width. Such stress-induced characteristics are presented and discussed in a generalized empirical form, allowing for their applicability with other polymer materials. The obtained stress-induced characteristics can now be included in the optical design of waveguide devices in order to achieve more accurate design results.

Abstract— **A novel Nearly Zero Dispersion Fiber (NZDF) at operating wavelength is designed having GeO_2 doped SiO_2 square defected core and investigated with Finite Element Method (FEM) using COMSOL. The proposed PCF shows promising dispersion characteristics (0.0001787ps/km-nm) with very low effective area (3.03μm^2) and high non-linear parameter (67.23 W^{-1} km^{-1}) at 1.55μm, making it suitable candidate for chromatic dispersion controller and nonlinear optical application.**

Index Terms—**FEM, NZDF, DCF, DFF**

I. Introduction

Photonic crystal fibers[1], consisting of a central defected region surrounded by multiple air holes running parallel to the fiber length, have been one of the most interesting developments in fiber optics. To achieve nearly-zero ultra-flattened chromatic dispersion in PCFs, several fascinating designs have been proposed so far. Among of them, the conventional PCF designs consist of uniform optimized air-holes [2]-[4]. Photonic crystal fibers guide light by arranging it within a periodic array of microscopic air holes that run along the entire fiber length [5]. In this case, light is guided by the total internal reflection, and the air holes are used to reduce the index of the cladding region. Different arrangement of air holes gives different dispersion characteristics. The task of controlling the chromatic dispersion is a very important problem in dispersion controllers [6], nonlinear systems [7] or designing practical optical communication systems [8]. A nonlinear PCF with several kinds of air-hole diameters [9] and a PCF with two–defected air-hole rings [10] have also been presented so far. Inserting a defected air hole [11] in the core shows ultra-flattened dispersion with low confinement loss. Zero dispersion is also seen at several irregular structures [12]-[13].

In this paper, a PCF containing GeO_2 doped defected SiO_2 square in the core with four rings of hexagonal air hole rings is proposed. Nearly zero dispersion is achieved at operating wavelength 1.55μm. A high nonlinear gain with low effective area has also been obtained at this wavelength. A full-vectorial finite-element method [14] with anisotropic perfectly matched layer has been used to compute the effective mode index. The RF physics feature of COMSOL MULTIPHYSICS 4.3b is used for simulation purpose.

II. Fiber Structure

The cross section of the proposed PCF structure is shown in Fig 1(a). It is composed of circular air holes in the cladding arranged in a triangular array with lattice constant Λ and diameter d. The central core region is perturbed by a GeO_2 doped SiO_2 square with side a. The host material is regular silica. The total number of air-hole rings was chosen to be four in order to simplify as much as possible the structural composition of the PCF. The insertion of the extra GeO_2 doped SiO_2 square in the core region is the novel concept of the present design and according to our extensive literature research is a novel idea hasn't been reported yet. The existence of the central defected air-hole has the function to control the waveguide dispersion properties of the fiber as will be demonstrated later on. The NZDF can be fabricated by the sol-gel method [15] which gives well-arranged air holes.

III. Theoretical Background

We carry out simulation of a GeO_2 doped SiO_2 square defected core PCF structure using COMSOL based on the following theoretical background. Results obtained are exported to MATLAB for further computation. We calculate the total dispersion by the exact definition of the total chromatic dispersion as [11]

$$D = -\frac{\lambda}{c}\frac{\partial^2 n_{eff}}{\partial \lambda^2} \tag{1}$$

where n_{eff} is the effective index of the fundamental mode. Refractive index of SiO_2 and GeO_2 can be found from Sellmeier's equation [16]

$$n^2 = 1 + \sum_{i=1}^{3} \frac{A_i \lambda^2}{\lambda^2 - l_i} \tag{2}$$

where A_i and l_i are the oscillator strength and oscillator wavelength respectively. The refractive index of GeO_2 doped SiO_2 can be computed from the following equation [16]

$$n^2 = 1 + \sum_{i=1}^{3} \frac{[SA_i + X(\mathrm{GA}_i - SA_i)]\lambda^2}{\lambda^2 - [Sl_i + \mathrm{X}(\mathrm{Gl}_i - Sl_i)]^2} \tag{3}$$

where SA, Sl, GA, Gl are the Sellmeier coefficients for the SiO_2 and GeO_2 glasses and X is the doping concentration of GeO_2 and the material dispersion based on Sellmeier's equation has been taken into account explicitly in the effective index of the PCF. We also calculate Effective Area by [17]

$$A_{eff} = \frac{\left(\iint_s |E_t|^2 \, dxdy\right)^2}{\iint_s |E_t|^4 \, dxdy} \tag{4}$$

Then using effective area we calculate the Nonlinearity parameter by [18]

$$\gamma = \frac{2\pi n_2}{\lambda A_{eff}} \tag{5}$$

where nonlinear refractive index, n_2 for GeO_2 doped SiO_2 can be calculated as [18]

$$n_2 \cong 2.507 + .505\Delta \tag{6}$$

IV. Results and Discussions

The wavelength dependence of Silica glass, GeO_2 and GeO_2 doped SiO_2 based on sellmeier's equation is shown in Fig 2. In Fig. 3 we calculate the chromatic dispersion for different doping concentration of GeO_2 in central core. We can clearly see that the continuous increment of the doping concentration of GeO_2 in the defected core downshift the chromatic dispersion to negative values. In Fig 4-6 we show the variation of the design parameters Λ, *d*, *a* to the total dispersion curve of the PCF to investigate the parameter dependence of the dispersion and nonlinear properties of proposed PCF keeping the doping concentration of GeO_2 doped SiO_2 defected core constant at 53.23%.

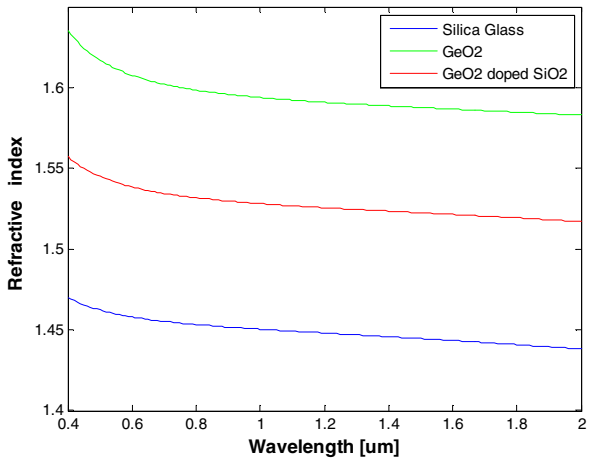

Fig. 2 Plots of refractive index as function of wavelength for Silica Glass, GeO_2 and GeO_2 doped SiO_2 square defected core with GeO_2 doping conc. X=53.23%.

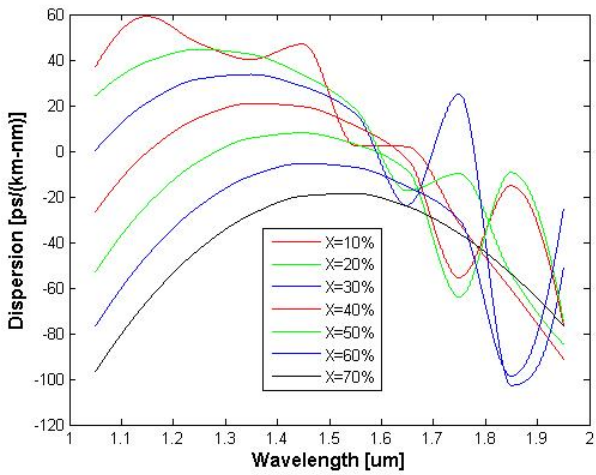

Fig. 3 Plots of dispersion coefficient D versus wavelength for a GeO_2 doped SiO_2 square defected core PCF for different doping concentration of GeO_2, X.

Specifically Fig. 4 shows the variation of the lattice constant Λ to the total dispersion obtained using Eq. (1), for Λ=1.50μm (blue line), Λ=1.55μm (red line), and Λ=1.60μm (green line). Figure 5 shows the variation of the air hole diameter d in the cladding of the PCF, for d/Λ=0.52 (blue line), d/Λ=0.53 (red line), d/Λ =0.54 (green line), while Fig. 6 shows the variation to variation of the defected air-hole diameter in the core of the PCF, for a/Λ=1.312 (blue line), a/Λ=1.325 (red line), and a/Λ=1.338 (green line). According to these numerical results, there exist an optimized set of design parameters that is Λ, d, a and X that lead to ultra-flattened total chromatic dispersion. These optimized values have been obtained through our numerical simulations to be Λ=1.55μm, d/Λ=0.53, a/Λ=1.325 and X=53.23%. Thus the optimized chromatic dispersion responses of the PCF under consideration correspond to the red lines in Fig 4-6. To quantify the performance of our proposed PCF we have achieved two zero dispersion wavelength in O-band and C-band.

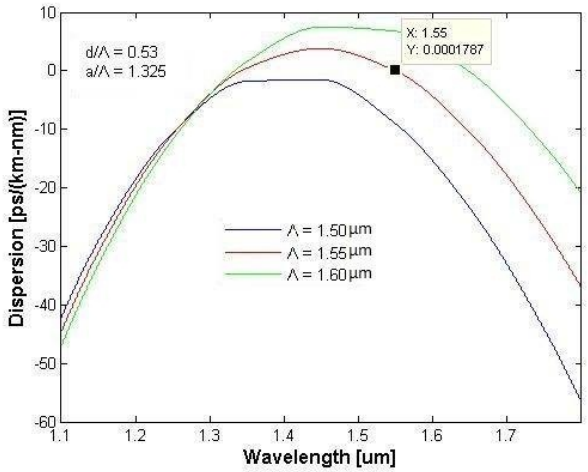

Fig.4 Variation of dispersion versus wavelength with lattice constant Λ as varying parameter for GeO_2 doped SiO_2 square defected core PCF with d/Λ =.53 and a/Λ =1.325 where Λ=1.50µm (blue line), Λ=1.55µm (red line), Λ=1.60µm (green line) with GeO_2 doping conc. X=53.23%.

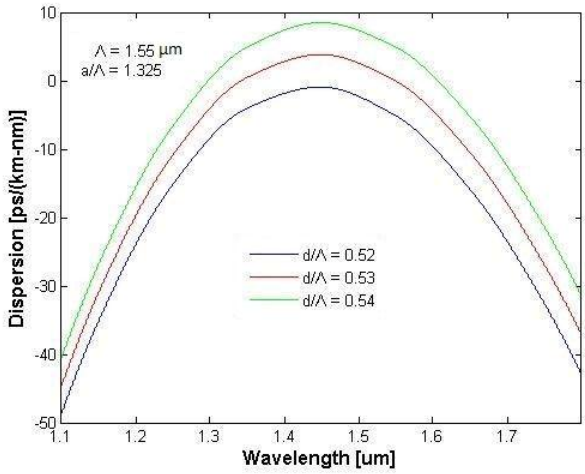

Fig. 5 Variation of dispersion versus wavelength with air hole diameter d as varying parameter for GeO_2 doped SiO_2 square defected core PCF with Λ =1.55 µm and a/Λ =1.325 where d/Λ=0.52 (blue line), d/Λ= 0.53(red line), d/Λ=0.54 (green line) with GeO_2 doping conc. X=53.23%.

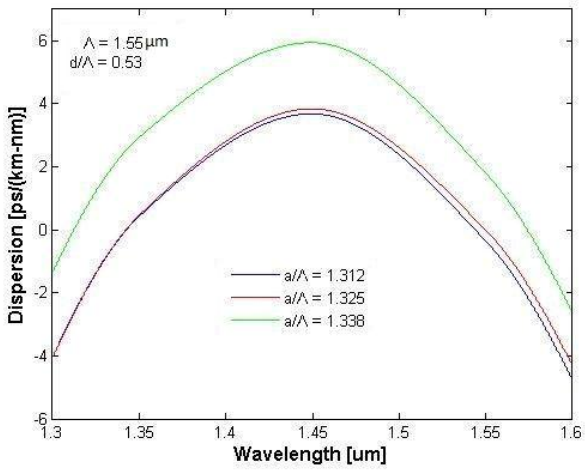

Fig. 6 Variation of dispersion versus wavelength with defected square side length 'a' as varying parameter for GeO_2 doped SiO_2 square defected core PCF with Λ =1.55 µm and d/Λ =1.53 where a/Λ=1.312 (blue line), a/Λ=1.325 (red line), a/Λ=1.338 (green line) with GeO_2 doping conc. X=53.23%.

These results Fig 3-6 show that the newly proposed structure is indeed sensitive to the design parameter X, Λ, d and a. The advantage of our structure is the fact that is much simpler from the design point of view, in comparison to previous designs because it contains less number of design parameters. We have shown already that the proposed PCF structure can exhibit ultra-flattened dispersion characteristics. In practical applications however only the near-zero dispersion characteristics may not be enough for justifying the usefulness of the fiber. Our proposed PCF structure has small effective mode area and high nonlinear gain for nonlinear applications. Fig 7 shows the effective area as a function of wavelength.

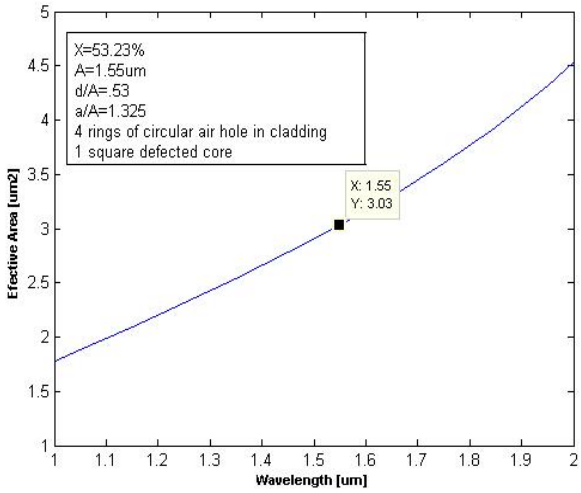

Fig. 7 Variation of Effective area in different wavelength difference for the proposed NZDF for optimized design parameters Λ=1.55 µm, d/Λ=0.53, and a/Λ=1.325.

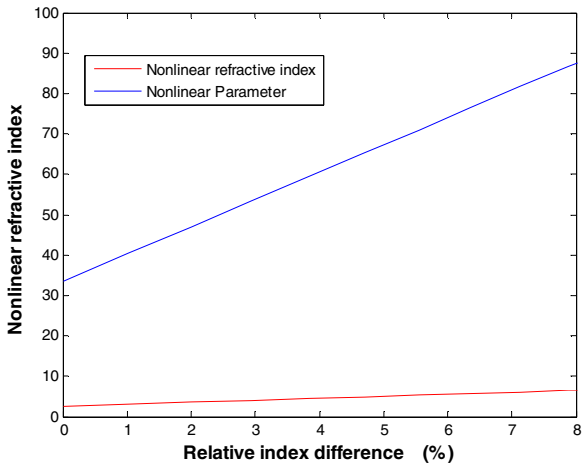

Fig. 8 Plots of Nonlinear refractive index and Nonlinear parameter as a function of relative index difference for the proposed NZDF for optimized design parameters Λ=1.55 µm, d/Λ=0.53, and a/Λ=1.325 d/Λ=0.53(red line), d/Λ=0.54 (green line) with GeO_2 doping conc. X=53.23%.

The nonlinear refractive index, n_2 was plotted using the Eq. 6 as a function of relative index difference as in Fig 8. The nonlinear gain increases while n_2 increases.As the effective area increase, so the nonlinear gain decreases as in Fig 9. At operating wavelength we get small effective area with high nonlinear gain which can be used for Super Continuum Generation, Four Wave Mixing and other nonlinear applications.

In comparison with the ultra-flattened structure, we clearly see in Fig 10 that at operating wavelength the chromatic dispersion is 0.304ps/(km-nm) [11] and proposed structure

gives 0.0001787ps/ (km-nm). The proposed structure also has low effective area than the ultra-flattened structure.

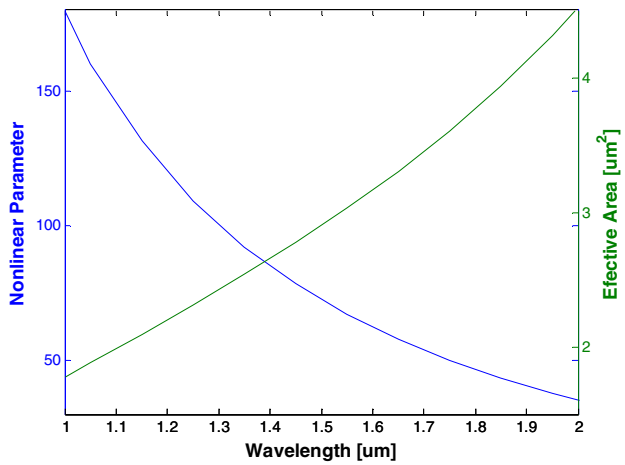

Fig. 9 Variation of effective area and nonlinear parameter as a function of wavelength for the proposed NZDF for optimized design parameters Λ=1.55 µm, d/Λ=0.53, and a/Λ=1.325 d/Λ=0.53(red line), d/Λ=0.54 (green line) with GeO_2 doping conc. X=53.23%.

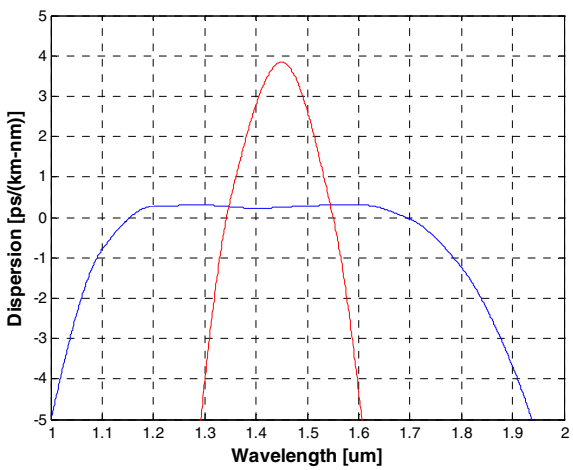

Fig. 10 Comparison of dispersion characteristics between proposed NZDF structure(red line) and ultra-flattened structure (blue line)[11].

V. Conclusions

Dispersion and nonlinear characteristics of GeO_2 doped SiO_2 square defected core PCF is modelled. It is found that at GeO_2 doping concentration 53.23% in defected core with lattice constant Λ=1.55µm, d/Λ=0.53, and a/Λ=1.325,the NZDF shows dispersion coefficient of 0.0001787ps/ (km-nm) with small effective area 3.03µm^2 and high nonlinear gain 67.23W^{-1}km^{-1} at operating wavelength. So this fiber is a suitable candidate for telecommunication application.

Abstract—**Zinc Sulphide (ZnS) is a promising candidate to be an alternative buffer layer to the commonly used cadmium sulphide (CdS) in CZTS solar cells. In this study, buffer layer parameters like layer thickness and buffer layer bandgap have been investigated by Analysis of Microelectronic and Photonic Structures (AMPS-1D) to find out the higher conversion efficiency. A promising result has been achieved with an efficiency of 14.49% (with Voc = 0.81 V, Jsc = 28.85 mA/cm^2 and Fill factor = 67.5) by using ZnS as a buffer layer. It is also found that the high efficiency of CZTS absorber layer thickness is between 2 µm and 4 µm. From the simulation results, it is revealed that higher efficiency can be achieved for the buffer layer bandgap around 3.10 eV - 3.25 eV. This result can be explained by the practical work as the bandgap of ZnS is largely dependent on the preparation conditions and stoichiometry. In conclusion, numerous influences of buffer layer are investigated in CZTS solar cell that can lead to the fabrication of high efficiency devices.**

Index Terms—**CZTS absorber layer, ZnS buffer layer, AMPS 1-D, Thin film solar cells.**

I. Introduction

Thin film photovoltaics (PV) has achieved greater interest during the last few decades for its low material usage, low temperature processing method, variety of deposition process, compatibility with low cost substrates, and also low production costs [1], [2]. Thin film solar cells based on Cadmium Telluride (CdTe), Copper Indium Diselenide (CIS) and Copper Indium Gallium Diselenide (CIGS) has already reached commercialization stage. However, factors like the limitations in the supply of Indium (In) and Tellurium (Te) due to scarcity issue and the restrictions in the usage of heavy metal Cadmium (Cd) because of the toxicity issue have raised concerns about limitations in PV production capacity [3]. In this context, Cu_2ZnSnS_4 (CZTS) as a p-type compound semiconductor having an optimal bandgap of 1.4-1.6 eV in the visible range and a high optical absorption co-efficient (>10^4 cm^{-1}) has attracted much attention [4], [5]. It consists of abundant, inexpensive and non-toxic materials which makes it a strong and promising candidate as a photovoltaic absorber layer to replace CIGS [6], [7]. CZTS based thin film solar cells are still in the R&D stage and are being examined by extensive research activities in order to enhance the overall efficiency for using as a potential absorber for thin film solar cells [8]. To date, the highest efficiency obtained from CZTS solar cells are found as 8.4% and 11.1% for pure sulphur (CZTS) and mixed selenosulpfur (CZTSSe), respectively [9], [10].

To achieve well-behaving PV devices, the selection of an appropriate buffer layer material is very important. In thin film solar cells, buffer layer is an intermediate layer which lies between the absorber and window layer [11]. A buffer layer is expected to make a stable and good p-n junction with the p-type absorber to facilitate electrical conduction. An n-type material with higher bandgap is desired as a buffer layer in order to ensure maximum transmission of photons to reach the absorber layer [12]. Till now, the n-type compound semiconductor Cadmium Sulphide (CdS) having a bandgap of 2.45 eV is the most common and widely used material as a buffer layer [13], [14]. But researchers are in the quest for alternative non-toxic buffer layer materials due to the presence of toxic Cd in CdS [15]. Among different potential alternative materials Zinc Sulphide (ZnS) an n-type compound semiconductor having a wide direct bandgap of 3.5-3.8 eV is considered as one of the most promising materials [16], [17]. The higher bandgap energy of ZnS, compared to CdS is capable of enhancing the blue response of the photovoltaic cells by reducing photon absorption loss. Also the study of the lattice parameters of ZnS and CZTS reveal that, it is an excellent choice for obtaining lattice matched buffer-absorber interface which is another crucial factor for obtaining a high efficiency solar cell [18].

The main theme of this simulation work is to investigate the performance of a CZTS solar cell containing an alternative Cd-free non-toxic buffer layer of ZnS.

II. Methodology

Numerical simulation has now become an essential part of thin film photovoltaic cell designing. It is an important way to predict cell performance and to test the viability of the proposed structure. In this work, Analysis of Microelectronic and Photonic Structures (AMPS-1D) was used to investigate the CZTS solar cell performance with ZnS as the buffer layer. The AMPS-1D program has been developed to realistically simulate the electrical characteristics of the thin film heterojunction solar cells. It has already proven its role as a powerful tool in understanding the device operation and physics for single crystal, poly-crystal and amorphous structures. The schematic view of the structure used in this study is shown in Fig. 1. In the simulation, n-type ZnO:Al, n-type ZnS, p-type CZTS layer parameters are emphasized to investigate the benefits of using ZnS as an alternative buffer

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

layer in CZTS solar cells. By incorporating the various material parameters into AMPS-1D, for all the analysis aspects, changes in the values for efficiency, open circuit voltage, short circuit current and fill factor as well as the effect of different operating temperatures are observed. CZTS is a polycrystalline material and some physical parameters, especially bandgaps depend on doping conditions and compositional ratio as well [20]. The same goes true for other poly crystalline compound semiconductors as well. The role of CZTS absorber layer thickness on the cell performance is investigated by varying the thickness from 1 µm to 4 µm. For the ZnS buffer layer, the bandgap is varied from 3.10 eV to 3.40 eV. The thickness of the same layer is varied from 30 nm to 80 nm to observe the role of buffer layer thickness. Finally, the effect of operating temperature on the cell performance is explored for temperatures ranging from 300 K to 400 K. Table I shows the description of the entire parameters used in this analysis. These values were chosen on the basis of theoretical considerations, experimental data and existing literature or in some cases by reasonable estimations [19], [20].

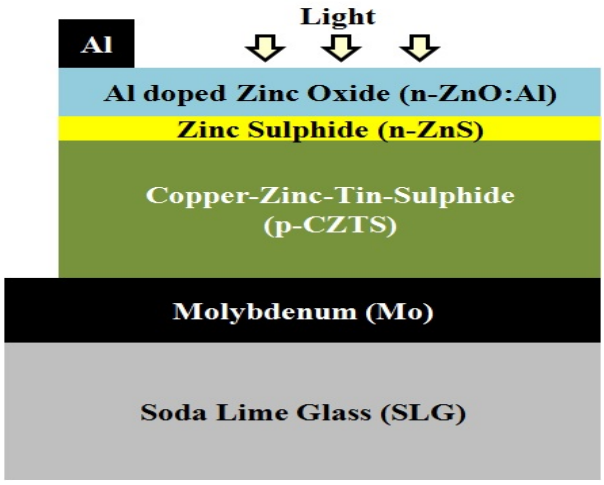

Fig. 1 CZTS solar cell structure used in the simulation.

TABLE I
SEMICONDUCTOR PARAMETERS USED IN THE SIMULATION

Parameters	n-ZnO:Al	n-ZnS	p-CZTS
Thickness, W (µm)	0.2	0.03-0.08	1-4
Dielectric ratio, $\varepsilon/\varepsilon_o$	9.0	10	10
Electron mobility, μ_n (cm^2/Vs)	100	100	100
Hole mobility, μ_p (cm^2/Vs)	25	25	25
Carrier concentration, n/p (cm^{-3})	10^{18}	9.0×10^{17}	2×10^{15}
Bandgap, Eg (eV)	3.30	3.10-3.40	1.40
CB Density of states, N_C (cm^{-3})	2.2×10^{18}	1.5×10^{18}	2.2×10^{18}
VB Density of states, N_V (cm^{-3})	1.8×10^{19}	1.8×10^{18}	1.8×10^{19}
Electron affinity, χ (eV)	4.60	4.50	4.10

III. RESULTS AND DISCUSSION

A. Variation of CZTS absorber layer thickness

In order to explore the effects of absorber layer thickness in the overall cell performance, the CZTS absorber layer is varied from 1 µm to 4 µm. During the simulation, the ZnS buffer layer thickness was considered as 40 nm. It has been found that, the efficiency of the solar cell increases with the increase in absorber layer thickness as shown in Fig. 2. Actually thicker absorber layer increases the minority carrier diffusion length. This means the diffusion length for the electrons in the p-type absorber increases. The thicker absorber layer allows more photons with longer wavelengths to be absorbed resulting in more electron-hole pair (EHP) generation. The generated electrons are subsequently collected resulting improved cell efficiency. Moreover, the depletion region also increases with the increased absorber layer thickness. Hence, electrons can drift towards the n-type buffer due to the electric field produced by the depletion region easily.

From Fig. 2, it is observed that, the solar cell output parameters are almost constant for the absorber layer thickness over 3 µm. This phenomenon indicates that, there lies an optimum value of thickness beyond which the output parameters do not show significant improvement. For the proposed cell in this work, the optimum value of absorber layer thickness is considered as 3 um. A conversion efficiency of 14.49% (V_{oc}= 0.81 V, J_{sc}= 28.85 mA/cm^2, FF = 67.5) has been achieved with the optimum thickness of 3 µm CZTS absorber layer.

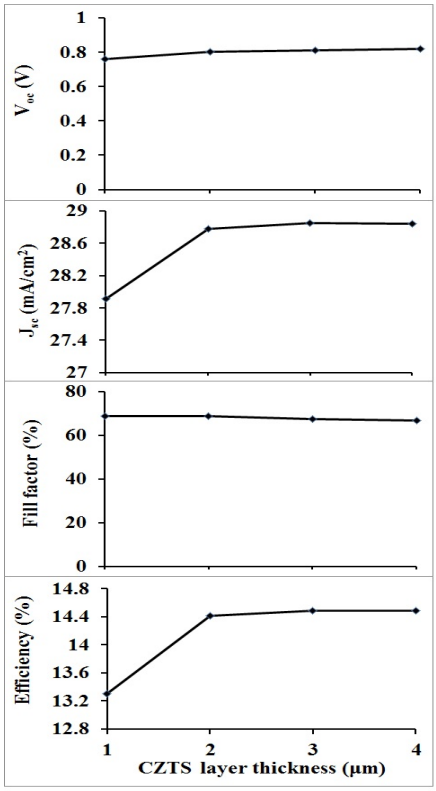

Fig. 2 Cell performance with various CZTS thickness.

B. Variation of ZnS buffer layer thickness

The proposed alternative ZnS buffer layer is free from toxic elements. Both zinc and sulphur are cheap and abundant in the nature. In this simulation, the ZnS buffer layer thickness has been varied between 30 nm to 80 nm to observe the effect of buffer layer thickness. It is found that, the more thinner the buffer, the higher is the efficiency of the overall cell. Basically

thinner buffer layers allow the majority of the photons to be transmitted towards the absorber layer reducing undesired electron hole pair generation in the buffer region. As the thickness of the buffer layer is raised, the efficiency tends to drop as the photons are being absorbed in the buffer layer portion of the thin film solar cell.

Solar cell with 40 nm of ZnS buffer layer recorded the highest efficiency for the proposed thin film solar cell. Although from the simulation results, shown in Fig. 3 depicts the possibility of raising the efficiency value with thinner buffer layers, but from the practical point of view a question will be raised about their feasibility. A trade off or an optimum value of buffer layer thickness must be maintained, as the buffer layer serves as a heterojunction partner for the CZTS absorber layer. Moreover, it serves as a protection layer during TCO sputtering and insulates pin-holes to avoid shorting between the TCO and absorber layers. Fabricating a thin film solar cell with minimum buffer layer thickness may damage the whole cell by shorting the absorber layer and TCO layer (used for the collection of carriers).

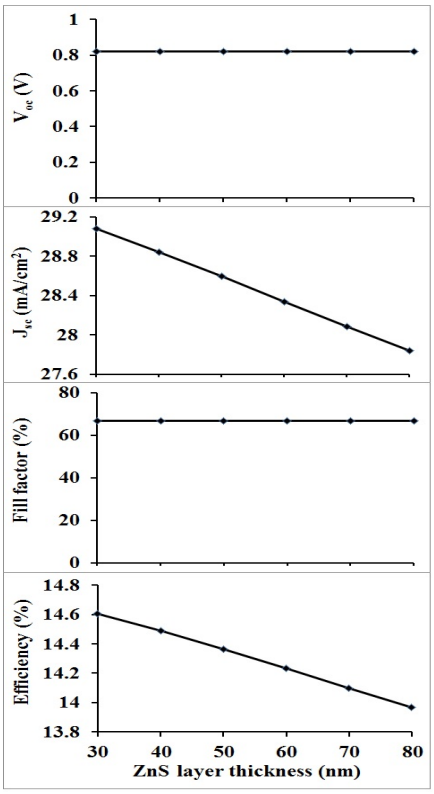

Fig. 3 Overall performance in respect to various ZnS thickness.

C. Effect of the buffer layer bandgap

The bandgap of the buffer layer plays an important role for heterojunction thin film solar cells. The bandgap value for ZnS is typically 3.54 eV for cubic phase. Whereas, the bandgap for conventional CdS buffer layer is 2.45 eV. The higher bandgap of ZnS compared to the conventional CdS can enhance the blue response of the photovoltaic cell by reducing absorption towards the lower wavelength region. Although theoretically, the buffer layer of ZnS lies between 3.5-3.7 eV but it can be tuned to match with the absorber and window layer by varying different deposition parameters like substrate temperature, pressure, stoichiometry, deposition techniques, etc. In our previous work [13], smaller values of ZnS bandgap than the theoretical range stated earlier were found by practical deposition. In this study, the bandgap of ZnS is varied between 3.10 eV to 3.40 eV. The reason for choosing slightly lower bandgap value than the typical for ZnS is because of the band bending in the TCO/ZnS interface. Since the TCO material ZnO:Al has a bandgap of 3.30 eV, therefore, ZnS having bandgaps higher than the ZnO:Al will result in lower efficiencies. Fig. 4 shows the variation of V_{oc}, J_{sc}, Fill factor and efficiency with the change of bandgap for the ZnS buffer layer.

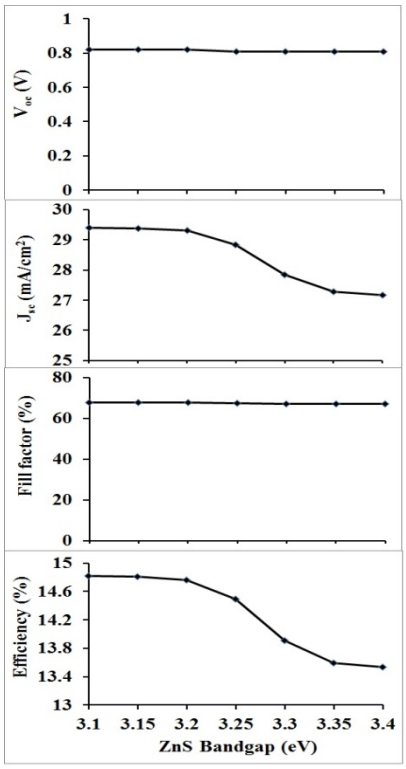

Fig. 4 Cell performance with various ZnS bandgap.

D. Operating temperature effects

The operating temperature of the solar cell plays a crucial role in determining the performance of the solar cell. It affects the parameters such as: effective density of states, absorption coefficients, electron and hole mobility, bandgaps and carrier concentration of the materials. The effect of operating temperature has been investigated in this work for the temperatures ranging from 300 K to 400 K. From Fig. 5 it is observed that, the efficiency and other output parameters degrade drastically with the increase in the operating temperature. With higher temperature, an additional thermal energy is gained by the electrons. This extensive energy gained by the electrons create an unstable situation and causes to recombine with the holes before they could reach the depletion region and get collected.

The reason for the decreasing trend of V_{oc} and J_{sc} with higher operating temperatures can be understood from this phenomenon. The optimum temperature for solar cell operation is 300 K, which is room temperature. But in practical scenarios, the solar panels are installed outside with direct exposure of sunlight in an open environment. The operating temperature of a solar panel increases as the sun light causes heating of the solar panels. Hence the solar cell usually operates at temperatures higher than 300 K.

Considering the baseline parameters, the final J-V curve is shown in Fig. 6.

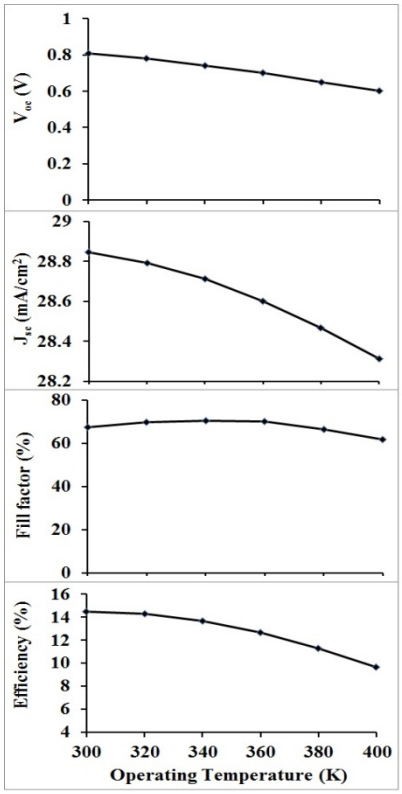

Fig. 5 Cell performance with various operating temperatures.

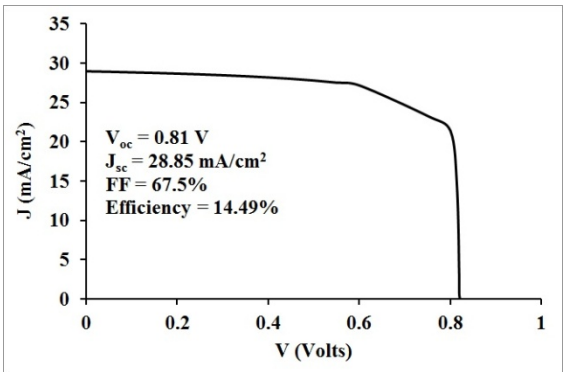

Fig.6 J-V characteristics of the best CZTS cell.

IV. Conclusions

From this numerical analysis, the electrical performances of the CZTS solar cells having ZnS as an alternative to conventional CdS buffer layer have been investigated in terms of buffer layer bandgap and thickness. Increasing absorber layer thickness results in higher efficiency upto a certain extent. Changing the buffer layer thickness also results in higher efficiency as well as improved J_{sc}. There is also room for improvement of the overall efficiency of the proposed solar cell by tuning the bandgap of the buffer layer material. The highest efficiency of 14.49% (with Voc = 0.81 V, Jsc = 28.85 mA/cm2 and Fill factor = 67.5) has been achieved after optimization of the structure. A new challenge to fabricate large-area CZTS thin film solar cell with ZnS as a non toxic and Cd-free buffer layer has been opened up by transferring the new device structure case developed in AMPS-1D.

Abstract— **In this paper, a modified structure for CdTe thin film solar cell was proposed by numerical analysis with an addition of a novel ZnO buffer to improve the conversion efficiency. The CdS window layer was reduced to 50 nm together with the insertion of zinc oxide (ZnO) as the buffer layer to prevent forward leakage current. The thickness of CdTe absorber layer was varied from 1000 nm to 5000 nm and as well as the operating temperature was also varied from 25°C to 165°C. The numerical simulation was done by Analysis of Microelectronic and Photonic Structures (AMPS-1D) simulator. The highest conversion efficiency obtained was 20.27% (Voc = 1.08 V, Jsc = 24.93 mA/cm^2, FF = 0.83) with 5000 nm CdTe absorber layer and 50 nm CdS window layer. Moreover it was observed that with the increase in operating temperature, the normalized efficiency decreased linearly at a gradient of 0.2%/°C, which reveals that the CdTe thin film solar cell has higher stability.**

Index Terms—**Thin film solar cell, CdTe, ZnO, AMPS-1D.**

I. Introduction

The solar energy is the most reliable and abundant form of renewable energy today that may serve as a major alternative option for the ever growing need of energy where energy from non-renewable sources are becoming scarce with time. The environmental friendly feature and its abundant nature made renewable energy as one of the most promising topic in present times. The solar cells which work on the principle of photovoltaic effect could be a possible alternative energy supplier to meet the crisis. Thin film based solar cells are now becoming a popular topic among the researchers and commercials because of its higher efficiency, low manufacturing cost and better stability [1]-[4]. Cadmium Telluride (CdTe) based solar cells are ideal because of its higher absorption coefficient (>5×10^5/cm) and direct band gap energy (Eg) of 1.45eV which corresponds quite significantly with the sunlight spectra [5]-[7]. CdTe is a very promising absorber layer because of its long term performance stability in thin film heterojunction solar cells [8]. Furthermore, various deposition techniques could be used to deposit CdTe thin films which include close space sublimation (CSS), vapour transport deposition (VTD), physical vapour deposition (PVD), metal organic chemical vapour deposition (MOCVD), electro-deposition and screen printing [9]. The objective of this paper is to obtain a highly efficient and stable CdTe solar cell which had been studied using AMPS-1D simulator. The effect of varying absorber layer thickness and variation in cell operating temperature were analysed in this work. The highest efficiency (□) obtained for the variation in CdTe absorber layer thickness and variation in operating temperature were 20.27% and 18.89% respectively.

II. Modelling and Simulation

The reason behind numerical analysis for a solar cell is a vital way to predict the cell performance and to check the feasibility of the proposed structure. The parameters that can be varied during modelling of a solar cell are more than 50 and these parameter values depend on deposition methods, fabrication techniques, ambient condition, etc. The simulation for this work was done by Analysis of Microelectronic and Photonic Structures (AMPS-1D) to study the performance of CdTe thin film solar cell. The AMPS-1D simulation program has been tested for CdTe and CIGS thin film solar cells and the program has been developed to realistically simulate the electrical characteristics of the thin film heterojunction solar cells.

Fig.1 below shows the conventional baseline structure for CdTe thin film solar cell as well as the modified superstrate structure (Glass/SnO_2/ZnO/Cds/CdTe/Ag) to obtain better conversion efficiency. The modified structure has a new or an extra layer (ZnO) in between TCO and CdS to obtain better performance and thus it can be said that the front contact consists of TCO and a buffer layer (ZnO). In the modified structure, silver (Ag) is used as the back contact instead of gold (Au) keeping the low cost feature into consideration.

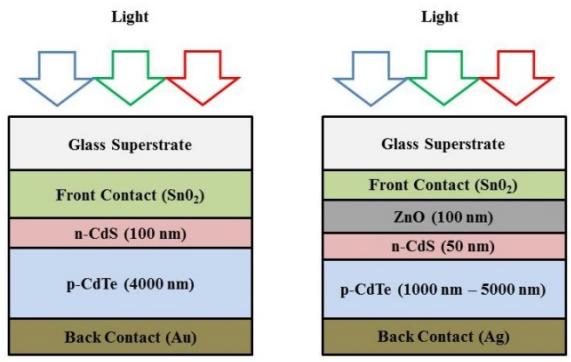

Fig.1 (a) Conventional CdTe Solar Cell Structure (b) Modified CdTe Solar Cell Structure

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

In this analysis after introducing a buffer layer (ZnO), at first the thickness of the CdTe absorber layer were varied from 1000 nm to 5000 nm and secondly the operating temperature were varied from 25°C to 165°C . It was ensured that only one parameter varied at a time during the simulation process whereas the other parameters were kept fixed.

The table below illustrates the details of all the parameters used in this analysis which were selected on the basis from literature, theory and experimental data [7], [10]-[11].

TABLE I
PARAMETERS USED FOR SIMULATION

Parameters	SnO_2	ZnO	n-Cds	p-CdTe
Thickness, W (μm)	0.5	0.1	0.05	1.00 - 5.00
Dielctric ratio, ε/ε□	9.0	9.0	10.0	9.40
Electron mobility, μ_C (cm^2/Vs)	100	100	100	320
Hole mobility, μ_P (cm^2/Vs)	25	25	25	40
Carrier concentration, n, p, (cm^{-3})	1.0×10^{20}	1.5×10^{18}	1.1×10^{18}	1.0×10^{18}
Band gap, E_g (eV)	3.30	3.30	2.40	1.50
Density of states, N_C (cm^{-3})	2.2×10^{18}	2.2×10^{18}	2.2×10^{18}	7.5×10^{17}
Density of states, N_V (cm^{-3})	1.8×10^{19}	1.8×10^{19}	1.8×10^{19}	1.8×10^{19}
Electron affinity, χ (eV)	4.20	4.50	4.50	4.28

III. RESULTS AND DISCUSSION

This simulation work is done by insertion of a new layer of ZnO to the baseline structure to improve the performance of the conventional CdTe solar cells. The Cds layer was reduced to 50 nm in order to achieve better performance of CdTe thin film solar cells but this reduced thickness might allow forward leakage current to flow to the front contact through possible pinholes in CdS layer. To prevent this undesired forward leakage current a high resistive buffer layer of ZnO was inserted in between the front contact TCO and CdS window layer. The starting point of this work was by modelling a device which comprises of four layers SnO_2/ZnO/CdS/CdTe respectively. The structure for the device was kept fixed during the full simulation process. The performance of the cell and its dependency on the CdTe layer thickness from 1000 nm to 5000 nm and on the operating temperature from 25 °C to 165 °C had been simulated using the AMPS-1D simulator.

A. Effect of CdTe Layer Thickness

The theoretical document shows that the minimum thickness required for CdTe thin films to absorb 99% of the incident photons with energy greater than the band gap (Eg) is approximately 1 to 2 μm [12]. In this work, the CdTe layer thickness was varied from 1000 nm to 5000 nm and the cell output parameters such as Jsc, Voc, FF and η were measured using AMPS-1D simulation. Then the J-V curve and graph for Q.E was plotted for the parameters which showed the highest efficiency during thickness variation. The cell output parameters which are Jsc, Voc, FF and η had been shown in Fig: 2 with the variation in CdTe layer thickness.

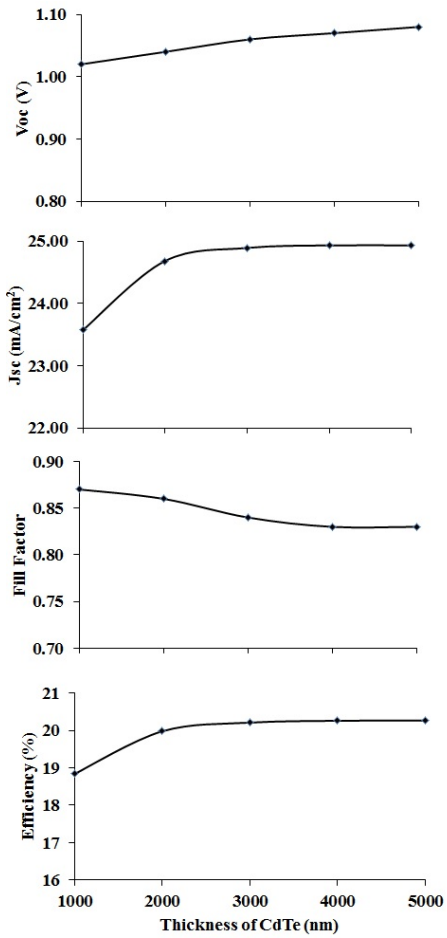

Fig.2 Effect of CdTe thickness on cell output parameters

The variation in CdTe absorber layer thickness caused the output parameters to change gradually. The value of Voc improved at a slow rate with the increase in thickness but the change in Jsc was significant when the thickness of CdTe absorber layer increased from 1000 nm to 2000 nm and after that the Jsc value increased at a slow rate and had a value of 24.93 mA/cm^2 when the thickness went up to 5000 nm. On the other hand, the FF reduced slightly and then almost remained constant from 3000 nm to 5000 nm thickness of CdTe absorber layer. However the efficiency improved significantly with the increase in CdTe absorber layer thickness from 1000 nm to 3000 nm and then the rate of increase became less and the highest conversion efficiency attained was 20.27% (Voc = 1.08 V, Jsc = 24.93 mA/cm^2, FF = 0.83) at 5000 nm thickness of CdTe absorber layer. The J-V curve and the QE graph were illustrated in Fig: 3. Improvement in cell efficiency with the increase in thickness of CdTe absorber layer was evident from the J-V curve and the figure also showed that the final cell output characteristics were having acceptable low series resistance and high shunt resistance, confirming higher Jsc, Voc, FF and which eventually contributed to higher conversion efficiency. The QE graph showed that the light absorption was good from wavelengths of 450 nm to 750 nm.

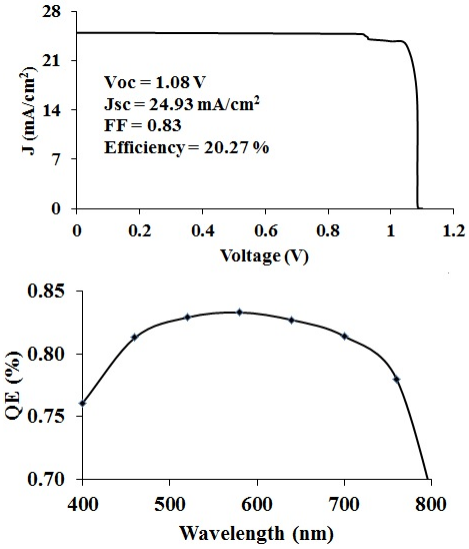

Fig.3 J-V and QE characteristics for thickness variation of CdTe

B. *Effect of Operating Temperature*

The operating temperature plays a very important part in real situations that affects the performance of the overall solar cell. The parameters like the effective density of states, absorption coefficients, electron and hole mobility, carrier concentrations and band gaps of the materials are affected at higher operating temperatures [13]. In this part of the simulation work, the operating temperature of the solar cell was varied from 25 °C to 165 °C. The parameters such as Voc, Jsc, FF and η were measured and illustrated in Fig.4.

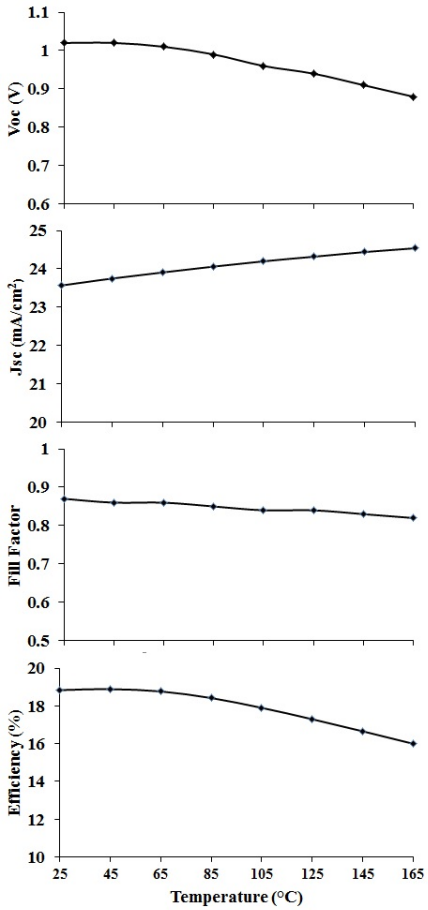

Fig.4 Effect of temperature on cell output parameters

The value of Voc decreased gradually with the increase in operating temperature and similar trend was observed for the FF graph. However the value of Jsc somewhat increased steadily with the rise in operating temperature. The highest conversion efficiency obtained was 18.89% (Voc = 1.02 V, Jsc = 24.54 mA/cm^2, FF = 0.82) at 45 °C and after that the efficiency (η) decreased with the increase in temperature up to 165 °C. Then the graph for J-V and QE was plotted for the CdTe thin film solar cell that obtained the highest efficiency during the variation in operating temperature. From the QE plot in Fig.5, it is observed that the maximum light absorption were from between wavelengths of 450 nm to 650 nm.

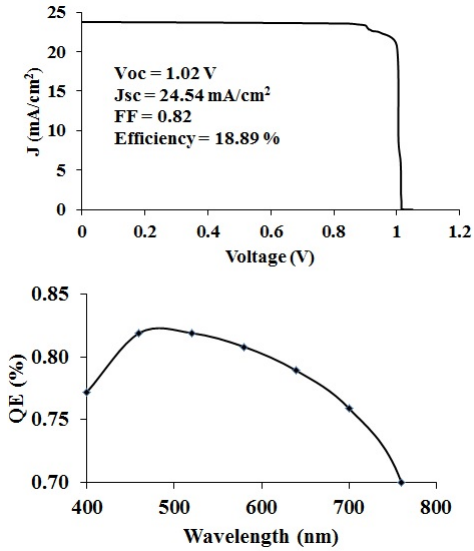

Fig.5 J-V and QE graph for operating temperature variation of CdTe

The effect of temperature could be measured by another parameter named as the temperature coefficient, which means the change of power of solar cell for increase or decrease of operating temperature per degree centigrade. From Fig.6, it is observed that the normalised efficiency (η) decreased linearly at a gradient of 0.2% / °C with the increase in operating temperature which also showed the higher degree of stability of the CdTe thin film solar cell at higher operating temperature or in stressed conditions. The above mentioned statements are in good agreement with the related works [14] – [15].

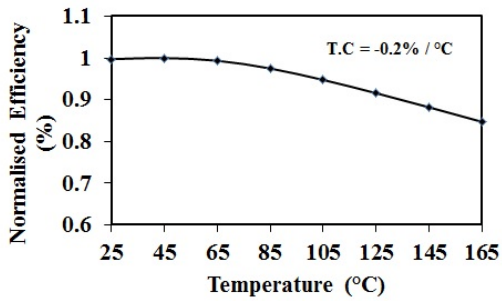

Fig.6 Effect of operating temperature on normalized efficiency

IV. CONCLUSIONS

The numerical analysis in this work showed design optimization of the conventional CdTe based solar cells with minimal changes keeping a cautious concern over minimal production cost. A highly efficient CdTe thin film solar cell with an absorber layer thickness of 5000 nm and CdS thickness of 50 nm has been achieved. Furthermore, by

reducing the thickness of CdS window layer and insertion of ZnO as a buffer layer helped to raise the conversion efficiency up to 20.27% (Voc = 1.08 V, Jsc = 24.93 mA/cm^2, FF = 0.83). Finally, from the temperature coefficient (T.C = -0.2%/°C), it showed that the stability of this CdTe thin film solar cell was good at higher operating temperatures. Therefore, it is hoped that with this modified structure with all realistic approaches or modification, an efficient and cost effective CdTe thin film solar cell can be fabricated using standard fabrication technique for practical implementation.

ACKNOWLEDGMENT

The authors would like to acknowledge and appreciate the contribution of the Ministry of Education of Malaysia through its research grant with code FRGS/1/2013/TK07/UKM/01/3. Appreciations are also extended to the VP unit of the King Saud University (KSU) of Saudi Arabia.

Abstract— **The main objective of this paper is to make a detailed modelling of a single solar cell incorporating basic operating equations and include the dependence of cell temperature on irradiance as a combined effect in the model. For this purpose at first the change of open circuit voltage and short circuit current at varying operating conditions like irradiance and temperature is theoretically explored. After that, a simulink model is made using MATLAB to simulate the separate and combined effect of irradiance and temperature on single solar cell and the output curves are analyzed to compare the model with used module's datasheet. Then fall of open circuit voltage with irradiance due to temperature effect is illustrated and explained in detail .**

Index Terms— **NOCT, PV module, sun simulator, SRE.**

I. Introduction

Due to diminishing fossil fuel energy resources and increasing demand for power, the world is gradually moving towards sustainable renewable energy resources. Sustainability and abundance of solar radiant energy are important factors characterize the energy through the PV (photovoltaic) effect among the renewable resources. Despite the intermittent nature of sunlight solar energy is widely available and completely free of cost. Solar irradiance and temperature are the essential factors that affect the output characteristics of a solar cell. The open circuit voltage increases in logarithmic way with solar irradiation whereas the short circuit current increases linearly. The dominant effect with increasing cell's temperature is the linear decrease of open circuit voltage, the cell is then subjected to less efficiency. The short circuit current slightly increases with temperature.

In brief temperature and irradiance are the key factors which have a substantial effect on the performance of solar cell. Prior to our thesis work, we have come across theoretical and experimental data where the effect of temperature on solar cell is shown but the irradiance is kept constant and other data are found where the temperature is kept constant and irradiance is kept constant. However, it is quite preposterous to assume that one of these variables is kept constant and other is varied indefinitely in environmental operating condition. In reality, both irradiance and temperature can vary simultaneously in environmental operating condition. In our thesis work we have constructed a simulink model of solar cell using MATLAB which can simulate the effect of simultaneous change of irradiance and temperature on solar cell and approximate the environmental operating condition where both the irradiance and temperature of solar cell is liable to change.

II. General Model Representation

A general theoretical model of PV module is studied from the reference [1-3]. As shown in Fig. 1, the equivalent circuit of the general model is composed of photo current source, diode, parallel resistor expressing the leakage current, and series resistor describing the internal resistance to the current flow. The *I-V* characteristic equation of a PV cell is given as:

$$I = I_{PH} - I_S\left(\exp\left[\frac{q(V+IR_S)}{kTA}\right]-1\right) - \frac{(V+IR_S)}{R_{SH}} \quad (1)$$

where, I_{PH} is a light-generated current or photo current, I_S is the cell saturation f dark current, q (=1.6×10^{-19}C) is the electron charge, k (=1.38×10^{-23}J/K) is Boltzmann constant, T is the cell working temperature, A is the ideality factor, R_{SH} is the shunt resistance, and R_S is the series resistance.

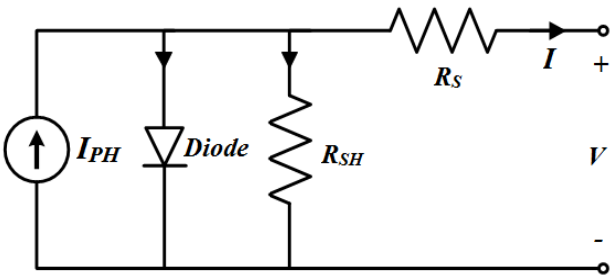

Fig. 1 Equivalent circuit of a solar cell

The photocurrent mainly depends on the solar irradiance and cell working temperature, which is given as:

$$I_{PH} = \lambda\left(I_{SC} + K_I\ (T - T_r)\right) \quad (2)$$

where, I_{SC} is the cell short-circuit current at a 25 ^{0}C and 1 kW/m^2, K_I is the cell short-circuit current temperature coefficient, T_r is the cell reference temperature, and λ is the ratio of ambient solar irradiance to 1sun irradiance (1000 W/m^2). On the other hand, the cell saturation current varies with cell temperature, which is described as:

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

$$I_S = I_{RS} \left(\frac{T}{T_r}\right)^3 \exp\left[q\, E_G \frac{\left(\frac{1}{T_r} - \frac{1}{T}\right)}{kA}\right] \quad (3)$$

where, I_{RS} is the cell reverse saturation current at a reference temperature and a solar radiation, E_G is the band gap energy of the semiconductor used in the cell which can is related to temperature as [4]:

$$E_G(T) = E_G(0) - \frac{\alpha T^2}{T + \beta} \quad (4)$$

where, α and β are constants specific to each semiconductor. For silicon $E_G(0) = 1.169\ eV$, $\alpha = 4.9 \times 10^{-4}\ eV/K$ and $\beta = 655\ K$ [5].

Finally, the reverse saturation current at reference temperature (T_r) can be approximately obtained as:

$$I_{RS} = \frac{I_{SC}}{\exp\left[\frac{qV_{OC}}{N_s kAT}\right] - 1} \quad (5)$$

where, I_{SC} is the short circuit current, N_s is the number of series connected cell and V_{OC} is the open circuit voltage of the module at reference temperature.

III. Temperature Effect

In this section, change of open circuit voltage (V_{OC}) and short circuit current (I_{SC}) with temperature is theoretically explored keeping irradiance level constant.

A. Change of V_{OC}

Temperature has a dominant effect on V_{OC} which can be described by the following equation [6]:

$$V_{OC2} = V_{OC1} \left(\frac{T_2}{T_1}\right) + \frac{E_G}{e}\left(1 - \frac{T_2}{T_1}\right) \quad (6)$$

where, V_{OC1} is the open circuit voltage at temperature $T_1{}^0K$ and V_{OC2} at $T_2{}^0K$. If we take the differential form of equation (5) then we get:

$$\frac{dV_{OC}}{dT} = \frac{1}{q}\frac{dE_G}{dT} - \frac{1}{T}\left(\frac{E_G}{q} - V_{OC}\right) \quad (7)$$

After analyzing these equations we can conclude that for silicon solar cell, for every 1^0C increase in temperature V_{OC} drops by about 0.002/0.55≈0.4% from its room temperature value [7].

B. Change of I_{SC}

Change of short circuit current with temperature is negligible. Actually, there is a very small increase of short circuit current with temperature.

IV. Irradiance Effect

In this section, change of open circuit voltage (V_{OC}) and short circuit current (I_{SC}) with irradiance is theoretically studied keeping temperature constant.

A. Change of V_{OC}

Open circuit voltage changes logarithmically with irradiance (indicated by I_1 and I_2) as follows:

$$V_{OC2} = V_{OC1} + \frac{nk_B T}{e} \ln\left(\frac{I_2}{I_1}\right) \quad (8)$$

B. Change of I_{SC}

Short circuit current is linearly dependent on irradiance which is given by the following equation:

$$I_{SC2} = I_{SC1} \left(\frac{I_2}{I_1}\right) \quad (9)$$

V. Combined Effect of Temperature and Irradiance

Cell temperature is a parameter of great importance as it has immense effect on cell efficiency and other output parameters. It depends on module encapsulating material, it's thermal dissipation, absorption properties, working point and also on atmospheric parameters such as irradiance level, ambient temperature, wind speed etc.

It is very common to use a parameter named NOCT (Nominal Operating Cell Temperature) as an indication of module temperature. NOCT is defined as the mean solar junction temperature with an open rack mounted nodule in SRE (Standard Reference Environment) which is defined as a condition when the tilt angle is at normal incidence to the direct solar beam at local solar noon, total irradiance is 800 W/m^2, ambient temperature is 20 ^{0}C, wind speed is 1m/s, with no electrical load.

To relate the cell temperature with the change of irradiance Ross, R.G. (1980) approximation is used in the mode. The approximation is described as [8]:

$$T_{Cell} = T_{air} + \frac{NOCT - 20}{80} S \times \frac{1000}{10000} \quad (10)$$

where, T_{Cell} is the cell temperature T_{air} is the air temperature and S is the irradiance level.

VI. Simulink Model and Output Curves

The characteristics of MSX 60 PV module as shown in Table I is used in the MATLAB model of single solar cell [9].

Table I
Electrical characteristics of MSX 60 PV module

Description	MSX 60
Maximum power (P_m)	60 W
Voltage at P_{max} (V_m)	17.1 V
Current at P_{max} (I_m)	3.5 A
Guaranteed minimum power	58 W
Short circuit current (I_{SC})	3.8 A
Open circuit voltage(V_{OC})	21.1 A
Temperature co-efficient of V_{OC}	-(80±10) mV/ ^{0}C
Temperature co-efficient of I_{SC}	(0.065±0.15) % / ^{0}C
Temperature co-efficient of power	-(0.5±0.05) % / ^{0}C
NOCT	47±2 ^{0}C

As this module consists of 36 polycrystalline silicon solar cells electrically configured as two series strings of 18 cells each so we divided the voltage parameters by 36 in our model. The used values of parameters in the model are shown in TABLE II.

TABLE II Model parameters	
Parameters	Value
Voltage at P_{max} (V_m)	17.1/36 V
Current at P_{max} (I_m)	3.5 A
Open circuit voltage(V_{OC})	21.1/36 V
Short circuit current (I_{SC})	3.8A
Temperature co-efficient of I_{SC} (K_I)	3 mA/°C
Air temperature (T_{air})	25°C
Reference temperature (T_r)	25°C
NOCT	47°C

Using the parameter values from TABLE II and incorporating the equations from (1) to (5) and (10), a simulink model for single silicon solar cell is procured. By this model, *I-V* and *P-V* curve can be obtained by varying temperature with fixed irradiance as shown in Fig.2 and Fig.3 or varying irradiance with fixed temperature as shown in Fig.4 and Fig.5.

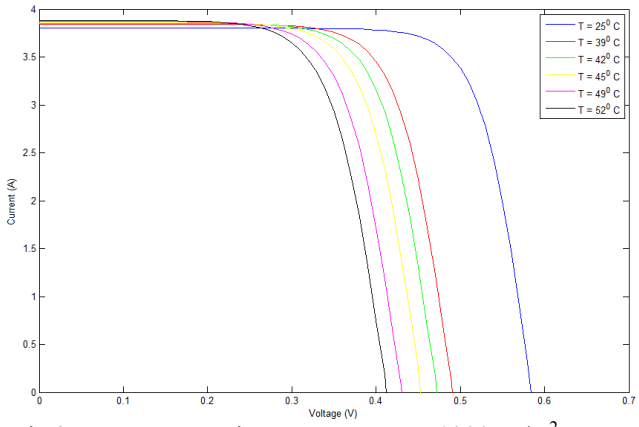

Fig.2 *I-V* curve varying temperature at 1000 W/m^2 constant irradiance level

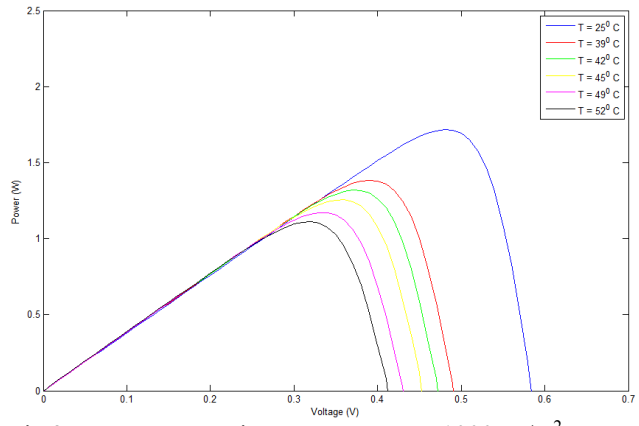

Fig.3 *P-V* curve varying temperature at 1000 W/m^2 constant irradiance level

Again when the relation in equation (10) is used then the combined effect of irradiance and temperature on *I-V* and *P-V* characteristics can be obtained as shown in Fig.6 and Fig.7.

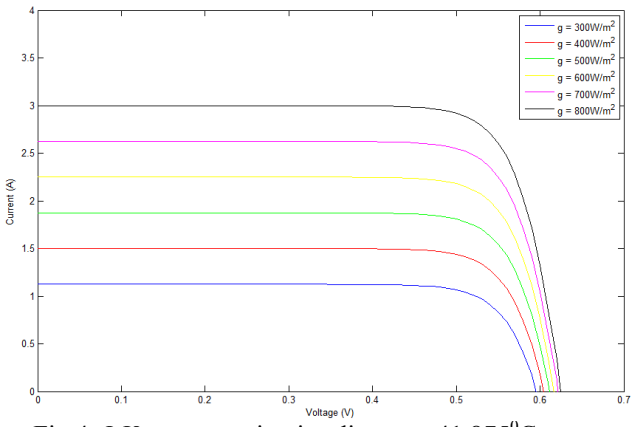

Fig.4 *I-V* curve varying irradiance at 41.875^{0}C constant temperature

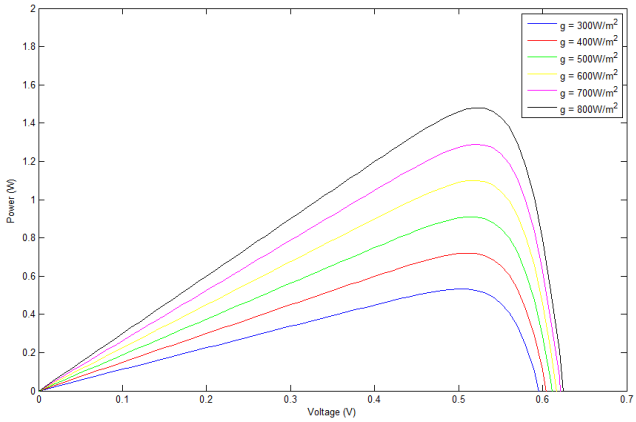

Fig.5 *P-V* curve varying irradiance at 41.875^{0}C constant temperature

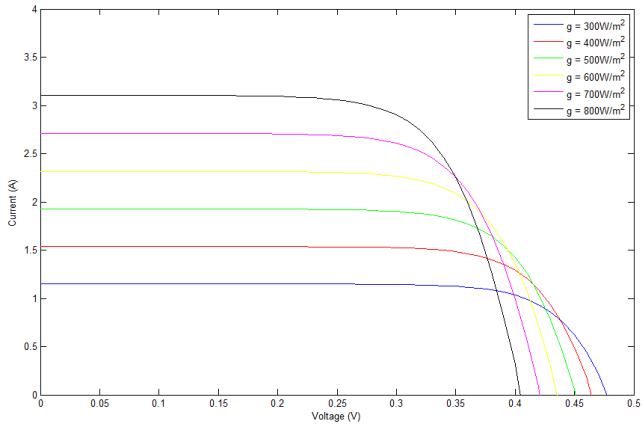

Fig.6 *I-V* curve of the combined effect

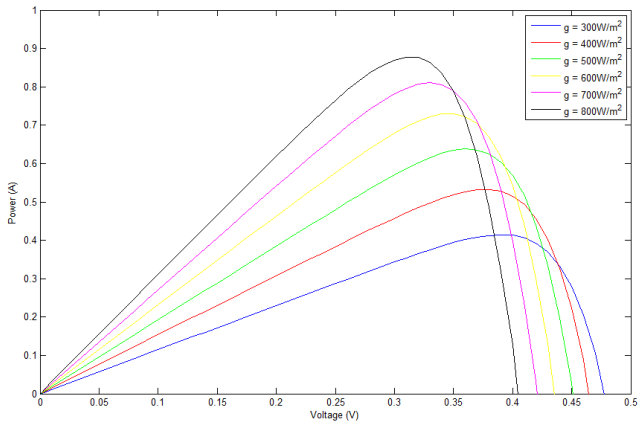

Fig.7 *P-V* curve of the combined effect

In the last case, irradiance is varied as result the cell temperature does not remain constant as in normally practiced modelling cases, rather it varies inherently according to the approximation in equation (10). As a result we get a practical operating scenario of varying cell temperature with irradiance.

VII. Analysis and Discussion

A. Conformity with practical module

In Fig.2 the blue curve is for 1000 W/m^2 irradiance and 25^{0}C operating cell temperature which is the reference operating condition of MSX 60 PV module. From the data sheet of MSX 60 PV module it can be verified that output curve (i.e. V_{OC}= 0.586V=21.1/ 36 and I_{SC}= 3.8A) is almost same at the reference condition as the data sheet value; which implies the accuracy of the simulink model [10].

B. Temperature and Irradiance effect separately

From Fig.2 it is observed that, with the rise of temperature there is a small increase in short circuit current and a remarkable decrease in open circuit voltage as expected theoretically from equation (7). One additional thing from Fig.3 is the fall of power output with the rise of temperature as expected.

From Fig.4, it can be noticed that, with the rise of irradiance the short circuit current rises remarkably as a result of linear relation as shown in equation (9) but the rise open circuit voltage is not so remarkable because of having a logarithmic relation as discussed by equation (8). Fig.5 can be explained as a manifestation of the rise of power with irradiance level.

C. Temperature and Irradiance effect combindly

From Fig.6 it is noticed that, as with the rise of irradiance the cell temperature also rises; both the open circuit voltage and short circuit current changes simultaneously by their dominant issues called temperature and irradiance respectively. Short circuit current rises with irradiance and open circuit voltage falls with temperature remarkably. As a result we get a rarely cited but practically obvious scenario. That is the fall of open circuit voltage with the rise of irradiance due to temperature effect. This is because temperature has a dominant influence on open circuit voltage as the temperature level increases the open circuit voltage drops steeply. Though the open circuit voltage increases logarithmically with irradiance the decrease due to increase of temperature has more far reaching effect on open circuit voltage which not only overcomes this increased amount but also decreases open circuit voltage to some extent. So, we observe an overall decrease in open circuit voltage.

Fig.7 also demonstrates the same concept as in the case of Fig.6. This fall of open circuit voltage with irradiance can be verified experimentally by using sun simulator. As a result of unavailability of this equipment, an experimental data in almost same scenario taken from reference [11] is shown in Fig.8. In this experiment, a polycrystalline silicon solar cell is attached to a metal plate and its temperature is stabilized at different levels like 50^0, 40^0, 30^0 and 20^0 C for various irradiance levels regulated by sun simulator. As shown in Fig.8 it is obvious that, open circuit voltage at high irradiance value (for example 100 mw/cm^2) may fall below of its lower irradiance value (for example 20 mw/cm^2 at 20^{0}C) at an elevated temperature (50^{0}C).

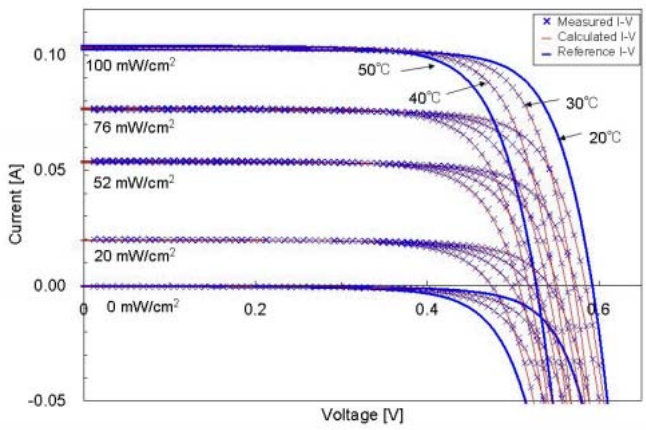

Fig.8 Measured (circles) and calculated (lines) *I-V* curves of a polycrystalline Si solar cell. *I-V* curves measured at irradiance 0 mw/cm^2 and 100 mw/cm^2 and T=20^{0}C and 50^{0}Cwere used for reference *I-V* curves [11].

VIII. Conclusions

In most of the previous modelling practices only the separate effect of irradiance and temperature are focused. So according to them, with the rise of irradiance the open circuit voltage invariably rises. Temperature effect is not considered so much. From the analysis of this paper, finally it is obvious that, with the rise of irradiance at a very higher value when the temperature of the cell is also increased remarkably then open circuit voltage must fall than its lower irradiance value due to the temperature effect if the cell temperature is not controlled appropriately.

***Abstract*—In this paper, a device model that describes the current-voltage characteristics of polymer:fullerene bulk heterojunction solar cell has been developed. Two organic PV cells of two different materials are cascaded together to form a tandem organic solar cell. In the design, PPV is implemented as the top cell and P3HT:PCBM blend is used as bottom cell. The simulation has been carried out using Silvaco ATLAS software. The power curve is also derived. Furthermore, the ideal efficiency and the Fill Factor of the tandem cell have been predicted from the curve. The stability of the model is ensured by introducing a thin buffer layer of ZnO coated on top of the solar cell.**

***Index Terms*—Fill Factor, exciton, tandem, heterojunction, solar cell**

I. Introduction

In today's world, the increasing rate of fossil-fuel consumption and its accompanying greenhouse effect have resulted in research efforts that focus on renewable energy. Among various other renewable energy sources photovoltaic cells (PV) comprises a large portion. Photovoltaic cells allow for device fabrication of large areas of lightweight and flexible substrates using low-cost solution-processing methods [1]. Thin film PV cells are promising approach and it has tremendous potential. After the introduction of silicon as the prime semiconductor material, silicon PV diodes became widely available [2]. Photoconductivity and electroluminescence were reported in organic crystals for the first time in the 1950s [3]. The first highly conductive polymer was chemically doped polyacetylene, reported in 1977 [4]. Since then, organic molecules as semiconducting polymers are being increasingly used in optoelectronic devices. Organic materials were introduced to photovoltaic devices because they can be chemically synthesized and low cost. They can be easily manufactured compared to silicon based cells, and this is due to the molecular nature of the materials used. Organic materials are easier to work with and can be used with thin film substrates that are 1,000 times thinner than silicon cells. They are becoming established as one of the future photovoltaic technologies for lowest-cost power production.

Solution-processed tandem bulk-heterojunction solar cells have gained serious attention during the last few years and are becoming established as one of the future photovoltaic technologies for lowest-cost power production. The organic photovoltaic(OPV) cells are normally comprised of p-doped and n-doped materials that are combined to form an active layer, as called bulk heterojunction (BHJ). In this type of photovoltaic cell, the electron donor and acceptor are mixed together, forming a polymer blend. One of the most challenging parts to further increase the efficiency potential of organic solar cells undoubtedly is the design of organic semiconductors that offer better photon harvesting across the entire solar spectrum, better charge-transport properties and better environmental stability. Here, an attempt is made to design an organic solar cell with high stability, high hole mobility, high crystallinity and able to absorb wavelength up to about 650 nm. P3HT:PCBM is used as the organic material to fulfill these criterion. A higher stability is achieved by using a thin coating layer of ZnO on top of the solar cell. Recently, Engineering researchers at the University of Arkansas have achieved the highest efficiency ever in a solar cell, after coating the solar cells with a thin layer of zinc oxide [5]. The purpose of this oxide layer is practiced here too.

The purpose of this contribution is to simulate a tandem organic solar cell structure using Silvaco ATLAS [6] software and give a state of art report on that plastic tandem solar cell based on conjugated polymers and analysis the operating characteristics of the tandem OPV consisting of two sub-cells. In the design of the tandem cell, PPV is implemented as the top cell and P3HT:PCBM blend is used as the bottom cell. A ZnO layer is implemented on top of the solar cell to provide better stability [7]. Afterwards simulated device data are used to extract physical parameters that are subsequently used to model tandem device operation under a variety of conditions.

II. Device Principle

Solar cell is the device that converts the light energy of the sun to electricity. The conversion steps and loss mechanism of light power into electric power are shown in Fig. 1.

In solar cells, the photovoltaic process of converting energy is composed of four steps [8].

$$\eta_{eff} = \eta_{abs} \times \eta_{diss} \times \eta_{trans} \times \eta_{col} \quad (1)$$

Where,

η_{abs} = light absorption efficiency
η_{diss} = exciton dissociation efficiency
η_{trans} = charge transport efficiency
η_{col} = charge collection efficiency

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

An organic semiconductor is an organic material with semiconductor properties [9]. Single molecules, short chain (oligomers) and organic polymers can be semiconductive. These materials are based on the unconventional properties of the carbon atom. The principle of operation of Organic photovoltaic cells utilizes conjugated π and π^* electron orbitals for light absorption, emission, charge generation and transportation. Light absorption leads to generation of excitons. When sunlight is directed onto photosensitive semiconducting organic materials, electrons in HOMO are excited to LUMO. After light absorption, inorganic semiconductors produce free carriers at once, while organic semiconductors require additional processes to produce free carriers. First, organic semiconductors form excitons, which are strongly bound electron hole pairs. These pairs then diffuse inside of the organic semiconductor, which is independent on an applied electric field. The typical exciton diffusion length in an organic semiconductor is around 10-20nm, and exciton dissociation occurs only at the interface between the donor and the acceptor. This is due to the offset of HOMO states of the donor and the acceptor. If excitons do not reach the interface, they recombine and the absorbed energy is dissipated without generating photocurrent. Therefore, to generate power efficiently, the excitons have to be dissociated and collected at electrodes before recombination.

If a solar cell is short circuited with illuminating by sunlight there will have a short circuit current. This current is known as photo current I_{ph}. The greater is the light intensity, the higher is the photo generation rate and larger is I_{ph}.

$$I_{sc} = -I_{ph} = -KI \tag{2}$$

Here K is a constant that depends on the particular device. When a resistance is connected across the solar cell the total current flow through the resistance is given by,

$$I = I_d - I_{ph} \tag{3}$$

I_d is due to the normal pn junction behavior. It is given by the diode characteristics,

$$I_d = I_o[\exp\left(\frac{eV}{nkT}\right) - 1] \tag{4}$$

Here I_o is the reverse saturation current and n is the identity factor that depends on the semicondutor material. In an open circuit the net current is zero. This means $I_d = I_{ph}$. So the total current through the resistor is,

$$I = -I_{ph} + I_o[\exp\left(\frac{eV}{nkT}\right) - 1] \tag{5}$$

III. SIMULATED TANDEM OPV CELL STRUCTURE

Realization of a photovoltaic product requires excellent materials for outstanding good cells. The tandem organic solar cell simulated here consists of two organic PV subcells of two different materials cascaded together to form a solar cell. In the top cell PPV polymer is used and in the bottom Cell P3HT:PCBM polymer layer is used. Low Work Function Polymer Electrode for anode and Aluminum Cathode are used as contacts [10]. The simulation is done using Silvaco ATLAS. ATLAS is a device simulation framework which enables device technology engineers to simulate the electrical, optical, and thermal behavior of semiconductor devices.

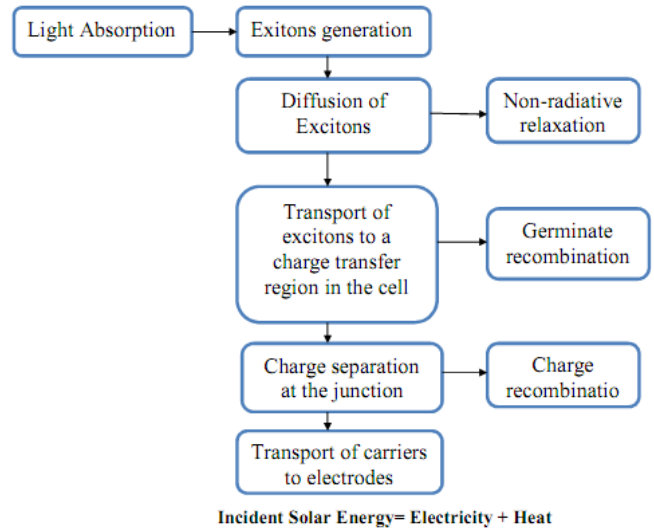

Fig. 1. Conversion steps and loss mechanism of light power into electric power

PPV (polyphenylene vinylene) is a conducting polymer of the rigid-rod polymer host family [11]. They can be easily synthesized in good purity and high molecular weight. P3HT: PCBM or poly(3-hexylthiophene):1-(3 methoxycarbonyl) propyl-1-phenyl[6,6]-C61 is the most efficient OPV material so far [12]. This is because the characteristics of P3HT:PCBM favors high stability, high hole mobility, high crystallinity and able to absorb wavelength up to about 650 nm. In addition, C60 in PCBM is strong electron acceptor, enables fast charge separation and is the least expensive and most energy saving fullerene. The molecular structures of PCBM and P3HT are shown in Fig. 2. Organic polymers have wider gap than semiconductors. Thus they give an efficient absorption at near UV part. So is P3HT:PCBM blends. The gap of the blend is approximately 1.8eV. So the longest absorption wavelength should be around 650 nm. The Absorptance spectrum of P3HT film, PCBM film, and P3HT:PCBM film is shown in Fig. 3.

One of the greatest obstacles that must be overcome before organic photovoltaic cells become commercially viable is the inability to produce stable solar cells with long lifetimes. Semiconducting polymers are generally unstable in the presence of light and oxygen. The diffusion of oxygen and water into the cell is recognized as the greatest source of device degradation when OPVs are tested in ambient air. To overcome this problem a thin buffer layer of ZnO is used on top of the OPV cell which scavenges for oxygen and humidity, improving the stability of the organic Layer and increasing

Fig. 2. Structures of P3HT and PCBM

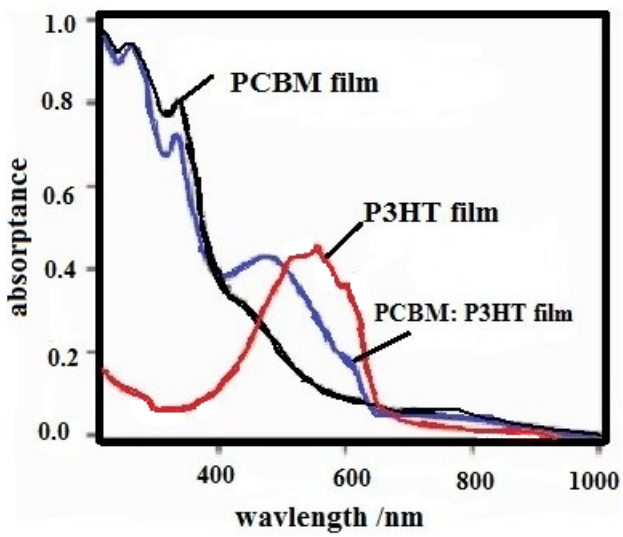

Fig. 3. Absorptance spectrum of P3HT film, PCBM film, and P3HT:PCBM film

the efficiency as well.

For simulation purposes, AM1.5 solar spectrum condition has been used. Which means input optical power is approximately 1000KW/m2 or 100mW/cm2 [13].

The simulated structure of Tandem Organic Solar Cell is shown in Fig. 4.

IV. Simulation and Analysis

J-V Characteristics and output power curve of the tandem cell are predicted using the Silvaco ATLAS software. They are shown in Fig. 5 and Fig. 6.

Using these plots simulation outputs are analyzed and following output parameters are obtained:

1. J-V Characteristics
2. Power Curve
3. Short-circuit Current Density (J_{sc})
4. Open Circuit Voltage (V_{oc})
5. Fill Factor (FF)
6. Efciency (η)

Calculation of J_{sc}, V_{oc} are done by the following equations:

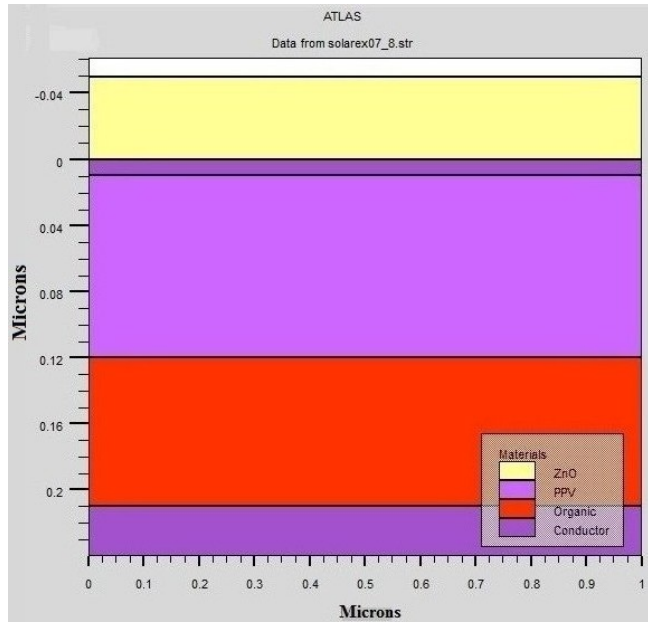

Fig. 4. Structure of the simulated tandem organic solar cell

J_{sc}=value of current when V=0 in J-V curve
V_{oc}=value of voltage when J=0 in J-V curve
P_m = peak value of power in power curve

$$P_m = V_m J_m \tag{6}$$

The Fill Factor (FF) and efficiency (η) of the solar cell is calculated from:

$$FF = \frac{P_m}{V_{oc} \times J_{sc}} \tag{7}$$

$$\eta = \frac{FF \times V_{oc} \times J_{sc}}{P_{in}} \tag{8}$$

The Simulated results are given in tabulated form in table I

TABLE I
Extracted Data from Simulation of Tandem Organic Solar Cell

Parameters	Results Under Illumination
J_{sc}(mA/cm2)	36.70
V_{oc}(V)	0.68
P_m (mW/cm2)	10.73
V_m(V)	0.43
J_m (mA/cm2)	23.94
Fill Factor (FF)	0.43
Efficiency η	10.73%

It is found that an Ideal efficiency of 10.73% can be obtained from this solar cell with a Fill Factor of 0.43. The open circuit voltage of the proposed cell is 0.68V and the short circuit current is 36.70 mA/cm2, which is quite good.

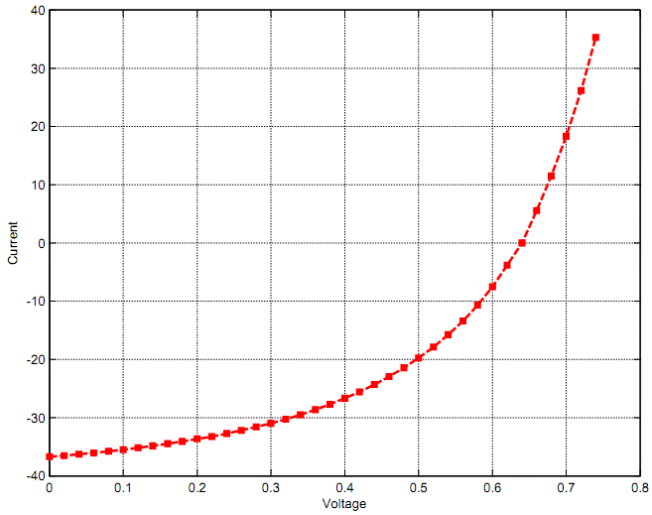

Fig. 5. J-V Characteristics of Tandem Organic Solar Cell

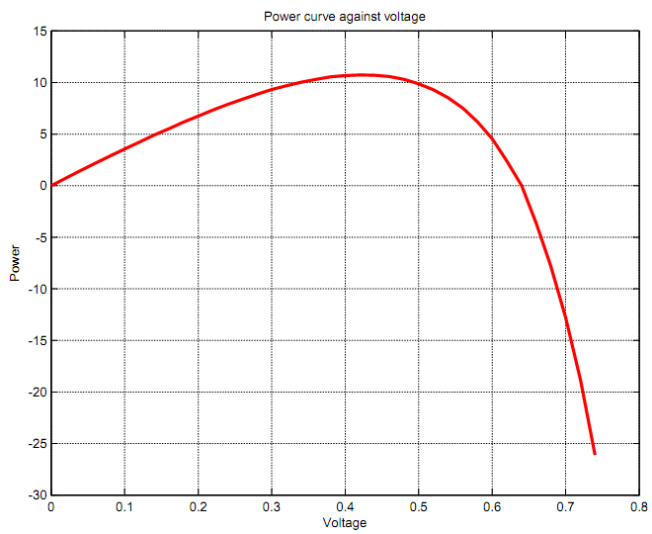

Fig. 6. Output power curve of Tandem Organic Solar Cell

V. Conclusion

In this paper, an efficient tandem organic solar cell based on polymer bulk heterojunction has been designed and its J-V characteristics are studied. The top cell comprises of PPV and the in bottom cell a P3HT:PCBM fullerene polymer layer is used. A thin layer of ZnO is coated on top of the solar cell to ensure the stability of the solar cell. Furthermore, this buffer layer increases the efficiency of the solar cell as well. An overall ideal efficiency of 10.73% is attained which is quite compatible. The efficiency of this photovoltaic cell can be further increased by introducing advance light trapping management [14].

***Abstract* —The main objective of this paper is the modeling and analysis of inorganic homo-junction and inorganic-organic hybrid solar cells. For this, an independent model is developed that is capable of simulating the I-V characteristics of any homo-junction solar cell. The efficiency from the model is 14.897% at standard conditions and from PC1D, a commercial software the efficiency is 14.37% under the same conditions. Also hybrid series and hybrid parallel solar cells are modeled. The efficiency of the single inorganic cell is increased from 15% to 19.5% by the hybrid parallel connection.**

***Index Terms*—Inorganic cell, Hybrid cell, Efficiency**.

I. INTRODUCTION

The research in renewable energy has become an increasingly important topic in the 21st century with the problem of energy crisis becoming more and more aggravated, resulting in increased exploitation and search for new energy resources such as wind, water, geothermal and solar energy around the world. Photovoltaic solar energy, which is inexhaustible, environment friendly and widely available, has been increasingly used to generate electric power from sunshine. A solar cell (also called a photovoltaic cell) is an electrical device that converts the energy of light directly into electricity by the photovoltaic effect.

In this paper, an independent model is developed that is capable of simulating the I-V characteristics of any homo-junction inorganic solar cell. This paper also includes the modeling and study of inorganic-organic hybrid solar cells.

II. SOLAR CELL MODEL

A general mathematical description of I-V output characteristics for a PV cell is studied from [1]-[2]. The equivalent circuit of solar cell comprises of a current source connected in anti-parallel with a diode, series resistance of the cell R_s and the shunt resistance of the cell R_{sh} as shown in Fig. 1. The voltage-current characteristic equation of a solar cell is given as

$$I = I_{ph} - I_s[e^{\frac{q(V+IR_s)}{nKT_c}} - 1] - \frac{V + IR_s}{R_{sh}} \quad (1)$$

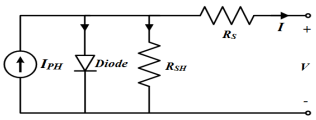

Fig. 1 Equivalent circuit of a solar cell.

where I_{ph} is a light-generated current or photocurrent, I_s is the cell saturation of dark current, q (= 1.6×10^{-19} C) is an electron charge, K (= 1.38×10^{-23} J/K) is Boltzmann's constant, T_c is the cell's working temperature, n is the ideality factor, R_{sh} is the shunt resistance, and R_s is the series resistance. The photocurrent mainly depends on the solar insolation and cell's working temperature, which is described as

$$I_{ph} = [I_{sc} + K_I(T_C - T_{Ref})]\lambda \quad (2)$$

where I_{sc} is the cell's short-circuit current at 25°C and 1kW/m^2, K_I is the cell's short-circuit current temperature coefficient, T_{Ref} is the cell's reference temperature, and λ is the solar insolation in kW/m^2. The cell's saturation current varies with the cell temperature, which is described as

$$I_s = I_{RS}\left(\frac{T_C}{T_{Ref}}\right)^3 e^{\frac{qE_g}{nK}\left(\frac{1}{T_{Ref}} - \frac{1}{T_C}\right)} \quad (3)$$

where I_{RS} is the cell's reverse saturation current at a reference temperature and a solar radiation, E_g is the bang-gap energy of the semiconductor used in the cell and varies with temperature as (e.g., $E_g(T) \approx E_g(0) - \frac{\alpha T^2}{T+\beta}$). The reverse saturation current at reference temperature can be approximately obtained as

$$I_{RS} = \frac{I_{sc}}{e^{\frac{qV_{oc}}{nKT_{Ref}}} - 1} \quad (4)$$

The short-circuit current at standard conditions, I_{sc}, is analysed by dividing the solar spectrum into many segments, each having a narrow range of wavelength and finding the current due to each spectral segment. Since each spectral segment is essentially monochromatic, it may be assigned a single wavelength λ and absorption coefficient $\alpha(\lambda)$. The generation rate of electron-hole pairs at a distance x from the semiconductor surface as shown in Fig. 2 is given by

$$G(\lambda, x) = \alpha(\lambda)F(\lambda)[1 - R(\lambda)]e^{-\alpha(\lambda)x} \quad (5)$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

where $\alpha(\lambda)$ is the absorption coefficient, $F(\lambda)$ the number of incident photons/cm^2/s per unit bandwidth in this spectral segment, and $R(\lambda)$ is the fraction of these photons reflected from the surface. α depends on k_e, the extinction coefficient (e.g., $\alpha = \frac{4\pi k_e}{\lambda}$) and R depends on n_r, the refractive index and k_e (e.g., $R = \frac{(1-n_r)^2 + k_e^2}{(1+n_r)^2 + k_e^2}$) where

$$\overline{n} = n_r - ik_e \tag{6}$$

is the complex index of refraction.

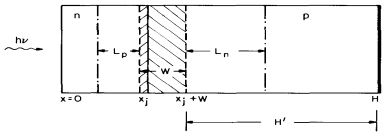

Fig. 2 Solar-cell dimensions and minority-carrier diffusion lengths.

The total short-circuit photocurrent density at a given wavelength is the sum of electron, hole and depletion-region short-circuit currents as taken from [3]-[4]. The total cell short-circuit current density is the sum of the contributions from all the spectral segments

$$J_{sc} = \sum_i qF(\lambda_i)[1 - R(\lambda_i)]SR(\lambda_i) \tag{7}$$

where

$$SR(\lambda) = \frac{J_n(\lambda) + J_p(\lambda) + J_{dr}(\lambda)}{qF(1-R)} \tag{8}$$

The open-circuit voltage, V_{oc} at standard conditions is determined using the following equation

$$V_{oc} = \frac{nKT}{q}\ln(\frac{I_{sc}}{I_s} + 1) \tag{9}$$

III. HYBRID SOLAR CELL

A hybrid solar cell is basically a combination of an inorganic and an organic solar cell. These two cells can be connected in either series or parallel connection. The I-V relationship of the organic cell is studied from [5].

$$J = J_{ph} - J_{01}[e^{B_1(V+JR_s)} - 1] - J_{02}[e^{B_2(V+JR_s)} - 1] - \frac{V + JR_s}{R_{sh}} \tag{10}$$

J_{01} represents the electronic conduction phenomena in the quasi-neutral region of the junction, such as diffusion, recombination and the drift effects, J_{02} corresponds to the carrier recombination via deep levels in the space charge region of the junction.

1) *Series Connection:* The I-V characteristics of a hybrid series cell is given by

$$V = \frac{n_1KT}{q}\ln(\frac{I_{ph1} - I}{I_{s1}} + 1) + \frac{n_2KT}{q}\ln(\frac{I_{ph2} - I}{I_{s2}} + 1) - IR_{s1} - IR_{s2} \tag{11}$$

where I_{ph1} and I_{ph2} are the photocurrents, R_{s1} and R_{s2} are the series resistances and I_{s1} and I_{s2} are the diode reverse saturation currents of the inorganic and organic cells respectively as shown in Fig. 3.

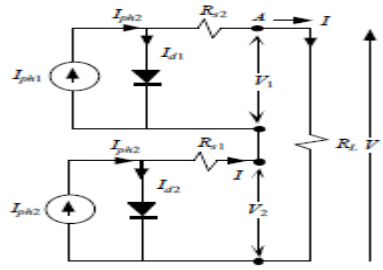

Fig. 3 Two mismatched solar cells in series under a load R_L

2) *Parallel Connection:* When an inorganic cell and an organic cell with photocurrents I_{ph1} and I_{ph2}, series resistances R_{s1} and R_{s2} and parallel resistances R_{sh1} and R_{sh2} respectively are connected in parallel driving a load R_L, the I-V characteristics of the hybrid cell is given by

$$I = (I_{ph1} + I_{ph2}) - I_{s1}[e^{\frac{q(V+IR_{se})}{n_1KT}} - 1] - I_{s2}[e^{\frac{q(V+IR_{se})}{KT}} - 1] - I_{s3}[e^{\frac{q(V+IR_{se})}{2KT}} - 1] - \frac{V + IR_{se}}{R_{sh1}} - \frac{V + IR_{se}}{R_{sh2}} \tag{12}$$

where

$$R_{se} = \frac{R_{s1}R_{s2}}{R_{s1} + R_{s2}} \tag{13}$$

IV. MODELING AND ANALYSIS

1) *Inorganic Cell Modeling:* A typical Si solar cell is first simulated using PC1D. Next, the same solar cell structure is modeled using MATLAB coding. For this, First I_{sc} and V_{oc} are determined at standard conditions and compared with I_{sc} and V_{oc} from PC1D simulation. The resulting I_{sc} and V_{oc} values at standard conditions are then used for modeling the solar cell at different irradiance and temperature conditions. The parameters used in the simulation are summarized in Table I.

Table I
Si solar cell parameters

Parameter	Value
Cell area, A	100 cm^2
Width of entire cell, H	100 µm
Width of n-layer, T_n	0.5 µm
Doping of n-layer, N_D	1×10^{18} cm^{-3}
Doping of p-layer, N_A	1×10^{16} cm^{-3}
Surface recombination velocity, S_p, S_n	1×10^{5} cm/s
Recombination lifetime, τn, τp	1000 µs
Irradiance, G	1000 W/m^2

Parameter	Value
Temperature, T	$25°C$
Effective density of states in conduction band, N_c	$2.8\times10^{19}\ cm^{-3}$
Effective density of states in valence band, N_v	$1.04\times10^{19}\ cm^{-3}$
α	4.9×10^{-4} eV/K
β	655 K
$E_g(0)$	1.169 eV
Ideality factor, n	1.2
Electron mobility, μn	$1110\ cm^2V^{-1}s^{-1}$
Hole mobility, μp	$196\ cm^2V^{-1}s^{-1}$

The complex index of refraction at each wavelength from 0.2066 μm to 0.835 μm with a wavelength separation of 0.025 μm is taken from [6] and from this α and R at each wavelength are determined. Table II shows the I_{sc} and V_{oc} values obtained from simulation for Si cell and Table III shows the resulting parameters of the solar cell using these values.

Efficiency (%)	15.0159	Efficiency (%)	4.7792	Efficiency (%)	19.5354

Comparing the characteristics of the hybrid series cell with the single Si solar cell it is found that the performance of the hybrid cell is extremely poor. The main reason for this is the limiting of the cell short-circuit current by the short-circuit current of the organic cell. The short-circuit current of the organic cell is low because of its very high series resistance. Although the open-circuit voltage of the hybrid cell is improved much on account of the series connection, the lower short-circuit current reduces the overall efficiency of the cell to a much lower value than that of the Si solar cell. Conversely, the performance of the hybrid parallel cell is better than that of the single Si cell. This is also mainly because of the short-circuit current but in an opposite sense. The short-circuit current of the organic cell increases that of the Si cell due to the parallel connection. The open-circuit voltage of the hybrid cell is also high. As a result, the overall cell efficiency is improved.

A probable way of improving the performance of the series cell is paralleling multiple organic cells and connecting that combination in parallel with the Si cell. This would improve the short-circuit current of the total cell and hence enhance the efficiency.

V. CONCLUSIONS

In this paper the I-V and P-V characteristics of inorganic and organic solar cells are modeled. From this modeling the short-circuit current, open-circuit voltage, maximum power, fill factor and efficiency of homo-junction Si is obtained. The results are compared with that of a commercial software and it is found that the model gives nearly the same results as a software. This model can be applied to any homo-junction solar cell given the parameters like doping concentrations, layer widths, area, complex indices of refraction, minority carrier lifetimes etc.

Two hybrid solar cells are also modeled. It is observed that the parallel connection increases the efficiency of the single Si solar cell by an appreciable amount but the series combination degrades the efficiency.

Abstract—**Thin Film Solar Cell is a technology which has a great potential as it has low material consumption and relatively high efficiency to others. Among thin film solar cells CIGS is a promising one. But due to scarcity of gallium and indium its industrial production can be affected. Here in this paper via simulation (using device simulator) we have tried to achieve good acceptable efficiency using very thin layer of CIGS absorber layer with the help of grading and appropriate gallium composition and by optimizing emitter efficiency which is close to the efficiency of CIGS cells having thick absorber layer.**

Keywords—Thin Film; CIGS Solar Cell; Composition Grading.

I. Introduction

Solar cell is usually made of semiconducting materials (including compound materials) which converts radiant optical energy into useful electrical energy. At present most of the solar devices or cells manufactured from wafers of mono crystalline or polycrystalline silicon or amorphous silicon which are the dominant technology in the commercial market. Solar cells based on the thin film of direct band gap semiconducting materials are other technologies with great potential in harvesting green energy. One such thin film technology is based on a compound of Copper, Indium, Gallium and Selenium abbreviated as $Cu(In,Ga)Se_2$ or CIGS [1]. As CIGS is a direct band gap material the absorber thickness for CIGS solar cell is much less than Silicon solar cells usually in between 1.5 to 2.5 micro meter. But materials used in CIGS solar cell are not abundant in nature. The critical material for CIGS solar cell is Indium and gallium. The production capability of gallium is 167 metric tons per year where the production capability of indium is at 600 metric tons per year [2]. With the increasing demand of electricity if CIGS solar cells have to keep impact on solar power supply then material used for CIGS solar cell device has to be reduced by not degrading its efficiency. In this work by device simulation we have tried to find a way to lessen the absorber thickness by not affecting the efficiency.

II. Grading Effect

One of the very common ways used to increase the efficiency of a CIGS solar cell is composition grading in the CIGS absorber [3]-[5] Grading can be of various types:

- Front Grading
- Back Grading
- Double Grading
- Full reverse grading

Grading in CIGS is of course a complex manufacturing process. Here in this work we have tried only the full reverse grading.

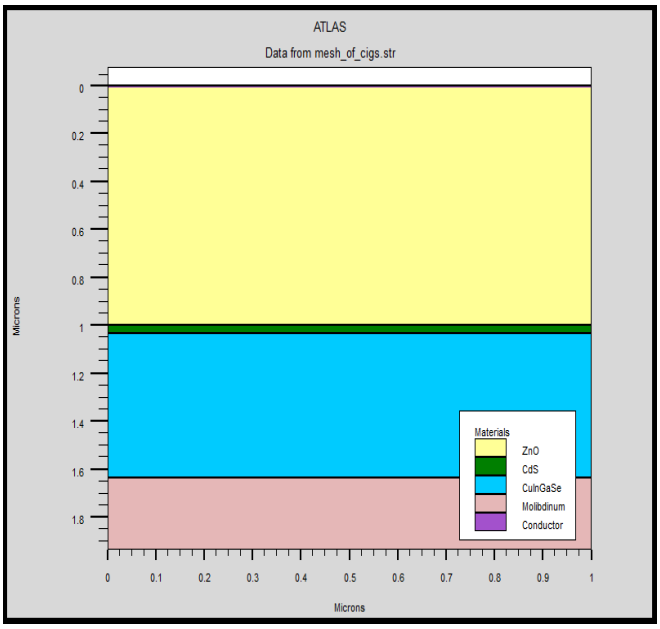

Fig. 1 Structure of CIGS solar cell.

The optimum thickness for a CIGS absorber is usually 1.5 to 2 micro meters. Here we first simulated the cell under AM1.5 for different thickness from 0.4 micron to 2 micron. The gallium composition was fixed for 0.3 throughout the absorber. We did not use higher gallium composition because it is already shown in literature that the optimized gallium composition for CIGS absorber is in the 0.3 to 0.4 range. We considered the possible defects in CdS and CIGS. We vary the thickness of CIGS absorber from 0.4 micro meters to 1.5 micro meters. For both uniform and reverse graded gallium composition the important findings open circuit voltage, short circuit current, fill factor and finally efficiency are shown below:

III. Simulation And Results

The simulation was done under AM1.5 spectrum.

A. Thickness Variation:

1) Open Circuit Voltage: Open circuit voltage change for different thickness level is shown in the following figure.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

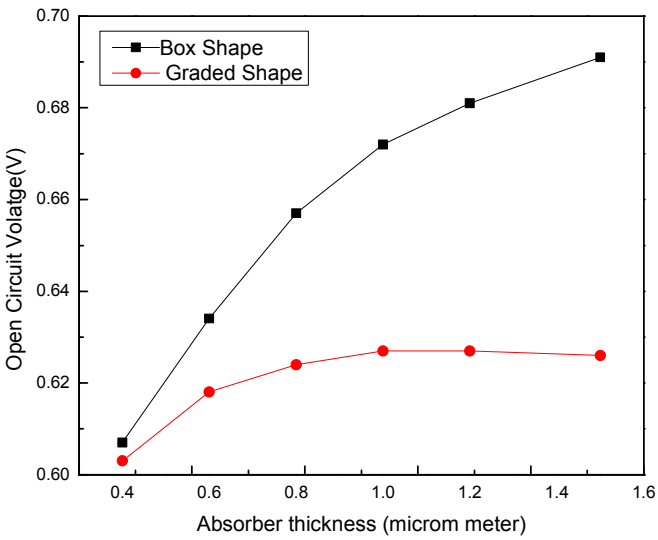

Fig. 2 Open circuit voltage vs. thickness variation (both for uniform and graded composition).

Open circuit voltage was lower in graded than uniform gallium composition for thickness level from .4 micro meters to 1.5 micro meters.

2) Short Circuit Current: Short circuit current density variation for different thickness level is shown in the following figure.

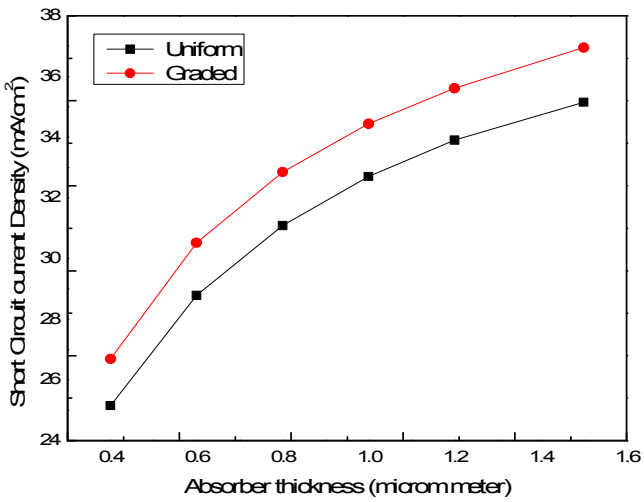

Fig. 3 Short circuit current density vs. thickness variation (both for uniform and graded composition).

Short circuit current density increased for both uniform and graded gallium composition as the thickness of the absorbing layer is increased which is very much expected as the photo generation gets better for thick absorbing layers. But for graded composition short circuit current density was higher than uniform composition for all level of thickness.

3) Fill Factor: Fill factor is defined as-

$$Fill\ Factor = \frac{V_m I_m}{V_{OC} I_{SC}}$$

where,

V_{oc} = Open circuit voltage

I_{sc} = Short circuit current

V_m = maximum obtainable voltage

I_m = maximum obtainable current

Fill factor variation for different thickness level is shown in the following figure.

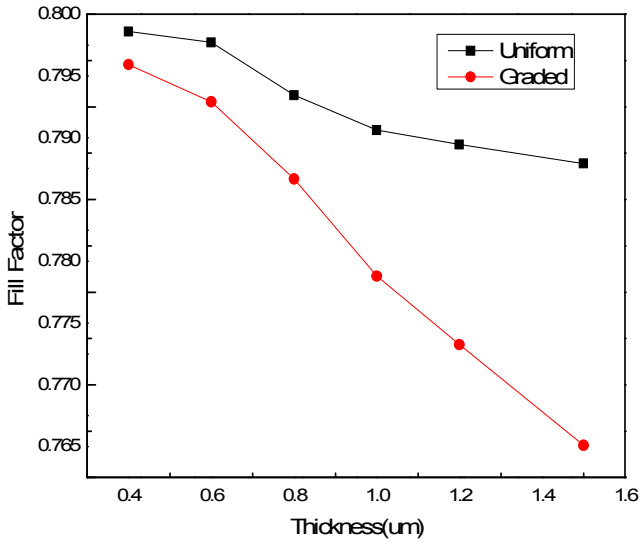

Fig. 4 Fill factor vs. thickness variation (both for uniform and graded composition).

In case of fill factor we have found that at low thickness fill factor obtains much better value and with increase of thickness it decreases for both uniform and graded gallium composition. In case of graded composition we see that fill factor is lower than uniform composition for all level of thickness and for higher thickness (especially after thickness of .8 micro meter) difference of fill factor between graded and uniform gallium composition is greater which can be good reason for low efficiency at high thickness level for graded composition than uniform composition.

4) Efficiency: Efficiency of the solar cell did not increase for graded gallium composition for higher thickness level. Efficiency of the solar cell increased with a nonlinear shape for uniform gallium composition for thickness level of .4 micro meters to 1.5 micro meters. The increase of efficiency can be explained simply that with more absorber the current generation gets enriched and also the diode characteristic gets better and so the open circuit voltage. But efficiency is higher for graded than uniform gallium shape for lower absorber thickness level. For thickness level up to 0.8 micro meter graded composition of gallium gives higher efficiency than uniform. But above 0.8 micro meters efficiency is lower than uniform composition of gallium for graded.

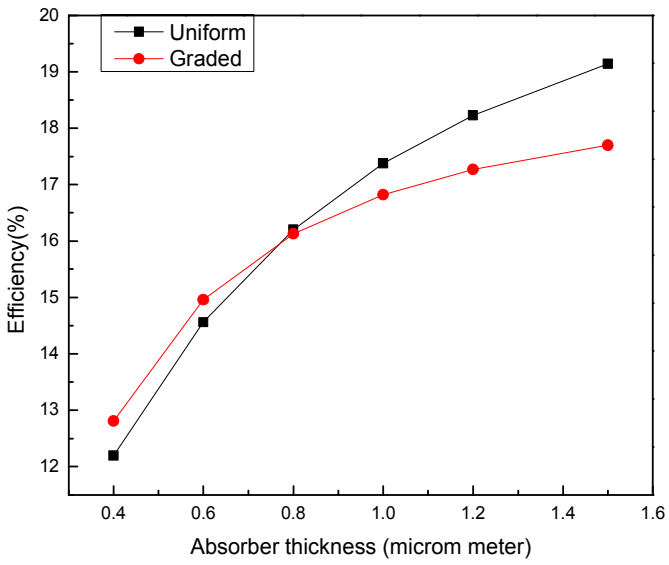

Fig. 5 Efficiency vs. thickness variation (both for uniform and graded composition).

B. *Grading Effect Optimization*

Our goal is to obtain better efficiency having an absorbing layer of low thickness so we kept the absorber thickness at 0.6 micro meter and as we found grading is useful in obtaining better efficiency when the absorber thickness is low, we increase the grading by increasing the peak value of gallium composition at the back contact. The grading combinations used here were 0 to 0.4 (Type A), 0 to 0.5 (Type B), 0 to 0.6 (Type C) and 0.1 to 0.6 (Type D).

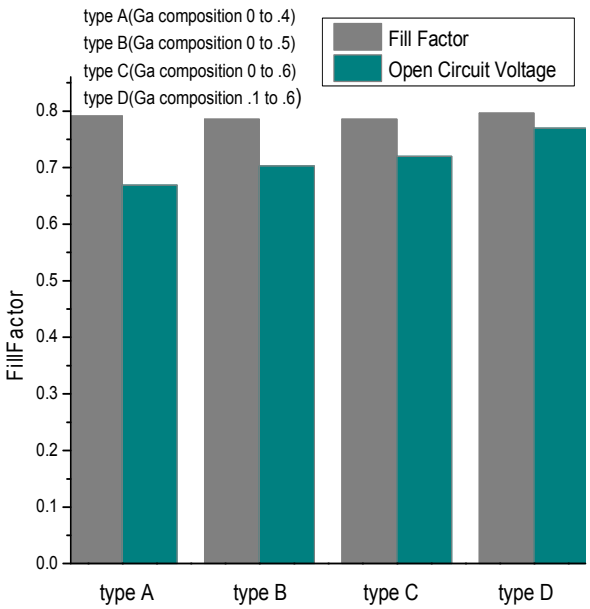

Fig. 6 Fill factor and open circuit voltage for different grading levels.

The Open circuit voltage of the cell was mostly affected by higher grading and it increased with the increase of grading. In case of type D where the Gallium composition was increased from 0.1 to 0.6 the open circuit voltage was further increased whereas the fill factor remained almost constant for all the types.

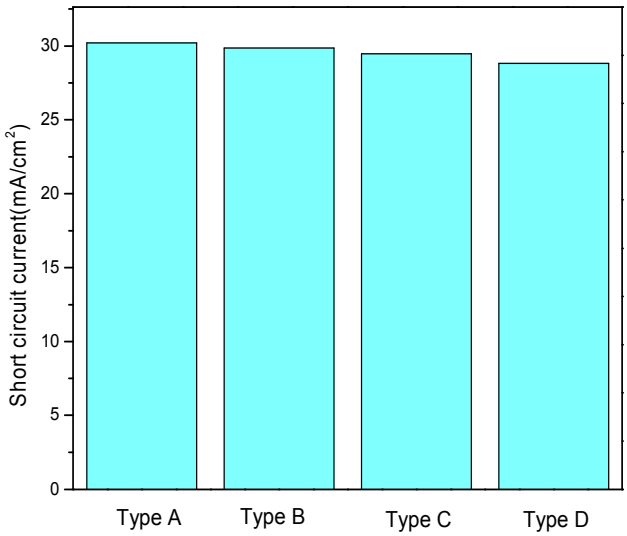

Fig.7 Short circuit current for different grading levels.

The short circuit current of the solar was adversely affected d with the increase of grading though it is previously shown that for graded composition short circuit current density is higher than uniform composition. But increasing the grading didn't help increasing the short circuit efficiency. But the key factor is that which is dominant factor affecting efficiency open circuit voltage or short circuit current. Here comes the necessity of optimization and by perfect optimization accurate profile can be give better efficiency.

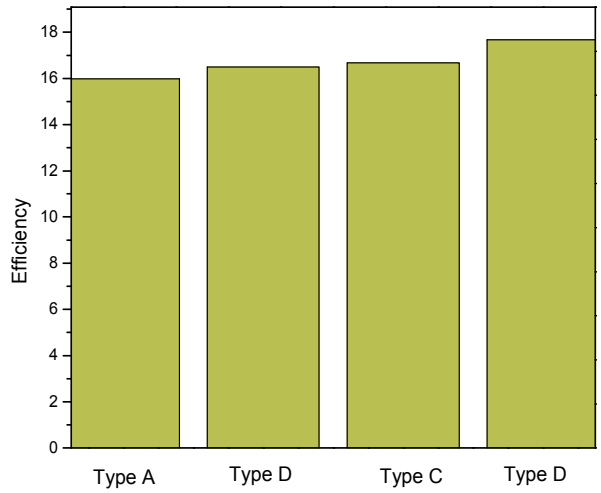

Fig. 8 Efficiency for different grading levels.

Short circuit current density variation for different graded gallium composition profile is shown in the following figure. It is already shown in literature that the efficiency of a solar cell gets increased with the increase in the gallium composition (not more that 30-40%) our goal was to achieve the higher efficiency (which is possible in the greater thickness level) in the lower thickness level by using graded composition of gallium. The efficiency of the solar cell got increased with the higher graded composition of gallium for type A, Type B and Type C. The efficiency was further increased at type D where more gallium was introduced and composition was changed from 0.1 to 0.6 and it obtained highest efficiency at 0.6 micron thickness level and the reason of this can be the more induced gallium and also the high grading effect.

C. Emitter Optimization: Lowering Thickness of Cds:

Our goal is to achieve efficiency as close as the highest efficiency using thinner absorber layer of CIGS. Hence so far we have done reverse grading and chosen optimized gallium composition to gain efficiency of 17% which is 2% lower than the highest efficiency. We varied the thickness of the Cds emitter thickness from 10 nm to 40 nm and for l0 nm.

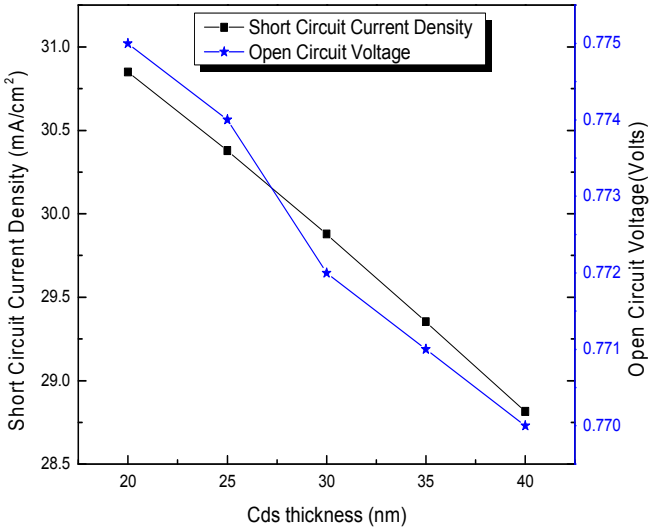

Fig. 9 Short circuit current density and open circuit voltage variation for different emitter thickness.

We achieved the highest efficiency of 19.1% at 0.6 micron with gallium composition 0.1 to 0.6 using a very thin emitter of 10 nm. The following figures: Fig.9 shows the CdS thickness effect on open circuit voltage and short circuit current, Fig.10 shows the effect on fill factor and Fig.11shows the effect on overall efficiency.

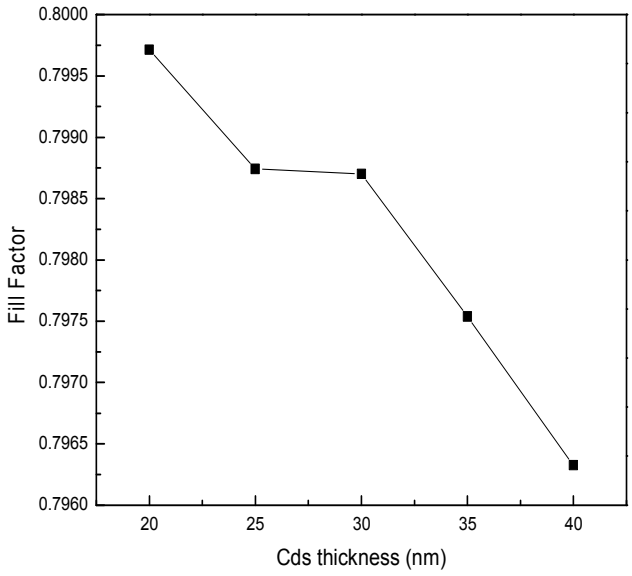

Fig.10 Fill factor variation for different emitter thickness.

Fill Factor is not that much affected by lowering Cds thickness though it gets better for lower Cds thickness. Efficiency is greatly included by emitter thickness. Efficiency reaches up to 19% for by lowering emitter thickness from 40 nm to 10 nm.

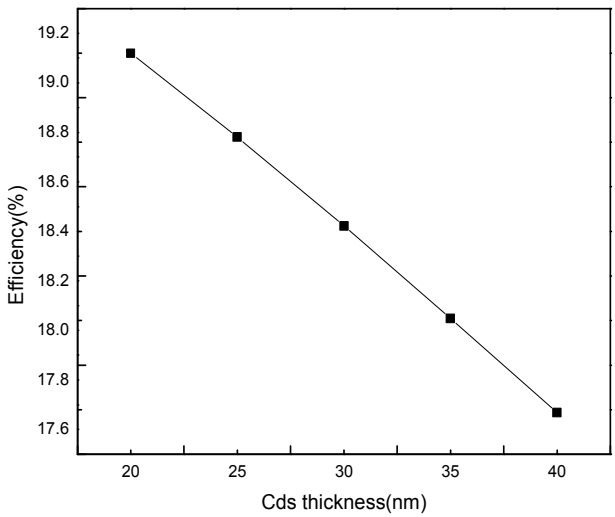

Fig. 11 Efficiency variation for different emitter thickness.

Our goal was to achieve near highest efficiency of the thick film CIGS solar by optimizing all possible ways. Here by reverse grading and Cds thickness optimization we show that it is possible to achieve high efficiency though using very thin absorber layer (0.6um).

IV. Conclusions

In this paper by simulation we have tried to optimize the thickness of CIGS solar cell. For mass production the thickness of cigs absorber must be reduced to a marginable limit by keeping good conversion efficiency as Indium and Gallium are not abandoned in nature. Grading which can be helpful in achieving high efficiency has been used here and using a lower thickness and higher band gap grading and also by increasing gallium component in the absorber the efficiency achieved is near the highest efficiency. Here we want to clarify that though the gallium composition has been increased for achieving high efficiency but as total quantity it is still a lot lower than conventional 1.5 to 2.5 micron thick CIGS solar cell. Again for achieving high efficiency having a thinner absorber layer it is quiet important to increase the emitter efficiency by using an appropriate emitter thickness. So by appropriate grading and emitter thickness it possible to have good high efficiency using thinner absorber layer.

Abstract— **Power conversion efficiency of conventional solar devices are low because low energy photons cannot excite carriers to the conduction band, therefore do not contribute to the device's current and high energy photons are not efficiently used due to a poor match to the energy gap. Efficiency of solar cell may be increased in various ways; now-a-days quantum dot intermediate band solar cell (QDIBSC) is most promising approach among them. Introducing intermediate levels into the energy gap of a conventional solar cell; low energy photons can be used to promote charge carriers in a stepwise manner to the conduction band thereby enhancing the current while maintaining a large open-circuit voltage. In this thesis $In_xGa_{1-x}N$/InN quantum-dot intermediate band solar cell is calculated by means of solving schr□dinger equation according to the kronig-penney model. On the basis of particular assumptions, the power conversion efficiency is calculated. The results reveal that the $In_xGa_{1-x}N$/InN quantum dot intermediate-band solar cell gives much larger power conversion efficiency than that of conventional solar cells and the power conversion efficiency strongly depends on the size of the quantum dot and the inter dot distance.**

Index Terms—**Quantum dot, intermediate band, concentration factor, interdot distance, $In_xGa_{1-x}N$.**

I. Introduction

The efficiency limit for a single junction solar cell is 33.5%. As for example the efficiency of non-concentrator solar cell has now reached 28.8% in single junction thin film GaAs solar cells under the global Air Mass 1.5 spectrum at 25°C [1]. Various researches have been performed for increasing the efficiency of solar cell with the composition of different semiconductor material.

Multi-junction solar cells (MJSCs) and intermediate band solar cells (IBSCs) are the two major designs for concentrator photovoltaic using inorganic III–V semiconductors. In case of MJSC; several PN junctions are connected in series. In this design each PN junction contributes to the absorption which produces broader solar spectrum. But for efficient absorption the photon energy should be nearest to the bandgap energy because only those photons will be absorbed with energy larger than the band gap energy of the material. Other parameter such as lattice constant or strain balance or thermal expansion co-efficient of each material should be same. For these criteria to be maintained the choice of the material combination become limited. The highest efficiencies of 43.5% have been demonstrated for MJSCs. Neglecting losses a modelled efficiency of 52.4% has been found for a triple junction photovoltaic cell with Ge, GaInP and GaAs [2]. Again the efficiency for non concentrator 3 junction solar cell composed of InGaP/GaAs/InGaAs is found 37.5%. From these results it has been shown that the efficiency of 3 junction solar cells exceeds the limit of single junction solar cell with the increased complexity [1].

For achieving higher efficiency limit; the intermediate band solar cell (IBSC) can be a novel approach. Assuming maximum sunlight concentration; the efficiency limit for IBSC solar cell is 63.2 % whereas 40.7% for single gap solar cell [3].The concept of IBSC was proposed by A. Luque and A. Marti in 1997. It has high conversion efficiency in comparison to the MJSC at a low level of complexity. IBSC is a single junction solar cell. Without affecting the open circuit voltage (Voc) it increases the photocurrent keeping the advantages of the single junction solar cell present [1].

Various types of material combinations are being used for IBSC such as the intermediate band solar cell concept can be implemented using InAs quantum dots (QDs) in a GaAs barrier material. The non-concentrator efficiency of 30.2% has been predicted for this material system. But under concentration, the efficiency of intermediate band solar cell in this material system increases to 51.6%, as compared to 36.7% for bulk GaAs solar cells, under a 1000 sun concentration [1].

In this paper we investigated the $In_xGa_{1-x}N$ /InN Quantum-Dot Intermediate-Band Solar Cell. The III–nitride material system is promising for integration into high efficiency PV systems [4]. One of the advantages of using the Indium Gallium Nitride ($In_xGa_{1-x}N$) material is the range of the bandgap energy from 0.64 eV to 3.4 eV by varying the indium composition (x), which covers most of the solar spectrum from ultraviolet to infrared region with characteristics of direct bandgap, high absorption coefficients, and excellent irradiance resistance. In low–dimensional semiconductor devices the $In_xGa_{1-x}N$ material system presents excellent properties[5]. By tuning the size of QDs and the interdot distance; Deng et al. theoretically investigated the InxGa1–xN/GaN QD–IBSC and $In_xGa_{1-x}N$ /InN QD–IBSC [6]. These works do not clarify about the effects of QD size, interdot distance and indium content on IB position and width which are very important factors for the realization of the performance of a QD–IBSC [7].

In our work, we have investigated the effect of variation of Concentration factor, interdot distance and indium content of InxGa1-xN /InN QD-IBSC and also on solar cell performance which may open the door for future experiment. The $In_xGa_{1-x}N$/InN QDIB solar cells are computed according to the Schrödinger equation and the Kronig–Penney model. The results reveal that the optimum indium content in InxGa1-xN is about 55% and the maximum efficiency under the maximal concentrated sunlight is about 60.3% with the optimum size of the QD (about 3.3nm) and optimum ID (about 2nm) based on specific assumptions.

II. THEORY

A quantum dot is confined in three dimensions and has a size limited by the de Broglie wavelength in all directions. For simplicity, the orthorhombic symmetry for QDs is shown in Fig. 1. The QDs are embedded in periodic arrays. A single electron in such a system can be described by the Schrödinger equation [8]

$$[-\frac{\hbar^2}{2}\nabla_r \frac{1}{m^*}\nabla_r + V(r)]\varphi(r) = E\varphi(r) \quad (1)$$

Where m^* is the effective mass of electron, the potential V(r) corresponds to an infinite sequence of QDs of sizes Wx, Wy and Wz separated by the barriers of the thickness bx by and bz. Here Lx Ly Lz are periods of co-ordinates x,y and z, respectively $L\varsigma = W\varsigma + B\varsigma$

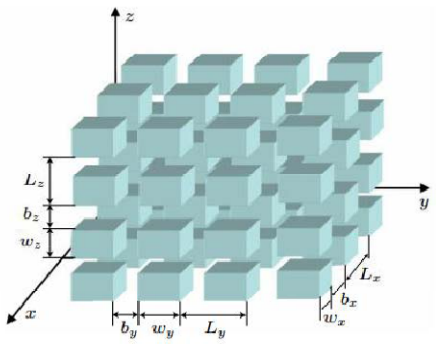

Fig. 1 Schematic Diagram of the Orthorhombic QDs.

where m^* is the effective mass of electron. The potential *V(r)* corresponds to an infinite sequence of QDs of the sizes *wx, wy* and *wz* separated by the barriers of thicknesses *bx*, *by* and *bz* as shown in Fig. 1. Here *Lx*, *Ly* and *Lz* represent the periods of QDs in the coordinates *x*, *y* and *z* respectively. The size of QDs and interdot distance are assumed to be equal (*wx* = *wy* = *wz* and *bx* = *by* = *bz*).

According to the Kronig–Penney model, solution of the Schrödinger equation has already been accomplished by following the Lazarenkova and Balandin envelope function approximation, which has the following form [8]

$$\mathrm{Cos}(L\varsigma q\varsigma) = \cos(K_\varsigma^w W_\varsigma)\cos(K_\varsigma^b b_\varsigma) - .5\left(\frac{K_\varsigma^w}{K_\varsigma^b}\frac{m_b^*}{m_w^*} - K\varsigma b K\varsigma w\, mw{*}mb{*} \times \sin(K\varsigma w W\varsigma)\sin(K\varsigma b b\varsigma)\right. \quad (2)$$

If $E_\varsigma \geq V_0$

$$\mathrm{Cos}(L\varsigma q\varsigma) = \cos(K_\varsigma^w W_\varsigma)\cosh(K_\varsigma^b b_\varsigma) - .5\left(\frac{K_\varsigma^w}{K_\varsigma^b}\frac{m_b^*}{m_w^*} - K\varsigma b K\varsigma w\, mw{*}mb{*} \times \sin(K\varsigma w W\varsigma)\sinh(K\varsigma b b\varsigma)\right. \quad (3)$$

If $0 < E_\varsigma < V_0$

Where

$$K_\varsigma^w = \frac{1}{h}\left(\sqrt{2m_w^* \times mod(E_\varsigma)}\right),\ K_\varsigma^b = \frac{1}{h}\left(\sqrt{2m_b^* \times mod(E_\varsigma - V_0)}\right)$$

where m_b^* and m_w^* are the effective masses of barrier region and quantum dot (QD) region, respectively, $\hbar$ is Planck's constant, $E\varsigma$ is the single electron energy along the particular coordinate axis direction and V_0 is the potential barrier.

III. PERFORMANCE ANALYSIS OF $IN_XGA_{1-X}N$/INN QD-IBSC

The effects of the variation of the concentration factor and interdot distance of $In_XGa_{1-X}N$ QD-IBSC will be shown in this section.

A. Effect of Variation of Concentration Factor x of $In_XGa_{1-X}N$

The maximum efficiency and short circuit current density, open circuit voltage has been calculated for the devices with the various concentration factor x. The other parameter including width of QD and inter dot distance of the cell kept constant.

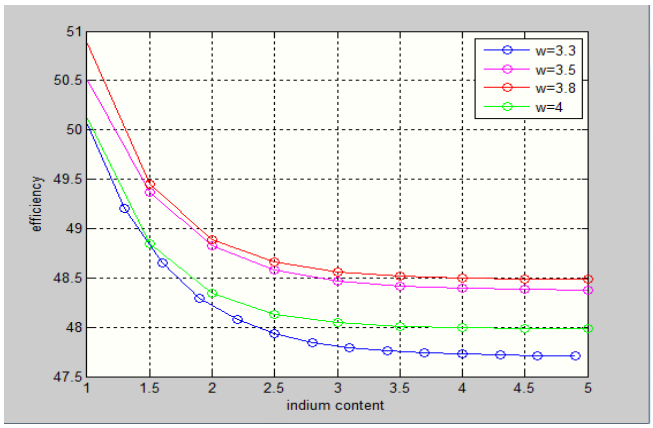

Fig. 9 ID and the Size of Each QD-Dependent Efficiency in the InxGa1-xN/InN QDIB Solar Cell.

IV. CONCLUSION

The results have been achieved under maximum concentrated sunlight. The size of each QD and the ID are not selected arbitrarily, but are chosen after calculation. Fig. 3 reveals that the optimal indium content depending on ID is about 0.42 and maximum efficiency is about 54.72%, which is obviously lower than the limit efficiency of 63.1%. This is mainly because the ID and size of each QD are not optimum, and the restriction of the existence of only one IB in the potential well ; which results in the different ranges of indium content to the differences of ID in fig. 3. The intermediate band makes the electron transition easier from valence band to conduction band and improves the absorption of sunlight. The intermediate band divides the band gap of InxGa1-xN into three parts, the photons whose energies between the band gap of intermediate band to conduction band and the valence band to conduction band are absorbed for the existence of intermediate band, while not be absorbed in bulk materials solar cells. Therefore, the power conversion efficiencies of QDIB solar cells are higher than those of bulk material solar cells. The smaller interdot distance causes the easier coupling of electrons wave functions from adjacent QDs and the easier formation of intermediate band.

The size of each QD and the ID are tuned in fig. 9 but they are not changed arbitrarily. The different ranges of the ID depend on the differences of the size of one QD so as to fulfill assumption 1. Fig. 9 reveals that the optimal size of each QD is about 3.8 nm and the optimal ID is about 1nm. The maximum efficiency is about 50.87% under the maximum concentrated sunlight which is close to limit efficiency of 63.1%. The smaller size of QD makes the quantum effect more obvious and the formation of intermediate band easier. The size of one QD and the ID vary the width and the location in potential well of IB, and the power conversion efficiency ultimately depends on the width and location of IB. Therefore, the power conversion efficiency dependent on the size of each QD and ID is depicted as fig. 9.

In summary, the InxGa1-xN/InN QDIB solar cells are computed according to the Schrödinger equation and the Kronig–Penney model. The results reveal that the optimum indium content in InxGa1-xN is about 55% and the maximum efficiency under the maximal concentrated sunlight is about 60.3% with the optimum size of the QD (about 3.3nm) and optimum ID (about 2nm) based on specific assumptions.

Abstract—**This paper deals with the injection of reactive power, which is vitally important in case of too much load variations, by means of Static VAR Compensator (SVC) so that both, the voltage profile and voltage stability of the power system can be improved. The reactive power management is formulated as an optimization problem that can be solved by the evolutionary advanced optimization algorithms. Two well known algorithms, namely linear algorithm and genetic algorithm are applied in this case and it has been found that the genetic algorithm gives more efficient outputs compared to the linear algorithm as it is based on the biological metaphor, in which best individuals are selected among parents and offspring generation. As far as this paper is concerned, 0.2 MVAR reactive power would be enough for voltage compensation and maintaining stability throughout the system.**

Index Terms—**System Stability, SVC, Linear Algorithm, Genetic Algorithm.**

I. Introduction

One important fact is that power system operators and planners are still facing challenges of integrating renewable energy sources into power system grids with ensuring security, reliability and stability. Out of this context, Reactive Power Management (RPM) has been arisen as a critical issue that entails the requested operation and planning actions to be implemented so that not just the voltage profile but the voltage stability can be improved [1]. Moreover, the reactive power planning of VAR sources are defined by RPM and the precise implementation of it has been permitted by the active power networks, in which active power flow is influenced by Flexible AC Transmission Systems (FACTS) devices [2-3]. Conventionally, reactive power planning has been formulated as an optimization problem and Optimal Power Flow (OPF) solutions can be applied to solve this [4]. In this situation, the utilization of optimization techniques, including Linear Algorithm (LA) and Genetic Algorithm (GA), a type of evolutionary optimization algorithm developed by Holland in 1975 [5], are fruitful.

This paper gives a clear idea on linear algorithm and genetic algorithm and also proofs the advantages of genetic algorithm over linear algorithm in solving linear objective function, involving load factor, fluctuated voltage and amount of reactive power. It goes without saying that the proposed methodology will aid the power system operators to investigate reactive power management in smart grid system integrated with renewable energy for the improvement of system stability.

II. Reactive Power Management

Active network requires a dynamic reactive power support so that voltage can be regulated but the exceeding voltage limit variation is one of the technical barriers for the integration of renewable energy source. The implementation of FACTS devices, such as SVC solves this problem as they monitor the network. Moreover, the local generation of reactive power reduces its import from the feeder, thus reduces the associated losses, and improves the voltage profile and voltage security [6].

Usually, the load of a system is never constant rather it varies from time to time. Slight variation of load does not affect the system but large load variation is problematic as it changes constant supply voltage and urges the reactive power management [7]. Load variations with respect to time can be realized from load curve.

The ratio of average load to maximum demand is called load factor which is always less than 1 because average load is smaller than maximum demand. The load factor plays a key role in determining the overall cost per unit generated as higher value of it makes the cost per unit generation lesser.

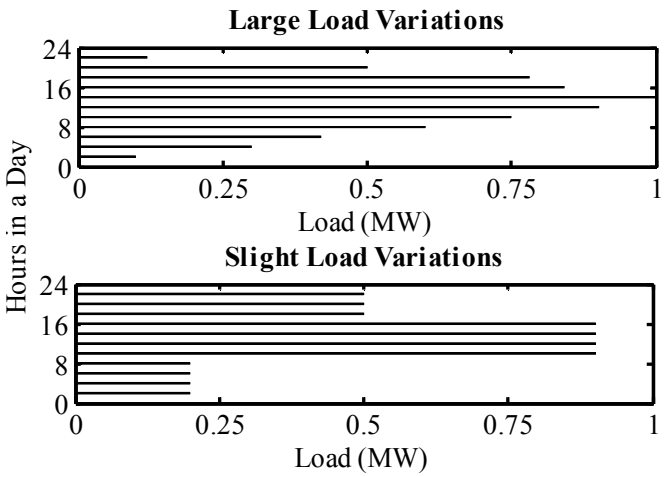

Fig. 1. Daily load curve.

However, too much reduction in load causes overvoltage. The effects of it are large magnetizing current, overheating and low power factor, which urges the large KVA rating of the equipments.

On the other hand, large enhancement in load causes the voltage to drop and induction motors connected to the system may not start due to the lack of sufficient torque.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Therefore, voltage of the system should be kept constant [8] and to make sure of it, the provision should be made for the injection of reactive power [9]. In this paper, SVC, which is capable of exchanging reactive current to control certain parameters used in power system, is taken into account for this purpose. The dynamic nature of the SVC lies in the use of thyristor devices such as GTO, IGCT.

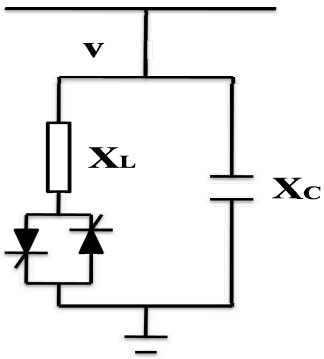

Fig.2. Static VAR compensator diagram.

As is observed that v is the voltage at Thyristor based SVC connection point that is being controlled. X_L is the total inductance and X_C is the capacitance.

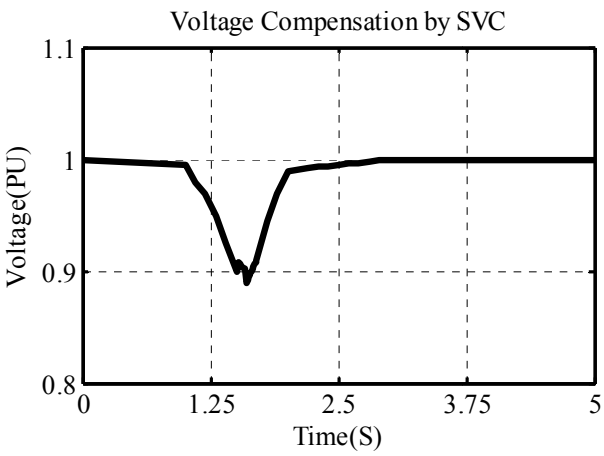

Fig. 3. Reactive power injections by SVC.

III. Advanced Optimization Techniques

Optimization techniques are used to find a set of design parameters, x = {x_1, x_2, ...,x_n}, that can in some way be defined as optimal. In a simple case this might be the minimization or maximization of some system characteristic that is dependent on x. In a more advanced formulation the objective function, f(x), to be minimized or maximized, might be subject to constraints in the form of equality constraints, inequality constraints, and/or parameter bounds ; both upper and lower. When both the objective function and the constraints are linear functions of the design variable, the problem is known as a Linear Programming (LP) problem. Quadratic Programming (QP) concerns the minimization or maximization of a quadratic objective function that is linearly constrained.

The objective of utilizing optimization algorithms in this paper is to find the optimal values of load factor, λ, voltage fluctuation, V caused by the undesired load variations and also the optimum amount of reactive power, Q that is needed to be injected for voltage compensation by SVC.

To begin with, two assumptions are made. Firstly, voltage should be decreased by high load factor and secondly, higher amount of reactive power should be injected if voltage decreases.

TABLE I
INITIAL CONSIDERED VALUES IN PER UNIT (PU)

Load factor, λ (PU)	Fluctuated voltage, V (PU)	Reactive power injection, Q (PU)	Objective function, f(λ,V,Q)
0.12	0.98	0.80	0.18
0.17	0.95	0.89	0.21
0.45	0.87	0.97	0.33

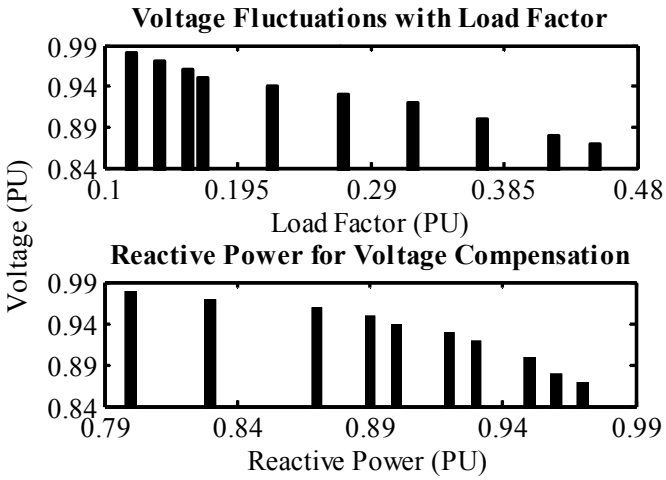

Fig. 4. Assumed conditions to start optimization algorithms.

From table, solved linear equations,

$$0.12x+0.98y+0.8z=0.18 \quad (1)$$

$$0.17x+0.95y+0.89z=0.21 \quad (2)$$

$$0.45x+0.87y+0.97z=0.33 \quad (3)$$

Solutions: x=0.404; y=0.0357; z=0.1206

Derived objective function,

$$f(\lambda,V,Q)=0.404\lambda+0.0357V+0.1206Q \quad (4)$$

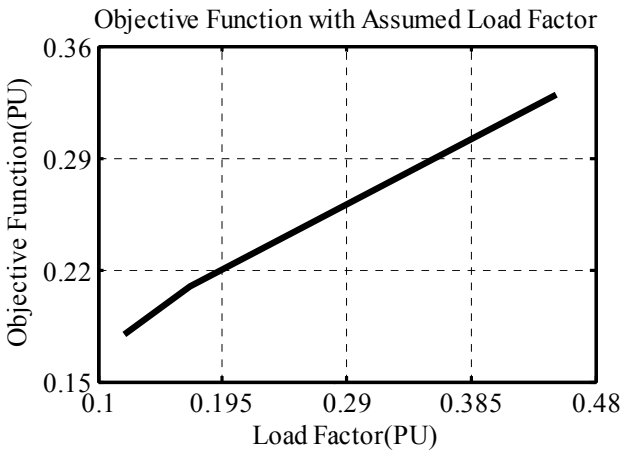

Fig. 5. Relation of load factor to the estimated objective function.

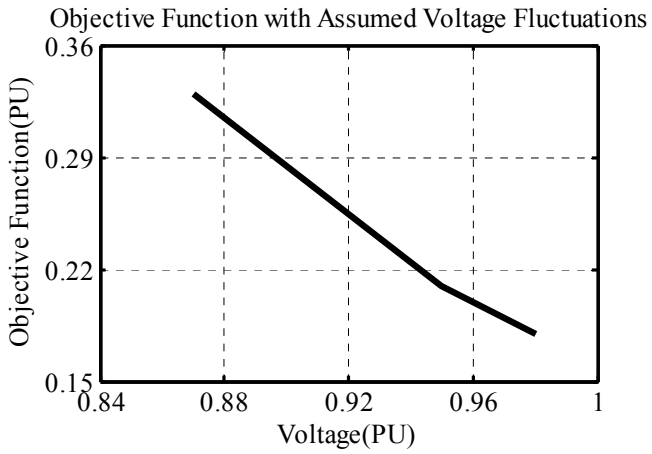

Fig. 6. Relation of voltage fluctuations to the estimated objective function.

A. Linear Algorithm

Since the objective function is linear, linear algorithm has been applied so that the optimal values of the required parameters can be determined. In linear algorithm, the constraints are also linear but solutions derived from it are minuscule values and are not satisfactory as seen from Fig. 7, and to overcome these, the implementation of an advanced algorithm is necessary.

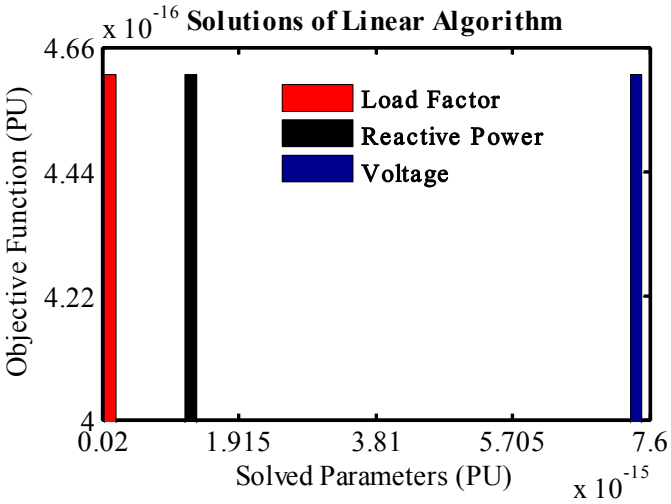

Fig. 7. Optimum values solved by linear algorithm.

B. Genetic Algorithm

Genetic algorithm is the most up-to-date optimization technique that is operated according to the biological concept. It is a meta-heuristic optimization method, in which a problem is solved by improving the candidate solution based on certain criteria [10]. It is begun with the initialization of population. Each solution of population is called chromosomes which simply represent the values of the parameters to be optimized. Then the objective function is evaluated and the chromosomes are selected based on higher values of objective function. Cross is made between two parent values. Mutation brings variety in the values. This process continues until the best possible optimum values of the parameters are achieved and finally after providing results, the algorithm procedure is terminated [11-12].

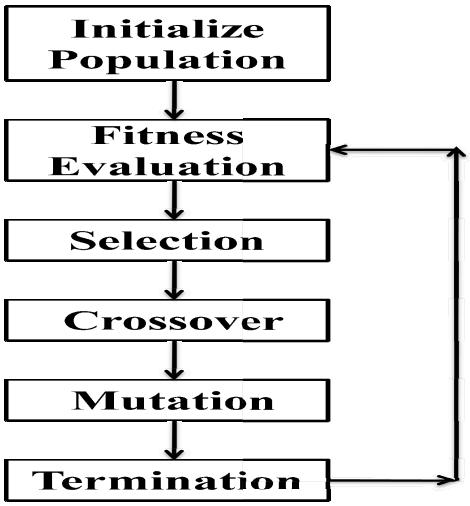

Fig.8. Basic structure of Genetic Algorithm (GA).

TABLE II
DATA FOUND AFTER 20 GENERATIONS

Generations	Best f(λ,V,Q)	Mean f(λ,V,Q)
1	0.12320	0.23490
2	0.09140	0.20250
3	0.06830	0.15330
4	0.06830	0.12700
5	0.06830	0.09560
6	0.06830	0.09057
7	0.06830	0.07959
8	0.06830	0.07412
9	0.06830	0.06872
10	0.06830	0.06870
11	0.06830	0.06853
12	0.06830	0.07097
13	0.06830	0.07353
14	0.06830	0.06830
15	0.06830	0.06830
16	0.06830	0.06830
17	0.06830	0.06830
18	0.06830	0.06830
19	0.06830	0.06830
20	0.05932	0.06785

TABLE III
OPTIMIZED SOLUTIONS of GENETIC ALGORITHM

Load Factor, λ (PU)	Fluctuated voltage, V (PU)	Reactive power injection, Q (PU)	Objective Function, $f(\lambda, V, Q)$
0.07639978387976154	0.6617988711062396	0.04006849638182075	0.059323993049564

TABLE IV
ASSUMED BASE VALUE of the PARAMETERS

Maximum demand	Supply voltage	SVC rating
1 MW	230 V	5 MVAR

$$\text{Average load} = \text{Load factor} \times \text{Maximum demand} \quad (5)$$

The actual values of the parameters can be found from the following equation

$$\text{Actual value} = \text{Base value} \times \text{Per unit value} \quad (6)$$

TABLE V
EVALUATED ACTUAL VALUES of the PARAMETERS

Average load	Supply voltage	SVC rating
0.07639978387976154 MW	152.2137265 V	0.200342481 MVAR

Therefore, if it is considered that the maximum demand of the system is 1 MW, while the maximum values of supply voltage and the maximum rating of available SVC are 230 V and 5 MVAR respectively, then the solution of genetic algorithm in terms of actual value suggests that 76.4 kW average load causes the voltage to fluctuate approximately to 152 V and 0.2 MVAR reactive power is needed to supply to the system for voltage compensation.

IV. CONCLUSIONS

The procedure of attaining system stability with the help of Static VAR Compensator (SVC) has been presented in this paper as it has the capability of providing reactive power. The utilization of optimization algorithms is fruitful in this case as they give optimum values. Two algorithms are applied and the comparative solutions show that genetic algorithm solves the linear objective function and gives the optimum values of load factor, voltage fluctuation and reactive power in a more precise way than that of linear algorithm.

In future, these optimized methodologies would find its extensive utility when it comes to dealing with reactive power management in a large power system.

Power System Stabilizer Tuning Based on Frequency Response Method

Asif Ferdoush,* M. G. Rabbani

Department of Electrical & Electronic Engineering, Eastern University
Dhaka-1205, Bangladesh
*asifferdoush@gmail.com

Abstract— **Stability phenomena of the power system are largely studied by the researchers over the last few decades. In order to ensure a stable power system, power system stabilizer (PSS) is adopted which can increase the stability margin by providing supplementary feedback signal. For an efficient stabilization, the proper tuning of PSS parameters is very important. Now a days, the tuning appears a big challenge as the changes in power requirement take place continually. This paper deals with the tuning process of PSS connected to the single machine infinite bus (SMIB) system. The tuning method is decided based on the transfer function from SMIB model and the system frequency response. Simulation results are presented with and without PSS to demonstrate the effectiveness of proposed tuning method.**

Index Terms— **Stability, low frequency oscillation, damping torque, PSS, transfer function, frequency response.**

I. Introduction

To ensure power system security and protection, an extensive research has been carrying out worldwide on the stability of power system. It is very important and a major requirement to secure system operation for an efficient power system [1]. Continuous network extension and ongoing interconnection due to increased load demand raises complexity of the power system [2]. After being perturbed by any kind of disturbances (i.e. continuous load change, line to line or line to ground fault, lightening etc.) from power grid, the rotor oscillation of the synchronous generator takes place. This low frequency oscillation must be damped out quickly before it gets stronger with increasing amplitude [3]. Otherwise, the synchronism may be deteriorated and synchronous generator will be tripped out from the grid by means of protective relays. Therefore, it is imperative that special control methods are used to perform the stabilization and adequately damping these low frequency oscillations [1]. In order to do that, PSS is employed with the system which is equipped with generator control system to provide adequate damping torque to the rotor during oscillations. As a result, power system stability gets improved and thereby extends the power transfer capability [4]. Now a days, population based methods like Particle Swarm Optimization (PSO), Genetic Algorithm (GA) etc. are very commonly used for PSS tuning problems [4]. In this tuning approach, conventional power system stabilizer (CPSS) is studied and its parameters are tuned by using frequency response.

II. Background of Rotor Oscillation

When power system is subjected to any kind of disturbances, the rotor angle of synchronous generator oscillates [5]. The oscillation mainly comes from the change in power requirements. Normally under steady state operation, there maintains a balance between mechanical power given by the prime mover and electrical power output of the generator [6]. But with the increase in load, the output of electrical power also increases relative to the input of mechanical power and in turn, both powers appear to be unbalanced. As a result, the stator revolving field of generator increases with constant rotor field. Therefore, the resulting electromagnetic torque, which opposes the rotor rotation, also changes [7]. So, rotor speed tends to decrease for increasing load. But input mechanical torque given by the prime mover opposes this speed to be changed. Hence, an electromechanical oscillation occurs according to the laws of motion of a rotating body [6]. When load decreases, the same interaction as mentioned above between rotor and stator field occurs but in reverse way and rotor speed tends to increase. When rotor oscillates, its speed deviates slightly from the rated speed in positive and negative manner. So field must be increased when speed deviation is negative and vice versa. In general, the excitation system of generator is equipped with PSS which can sense the speed change and provides appropriate damping torque based on the proper tuning technique [3].

III. System Model

The following is the feedback power control model where GS is generator and E_g is generated voltage to the grid which is fed back to the summing point to regulate itself by modulating the rotor field, E_{FD}. Turbine provides mechanical power P_m to the generator shaft. In this model, PSS is added to provide more damping by controlling the field current I_f. It senses the change of rotor speed and gives supplementary feedback signal E_{PSS} following a disturbance. So, with the change of rotor speed ω, the rotor field also changes by PSS. For a proper stabilization, the change of field current must be in phase with the change in rotor speed [3].

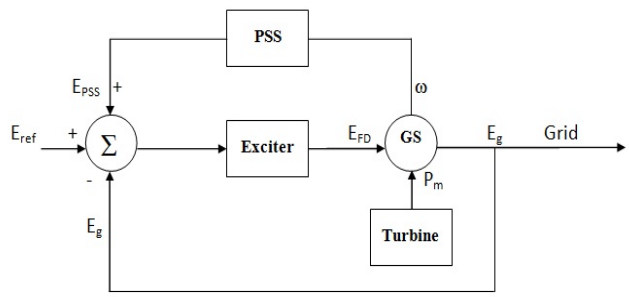

Fig. 1. Feedback power control model

A. Linear Model

The real power control model is a very highly nonlinear model and sophisticated to use. Hence the following

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

simplified linear model is used for synchronous generator system [8].

$$\Delta E'_q = \frac{k_3}{1+sk_3T'_{d0}}\Delta E_{FD} - \frac{k_3k_4}{1+sk_3T'_{d0}}\Delta\delta \quad (1)$$

$$\Delta T_e = k_1\Delta\delta + k_2\Delta E'_q \quad (2)$$

$$\Delta V_t = k_5\Delta\delta + k_6\Delta E' \quad (3)$$

$$2H\Delta\dot{\omega} = \Delta T_m - \Delta T_e - \Delta T_D \quad (4)$$

$$\Delta T_D = D\Delta\omega \quad (5)$$

$$\Delta\delta = \frac{\omega_0}{s}\Delta\omega\ ;\quad H \overset{\Delta}{=} \frac{\frac{1}{2}J(\omega_B\frac{2}{P})^2}{S_B} \quad (6)$$

The parameters of the above equation are summarized below:

TABLE I
SYSTEM PARAMETER

Parameter	Description
E_{FD}	Field voltage
δ	Rotor angle
V_t	Terminal voltage of generator
E'_q	Excited voltage
T'_{d0}	d-axis transient time constant
H	Inertia
T_D	Damping torque
T_e	Electrical torque
T_m	Mechanical torque

B. PSS

A commonly used approach is based on the conventional PSS structure which is composed of a gain, a wash out circuit and a cascade of two-phase lead network [9]-[11]. The output of PSS is then limited by the limiter to its required value. The PSS output is normally a signal applied to the reference input of the excitation system. The generator speed is assumed as the input of the PSS structure [12].

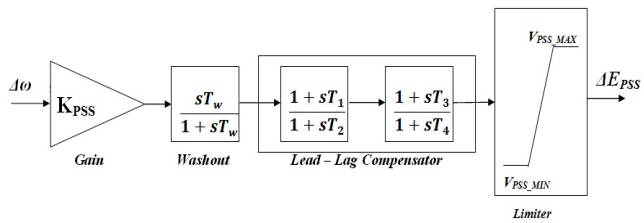

Fig. 2. Conventional PSS structure.

The transfer function of the PSS block is given below:

$$PSS = K_{PSS}\left(\frac{sT_w}{1+sT_w}\right)\left(\frac{1+sT_1}{1+sT_2}\right)\left(\frac{1+sT_3}{1+sT_4}\right) \quad (7)$$

TABLE II
PSS PARAMETERS

Parameter	Description
K_{PSS}	PSS gain compensator
T_w	Washout time constant
T_1, T_2, T_3, T_4	PSS phase compensator parameters

C. Single Machine Infinite Bus (SMIB) System

From the above linear equation a model is found which is also called Heffron-Phillips SMIB model and given next [13]. Equations of the constants k_1-k_6 are given in the appendix [14].

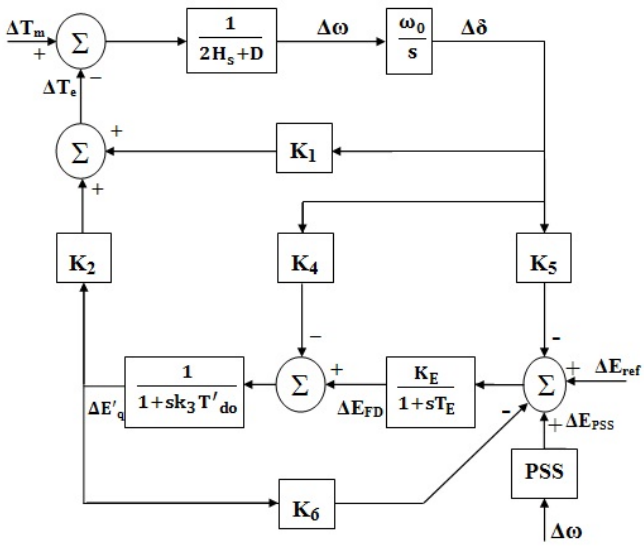

Fig. 3. Linearized synchronous generator control model.

From the above model, the stabilization of the power system means the stabilization of the power angle δ. By controlling the power angle, speed deviation can be damped out. But from the equation (4), δ depends on electromagnetic torque T_e and damping torque T_D. In the short period of time, the input mechanical torque T_m from turbine has no effect on δ, following a disturbance, because of its high inertia. And from the equation (5) damping torque always changes with the speed change Δω. Then, to make the system stable, the controlling parameter left is T_e in order to create more damping. And maximum damping can be obtained by keeping ΔT_e in phase with Δω [10, 13]. In that case, the frequency response method is applied to adjust the phase. So the transfer function between ΔT_e and Δω with and with PSS is derived from the SMIB model. In the above, torque and power have been used as substitute to each other; since, in per unit system, they are very nearly equal [7].

1) *System Transfer Function in Absence of PSS*: When PSS is not equipped with the model the transfer function between ΔT_e and Δω can be found as:

$$\Delta E_{FD} = -\left(\frac{K_E}{1+sT_E}\right)\left(k_5\Delta\delta + k_6\Delta E'_q\right) \quad (8)$$

$$\Delta E'_q = \frac{\left(\frac{k_3}{1+sk_3T'_{d0}}\right)\left(-\frac{K_Ek_5}{1+sT_E} - k_4\right)}{\left(1+\frac{k_3k_6K_E}{(1+sk_3T'_{d0})(1+sT_E)}\right)}\Delta\delta \quad (9)$$

So the close loop transfer function from Δω to ΔT_e in absence of PSS is:

$$G_0(s) = \frac{\Delta T_e}{\Delta\omega};$$

$$G_0(s) = \frac{\omega_0}{s}\left(k_1 - \frac{\left(\frac{k_2k_3}{1+sk_3T'_{d0}}\right)\left(\frac{K_Ek_5}{1+sT_E} + k_4\right)}{\left(1+\frac{k_3k_6K_E}{(1+sk_3T'_{d0})(1+sT_E)}\right)}\right) \quad (10)$$

2) *System Transfer Function in presence of PSS:* The relation between ΔT_e and $\Delta\omega$ in presence of PSS is:

$$\Delta E_{FD} = \left(\frac{K_E}{1+sT_E}\right)\left(\Delta E_{PSS} - k_5\Delta\delta - k_6\Delta E'_q\right) \quad (11)$$

$$\Delta E'_q = \frac{\left(\frac{k_3}{1+sk_3T'_{d0}}\right)\left(\frac{K_E}{1+sT_E}\right)PSS}{\left(1+\frac{k_3k_6K_E}{(1+sk_3T'_{d0})(1+sT_E)}\right)}\Delta\omega - \frac{\left(\frac{k_3}{1+sk_3T'_{d0}}\right)\left(\frac{k_5K_E}{1+sT_E}+k_4\right)\frac{\omega_0}{s}}{\left(1+\frac{k_3k_6K_E}{(1+sk_3T'_{d0})(1+sT_E)}\right)}\Delta\omega \quad (12)$$

So, in presence of PSS the transfer function becomes

$$G_{PSS}(s) = k_1\frac{\omega_0}{s} + \frac{\left(\frac{k_3}{1+sk_3T'_{d0}}\right)\left(\frac{K_E}{1+sT_E}\right)PSS}{\left(1+\frac{k_3k_6K_E}{(1+sk_3T'_{d0})(1+sT_E)}\right)} - \frac{\left(\frac{k_3}{1+sk_3T'_{d0}}\right)\left(\frac{k_5K_E}{1+sT_E}+k_4\right)\frac{\omega_0}{s}}{\left(1+\frac{k_3k_6K_E}{(1+sk_3T'_{d0})(1+sT_E)}\right)} \quad (13)$$

The phase of the Bode diagram will be considered based on the above transfer function between ΔT_e and $\Delta\omega$ with or without PSS. The proposed tuning method will be described as follows keeping ΔT_e in phase with $\Delta\omega$.

IV. Tuning Methodology and Results

The tuning method applied for PSS parameters in this study is based on the frequency response. As described earlier that the change in electrical torque must be in phase with speed change. Hence from the transfer function above between ΔT_e and $\Delta\omega$, either with or without PSS, we get Bode phase plot.

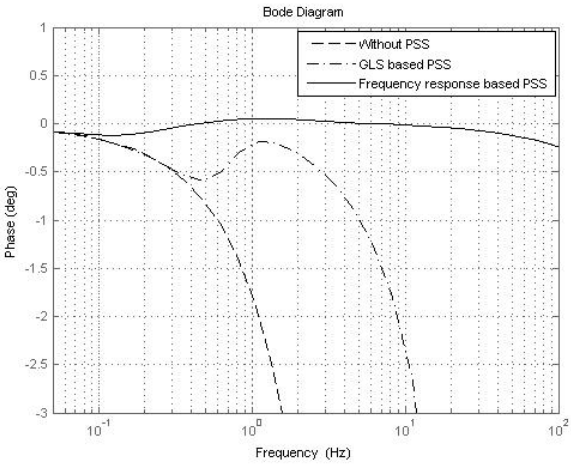

Fig. 4. Frequency response of the system.

As it is not possible to arrange for the phase to be zero for all frequencies, so concentration must give on the frequency range where most of the power oscillations exist, between 0.1 and 3 Hz [13]. For the proper stabilization, the phase lag between ΔT_e and $\Delta\omega$ in this frequency range must be less than 90 degree [15]. Although in Fig. 4, without PSS the phase lag between them is less than 90 degree in this frequency range, the phase lag, for optimal tuning, is further studied to reduce it nearly to zero. So the value of gain and lead-lag compensator parameter by using frequency response is optimized. Initially, during tuning process, the value of $T_1 = T_3 = 0.01$ sec, $T_2 = T_4 = 0.05$ sec and $T_w = 10$ sec were selected. The value of K_{PSS} was increased slowly starting from 1.0 with the change of T_1 and T_2. It is found that the lower value of K_{pss} provides negligible effect on the tuning. K_{PSS} was increased until leading phase is appeared in the above frequency range. Then T_1 was increased and T_2 was decreased simultaneously to make the lagging phase between ΔT_e and $\Delta\omega$ near to zero. The parameters of the system used in this study for simulation has been taken from elsewhere where the approach was to tune the PSS parameter using genetic local search algorithm [16]. From the Bode plot in the frequency range from 0.1 to 3 Hz, the GLS based PSS shows the phase lag very close to that for without PSS. But after tuning by the present approach described above, the phase lag in 0.5 Hz is reduced near to zero, where the phase was - 0.75 degree without PSS and -0.6 degree with GLS based PSS.

The simulation results of the proposed tuning, for step disturbance of 3.5% and 5% in mechanical input, are shown in Fig. 5 and Fig. 6 for SMIB system as discussed above.

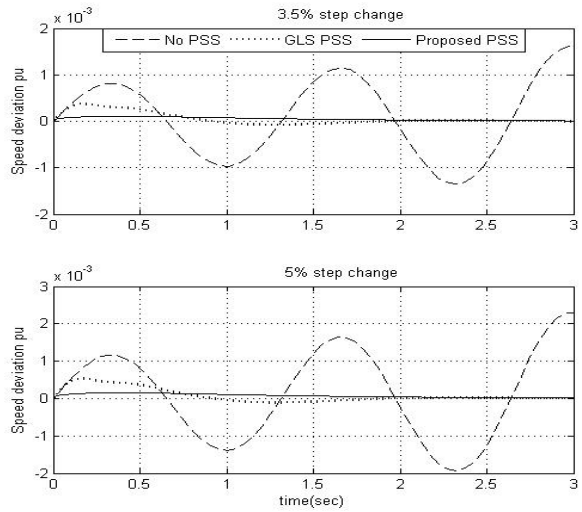

Fig. 5. Speed deviation $\Delta\omega$ vs time for disturbance ΔT_m=3.5% & 5%.

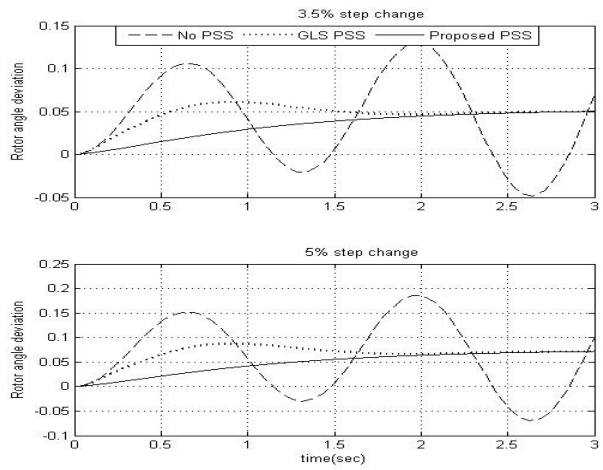

Fig. 6. Rotor angle deviation $\Delta\delta$ vs time for disturbance ΔT_m=3.5% & 5%.

If no PSS is equipped with the excitation system, the speed deviation of the rotor following a step disturbance will continue with increasing amplitude as depicted in Fig. 5. The GLS based PSS shows adequate damping but this is not optimum for perfect stabilization. The more damping, as shown by solid line in Fig. 6, is created after tuning the PSS parameters by frequency response and the deviation is reduced significantly. After the tuning, the rotor angle deviation is also damped out more quickly than GLS based PSS. In Fig. 6, it is shown that rotor angle starts to be stable after 2.5 seconds without any overshoot which justifies the effectiveness of the proposed tuning method.

V. Conclusions

In this paper, a design scheme of power system stabilizer for a single machine infinite bus system has been developed. The PSS parameters are tuned as per requirement while other system parameters remain the same. The proposed tuning method is based on the frequency response of the system. The transfer function between the electrical output torque change and corresponding speed deviation is derived. Thus, by decreasing the phase lag between them, the rotor angle oscillation is undermined. The system performance is observed under MATLAB environment. The result shows the effectiveness of the proposed tuning scheme.

Appendix

Generator parameters:

$x_d = 0.973$ p.u.; $x'_d = 0.19$ p.u.; $x_q = 0.55$ p.u.; $v_{t0} = 1.00$ p.u.; $\omega_0 = 314$ rad/sec; $T'_{d0} = 7.765$ sec;

Exciter parameters:

$K_e = 50$, $T_e = 0.05$ sec;

Transmission line parameters:

$r_e = 0$ p.u.; $x_e = 0.997$ p.u.;

PSS parameters:

$T_w = 10$ sec;

PSS	K_{PSS}	$T_1=T_3$	$T_2=T_4$
GLS based PSS	35.1469	0.2078	0.05
Frequency Response based PSS	200	0.15	0.002

Calculation of Heffron-Phillips constants:

$$k_1 = \frac{x_q - x'_d}{x_e + x'_d} i_{q0} E_0 \sin\delta_0 + \frac{E_{q0} E_0 \cos\delta_0}{x_e + x_q};$$

$$k_2 = \frac{E_0 \sin\delta_0}{x_e + x'_q}; \; k_3 = \frac{x_e + x'_d}{x_e + x_d}; k_4 = \frac{x_d - x'_d}{x_e + x'_d} E_0 \sin\delta_0;$$

$$k_5 = \frac{x_q}{x_e + x_q}\frac{e_{d0}}{e_{t0}} E_0 \cos\delta_0 + \frac{x'_d}{x_e + x'_d}\frac{e_{q0}}{e_{t0}} E_0 \sin\delta_0;$$

$$k_6 = \frac{x_e}{x_e + x'_d}\frac{e_{q0}}{e_{t0}};$$

The parameters i_{q0}, e_{d0}, e_{q0}, i_{d0}, E_{q0}, E_0 and δ_0 can be calculated from the following equations.

$$i_{q0} = \frac{P_0 e_{t0}}{\sqrt{(P_0 x_{q0})^2 + ({e_{t0}}^2 + Q_0 x_q)^2}};$$

$$e_{d0} = i_{q0} x_q; \quad e_{q0} = \sqrt{{e_{t0}}^2 - {e_{d0}}^2}; \quad i_{d0} = \frac{Q_0 + {i_{q0}}^2 x_q}{e_{q0}};$$

$$E_0 = \sqrt{(e_{d0} + i_{q0} x_e)^2 + (e_{q0} - i_{d0} x_e)^2};$$

$$E_{q0} = e_{q0} + i_{d0} x_q; \quad \delta_0 = \tan^{-1}\left(\frac{e_{d0} + i_{q0} x_e}{e_{q0} - i_{d0} x_e}\right).$$

Transient Performance Improvement of Power System by Optimal Design of SVC Controller Employing Genetic Algorithm

Abstract- **With the increase of loading of long transmission line, transient stability of power system on the occurrence of a fault become one of the major concern for power engineers. Instability problem of power system on occurrence of the fault can be solved with the use of Static VAR Compensator (SVC) controller. Assessing the transient stability of a large inter connected power network very much nonlinear and tremendously complicated. To mitigate this complication and nonlinearity, a substantial research with SVC controller has been done in the power industry. To improve the system stability for dynamic and transient disturbances SVC plays a very important role, which is a shunt connected FACTS devices. In this work, genetic algorithm based optimal design of SVC controller to improve the transient performance of power system is proposed. The parameters of the damping controller by optimal selection of damping ratio of the critical eigenvalue employing genetic algorithm are tuned. The effectiveness of the developed optimal controller is investigated by simulating different abnormal conditions of a single machine infinite bus (SMIB) system using MATLAB based PST.**

I. INTRODUCTION

Power system network is the largest and the most complex system ever devised by man, which consist of thousands of buses and hundreds transformers, generators, capacitor banks, cables and lines. The power export import arrangements are done through transmission networks but due to the growth of demand on such large system the capacity of the transmission networks have to be enhanced by adding new parallel lines. The construction of new transmission line requires significant amount of time as well as it requires huge amount of investment, consequently the utility planners look forward to utilize full capacity of the existing resources and transmission lines but getting maximum power transfer through the existing transmission networks with minimum price has become one of the utmost challenges for today's transmission system operators. In meeting this challenge, early researchers explored the possibility of using series compensation of transmission line. In [1], R.E. Marbury et. al. introduced series capacitor as an element connected in series with the line to improve the voltage by interleaving negative reactance whereas in [2] several methods of applying series capacitor are discussed. The concepts of thyristor assisted FACTS was first introduced by N. G. Hingorani [3] to reduce transmission cost. To facilitate initialization of the steady state parameters a new linear continuous TCSC model in state-space form was derived [4]. A hybrid power system having both TCSC and series capacitors, a SDC is proposed by X. Zheng, Z. Xu, and J. Zhang [5] to mitigate sub synchronous resonance (SSR) caused by the series capacitors. The proposed damping controller is composed of a band pass filter, a gain, two or more lead-lag blocks and a limiter. The authors used the deviation of the generator speed as the input signal than that of bus voltage magnitude, line current, active power etc. as reported in [6, 7]. A. A. Edris proposed VAR compensator to enhance load-ability of low capacity power system in [8].

Power transmission capacity and system stability improvement by Static VAR Compensator (SVC) have been presented in [9] where with the help of voltage control loop the bus voltage has been controlled. The voltage control loop is comprised of thyristor controlled reactor (TCR), voltage regulator, voltage magnitude transducer and thyristor switched capacitor (TSC) firing circuit. In real time operation there are uncertainties in power system reactance of the transmission path and SVC regulator time constant so the retuning the SVC controller is necessary when these uncertainties are large enough besides those uncertainties power system parameters and quantities are changed due to the change in system structure such as load addition, generation outage over time. In order to minimize above difficulties, a new nonlinear robust adaptive SVC controller which can deal with both constant and time varying systems is proposed in [10]. R. Griinbaum in [11] presented several benefits of FACTS devices in power transmission systems, TCSC and SVC are shown to be very vigorous and effective means to enhancing damping for long distance transmission system.

As the demand of energy is increasing every day and to

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

meet the new demands some portion of the transmission network becomes overloaded as well as because some disturbances the power system become unstable, the transient stability refers the ability of a power system to maintain synchronism through finding a new equilibrium point (operating point) subjected to a large disturbance [12] has become a matter of fact at the power system industry. The improvement of transient stability using UPFC and SVC are reported in [13] whereas Abedin and Malik reported in [14], with the help of dynamic action the SVC can offer damping and can enhance overall power system stability. Low frequency oscillation of power system can be well damped employing SVC which has been discussed [15] whereas in [16] a novel genetic algorithm based PI controller has been designed to improve system stability. PSO algorithm is effectively utilized, here by synchronized tuning of synergetic excitation damping controller and SVC based damping controllers the power system stability has been improved which has been addressed in [17] where as a supplementary controller a lead - lag compensator is employed for the SVC. A novel optimization technique for simultaneous coordination between PSS and SVC for multimachine power system as a damping controller to damp the oscillation is reported in [18] where chaos theory and particle swarm optimization technique are hybridized to form a chaotic particle swarm optimization (CPSO). In [19] a popular meta-heuristic optimization technique usually known as Firefly Algorithm (FA) is addressed to design SVC controller in multi machine power system. With the coordination PSS and SVC the enhancement of power system stability is investigated in [20].

This work proposes a genetic algorithm based SVC controller to damp system oscillation to improve transient stability upon occurrence of fault and the developed optimal controller is applied to a SIMB to validate by simulating abnormal conditions using MATLAB based PST.

II. POWER SYSTEM MODELING

A. Synchronous Generator

In this work a SMIB system has been taken and an SVC has been set up in transmission network as shown in fig. 1. A local load with admittance $Y_L = g + jb$ is connected to the bus of generator and the transmission line has two impedances for two sections named $Z_1 = R_1+jX_1$ and $Z_2 = R_2+jX_2$ which has been shown in the following figure.

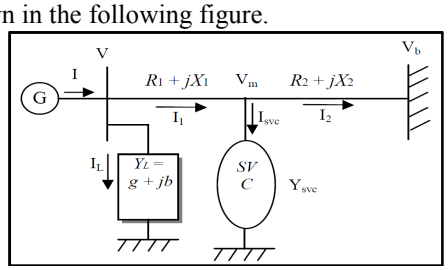

Fig.1 SVC connected Single Machine Infinite Bus System

The fourth order model of the generator has been considered which comprising of the generator internal voltage (produced by generated EMF) equation, IEEE standard type excitation system as well as the electromechanical swing equation. Equations (1) and (2) show the electromechanical swing equation. Internal voltage produced by generated EMF can be represented by equation (3) and the regulator exciter system is represented as in IEEE type ST in equation (4):

$$\dot{\delta} = \omega_b(\omega - 1) \quad (1)$$

$$\dot{\omega} = \frac{1}{M}(P_m - P_e - P_D) \quad (2)$$

$$\dot{e'_q} = \frac{1}{T'_{d0}}\left[E_{fd} - e'_q - (x_d - x'_d)i_d\right] \quad (3)$$

$$\Delta E_{fd} = \frac{k_E}{1+sT_E}\left[v_{tr} - v_t + u_E\right] \quad (4)$$

The terminal voltage can be expressed in terms of direct axis and quadrature axis voltage which is shown in equation (5). Equations (6) and (7) show the expressions for direct axis and quadrature axis voltages respectively.

$$v_t = (v_d + jv_q) = \sqrt{(v_d^2 + v_q^2)} \quad (5)$$

$$v_d = x'_q i_q \quad (6)$$

$$v_q = -x'_d i_d + e'_q \quad (7)$$

Output power of the generator is expressed in terms of quadrature and direct axes quantities as shown in equation (8)

$$P_e = v_d i_d + v_q i_q \quad (8)$$

System data for the proposed model of fig.1 is given below in table I

Table I: System Data

Line Data (pu)	Generator Data (pu)
$X_1 = 0.4985$	$x_q = 0.55$
$X_2 = 0.4985$	$x_d' = 0.19$
$R_1 = 0.017$	$x_d = 0.973$
$R_2 = 0.017$	D=0
b= 0.262	M=9.26
g= 0.249	$T_{do}' = 7.76$

B. SVC based Stabilizer

To control the reactive power injection of a chosen bus a special type of shunt compensation device is used in transmission network which is commonly known as static VAR compensator (SVC). By regulating the reactive power injection SVC enhances steady state power transmission limit, hence it improves the stability (transient) of the power system [21]. The power swing damping controller [9] is shown in Fig. 2. To provide the compensation two or more lead-lag blocks are used and to produce modulation signal the output of the compensator is passed through first order lag which is commonly known as a limiter. To deactivate the controller in steady state operation a washout/rest block is connected. Here the input signal is the change in generator angular frequency and the output is the state x_8.

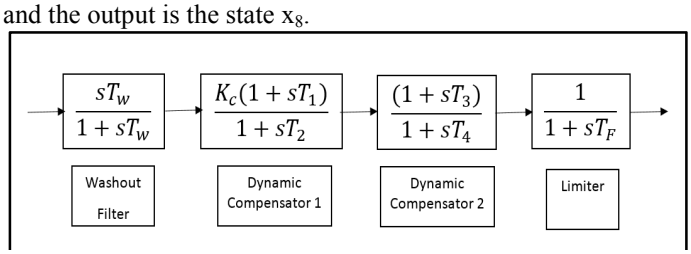

Fig. 2 SVC power swing damping controller

C. System Linearized Model

The incremental linearized model around an operating point is usually employed in the design of damping controllers but the fourth order generator model represented by equations (1)-(4) are nonlinear, so we have to linearize the equations to find

$$\dot{x} = f(x, u_E) \quad (9)$$

$$x \text{ are the states and } u_E \text{ is the input}$$

For the purpose of linearization first of all, we have to linearize the direct and quadrature axes currents [22] then substituting in equations (1)-(7) to have the following linearized equations.

$$\Delta\dot{\omega} = a_{11}\Delta\omega + a_{12}\,\Delta\delta + a_{13}\,\Delta e_q' \quad (10)$$

$$\Delta\dot{\delta} = a_{21}\Delta\omega \quad (11)$$

$$\Delta\dot{e_q'} = a_{32}\,\Delta\delta + a_{33}\Delta e_q' + a_{34}\,\Delta E_{fd} \quad (12)$$

$$\Delta\dot{E}_{fd} = a_{42}\,\Delta\delta + a_{43}\,\Delta e_q' + a_{44}\,\Delta E_{fd} + a_{48}\,x_8 \quad (13)$$

$$\dot{x_5} = a_{51}\,\Delta\omega + a_{52}\,\Delta\delta + a_{53}\,\Delta e_q' + a_{55}\,x_5 \quad (14)$$

$$\dot{x_6} = a_{61}\Delta\omega + a_{62}\Delta\delta + a_{63}\,\Delta e_q' + + a_{65}x_5 + a_{66}\,x_6 \quad (15)$$

$$\dot{x_7} = a_{71}\,\Delta\omega + a_{72}\,\Delta\delta + a_{73}\,\Delta e_q' + a_{75}x_5 + a_{76}\,x_6 + a_{77}\,x_7 \quad (16)$$

$$\dot{x_8} = a_{87}\,x_7 + a_{88}\,x_8 \quad (17)$$

III. SVC PARAMETERS TUNING USING GA

Genetic algorithms are probabilistic search methods and it is based on the ideas of evolutionary processes. It is a global search algorithm that is founded on the concept of natural genetics and the Darwinian survival-of-the-fittest code [23]. The GA based SVC controller parameters found using GA are shown in Table II. The Eigen values of the disturbed system and the system with damped controller are presented in Table III. The Eigen values in the left half plane shows the system stability with SVC.

Table II: Optimal parameters found GA based SVC

Gain (K_c)	Lead time (T_1=T_3)	Lag time (T_2=T_4)
90.4278	2.0686	0.5175

Table III: Eigen Values associated with fourth order linear model and with SVC based controller

Fourth Order Linear Model	With SVC Controller
-204	-204.01
-.36 + 5.70i	-3.01 + 7.12i
-0.36 - 5.70i	-3.01 - 7.12i

--	-0.42 + 1.23i
--	-0.42 - 1.23i
--	-0.45 +.01i
--	-0.45 -.01i

IV. SIMULATION TOOL

For the simulation purpose MATLAB and MATLAB based Power System Toolbox (PST) has been used. To find the optimal values SVC parameters genetic algorithm has been coded in MATLAB environment. These optimal values are used to simulate a three phase fault in PST. The details information about the tool are available in [24].

V. SIMULATION RESULTS

Transient analysis of a SIMB system has been performed without and with GA based SVC controller to show positive effect of damping controller on damping power system oscillation. A three phase disturbance has been applied at t=0.3 second at infinite bus with subsequent tripping of line. Improvement in transient performance of the system is observed in time domain simulation with GA based SVC controller than that of without controller. The maximum level of compensation is depicted in fig. 3 provided by the SVC in the after fault scenario and then it decreases gradually. Bus voltage behavior with and without GA based SVC is presented in fig. 4. The figure shows after experiencing an oscillation of few seconds the bus voltage become flattened with a GA based optimal controller whereas for uncontrolled system oscillation stays live.

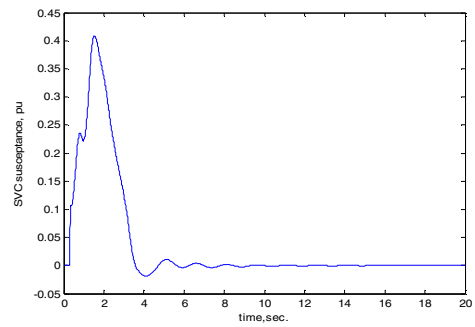

Fig. 3Variation of SVC susceptance with respect to time

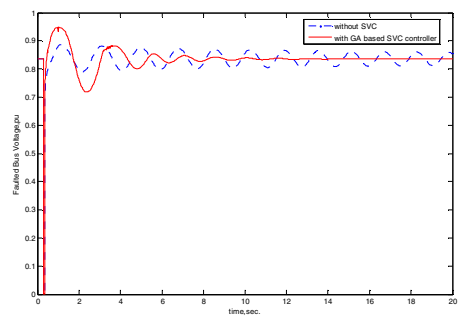

Fig. 4 Comparison of voltage profile with and without GA based SVC controller

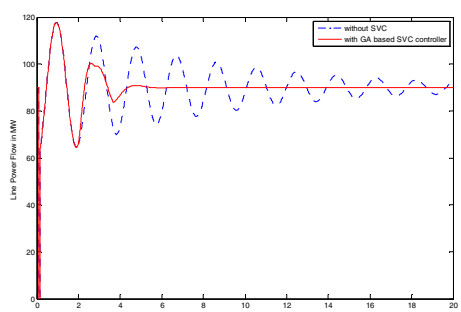

Fig. 5 The line power flow

Line power flow settles to its steady state value after a few seconds of oscillations with a GA based SVC damping controller; however, without SVC controller line power oscillates throughout the entire simulation period, which is not desired in power system operation at all. Line power flow behavior is shown in fig. 5. Oscillation in machine angle is well damped with GA based SVC damping controller parameters is depicted in fig. 6. The figure clearly depicts that system is stable with optimal controller. Finally, the fig. 7 shows the effectiveness of GA based SVC damping controller to damp machine speed deviation. Oscillation in machine speed deviation is observed during the entire simulation period without designed SVC. However, GA based SVC damping controller damps machine speed deviation and shows stable operation.

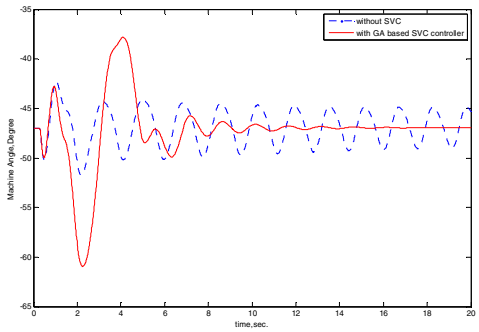

Fig. 6 Comparison of oscillation in machine angle

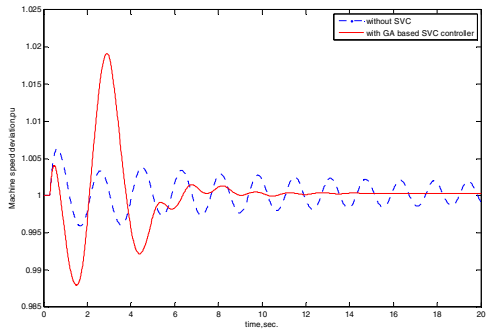

Fig. 7 Comparison of angular speed deviation

VI. CONCLUSIONS

In this work, a GA based SVC controller is designed for damping oscillations in power system. The proposed controller has been applied to SMIB system. Simulation has been performed in MATLAB based PST software and simulation results show the effectiveness of the designed controller. As at severe contingencies and stressed operating conditions the mathematical model of a power system is usually involved with a huge set of nonlinear equations, to ensure improved dynamic performance of the system the controller could be designed to reflect the nonlinearity.

VII. APPENDIX

The parameters used in equations (10)-(17) are given below:

$$a_{11} = -\frac{D}{M}, a_{12} = -\frac{K_1}{M}, \quad a_{13} = -\frac{K_2}{M}, \qquad a_{21} = \omega_0,$$

$$a_{32} = -\frac{K_4}{T'_{d0}}, \; a_{33} = -\frac{1}{K_3 T'_{d0}}, \; a_{34} = -\frac{1}{T'_{d0}}, a_{42} = -\frac{K_E K_5}{T_E},$$

$$a_{43} = -\frac{K_E K_6}{T_E}, \; a_{44} = -\frac{1}{T_E}, \; a_{48} = \frac{K_E}{T_E}, a_{51} = -\frac{D}{M},$$

$$a_{52} = -\frac{K_1}{M}, \; a_{53} = -\frac{K_2}{M}, a_{55} = -\frac{1}{T_w}, a_{87} = \frac{1}{T_F}$$

$$a_{61} = -\frac{DT_1K_c}{MT_2}, \; a_{62} = -\frac{T_1K_1K_c}{MT_2}, \; a_{63} = -\frac{T_1K_2K_c}{MT_2}$$

$$a_{65} = \left(\frac{K_c}{T_2} - \frac{T_1K_c}{T_2T_w}\right), \; a_{66} = -\frac{1}{T_2}, \qquad a_{71} = = -\frac{DT_1T_3K_c}{MT_2T_4}$$

$$a_{72} = -\frac{T_1T_3K_1K_c}{MT_2T_4}, \; a_{73} = -\frac{T_1T_3K_2K_c}{MT_2T_4}, a_{77} = -\frac{1}{T_4},$$

$$a_{75} = \frac{T_3}{T_4}\left(\frac{K_c}{T_2} - \frac{T_1K_c}{T_2T_w}\right), \; a_{76} = \left(\frac{1}{T_4} - \frac{T_3}{T_2T_4}\right), a_{88} = -\frac{1}{T_F}$$

***Abstract*—The simultaneous ac-dc power transmission system can improve the transient stability of a power system. A mathematical model for ac-dc composite system, suitable for stability analysis, is developed in this paper. To compare the ac transmission system with the composite system a comprehensive analysis in terms of stability is made using the proposed model. A numerical analysis is also carried out to compare the stability of the composite system with that of a system with ac transmission only.**

NOMENCLATURE

P_l	Steady state power flow through unconverted ac line in p.u
E_g	Internal generated voltage of the generator in p.u
E_r	Receiving end voltage in p.u
X	Transfer reactance of unconverted ac system in p.u
I_{th}	Thermal limit of the conductor
I_L	Steady state current of unconverted line
δ	Load angle of the generator for unconverted system
H	Inertia constant
ω_s	Angular frequency
δ_0	Prefault steady state load angle for unconverted system
δ_{cr}	Critical clearing angle for unconverted system
T_{cr}	Critical clearing time for unconverted system
P_{comb}	Combined steady state ac-dc power flow
I_{dc}	DC component of the composite system line current
I_{AC}	AC component of the composite system line current
δ_{ac}	Rotor angle due to ac power transfer
δ_{dc}	Rotor angle due to dc power transfer
δ_{CR}	Critical clearing angle in converted system
P_{dcmax}	Maximum transmissible dc power
P_{acmax}	Maximum ac power in ac-dc composite system
P_{emrg}	Maximum combined ac-dc power that can be transfer at any emergency period

I. INTRODUCTION

Long EHV ac transmission line has a limitation of being loaded heavily because of transient stability problem. Flexible AC Transmission System (FACTS) can be used in existing EHV ac transmission line to improve stability [1-2]. A combined system like EHV ac and HVDC system can be operated in parallel for stability improvement [3]. A generic concept combining both transient angle and voltage stabilities of parallel ac-dc transmission is introduced in [4]. The authors of this paper clearly exposed that the utilization of inherent short term overload capacity of the dc system converters can increase the stability margin of ac system.

Another new approach, which is very much close to ac-dc parallel system, is proposed to increase stability of existing transmission line in [5]. In this proposed approach same transmission line carries ac power along with dc power simultaneously. The main benefit of simultaneous ac-dc power transmission is that it does not require separate HVDC transmission line with its right-of-way. The authors of [5] shows stability improvement through numerical simulation, considering transient fault at different location of transmission line but did not considered the impact of dc portion of power on the rotor angle of generating unit. K.P. Basu [6] proposed a methodology to improve the stability of simultaneous ac-dc system where the system is no more ac-dc system after clearing the fault until the system enters into the normal state. In this proposed methodology ac-dc composite system would be converted into dc system just after clearing the fault by tripping the ac circuit breaker and when the system becomes healthy ac breakers would be turned on and its need special control mechanism for circuit breaker operation. To date, all the works those have been done on stability analysis for simultaneous ac-dc transmission in the literature are based on numerical approach but no work has been found on the basis of analytical approach.

To investigate the behavior of a system comprehensively an appropriate mathematical model is required. Moreover, the

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

change of which parameter of the system impact how much on its performance by using the mathematical model someone can evaluate easily.

In this paper, a comprehensive analysis is presented on simultaneous ac-dc system by developing appropriate mathematical model for improving the transient stability of an existing long ac transmission line. A numerical analysis also performed for the validation of developed mathematical model.

II. Simultaneous AC-DC Power Flow

In simultaneous ac-dc power transmission system same conductor is used to transmit ac power along with dc power, the schematic diagram of simultaneous ac-dc flow is shown in fig. 1. The main concern of this paper is to convert existing long EHV ac line into ac-dc composite line. According to the figure, a remote generating unit is feeding to an infinite bus through a long transmission line. A portion of ac power, taking from the generator bus, converted into dc form and feeding to the existing ac transmission line through the neutral point of zigzag transformer.

At the receiving end, dc portion of power is taking away from the neutral point of zigzag transformer and converted into ac before feeding to the infinite bus. Zigzag connection is used at both ends of the transmission line to avoid magnetic saturation in the transformer core due to dc current.

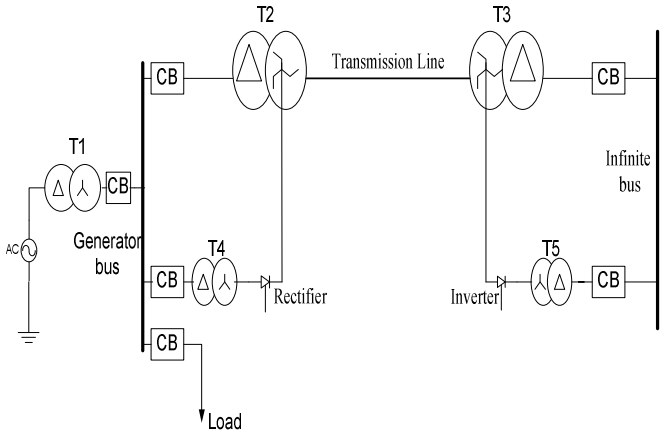

Fig. 1 AC-DC composite power transmission system

In converting ac line into ac-dc composite line the insulator remain unchanged and thus the maximum value of the phase voltages must be kept same. The output dc current of rectifier is equally divided among all the three phases and each conductor carries ac-dc modulated current wave. A communication link is needed between rectifier and inverter for better control of dc power flow.

III. Stability Model

In case of ac transmission line the power flow equation is given as follows.

$$P_l = \frac{E_g E_r}{X} sin\delta \quad (1)$$

$$X = X_{te} + X_{Tr} \quad (2)$$

Here,

X_{te} = Reactance that includes the reactance of generator and transformer in p.u.

X_{Tr} = Reactance of the transmission line in p.u.

For long ac transmission line minimum steady state stability margin is recommended as 30% and steady state power transfer angle would be 40^0 – 44^0 [7]. Although the thermal limit is qualified as line design and it depends on conductor selection but according to the loadability characteristics of a long transmission line the thermal limit is much higher than the steady state stability limit.

According to the equal area criteria of transient stability analysis of an ac system, the critical fault clearing angle and time for ac system are presented in (3) and (4) respectively.

$$\delta_{cr} = cos^{-1}[(\pi - 2\delta_0)sin\delta_0 - cos\delta_0] \quad (3)$$

$$T_{cr} = \sqrt{\frac{4H(\delta_{cr}-\delta_0)}{\omega_s P_l}} = \sqrt{(\delta_{cr} - \delta_0)}\sqrt{\frac{4H}{\omega_s P_l}} = \lambda_{ac}\sqrt{\frac{4H}{\omega_s P_l}} \quad (4)$$

Here

$\lambda_{ac} = \sqrt{(\delta_{cr} - \delta_0)}$

A generalize mathematical model for steady state power flow in ac-dc composite system is presented in (5)

$$P_{comb} = k\beta P_l + \sqrt{2}(1-k)\gamma P_l \quad (5)$$

Here

k = Percentage of ac voltage mix

1- k = Percentage of dc voltage mix

β = Ratio between I_{AC} and I_L

γ = Ratio between I_{dc} and I_L

The main advantage of ac-dc composite system is that in case of emergency period after clearing a transient fault huge energy can be transferred from sending end to the receiving end by increasing the dc power using converter control within a shorter period of time. In this case emergency short term over loading capacity of the converters can be utilized. The power transfer at the emergency period considering 50% short term over loading of the converters is as follows[4].

$$P_{emrg} = P_{acmax} \sin \delta_{ac} + P_{dcmax} \quad (6)$$

$$P_{dcmax} = \frac{3}{\sqrt{2}}(1-k)\gamma P_l \quad (7)$$

$$P_{emrg} = k\beta P_l + \frac{3}{\sqrt{2}}(1-k)\gamma P_l \quad (8)$$

After being subjected to a transient fault the critical clearing angle for the composite system can be derived as,

$$P_{dcmax}\delta_{CR} - P_{acmax}\cos(\delta_{CR} - \delta_{dcm}) = P_{dcmax}\delta_{max} + P_{acmax}\cos(\delta_{max} - \delta_{dcm}) - P_{comb}(\delta_{max} - \delta_0) \quad (9)$$

Here
δ_{CR} = Critical fault clearing angle for composite system.
δ_{dcm} = Rotor angle due to emergency dc power
δ_0 = Rotor angle due to steady state combined power
$\delta_{max} = \pi + \delta_{dc} - \delta_{ac}$

For a pure ac system it is easier to establish the simple expression for critical clearing angle that is presented in (3) but it is not feasible in composite ac-dc system by solving the equation (9). In this case several numerical techniques can be applied to evaluate the critical clearing angle. Nevertheless, a simple expression for Critical fault clearing angle is presented in (10) considering some approximation for evaluating the ac part of the combined emergency power.

$$\delta_{CR} = \delta_{max} - \frac{P_{comb}}{P_{emrg}}(\delta_{max} - \delta_0) \quad (10)$$

$$P_{emrg} = \frac{1}{2}(\beta_m + \beta_s)kP_l + \frac{3}{\sqrt{2}}(1-k)\gamma P_l \quad (11)$$

Here
B_m = The value of β for maximum ac power transmission
β_S = The value of β for steady state power transmission

The critical fault clearing time of composite system has similar type of expression of unconverted ac system that is presented below.

$$T_{CR} = \sqrt{\frac{4H(\delta_{CR}-\delta_0)}{\omega_s P_{comb}}} \quad (12)$$

$$T_{CR} = \lambda_{comb}\sqrt{\frac{4H}{\omega_s P_l}} \quad (13)$$

Combining the equation (4) and (13) the expression for critical clearing time can be further modified as,

$$T_{CR} = \frac{\lambda_{comb}}{\lambda_{ac}} T_{cr} \quad (14)$$

$$T_{CR} = C\, T_{cr} \quad (15)$$

Here, $C = \frac{\lambda_{comb}}{\lambda_{ac}}$

For the improvement in transient stability for ac-dc combined system in comparison with the unconverted ac system the value C must be greater than one, i.e. $C > 1$. For example, if the value of k is 0.5 that gives 50% ac voltage and 50% dc voltage mix and if the value of α is considered 0.5 the value of C would be 1.55. This represents 55% improvement in transient stability when ac-dc combined system is considered. In this case same power transfer angle is considered for ac power transmission in composite ac-dc system and for unconverted ac system which is 44^0 [7]. Considering some reasonable values of k and α the Stability Improvement(SI) is presented in Table I.

Table I clearly show that for a particular value of α if the value of k is increased the transient stability of the composite system will decrease. The increase in k means increase in ac voltage mix and decrease in dc voltage mix. The value of α has also a significant impact on SI. For a particular value of k smaller decrease in α gives a greater increase in SI.

TABLE I
TRANSIENT STABILITY OF AC-DC COMPOSITE SYSTEM IN COMPARISON WITH THE UNCONVERTED AC SYSTEM

k	$\alpha = \frac{I_L}{I_{th}}$	C	Stability Improvement(SI) (%)
0.5	0.50	1.55	55
	0.45	1.60	60
	0.40	1.65	65
0.52	0.50	1.54	54
	0.45	1.59	59
	0.40	1.63	63
0.54	0.50	1.52	52
	0.45	1.57	57
	0.40	1.62	62
0.56	0.50	1.51	51
	0.45	1.56	56
	0.40	1.61	61
0.58	0.50	1.49	49
	0.45	1.54	54
	0.40	1.59	59

IV. NUMERICAL ANALYSIS WITH SIMULATION RESULT

For the numerical simulation, a power system is considered that presented in appendix. In case of unconverted pure ac line, considering 30% steady state stability margin [7], following results are found after simulation.

Steady state loading = 436MW
Steady state power transmission angle = 44.44^0
Line current = 0.7574kA
Value of α = 0.4208
Critical clearing time T_{cr} = 210ms.

Now, ac-dc composite system is analyzed through developed mathematical model and obtained results are compared with those obtained from the numerical simulation using MATLAB. Table II shows that the improvement in stability found from developed mathematical model are very much close to those found from numerical simulation.

TABLE II
COMPARISON OF STABILITY IMPROVEMENT BETWEEN DEVELOPED MODEL AND NUMERICAL SIMULATION

$\alpha = \frac{I_L}{I_{th}}$	k	Improvement in critical clearing time (%)		% of error
		with developed model	with numerical simulation	
0.4208	0.50	63.63	65.50	2.85
	0.52	62.44	64.40	3.04
	0.54	61.20	63.29	3.30
	0.56	59.89	62.04	3.47
	0.58	58.52	60.77	3.70
	0.60	57.08	59.50	4.06

The developed model gives a small percentage of errors due to the fact that some logical assumptions are considered in the expression of β and δ_{CR} for bringing the simplicity in the mathematical model of ac-dc composite system.

Again the ac-dc composite system is analysed, using developed mathematical model, to investigate the impact of different dc voltage mix on stability improvement. In this case steady state loading is considered as much as the steady state loading of unconverted ac system. The change in dc voltage in composite system has huge impact on SI that is shown in fig.2. It is clearly observed from the figure that the stability improvement increases with the increase in the value of dc voltage mix and obtained improvements for this particular system varies from 22% to 64% with the dc voltage mix variation from 10% to 50% respectively.

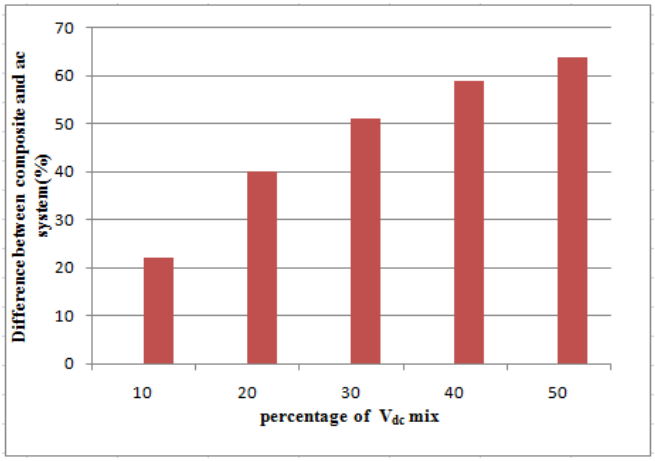

Fig. 2 Stability Improvement(SI) of ac-dc composite system.

V. Conclusion

Simultaneous ac-dc power transmission through the existing ac line improves the transient stability. The improvement in stability for the composite system (ac-dc simultaneous power flow) is shown in the paper both analytically and through numerical simulation. Moreover, ac-dc composite power transfer system provides the benefit of ac-dc parallel transmission system without claiming separate line and right-of- way. The mathematical model developed in this paper will be helpful and analytical tool for power transmission planner to take right decision whether they will go for ac-dc composite system.

Appendix

A sample power system is considered for the simulation study with numerical data

A. Unconverted AC line configuration

Base power=550MVA

Line voltages are 24kV, 132kV, 345kV for the generator, generator bus and transmission line respectively.

Ratings of different components are as follows:

Two identical generators each has the following rating 550MVA, 24kV, 50Hz, H=3.5sec, 30% transient reactance.

Transformer T_1&T_2(Between generator and generator bus) each of 550MVA, 24/132 kV, 50Hz, 10% reactance.

Transformer T_3 : 1100MVA,132/345 kV,50Hz, 8% reactance.(At the sending end of the line)

Transformer T_4 : 1100MVA,345/132 kV,50Hz, 8% reactance.(At the receiving end of the line)

Transmission line: ACSR(Moose; commercial name) twin bundle conductor, 345kV, 50Hz, 400km single circuit line has following parameters

X_{Tr} = 0.33086 Ω/km/phase, R = 0.03252 Ω/km/phase

$Y = 3.33797*10^{-6}$ S/km/phase

current carrying capacity of each sub conductor is 0.9kA.

I_{th}(thermal limit)=1.8kA,

B. Composite AC-DC configuration

Transformer T_3 = 550MVA, 132/172.5kV, 50Hz, 8% reactance.

Transformer T_4 = 550MVA,172.5/132kV, 50Hz,8% reactance.

Load Frequency Control of Multi-Microgrid Using Energy Storage System

A. Hasib Chowdhury, Md. Asaduz-Zaman*
Dept. of EEE, Bangladesh University of Engineering & Technology
Dhaka-1205, Bangladesh
*masad.eee06@gmail.com

Abstract—**Control of active power and frequency in a power system is referred to as load frequency control (LFC). A linear combination of tie line power between interconnected system and frequency deviations, defined as area control error (ACE), is regulated to zero by LFC such that frequency and tie-line power errors are forced to zeros and a balance is achieved between generation and load. This paper presents an investigation on the LFC of multi-microgrid (MMG) using energy storage system (ESS). The tie-line connected MMG system consists of two microgrids, each made up of a synchronous generator, a PV source, a wind power system, ESS and load. Control strategies are developed based on both, frequency deviation and ACE, to regulate the ESS output. A performance index is defined for comparative assessment of control strategies. Effectiveness of the frequency control strategies is studied through simulation.**

***Index Terms*—Load frequency control, Multi-microgrid, Energy storage system, Area control error, Integral square error**

I. Introduction

Conventional power generation from fossil fuels face the issues of climate change, depletion of fossil fuel resources, and rising energy demand. These challenges can be addressed by integrating distributed generators with the distribution system to supply electricity from renewable energy sources such as wind, photovoltaic and biomass [11].

Microgrids (MG) are low voltage (LV) grids that interconnect distributed generation (DG) microsources and storage devices via feeders with small loads. They can either operate grid-connected to the medium voltage (MV) distribution system or in autonomous mode. However, an MG can only supply a maximum load capacity of 10 MVA [11].

The new concept of multi-microgrids (MMGs) is related to a higher level structure, formed at the medium voltage level, consisting of several LV MGs and DG units connected on adjacent MV feeders. The possibility of having a large number of controllable MGs, DG units and MV loads under demand side management (DSM) control requires the use of a hierarchical control scheme that enables an efficient control and management of this kind of system. These concepts are being developed under the EU financed More-Microgrids Project [10].

Control of active power and frequency in a power system is referred to as load frequency control (LFC). Since energy storage system (ESS) is an integral part of MGs and it can provide fast active power compensation, it also can be used to improve the performance of LFC. ESSs show much promise for mitigating the dynamics introduced by non-dispatchable variable generation [13]. Storage facilities possess additional dynamic benefits such as load levelling, spinning reserve, area regulation, long line stabilization, power factor correction and black start capability [12].

MMG is a new concept and load frequency control of MGG using ESS yet is not studied. This paper presents an investigation on the load frequency control of MMG using ESS. The MMG consists with two MGs, each made up of a diesel generator, a PV sources, a wind power generator, ESS and load. The MGs are interconnected by tie-lines. Schematic diagram of an MG and an MMG are shown in Figs. 1(a) and 1(b). Control strategies are developed based on both, frequency deviation and ACE, to regulate the ESS output. A performance index is defined for comparative assessment of control strategies. Effectiveness of the frequency control strategies is studied through simulation.

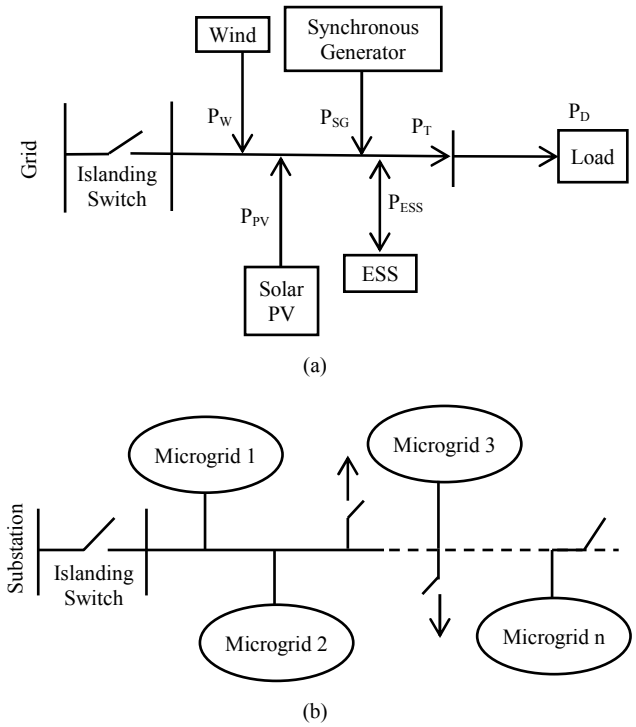

Fig.1 Schematic diagram of (a) microgrid system, (b) multi-microgrid system

II. System Modelling

In this section the modelling of different component of microgrid system is presented.

A. Synchronous Generator System

Standby synchronous generator (SG) work autonomously to supply the deficit power to the microgrid system to meet the supply-load demand balance condition. Smaller MGs usually use diesel generator but larger MGs may use turbine driven generator. The synchronous generator system considered here consists of speed-governor and turbine system. The transfer function of governor and the turbine can be expressed by [2]:

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

$$G_G(s) = \frac{\Delta P_V(s)}{\Delta P_g(s)} = \frac{K_g}{1+sT_g} \quad (1)$$

$$G_T(s) = \frac{\Delta P_m(s)}{\Delta P_V(s)} = \frac{K_T}{1+sT_T} \quad (2)$$

where T_g and T_T are the time constant of governor and turbine, respectively. The value of governor gain constant (K_g) and turbine gain constant (K_T) is set to 1.0. The details of modelling is given in [1,2]. The governors typically have a speed regulation (R) of 5-6 percent from zero to full load [2].

B. Wind Power Generation System

In this paper, the standard deviation for wind power output has been simulated by the following function.

$$dP_{WP} = 0.8\sqrt{P_{WP}} \quad (3)$$

Random output fluctuation is derived from white noise block with some manipulation in MATLAB/SIMULINK is shown in Fig. 3. It is multiplied by the standard deviation to calculate output fluctuation on the model [7,9].

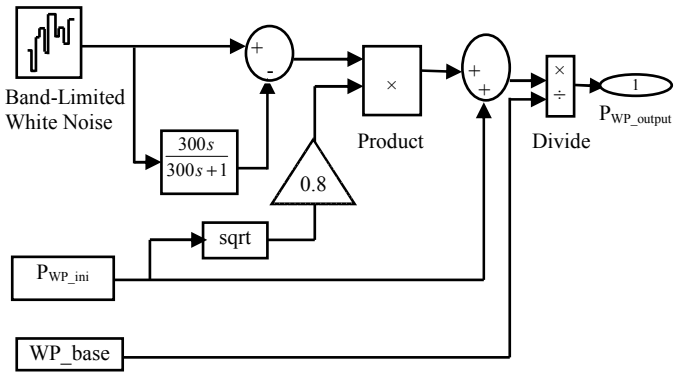

Fig.3 MATLAB/SIMULINK model of wind power system

C. Solar Photovoltaic Model

A PV system consists of many cells connected in series and parallel to provide the desired voltage and current. The voltage and current relationship is non-linear in nature. The maximum power output of the PV array varies according to solar radiation or load current. Therefore, control strategy is required to use solar radiation effectively in order to obtain maximum power. The output power of the PV system can be expressed as,

$$P_{PV} = \eta S\varphi[1 - 0.005(T_a + 25)] \quad (4)$$

Where η is conversion efficiency of the PV array, S is measured area of PV array (m^2), φ is solar irradiation (kW/m^2) and T_a is ambient temperature (^0C). The transfer function of the solar PV system can be expressed by a simple linear first order lag [3,4],

$$G_{PV}(s) = \frac{\Delta P_{PV}}{\Delta\varphi} = \frac{K_{PV}}{1+sT_{PV}} \quad (5)$$

where K_{PV} is gain constant and T_{PV} is time constant.

D. Energy Storage System

Energy storage systems play an important role to effectively supply deficit energy of power generation subsystems of the hybrid power system very fast to maintain system stability [3]. With the rapid advances in power electronics technology, the battery energy storage system has recently been shown to have the capability to quickly control both its active and reactive power output at switching frequency well above the kHz range. While the main applications of such a device are usually for load levelling, harmonic cancellation and voltage control, once installed, it can also be utilized to provide additional damping to power system swings to improve both transient and dynamic stability [4].

The transfer functions of the energy storage systems (ESS) can be taken as first order lag,

$$G_{ESS}(s) = \frac{\Delta P_{ESS}}{\Delta\omega} = \frac{K_{ESS}}{1+sT_{ESS}} \quad (6)$$

where K_{ESS} is gain constant and T_{ESS} is time constant.

E. Power Deviation and System Frequency Variation

To maintain a stable operation of an autonomous system, the total power generation must be effectively controlled and properly dispatched to meet the total power demand of the connected loads [3].

The total power generation (P_T) by the microgrid system shown in Fig.1 is the algebraic summation of synchronous generator power (P_{SG}), wind power (P_W), solar photovoltaic power (P_{PV}) and power of energy storage system (P_{ESS}).

$$P_T = P_{SG} + P_W + P_{PV} \pm P_{ESS} \quad (7)$$

The difference between total power generation P_T and power demand reference P_D is given by Eq. 8.

$$\Delta P_e = P_T - P_D \quad (8)$$

Because system frequency is changed with net power variation, the system frequency variation $\Delta\omega$ is calculated by

$$\Delta\omega = \frac{\Delta P_e}{K_{sys}} \quad (9)$$

where K_{sys} is system frequency characteristic constant of the microgrid system. Since an inherent time delay exists between system frequency variation and power deviation, the transfer function for system frequency variation to per unit power deviation can be expressed by

$$G_{sys}(s) = \frac{\Delta\omega}{\Delta P_e} = \frac{1}{K_{sys}(1+sT_{sys})} = \frac{1}{D+Ms} \quad (10)$$

where M and D are, the equivalent inertia constant and damping constant of the microgrid system, respectively.

III. Interconnection Of Microgrids With Tie-Line

Reliable power supply to the connected load may be achieved by the interconnection of neighbouring isolated MGs through tie-line. Each isolated MG is assumed as control area. Tie-line bias is a control characteristic that determines how much a particular area of an interconnected system should respond to system frequency variation. Tie-line is used to exchange energy between control areas to provide inter-area support in case of any abnormal condition. If there is a mismatch between the power generation and load demand, the deviation in frequency for a particular area occurs [4]. Interconnected microgrid with two-area interconnection is represented as shown in Fig.4.

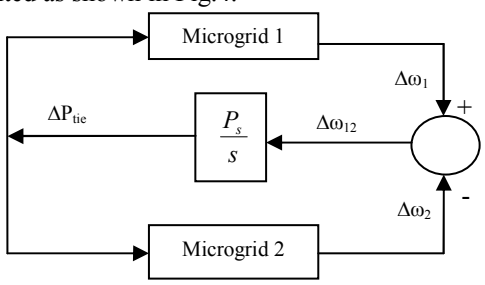

Fig.4 Modelling of tie-line connection

Expressing the tie-line power deviation (ΔP_{tie}) in terms of frequency deviation ($\Delta\omega$) and synchronizing power co-efficient (P_s) is represented as

$$\Delta P_{tie} = P_s(\int \Delta\omega_1 dt - \int \Delta\omega_2 dt) \tag{11}$$

Taking the laplace transform we have

$$G_{tie} = \frac{\Delta P_{tie}(s)}{\Delta\omega(s)} = \frac{P_s}{s} \tag{12}$$

The area control error (ACE) of the i^{th}microgrid is given by,

$$ACE_i = \sum_{j=1}^{n} \Delta P_{ij} + B_i \Delta\omega_i \tag{13}$$

where B is the frequency bias factor for i^{th}microgrid. Fig. 5 shows the block diagram of two interconnected MG system. It shows that the ESS may be controlled either by frequency deviation ($\Delta\omega$) or ACE.

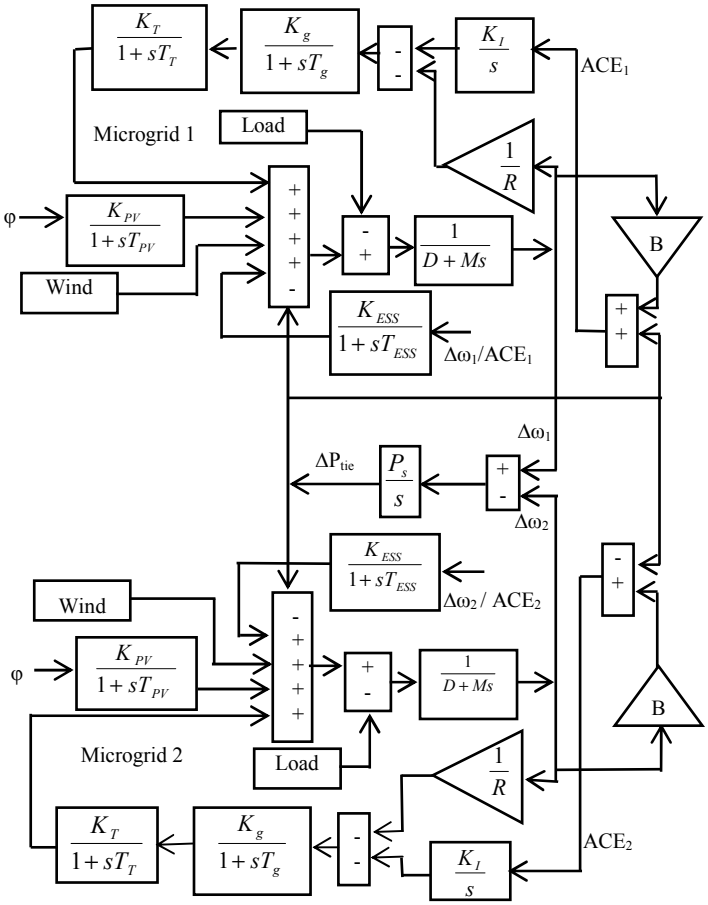

Fig.5 Block diagram of two interconnected microgrid system

IV. Simulation Results and Analysis

The block diagram of interconnected MMG systems shown in Fig. 5 are simulated and analysed. Parameter values of the configurations are taken from [1-4,14-16] and listed in Table I. The synchronizing power co-efficient (P_s) is set to 1.5pu. The average value of wind power and solar power is kept about 0.4pu and 0.2pu for MG1 and 0.3pu and 0.2pu for MG2, respectively. The load at both MG is 0.7pu. During all simulation process a load change of 0.1pu at MG1 from 0.7pu to 0.8pu at t=1.0s is considered.

Figures 6 and 7 present simulation results with $\Delta\omega$ and ACE feedback to ESS, respectively. Frequency deviation ($\Delta\omega$), output power of energy storage system (P_{ESS}) and tie-line power flow deviation (ΔP_{tie}) is presented in both the figures. All quantities in the plots are in per unit (pu) values. The suffix 1 and 2 used for MG1 and MG2 quantities, respectively.

TABLE I
PARAMETER VALUES OF STUDIED MG SYSTEMS

Parameter	Definition	MG1	MG2
R(pu)	Speed regulation	0.05	0.04
$T_g(s)$	Governor time constant	0.1	0.1
$T_T(s)$	Turbine time constant	0.4	0.4
$T_{PV}(s)$	Solar PV time constant	1.5	1.4
$T_{ESS}(s)$	ESS time constant	0.1	0.1
K_{ESS}	ESS gain constant	-10	-8
K_I	Integral gain	5	7
B(pu)	Frequency biasing factor	10	12.5
M(pu)	Inertia constant	0.8	0.7
D (pu)	Damping constant	0.02	0.03

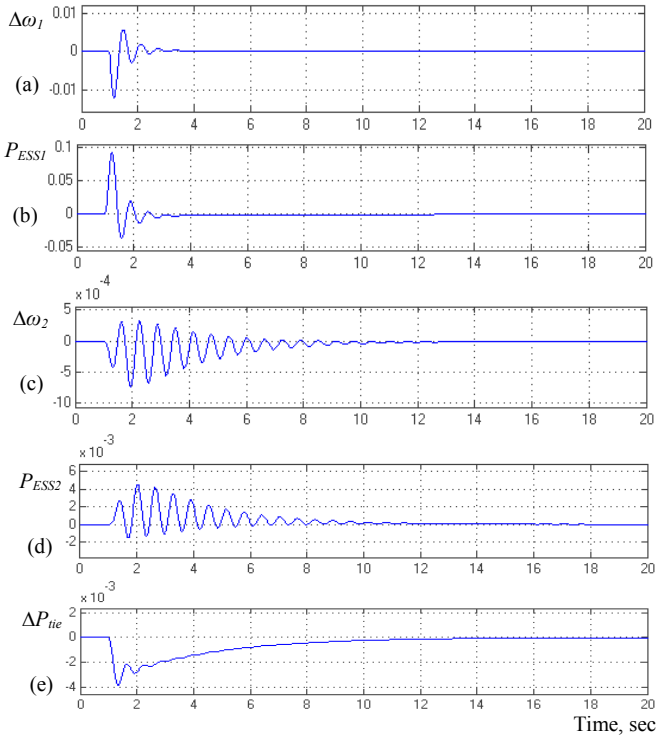

Fig.6 Simulation output for $\Delta\omega$ feedback to ESS control

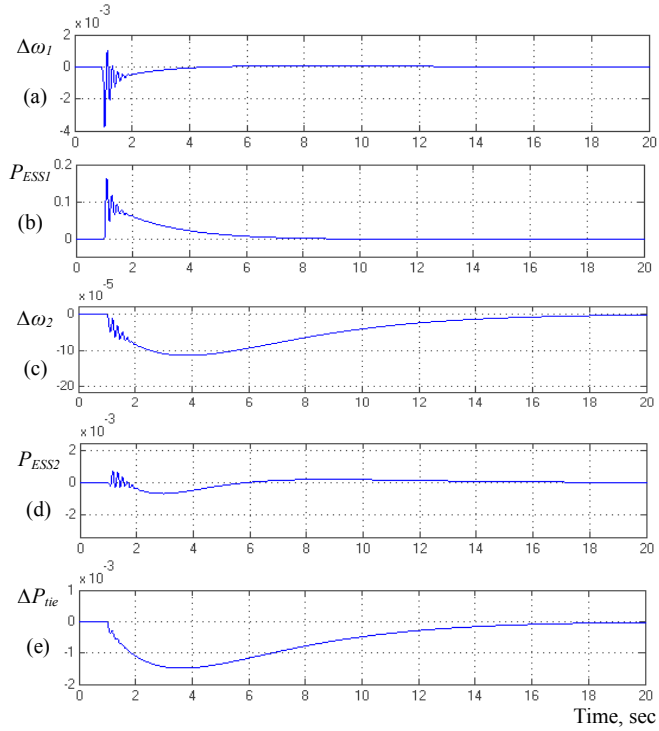

Fig.7 Simulation output for ACE feedback to ESS control

From Figs. 6 and 7, it can be seen that the frequency deviation and tie-line power flow deviation is lower when the ACE is used as the feedback for load frequency control using ESS compare to frequency deviation feedback. An integral square error (ISE) is considered as performance index (PI) to quantify the result analysis. ISE is given by [4,15],

$$ISE = \int e(t)^2 dt \tag{14}$$

where $e(t)$ is the error signal which may be frequency deviation or tie-line power flow deviation. The ISE values for such deviation are tabulated in Table II.

TABLE II
ISE FOR FREQUENCY DEVIATION AND TIE-LINE POWER FLOW DEVIATION

Error Signal	ISE (pu) for	
	$\Delta\omega$ feedback	ACE feedback
Frequency deviation at MG1	3.177×10^{-5}	1.445×10^{-6}
Frequency deviation at MG2	4.198×10^{-7}	6.946×10^{-8}
Tie-line power flow deviation	1.827×10^{-5}	1.120×10^{-5}

It can be seen from Table II that the ISE for frequency deviation and tie-line power flow deviation is low when ACE is feedback to ESS control compared to that when frequency deviation is feedback. From qualitative and quantitative comparison it can concluded that the ACE controller has a better performance for load frequency control using the ESS.

V. CONCLUSION

This paper presented load frequency control (LFC) of two interconnected microgrid systems where both frequency deviation and area control error (ACE) are tested as feedback signals for controlling the output power of energy storage system. The employed mathematical models for the various component of the system are represented by first-order transfer functions to simplify the tasks of system simulation. During simulation process a step load change is applied. The frequency deviations and tie-line power flow deviation profile for interconnected multi-microgrid system were studied, both qualitatively and quantitatively. Integral square error (ISE) is considered as performance index for comparative assessment of control strategies. It is observed that control strategy that regulates the ACE to zero is most suitable for load frequency control in multi-microgrid system.

Abstract—**Active disturbance rejection control (ADRC) has gained significant attraction due to its simple tuning method and robustness against process parameter variations, whether the plant is linear or non-linear, time-varying or time-invariant. In load frequency control, the use of ADRC is proposed to regulate the area control error, frequency error and tie-line error in the presence of internal dynamics and external disturbance. This paper presents a study on the effects of state observer bandwidth, controller bandwidth and sampling period on the performance of the ADRC based load frequency control of single- and multi- area power systems. The study gives good insight in choosing controller parameters for ADRC based LFC.**

Index Terms — **Load frequency control, Active disturbance rejection control, Parameterization**

I. Introduction

The control of active power and frequency in a power system is referred to as load frequency control (LFC). Stable operation of interconnected power system requires both constant frequency and constant tile-line power exchange [1]. An area control error (ACE), defined as a linear combination of tie line power and frequency deviations, is taken as the controlled output of LFC. LFC regulates ACE to zero such that frequency and tie-line power errors are forced to zeros.

PID controller is widely used in LFC. It is simple to implement but usually gives long settling time and produces large frequency deviation [2]. Fuzzy logic based PID and linear matrix inequality (LMI) tuned PID are also implemented for LFC. In recent years, active disturbance rejection control (ADRC) based LFC has been proposed [3-6]. The ADRC technique was first proposed by J. Han [7] and modified by Z. Gao [8, 9]. It does not require precise model information of the physical system, is very robust against parameter uncertainties and external disturbance, and shows fast dynamic response with no overshoot [10].

In practical applications, there are multiple parameters that require tuning in an ADRC controller. A concept of bandwidth parameterization is proposed in [8]. Using this concept, ADRC has only two tuning parameters, the observer bandwidth (ω_0) and feedback controller bandwidth (ω_c). Researchers have considered different values for ω_0 and ω_c. A range of ω_0 is presented in [8] but no procedure for selecting the observer bandwidth is offered. A thumb rule has been illustrated between the relationship of ω_0 and ω_c in [8,11]. For LFC of a multi-area power system, ω_0 is considered as four times to ω_c [9]. In other works on LFC [5,6] ω_0 is considered as five times of ω_c. In [12] a third controlling parameter, the sampling frequency (T), has been considered, which improves the response time.

This paper presents a comprehensive study on the effects of change in the three parameters (ω_c, ω_0 and T) on the performance of an ADRC based LFC in single- and multi-area power systems. The study gives good insight in choosing the controller parameter for an ADRC based LFC.

II. ADRC based LFC model

The block diagram of an ADRC based LFC is presented in Fig. 1. The 'Plant' block represents a single area of a power system, outputs of this block are frequency and tie flow deviations that are combined to form ACE. The ADRC block takes in the ACE and produces the input u for the plant. Frequency deviation is also feedback to the plant through the speed droop coefficient. What follows in this section is the detailed model of the controller.

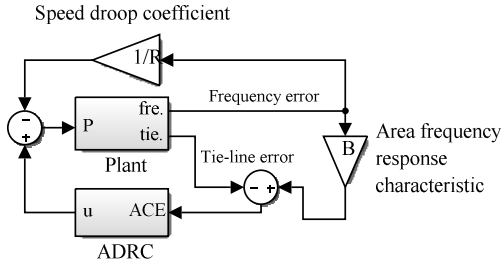

Fig. 1 Block diagram of ADRC based LFC

A. Transfer Function for an n-th Order Plant

A plant with disturbance can be represented as

$$Y(s) = G_p(s).U(s) + W(s) \quad (1)$$

Where $U(s)$ is the input, $Y(s)$ is the output, and $W(s)$ is the generalized disturbance. The transfer function of the physical plant $G_p(s)$ can be represented as

$$\frac{Y(s)}{R(s)} = G_p(s) = \frac{b_m s^m + b_{m-1}\ s^{m-1} + \cdots + b_1\ s + b_0}{a_n\ s^n + a_{n-1}\ s^{n-1} + \cdots + a_1\ s + a_0} \quad (2)$$

Where $R(s)$ is the reference input and a_i (i =1,….,n) and b_j (j =1,…, m) are coefficient of the transfer function.

The basic idea of ADRC design is based on the transfer function of the plant without zeros. Thus, in order to implement ADRC for the system represented by (1), it is necessary to develop an equivalent model of (2) so that the transfer function only has poles. Any error between the two models can be included into the generalized disturbance term. In order to develop the non-zero equivalent model of (2), the following polynomial long division is conducted on $1/G_p(s)$.

$$\frac{1}{G_p(s)} = \frac{a_n\ s^n + a_{n-1}\ s^{n-1} + \cdots + a_1\ s + a_0}{b_m s^m + b_{m-1}\ s^{m-1} + \cdots + b_1\ s + b_0}$$
$$= c_{n-m} s^{n-m} + bc_{n-m-1} s^{n-m-1} + \ldots + c_1 s + c_0 + G_{left} \quad (3)$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

In (3), c_i (i=0,…,n-m) are coefficients of polynomial division result, and the $G_{left}(s)$ is a reminder, which can be represented by

$$G_{left}(s) = \frac{d_{m-1}\ s^{m-1} + d_{m-2}\ s^{m-2} + \cdots + d_1\ s + d_0}{b_m s^m + b_{m-1}\ s^{m-1}\ + \cdots + b_1\ s + b_0} \quad (4)$$

In (4), d_j (j=0,…,m-1) are coefficient of the numerator of the remainder. Substituting (3) into (1) gives,

$$[c_{n-m}s^{n-m} + bc_{n-m-1}s^{n-m-1} + \cdots + c_1 s + c_0 + G_{left}(s)].Y(s) = U(s) + W'(s) \quad (5)$$

Where, $W'(s) = W(s)/G_p$

Equation (5) can be rewritten as

$$[c_{n-m}\ s^{n-m}]\,Y(s) = U(s) - [bc_{n-m-1}\ s^{n-m-1} + \ldots + c_1 s + c_0 + G_{left}(s)].Y(s) + W'(s) \quad (6)$$

Finally we have,

$$s^{n-m}\,Y(s) = \frac{1}{c_{n-m}}U(s) + D(s) \quad (7)$$

Where,

$$D(s) = -\frac{1}{c_{n-m}}[bc_{n-m-1}\,s^{n-m-1} + \ldots + c_1 s + c_0 + G_{left}(s)].Y(s) + \frac{1}{c_{n-m}}W'(s) \quad (8)$$

From (3), it can be seen that

$$c_{n-m} = \frac{a_n}{b_m} \quad (9)$$

However, it is difficult to get the expression of the other coefficients in (3) and (4). But, for the development process of ADRC, $D(s)$ is treated as the generalized disturbance and estimated in time domain so that the exact expression for the c_i and d_j are not needed.

From (7), it is seen that the two characteristics (relative order between input and output and controller gain) have been extracted from the plant by modifying the Laplace transform. Instead of using the order of plant n, the relative order n-m may be utilized as the order of the controller system and equation (7) can be written as

$$s^{n-m}\,Y(s) = bU(s) + D(s) \quad (10)$$

Where,

$$b = \frac{1}{c_{n-m}}$$

B. Design of ADRC

ADRC can be understood as a combination of an extended state observer (ESO) and a state feedback controller. The ESO is utilized to observe the generalized disturbance, which is also taken as an extended state, and the state feedback controller is used to regulate the tracking error between the real output and a reference signal for the physical plant [7]

Extended state observer

The effectiveness of ADRC is dependent on the accurate estimation of the generalized disturbance $D(s)$. Consequently an ESO needs to be developed to estimate $D(s)$ in real time.

Now the state space model of (7) is,

$$sX(s) = AX(s) + BU(s) + E(s)\,D(s) \quad (11)$$

$$Y(s) = CX(s)$$

Where, $X(s) = \begin{bmatrix} X_1(s) \\ X_2(s) \\ \vdots \\ X_{n-m}(s) \end{bmatrix}$

$$A = \begin{bmatrix} 0 & 1 & 0 & \ldots & 0 \\ 0 & \ddots & 1 & \ddots & \vdots \\ \vdots & \ddots & 0 & \ddots & 0 \\ \vdots & \ddots & \ddots & \ddots & 1 \\ 0 & 0 & \ldots & \ldots & 0 \end{bmatrix}_{(n-m+1)*(n-m+1)} \qquad B = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ b \\ 0 \end{bmatrix}_{(n-m+1)*1}$$

$$C = [1 \quad 0 \quad \ldots \quad 0]_{1*(n-m+1)} \qquad E = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix}_{(n-m+1)*1}$$

The ESO of the plant is

$$SZ(s) = AZ(s) + BU(s) + L(Y(s) - \hat{Y}(s)) \quad (12)$$

$$\hat{Y}(s) = CZ(s)$$

Where Z(s) is the estimated state vector given by

$$Z(s) = [z_1(s) \quad z_2(s) \ldots \quad z_{n-m}(s)]^T$$

L is the observer gain vector given by

$$L = [\beta_1 \quad \beta_2 \ldots \quad \beta_{n-m}]^T$$

In order to locate all the Eigen values of the ESO to $-\omega_0$, the observer gains are chosen as

$$\beta_i = \binom{n-m}{i}.\,\omega_0^i, \qquad i = 1, \ldots, n\text{-}m$$

With a well tuned ESO, $Z_i(s)$ will be able to estimate the value of $X_i(s)$ closely (i= 1 ,…, n-m). Then we have

$$Z_{n-m}(s) = \hat{D}(s) \approx D(s) \quad (13)$$

Feedback Controller

If the control input is designed as

$$U(s) = (U_0(s) - Z_{n-m}(s))\,/\,b \quad (14)$$

Equation (10) will reduce to a pure integral part, i.e.,

$$s^{n-m}\ Y(s) = b.\frac{u_0(s) - Z_{n-m}(s)}{b} + D(s) = U_0(s) - \hat{D}(s) + D(s) \approx U_0(s) \quad (15)$$

The control law for the pure integral plant is

$$U_0(s) = k_1\,(R(s) - Z_1(s)) - k_2\,Z_2(s) - \ldots - k_{n-m-1}\,Z_{n-m-1}(s) \quad (16)$$

Where R(s) is a reference input. With the control law in (16), Y(s) will be drive to R(s) which is zero for LFC. To further simplify the process, all the closed loop poles of the PD controller are set to $-\omega_c$. Then the controller gain in (16) has to be selected as

$$K_i = \binom{n-m-1}{n-m-i}.\,\omega_c^{n-m-1} \quad (17)$$

where i = 1,…., n-m-1

III. Simulation Results

The efficacy of the ADRC based LFC with change in observer bandwidth (ω_0), controller bandwidth (ω_c) and controller sampling time (T) is studied for single area and multi-area power system using MATLAB Simulink. Controller bandwidth is selected based on the time required to settle down the response. Feedback controller will reject the internal dynamics and external disturbance which will be estimated by the ESO. So the observer bandwidth must be higher than the feedback controller bandwidth [8]. Effectiveness of observer's disturbance estimation depends on the observer gain vector and the gain vectors are represented as the function of observer bandwidth (ω_0).The parameters of the single- and multi- area power systems are taken from [3] and [4], respectively.

A. Single Area Power System

The block diagram model of a single area power system with ADRC based LFC is shown in Fig. 2. Assuming coherency generators are represented by a single equivalent generator. A non-reheat turbine system is considered. Effects of parameter variation and for a step load change on frequency and tie flow deviations and, ACE are presented in Figs. 3 and 4 and in Table I. It can be seen that the peak amplitudes do not change much. This is because for all the cases the disturbance considered is the same.

The controller bandwidth (ω_c) is tuned according to the requirement of how fast and steady the output is wanted to track the set point. Higher bandwidth corresponds to better command following, disturbance rejection and sensitivity to parameter variations. However, bandwidth is limited by the presence of sensor noise and due to the higher value of controller bandwidth (ω_c= 5 rad /sec), it may push the system to its limit, leading to oscillations or even instability as shown in Figs. 3(a) and (c).

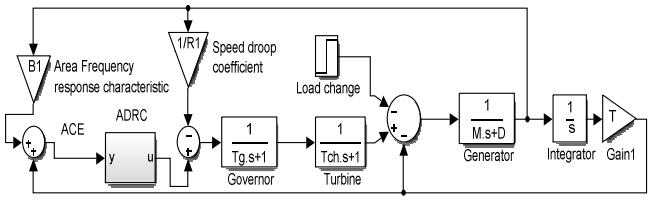

Fig. 2 Model of a single area power system with ADRC based LFC

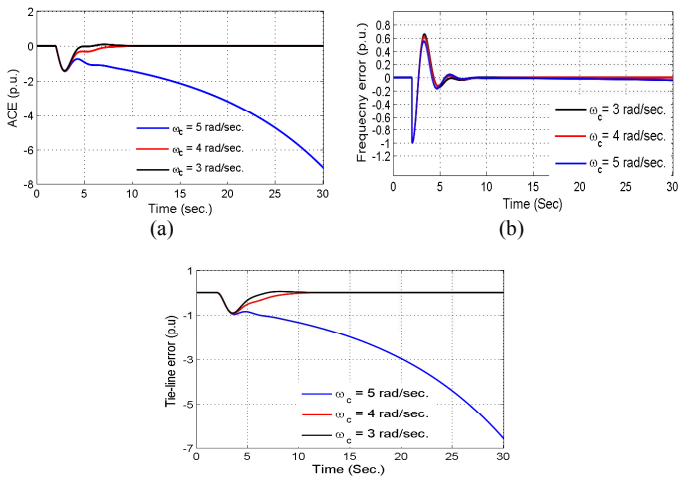

Fig. 3 Effect of controller bandwidth (ω_c) on (a) ACE, (b) frequency error, and (c) tie-line error

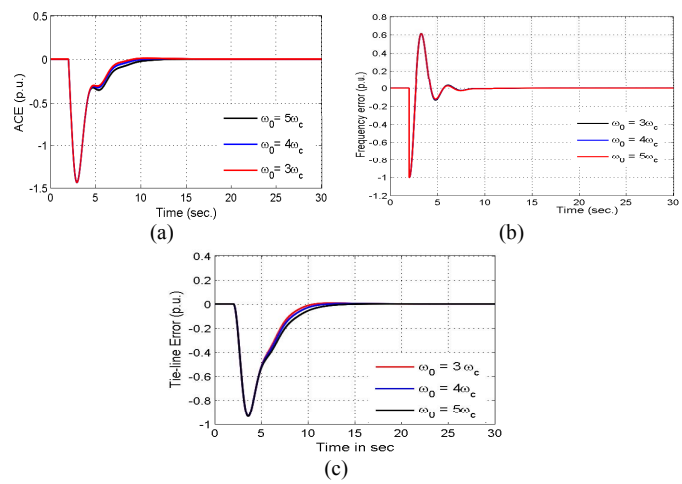

Fig. 4 Effect of observer bandwidth (ω_0) on (a) ACE, (b) frequency error, and (c) tie-line error

TABLE I

PERFORMANCE OF SINGLE AREA POWER SYSTEM

Error type	Parameters variation	Peak Amplitude (p.u.)	Time at peak overshoot (sec.)	Settling time (sec.)
Effects of change in controller bandwidth (ω_c) (rad/sec)				
ACE	ω_c=3	-1.7	3.0	10.0
	ω_c=4	-1.7	3.0	10.0
	ω_c=5	-1.7	3.0	unstable
Frequency error	ω_c=3	-0.65	2.0	9.0
	ω_c=4	-0.6	2.0	8.0
	ω_c=5	-0.55	2.0	7.5
Tie-line error	ω_c=3	-0.9	3.5	10.0
	ω_c=4	-0.9	3.5	12.0
	ω_c=5	-0.9	3.5	unstable
Effects of change in observer bandwidth (ω_0) (rad/sec)				
ACE	$\omega_0 = 3\omega_c$	-1.4	3.0	11.0
	$\omega_0 = 4\omega_c$	-1.4	3.0	9.0
	$\omega_0 = 5\omega_c$	-1.4	3.0	10.0
Frequency error	$\omega_0 = 3\omega_c$	-0.6	2.5	8.0
	$\omega_0 = 4\omega_c$	-0.6	2.5	8.0
	$\omega_0 = 5\omega_c$	-0.6	2.5	8.0
Tie-line error	$\omega_0 = 3\omega_c$	-0.9	4.0	11.0
	$\omega_0 = 4\omega_c$	-0.9	4.0	12.0
	$\omega_0 = 5\omega_c$	-0.9	4.0	12.0

As ω_c and ω_0 are increased, the noise in control signal u also increases. Any notable change does not found in magnitude of ACE due to change in observer bandwidth in Fig. 4(a) but for higher bandwidth, the response take longer time to settle down in case of tie-line error in Fig.4(c). It is very difficult to establish any relationship between observer bandwidth and controller bandwidth but simulation results indicates that observer bandwidth should be chosen four times of controller bandwidth to get the shortest settling time as can be seen from Figs. 4(a), (b) and (c) and Table I.

In general, the shorter the sampling period the higher the control degree of accuracy for the same plant with increasing observer bandwidth [12]. However, for load frequency control, larger observer bandwidth increases the settling time as can be seen in Figs. 4(a) and (b) and Table I. However, it increases the noise sensitivity of the system.

B. Multi-Area Power System

An ADRC based LFC for a three area interconnected power system is also modelled and simulated. The model consists of three generation units, each of which is composed of three major parts: governor, turbine and generator. All generators in one area respond coherently, so they are represented by an equivalent generator. All turbine units are to be considered non-reheat type. Fig. 5 presents the dynamic model of one-area in the multi-area power system.

A 0.01 p.u. load change is added to each area. The simulation results are presented in Table II for area-1 by varying the three controlling parameters. Peak amplitude is still same for most of the cases due to same load change consideration. The settling time is calculated by considering the tolerance limit of the response 0.01 p.u. It is seen that the time required reaching the peak overshoot and settling time increases with increasing controller bandwidth (ω_c) and controller sampling period, respectively. However, a small change in settling time is noted when the multiplying factor

between ω_0 and ω_c is increased. This is because a large observer bandwidth increases noise sensitivity.

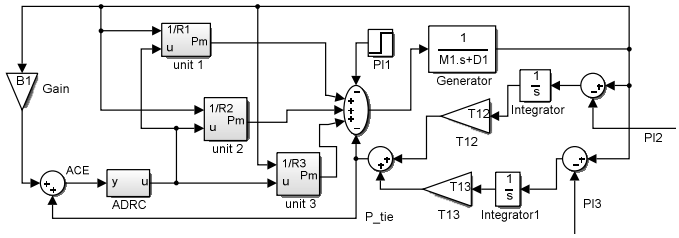

Fig. 5 Dynamic model of one-area in a multi-area power system

TABLE II

PERFORMANCE OF MULTI-AREA POWER SYSTEM

Error type	Parameters variation	Peak amplitude (p.u.)	Time at peak overshoot (sec.)	Settling time (sec.)
Effects of controller bandwidth variation (ω_c) (rad/sec)				
ACE	ω_c=3	-0.02	2.0	25
	ω_c=4	-0.02	2.5	25
	ω_c=5	-0.02	3.5	27
Frequency error	ω_c=3	-0.0075	1.5	26
	ω_c=4	-0.005	2.0	27
	ω_c=5	-0.008	3.5	27
Tie-line error	ω_c=3	-0.002	3.5	23
	ω_c=4	-0.008	3.0	23
	ω_c=5	-0.023	3.0	22
Effects of observer bandwidth variation (ω_0) (rad/sec)				
ACE	$\omega_0 = 3\omega_c$	-0.02	2.5	22
	$\omega_0 = 4\omega_c$	-0.02	2.5	24
	$\omega_0 = 5\omega_c$	-0.02	2.5	24
Frequency error	$\omega_0 = 3\omega_c$	-0.008	2.0	22
	$\omega_0 = 4\omega_c$	-.0008	2.0	23
	$\omega_0 = 5\omega_c$	-0.008	2.0	22
Tie-line error	$\omega_0 = 3\omega_c$	-0.002	2.5	22
	$\omega_0 = 4\omega_c$	-0.008	2.0	21
	$\omega_0 = 5\omega_c$	-0.022	2.5	20

IV. CONCLUSION

This paper presents a comprehensive study on the effects of change in the ADRC parameters in load frequency controller to regulate the area control error, frequency deviations and tie-line error in single- and multi- area power systems. It is observed that for ADRC based load frequency control, a controller bandwidth of 4 rad/sec for both power system and observer bandwidth of four times of controller bandwidth gives good result for single area power system in Table I. However, observer bandwidth should five times of controller bandwidth for multi-area power system to get the lower settling time in Table II. In the future, the parameters for LFC of two- and three- area power system with re-heat turbines and hydro-electric turbine should be studied. It will help to enhance the range of applications of higher order ADRC to the power system.

***Abstract*— In this paper, a low power CMOS UWB low noise amplifier (LNA) suitable for 6.2−10.6 GHz application is presented. Using simultaneous noise matching (SNIM) and self-body-bias technique, the proposed LNA is designed to operate with low supply voltage in order to reduce power consumption. The simulated results showed that at 0.62V supply voltage, the LNA consumed 3.84mW with a maximum gain of 10 dB and average noise figure of 4.55 dB over the band of interest. Minimum port reflection parameters, S_{11} and S_{22} for the proposed amplifier were found <-10 dB whereas 1−dB compression point was found at -16.2 dBm.**

Keywords*— *Ultra Wideband; FCC; CMOS; RF; LNA

I. Introduction

Due to broad application scopes for ultra wideband (UWB) systems, radio frequency circuit designers are motivated to design unique, power efficient circuits that can facilitate such applications. According to FCC regulation released in 2002, 3.1−10.6 GHz band has been allocated for unlicensed wideband wireless communication. Moreover, recent IEEE 802.15.3 standard is focused on using two sub bands of the unlicensed band, 3.1−4.85 GHz and 6.2−9.7 GHz for high speed data transmission [1−2]. To support high speed data communication, the frontend of the receiver must be efficient enough to suppress the noise, minimize the return losses and provide sufficient gain within a low power budget.

Low Noise Amplifier (LNA) is the most crucial part of receiver frontend as the sensitivity of overall receiver end is dependent on it. Because of higher level of integrability, lower feature size, higher power efficiency and lower cost, CMOS technology has become a more obvious choice for on-chip radio transceiver implementation. But, designing of an LNA involves consideration of many trade-offs among gain, noise, linearity, return losses and power dissipation [3]. Various topologies for wideband and ultra wideband CMOS LNAs have been developed over the past few decades [1−2][4−11]. Among them, simultaneous input noise matching (SNIM) technique offers simultaneous noise and input matching [4]. Recently reported self-body-biasing has demonstrated ultra low power operation at low voltage supply [5]. Integration of SNIM technique with self-body-bias technique can be used to design an ultra low power UWB CMOS LNA that is capable of operating at low supply voltage.

In this paper, a low power; fully integrated UWB LNA using SNIM and self-body-bias technique for 6.2−10.6 GHz application in 0.18μm CMOS technology is proposed. In section II, the circuit analysis is introduced and the design equations are discussed. Section III provides the simulated results, demonstrates the effects of layout parasites on overall performances and draws the summary as well as comparisons of the result with several published works. The conclusion is presented in section IV.

II. Circuit Analysis

The equation for threshold voltage of an n−channel MOSFET can be written as [12]:

$$V_{th} = V_{th0} + \gamma\left(\sqrt{\left|2\varphi_f - V_{bs}\right|} - \sqrt{\left|2\varphi_f\right|}\right) \qquad (1)$$

Where, V_{th} is the threshold voltage, V_{th0} is the threshold voltage for body-source voltage, V_{bs}=0, γ is a process dependent parameter, φ_f is dependent on semiconductor. For a standard CMOS technology, V_{bs} adds an extra parameter to change V_{th}. Thus, a CMOS amplifier can be operated at a lower supply voltage by lowering V_{th} which can be achieved changing V_{bs}. But, this technique raises the need for extra biasing (body biasing) in the circuitry. If the body biasing is done within the circuit, it transforms self-body-bias technique. This technique reduces the need for extra bond pads, thus reducing the effective die area.

The proposed two-stage 0.18μm LNA circuit is design based on a self-body-biased degenerated common source common gate cascode structure using SNIM technique. The first stage, which is degenerated common source amplifier, performs the main amplification and cascoded common gate amplifier creates effective isolation between input and output. The second stage is a common source amplifier, which performs further amplification and designed to lower the return loss at output. Fig. 1 shows the proposed circuit schematic.

A. Input matching

In order to ensure minimum reactive part of the input impedance throughout the band of interest to achieve flat gain and optimum noise figure, a chebyshev filter is used at the input of the LNA shown in fig. 1. The gate voltage of degenerated common source MOS is provided within the circuit by connecting the drain terminal of cascaded common gate MOS by a resistance, R_{bias}. C_{bias} is provided for an ac

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

ground. So, the input impedance remains unaffected by inclusion of R_{bias} and C_{bias}. Considering the small signal model of an inductively degenerated LNA, the input impedance of the MOS transistor from node x [6]:

$$Z_{in}(s) = 1/sC_{gs} + s(L_s + L_g) + g_{m_1} L_s / C_{gs}$$
$$= 1/sC_{gs} + s(L_s + L_g) + \omega_T L_s \qquad (2)$$

where, g_{m1} is the transconductance of the M_1 transistor, C_{gs} is gate-source capacitance the real part of $Z_{in}(s)$, $\omega_T L_s$ is equal to the real part of source impedance R_s, where $\omega_T = g_{m1}/C_{gs}$. Size of M_1 was chosen for proper input impedance matching.

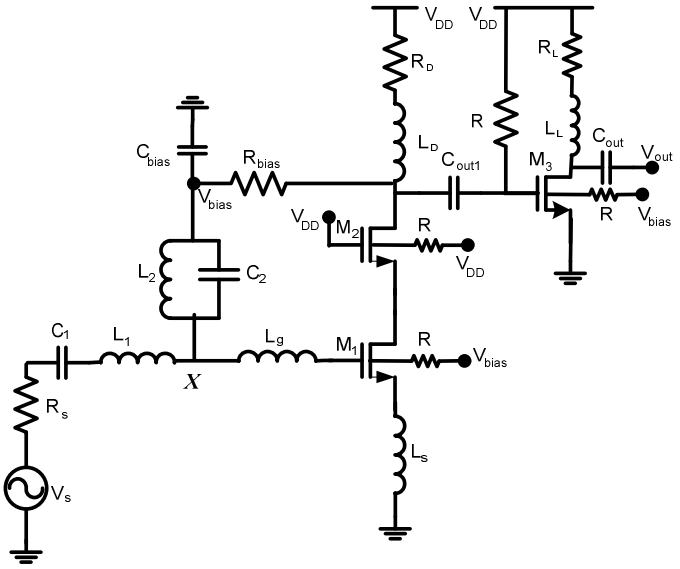

Fig. 1 Proposed circuit for ultra wideband LNA

B. Noise Figure Analysis

In SNIM technique [4], the optimum noise impedance, Z_{opt} can be shifted by varying the width of the MOS transistor so that, $Z_{opt}=Z_{in}^*=Z_s$ is achieved. This ensures both input and noise matching at the same time. Equation (2) defines the parameters on which Z_{in} is dependent. The width of the transistor, gate voltage and transconductance was chosen to match the aforementioned requirements. The noise figure is mostly affected by the noise contribution from the first amplifying stage whereas the noise originated from other stages is reduced by gain of previous stages.

C. Self-Body-Biasing and Self-Biasing

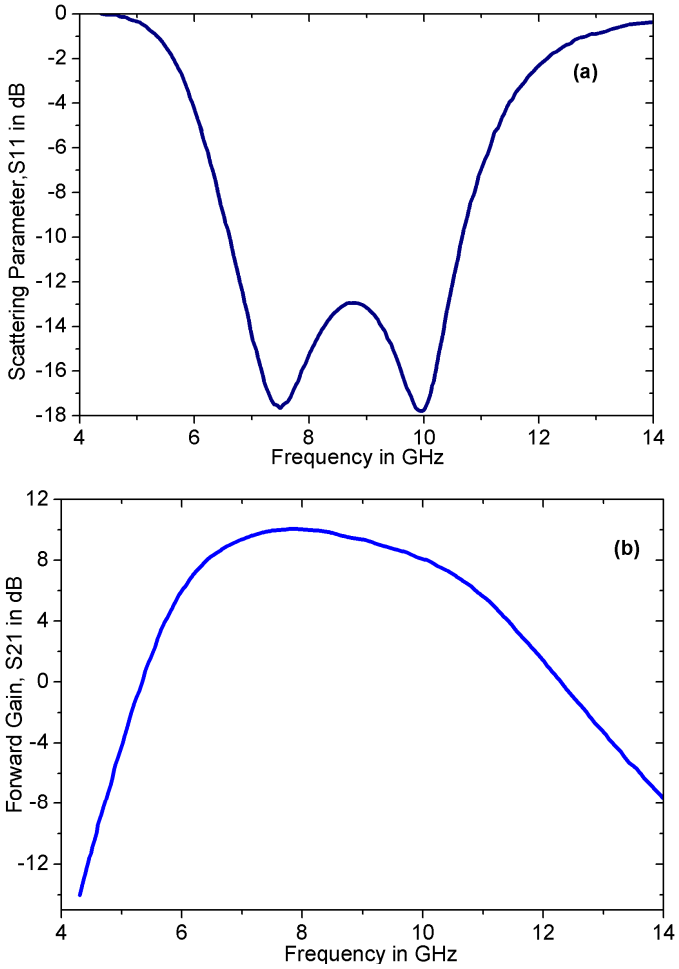
The proposed LNA architecture includes three NMOS transistors and all the transistors are forward body biased. Body biasing introduces two problems to be addressed; body biasing may introduce additional bondpads in the die and forward body bias which turns on the source to body junction that results in additional power consumption. That is why the proposed architecture has adopted self-body-bias technique, where all the forward body biasing is done through a resistance (R≈10KΩ). For most of design topologies proposed on LNA design [2][9-11], at least one of the MOS transistors is needed to be gate biased from external supply. The proposed design has biased all the MOS transistors inside the main circuit design. The degenerated common source amplifier's MOS transistor is biased through R_{bias}.

D. Output Impedance Matching

The filtered and amplified signal from cascade stage is fed to a second amplifying stage for further amplification. In fig. 1, the output is seen through capacitor, C_{out}(~1pF) . To reduce the quality factor of the inductor L_L, R_L in series with load inductor is used and widen the bandwidth of the signal received at output. The common source amplifier used in the second stage is biased through resistance, R. Capacitor C_{out1} is used to filter out any dc component from incoming signal to M_3 transistor.

III. Simulated Results and Comparison

The proposed UWB LNA has been designed in 0.18µm CMOS model parameters and simulated in Hspice RF. V_{bs1}, V_{bs2} and V_{bs3} were self forward biased to reduce the threshold voltage of M_1, M_2 and M_3 respectively. For a fixed bias current, lowering V_{th} results in lower supply voltage requirement thus lowering overall power consumption. Simulated results have shown that the proposed LNA consumes 3.84mW from a 0.62V supply voltage. The drain current drawn by cascode amplifying stage and the second amplifying stage have been found 2.06mA and 4.16mA respectively. The chebyshev filter used at input has ensured a better input impedance matching. Fig. 2 illustrates the input



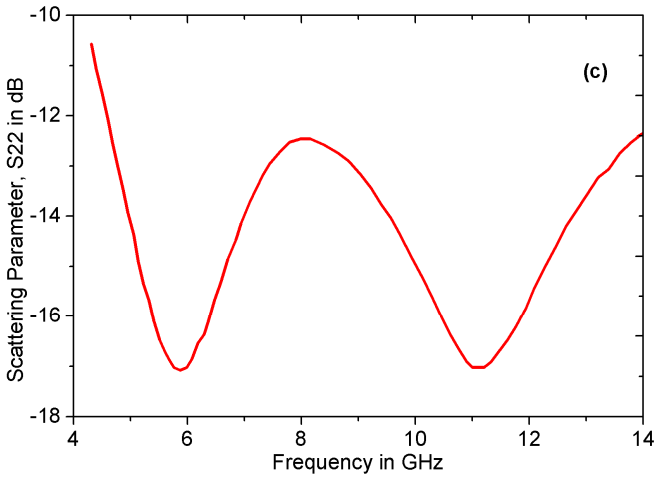


Fig. 2 Simulated results of scattering parameters (a)S_{11}, (b)S_{21} and (c)S_{22} in dB

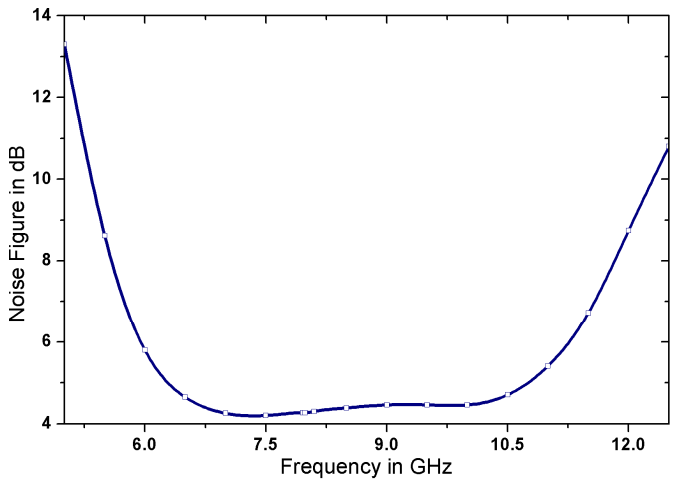

Fig. 3 Simulated results of Noise Figure

reflection coefficient (in Fig. 2(a)) in dB to demonstrate the input matching of the LNA in which S_{11}<-10 dB from 6.6−10.6 GHz. The maximum forward gain, S_{21} is achieved 10 dB at 7.98 GHz (in Fig. 2(b)). Output matching parameter, S_{22} is found <-13 dB throughout the operational band(in Fig. 2(c)). The circuit has shown better reverse isolation (<-35 dB over the whole frequency range). The simulated noise figure of the LNA is shown in fig. 3. The noise figure is minimum (4.20 dB) at 7.5 GHz and average noise figure is ~4.55 dB.

Fig. 4 depicts the range of linearity for the LNA. The input-port referred 1-dB compression point for the LNA is found -16.2 dBm. According to the harmonic balance analysis (simulation was performed in HSpice RF), the 3rd –order input referred inter-modulation product was found -6.77 dBm at 8 GHz. All the capacitor used in this design is metal-insulated-metal type capacitor (0.2p-1pF) where model parasites were considered. The inductors used in this design ranges between 0.4n-1.7nH. Parasitic resistances and capacitances of the spiral inductor model were also considered in the design. The simulated unconditional stability factor, μ for the proposed design was found greater than 1 from 5.5−12.5 GHz.

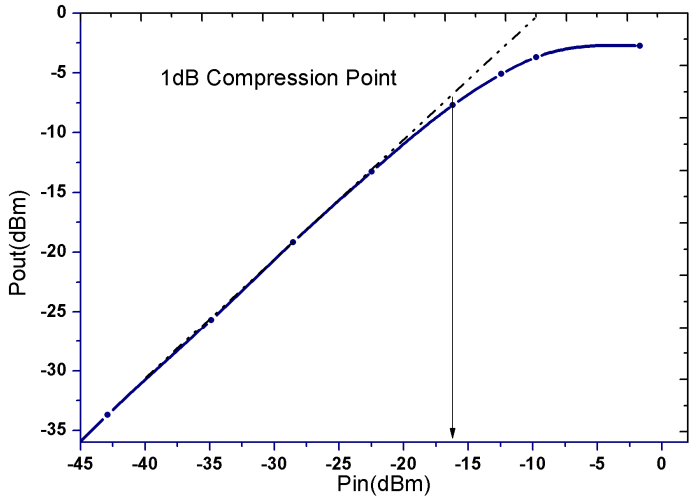

Fig. 4 Input referred 1-dB Compression Point

Table I summarizes the results and compares the design performances with several published UWB LNA designs.

TABLE I
SUMMARY OF THE PROPOSED LNA AND COMPARISON WITH OTHER PUBLISHED WORKS

Specification	This Work	[7]	[8]	[9]	[10]	[11]
Data	*Simulated*	*Measured*	*Simulated*	*Simulated*	*Measured*	*Measured*
Year	2014	2010	2007	2014	2012	2013
CMOS Process(μm)	0.18	0.18	0.18	0.09	0.18	0.18
Supply (V)	0.62	1.8	0.6	0.75	1.1	1.1
BW (GHz)	4.4	7.5	7.5	7	7.5	7.5
S_{21}(dB)	10	13.2	10	10-32	10.8	14.8
S_{11}(dB)	-10~-18.5	-20	-10	-10	-8.1	<-11.5
S_{22}(dB)	<-13	N/A	<-10	-15	-9.5	<-10.7
NF_{min}(dB)	4.20	4.5	3.8	.2	5.5	3.5

ICP (dBm)	-16.2	-11	N/A	N/A	<-16	N/A
IIP3 (dBm)	-6.77	-1.4	1	1	-6.4	-13
P_{diss}(mW)	3.84	23	7	19.3	6.4	7.8
Operating Range (GHz)	6.2−10.6	3.1−10.6	2.8−9.1	1−11	3.1−10.6	3.1-10.6
FOM	7.9	0.53	5.02	5*	2.1	3.7

*calculation was done performance parameters seen at 7 GHz

The figure of merit (FOM) is defined here to evaluate the circuit performance as,

$$FOM = \frac{S_{21}(dB).Operating\ Freq(GHz)}{Power(mW).V_{dd}(Supply)NF_{\min}(dB)}$$

These results imply that the proposed 10dB, 3.84mW, UWB CMOS LNA is suitable for low voltage, high-gain and low power application.

IV. Conclusion

This paper presents an optimized low power self body biased UWB CMOS LNA. Simulated results illustrate the circuit performs better in terms of gain, input output matching and linearity. These results indicate that the proposed architecture is suitable for low power 6.2−10.6 GHz UWB applications.

***Abstract*—Design and simulation of an Ultra Wide Band Low Noise Amplifier for 10.8 to 20.1 GHz applications is presented. A CG-CS topology is adopted in this work. CG is used for input matching in the whole band of operation. Output of the CG is fed to the CS amplifier input to increase the gain of the overall amplifier. The circuit is designed in IBM 130 nm CMOS Technology and simulated in HSPICE RF. The simulated results of the circuit shows 10.2 dB of forward gain (S_{21}) with a bandwidth of 9.3 GHz, -18 dB input return loss (S_{11}), reverse isolation (S_{12}) of -44 dB and -32 dB of output matching parameter (S_{22}) at center frequency, 14 GHz. This circuit exhibits a Nf of 5.03 dB at center frequency and 5.44 dB of average Nf. ICP is -17.2 dBm at the center frequency. It consumes only 7.38 mW when driven from 1.2 V source.**

Keywords*—Ultra-wide-band (UWB), low noise amplifier (LNA), noise figure (Nf), S-parameters, common gate (CG), common source (CS).

I. Introduction

With an increasing trend towards utilizing higher frequencies for wideband communication applications, Ku-Band (12 to 18 GHz) is of special interest as there are many important commercial and research applications in this frequency band such as: satellite communication for entertainment, high speed internet access [1], global snow-cover monitoring, weather prediction, air-borne scatterometers and DVB-S applications [2].

As the demand increases, the operating frequency of the transceiver system increases because the frequency band below 10 GHz is becoming more and more crowded [3]. GaAs, AlGaN materials are used in high frequency wireless system design for lower noise figure and higher frequency applications. But, the major drawback of those systems is cost. CMOS wireless system is used for lower cost, flexibility, and available technology.

Integral part of wireless system is the RF front end LNA (Low Noise Amplifier). As this is the first component, it should have higher gain, lower noise figure and lower area [4]. Moreover, higher is the gain provided by the LNA, lower will be the overall noise figure of the RF receiver. Bandwidth is also major concern for ultra-wide-band communication. In order for the receivers in a single chip to support multiple frequencies, the bandwidth of the receivers has to be very high. Apart from that, short distance data communication uses short pulse for communication. To support this type of communication, ultra wide-band receiver is the first requirement. Ultra-Wide-Band (UWB) communication is also a possible solution for wireless interconnects.

High frequency UWB systems are a new wireless technology capable of transmitting data over a wide frequency spectrum with very high data rates and very low power consumption [5]. For a wireless UWB systems, UWB LNA design is vital. This amplifier should have high gain, low noise figure and low power consumption. The gain and bandwidth of an amplifier cannot be simultaneously increased beyond a limit [6]. Hence, designing an amplifier circuit providing high gain and large bandwidth is quite a challenging task.

Several works have been reported in the frequency range of 12 to 18 GHz [1, 7–9]. Gil has reported a CMOS LNA operating in the 13 GHz region with a very low forward gain and relatively high power consumption [7]. A 14 GHz LNA reported by Kuo-Liang has moderate forward gain, but the power consumption is very high [9]. Meanwhile, Cheng-Chi Yu has reported a low voltage and low power LNA having a wide bandwidth in the 12 to 18 GHz frequency range at the expense of large number of stages [10]. All the above works are done using TSMC 180 nm technology. Very few works have been done using IBM 130 nm CMOS technology. However, use of 130 nm technology allows smaller chip area with low power consumption.

Here the design and simulation of a UWB LNA using IBM 130 nm CMOS technology is reported. A CG-CS structure is used to implement this design. This amplifier is designed especially for the applications utilizing frequencies in between 12 to 18 GHz.

II. Circuit Analysis

The proposed low noise amplifier has been shown in Fig. 1. The common gate stage provides an excellent and a relatively easy way to match input impedance for a wide range of frequency. For maximum power transfer from antenna to amplifier, the input impedance of the amplifier has to be 50 Ω. The input impedance for the common gate (CG) stage is nearly equal to $1/g_m$. Hence, in this stage, the values of width (w) and length (L) of the n-channel MOSFET, M_1 have been chosen so that the input impedance is very close to 50 Ω. The values of capacitance C_i (=500 pF) and inductor L_i (=160 fH) have ensured the input reactance to be resonated out at a

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

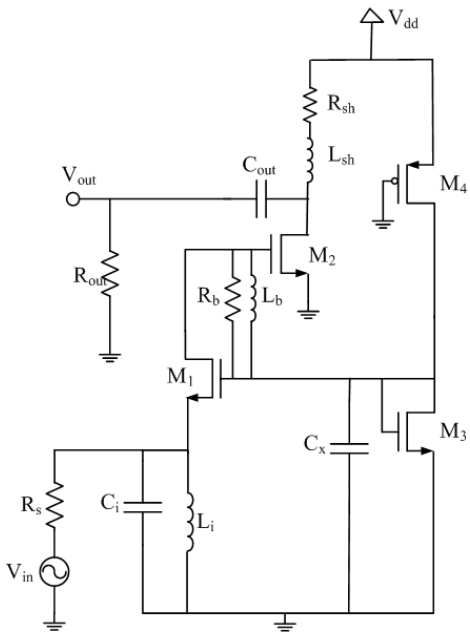

Fig. 1: Proposed LNA Circuit.

frequency not greater than $1/(2\pi\sqrt{L_i C_i})$ (=17.8 GHz) because of the presence of C_{gs}. Besides, the reverse isolation is better for this stage because of the absence of the C_{gd} path.

Since the gain of a CG amplifier is not sufficiently high compared with its inherent noise figure, a CS stage has been added at the output of the CG stage for providing a better amplification while adding very little to the noise figure. The value of inductance L_b (=1.7 nH) has been chosen so that it resonates with the parasitic capacitances ($C_{gs} = 51$ fF and $C_{gd} = 15.87$ fF) of the n-channel MOSFET, M_2 at a frequency which is equal to the resonant frequency obtained at the CG input stage. Here the resonant frequency is approximately 14.9 GHz.

The n-channel MOSFET, M_3 and the p-channel MOSFET, M_4 have been used to ensure the proper biasing of M_1 and M_2. The capacitance, C_x reduces the effect of the gate to source parasitic capacitance of M_1.

The load is designed to achieve considerably flat and large gain. The load is a shunt peaking load. To increase the gain, load impedance has to be high. L_{sh} is used to reduce the capacitive effect at the output node. Large inductor means higher quality factor, which will decrease the bandwidth of the amplifier. So, L_{sh} is a compromise in between large gain and bandwidth. R_{sh} is introduced to control the quality factor of the inductor. High value of R_{sh} ensures lower quality factor for higher bandwidth. Higher value of R_{sh} reduces the load impedance and finally reduces the gain of the amplifier.

III. Simulation and Results

This proposed circuit is designed in IBM 130 nm CMOS 8RF process. The circuit is simulated in HSpice RF. Variation of forward gain, S_{21} is shown in Fig. 2. S_{21} should be as high

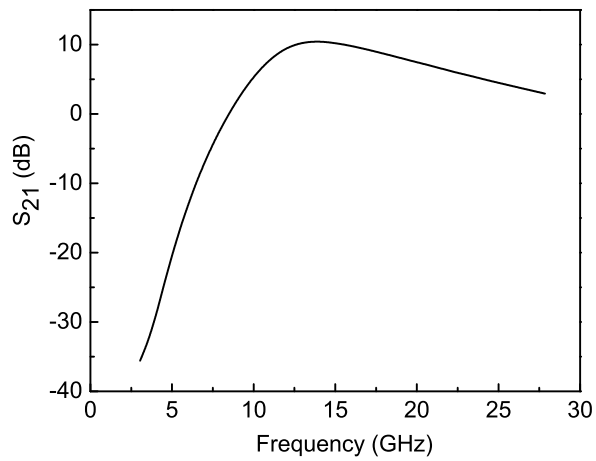

Fig. 2: Forward Gain vs. Frequency

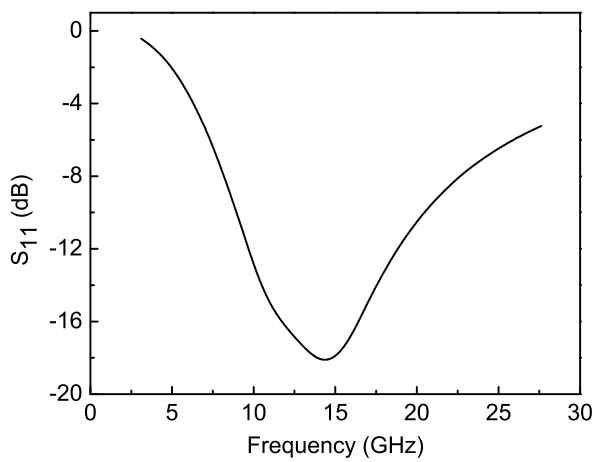

Fig. 3: Input Impedance Matching (S_{11}) vs. Frequency

as possible for an amplifier. The peak forward gain of the LNA is 10.2 dB at a frequency of 14 GHz. It is obvious from the Fig. 2 that 3-dB bandwidth of the amplifier is 9.3 GHz. The wide band impedance matching achieved by using the CG portion at the input followed by a high gain provided by the CS portion is responsible for such a wide bandwidth. The input return loss, S_{11} should be as low as possible. Generally, S_{11}, below -10 dB, ensures sufficient input impedance matching.

As seen from the Fig. 3, S_{11} is -18 dB at 14 GHz. Apart from that, S_{11} stays below -11 dB in the entire bandwidth. The reverse isolation, S_{12} has to be very low. Reverse isolation characterizes the leakage of power from output node to input node. A very low value of S_{12} indicates that the amplifier is stable in the entire bandwidth. S_{12} is below -40 dB in the entire BW for the present work as seen from in Fig. 4. Any value of output impedance matching parameter, S_{22} less than -10 dB is preferable. S_{22} is -28.1 dB at 14 GHz as indicated by Fig. 5. Moreover, S_{22} remains below -10 dB in the entire bandwidth.

The noise figure (Nf) is 5.03 dB at 14 GHz as seen from

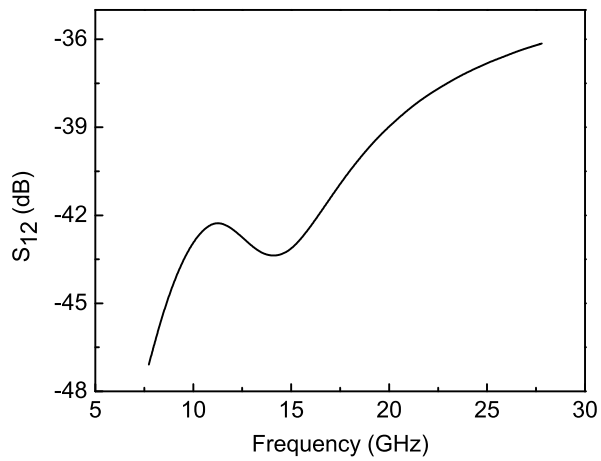

Fig. 4: Reverse isolation vs. Frequency

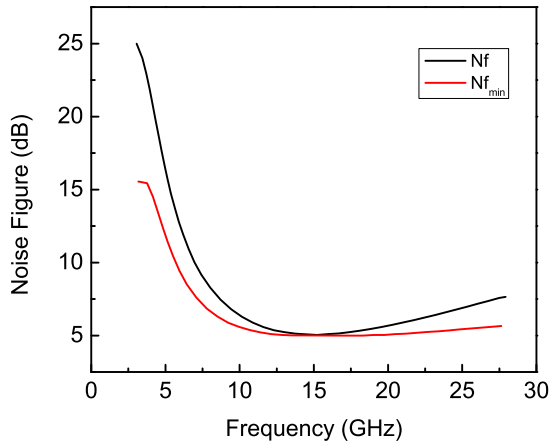

Fig. 6: Noise Figure vs. Frequency

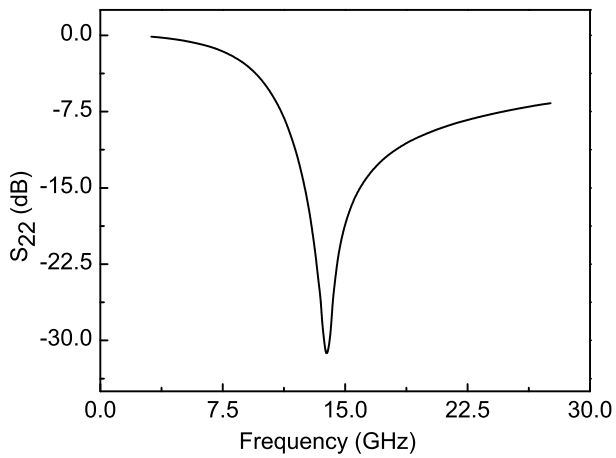

Fig. 5: Output Impedance Matching vs. Frequency

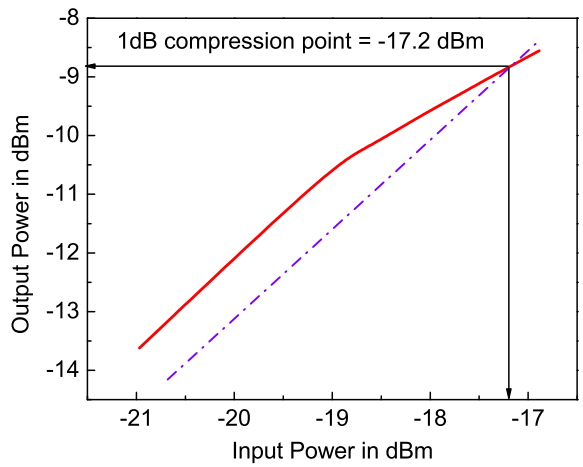

Fig. 7: Output Power vs. Input Power

Fig. 6. However, for such ultra wide band applications, an average noise figure, 5.44 dB is better figure of merit than spot noise figure. Fig. 7 depicts that the 1-dB compression point is -17.2 dBm.

IV. Comparison with Previously Reported LNAs

Table I presents a thorough comparison of this work with different reported state-of-the-art LNAs. All but the proposed LNA in this work have been designed using 180 nm CMOS technology. Apart from ref. [11], all other previously reported amplifiers have more than one stage. Infact, ref. [12] (cascade) and [10] have used three stages to provide sufficient gain as well as input and output matching. The bandwidth that can be utilized by the LNA proposed here, far outnumbers all reported LNAs. The reverse isolation of this LNA is also very impressive when compared with the rest. The power consumption is less when compared with the most of the designs. The output return loss (S_{22}) of the designed LNA is also less than the reported LNAs.

TABLE I: Comparison of Reported CMOS LNAs

Ref.	Freq. (GHz)	BW (GHz)	S_{21} (dB)	S_{11} (dB)	S_{12} (dB)	S_{22} (dB)	P_{DC} (mW)
[11]	10	4.5	14	-10	-25	-13	15
[12] (cascade)	13	<4	14.48	-18.15	na	-16.52	24.61
[12] (cascode)	13	<3	14.73	-18.68	na	-21.56	5.82
[4]	15	6	9.72	-11.05	-22.56	-10.2	10
[10]	15	6	13.83	< -10	< -30	> -10	7.6
This work	14	9.3	10.2	-18	-44	-32	7.38

Nonetheless, all those boons have been achieved at the expense of slightly higher noise level. Apart from that, the 1-dB compression point of this amplifier is slightly less than that of the other reported LNAs. Nonetheless, the 1-dB compression point evaluated for the proposed LNA closely matches with that of ref. [10]. However, this LNA can be used up to a reasonable power level of the input signal.

V. Conclusion

The design and performance of an UWB Low Noise Amplifier for the applications ranging for 10.8 to 20.1 GHz has been analyzed in this work. Comparing with the other state-of-the-art LNAs, this amplifier has higher bandwidth with superior input and output matching. Due to the lack of available data, this design cannot be compared with 130nm technology. The presented design has center frequency of 14 GHz with a bandwidth of 9.1 GHz ranging from 10.8 to 20.1 GHz. The use of CG-CS configuration permits wideband input impedance matching along with sufficient gain. The forward gain is 10.2 dB and the reverse isolation is less than -35 dB at the center frequency of 14 GHz. This LNA takes the advantage of less power consumption (7.38 mW) and higher bandwidth simultaneously. Hence, LNA is suitable for low power applications of 10.8 to 20.1 GHz.

Abstract— **The aim of this paper is to construct an absorber using metamaterial structure which operates at narrow band. The proposed structure is simulated using Microwave studio by CST. Simulations show that S11 of our first structure is -15.20 dB and the absorbance is 97.74% in the resonant frequency at 5.962 GHz and for second structure absorption occurs at 5.296 GHz with absorbance of 99.859% and S11 of -28.243 dB. The frequency of the proposed structures where absorption occurs is reduced significantly as compared to existing structure, but can be more efficient in absorbance.**

Index Terms—**Metamaterial absorber; ELC resonator; absorbance**

I. Introduction

Electromagnetic (EM) metamaterials (MTMs) are usually artificial composite materials consisting of periodic structural units much smaller than the wavelength of the incident radiation are designed to usually gain their properties from their structure and that are not found in nature [1].

A metamaterial absorber manipulates the loss components of the complex effective parameters, electric permittivity and magnetic permeability of metamaterials, to create a high electromagnetic absorber.

To obtain high absorption through resistive and dielectric loss, MTMs can be characterized by electric permittivity and magnetic permeability which can be minimized both transmittance and reflectance simultaneously at resonance frequency [6]. Initially metamaterials absorber was structured by Split ring resonator (SRR) [3], but Electric field driven (ELC) resonating structures [4] are now extensively used as absorbers since EM waves travel lesser distance in ELC compared to the conventional SRR based structure [8].

The coupling between metamaterial structures and electromagnetic radiation via capacitance and inductance suggests that it is to change the resonance frequency also refraction index, and electromagnetic energy may also be stored and to yield a large absorption. Since permeability and permittivity are characterized by a real part (which describes propagation in a medium) and an imaginary part (which describes absorption and loss in a medium), perhaps it is possible to manipulate the imaginary component of ε and μ to be simultaneously large over a given frequency range and thus absorb radiation well. The approach is similar to the one used for negative index metamaterials, to optimize the imaginary portion of the permittivity and permeability. In 2008, Landy et. al introduced a metamaterial structure with high effective absorption over a narrow band in the microwave range (10-12.5 GHz) and near unity absorption at 11.5 GHz [7]. This was accomplished with a metamaterial structure consisting of a silver double split ring resonator (similar to the electrically resonant structures described in [8]). The electrically resonant split rings couple to the electric field without any magnetic interaction, while the magnetic response was a product of the induction current driven between the cut wire and the center conductor of the split ring resonator. The resonance that is established between the inductive and capacitive portions of the "circuit" allows energy to be stored and subsequently dissipated via ohmic and dielectric loss.

The ELC resonator can be described qualitatively in terms of its equivalent circuit [e.g. Fig. 2(b)]. A capacitor-like structure couples to the electric field and is connected in parallel. Two capacitive loops are connected in parallel, so that the resonant frequency of the circuit model is $\omega=\sqrt{(2/(LC))}$ [10]. This allows the electric field to drive the LC resonance providing both positive and negative electric polarization at different frequencies along the resonance curve.

To get a high absorption metamaterial structure need to be much smaller dimension than the wavelength. The performance of the metamaterial absorber is considered by bandwidth and the sensitivity to the incident electric polarization. Previously split ring resonator (SRR) based metamaterirals structure is used for the absorber which is travel at the long distance, Landy et al. has preferred metamaterial absorbers using the Electric Field Driven LC (ELC) resonator structure where the wave has to travel much shorter distance [7].

In here compact ELC driven metamateral absorber structures has been proposed, where the resonance frequency reduces to 5.296 GHz and 5.962 GHz from 6.46GHz [2]. In this paper, we consider absorbance (e.g. sensitivity) of the material in a particular bandwidth where the 2nd proposed structure shows 99.859% absorbance which is more efficient than the existing structure [2].

II. Design

The design of these metamaterial structures is based on simultaneous resonant excitation of an electric dipole and magnetic dipole at a particular bandwidth. The structures consist of a tri layer. Top layer, on which radiation is incident is a structured metallic layer created by copper sheet, separated from the bottom by an intermediate dielectric layer of FR4 substrate. The structure is backed by copper sheet. When EM wave is incident on the structure, the electric field is coupled with the top ELC structure [3], which can control the value of electric permittivity $\varepsilon(\omega)$ and the anti-parallel current between the top layer and the metal ground plane can

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

be coupled with the magnetic field which controls the magnetic permeability $\mu(\omega)$ of the resonating structure [9].

The frequency dependent reflectance [R(ω)] and transmittance [T(ω)] were obtained from the S-parameters in the simulation package and the absorbance was calculated as, $A(\omega)= 1-R(\omega)-T(\omega)$.where $A(\omega)$, $|S11(\omega)|^2$ and $|S21(\omega)^2|$ are the absorbance, reflected power and transmitted power respectively at an angular frequency ω. We can see that, if we want to get the perfect absorption, (e.g. $A(\omega) = 1$). We should make both $T(\omega)$ and $R(\omega)$ equal to 0. However, it is much difficult to get the two parameters to be 0 simultaneously. To simplify the design, here we adopt a ground plane which filled with copper to make sure that the transmission is 0 during the simulation. Therefore, we only need to minimize the reflection in the absorber design.

The absorbance equation can also be defined as,

$$A(\omega) = 1 - |S11|^2 - |S21|^2 \quad (1)$$

Here, S21 is zero because of the copper ground plane, so equation (1) can be written as,

$$A(\omega) = 1 - |S11|^2 \quad (2)$$

So the absorbance of our structure is only dependent on |S11|.

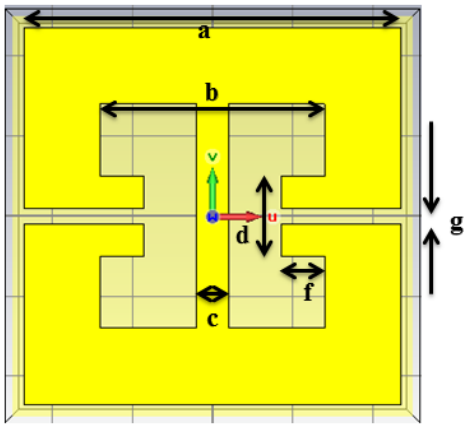

Fig. 3 Front side of the 2nd proposed structure

TABLE I

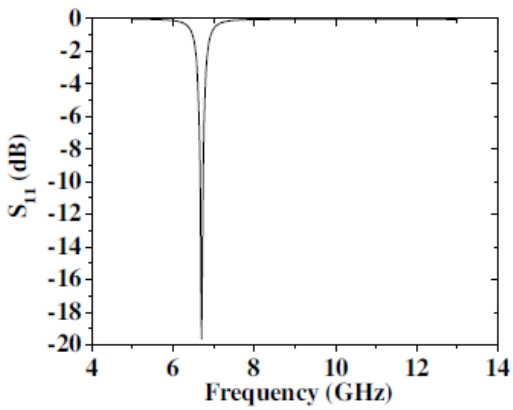
DIMENSIONS OF THESE STRUCTURES

Symbol	Dimension (Fig.2)	Dimension (Fig.3)
a	4.2(mm)	4.7(mm)
b	2.8(mm)	2.8(mm)
c	0.4(mm)	0.4(mm)
d	1.0(mm)	1.0(mm)
e	0.25(mm)	NA
f	0.55(mm)	0.55(mm)
g	0.2(mm)	0.2(mm)

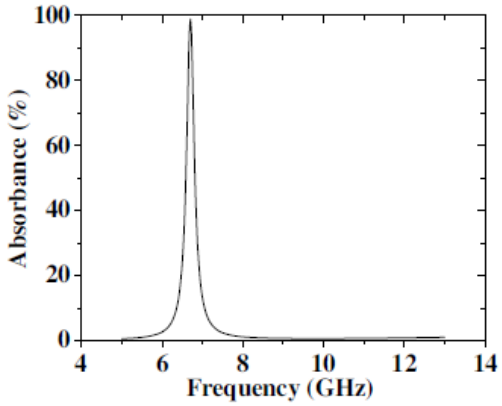
III. Simulated Results

We performed computer simulations of proposed metamaterial absorber structures using the commercial transient solver Microwave Studio by CST. A unit cell was simulated using boundary conditions H(t)=0 in Xmin and Xmax direction and E(t)=0 in Ymin and Ymax direction. We used FR4 substrate with square of 5mm edge and the copper layers have the thickness 0.035 mm.

Somak Bhattacharyya and Kumar Vaibhav Srivastava [2], showed for their structure an absorbance of 99.2% at 6.70 GHz using HFSS software.

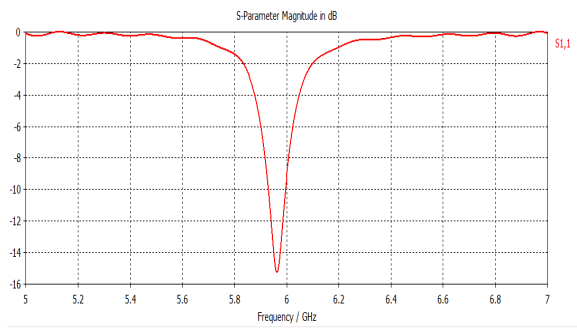


4(a)

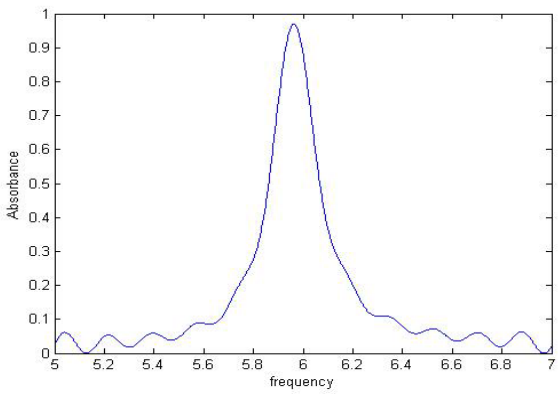


4(b)

Fig.4 (a) s11 plot and (b) absorbance at 6.46 GHz is about 99.2% of the reference structure in [2].



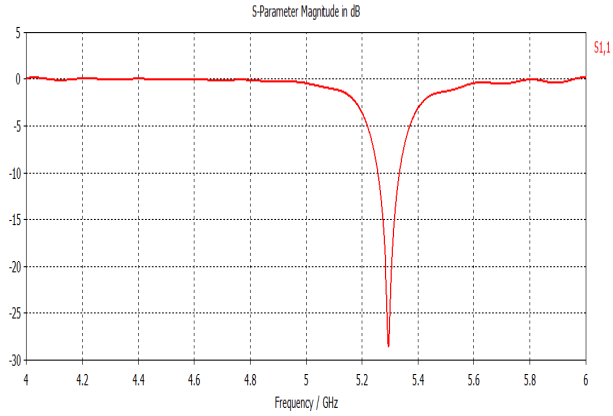
5(a)



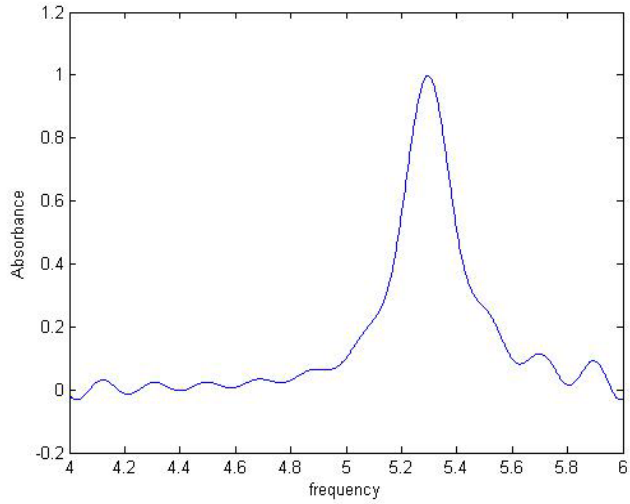
5(b)

Fig.5 (a) s11 plot and (b) absorbance at 5.962GHz is about 97.74% of the 1st proposed structure.

The simulation of the 1st proposed structure shows S11 of -15.20dB and the absorbance is 97.74% at the resonant frequency of 5.962GHz. The absorbance curve (fig. 5(b)) is plotted using MATLAB.



6(a)



6(b)

Fig. 6 (a) s11 plot and (b) absorbance at 5.296GHz is about 99.859% of 2nd proposed structure.

The simulation of the 2nd proposed structure shows a spike in the plot of S11 to -28.243 dB and the corresponding absorbance value A(ω) of 99.859% at the resonant frequency 5.296 GHz as shown in fig. 6(a). The absorbance value is calculated from Eq.(2) and the MATLAB plot is shown in fig 6(b).

The resonant frequency of our structure changed due to the change in capacitance as a result of change in the structure.

IV. Conclusions

We present two metamaterial absorber structures that works at narrow frequency band and the first structure shows absorbance of 97.74% in the resonant frequency 5.962 GHz and for second structure absorption occurs at 5.296 GHz with absorbance of 99.859% which is more efficient than the existing structure in [2]. The structure can be used for battle field and airborne radar applications [11].

***Abstract* - A microstrip transmission line on a Binomial distributed hybrid defected ground structures (DGS) with interleaving photonic bandgap structures (PBGS) are proposed. Four different approaches are utilized to realize the better performance of the low pass filter (LPF). In all these cases, the length, width or both is made non-uniform in accordance with the co-efficient of Binomial distribution. It can be seen that, by applying Binomial distribution on DGS and interleaving PBGS the performance of LPFs are significantly improved.**

Index Terms* - *Defected ground structure (DGS), photonic bandgap structure (PBGS), low pass filter (LPF), Binomial distribution.

I. Introduction

The modern microwave communication system requires high performance, compact size and low cost devices. To fulfil the requirement and to enhance performance some new structures like Photonic Bandgap Structure (PBGS), Defected Ground Structure (DGS), Substrate integrates waveguide (SIW) etc. are existing on the communication system. In 1987, Yablonovitch and John proposed PBG [1, 2] which utilizes metallic ground plane properly and breaks the traditional microwave circuit fixed design to surface components and distributions of the medium circuit plane [3]. Recently many researchers have paid more attention to photonic bandgap structures (PBGSs) due to their unique properties. PBGSs are photonic analogous to semiconductor and the electromagnetic (EM) waves are impeded in PBG perturbed substrates as photons are impeded in the semiconductor. Due to their periodic nature, they are called electromagnetic bandgap structure (EBGS). The advantages of PBG structured components and devices have the ability of creating wider stopband which is very useful for suppressing the surface wave, spurious transmission and leakage in waveguides, striplines and filters [4]-[6].

Several DGS configurations have been described in this paper. MD. N. Mollah [7] proposed two 1-D hybrid DGSs for the low pass filter in the ground plane of a microstrip transmission line. He reported the optimum filling factor (FF) value as 0.46 to generate a very low ripple passband and wide rejection band. FF is defined as the volumetric ratio of one PBG element to one unit cell [8]. In this paper, we have reported that the performance of a microstrip transmission line having non uniform distribution (Binomially distributed) of DGS at a single frequency.

In this paper, we have focused on different binomially distributed DGSs at different FFs. In Binomial distributions, the amplitudes of PBG elements are non-uniform [9]. Therefore, FF is not a single valued parameter. In our study, we have defined the FF as the ratio of central DGS element and inter-element spacing. This research conveys the message of optimum FF at about 4 GHz cutoff frequency. Binomially distributed DGSs with optimum FF are applied to unwanted insertion loss in the band rejection region. Sufficient experimental investigations will be reported on the variation of number of DGSs and interleaved PBGSs in order to observe the effect on the low pass characteristic in a LPF.

Finally, comparing the insertion loss (IL) and return loss (RL) performances of the LPFs with Binomially distributed DGSs and hybrid DGSs, Binomially distributed DGSs and hybrid DGSs provide better performance than uniformly distributed DGSs in terms of suppression of the ripple in the passband and return and insertion-loss bandwidths.

II. Theory

Binomial Distribution

Binomial distribution is the determination of the probability distribution for the discrete number of successes in an independent sequence of experiments. The coefficients of the polynomial are determined by the expression (1).

$$(1+x)^{N-1} = 1 + (N-1)x + \frac{(N-1)(N-2)}{2!}x^2 + \frac{(N-1)(N-2)(N-3)}{3!}x^3 + \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots \quad (1)$$

The coefficients of the series expansion for different values of N are expressed in terms of the Pascal's triangle [6]. N represents the number of EBG elements at the ground plane, then the amplitudes of the different EBG elements are calculated from the coefficients. We have taken seven (7) EBG elements in our designs by using the coefficient of the Pascal's triangle.

$N = 7$	1	6	15	20	15	6	1

Fig. 1 Binomial coefficient in Pascal's triangle

The proportional amplitude coefficients (P) are as follows:
$P_4=0.05$ $P_3=0.30$ $P_2=0.75$ $P_1=1$ $P_2=0.75$ $P_3= 0.30$ $P_4=0.10$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

These values are calculated from Pascal's triangle for $N = 7$.

III. Proposed Designs

The conventional PBGSs are connected by narrow vertical slots to form dumbbell shape periodic structures. This is known as dumbbell shaped DGS [10] which is shown in Figure 2. This is constructed by etching defected areas on the ground plane and a connecting slot between defected rectangles. The equivalent circuit of DGS consists of the additional inductance and capacitance, and the equivalent inductance is dominant over the capacitance. It is much easier to establish the equivalent circuit because the transmission, reflection, and suppression characteristics of DGS microstrip line are very clear and definite [9]. The arm length of the larger rectangle is 'b' and width is 'a'. The vertical slot is rectangular with 'w' × 'g' dimension; 'w' is known as width and 'g' is known as gap.

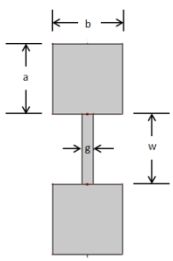

Fig. 2 Geometry of a unit cell of a dumbbell shape DGS.

Bragg's condition [11] is used to calculate the dimension of the uniform PBGS. By using dumbbell shaped DGS, we have proposed three (3) types of designs based on Bragg's condition to improve the performance of the LPF. The following designs are explained below one by one.

A. Design 1

In design 1, we have used Taconic substrate having dielectric constant 2.45 and height of 31 mils. The geometry of LPF designed by non-uniform dumbbell shaped DGS is shown in figure 3. The PBGS elements of the DGS are square in size and each PBGS has both arm's length is calculated to be 205 mils corresponding to FF=0.5 to analyse S-parameter performance. The non-uniform dumbbell shaped DGS elements have the period of 411 mils. The length and width of the narrow slot are 30 and 200 respectively. For the width of the narrow slot of non-uniform dumbbell shaped DGS, we have used the coefficient of the Binomial distribution for 7 element DGSs. We have applied Binomial distribution on the length (b) of every DGS. For N=7 the coefficients are 1, 0.75, 0.3, 0.05 and the length (b) of the PBGSs are taken 205, 153.75, 61.5, 6.15 mils. The FF of the central element is 0.5 for both PBGS and narrow slot of the DGS. The design is shown in Figure 3.

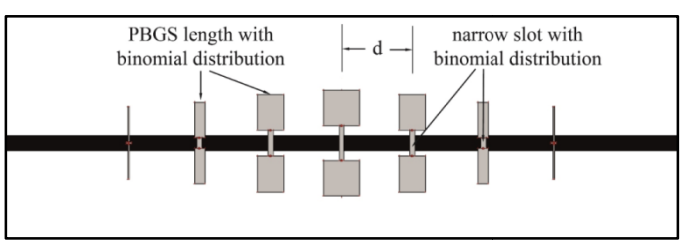

Fig. 3 Geometry of a Binomially distributed LPF designed by varying narrow slot width (w) and length (b) of PBGS of dumbbell shaped DGS etched in the ground plane. The period of DGS is 'd' and the substrate is Taconic with dielectric constant= 2.45 and height= 31 mils.

B. Design 2

In design 2 we have kept the area of narrow slot constant (30×100). The FF of the central element is 0.5 for PBGS of the DGS. The other design pattern is similar as design 1. The design is shown in Figure 4.

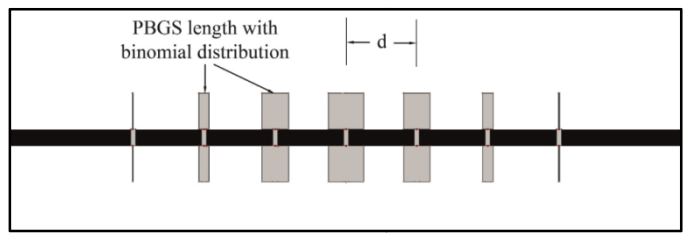

Fig. 4 Geometry of a Binomially distributed LPF designed by varying length (b) of PBGS of the dumbbell shaped DGS etched in the ground plane. The period of DGS is 'd' and the substrate is Taconic with dielectric constant= 2.45 and height= 31 mils.

C. Design 3

In design 3, the dumbbell shaped DGS pattern is followed by design 2. But the square EBGSs have been interleaved that is 1-D in nature and the square PBGSs are reduced by Binomial distribution. The arm lengths of square PBGS are taken as 200, 120, 40, 6 mils for the coefficients of 1, 0.6, 0.2, 0.03 for N=8 as of Binomial distributions. With a view to generating low pass filter (LPF), this interleaved PBGS will be useful. The combined design of the PBGS - DGS is shown in Fig. 5.

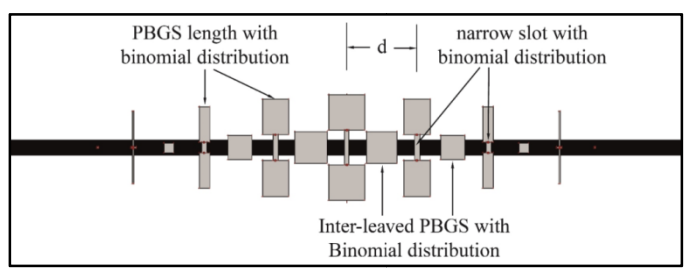

Fig. 5 Geometry of a Binomially distributed LPF designed by varying both length (b) of PBGS and width (b) of the narrow slot of the dumbbell shaped DGS and interleaved square PGBS etched in the ground plane. The period of dumbbell shaped DGS is 'd' for both DGS and interleaved PBGS and the substrate is Taconic with dielectric constant= 2.45 and height= 31 mils.

D. Design 4

The design 4 is different from previous designs. The widths (a) of PBGSs and the width of narrow slot of the dumbbell

shaped DBGs and lengths of the interleaved PBGSs are changed by Binomial distribution. The widths (a) of PBGSs of dumbbell shaped DGSs are 200, 150, 60, 10 mils with lengths (b) were kept constant. The lengths of those EBGS are 205, 153.75, 61.5, 6.15 mils. For PBGS of dumbbell shaped DGS the filling factor of the central element has kept 0.48 and for interleaved PBGS the filling factor has kept 0.5. The narrow slots have designed similar as Design 1. The combined design of the PBGS - DGS is shown in Fig. 6.

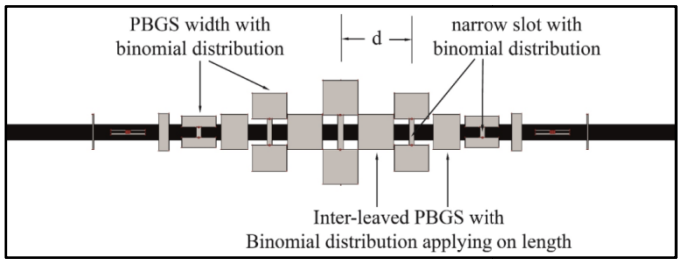

Fig. 6 Geometry of a Binomially distributed LPF designed by varying both width (a) of PBGS and width (w) of the narrow slot of the dumbbell shaped DGS and lengths of the interleaved PGBS etched in the ground plane. The period of dumbbell shaped DGS is 'd' for both DGS and interleaved PBGS and the substrate is Taconic with dielectric constant= 2.45 and height= 31 mils.

IV. Results and Discussions

We have simulated all designs by method of moment (MOM) based EM software Zealand IE 3D which is commercially available for researchers. We have investigated the performance of different designs in terms of cut-off frequency, ripple height and depth and width of the rejection band.

A. Design 1

The S-parameters vs. frequency of Design 1 is shown in Figure 7. It can be seen that the return loss curve is almost straight after 4GHz. But it is observable that there is a ripple on the passband in insertion loss curve. Maximum isolation of the rejection band is -69 dB and minimum isolation is -25 dB.

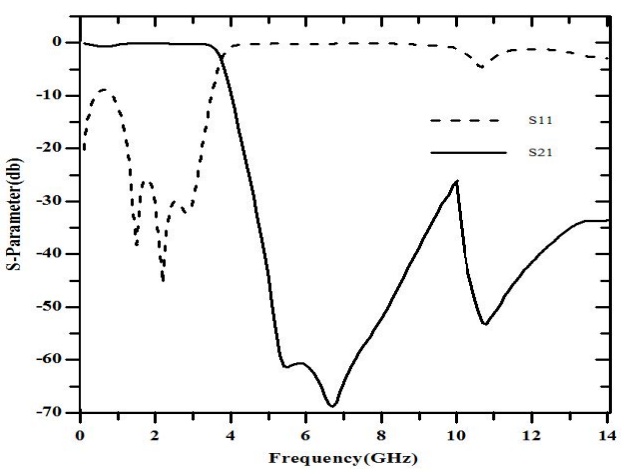

Fig. 7 S-parameters performance of a transmission line over dumbbell shaped DGSs according to design 2 with FF=0.5 for center element. The substrate is Taconic with dielectric constant= 2.45 and height= 31 mils.

B. Design 2

The S-parameters vs. frequency of Design 2 is shown in Figure 8. It can be seen that return loss curve is almost straight after 4GHz. But it is observable that there is a ripple on the passband in insertion loss curve. Maximum isolation of the rejection band is -55 dB and minimum isolation is -29 dB. For design 2 we observe that the improvement of the IL curve at 10GHz than design 1. The pick point is being reduced for design 2 in the IL curve.

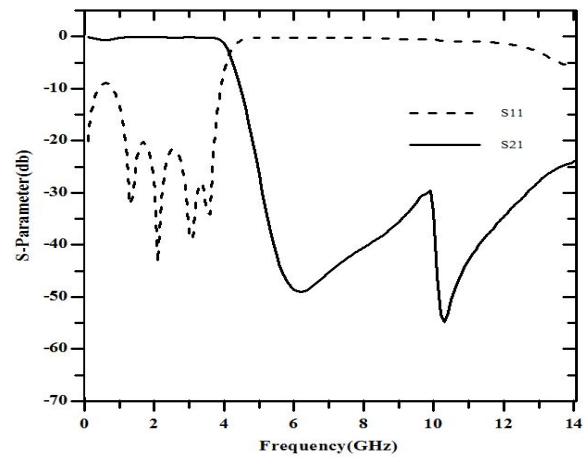

Fig. 8 S-parameters performance of a transmission line over dumbbell shaped DGSs according to design 3 with FF=0.5 for center element. The substrate is Taconic with dielectric constant= 2.45 and height= 31 mils.

C. Design 3

The S-parameters vs. frequency of a dumbbell shape DGS with inter-leaved PBGS of Design 3 is shown in Figure 9. There is a single ripple on the passband in IL curve. Maximum isolation of the rejection band is -65 dB and minimum isolation is -31 dB.

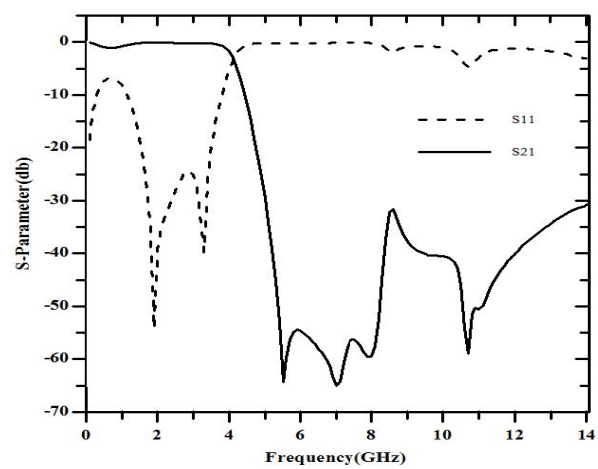

Fig. 9 S-parameters performance of a transmission line over hybrid dumbbell shaped DGSs according to design 4 with FF=0.5 for center element. The substrate is Taconic with dielectric constant= 2.45 and height= 31 mils.

D. Design 4

The S-parameters vs. frequency of a dumbbell shape DGS with inter-leaved PBGS of Design 4 is shown in Figure 10.

There is a single ripple on the passband in IL curve. Maximum isolation of the rejection band is -75 dB and minimum isolation is -28 dB. This design gives the best performance among all the designs that we have proposed. Passband of the insertion loss curve is smoother and the rejection band curves are below -20db and going down gradually. The changing of the width of PBGS of dumbbell shaped DGS and at the same time the changing of the length of interleaving PBGSs have caused a great impact on the results.

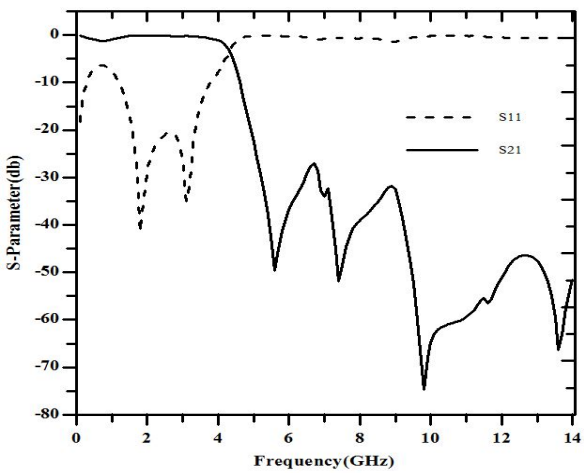

Fig. 10 S-parameters performance of a transmission line over hybrid dumbbell shaped DGSs according to design 5 with FF=0.5 for center element. The substrate is Taconic with dielectric constant= 2.45 and height= 31 mils.

V. Conclusions

We have investigated S-parameter performances 50Ω transmission line on binomially distributed dumbbell shaped DGS and hybrid DGS having FFs of 0.5 for the center element. For these S-parameter performance's investigations, we have used Taconic substrate with dielectric constant of 2.45 and height of 31 mils. It can be seen that Binomial distribution for dumbbell shaped DGS or hybrid dumbbell shaped DGS offers promising performance. Considering the improved performance in terms of RL, IL, ripples, passband and rejection band we have got the best performance for design 5. The depth of stopband and performance of the passband is different for different designs, but they provide a wider scope to the designer for the specific design purposes of a low pass filter. In these investigations conductor losses, substrate loss and loss due to conductors are not included. All the investigations have been done on an infinite ground plane. Additionally, fabrication may cause variation in the size and period of the lattice structures.

To evaluate the performance of binomially distributed dumbbell shaped DGSs and hybrid dumbbell shaped DGSs, we have tested many structures and found the best designs we have provided in this paper. Our main purpose of this design is to reduce ripple from the passband of the LPF and to get improved performance from the band rejection portion. The idea is a novel idea as far of the author's knowledge. Therefore, the design with DGSs and hybrid DGSs are more attractive and may find applications in microwave devices and components.

Abstract—**In this article, a dual-band band-pass filter is developed for Global Positioning System (GPS) and Fixed Satellite (FS) applications. The filter is a planar structure composed of parallel coupled lines with reduced length. The dual band filter is developed using the cascaded coupled lines. High isolation between two pass-bands is achieved. Compared to the previous works, the proposed filter has lower insertion loss at 1.5 GHz and 7.5 GHz. A compact size of 15.7 mm × 33.4 mm is achieved for the proposed filter using Arlon DiClad 880 substrate with a thickness of 0.508 mm.**

Index Terms—**Bandpass filter (BPF), Dual-band, Global Positioning System (GPS), Fixed Satellite (FS).**

I. Introduction

With the rapid growth of microwave applications and services of communication, the desire for multi-frequency equipment is increasing. Moreover, the frequency is divided into categories for different applications. To separate one frequency from another, filter is an essential element. Low cost, compactness and heavy duty products are in great need for the present microwave applications. High performance multi-band filters such as in [1, 2] are making their marks towards the use of multi-band. In recent years, a number of journals are published focusing on multi-band filters for microwave frequencies [3-6]. Currently, there are a large number of literatures promoting multi-band antennas such as [7-9]. To use multi-band antennas it is required for the backend of the antenna to be developed for multi-band accessibility.

To design band-pass (BPF) filter, a transmission line varying continuously is used to match the impedance in [10]. Non-uniform coupled filter design method is shown in [11] realizing arbitrary transmission line filters. While designing dual-band BPF filter, the challenge for microwave circuit designer is to design the filter in a compact area with high performance. Previously, microwave circuit designers used to develop two individual BPF filters to achieve dual-band BPF response from a filter [12]. To combine the performance of the two filters, diplexer type structures are introduced to match the impedance of both filters and hence resulting larger dimension for the filter design. In the later version of dual-band BPF filter design, open-stub cascaded structures are used to achieve the performance increasing the complexity of the circuit and size increment [13].

In this paper, a planar dual band filter is proposed with band pass characteristics. The two centre frequencies of the filter are 1.5 GHz and 7.5 GHz. High transmission characteristics is achieved at both bands by utilizing cascaded coupled lines. The proposed antenna is well matched for 50 Ω impedance microwave circuits. At both pass-bands low insertion loss is achieved. The presented dual-band BPF is designed at a compact dimension of 524.38 mm^2 with a substrate thickness limited to 0.508 mm.

II. Design of the Filter

Fig. 1 shows the layout of the dual-band BPF. Arlon DiClad 880 substrate with a thickness of h = 0.508 mm is used to design the filter. The dielectric constant and loss tangent of the selected substrate are ε_r = 2.2 and tan δ = 0.0009. the basic structure of the filter consists of two tapered I/O paths and a coupled structure in the middle. The coupled structures shown in the fig. 1 follows a pattern that can be described as stepped impedance resonators. By using the coupling mechanism between the microstrip lines, the higher order mode resonances of the filter can be omitted or shifted to another resonance point [14]. Two identical microstrip structures are coupled with each other at the middle of the BPF filter. The arms of the coupling structures are folded to decrease the total size of the filter which makes the filter design more compact. At the edge of each microstrip coupling structure, a cascaded structure is introduced to cope with the different impedance characteristic. It can be observed from the layout that two different thickness microstrip lines are coupling with each other. It is valid for both identical microstrip coupled structures. The irregularity of the thickness can be expressed as: for the long length ($2\theta_1$) in the middle of a cascaded structure the higher impedance is (Z_1) and at both end of the long length, two short length (θ_2) with an impedance (Z_2) lower than the impedance (Z_1), the resonance condition for both even and odd mode can be derived as followed [15]:

$$K * \cot\theta_2 = -\cot\theta_1 \quad \text{(Even-mode)} \tag{1}$$

$$K * \cot\theta_2 = \tan\theta_1 \quad \text{(Odd-mode)} \tag{2}$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Where, $K = (Z_2/Z_1)$ the ratio between two impedances [14]. The length θ_2 is corresponding to the physical length of the stepped impedance resonator. The ratio 'τ' of the total length of the cascaded structure can be expressed as follows:

$$\tau = \frac{\theta_2}{(\theta_1 + \theta_2)} \tag{3}$$

By substituting (3) into the equation (1) and (2) where $\theta_1+\theta_2 = \theta_t$ we find:

$$K * \cot(\tau\theta_t) = -\cot(\theta_t(1-\tau)) \tag{4}$$

$$K * \cot(\tau\theta_t) = \tan(\theta_t(1-\tau)) \tag{5}$$

The resultant θ_t is dependent on the ratios τ and K where θ_t can have several types of solution. For design presented in this paper, the characteristics of this structure are changed repeatedly to optimize the design to resonate at the frequencies 1.5 GHz and 7.5 GHz respectively. The I/O paths of the proposed filter are tapered so that the impedance of the coupled structure can be matched with the 50 Ω impedance of the backend structure it is mounted on. The feed-line of the filter starts from two identical points at both sides of the filter. After an increment of '*a*' the feed-line is banded to reduce the dimension of the filter from both sides. The bending of the feed-line extensively decreases the total size of the filter, making it an ideal filter device for any compact system. At the end of the feeding, the line is tapered and the thickness is increased until the length '*d*' where, at the edge it touches the excitation point.

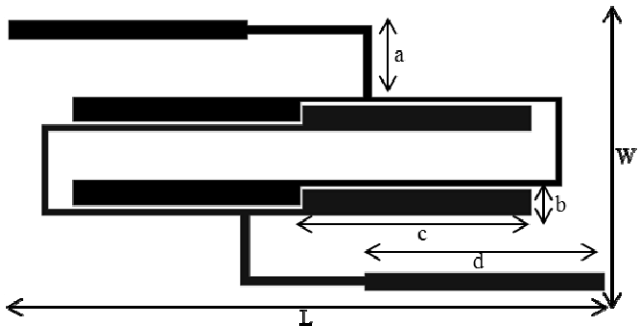

Fig. 1 Layout of the proposed BPF filter. The filter dimensions are: L = 33.4 mm, W = 15.7 mm, a = 4 mm, b = 1.4 mm, c = 12.8 mm, d = 13.4 mm.

III. Results

The proposed dual-band BPF is designed using the commercially available software High Frequency Structural Simulator (HFSS) version 15.0. A plane copper layer is assigned at the bottom of the substrate and assigned as the ground plane of the filter. The calculation is carried out using two lumped ports assigned 50 Ω impedance so that the filter can be assembled with 50 Ω microwave structures. Fig. 2 shows the S-parameter response of the proposed filter. It can be observed from the figure that an insertion loss of less than -39 dB is achieved at 1.5 GHz and -23.8 dB is achieved at 7.5 GHz. The S_{11} and S_{22} response are almost identical to each other and overlaps each other throughout the frequency span. The S_{21} response of the filter shows that at the first resonance of the BPF, the transmission loss is as low as -0.11 dB and the -3 dB bandwidth starts from 1.2 GHz till 1.8 GHz with a 40% fractional bandwidth (FBW) centred at 1.5 GHz frequency. At the second resonance the transmission loss is lower at 7.5 GHz with a value of -0.53 dB and the -3 dB bandwidth starts from 7.1 GHz till 7.8 GHz with the FBW of 10% centred at 7.5 GHz. The -10 dB bandwidth of S_{11} and S_{22} at the first resonance starts from 1.3 GHz till 1.7 GHz and at the second resonance, the bandwidth starts from 7.3 GHz until 7.7 GHz.

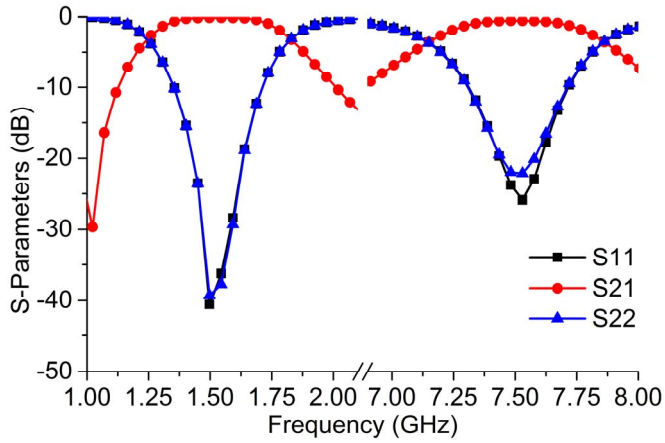

Fig. 2 S-parameter responses of the BPF with respect to the frequency.

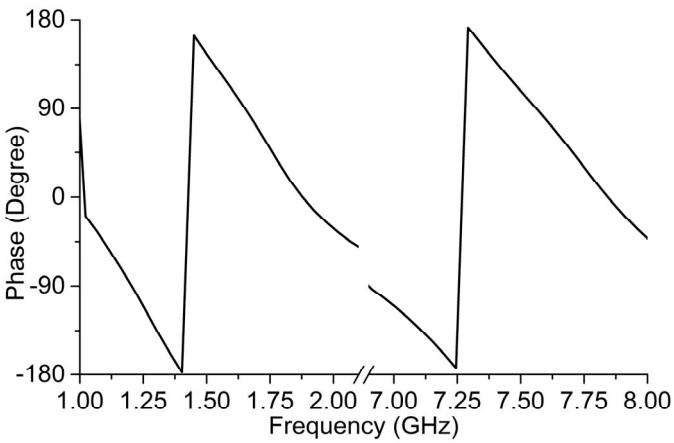

Fig. 3 Phase response of the BPF at resonance frequencies.

Fig. 3 depicts the phase response at the resonance bands of the BPF. It can be observed from the figure that the phase response change with the frequency is smooth and there is no irregularity of phase change within the pass-bands of the BPF.

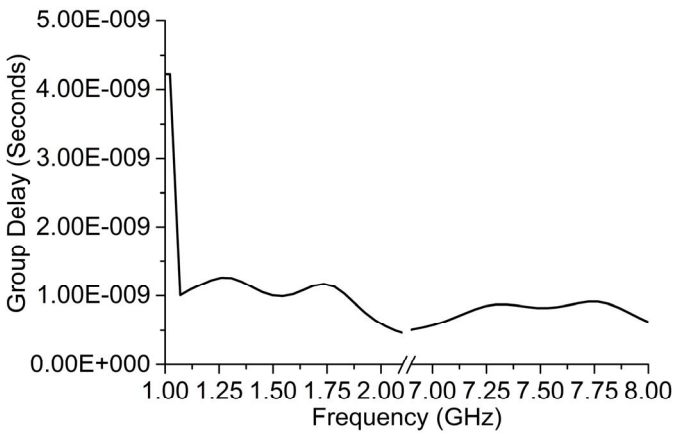

Fig. 4 Group delay within the I/O of the BPF.

Fig. 4 shows the group delay between two I/O ports of the filter. From the figure, it can be perceived that the group delay is not constant throughout the frequency. However, within the resonance bandwidths, the average group delay is below 1 ns. Although some ripples can be noticed, nonetheless, the fluctuation of time is very narrow which can be ignored.

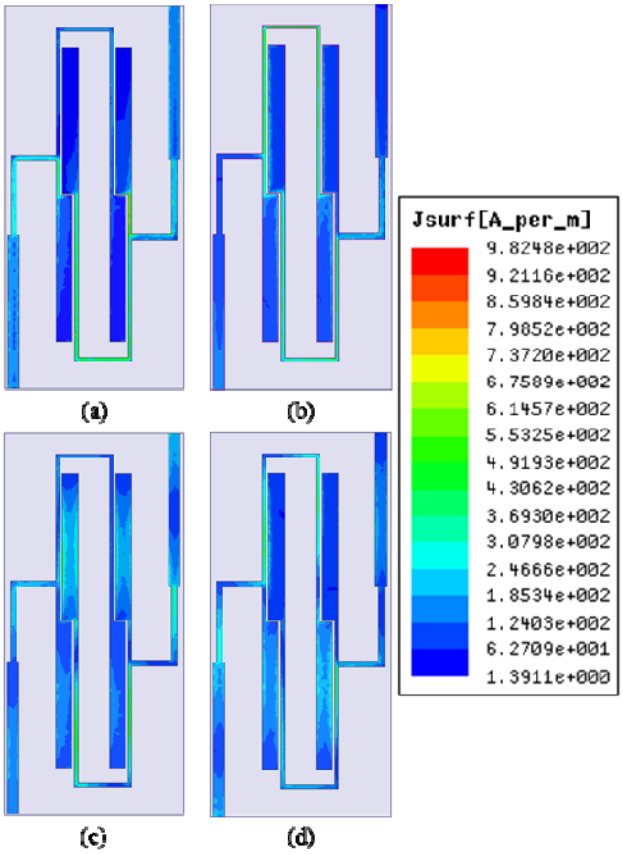

Fig. 5 Current distribution pattern of the BPF at (a) 1.5 GHz and 0° phase, (b) 1.5 GHz and 90° phase, (c) 7.5 GHz and 0° phase and (d) 7.5 GHz and 90° phase.

Fig. 5 shows the current distribution pattern of the filter at both resonance frequencies. The current distribution shows a peak of $9.8248\times e^2$ Amp/meter at all the current distribution patterns. In fig. 5 (a) the current distribution is shown for 1.5 GHz at a phase of 0°. It can be observed that the current density is at its peak over the feed-lines. The current distribution in Fig. 5 (b) depicts that the current density is increasing at the band lines connecting the coupling hands of the filter for 90° phase difference at 1.5 GHz. At 7.5 GHz 0° phase, current is dense mostly at the edge of the feeding point and the coupling hands shown in Fig. 5 (c). Fig. 5 (d) presents the current distribution pattern of the filter for 7.5 GHz 90˚ phase. One side of the coupled hands are excited with more current compared to the other side. The connecting line of the coupling hand also shows highly dense current distribution.

IV. Conclusions

A compact, low loss novel dual-band BPF is presented by means of coupled structures. The filter is designed for GPS and FS system for which the frequency mostly comes from satellites and filter is required for high cancellation from noise. The proposed filter shows good frequency responses at 1.5 GHz and 7.5 GHz with a bandwidth of 600 MHz and 700 MHz respectively. The filter has a very low transmission loss. Good isolation between two operating bands is achieved. The phase response gives a stable performance at both operating bands. An average group delay of less than 1 ns is achieved between two I/O ports. The proposed filter comprises a dimension of 15.7 mm × 33.4 mm and the Arlon Diclad 880 substrate thickness of 0.508 mm.

Abstract—**The metallic single walled carbon nanotubes have been proposed as a promising inter connector in intra-chip and inter-chip packaging applications as well as passive devices for future generation terahertz IC (Integrated Circuit) technology, due to their superior electrical and thermal properties compared with those of copper. In this paper a theoretical investigation is carried out to predict phase and group velocities and the attenuation characteristics of single walled metallic carbon nanotubes (SWCNTs), and bundled SWCNTs in the terahertz regime. The expressions for attenuation constant, phase constant, phase velocity, and group velocity have been derived using transmission line theory. It is found that the predicted phase and group velocities in single SWCNT, bundled SWCNTs are strongly frequency dependent and increases with frequency. It is also noticed that the group velocity decreases after having a peak at around 100 GHz for both single SWCNT and bundled SWCNT.**

Index Terms—**Attenuation Constant, Phase Velocity, Group Velocity, Bundled SWCNT.**

I. Introduction

One of the latest trends in GHz to THz technology [1] is to use single-walled carbon nanotubes (SWNTs) as building blocks of novel high-frequency devices and interconnects. CNTs have been drawn great interest due to their outstanding electronic, thermal, electromagnetic and mechanical properties. CNTs are basically rolled-up graphene sheets and are of two types: metallic and semiconducting depending on the chirality. Recent trend of technology reveals that metallic CNTs are going to replace the conventional copper as on-chip interconnect in VLSI circuits, transmission lines and coplanar waveguides in microwave integrated circuits (MIC), and dipole antennas for terahertz radiation [2]. Conventional copper does not offer reliable performance when it comes to transmit or detect very high frequency signal due to their skin effect at nanoscale dimensions. CNTs outperform copper as interconnect in VLSI circuits. The superior electrical and thermal properties of CNTs over copper are: (i) high current density (SWCNT: 10^9 A/cm^2, Cu: 10^7 A/cm^2) [3]; (ii) Large mean free path (SWCNT: 2.8 µm, Cu: 40 nm) [4]; (iii) High thermal conductivity (SWCNT: 5800 W/m-K, Cu: 385 W/m-K) [5]; (iv) Negligible skin effect at THz regime compared with copper [6]; (v) smaller resistance at THz regime compared with copper [4, 6]; (vi) high melting point (SWCNT: 3800 K, Cu:1356K). The mechanical properties of CNTs are also worth noting over copper. CNTs have high tensile strength (CNT: 22 GPa, Cu:0.22 GPa) [7] due to its sp^2 hybridization; thus, stronger than diamond.

Based on the Luttinger liquid theory, Burke [8] proposed the *RLC* equivalent circuit model of SWCNT considering only the length independent quantum resistance, quantum and electrostatic capacitances and kinetic and magnetic inductances. Later on, that model was revised adding the length dependent scattering resistance and imperfect metal-CNT contact resistances [4, 9-10]. Koo *et al* [4] discussed the latency and power dissipation of CNT based on *RLC* circuit model. Naemee *et al* [11] also discussed the latency of CNT based on similar type of *RLC* circuit model, and they also found that the phase velocity in SWCNT is about 1.76×10^6 m/s. But their phase velocity calculation was over simplified as they neglected the resistance of SWCNT (assuming lossless transmission line). Therefore, that result is valid only for an SWCNT whose length is less than the mean free path of electron. But in reality, SWCNTs are synthesized having a length of several millimeters, which offer a high resistance and therefore, huge power dissipation when used as a transmission lines at GHz to THz frequencies. As the use of CNTs in the GHz and THz applications (interconnect in ultra high speed VLSI circuits, transmission line, waveguides etc) are emerging; thus it is crucial to carry on the comprehensive investigation of wave velocities (both phase and group velocities) in SWCNTs taking into account the resistance.

In this paper, novel simple expressions of attenuation constant, phase constant, phase and group velocities are derived analytically from the expressions of complex propagation constant taking into account the high resistance, capacitance and inductance of SWCNT. We shall also compare the phase and group velocities among single SWCNT, bundled SWCNT.

II. Electrical properties of SWCNT

The properties of SWCNT are very different than those of conventional metal conductors. Some of the electrical properties of SWCNT relevant to interconnect applications are described in this section.

A. Electrical Resistance

The electrical resistance of SWCNT consists of three components: (i) Quantum resistance, (R_Q) (ii) Scattering resistance (R_QL/l_0), and (iii) Contact resistance arises from metal-CNT imperfect contacts, (R_c). The quantum resistance is the intrinsic resistance of CNT, which is independent of the length of CNT. However the quantum resistance is diameter dependent [12]. The scattering resistance attributed from the scattering effects, is length dependent. Hence the total resistance of SWCNT can be expressed as:

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

$$R_{CNT} = R_c + R_Q\left(1 + \frac{L}{l_0}\right) \quad (1)$$

Here, L: length of the SWCNT, and l_0: electron's mean free path in SWCNT, R_Q: quantum resistance (6.5 kΩ), and R_c: metal-CNT contact resistance.

The high resistance of SWCNT may be reduced using bundle of SWCNTs. The resistance for a bundle of SWCNT consists of "n" number of SWCNTs can be expressed as:

$$R_{bundle} = \frac{R_{CNT}}{n} \quad (2)$$

B. Capacitance

In an SWCNT, there are two conducting channels, and due to the electron spins (spin-up and spin-down) each channel has two degeneracy. Therefore, in an SWCNT, there are four conducting channels. According to the circuit model of Burk [8], there are two types of capacitances: (i) electrostatic capacitance, C_E and (ii) Quantum capacitance, C_Q. The total capacitance of an SWCNT can be expressed as:

$$C_{CNT} = \frac{4C_Q C_E}{4C_Q + C_E} \quad (3)$$

The capacitance for a bundle of SWCNT consists of "n" number of SWCNTs can be expressed as:

$$\frac{1}{C_{bundle}} = \frac{1}{C_Q^{bundle}} + \frac{1}{C_E^{bundle}} \quad (4)$$

Where, $C_Q^{bundle} = 4 \times C_q \times n$ and

$$C_E^{bundle} = 2C_{En} + \frac{n_w - 2}{2}C_{Ef} + \frac{3(n_H - 2)}{5}C_{En}$$

Here, n_H is the number of rows and n_w is the number of columns in the interconnect bundle; here $n=(n_H \times n_W)-n_H/2$ if n_H is even and $n=(n_H \times n_W)-(n_H-1)/2$ if n_H is odd [13].

C. Inductance

The total inductance of SWCNT consists of kinetic inductance and mutual inductance. In a single SWCNT the kinetic inductance is dominating, thus we can ignore the effects of mutual inductance. The kinetic inductance can be expressed as:

$$L_{CNT} = \frac{h}{8e^2 v_F} \quad (5)$$

The inductance for a bundle of SWCNT consists of "n" number of SWCNTs may be expressed as:

$$L_{bundle} = \frac{L_{CNT}}{n} \quad (6)$$

III. Expression of Wave velocities

The velocity of electromagnetic waves travelling through a transmission line has been characterised by: (i) phase velocity and (ii) group velocity. Phase velocity is defined as a mathematical formulation but not a realistic velocity. Group velocity is the real velocity of a travelling wave. Here we shall derive the expressions of phase velocity and group velocity in SWCNT, considering the SWCNT as a transmission line. The well known telegrapher equations can be written as follows [14]:

$$\frac{dV(z)}{dz} = -(R + j\omega L)I(z) \quad (7)$$

$$\frac{dI(z)}{dz} = -(G + j\omega C)V(z) \quad (8)$$

Where, R, G, L and C are the series resistance, parallel conductance, series inductance and parallel capacitance respectively. $V(z)$ and $I(z)$ are the voltage and current respectively at any location of the transmission line, and z is the direction of propagation. From theses equations after manipulation, we can write the voltage and current waves as:

$$\frac{d^2V(z)}{dz^2} - \gamma^2 V(z) = 0 \quad (9)$$

$$\frac{d^2I(z)}{dz^2} - \gamma^2 I(z) = 0 \quad (10)$$

The solution of equations (9) and (10) can be written as follows:

$$V(z) = V_0^+ e^{-\gamma z} + V_0^- e^{\gamma z} \quad (11)$$

$$I(z) = I_0^+ e^{-\gamma z} + I_0^- e^{\gamma z} \quad (12)$$

Where, the propagation constant, γ can be expressed as follows.

$$\gamma = \alpha + j\beta = \sqrt{(R + j\omega L)(G + j\omega C)} \quad (13)$$

In SWCNT we may assume G=0. Hence, from equation (13), we derived the following equations for attenuation constant (α) and phase constant (β).

$$\alpha = \frac{1}{\sqrt{2}}\left[\sqrt{\omega^4 L^2 C^2 + \omega^2 R^2 C^2}\right]^{\frac{1}{2}} \quad (14)$$

$$\beta = \frac{1}{\sqrt{2}}\left[\sqrt{\omega^4 L^2 C^2 + \omega^2 R^2 C^2} + \omega^2 LC\right]^{\frac{1}{2}} \quad (15)$$

According to the definition of phase velocity, it can be expressed as:

$$v_p = \frac{\omega}{\beta} \quad (16)$$

From equations (14), (15) and (16), the expression of phase velocity can be written as:

$$v_p = \frac{\sqrt{2}}{\left[L^2C^2 + \left(\frac{RC}{\omega}\right)^2 + LC\right]^{\frac{1}{2}}} \quad (17)$$

The group velocity, v_g can be defined as:

$$v_g = \frac{1}{\frac{d\beta}{d\omega}} \quad (18)$$

From equations (15) and (18), we may derive the expression of group velocity as:

$$v_g = \frac{4\sqrt{2}\left(\sqrt{\omega^4 L^2 C^2 + \omega^2 R^2 C^2} + \omega^2 LC\right)\sqrt{\omega^4 L^2 C^2 + \omega^2 R^2 C^2}}{3\omega^3 L^2 C^2 + 2\omega R^2 C^2 + 4\omega LC\sqrt{\omega^4 L^2 C^2 + \omega^2 R^2 C^2}} \quad (19)$$

IV. Results and discussions

The performance of electromagnetic wave propagation through the SWCNT may be quantified using the phase and group velocities profiles. The velocities in single SWCNT and bundled SWCNT have been calculated using the derived expressions in the previous section. Fig.1 and Fig.2 describe the dependence of phase and group velocity for single SWCNT and bundled SWCNT. From these figures, it is found that the both the wave velocities (phase velocity and group velocity) are strong functions of operating frequency, especially at the lower frequency range. It is observed that at higher frequency regime, the phase velocity becomes saturated [Fig.1] and the group velocity has a peak at around 100 GHz and then decreases with frequency [Fig.2]. It is also noticed that in both cases the wave velocity is much higher in bundled SWCNT compared with that in single SWCNT. This is due the reduced values of resistance and inductance in a bundled SWCNT. In a bundle, SWCNTs are considered in parallel. The phase velocity in single SWCNT found in this work, is in good harmony with that of Ref. [11]. Fig.3 shows the evolution of attenuation constant with frequency. Attenuation constant increases with the increase of frequency due to the reduction of skin depth at higher frequency [6], and attenuation constant is inversely proportional to skin depth. It is also found that the attenuation is much lower in a bundle of SWCNT than that of in a single SWCNT.

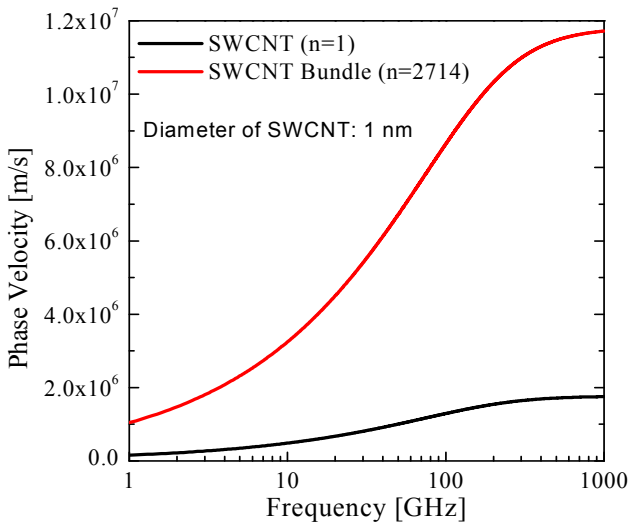

Fig.1 Frequency dependence of phase velocity for single SWCNT and bundled SWCNT

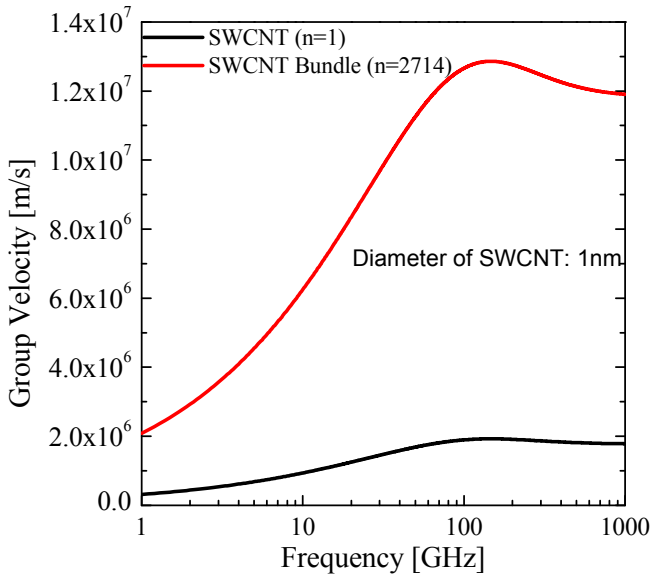

Fig.2 Frequency dependence of group velocity for single SWCNT and bundled SWCNT

We have also investigated the effects of CNT diameter on the group velocity and attenuation constant. The diameter (D) of SWCNT is related to the mean free path of electrons (l0) in the SWCNT by l0=1000D [6]. Fig.4, describes the effects of diameter of SWCNT on the group velocity of single and bundled SWCNTs at 100 GHz. It is noticed that the diameter has a very insignificant effect on the group velocity of single SWCNT; however, the group velocity of bundled SWCNT drastically falls with the increase of diameter of SWCNT. This is because, if we use larger diameter SWCNTs in a bundle (with a fixed dimension of bundle), the number of SWCNTs decreases. As a result the equivalent resistance and inductance of a bundle decrease, which in turn reduces the group velocity. Therefore, it is advantageous to use smaller diameter SWCNTs in a bundle to have higher group velocity. Fig.5 shows the effects of diameter of SWCNT on the attenuations constant of single and bundled SWCNTs at 100 GHz. It is found that in single SWCNT attenuation constant decreases with larger diameter, because larger diameter CNTs offer smaller resistance. On the other hand, the attenuation of bundled SWCNT slightly increases with diameter. The reason is similar as described in Fig. 4.

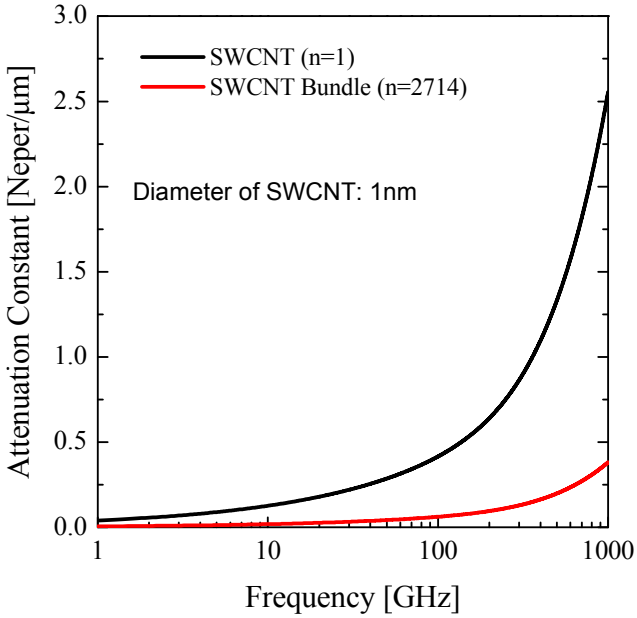

Fig.3 Frequency dependence of attenuation constant for single SWCNT and bundled SWCNT

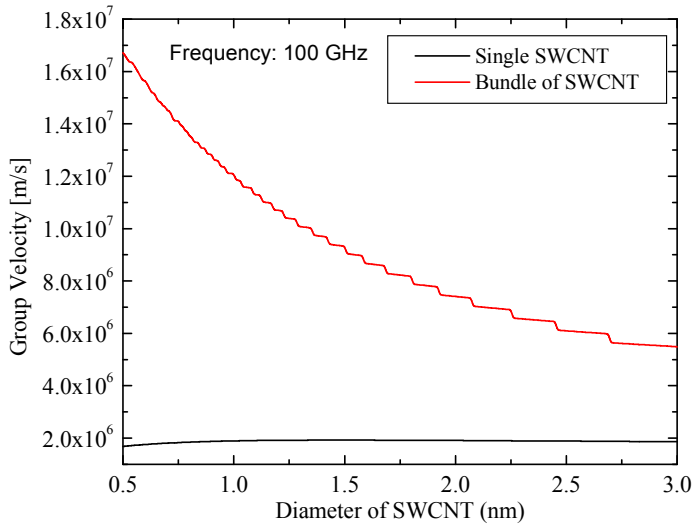

Fig.4 Effects of SWCNT's diameter on the group velocity at 100 GHz.

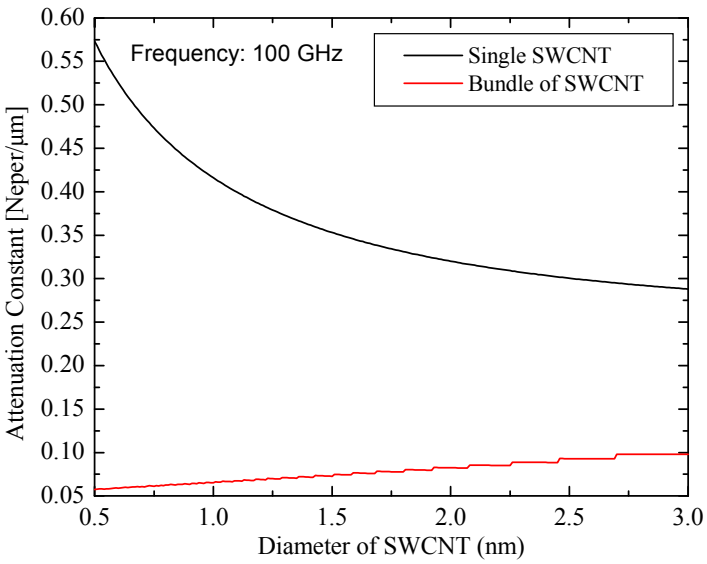

Fig.5 Effects of SWCNT's diameter on the attenuation constant at 100 GHz.

V. Conclusion

In this paper the novel expressions for phase and group velocity, and attenuation constant have been derived taking into account the losses in the SWCNT. We have discussed the electrical properties of single SWCNT and bundled SWCNT related to interconnect applications. It is found that the wave velocities and attenuation are strong functions of frequency. The wave velocities are much higher in an SWCNT bundle than that of in a single SWCNT. In contrast, the attenuation in a bundle of SWCNT is much lower than that of in a single SWCNT. Moreover, the diameter of SWCNT significantly affects the group velocity of bundled SWCNT and attenuation in single SWCNT. It may be recommended that to have higher group velocity and smaller attenuation, we should use bundle of smaller diameter SWCNTs.

Minimization of Output Fluctuation of a Fixed Speed IG Based Wind Farm without Capacitor by using PMSG

M.R.I. Sheikh,[1] and Zinat Tasneem[2,*]

[1,2]EEE Department, Rajshahi University of Engineering & Technology
Rajshahi-6204, Bangladesh
[*]tasneemzinat@gmail.com

Abstract—**Capacitors are considered as the prime element in a fixed speed Induction Generator (IG) based wind farm along with the other external controlling devices for providing the necessary reactive power compensation. But this paper proposes that the capacitors as well as the external controlling devices can be eliminated from the wind farm if Permanent Magnet Synchronous Generator (PMSG) is included in the system. The proposed model of PMSG works not only as a power producing generator but also as a controlling device for IG. A 50 MW wind farm has been considered for this study which consists of both IG and PMSG without any capacitors or controlling devices. Varying load condition has also been considered for a composite wind farm with Synchronous Generator (SG). Simulation results prove the effectiveness of the proposed system. Both the dynamic and transient analyses have been carried out by using the laboratory standard power system software package, PSCAD/EMTDC.**

Index Terms—**IG; PMSG; capacitor; variable load.**

I. Introduction

In recent years the world consumption of energy has increased enormously due to the massive industrialization which has been intensified rapidly in some geographical areas of the world remarkably in the countries of Asia. This consumption mostly depends on non-renewable energy sources, i.e. on fossil fuels and nuclear power resources. But these non-renewable energy sources are limited and they are the main reason of green house effect and environment pollution. Hence renewable energy sources are now rapidly taking their places as a clean and non-polluting energy source. Among the renewable energy sources, wind is a promising one. It is currently one of the most cost effective ways to produce electricity. Worldwide there are now over two hundred thousand wind turbines operating, with a total nameplate capacity of 282,482 MW as of end 2012 [1]. Since, the demand for wind energy is increasing day by day, it is important to assure that the power developed by the wind farm must be of good quality and the operation of the wind farm must be stable [2]. Since the wind speed is dynamic so the output parameters of a wind farm like the terminal voltage, output power, frequency etc fluctuate with the variable wind speed. To reduce this fluctuation, in conventional Induction Generator (IG) based wind farms, some external controlling FACTS (Flexible AC Transmission System) devices like STATCOM (Static Compensator), Unified Power Flow Controller (UPFC) etc are used. These are the non-producing element for a wind farm, they make the system more complicated and increase the system overall cost. Over recent years, a new scheme for the wind generators has become popular, which includes a Variable Speed Wind Turbine with Permanent Magnet Synchronous Generator (VSWT-PMSG). In this concept, PMSG can be directly driven by a wind turbine without gearbox and it is connected to the ac power grid through the power converters.

In our previous study [3-4], it is seen that PMSG can enhance the stability of the fixed speed wind farm if it is used in combination with IG. In [5] a PMSG based wind farm has been used to enhance the fault ride through capability of a fixed speed wind farm with a three-level IGBT converter-inverter set. In [6] a VSWT-PMSG has been used in HVDC connected offshore wind farm. Again a stabilization of a grid connected wind farm using PMSG is depicted in [2]. In these papers capacitor bank was used with IG to compensate for the reactive power. But capacitor banks are quite expensive and in case of varying wind speed, the reactive power demand from capacitor bank also become varying. Thus switching is needed, which reduces their lifetime. Therefore, this paper presents a unique technique to minimize the output fluctuation of a wind farm by using PMSG, which eliminates the need of external controlling devices and even the capacitors. The proposed model of PMSG is able to provide the necessary reactive power compensation and hence to maintain a constant voltage and less fluctuating power at the grid for which the capacitor bank is generally used along with IG. Variable load conditions have also been considered for a composite wind farm where IG and PMSG are used along with SG. It can be seen from the simulation results that PMSG itself works as a controlling device for the wind farm not only in dynamic and transient conditions but also in varying load conditions.

II. System Layout

Four cases have been considered in this study to show the effectiveness of the proposed wind farm model. These cases are explained in the following paragraphs.

A. Case-1, Wind Farm with IG

In the first case, a conventional wind farm with IG has been considered without any external controlling devices and capacitor bank. The total capacity of the farm is 50 MW. Fig. 1(a) shows the schematic diagram of case-1.

B. Case-2, Wind Farm with IG and Capacitor Bank

In the second case, conventional IG has been used along with a capacitor bank. This farm also has a capacity of 50 MW. But it doesn't include any controlling devices. Fig. 1(b) shows the schematic diagram of this farm.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

C. Case-3, Wind Farm with IG and PMSG

Case-3 includes a wind farm with both IG and PMSG. No capacitor bank or other controlling FACTS devices have been used. Here, a PMSG of 5 MW has been considered along with an IG having capacity of 45 MW. Thus the total capacity of the farm is 50 MW. Fig. 1(c) shows the schematic diagram of this farm.

D. Case-4, Wind Farm with IG, PMSG and SG

To observe the varying load conditions, a composite wind farm with IG, PMSG and SG have been considered in case-4. An IG of 5 MW along with a PMSG of 3 MW has been used with an SG of 100 MW capacity. Thermal governor is used to control the SG. SG depicted in [7] has been used. The schematic diagram is shown in Fig. 1(d).

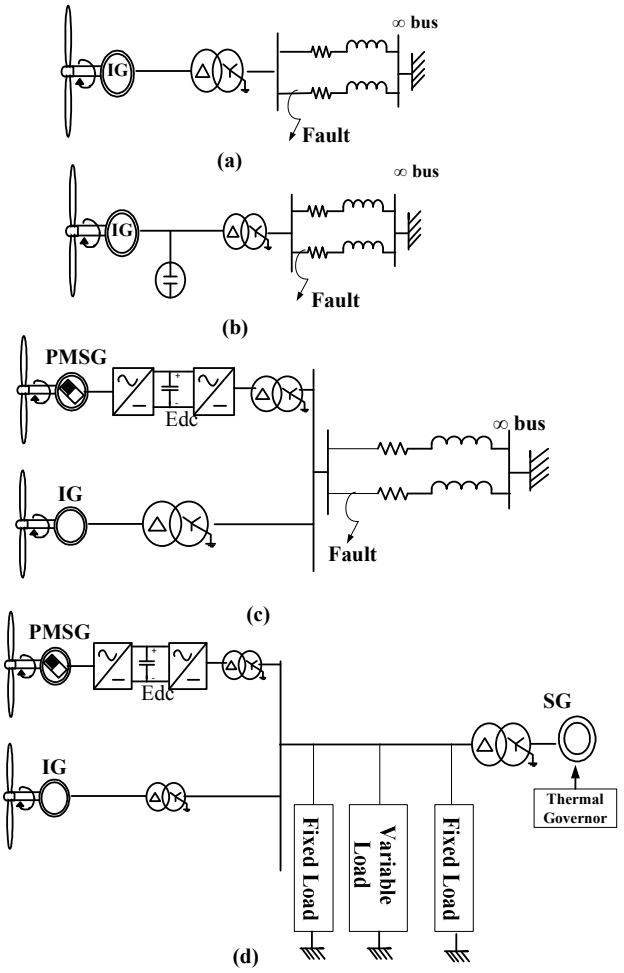

Fig. 1 Schematic diagram for (a) case-1, (b) case-2, (c) case-3 and (d) case-4.

III. PMSG Model

Fig. 2 shows a VSWT-PMSG system which is modelled with a fully controlled frequency converter. The PMSG model available in the package software PSCAD/EMTDC is used [8] in this study. The frequency converter consists of a generator side AC/DC converter, a DC link capacitor and a grid side DC/AC inverter. Each of the converter/inverter is a standard three phase two-level unit, composed of six insulated gate bipolar junction transistor (IGBTs) and anti parallel diodes. The full-rating power converter which is made up of two back- to-back IGBT bridges (the generator side converter and grid side inverter) are linked by a DC bus. The three phase AC output of the generator is rectified, and the DC output from the rectifier is fed to an IGBT-based grid side inverter. Its output is fed to a step-up transformer and then to the grid. The rating of the power converters corresponds to the rated power of generator plus losses. The power converters control the power flow to the grid.

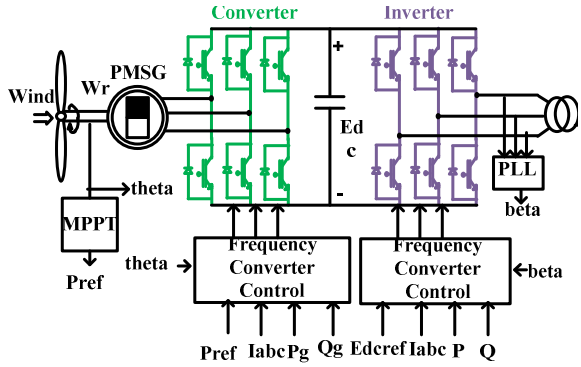

Fig. 2 Electrical scheme of VSWT-PMSG.

IV. Simulation Results

Simulations have been done by using Power System Computer Aided Design / Electromagnetic Transient including DC (PSCAD/EMTDC) program [8] for 350 seconds. The timing step of the simulation is chosen to be 0.01 sec. As mentioned earlier, four case studies have been considered in this study. The results have been shown for dynamic, transient analysis for the first three cases and variable load conditions for the last case.

A. Dynamic Stability Analysis

Fig. 3 shows the variable wind speed data used in the simulation. Fig. 4 shows the grid side voltage response for the first three cases. It can be seen that PMSG maintains almost a constant voltage without the capacitor bank of IG. The real power response is shown in Fig. 5. Here also the third case, that is IG and PMSG has the best response among the three cases, since this case provides the necessary reactive power compensation to the grid as can be seen from Fig. 6. And it also helps to maintain the frequency response stable as shown in Fig. 7.

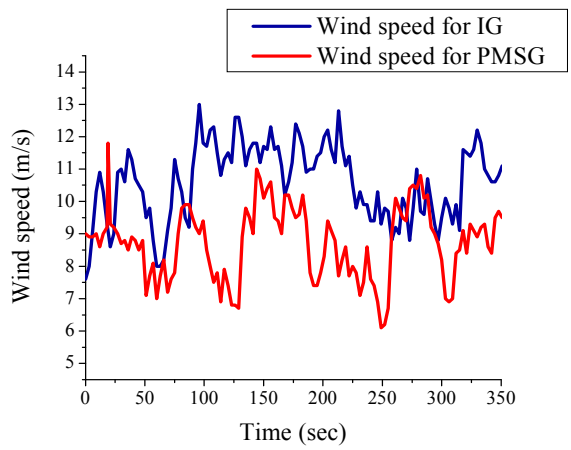

Fig. 3 Wind speed data.

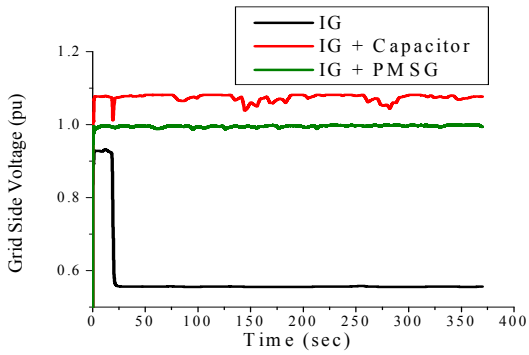

Fig. 4 Grid side voltage.

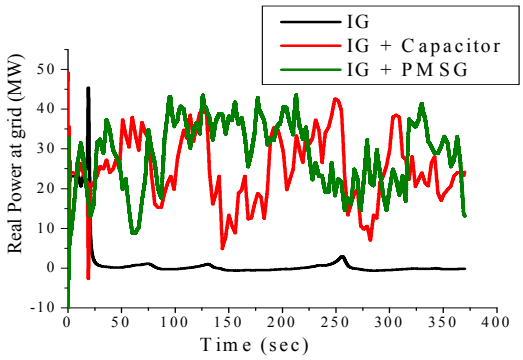

Fig. 5 Real power available at the grid.

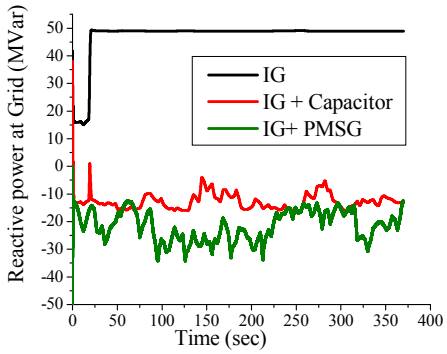

Fig. 6 Reactive power available at the grid.

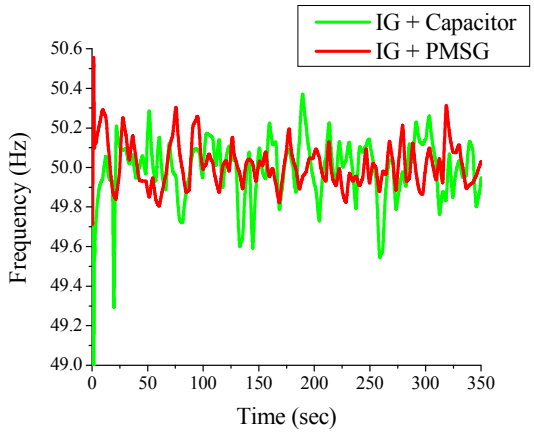

Fig.7 Frequency response.

B. *Transient Stability Analysis*

In this study, the dynamic wind speed data shown in Fig. 3 is used for transient stability analysis to make the response of the proposed system more practical. For this, a three line to ground (3LG) fault has been considered, which occurs at 27s, and the fault is cleared within 0.05s. Fig. 8 shows the grid side voltage response, where PMSG is able to recover the voltage to its normal state after the clearance of the fault just like the capacitors.

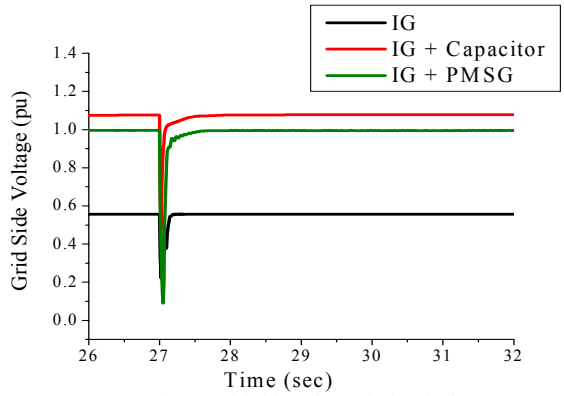

Fig. 8 Grid side voltage during fault.

Fig. 9 and Fig. 10 show the real and reactive power response at the grid respectively. As a results of the reactive power compensation during fault, in the third case (PMSG+IG), the real power attains the normal value after the fault as quickly as possible.

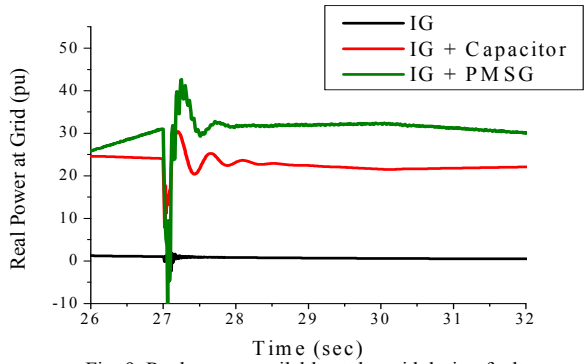

Fig. 9 Real power available at the grid during fault.

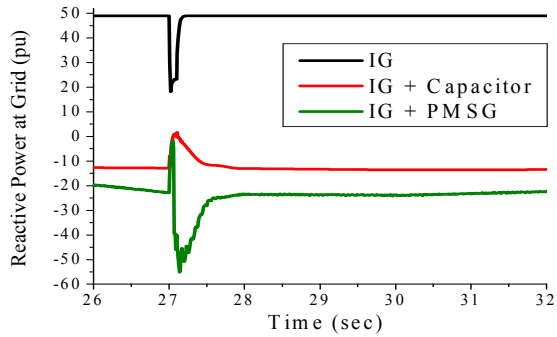

Fig. 10 Reactive power available at the grid during fault.

C. *Variable Load Conditions*

In case-4, variable load conditions have been considered. A 100 MW fixed load has been considered, where a 2MW load has been added at 50th second, a 3 MW load has been added at 60th second. At 70th second, 4 MW load has been reduced and at 80th second the 1 MW load has been removed. The variation of the power in the load side is shown in Fig. 11.

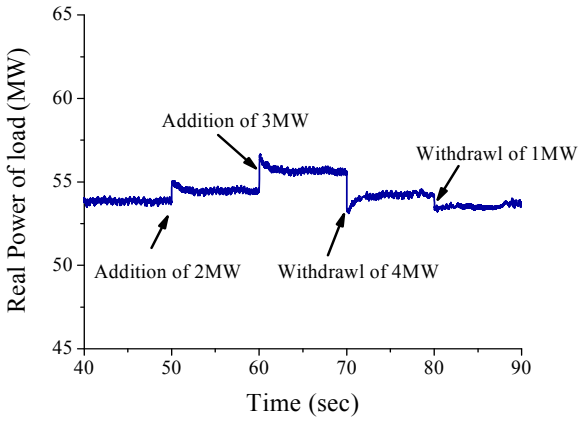

Fig. 11 Variation of real power with the variation of load.

The variation of the real power of SG and the frequency are shown in Fig. 12 and Fig. 13 respectively. As can be seen from these figures, there is an acceptable variation in frequency for the variation of load. This has been done by PMSG without any capacitor bank connected with IG. Moreover it doesn't need other controlling devices.

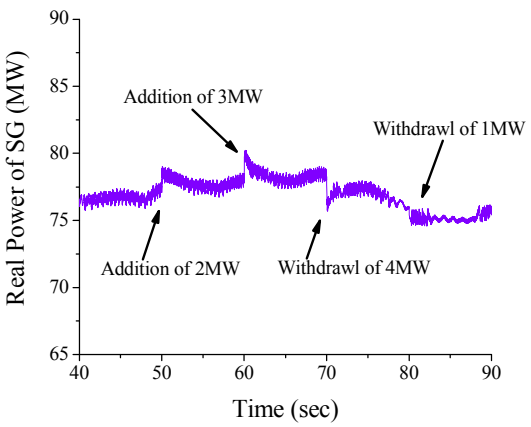

Fig. 12 Variation of SG's real power with the variation of load.

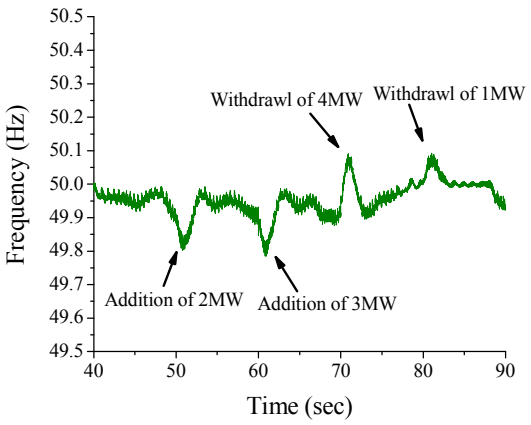

Fig. 13 Variation of frequency with the variation of load.

So, it is seen that PMSG can ensure the reliable operation of a fixed speed IG based wind farm. Therefore capacitor bank or other FACTS devices can be avoided. The simulation results show the effectiveness of the proposed wind farm during dynamic, transient and variable load conditions.

V. Conclusions

The proposed model of the wind farm consisting of both IG and PMSG has the ability to reduce the output fluctuations of a conventional fixed speed wind farm. To attain this, capacitor banks and other external controlling devices can be ignored. Simulation results prove that the PMSG itself can work as a generator as well as a controlling device and also it eliminates the need of the capacitor bank. Thus a large scale wind farm can be established by using the proposed technique. This method is equally effective for both new wind farms and for existing wind farms where expansion of installed capacity is required. Therefore, it is concluded that, the proposed system is a good tool for power system stability improvement of fixed speed wind generators by contributing to the electrical output and eliminating the costs of external controlling devices and capacitor banks.

Abstract—**Frequency response is a key concern for power system security. Usually, it is estimated in a deterministic approach. But in most cases, power systems behave stochastically. Moreover, presence of wind power imposes further variability on generation profile of a power system. Hence, it appears more pragmatic to address these uncertainties during an evaluation of frequency response. This paper develops an index to assess frequency response of a power system with high wind power penetration. A probabilistic method is used for this purpose. K-means algorithm, a well-known data mining technique is employed. The developed index is called a 'probabilistic frequency response index'. A realistic interconnected power system is investigated for a case study. Impact of increased wind power penetration on probabilistic frequency response index is analysed.**

Index Terms—**Frequency response, Headroom, Inertia, K-means algorithm, Wind power.**

I. Introduction

Secure operation of an electric power system relies on appropriate balance between generation and load. One of the major objectives of a power system operator is to maintain system frequency within an acceptable range. However, maintaining system frequency within a desired limit is a challenge due to continuous variation of consumers' demand. Moreover, occasional events such as sudden loss of a large generating unit or load can cause an abrupt deviation in system frequency. Frequency response is a measure of the ability of a power system to arrest and then stabilize rapid change in frequency [1]. Frequency sensitivity index (β, in MW/0.1 Hz) is used as one of the measuring parameters of frequency response [1]. It is estimated by relating a mismatch between load and generation to a corresponding sudden change in system frequency.

Integration of renewable energy sources such as wind power is increasing rapidly in many countries. Addition of wind power replaces conventional synchronous generators. Unlike synchronous generators, modern wind turbine generators do not provide automatic frequency support when there is an imbalance between load and generation. Therefore, inclusion of a substantial amount of wind power plants complicates the frequency response issue of a power system.

A significant number of researches on power system frequency response have been reported in the current literature [2]-[8]. Computer models are developed in [2] to estimate an impact of Western Electricity Coordinating Council (WECC) utility's inertia on the system frequency response. Frequency transients are observed and recorded for this purpose. When there is a generator outage in a hydro based system, frequency response may exacerbate due to temporary decrease of power output by hydro generators. Hydro-fossil coordination can improve the situation [3]. A study from the utilisation of phasor measurement units is presented in [4] to estimate inertial frequency response of the Great Britain (GB) transmission network. Reduction of inertial response due to inclusion of renewable energy is observed. This method utilizes historical data of large generator losses.

Non-synchronous penetration level in the Ireland grid can be increased up to 50% in current network structure [5]. It is suggested that synthetic wind inertia and adjustment in protective relay settings can facilitate 75% non-synchronous generation. A study on frequency response of California and WECC due to high wind and solar penetration is presented in [6]. Here, influences of various generation mix and system headroom on frequency response are addressed. Electric vehicle (EV) loads are growing in GB power system. Different EV charging strategies such as "dumb charging" and "off-peak charging" may be useful to provide primary frequency response [7]. Inertial response of a variable speed wind turbine depends on local wind speed. Consequently, there exists an uncertainty in inertial response capability of a highly wind penetrated power system [8]. However in [8], there is no guideline about stochastic measurement of frequency response. Statistical analysis of an island power system in [9] demonstrates a reduction of overall system stiffness due to excessive wind power. Again, there is no clear advice on statistical determination of frequency response characteristics.

It seems that in most researches, frequency response is estimated at a particular load level. Historical data of generator trips are sometimes employed. Thus, frequency response characteristics reported in literature are deterministic in nature. However, in reality, generation and load pattern of a power system exhibit probabilistic behaviour. No such frequency response index, which reflects the probabilistic nature of a power system, is presented in literature yet.

This paper proposes a methodology to develop a probabilistic index for estimating frequency response of a power system. K-means data clustering algorithm is used for this purpose. The proposed methodology is applied on an interconnected power system. This paper then investigates an effect of high wind power on probabilistic frequency response index of the studied power system.

II. K-means Algorithm

In this paper, K-means algorithm [10] is used to form clustered load scenarios. Assume that historical load data of a power system are to be divided into *NL* load levels. That is,

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

NL represents the total number of clusters. Steps of K-means algorithm are shown below.

Step-1: Initial cluster means (M_i) are selected, where i denotes the i-th cluster and i = 1, 2, … …, *NL*.

Step-2: The distance (D_{ki}) from each load point (L_k) to each cluster mean (M_i) is calculated by

$$D_{ki} = \left| M_i - L_k \right| \tag{1}$$

where k = 1 to total number of load points in historical load data (*NT*).

Step-3: Load points are grouped by assigning them to the nearest cluster.

Step-4: A new mean of i-th cluster is recalculated using

$$M_i = \frac{\sum_{k \in IC} L_k}{NI_i} \tag{2}$$

where NI_i refers to the total number of load points in i-th cluster and *IC* denotes a set of the load points in i-th cluster.

Step-5: Steps 2 to 4 are repeated until all cluster means remain unchanged between successive iterations. At the end of iterations, each cluster is represented by its centre value. This centre is effectively the mean value of all load points inside a cluster.

Step-6: Probability of occurrence of i-th cluster (P_i) is computed by

$$P_i = \frac{NI_i}{NT} \tag{3}$$

K-means algorithm is a local optimal sorting approach. Therefore, it may lead to multi-solutions. To avoid it, number of clusters and initial cluster means should be specified properly.

III. Methodology

This section presents a methodology to develop a probabilistic frequency response index of a power system. Steps of the proposed methodology are described below.

Step-1: Historical load data of a power system are clustered in 24 hourly load scenarios using the K-means algorithm.

Step-2: For a clustered load scenario, different synchronous generators are tripped, one at a time, to create a disturbance. Dynamic simulation is performed in PSS®E simulation environment [11]. PSS®E software is widely used by transmission system planners and electricity market operators. In PSS®E dynamic study, 100% constant current load model is used for active power and 100% constant impedance load model is used for reactive power. For a generator, dynamic models of governor, exciter and stabilizer are used. A Python [12] script is written to automate the dynamic simulation process.

For a tripping of any synchronous generator, rotational speeds of other generators are recorded. Then the equivalent system frequency (f_{eq}) is calculated using (4) [6]

$$f_{eq} = \frac{\sum_{k=1}^{k=n} (S_k \times \omega_k)}{\sum_{k=1}^{k=n} S_k} \tag{4}$$

where S_k is the MVA rating of k-th generator, ω_k is the speed of k-th generator (in p.u.) and n is the total number of synchronous generators.

Step-3: Dynamic simulation after a disturbance is performed for a time frame t_0 to t_f. Here, t_0 refers to the moment when a disturbance is initiated and t_f denotes the final simulation time. Equivalent frequencies at different time samples (within t_0 to t_f) are computed using (4). The minimum equivalent frequency is then calculated, which represents the frequency nadir after a generator trip.

Step-4: System frequency nadirs (in Hz) for different synchronous generator trips in a specific clustered load scenario are recorded. Frequency nadir (*FN*) is modelled as a function of power outage due to a synchronous generator trip (P_o, in MW) using linear regression method. It can be expressed by (5) [13]

$$FN = (S_p \times P_o) + f_c \tag{5}$$

where S_p is the slope (in Hz/MW) and f_c is the constant part of linear regression model (in Hz).

The frequency sensitivity index (β, in MW/0.1 Hz) is calculated using (6) [13].

$$\beta = \frac{1}{\left| S_p \right|} \times 0.1 \tag{6}$$

Step-5: Frequency sensitivity indices for all 24 clustered load scenarios are evaluated using steps 2 to 4. Finally, a probabilistic frequency response index of a power system (β_{sys}) is estimated by

$$\beta_{sys} = \sum_{i=1}^{i=NL} (\beta_i \times P_i) \tag{7}$$

where β_i is the frequency sensitivity index of i-th clustered load scenario, P_i is the probability of occurrence of i-th cluster and *NL* = 24.

IV. Overview of the Studied Power System

A practical power system is studied in this paper. Installed capacity of the studied system is around 3,000 MW. In transmission level, 220 kV and 110 kV are used. The system has 250 buses, 65 synchronous generators and 4,000 circuit kilometres of transmission lines. The system is connected to its adjacent power network through a high voltage back to back DC interconnection. The maximum limit for both power export and import through this interconnection is 500 MW.

There are two large-scale wind farms in operation in the studied system. Capacity of the 1st wind farm is 140 MW and that of the 2nd is 170 MW. Another wind farm of capacity 300 MW is under construction and it is expected to be connected to the grid by the next few years. Total installed capacity of wind power will then be 610 MW. In this study, all wind farms are modelled as Type-3 (Doubly-fed induction generator) wind turbine generators. None of the wind farms has synthetic inertia and active power control (APC) features.

Wind power penetration level (*WPL*) of the studied system is estimated using (8) [13]

$$WPL = \frac{P_{wind}}{P_{sync} + P_{wind} + P_{import}} \tag{8}$$

where P_{wind} specifies the wind power in the studied system, P_{sync} is the power generation from synchronous generators and P_{import} denotes the power import to the studied system from the adjacent network through interconnection. In this paper, power export to the adjacent network from the studied system through interconnection (P_{export}) is modelled as a load supplied by the generators of the studied system. So, it is not shown as a separate quantity in (8).

V. Results and Discussion

Case studies are carried out for three different seasons, summer, winter and spring. The maximum, minimum and average load of the studied power system fluctuate from each other in various seasons. Historical hourly load data for last 8 years (2006-2013) are investigated. Table I shows a seasonal load profile of the system. It is observed that the system is of winter peak in nature.

TABLE I
SEASONAL LOAD PROFILE

Season	Maximum load (MW)	Minimum load (MW)	Average load (MW)
Summer	1460	690	1070
Winter	1760	820	1260
Spring	1640	685	1130

In this paper, a probabilistic frequency response index (β_{sys}) is separately estimated for three seasons. In each season, 24 hourly clustered load scenarios are formed. Estimation of β_{sys} and impact of high wind power generation on β_{sys} in different seasons are presented in the following subsections. Significant observations are also discussed.

A. Probabilistic Frequency Response Index

(i) Summer: 24 hourly clustered load scenarios are constructed using (1) and (2). Table II shows the clustered load, corresponding synchronous generation, wind power and interconnection power flow for summer.

Probability of occurrence of each cluster is calculated using (3). For each load level, dynamic simulation of the system is performed for different generator trips. Frequency sensitivity indices are computed using (4)-(6). Table III shows dynamic simulation results and probability of occurrence of different clusters during summer.

TABLE II
CLUSTERED LOAD PROFILE OF SUMMER

Cluster No.	Load (MW)	P_{sync} (MW)	P_{wind} (MW)	P_{import} (MW)	P_{export} (MW)
1	967	423	131	413	0
2	911	456	32	423	0
3	914	479	5	430	0
4	1035	510	78	447	0
5	1050	528	53	469	0

17	1169	1125	120	0	76
18	1235	1238	125	0	128
19	1141	1334	60	0	253
20	1158	1200	92	0	134
21	1132	1368	36	0	272
22	1093	1434	78	0	419
23	1102	911	124	67	0
24	1056	847	121	88	0

TABLE III
FREQUENCY SENSITIVITY INDICES AND CLUSTER PROBABILITIES

Cluster No.	β (MW/0.1 Hz)	Probability	Cluster No.	β (MW/0.1 Hz)	Probability
1	5.9948	0.0105	13	11.7980	0.0249
2	5.7097	0.0229	14	15.9160	0.0082
3	6.5236	0.0345	15	14.8500	0.0431
4	8.6207	0.0504	16	15.6495	0.0580
5	6.9784	0.0532	17	10.1225	0.0586
6	8.5172	0.0579	18	10.8284	0.0557
7	10.5241	0.0538	19	12.7178	0.0591
8	8.0978	0.0327	20	10.2923	0.0557
9	16.9434	0.0163	21	13.5722	0.0565
10	9.6787	0.0028	22	13.1475	0.0562
11	16.0359	0.0404	23	10.5031	0.0529
12	11.8821	0.0468	24	10.6338	0.0489

Now using (7), probabilistic frequency response index during summer ($\beta_{sys,sm}$) is found to be 11.15 MW/0.1 Hz. That is, on an average 11.15 MW imbalance between generation and load causes 0.1 Hz frequency deviation during summer.

(ii) Winter and spring: Following the similar procedure of summer, probabilistic frequency response index during winter and spring ($\beta_{sys,wt}$ and $\beta_{sys,sp}$ respectively) are computed. Table IV presents the results.

TABLE IV
PROBABILISTIC FREQUENCY RESPONSE INDICES

Season	Notation	Value (MW/0.1 Hz)
Summer	$\beta_{sys,sm}$	11.15
Winter	$\beta_{sys,wt}$	10.50
Spring	$\beta_{sys,sp}$	17.55

It is observed from Table IV that β_{sys} is minimum during the winter season. That is, this power system becomes most vulnerable in terms of frequency response during winter. During spring, β_{sys} is the maximum. So, the ability of the system to arrest frequency excursion after a disturbance is highest during spring, lowest during winter and in-between during summer.

Variation of β_{sys} during different seasons can be explained using the concepts of system inertia and headroom [5], [6]. When there is an imbalance between generation and load due to a generator trip, a portion of the stored kinetic energy from committed synchronous generators' rotor are released immediately. This is known as inertial response of a power system and it dominates initial frequency decline after a disturbance. Total inertia (IR) of a power system can be computed by

$$IR = \sum_{j=1}^{j=n} (S_j \times H_j) \tag{9}$$

where S_j is the rated MVA of j-th synchronous generator, H_j denotes the inertia constant (in s) of j-th synchronous generator and n is the total number of committed synchronous generators.

Headroom (HR) is an amount of generation that can be provided by committed synchronous generators (for arresting frequency decline) after a disturbance using governor control function. Frequency nadir after a generator trip is determined by the combination of inertia and headroom of a system. Headroom can be calculated using

$$HR = \sum_{j=1}^{j=ng} (P_{max,j} - P_{gen,j}) \tag{10}$$

where $P_{max,j}$ refers to the rated capacity of j-th synchronous generator (in MW), $P_{gen,j}$ is the power generation of j-th synchronous generator (in MW) and ng denotes the total number of synchronous generators with governor control enabled.

For the studied power system, the average inertia (IR_{sys}) and headroom (HR_{sys}) are estimated using

$$IR_{sys} = \sum_{i=1}^{i=NL} (IR_i \times P_i) \tag{11}$$

$$HR_{sys} = \sum_{i=1}^{i=NL} (HR_i \times P_i) \tag{12}$$

where IR_i and HR_i are the inertia and headroom of i-th clustered load scenario respectively.

Table V presents average inertia and headroom of the studied system for different seasons. It is observed that IR_{sys} and HR_{sys} are the maximum during spring. As a consequence, $\beta_{sys,sp}$ is the highest amongst three seasons. IR_{sys} of summer is less than that of winter. But HR_{sys} of summer is more than that of winter. However, $\beta_{sys,sm}$ is higher than $\beta_{sys,wt}$.

TABLE V
AVERAGE INERTIA AND HEADROOM

Season	IR_{sys} (MWs)	HR_{sys} (MW)
Summer	7900	332
Winter	8030	57
Spring	9770	600

Thus, it can be revealed that headroom has dominating impact on the probabilistic frequency response index.

B. Impact of Wind Power on Probabilistic Frequency Response Index

Impact of significant wind power penetration on the β_{sys} of the studied power system is investigated in this paper. Steps of the investigation are presented below.

Step-1: During a specific season, for each cluster, wind power penetration is increased incrementally. Penetration is expanded up to 610 MW, in a step of 30 MW at a time. To facilitate additional wind power, a certain amount of synchronous generators are replaced by wind machines. For each wind penetration case, average wind power penetration level (WPL_{sys}) is evaluated by

$$WPL_{sys} = \sum_{i=1}^{i=NL} (WPL_i \times P_i) \tag{13}$$

where WPL_i refers to the wind power penetration level at i-th clustered load scenario.

Step-2: In each wind penetration case, frequency sensitivity index (β) is determined using (4)-(6).

Step-3: Probabilistic frequency response indices (β_{sys}) are computed using (7) for different WPL_{sys}.

Step-4: β_{sys} is modelled as a function of WPL_{sys}. Model parameters are estimated using regression technique.

Fig.1 depicts a regression model between β_{sys} and WPL_{sys} during summer. Using extensive dynamic simulations, a mathematical relationship between β_{sys} and WPL_{sys} are estimated for each season. Relationships are given by (14), (15) and (16) for summer, winter and spring respectively.

$$\beta_{sys,sm} = -0.16(WPL_{sys,sm}) + 12.96 \tag{14}$$

$$\beta_{sys,wt} = -0.15(WPL_{sys,wt}) + 10.95 \tag{15}$$

$$\beta_{sys,sp} = -0.35(WPL_{sys,sp}) + 20.94 \tag{16}$$

Here, $WPL_{sys,sm}$, $WPL_{sys,wt}$ and $WPL_{sys,sp}$ denote average wind penetration level during summer, winter and spring respectively. It is observed that β_{sys} decreases with an increases of WPL_{sys} during different seasons. So, frequency response of the studied power system declines gradually due to high wind power penetration.

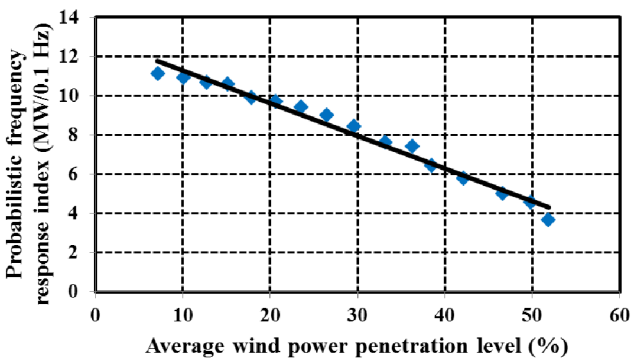

Fig. 1 Regression model between probabilistic frequency response index and average wind power penetration level during summer.

VI. CONCLUSIONS

This paper develops a probabilistic frequency response index (β_{sys}) for a power system using K-means clustering algorithm. Power export and import through interconnection at different clustered load scenarios affect the number of committed synchronous generators. As a consequence, system inertia and headroom are influenced. Frequency response index is thus found to be affected by both inertia and headroom.

It is observed that the studied power system shows more susceptible frequency response with increased wind power penetration. An estimated relationship between β_{sys} and average wind penetration level (WPL_{sys}) shall help a power system operator to assess the frequency behaviour in case of high wind power generation. In continuation to this study, further works will be done to find the implications of both wind and PV generation on probabilistic frequency response index, which can be useful for any power system.

Abstract— **Wind energy has an immense potential to play a vital role with conventional energy sources. Therefore, integration of wind power is increasing in many power systems. Unlike synchronous generators, modern wind farms have lack of automatic frequency support capability following a disturbance. Thus, an addition of wind power does impact the frequency response of a power system. Inadequate frequency response may occur due to presence of a large wind generation. This paper proposes a methodology for estimating the maximum wind power penetration level to ensure an adequate frequency response in a power system. Frequency nadir and rate of change of frequency after an outage of the largest generator of a power system are taken into consideration. Impact of two different wind power integration strategies (direct replacement of a synchronous generator with a wind machine and 2/3 de-commitment, 1/3 re-dispatch approach) on the maximum wind power penetration level are investigated. This paper also attempts to identify a system parameter that could most significantly influence a penetration of wind power.**

Index Terms—**Frequency response, Frequency sensitivity index, Headroom, Inertia, Wind power.**

I. Introduction

Conventional energy sources such as coal, oil and natural gas are fossil fuels and have limited availability. Moreover, they emit carbon dioxide (CO_2) and cause environmental pollution. On the contrary, renewable energy sources like wind and solar are amply available and they are pollution free. Among them, wind power has enormous possibility to become one of the major energy sources in many countries around the world. Global installed capacity of wind power at the end of 2013 is around 318 GW. It has increased by 35 GW than that of 2012 [1]. However, wind power penetration in a conventional system cannot be increased arbitrarily due to some technical issues. One major issue is the lack of sufficient generation reserve margin in a highly wind penetrated system. The other issue is associated with power system frequency response. Committed synchronous generators provide inertial and governor response after a generator in a system trips. In contrast, wind farms do not automatically provide these functions. Therefore, the maximum wind power, which can be integrated in a conventional system, is a major concern.

A number of investigations have been performed to identify the maximum allowable penetration level of wind power in a conventional system [2]-[9]. The Maximum wind penetration level is determined based on transient stability limit and frequency security constraints in [2]. Voltage stability margin and system capacity are employed for maximizing the wind penetration level in [3]-[5]. In [6], Particle Swarm Optimization (PSO) technique is used to develop an algorithm for attaining the maximum wind energy penetration level. A method incorporating modal analysis and Q-V curves for determining the maximum size of wind farms is presented in [7]. To identify the maximum wind penetration level, an integrated numerical algorithm using available information of the corresponding electricity generation system is proposed in [8]. A fast computational algorithm based on frequency response to calculate the maximum wind penetration level is presented in [9].

It is evident from the current literature that addition of wind power in a conventional system influences both frequency nadir (the minimum frequency following a disturbance) and rate of change of frequency (*ROCOF*) of a power system. However, none of the researches has considered these two criteria simultaneously in estimating the maximum wind power penetration.

Up to now, two different wind integration strategies have been reported in literature. In the first strategy, a certain quantity of synchronous generation is replaced with an equal amount of wind generation [2]. In the second strategy, wind power is added using 2/3 de-commitment, 1/3 re-dispatch approach (2/3-1/3 rule) [10]. This means that for every 3 MW of additional wind production, there is a 2 MW de-commitment of synchronous generation and a 1 MW reduction in dispatch of synchronous generation. In both strategies, system demand is assumed to be unchanged. Impact of these two approaches on the maximum wind power penetration is yet not found to be reported in literature.

This paper develops a methodology to estimate the maximum allowable wind power penetration level in a power system to maintain an acceptable frequency response. Both frequency nadir and *ROCOF* are taken into account to assess the frequency response after a disturbance. The proposed methodology is applied for a realistic power system. Six typical load scenarios based on different seasons are studied. Effect of different wind integration strategies on the maximum wind power penetration is investigated in this paper. A system parameter that could highly influence the maximum wind power penetration is also determined.

II. Key Terminologies

The important terminologies used in this paper are described below.

(i) Wind power penetration level (*WPL*): It is a ratio of total wind power generation to total load and losses. Alternatively, it can be computed using (1) [11].

$$WPL = \frac{P_{wind}}{P_{sync} + P_{wind} + P_{import}} \tag{1}$$

where P_{wind} is the total wind power in a system, P_{sync} is the total power generation from synchronous generators and

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

P_{import} denotes the power import through an interconnection. In this paper, power export through an interconnection is modelled as a load supplied by the synchronous generators of an exporting power system. Hence, it is not shown as a separate quantity in (1).

(ii) Maximum wind power penetration level (WPL_{max}): It is the highest limit of wind power that can be added in a power system maintaining system frequency or rate of change of frequency (after a disturbance) within an acceptable margin.

(iii) Frequency sensitivity index (β): It describes the responsiveness of system frequency when there is an imbalance between generation and load. It is measured in MW/0.1 Hz.

(iv) System inertia (IR): It is a measure of total stored kinetic energy in a power system. It can be computed by

$$IR = \sum_{i=1}^{i=n} (S_i \times H_i) \tag{2}$$

where S_i is the rated MVA of i-th synchronous generator, H_i denotes the inertia constant (in s) of i-th synchronous generator and n is the total number of committed synchronous generators.

(v) Headroom: It is an amount of generation that can be provided by committed synchronous generators for arresting frequency decline after a disturbance. Governor control function is used for this purpose. Headroom can be calculated using

$$HR = \sum_{i=1}^{i=ng} (P_{max,i} - P_{gen,i}) \tag{3}$$

where $P_{max,i}$ refers to the rated capacity of i-th synchronous generator (in MW), $P_{gen,i}$ is the power generation of i-th synchronous generator (in MW) and ng denotes the total number of synchronous generators with governor control enabled.

(vi) Proportion of governor responsive generation: It is a ratio between governor responsive power generation capacity and total power generation capacity of a power system [12]. It is denoted by K_t and computed using

$$K_t = (\sum_{i=1}^{i=ng} P_{max,i}) / (\sum_{i=1}^{i=n} P_{max,i}) \tag{4}$$

III. Methodology

This section presents the proposed methodology and essential computation techniques regarding this paper.

A. Estimation of the Maximum Wind Power Penetration Level

To estimate the maximum wind power penetration level, dynamic simulation of a power network is performed in PSS®E simulation environment [13]. PSS®E software is widely used in transmission system planning to provide stochastic and dynamic modelling features. In PSS®E dynamic case, 100% constant current load is used for active power and 100% constant impedance load is used for reactive power modelling. Steps of the proposed methodology are presented below.

Step-1: For a power system, the largest synchronous generator is tripped to create a disturbance. The equivalent system frequency (f) is then calculated using (5) [12]

$$f = [\sum_{i=1}^{i=n} (S_i \times \omega_i)] / [\sum_{i=1}^{i=n} S_i] \tag{5}$$

where S_i is the MVA rating of i-th synchronous generator, ω_i is the speed of i-th generator (in p.u.) and n is the total number of synchronous generators.

Step-2: Dynamic simulation is run for a duration of time (t) given by

$$t = t_{initial} : t_{final} \tag{6}$$

where $t_{initial}$ refers to the simulation starting time and t_{final} denotes the simulation ending time.

Frequency nadir due to a trip of the largest generator (f_{min}) is then computed using

$$f_{min} = min[f]_{t=t_{initial}}^{t=t_{final}} \tag{7}$$

Step-3: Rate of change of frequency after a trip of the largest unit is computed using (8) [14]

$$ROCOF = \frac{1}{2} \times \frac{\Delta P}{IR} f_0 \tag{8}$$

where ΔP refers to the power mismatch between generation and load (in MW), IR is the system inertia (in MWs) and f_0 denotes the nominal system frequency (in Hz).

Step-4: Wind power generation in a power network is increased incrementally. To facilitate additional wind power, first wind integration strategy (direct replacement of a synchronous generator with a wind machine) is followed. In each wind penetration level, f_{min} and $ROCOF$ are calculated using (5)-(8) after a trip of the largest synchronous generator.

Step-5: Wind penetration level (WPL) is increased until either f_{min} or $ROCOF$ reaches under frequency load shedding (UFLS) margin. That is, WPL is increased up to

$$f_{min} \le f_{LL} \text{ or } ROCOF \ge ROCOF_{max} \tag{9}$$

where f_{LL} is the lower limit of allowable system frequency band and $ROCOF_{max}$ is the upper limit of acceptable $ROCOF$ to avoid UFLS.

Step-6: A mathematical relationship between f_{min} and WPL or $ROCOF$ and WPL is modelled. It can be expressed as

$$f_{min} = g(WPL) \text{ if } f_{min} \text{ reaches its limit prior to } ROCOF \tag{10}$$

$$ROCOF = g(WPL) \text{ if } ROCOF \text{ reaches its limit prior to } f_{min} \tag{11}$$

where g (.) stands for a functional relationship. Unknown parameters of (10) and (11) are estimated using least square regression technique.

Step-7: Now, setting $f_{min} = f_{LL}$ in (10) or $ROCOF = ROCOF_{max}$ in (11), corresponding WPL is estimated. This WPL indicates the maximum wind power penetration level (WPL_{max}) in a power system.

Step-8: The above steps are repeated for the second wind power integration strategy (2/3-1/3 rule).

B. Computation of Frequency Sensitivity Index

Frequency sensitivity index (β) is determined by relating an imbalance between generation and load to the corresponding abrupt change in system frequency. To estimate β of a power system, following steps are executed.

Step-1: Different synchronous generators are tripped, one at a time, to create a single credible contingent event. After a contingency, dynamic simulation is performed in PSS®E software and frequency nadirs are recorded.

Step-2: Frequency nadir (FN) is modelled as a function of power outage due to a synchronous generator trip (P_o, in MW) using linear regression method. It can be expressed using (12) [11]

$$FN = (\alpha \times P_o) + f_c \tag{12}$$

where α is the slope (in Hz/MW) and f_c is the constant part of linear regression model.

Step-3: Finally, β (in MW/0.1 Hz) is computed by (13) [11].

$$\beta = \frac{1}{|\alpha|} \times 0.1 \tag{13}$$

IV. Case Study

A 250 bus practical power system is investigated in this paper. The studied power system is connected to its adjacent network through a DC interconnection, which facilitates both power import and export. The installed capacity of the system is around 3,000 MW including 310 MW of wind power installation. There are some wind farms under construction, which are expected to be connected to the grid by the next few years. Moreover, there are several suitable locations where further wind farms could be installed. Considering all prospective wind farms, it is observed that wind penetration level in the studied system might significantly increase.

Average demand of the system is around 1,500 MW. The maximum and minimum demand occurs during winter and summer season respectively. Six different load scenarios are studied in this paper. These scenarios are based on some typical load conditions depending on different seasons. The load scenarios are low and high loads of summer, winter and spring seasons.

V. Results and Discussion

This section presents the maximum wind power penetration level in the studied power system to provide a sufficient frequency response. Six different load scenarios are separately analyzed with two different wind power integration strategies. Simulation results and relevant discussion are presented below.

A. Maximum Wind Power Penetration Level

(i) First wind power integration strategy: To clarify the process of estimating WPL_{max}, summer high load scenario is considered as an example. Wind power penetration during summer high is increased incrementally using first strategy. In the studied system, power generation from the largest synchronous generator is 135 MW. For each *WPL*, 135 MW of synchronous generation is tripped. Corresponding f_{min} and *ROCOF* are computed using (5)-(8). As *WPL* increases, f_{min} starts to decrease and *ROCOF* starts to increase. It is observed that f_{min} reaches its UFLS margin prior to *ROCOF*. Hence, a mathematical relation between f_{min} and *WPL* is modelled. Fig.1 illustrates a regression model between f_{min} and *WPL* during summer high load scenario. Mathematical relationship between them is estimated by (14).

$$f_{min} = -0.036(WPL) + 49.43 \tag{14}$$

The lower limit of allowable frequency of the studied power system is assumed at 48 Hz. It is based on similar practices for small size power systems [15]. This lower limit of allowable frequency varies from system to system. Now setting $f_{min} = f_{LL} = 48$ Hz in (14), WPL_{max} during summer high load scenario is around 40%.

Similar procedures are followed for all other load scenarios. It is found that f_{min} reaches its limit prior to *ROCOF* for all load cases. Table I shows the maximum wind power penetration level at different load conditions.

(ii) Second wind power integration strategy: The maximum wind power penetration level is also estimated for six typical load scenarios using the second strategy. Like first integration strategy, f_{min} reaches its margin before *ROCOF* for all load cases. Table II shows the results and a comparison between the two strategies.

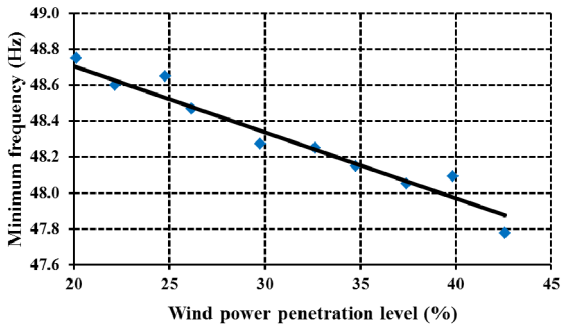

Fig. 1 Regression model between minimum frequency and wind power penetration level during summer high load scenario.

TABLE I
MAXIMUM WIND POWER PENETRATION LEVEL USING FIRST STRATEGY

Load scenario	Mathematical model between f_{min} and *WPL*	WPL_{max} (%)
Summer high	$f_{min} = -0.036(WPL) + 49.43$	40
Summer low	$f_{min} = -0.042(WPL) + 48.95$	23
Winter high	$f_{min} = -0.035(WPL) + 49.14$	33
Winter low	$f_{min} = -0.030(WPL) + 48.89$	30
Spring high	$f_{min} = -0.034(WPL) + 49.54$	45
Spring low	$f_{min} = -0.032(WPL) + 48.88$	28

TABLE II
MAXIMUM WIND POWER PENETRATION LEVEL USING SECOND STRATEGY AND COMPARISON TO THE FIRST STRATEGY

Load scenario	WPL_{max} (%)	
	Second strategy	First strategy
Summer high (SH)	43	40
Summer low (SL)	27	23
Winter high (WH)	36	33
Winter low (WL)	34	30
Spring high (SPH)	49	45
Spring low (SPL)	31	28

It is observed from Table II that, use of second wind integration strategy facilitates more wind power to be penetrated. In second strategy, 2/3 de-commitment and 1/3 re-dispatch approach is followed. For 1/3 re-dispatch, total system headroom may increase sometimes [12]. It can improve frequency nadir than that obtained using the first strategy. As a result, WPL_{max} is increased in all load scenarios when second wind integration strategy is implemented.

B. Computation of Correlation Coefficient

To detect a system parameter that could have the major impact on maximum wind power penetration level, correlation analysis is performed. Frequency sensitivity index of the investigated power system is estimated using (12) and (13). System inertia, headroom and proportion of governor responsive generation are calculated employing (2), (3) and (4) respectively. Table III shows the values at different load conditions.

Correlation coefficient between β and WPL_{max} is denoted by R_1 and expressed using (15).

$$R_1 = \frac{E(\beta \times WPL_{max}) - E(\beta) \times E(WPL_{max})}{\sigma_{\beta} \times \sigma_{WPL_{max}}} \tag{15}$$

where $E(.)$ refers to the expected value or mean value and $\sigma_{(.)}$ is the standard deviation. Similarly, the other correlation coefficients are computed using (16)-(18).

$$R_2 = \frac{E(IR \times WPL_{max}) - E(IR) \times E(WPL_{max})}{\sigma_{IR} \times \sigma_{WPL_{max}}} \tag{16}$$

TABLE III
FREQUENCY SENSITIVITY INDEX, INERTIA, HEADROOM AND PROPORTION OF GOVERNOR RESPONSIVE GENERATION

Load scenario	β (MW/ 0.1 Hz)	IR (MWs)	HR (MW)	K_t (%)
Summer high	14.30	9210	390	93
Summer low	6.00	5075	535	92
Winter high	12.00	9190	53	92
Winter low	9.60	6450	128	89
Spring high	16.70	9820	630	90
Spring low	9.25	6990	404	89

$$R_3 = \frac{E(HR \times WPL_{max}) - E(HR) \times E(WPL_{max})}{\sigma_{HR} \times \sigma_{WPL_{max}}} \quad (17)$$

$$R_4 = \frac{E(K_t \times WPL_{max}) - E(K_t) \times E(WPL_{max})}{\sigma_{K_t} \times \sigma_{WPL_{max}}} \quad (18)$$

where R_2 denotes the correlation coefficient between IR and WPL_{max}, R_3 is the correlation coefficient between HR and WPL_{max} and R_4 refers to the correlation coefficient between K_t and WPL_{max}.

Using the values from Table I, II and III, R_1 to R_4 are calculated for two wind integration strategies. Table IV presents the correlation coefficients.

To identify the most associated parameter with maximum wind power penetration level, the maximum value of correlation coefficient is computed by

$$R_{max} = max(R_1, R_2, R_3, R_4) \quad (19)$$

Using the values from Table IV, R_{max} is 0.99 and 0.98 in first and second wind power integration strategy respectively. The values correspond to the correlation coefficient between β and WPL_{max}. So, the frequency sensitivity index is mostly correlated to the maximum wind power penetration level. Fig.2 depicts WPL_{max} vs. β plot for both wind integration strategies. It is observed that for both cases, WPL_{max} exhibits a trend similar to that of β.

System inertia, headroom and proportion of governor responsive generation jointly contribute to the frequency sensitivity index. It is a composite term, which reflects the overall system characteristics. So, it seems rational to assume that frequency sensitivity index has the highest impact on maximum wind power penetration level.

TABLE IV
CORRELATION COEFFICIENTS

Correlation coefficient	First strategy	Second strategy
R_1	0.99	0.98
R_2	0.90	0.88
R_3	0.24	0.26
R_4	0.12	0.10

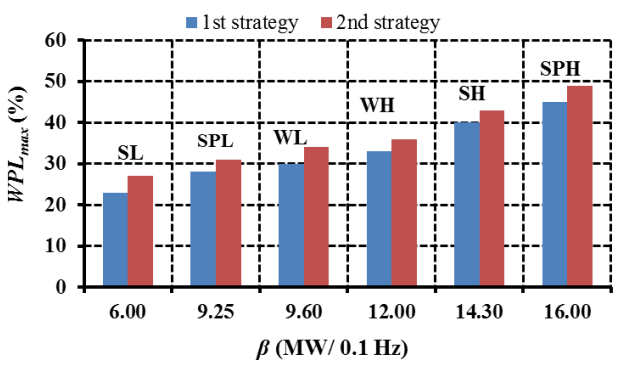

Fig. 2 Maximum wind power penetration level vs. frequency sensitivity index.

VI. CONCLUSIONS

This paper presents a methodology to estimate the maximum wind power penetration level to preserve a satisfactory frequency response in a given power system. If wind power penetration exceeds its maximum level, under frequency load shedding is likely to occur after a trip of the largest generating unit. As a consequence, service reliability of a power system might be affected. In this paper, a power system is studied in six different load scenarios with two wind power integration strategies. It is observed that amongst six load conditions, maximum wind power penetration level becomes the highest during spring high load condition. It is the lowest during summer low load scenario.

It reveals from this study that the key factors affecting the maximum wind power penetration can be system inertia, headroom, proportion of governor responsive generation and frequency sensitivity index. Amongst them, frequency sensitivity index may have the highest impact. Further works will be done to find a mathematical model, which will relate frequency sensitivity index with the maximum wind power penetration level.

Abstract—**Due to the recent expansion of renewable energy applications, wind energy conversion is receiving much interest all over the world. This is in no small part due to the rapid advances in the size of wind generators as well as the development of power electronics and their applicability in wind energy extraction, however, it has a great effect on the stability on power system. As wind turbine output is proportional to the cube of wind speed, the wind turbine generator output fluctuates due to wind speed variation. Thus this paper presents a new method to control the voltage stability by using reactive power compensation. It is observed that wind farm output voltage as well as grid voltage fluctuations can be controlled easily by applying this simple technique. Besides this, output voltage fluctuations can be smoothed by effectively controlling the reference voltage of the exciter of synchronous generator (SG). IEEE AC1A exciter is used in this study. Real wind speed data have been considered to obtained realistic responses. PSCAD/EMTDC software is used for simulation analyses.**

Index Terms—**Wind turbine; reactive power compensation; wind farm voltage; grid voltage; SG's exciter control.**

I. Introduction

Wind energy is the fastest growing and most widely utilized of the emerging renewable technologies in electrical systems [1]. The global energy challenge is to satisfy the growing demand to secure the energy sources and at the same time to face the threat equally urgent of climate change. In this regard renewable energies promise to be an important source for mankind. The rapid expenditure of fossil fuel has increased by leaps and bounds to improve our living standards. But it is a matter of great regret that, the world has limited amount of fossil fuel and nuclear power resources ([2], [3]).

One of the simplest methods of operating a wind turbine generation system (WTGS) is to use an induction generator (IG) connected directly to the power grid, because an induction generator is the most cost effective and robust machine for wind energy conversion. However, during start up, the induction generators need reactive power. As the reactive power drained by the induction generators is coupled to the active power generated by them, the variation of wind speed causes the variations of IGs real and reactive powers. These active and reactive power variations interact with the network and thus initiate voltage and power fluctuations.

Thus, reactive power compensation is a major issue; especially for fixed-speed WTGS for both steady state and transient conditions ([4] [5]). Usually, a fixed value capacitor bank is placed at wind farm terminal to provide the necessary reactive power demand at steady state. But it cannot maintain the wind generator terminal voltage constant under the randomly fluctuating wind speed. Moreover, IG needs a large reactive power during short circuit faults. In bulk power transmission systems, power electronics based controllers are frequently called Flexible AC Transmission Systems (FACTS). Presently, these devices are a viable alternative as they allow controlling voltages and currents of electric power systems. Voltage or current source inverter based FACTS devices such as static var compensator (SVC), static synchronous compensator (STATCOM), dynamic voltage restorer (DVR) etc. have been used for flexible power flow control, secure loading and damping of power system oscillation ([6], [7]). SVC is applied in [8] and [9] for reactive power compensation. Recently FACTS/ESS, i.e., FACTS with energy storage system (ESS), have emerged as more promising devices for power system applications [10]. But all the systems are very expensive. Some authors ([11], [12]) use new pitch control system to maintain output fluctuations, though this system can not control grid voltage with the fluctuating wind speed.

Therefore, this study investigate a new control system to maintain voltage fluctuation by correcting and controlling fixed capacitor bank as well as reference voltage of the exciter. Thus the system voltage performance improves effectively. Consequently, this study may be a good tool for power system application.

II. Model System For Simulation Analysis

The model system used in the simulation analysis is shown in Fig. 1. It consists of single wind generator (IG)

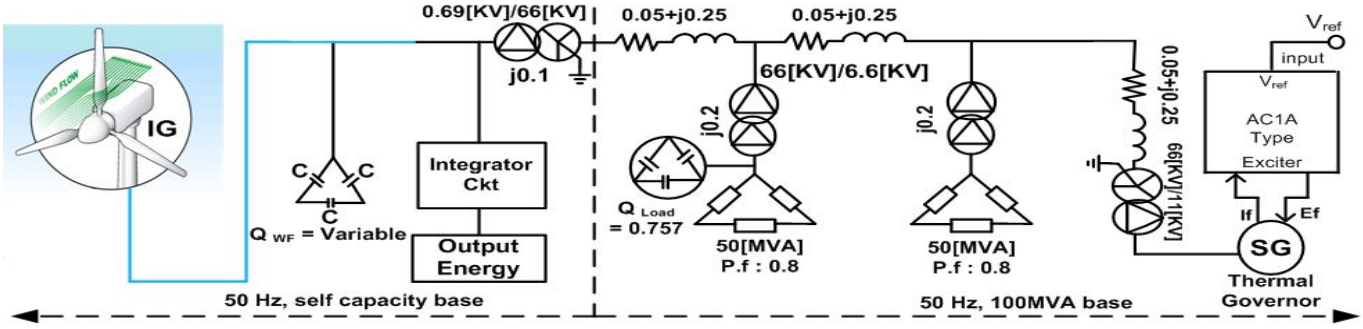

Fig. 1 Model circuit.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

and a thermal power generator (SG) with AC1A type exciter model. Here two loads have been considered and the total capacity of these loads is around 80MW. Core saturations of IG and SG are not considered for simplicity. The initial power flow and initial conditions are taken from [13]. In this model a capacitor bank has been considered and the values of the capacitor bank changes with respect to wind speed variations so that the p.f. becomes unity. The capacitor bank Q_{WF} performs the reactive power compensation in both steady state and dynamic wind variation. Similarly Q_{Load} is used at the terminal of load to compensate the voltage drop by the impedance of transmission lines.

III. Synchronous Generator Model

A. Governor [13]

The governor is such a device which automatically adjusts the rotational speed of the turbine and the generator output. The turbine is operated at a constant rotational speed, when the generator load remains constant. However, when the load changes, balance between the generator output and the load is not maintained and the rotational speed changes. When the load is removed, the governor detects the increase of the rotational speed and then the valve is closed rapidly so that an abnormal speed increase of the generators is prevented.

B. Governor for Thermal Generators [14, 15]

The governor model which is used in the simulation analysis is shown in Fig. 2 in which the values of 65M and 77M for thermal generator are shown in Table I. Where S_g is the revolution speed deviation [pu], 65M is the initial output, 77 M is the load limit (65M + rated MW output × PLM (%)), PLM is the spare governor operation (%) and Pm is the turbine output [pu].

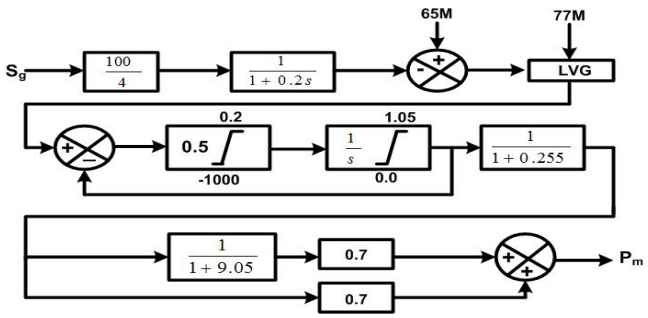

Fig. 2 Model of thermal governor.

TABLE I
Values of 65M and 77M for thermal generator

	IG: 20[MVA]
65M[pu]	0.653
77M[pu]	0.767
PLM[%]	15

IV. Pitch Controller

Conventional pitch controller as shown in Fig. 3 is used in the simulation analysis. The purpose of using the pitch controller is to maintain the output power of the wind generator at rated level by controlling the blade pitch angle of turbine blade when the wind speed is over the rated speed. Generally, the blade pitch operation system is complicated, but this paper simulates the pitch operation system by using a first order time delay system with time constant Tw = 5 sec. In addition, the pitch angle can not be changed instantly due to the rotational inertia of blade and mechanical limitations. Therefore, the rate of change of pitch angle is limited to 10 degrees per second in the simulations.

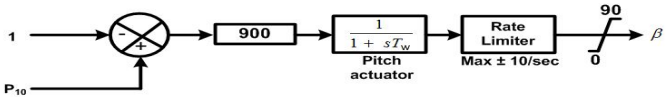

Fig. 3 Conventional pitch control system.

V. Proposed Capacitor Bank Correction System And SG's Exciter Control Technique

Generally, the value of capacitor bank for conventional model is kept constant. So when wind speed is larger than the rated value then output voltage becomes less than unity. On the other hand, when wind speed is less than rated value then output voltage fluctuates over the unity [16, 17]. This is the main problem for conventional model as it can not make the output voltage smooth. For this reason, a new technique has been proposed to control the output voltage fluctuations by making the capacitor value variable and the adjustment for different values of capacitor with respect to wind speed is shown in Table II. For the further smoothen of grid voltage, reference voltage of synchronous generator is also controlled to make the grid voltage approximately unity.

TABLE II
Capacitor Bank Correction

Wind Speed, V_w (m/s)	Capacitor Value, C (F) as shown in Fig. 1
Below 6	6600
7	7000
8	7600
9	9000
10	12000
11	16500
12	22200
13	24000
Above 13	26000

For this a decision circuit is used as shown in Fig. 4, where input voltage, Va is sensed by the control circuit and corresponding reference voltage (as shown in Fig. 1) is generated according to the Table III.

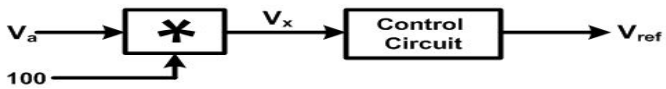

Fig. 4 Decision circuit.

TABLE III
Reference Voltage Correction

Input Voltage, V_x(Volt)	Reference Voltage, V_{ref} (Volt)
Below 99.4	1.08
99.5 to 99.7	1.07
99.8 to 99.9	1.06
100	1.05
100.1 to 100.2	1.04
Above 100.3	1.03

VI. Simulation Analyses

In this paper, simulation analyses have been carried out for three different cases as shown in Table IV. In order to investigate the performance of 3 cases with high wind power penetration real wind speed data have been considered which are measured in Hokkaido Island, Japan shown in Fig. 5. The simulation analyses have been performed by using PSCAD/EMTDC [18].

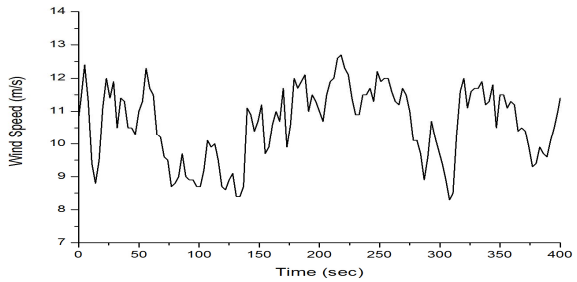

Fig. 5 Wind speed data.

TABLE IV
SIMULATION PATTERN

No. of Cases	Comparison Pattern
Case 1	Conventional model with capacitor bank control only
Case 2	Conventional model with reference voltage control only
Case 3	Conventional model with capacitor bank and reference voltage control

Simulation results for case 1 are shown from Fig. 6 to Fig. 9. Figure 6 shows the grid voltage, where the fluctuation is comparatively less when capacitor values are controlled with respect to wind speed variation instead of using fixed value of capacitor. From Fig. 7 and Fig. 8 it is seen that less reactive power compensation for both IG and SG is required than conventional model when capacitor bank is controlled. Figure 9 represents that the different values of capacitor changes proportionally with wind speed variation.

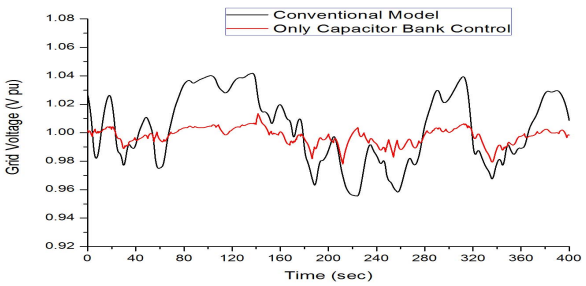

Fig. 6 Response of grid voltage [case 1].

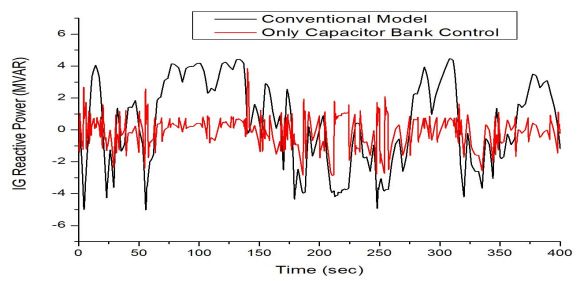

Fig. 7 Response of reactive power [case 1].

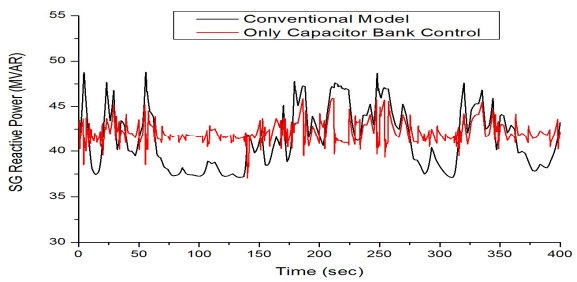

Fig. 8 Response of SG reactive power [case 1].

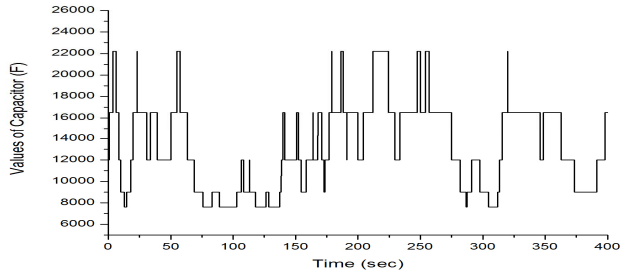

Fig. 9 Response of capacitor bank [case 1].

For case 2, only reference voltage is controlled with respect to grid voltage and fluctuation of grid voltage is comparatively less when reference voltage is controlled as shown in Fig. 10. For this case also less reactive power compensation is needed as shown in Fig. 11 and 12. The change of reference voltage with respect to grid voltage is shown in Fig. 13.

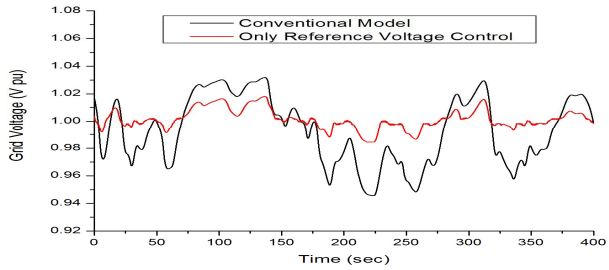

Fig. 10 Response of grid voltage [case 2].

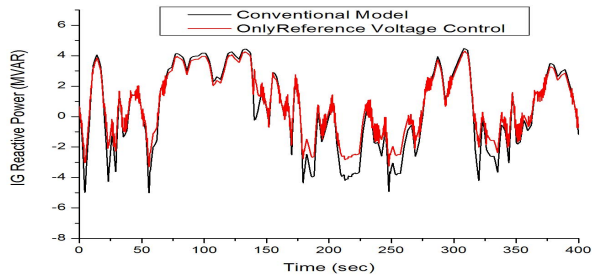

Fig. 11 Response of reactive power [case 2].

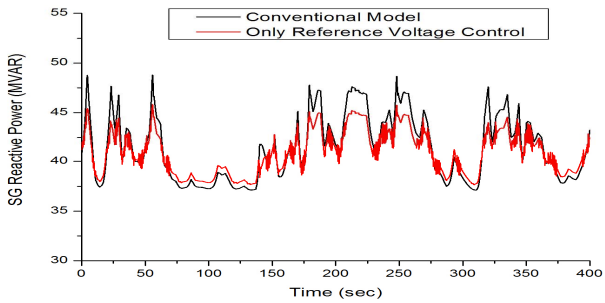

Fig. 12 Response of SG reactive power [case 2].

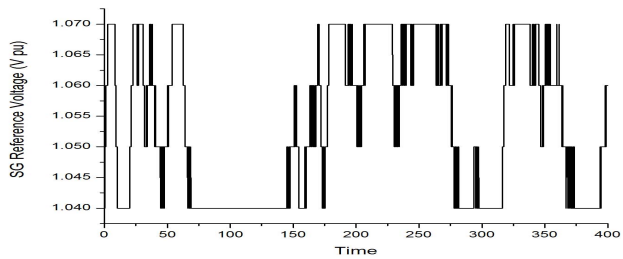

Fig. 13 Response of SG's reference voltage [case 2].

Both the values of capacitor bank along with reference voltage is controlled for case 3 and the grid voltage is almost near about unity which is shown in Fig. 14. Similarly, in this case less reactive power compensation is also required for IG and SG that is seen from Fig. 15 and 16 respectively.

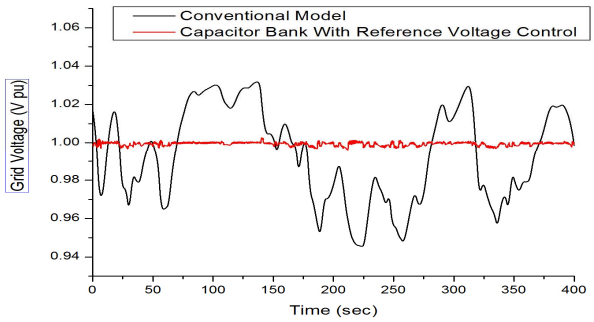

Fig. 14 Response of grid voltage [case 3].

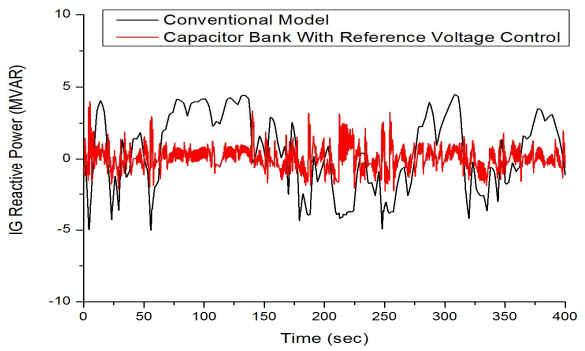

Fig. 15 Response of IG reactive power [case 3].

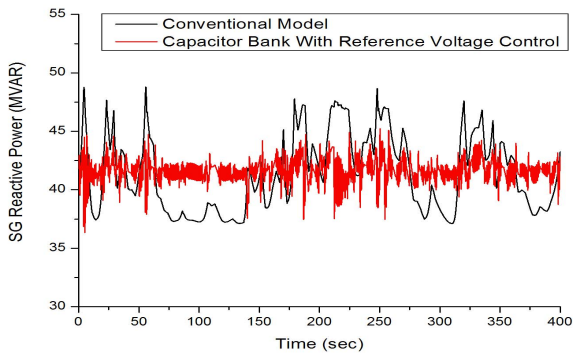

Fig. 16 Response of SG reactive power [case 3].

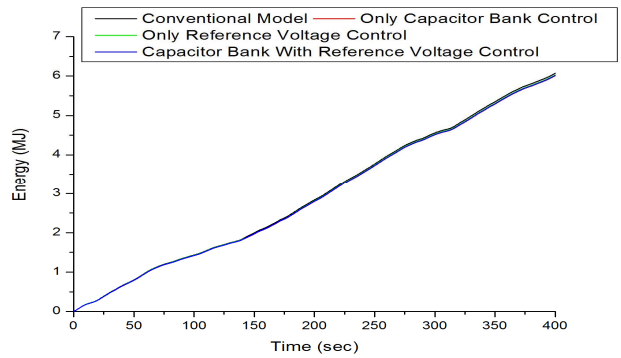

Fig. 17 Response of output energy [case 1, case 2, case 3].

An excellent result is observed from Fig. 17, which represents the comparison of output energy for 3 cases with conventional model and it is noticed that output energy is almost same to the conventional model. Hence there is no loss of energy.

VII. Conclusions

As grid voltage varies with the variation of wind speed, thus this study focuses on a new method to maintain the output voltage near about unity when wind speed remains in the acceptable level. It is confirmed from the above simulation results that by controlling capacitor bank and reference voltage along with conventional model, output grid voltage becomes smoother without any loss of energy, considering high wind penetration. Thus energy storage device can be neglected. As a result system may be more economic.

Abstract—**Wind energy, being an efficient and economically attractive Renewable Energy Source, attracts more and more investments as the electrical grids evolve into smarter grids. However, the stochastic nature of wind raises a lot of challenges for the system actors and planners. The different system actors (e.g. system operators, producers, consumers…), which are usually characterized by contradicting interests, use their own prediction models for taking into account the uncertainty of wind. The need for a framework that defines their interactions regarding prediction models is therefore mandatory, in order to allow a safe operation of the grid while ensuring a competitive framework for each of the stakeholders. In the present paper, a method for producing uncertainty forecasts is first presented. The uncertainty forecasts along with price scenarios for the day-ahead are used to investigate the potential conflicts of interests, with respect to the power forecast, between the major system actors (*i.e.* producers and the transmission/distribution system operator). The findings of this work indicate that the producer can maximize his income by inserting a bias in his prediction models which is in conflict with the System Operator's security constraints. In order to face this issue with a compromised solution, a competitive framework for the use of wind power predictions is suggested, according to which the interests of both actors will be satisfied.**

Index Terms—**Wind Power Forecasting, Scenarios, System Actors, Power Trading, Interactions Among System Actors.**

I. Introduction

Political decisions and the need for the use of more green energy sources, have led to the transformation of the classical distribution grids into smarter grids increasing integration of Renewable Energy Sources (RES), such as Wind Energy. However, the stochastic nature of wind, along with the lack of sufficient storage solutions, bring up the need for forecasting wind power in order to plan the future operation of the electric grid. Operational planning aims in taking preventive decisions to avoid, in day-ahead, critical situations such as over and under-voltages, congestions, etc. which are caused by the uncertain nature of the RES as well as the consumption patterns. The impact of the RES is further strengthened by the recent liberalization of the electricity market: when participating to the day-ahead market, wind power producers can only bid an expected value of power quantity, which will certainly deviate from the final delivered one. Therefore, a wind power forecast is needed in order to assist producers in estimating the quantity of power they are able to deliver.

Although wind power forecasting has been subject to an extensive research effort for the past years, there is no method that can provide a perfect forecast. The literature is very abundant on the topic, and concerns prediction horizons which range from very short-term [1]-[5] to day-ahead (DA) and long-term predictions [6]-[8]. Some of the most performant approaches regarding the prediction error make use of time series models [4], [7] and artificial neural networks [8]-[11].

As indicated before, a forecasting model can never provide a perfect forecast. Therefore, a wind power forecast is not that informative and helpful for operations regarding decision making. To cover this need an uncertainty forecast that provides information about the dispersion of observations around a forecasted value, should be achieved. However different system actors, are usually characterized by contradicting interests and use their own prediction models to cope with the uncertainty of wind. The need for a framework that defines their interactions regarding prediction models is mandatory, in order to allow a safe operation of the grid while ensuring a competitive framework for each of the stakeholders.

At subsection II.A of the current work we present a deterministic approach for wind power prediction based on AutoRegressive Moving Average models (ARMA) for the day-ahead. In order to use this point forecast for decision making, a method of constructing uncertainty forecasts consisting of wind speed scenarios is described at II.B. Wind speed scenarios are then transformed at II.C into wind power scenarios [12]. Finally, at section III, the wind power scenarios are employed along with the day-ahead price data to create realistic scenarios regarding the producer's participation to the energy market, the use of the wind power forecasts, and the conflicts of interests between the actors. The findings of this work indicate that the producer can maximize his income by inserting a bias in his prediction models which is in conflict with the System Operator's security constraints. A competitive framework is finally presented, which regulates the use of the forecast and proposes a compromised solution that aims to protect the interests of both actors.

II. Wind Power Forecasting For the Day-Ahead

For the purpose of this study, data from a wind site in the municipality of Wanze, Belgium were used. A wind speed prediction model is first proposed, followed by a transformation in the power domain.

A. Wind Speed Forecasting based on ARMA models

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

The available historical dataset consists of wind speed data for May 2013 in hourly measurements. The prediction horizon is one day-ahead, i.e. 01/06/2013. An ARMA model is described by (1), where Y_t is the investigated variable at time step t, φ_i and θ_i are the model's parameters, ε_t is white noise and p, q are the orders of the autoregressive and moving average part respectively:

$$Y_t = c + \varphi_1 Y_{t-1} + \varphi_2 Y_{t-2} + \cdots + \varphi_p Y_{t-p} + \varepsilon_t + \theta_1 \varepsilon_{t-1} + \theta_2 \varepsilon_{t-2} + \cdots + \theta_q \varepsilon_{t-q} \quad (1)$$

In order to fit a dataset in an ARMA model, it should respect the stationarity principle, thus we have to follow a standardization method as it is described in [11], which is based on extracting the average $\mu(t)$ of all data Y^*. The standardized value, Y_t, is then obtained by dividing the data with the standard deviation $\sigma(t)$, as given in (2),(3) and (4):

$$Y_t = \frac{Y_t^* - \mu(t)}{\sigma(t)} \quad (2)$$

$$\mu(t) = \frac{\sum_{i=0}^{d} Y^*_{m*i+t}}{d} \quad (3)$$

$$\sigma(t) = \sqrt{\frac{\sum_{i=0}^{d} (Y^*_{m*i+t} - \mu(t))^2}{d}} \quad (4)$$

where d is the number of considered days and m is the number of time intervals that comprise a day. Parameters p and q are calculated based on the Akaike Information Criterion (AIC) [13], which resulted in the set (p,q)=(1,3).

The Root Mean Square Error (RMSE) is compared in Fig. 1 with the RMSE of the persistence model. A forecast based on the persistence model is obtained by setting the forecasted value equal to the last measured one. This naïve predictor is usually used as a benchmark [7]. The selected ARMA model performs better than the persistence as seen in Fig. 1.

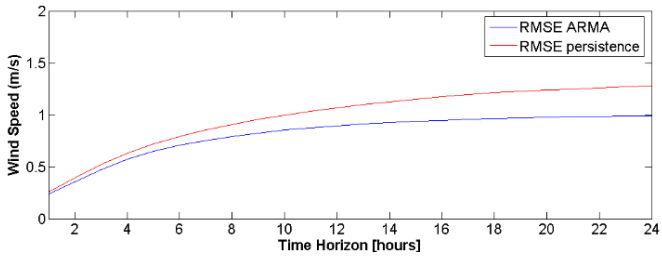

Figure 1: RMSE comparison between ARMA and Persistence models for the given dataset

B. Construction and Reduction of the Wind Speed Scenario Tree – Uncertainty Forecast

For the transformation of the point forecast into an uncertainty forecast, a method based on the simulation of the forecast error is used [14]. The absolute error of the prediction, i.e. the difference between observations and predicted values, is fitted into an ARMA(1,1) model as given in (5)-(6):

$$X_0 = \varepsilon_0 = 0 \quad (5)$$

$$X_t = \varphi_1 X_{t-1} + \varepsilon_t + \theta_1 \varepsilon_{t-1} \quad (6)$$

where X_t is the wind speed forecast error for the t-hour forecast and ε_t is a random Gaussian variable with standard deviation σ_z. The ARMA(1,1) parameters are defined by fitting the simulated RMSE to the available data, i.e. by minimizing (7):

$$Q(\varphi_1, \theta_1, \sigma_z) = \sum_{t=1}^{K} [RMSE_{measured}(t) - RMSE_{ARMA}(t)]^2 \quad (7)$$

$RMSE_{measured}$ is the real measured RMSE data and $RMSE_{ARMA}$ is the standard deviation of the forecast error $\sigma(X_t) = \sqrt{Var(t)}$, as given by (8)-(9):

$$Var(0) = 0, Var(1) = {\sigma_z}^2 \quad (8)$$

$$Var(t) = {\varphi_1}^2 Var(t-1) + \left(1 + {\theta_1}^2 + 2\varphi_1\theta_1\right) \sum_{i=1}^{t-1} {\varphi_1}^{i-1} \quad (9)$$

Once the model parameters are defined, the error of the prediction is simulated using Monte Carlo sampling, and a fan of error scenarios is constructed. For the current study, 1000 error scenarios with equal probabilities were generated. Each of these scenarios is added to the wind speed forecast resulting in a final fan of wind speed scenarios.

This big scenario tree, despite being well informative, is difficult to handle by the operational planning tool, mainly for computational issues. A reduction of the scenarios should be achieved, retaining as much as possible the information of the original tree. A reduction algorithm is used for this purpose, which clusters scenarios based on their mathematical distance and then deletes the one with the lowest probability. The probability of the remaining scenario will be equal to the sum of probabilities of the two clustered ones [15]:

$$d(\xi^i, \xi^j) = \left(\sum_{k=0}^{n_T} (v_k^i - v_k^j)^2\right)^{1/2} \quad (10)$$

where ξ are the investigated scenarios, n_T is the prediction time horizon and v^i_k is the wind speed at time k for the *i-th* scenario.

C. Transforming Wind Speed into Wind Power

A tool that will assist system actors in energy trading, should provide a prediction of the produced power. The power produced by a wind turbine is calculated by differencing the kinetic energy, E, of the turbine's wings under constant acceleration (11)-(12). The "power coefficient", C_p, that sets the limit according to Betz's law was set equal to 0.4.

$$E = m \cdot a \cdot d = m \frac{v^2 - u^2}{2} \quad (11)$$

$$P = \frac{dE}{dt} = \frac{1}{2} pAv(v^2 - u^2) C_p \quad (12)$$

where m is the mass of the moving object (kg), a is the acceleration (m/s^2), d is the distance covered (m), v is the wind speed (m/s), u is the initial wind speed (m/s), p=1.23 kg/m^3 is the air density and $A=\pi r^2$ is the swept area (m^2).

A commercial wind turbine with rotor diameter 116m and maximum capacity 3MW was used for the calculations. In Fig. 2 one can see the wind power scenarios after the reduction, followed by their probability of occurrence.

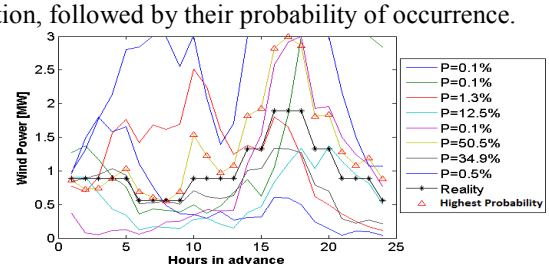

Figure 2: Reduced Wind Power Scenario Tree

III. Price Scenarios for the Day-ahead

Power trading at the DA market requires from the producer an evaluation of the real-time (RT) and day-ahead (DA) prices in order to optimize his market bid. At the current study Monte Carlo Sampling was used for the evaluation of the price scenarios.

A. Monte Carlo Sampling of Day-ahead and Real-time Prices

Price scenarios were constructed based on realistic hourly price data for March 2014, which are available online by the

New England Independent System Operator. Similarly subsection II.A, a standardization method is followed calculating the hourly average and the standard deviation. The desired scenarios are obtained according to (13)-(14), based on Monte-Carlo Simulations [16]:

$$Price_Scenarios_{DA}(j) = \varepsilon_{DA}(j) * \sigma_{DA}(t) + \mu_{DA}(t) \quad (13)$$

$$Price_Scenarios_{RT}(j) = \left(rho * \varepsilon_{DA}(j) + \sqrt{1 - rho^2}\right) * \varepsilon_{RT}(j) * \sigma_{RT}(t) + \mu_{RT}(t) \quad (14)$$

j=1,…,1000, rho is the correlation coefficient between RT and DA prices and ε are random samples in the range of [0,1]. The initial 1000 scenarios are reduced to 8, according to the same algorithm presented at subsection II.B.

B. *Conflicts of Interest at the Day-ahead Market with respect to Wind Power Predictions*

The producer's main interest in participating to the DA market is maximizing his income. Based on the tools presented we describe now how a producer can use an optimization algorithm to maximize his income, leading in many cases to high deviations between the bid and the delivered power, causing security and cost issues to the system operator (SO). On the other hand, the SO's main interest is to retain the stability and safety of the network and keep operational costs low. The procedure that is described is indicating the conflict of interests between the two major system actors with respect to the use of wind power predictions. A compromised scenario in the benefit of both actors is presented thereafter.

1) *Producer's profit maximization and conflicts of interest* [16]: The producer's profit at hour h can be calculated by the profit equation as given by (15):

$$profit_h = p_{DA,h} q_{del,h} + \left(p_{RT,h} - p_{DA,h}\right)\left(q_{del,h} - q_{bid,h}\right) \quad (15)$$

where $p_{DA,h}$, $p_{RT,h}$ are the day-ahead and real-time prices, $q_{del,h}$ is the delivered power and $q_{bid,h}$ is the bid placed by the producer for hour h of the DA. The first part of (15) describes the producer's profit if he settles all the produced power to the DA price whereas the latter part is the deviation settlement, which can be either negative (the producer pays the deviation) or positive (the producer is paid).

Considering this formula one can notice that the decision of the optimal bid value is based mostly on the difference between the RT and DA prices and not on the deviation between the delivered power and the bid. Decisions made by the producer in this direction can cause serious problems to the operation of the network as the deviation of power can be high and the SO will have to cover the missing power in real-time, and face at the same time stability issues. Therefore a deviation penalty is applied to the power producer, as given by (16):

$$profit_h = p_{DA,h} q_{del,h} + \left(p_{RT,h} - p_{DA,h}\right)\left(q_{del,h} - q_{bid,h}\right) - pen_{DA}\left|q_{del,h} - q_{bid,h}\right| \quad (16)$$

The maximization of the producer's expected profit, as stated in (17), is performed using a non-linear optimization algorithm defining the producer's point of view:

$$Q_h = \max_{q_{bid}} E[profit_h(q_{bid})] \quad (17)$$

The profit is maximized with respect to the placed bid, considering all scenarios for wind power production and RT/DA prices, along with their probability of occurrence. In Fig. 3, a bar plot with the suggested bid for each hour of the DA and for the two different cases (penalty/no penalty) is presented according to (17), along with the delivered power. As it is seen, if there is no penalty applied, the producer benefits from bidding maximum capacity (3MW) at hours 1AM, 3AM, 9AM, 10AM, 11AM and minimum at the rest hours. This is a strategy that obviously doesn't take into consideration the resulting deviation between bid and delivered power. In order to cope with this issue a penalty of \$5/MWh is applied to the deviation and the optimal bid from the producer's point of view is calculated. One notices that in this case (green bars the producer changes his strategy in most cases and bids based on the prediction, thus deviating less. However there are still cases where the producer benefits from bidding maximum capacity such as at hours 1PM, 10PM, 2AM, 4AM, 5AM. Those are the cases where the difference between RT and DA price is higher than the deviation penalty.

2) *Compromised solution for the best use of wind power predictions*: In order to face this conflict of interests that leads the producer to deliberately bid more aiming in higher profits, we suggest a framework based on an independent agent that will be responsible for the predictions according to which participating producers will place their bids. More particularly, the independent agent will be responsible for delivering wind power predictions for the day-ahead to the participating wind power producers who, in turn, will have to place a bid based on those predictions. A solution like this is obviously on the benefit of the SO as it will prevent from high deviations of power but is not that appealing for the producer since it reduces his profit. Therefore economic motivation should be provided to the producer to compensate his loss and motivate him for to participate. At the present work two different frameworks are suggested according to which producers are encouraged to participate to this service and both system actors are benefitted from their participation.

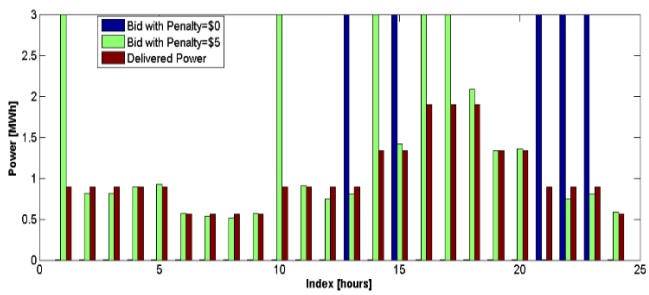

Figure 3: Bids based on the optimization of the producer's penalty

<u>Suggested Framework 1: Calculation of penalty costs based on the daily deviation</u>

Applying the penalty on the deviation of a longer time horizon (e.g. daily instead of hourly), offers the producer the possibility to counterbalance positive and negative hourly deviations, and thus get penalized on his daily deviation, which will be lower. Thus an accumulated daily penalty is applied under this framework instead of an hourly one. For the current case study we set the penalty at \$5/MWh as before, but instead of applying it on the hourly deviation we apply it on the daily one. The daily deviation is calculated by summing up positive and negative hourly deviations. For producers that do not bid under this framework (non-participating producers) the daily cost due to penalties will be \$50 for June 1st. In the contrary, a participating producer whose penalty is applied on his daily deviation, receives a daily penalty of \$37.8, which means \$12.2 less penalties at the end of the day. The same analysis for three more days, the

29th, 30th and 31st of May 2013, is presented in Fig. 4 (framework 1).

Suggested Framework 2: Establishment of a variable penalising factor based on the deviation at hour *h-1*

A variable penalty based on historical deviations is suggested as given at table 1, where *pen* is the penalty for non-participating producers. Considering the participation of the producer at this service we can calculate the changes in his decision making process, presenting the results for the current case study (June 1st, 2013). For a fixed penalty of \$5/MWh, the producer's bid results in high deviation at some hours, as described at III.B.1, gaining at the end of the day \$1007. On the other hand, for a variable profit as described at table 1, the producer follows the bidding strategy suggested by the independent agent which is based on the wind power prediction and his profit under this framework becomes \$1061. Therefore the producer will be recompensed, for compromising and deviating less, with \$54 higher profit at the end of the day. The result is presented also for the 29th, 30th and 31st of May 2013, as before, in Fig. 4 (framework 2).

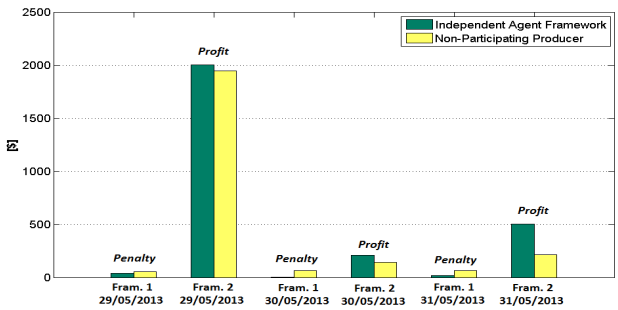

Figure 4: Producer's benefit for participating in the Independent Agent Service

Table 1: Adoption of the penalty according to the deviation history

Delivered Power and Bid deviation at hour *h-1*	**Corresponding penalty at hour *h***
$Dev \leq 20\%$	$50\% * pen$
$20\% < Dev \leq 30\%$	$80\% * pen$
$Dev > 30\%$	$100\% * pen$

IV. Conclusions

In this paper we have presented the construction of a complete tool that can assist the two major actors of an electricity network, DSO/TSO and wind power producers, in their decision making procedure regarding the use of wind power predictions. Wind power and DA/RT price scenarios were introduced in an optimization tool in order to maximize wind power producer's profit in the DA market.

This process has shown that the producer and the SO have conflicting interests and, in particular, even in the case that a deviation penalty is applied, the producer can maximize his income by deliberately bidding more energy than he is able to deliver. Therefore, we suggest a framework under which the predictions are given by an independent agent. In order to motivate the producer to participate to this regulated framework, a compromised solution can be reached by applying a variable deviation penalty and/or a penalty that is applied on a longer time horizon, increasing the producer's expected income motivating him to participate. Moreover this framework results in minimizing the power deviation, which is crucial for the stability of the network and thus for the SO.

Monte Carlo Sampling for the estimation of price scenarios will be replaced in the future by a multivariate ARMA-based prediction which will contribute to a more accurate input to the profit optimization algorithm. Furthermore, a combination of the two suggested frameworks while optimizing at the same time the penalty value with respect to the deviation history, will be further examined in order to approach an optimal framework considering also the economic cost and benefits from the producer's point of view.

Abstract— **Accidents caused by natural phenomena such as lightning are serious problems for the diffusions of wind power generations. To exploit high wind conditions, wind turbine generators are often constructed along the seashore where few tall structures exist; therefore, they are often struck by lightning. Most of the breakdowns and malfunctions of the electrical and control systems inside wind turbine due to lightning are caused by the voltage rise of the grounding system. At a disposal site like seashore where the resistivity of soil is very low, the voltage rise at grounding at the wave front typically becomes larger than that of the steady state because of the inductive behaviour of the grounding system. Voltage rise at grounding of wind turbine due to lightning at a disposal site are computed using electromagnetic analysis approach, and designing of proper grounding system at low resistivity soil is discussed. Finite Difference Time Domain (FDTD) method is used for electromagnetic analysis. Designing of grounding system of wind turbine at a disposal site is discussed.**

Index Terms—**Lightning, wind turbine grounding, voltage rise, FDTD method.**

I. Introduction

With the rapid growth of wind power generation, accidents associated with wind turbine generator systems have increased, including those caused by natural phenomena such as lightning and typhoons. Lightning, especially, causes extensive and serious damage [1–3]. According to statistics, annually 4-8% of wind turbines in northern Europe get damages by lightning; this percentage is 14 in southern Germany [4]. Most of the breakdowns and malfunctions of the electrical and control systems inside wind turbines are caused by a rise in ground potential due to lightning [5, 6].

Wind turbine grounding system has to be effectively designed in order to prevent excessive over-voltages and potential gradients that may cause damage to equipment or threaten human life. To design the wind turbine grounding properly, many researchers have been studied the transient and steady state behavior of wind turbine grounding [7-12]. However, studies on transient behavior of grounding at very low resistivity soil are very rear [13].

In this article, the lightning surge response of a wind turbine grounding at very low resistivity soil is analyzed using electromagnetic analysis approach. In case of low resistivity soil the transient voltage rise at the wavefront of the lightning impulse current is very large as compared to the steady state value due to the inductive behavior of the grounding. IEC 61400-24 [14] suggest use of additional grounding rod/wire to reduce the grounding resistance, in this study it is shown that though the additional grounding rod/wire reduces steady state grounding resistance, it cannot reduces the maximum voltage rise of the grounding if its length is longer than certain value which is depending on the resistivity of soil and front time of injection current. Designing of proper grounding system at low resistivity soil to reduce the maximum voltage rise at the current injection point is discussed.

II. Analysis Method

Virtual Surge Test Lab (VSTL) [15], developed by Central Research Institute of Electric Power Industry (CRIEPI), Japan is used for electromagnetic analysis. VSTL is an electromagnetic analysis code based on FDTD method [16]. Fig. 1 shows the model of grounding electrode of wind turbine. The modelled grounding electrode is similar to the grounding of a small size wind turbine. Though many nations are moving towards modern large size wind turbine, due to lack of manufacturing and construction facility many locations are favourable for small and medium size wind turbine. The analytical setup for FDTD calculation is shown in Fig. 2.

A current lead wire is used to inject the lightning impulse current and a voltage measuring wire is used to measure the voltage at the current injection point. The voltage measuring wire and current lead wire are set orthogonally to reduce electromagnetic interference between them.

The dimension of the analysis space is 100m×125m×100m, and is divided into 150×200×150 cells. Liao's second-order absorbing boundary condition [17] is adopted at each face of the working volume.

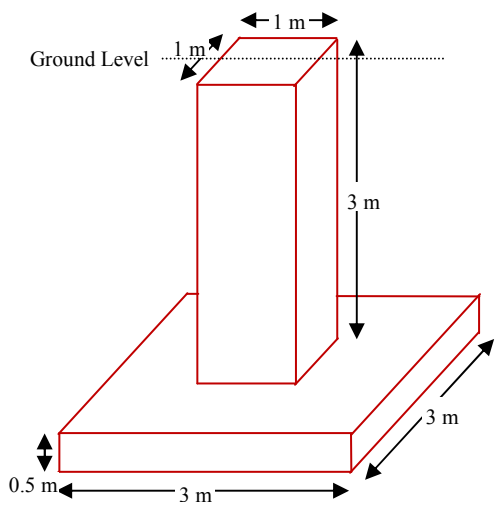

Fig. 1 Model grounding electrode of wind turbine. Steady-state grounding resistance is 30 Ω for ground resistivity of 500 Ωm.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Non-uniform cell sizes are used to reduce the calculation time and memory required. The side lengths of a cell vary from 0.5m to 1.5m. The lower 40 m of the space represents the soil. The radius of all the wires including the electrodes of grounding system is 10 mm.

Soil is postulated homogeneous with relative permittivity of 10. Lightning current of 50 kA with 0.25/100µs waveform representing subsequent return-stroke current [18], as shown in Fig. 3, are injected into the grounding. The waveform of injected current is expressed by Heidler function.

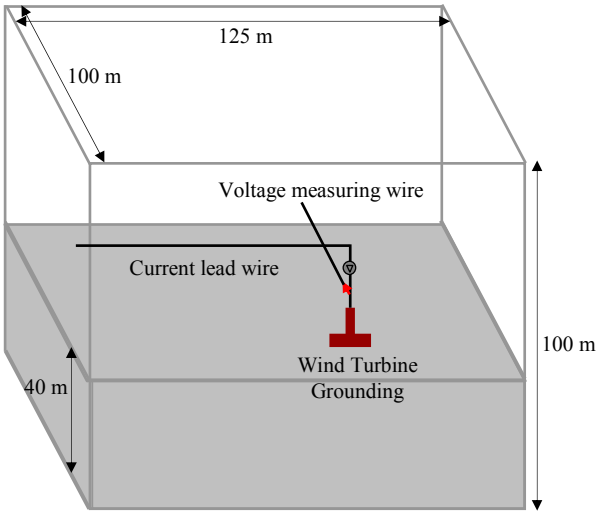

Fig. 2 Analytical setup for FDTD analysis.

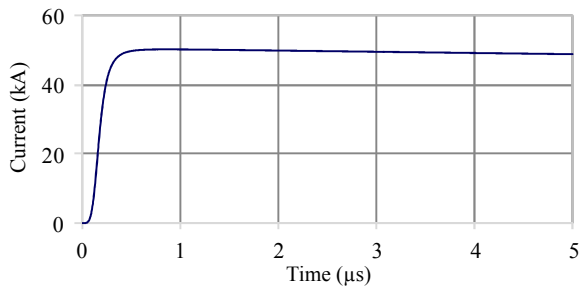

Fig. 3 Test current waveform, subsequent return-stroke current, rise time 0.25 µs.

III. Lightning Surge Response of Wind Turbine Grounding

The voltage rise at the current injection point of the modelled wind turbine grounding for injection of current waveform of Fig. 3 is shown in Fig. 4. When a wind turbine generator system is constructed at a place where resistivity of soil is very low, such as a coastal area, a significant potential rise occurs at wavefront due to the inductive behaviour of the grounding system. At high resistivity soil, the steady state voltage rise is very high, which is depending on the steady state grounding resistance. Steady state condition is generally emphasized during the design of any grounding system. Also the steady state response can be easily predicted using simple empirical formula. In this case the transient behaviour is not so prominent. However, at low resistivity soil the transient voltage rise is very high than the steady state voltage rise, also the transient characteristics cannot predicted without proper analysis. Therefore proper analysis of transient characteristics of grounding system at low resistivity soil is very important for their proper design.

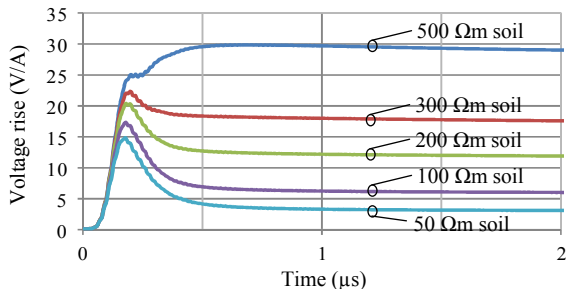

Fig. 4 Voltage rise at the current injection point of modelled wind turbine grounding for injection of subsequent return-stroke current, rise time 0.25 µs.

From Fig. 4, for 50Ωm soil the resistance of the wind turbine grounding is 3Ω, and the steady state voltage rise which is proportional to the grounding resistance is 3 volt per ampere of injection current. However, at wavefront the voltage rise is about 15 volt which is five times higher than steady state. This phenomenon is known as the inductive behaviour of grounding.

The inductive behaviour of grounding is dependent on the resistivity of soil and front time of the injection current, and increases with the decreases of the resistivity of soil and shorter the front time of injection current. As the transient voltage rise is higher at low resistivity soil than the steady state, therefore, transient characteristics should be consider during the design of grounding system at low resistivity soil.

IV. Design of Grounding System at Low Resistivity Soil

IEC- 61400-24 [14], recommend use of additional grounding rod or wire with the grounding system to reduce the maximum voltage rise at the current injection point. To investigate the influence of additional grounding rod/wire on the maximum voltage rise at the current injection point modification of grounding of Fig. 1 is considered as shown in Fig. 5.

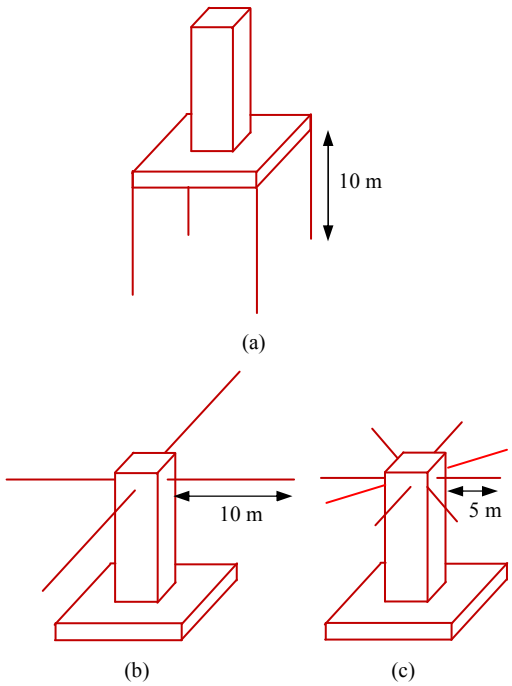

Fig. 5 Additional grounding rod/wire with the wind turbine grounding to reduce the maximum voltage rise, (a) 4 additional rods is at the bottom of the footing (b) 4 long grounding wires near the current injection point and (c) 8 short grounding wires near the current injection point.

Three modifications are considered for analysis, these are: Case a: 4 additional grounding rods is used at the bottom of footing; Case b: 4 additional long grounding wires is used near the current injection point; Case c: 8 additional short grounding wires are used near the current injection point.

The voltage rise at the current injection point for fundamental case (as Fig. 1) and case (a) of Fig. 5 varying the length of grounding rod is shown in Fig. 6. From Fig. 6, it is clear that if the length of the grounding rod at the bottom of the footing is longer than 3 m, the additional length have no effect on the maximum voltage rise at the current injection point, maximum voltage rise remain constant, though the effect of additional grounding rod is visible after the maximum voltage rise.

The voltage rise at the current injection point for fundamental case (as Fig. 1) and case (b) of Fig. 5 varying the length of grounding wire is shown in Fig. 7. From Fig. 7, it is clear that if the length of the grounding wire is longer than 10 m, the additional length have no effect on the maximum voltage rise. From previous section for case (a), it is found that if the length of grounding rod at the bottom of the footing of the grounding system is longer than 3m the maximum voltage rise at the current injection point remains the same. Therefore, the maximum length of the rod which effectively reduces the maximum voltage rise is 3m. However, if the grounding wire is used near the current injection point instead of the bottom of the footing of the grounding then the maximum length of the grounding wire which effectively reduce the maximum voltage rise at the current injection point is 10m.

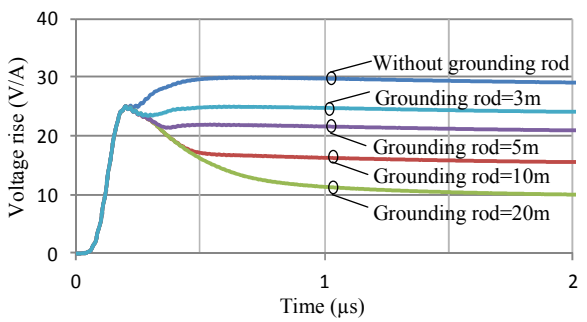

Fig. 6 Voltage rise at the current injection point for case (a) depending on the length of grounding rod, rise time of injection current is 0.25 µs. Resistivity of soil is 500Ωm.

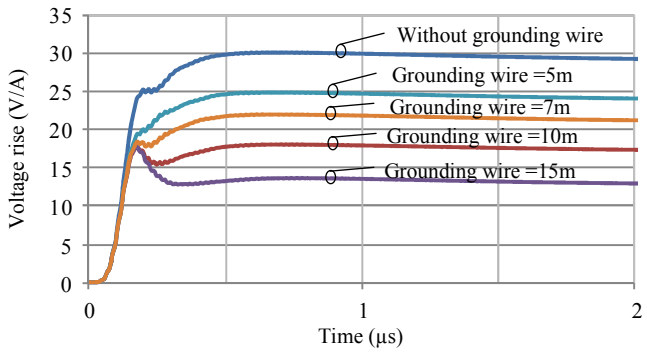

Fig. 7 Voltage rise at the current injection point for case (b) depending on the length of grounding rod, rise time of injection current is 0.25 µs. Resistivity of soil is 500Ωm.

The voltage rise at the current injection point for fundamental case (as Fig. 1) and case (c) of Fig. 5 varying the length of grounding wire is shown in Fig. 8. From Fig. 8, it is clear that if the length of the grounding rod is longer than 10 m, the additional length will have no effect on the maximum voltage rise.

The length of grounding wire effective to reduce the maximum voltage rise is same in this case as that of case (b), because of their same position. For case (b), if we use total 80m grounding wire, length of each grounding wire is 20m maximum voltage rise will be nearly 18 volt per ampere of injection current. For case (c) if we use total 80m grounding wire, length of each grounding wire is 10m maximum voltage rise will be reduced from 18 volt per ampere of injection current to nearly 15 volt per ampere of injection current. Therefore, at low resistivity soil, it is better to use several number of short grounding rod or wire instead of using few number of grounding rod or wire to reduce the maximum voltage rise at the current injection point. The additional grounding electrodes should be placed as close as the current injection point of the grounding system.

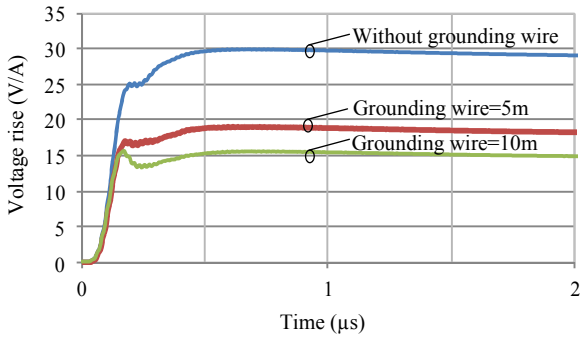

Fig. 8 Voltage rise at the current injection point for case (c) depending on the length of grounding rod, rise time of injection current is 0.25 µs. Resistivity of soil is 500Ωm.

V. Conclusions

This article has presented the results of analytical studies that investigated the grounding characteristics of a small or medium size wind turbine generation system at a low resistivity soil. Voltage rise at the grounding cause overvoltage of the power, communications, and control equipment placed in the tower and at the outermost insulating layer of any incoming cable, which could result in the breakdown or deterioration of the insulation. At a low resistivity soil, the grounding system shows inductive behaviour. Voltage rise at the wavefront becomes higher than the value calculated from the resistance of the grounding. This phenomenon is more significant at low resistivity soil.

IEC standard recommends using additional grounding rod or wire to reduce the grounding resistance, in this study, it is found that though the additional grounding rod/wire reduces steady state grounding resistance, it cannot reduces the maximum voltage rise of the grounding if its length is longer than certain value. Also the position of additional grounding wire/rod plays an important role to reduce the maximum voltage rise at the grounding. At low resistivity soil, it is better to use several number of short grounding rod or wire instead of using few number of long grounding rod or wire to reduce the maximum voltage rise at the current injection point. The additional grounding electrodes should be placed as close as the current injection point of the grounding system.

***Abstract*—This paper presents a nonlinear flux controller based wide speed operation of permanent magnet synchronous motor (PMSM) drive. An adaptive backstepping based nonlinear controller is developed to get the control laws while maintaining systems stability. For the nonlinear controller the flux is controlled based on maximum torque per ampere (MTPA) and flux weakening (FW) techniques for below and above the rates speed, respectively. The global asymptotic stability of the drive is demonstrated by Lyapunov stability criterion in conjuncture with Barbalat's lemma. The system nonlinearities are also accommodated through the online estimation of critical parameters. The proposed nonlinear flux controller based PMSM drive is investigated in simulation using MATLAB/Simulink software. The global stability and robustness of the driver are verified through simulation results.**

***Keywords*— Nonlinear control, IPMSM, adaptive backstepping, parametric estimation, flux control, and wide speed range operation.**

I. INTRODUCTION

Advances in the fields of semiconductor power electronics and magnetic materials have contributed to recent significant improvements in ac motor drives. In particular, permanent magnet synchronous machines (PMSM), have seen a rise in popularity; in part due to the increased availability of rare-earth alloys facilitating high density permanent magnets. Interior permanent magnet synchronous machines (IPMSM), a class of PMSM's, demonstrate excellent efficiency, nonlinear flux distribution, small effective air gap and high power density compared to other ac machines [1]. Further, reluctance torque can be realized as a function of the nonlinear flux distribution (i.e. non-saliency).

Despite advantageous features, control of IPMSM drives is a complex issue, resulting from nonlinear coupling of winding currents and magnetic saturation of the rotor core. Performance of the IPMSM drive varies with changing operating conditions due to magnetic saturation, affecting the d-q axis inductances. Thus to ensure robust machine performance, critical motor parameters need to be estimated adaptively. Significant research effort has been dedicated on various parameter estimation schemes [5]; and recently, adaptive backstepping has been gaining popularity in controller design for motor drives [6],[7]. These techniques allow for the accommodation of many machine nonlinearities and uncertainties.

Wide speed range operation of IPMS machines, principally above the rated speed remains a challenge [8]. When surpassing rated speed, phase voltage and current magnitudes can exceed the rated machine limits. Consequently, the magnetic saturation of the rotor core can cause the operating point of IPMS to shift, resulting in significant variation of d-q axis flux linkages [9]. Thus, performance of IPMSM drives may severely degrade above the rated speed. Performance drives in demanding applications require fast and accurate speed response and insensitivity to parametric variations. In particular, spindle drives, machine tools and traction drives require operation above rated speed (constant power operation). Motoring operation above the rated speed can be achieved by utilizing flux weakening (FW) techniques [9],[10], to ensure rated conditions are not exceeded. Furthermore, flux control below rated speed is necessary to exploit the reluctance torque, which is the principal advantage of IPMSM over other PM motors. In IPMSM drives, direct flux control is not possible; however, flux can be controlled indirectly through the demagnetizing effect of d-axis armature current. However, in the majority of reviewed papers, nonlinear control of IPMSM drives is established by first setting the d-axis current to zero [1]-[3]. This approach greatly simplifies mathematical design, however invariably limits the operating speed ranges and forfeits the contribution of reluctance torque due to the buried permanent magnets.

Consequently, this paper presents a nonlinear adaptive control technique for IPMSM drives, incorporating MTPA and FW based flux control algorithms to ensure wide speed range operation. The development of control laws is based on adaptive backstepping to provide robust system stability. Online estimation of key motor parameters ensures system uncertainties and nonlinearities are accommodated. The performance of the proposed nonlinear controller based IPMSM drive in Fig. 1 is tested in simulation at different operating conditions to demonstrate performance.

II. IPMSM MODEL

Through the use of the "*dq0*" transform, the machine model in stationary stator reference form is translated to the synchronously rotating d-q reference frame in as:

$$\dot{i}_d = \tfrac{1}{L_d} v_d + \tfrac{n_p L_q}{L_d} \omega_r i_q - \tfrac{R_s}{L_d} i_d \tag{1}$$

$$\dot{i}_q = \tfrac{1}{L_q} v_q - \tfrac{n_p L_d}{L_q} \omega_r i_d - \tfrac{n_p \phi_m}{L_q} \omega_r - \tfrac{R_s}{L_q} i_q \tag{2}$$

$$\dot{\omega}_r = \tfrac{1}{J}\left(\tau_e - \tau_m - B_m \omega_r\right) \tag{3}$$

$$\tau_e = \tfrac{3 n_p}{2}\left[(L_d - L_q) i_d i_q + \phi_m i_q\right] \tag{4}$$

where: v_d , v_q - *d-q* axis voltages; i_d , i_q - *d-q* axis currents; ω_r - angular velocity; τ_L - motor load torque; L_d , L_q - *d-q* axis inductances; B_m - viscous friction coefficient; J - moment of

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

inertia of motor and load; ϕ_m - rotor magnetic flux; R_s - stator resistance; " · " - derivative operation; n_p - motor pole pair.

III. Control Algorithm Design

This paper presents a high-performance adaptive speed controller that provides accurate motor control both above and below rated speed. Control is achieved by applying command control magnitudes v_d and v_q as per (15),(16). Most papers [1],[2] describing IPMSM control techniques set the *d*-axis current to zero, simplifying control, however restricting the motor performance characteristics. In this paper, the *d*-axis current is defined by flux control techniques above and below rated speed. Within rated speed range, i_d is defined by the maximum torque per ampere (MTPA) technique [2], and above rated speed i_d is defined by flux weakening [2],[4]. Thus, over the full speed range of the motor, i_d command current is defined as:

$$i_d^* = (1-n)\left[\frac{(L_d-L_q)}{\phi_m} i_q^2\right] - \frac{n}{L_d}\left[\phi_m - \frac{V_m^{'}}{n_p\omega_r} + \frac{L_q^2 n_p \omega_r}{2V_m^{'}} i_q^2\right] \tag{5}$$

where, $n(\omega_r) = \begin{cases} 0, & \omega_r \le \omega_{rated} \\ 1, & \omega_r > \omega_{rated} \end{cases}$

The principle objective is to achieve control of the IPMSM drive angular speed, thus by defining the speed error as the difference between set point and dynamic speed as:

$$e_\omega = \omega_r^* - \omega_r \tag{6}$$

An initial Lyapunov stability function can be defined as

$$V = \tfrac{1}{2} e_\omega^2 \tag{7}$$

By differentiating (7) and expressing in terms of the speed error dynamic

$$\dot{V} = e_\omega\left[\dot{\omega}_r^* + \frac{\tau_m}{J} + \frac{B_m}{J}\omega_r - \frac{3n_p(L_d-L_q)}{2J} i_d i_q - \frac{3n_p\phi_m}{2J} i_q\right] \tag{8}$$

In order to stabilize (8) the contribution of reluctance torque is regarded as minimal; if this assumption is not made, further control design becomes unfeasible. By choosing q-axis stabilizing current as

$$i_q^* = \frac{2J}{3n_p\phi_m}\left[\dot{\omega}_r^* + \frac{\tau_m}{J} + \frac{B_m}{J}\omega_r + k_\omega e_\omega\right] \tag{9}$$

then, $\dot{V} = -k_\omega e_\omega^2$

In order to force the d- and q-axis currents to track the reference trajectories error terms must be defined. Further, in light of the parametric uncertainty of the IPMSM and absence of direct torque measurement, parametric error dynamics are defined in terms of estimated parameters.

$e_d = i_d^* - i_d$, $e_q = i_q^* - i_q$, $e_D = \hat{L}_d - L_d$, $e_Q = \hat{L}_q - L_q$, $e_\lambda = \hat{\lambda} - \lambda$, $e_\beta = \hat{\beta} - \beta$ where, for convenience $\lambda = \frac{\tau_m}{J}$ and $\beta = \frac{B_m}{J}$

With the new error dynamics expressed, it becomes possible to define a comprehensive Lyapunov stability function as

$$V_2 = \tfrac{1}{2}(e_\omega^2 + e_d^2 + e_q^2 + \tfrac{1}{n_D}e_D^2 + \tfrac{1}{n_Q}e_Q^2 + \tfrac{1}{n_\lambda}e_\lambda^2 + \tfrac{1}{n_\beta}e_\beta^2) \tag{10}$$

Thus it is necessary to both redefine the speed error dynamics and express *d*- and *q*-axis errors in terms of the estimated command currents. By differentiating (10) the following is found

$$\dot{V}_2 = e_\omega\dot{e}_\omega + e_d\dot{e}_d + e_q\dot{e}_q + \tfrac{1}{n_D}e_D\dot{e}_D + \tfrac{1}{n_Q}e_Q\dot{e}_Q + \tfrac{1}{n_\lambda}e_\lambda\dot{e}_\lambda + \tfrac{1}{n_\mu}e_\beta\dot{e}_\beta \tag{11}$$

In order to express the error dynamic terms of (12)-(14), the initial speed error term in (6) must be expressed in terms of estimated functions of *d*-*q* axis currents, such that all error dynamics are functions of estimated parameters as:

$$\begin{aligned}\dot{e}_\omega = {} & \frac{3n_p(L_d-L_q)}{2J} e_d i_q - e_\lambda - e_\beta\omega_r - k_\omega e_\omega \\ & - \frac{3n_p(L_d-L_q)}{2J}\frac{(1-n)(\hat{L}_d-\hat{L}_q)i_q^3}{\phi_m} + \frac{3n_p\phi_m}{2J} e_q \\ & + \frac{3nn_p(L_d-L_q)i_q}{2J\hat{L}_d}\left[\phi_m - \frac{V_m^{'}}{n_p\omega_r} + \frac{\hat{L}_q^2 n_p\omega_r i_q^2}{2V_m^{'}}\right]\end{aligned} \tag{12}$$

$$\begin{aligned}\dot{e}_d = {} & \frac{2(1-n)(L_d-L_q)}{\phi_m} i_q\dot{i}_q + \frac{R_s}{\alpha L_d} i_d + k_d e_d \\ & - \frac{1}{L_d} v_d - \frac{n_p L_q}{L_d}\omega_r i_q - \frac{nV_m^{'}}{n_p L_d \omega_r^2} \\ & - \frac{nn_p L_q^2}{2L_d V_m^{'}}(\dot{\omega}_r i_q^2 + 2\omega_r i_q\dot{i}_q)\end{aligned} \tag{13}$$

$$\begin{aligned}\dot{e}_q = {} & \frac{2J\dot{\lambda}}{3n_p\phi_m} + \frac{2J\beta\dot{\omega}_r}{3n_p\phi_m} + \frac{3n_p(L_d-L_q)(B_m-k_\omega J)i_d i_q}{J\phi_m} + k_q e_q \\ & + \frac{(B_m-k_\omega J)i_q}{J} - \frac{2(B_m-k_\omega J)}{3n_p\phi_m}\lambda - \frac{2(B_m-k_\omega J)\omega_r}{3n_p\phi_m}\beta \\ & - \frac{1}{L_q} v_q + \frac{n_p L_d}{L_q}\omega_r i_d + \frac{n_p\phi_m}{L_q}\omega_r + \frac{R_s}{L_q} i_q\end{aligned} \tag{14}$$

With the error dynamics defined in terms of estimated parameters, the *d* and *q*-axis stabilizing command voltages are expressed as:

$$\begin{aligned}v_d = {} & R_s i_d - n_p\omega_r\hat{L}_q i_q + \frac{2(1-n)(\hat{L}_d-\hat{L}_q)\hat{L}_d i_q\dot{i}_q}{\phi_m} \\ & - \frac{nV_m^{'}}{n_p\omega_r^2} - \frac{nn_p\hat{L}_q^2}{2V_m^{'}}(\dot{\omega}_r i_q^2 + 2\omega_r i_q\dot{i}_q) + k_d e_d\hat{L}_d \\ & - \frac{3(1-n)n_p(\hat{L}_d-\hat{L}_q)^2\hat{L}_d i_q^3 e_\omega}{2J\phi_m e_d} + \frac{3n_p(\hat{L}_d-\hat{L}_q)\hat{L}_d e_\omega i_q}{2J} \\ & + \frac{3nn_p(\hat{L}_d-\hat{L}_q)\hat{L}_d i_q e_\omega}{2Je_d}\left[\phi_m - \frac{V_m^{'}}{n_p\omega_r} + \frac{\hat{L}_q^2 n_p\omega_r}{2V_m^{'}} i_q^2\right]\end{aligned} \tag{15}$$

$$\begin{aligned}v_q = {} & R_s i_q + k_q e_q\hat{L}_q + n_p\phi_m\omega_r + n_p\hat{L}_d\omega_r i_d \\ & + \frac{2\hat{L}_q(B_m-k_\omega J)}{3n_p\phi_m}\left(\frac{3n_p(\hat{L}_d-\hat{L}_q)i_d i_q}{2J} + \frac{3n_p\phi_m i_q}{2J} - \hat{\lambda} - \hat{\beta}\omega_r\right) \\ & + \frac{3n_p\phi_m\hat{L}_q e_\omega}{2J} + \frac{2J\hat{L}_q}{3n_p\phi_m}\hat{\beta}\dot{\omega}_r\end{aligned} \tag{16}$$

In order to find relations describing the parameters to be estimated, adaptive backstepping is employed to express the error dynamics e_D, e_Q, e_λ, e_β which are then differentiated to yield estimated values of d and q-axis inductance, load torque and mechanical coefficient respectively. Thus, having the Lyapunov derivative defined in (11), the next steps are to express the previously defined error dynamics (12)-(14) in terms of the *d* and *q*-axis command voltages defined in (15), (16). Grouping the resultant terms according to the respective error dynamics, cancelling opposing terms and simplifying terms containing higher order instances of error dynamics permits the expression of the parametric update laws. The update laws are as follows, consisting of d-q axis inductances, load torque and mechanical constant error dynamics respectively.

$$\dot{e}_D = -n_D \begin{bmatrix} -\frac{3nn_p e_\omega i_q}{2JL_d}\left(\phi_m - \frac{V_m^*}{n_p\omega_r} + \frac{L_q^2 n_p \omega_r i_q^2}{2V_m^*}\right) \\ -\frac{3n_p i_q e_d e_\omega}{2J} - \frac{2(1-n)i_q \dot{i}_q e_d}{\phi_m} - \frac{n_p \omega_r i_d e_q}{L_q} \\ +\frac{9(1-n)n_p e_\omega i_q^3 (L_d - L_q)}{2J\phi_m} - \frac{i_d i_q (B_m - k_\omega J) e_q}{J\phi_m} \end{bmatrix} \quad (17)$$

$$\dot{e}_Q = -n_Q \begin{bmatrix} \frac{n_p \omega_r i_q e_d}{L_d} + \frac{3nn_p e_\omega i_q}{2JL_d}\left(\phi_m - \frac{V_m^*}{n_p\omega_r} + \frac{L_q^2 n_p \omega_r i_q^2}{2V_m^*}\right) \\ +\frac{3n_p i_q e_d e_\omega}{2J} + \frac{nn_p(\dot{\omega}_r i_q^2 + 2\omega_r i_q \dot{i}_q) L_q e_d}{V_m^* L_d} \\ -\frac{9(1-n)n_p e_\omega i_q^3 (L_d - L_q)}{2J\phi_m} - \frac{2(1-n)i_q \dot{i}_q e_d}{\phi_m} + \frac{i_d i_q (B_m - k_\omega J) e_q}{J\phi_m} \end{bmatrix} \quad (18)$$

$$\dot{e}_\lambda = -n_\lambda \left[\frac{(B_m - k_\omega J)e_q}{n_p \phi_m} - e_\omega\right] \quad (19)$$

$$\dot{e}_\beta = -n_\beta \left[\frac{(B_m - k_\omega J)\omega_r e_q}{n_p \phi_m} - \omega_r e_\omega - \dot{\omega}_r\right] \quad (20)$$

By applying d and q-axis command voltages as defined in (15), (16) and with update laws as per (18)-(21), the resultant Lyapunov derivative can be shown to be negative semi-definite with bounded state variables as:

$$\dot{V}_2 = -k_\omega e_\omega^2 - k_d e_d^2 - k_q e_q^2 \le 0 \quad (21)$$

However, in order to demonstrate asymptotic stability of the non-autonomous controller, absolute stability criterion in the form of Barbalat's lemma is employed [11],[12]. Barbalat's lemma can be expressed in the following trio of conditions applied to the Lyapunov stability function [11].

I. As per (10) $V_2 \ge 0$, and is thus characterized by a lower bound

II. As per (22) $\dot{V}_2 \le 0$, thus the negative semi-definite condition is validated.

III. With $\ddot{V}_2 = -2k_\omega e_\omega \dot{e}_\omega - 2k_d e_d \dot{e}_d - 2k_q e_q \dot{e}_q$ verified to be bounded (error dynamics defined a priori; and with all design coefficients, command variables and error dynamics bounded), it can be validated that $\dot{V}_2$ is a continuous function of time.

Having satisfied Barbalat's lemma, it can be concluded that

$$\dot{V}_2 \to 0 \; as \{e_\omega, e_d, e_q\} \to 0$$

Thus, the system is shown to be convergent everywhere, demonstrating global asymptotic stability.

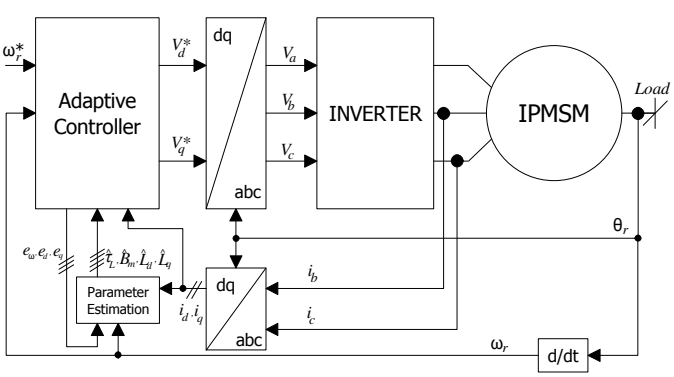

Fig. 1: Block diagram of the proposed controller

IV. Simulation Results

Simulation of the proposed nonlinear controller in Fig. 1 was carried out in a Matlab/Simulink software environment. Nominal machine parameters are as follows: R_s=0.242Ω, L_d=5.06mH, L_q=6.42mH, J=0.0133kgm^2, B_m=0.001Nm/rad/s, Φ_m=0.2449volts/rad/s, n_p=3, ω_r=183.3rad/s, V_m=183volts, P_{rated}=3.7kW.

To demonstrate the robustness of the adaptive laws, Fig. 2(a) compares the response of a scenario with an accidental incorrect mechanical coefficient to that using the adaptive estimation laws, at rated load condition. Fig. 2(b) shows reluctance torque contribution at rated conditons; comparatively this reluctance torque contribution is forfeit in control schemes using i_d=0. Fig. 3 shows the response of the proposed IPMSM drive for a step increase in speed, at full load from 183.3 rad/s at t=0s, to 350 rad/s at t=1s. It is seen from Fig. 3(a) that the drive can follow the command speed smoothly even with a command speed above rated. The increase in speed is also verified by the 'a' phase stator current in Fig. 3(b). The corresponding d-q axis currents are shown in Fig. 3(c). Flux weakening control can be seen from Fig. 3(c) as the d-axis current magnitude shifts downward as the command speed is increased above the rated speed. The corresponding dynamic error values of speed, i_d and i_q are shown in Fig. 3(d).

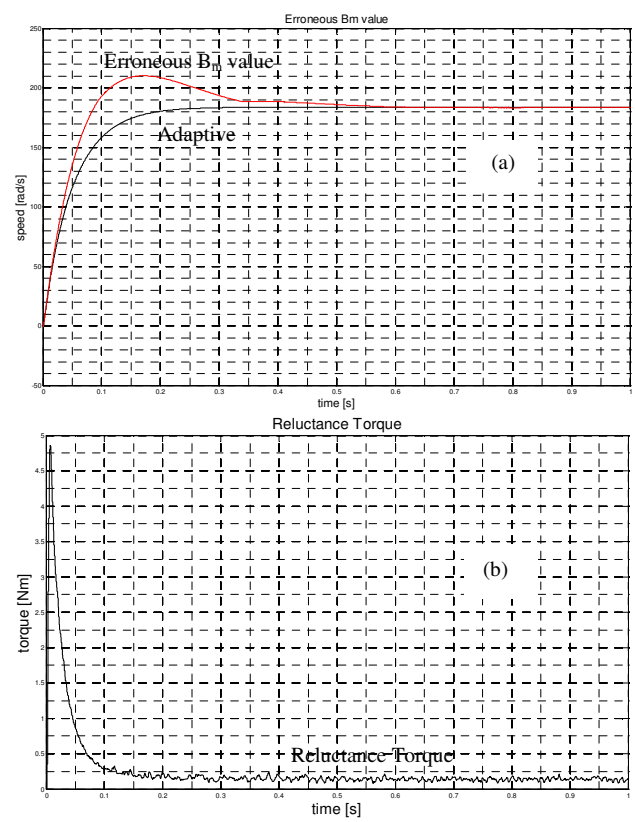

Fig 2: Robust operation and torque analysis of the proposed nonlinear controller based IPMSM drive: (a) speed response using erroneous B_m value at rated conditions (b) reluctance torque at rated conditions

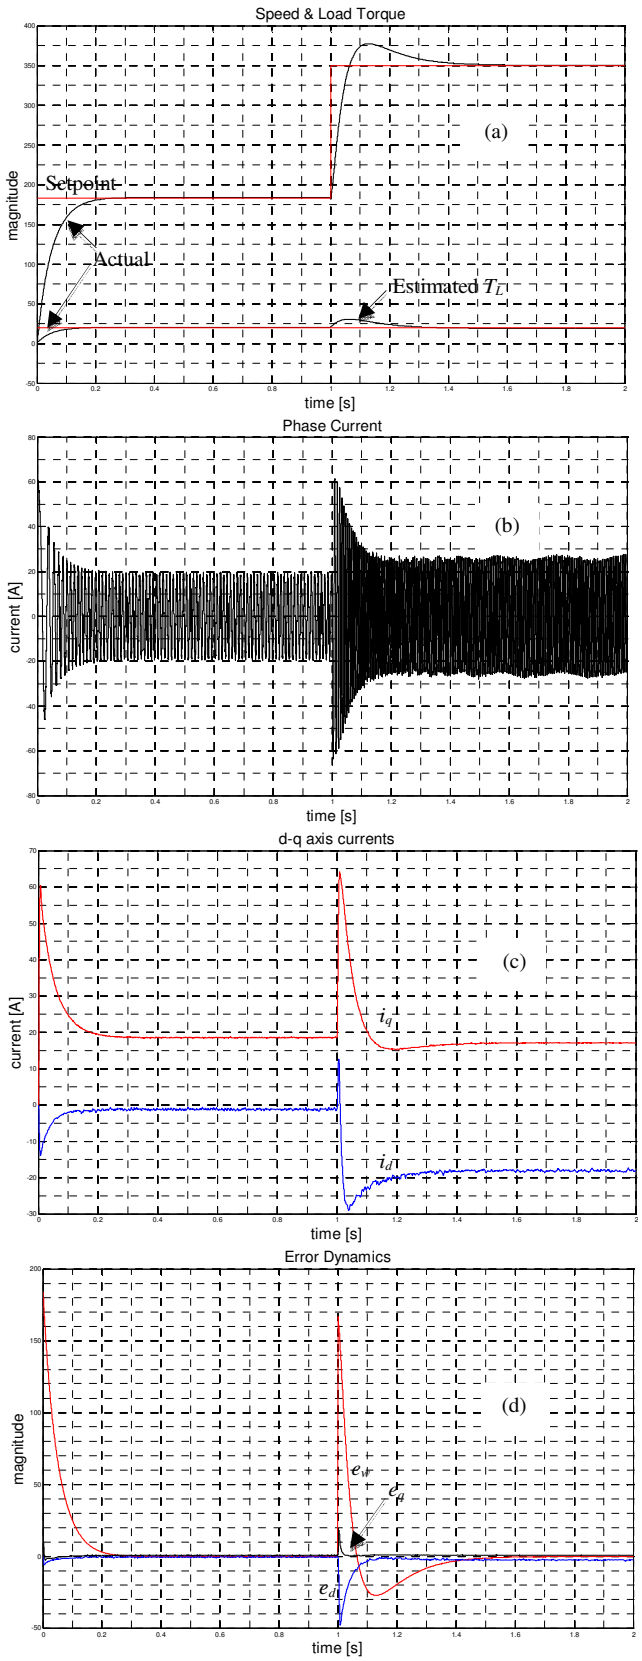

Fig 3: Simulated responses of the proposed nonlinear controller based IPMSM drive for step increase in speed (183.3 rad/s to 350 rad/s at 1s, with 20 Nm load): (a) speed and estimated torque (b) i_a (c) i_d , i_q (d) error dynamics

V. CONCLUSIONS

A nonlinear flux controller based wide speed operation of permanent magnet synchronous motor has been presented in this paper. The flux control based on MTPA and FW is considered in the design stage of the nonlinear controller. The MTPA and FW techniques are used to control the d-axis component of stator current, i_d, below and above the rated speed, respectively. To ensure system stability, control laws were developed based on adaptive backstepping technique; and system nonlinearities were considered through online estimation of motor parameters. Global asymptotic stability of the drive was validated through Lyapunov stability criterion and Barbalat's lemma. Effectiveness of the proposed nonlinear controller has been verified through simulation results at different operating conditions, demonstrating excellent dynamic performance.

Abstract— **A hysteresis interior permanent magnet (IPM) motor is a solid-rotor self-starting hybrid synchronous motor combining both hysteresis phenomena and permanent magnet excitation inside the rotor. The rotor of a hysteresis IPM motor consists of a solid hysteresis ring made of composite materials of high degree of magnetic hysteresis energy per unit volume. High energy density rare earth permanent magnets are buried inside the rotor hysteresis ring. This paper presents the modeling and transient analysis of a hysteresis IPM motor using finite element methods. Electrical equivalent circuits of a hysteresis IPM motor have been presented considering the *d-q* axis saliency of the rotor. Transient finite element analysis of a 2.5kW 208V 3-phase 4-pole hysteresis IPM motor has been carried out using ANSYS Maxwell Electromagnetic field simulation software. Simulation results are presented and explained in this paper.**

Index Terms—**Magnetic hysteresis, permanent magnet motors, analysis, modeling, equivalent circuits, simulation.**

I. Introduction

A hysteresis interior permanent magnet (IPM) motor is a self-starting solid rotor hybrid synchronous motor. Its rotor has a cylindrical ring made of composite material like 17%/36% cobalt steel alloy, special Al-Ni-Co, Vicalloy, etc. with high degree of hysteresis energy per unit volume [1-5]. The rare earth permanent magnets are buried inside the hysteresis ring. The ring is supported by a sleeve made of non-magnetic materials like Aluminum which forces the flux to travel circumferentially inside the rotor ring [1-11]. Fig. 1 illustrates the rotor of a hysteresis IPM motor. The cross section of a hysteresis IPM motor depicting the position and orientation of permanent magnets is shown in Fig. 2. The inclusion of permanent magnets creates rotor saliency without changing the length of the physical airgap and provides an additional permanent source of excitation in the rotor. The induced magnetization of the hysteresis material inside the rotor ring always lags behind the time varying magnetic field. This time lag produces a torque, called hysteresis torque. Also, the induced eddy currents in the hysteresis ring generate some additional starting torque called the eddy current torque. The combination of the hysteresis torque and the eddy current torque results in a high starting torque during line starting of a hysteresis IPM motor which overcomes the magnet brake torque [1-7]. The eddy current torque becomes zero when the motor synchronizes but the hysteresis torque still exists, and the hysteresis ring behaves like a temporarily magnetized permanent magnet. The synchronous torque of a hysteresis IPM motor consists of the magnet alignment torque, reluctance torque and hysteresis torque. As a result, a hysteresis IPM motor has a larger synchronizing torque than that of a conventional line start IPM motor

This paper presents modeling and finite element analysis of a hysteresis interior permanent magnet motor. Electrical equivalent circuits of a hysteresis IPM motor in *d-q* axis are illustrated and explained in this paper. Transient finite element analysis of a 2.5kW 208V 3-phase 4-pole hysteresis IPM motor has been carried out using ANSYS Maxwell Electromagnetic field simulation software. The nonlinear hysteresis phenomenon of the rotor material is approximated using advanced vector hysteresis modeling [12]. Simulation results are presented and explained in this paper. Simulation results exhibit that the hysteresis IPM motor has a moderate starting current, high starting torque and good synchronization capability.

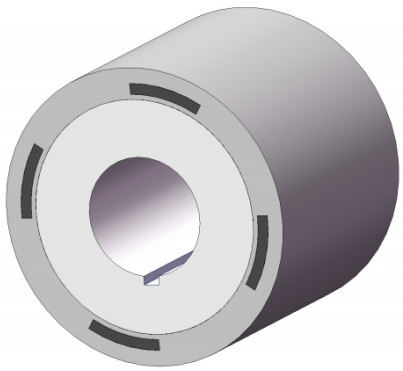

Figure 1. Rotor of a hysteresis IPM motor

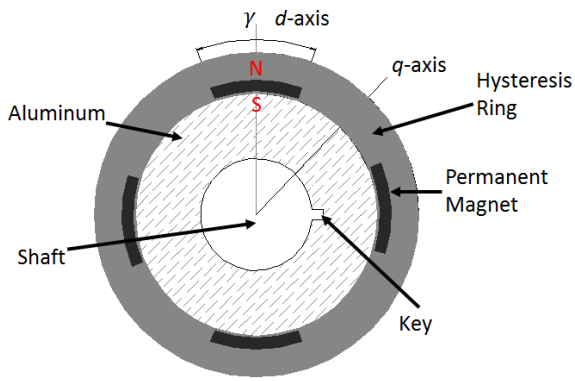

Figure 2. Cross section of hysteresis IPM rotor

II. Electrical Equivalent Circuits

The following assumptions are considered for developing the electrical equivalent circuit of a hysteresis IPM motor:

I. The stator is assumed to have a balanced 3φ sinusoidally distributed winding.

II. Only the fundamental component of the flux density *B* in response to the magnetizing field *H* is considered.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

III. The magnetic flux density is radial in the airgap, but circumferential inside the rotor hysteresis ring.
IV. The B-H curve of the hysteresis material is approximated using the elliptical modeling.
V. The permeability of the hysteresis material is assumed to be constant at its normalized saturated value.
VI. The maximum hysteresis lag angle is assumed to be between 30-70 degrees.
VII. The permanent magnet is assumed to be radially magnetized.

The *q-d* axis electrical equivalent circuits of a hysteresis IPM motor are depicted in Figs. 3a and 3b. The permanent magnet is modeled as a constant current source I_m. Eddy current effect is included in the circuit by modeling it as an equivalent resistance R_e. Hysteresis effect is modeled as an equivalent hysteresis resistance R_h, and an equivalent hysteresis inductance L_{hr}.

Hysteresis and eddy current resistances are divided into two components. One component reflects the hysteresis loss and the eddy current loss in the rotor, modeled by R_e and sR_h, respectively. The other component contributes to the output power of the motor, combining power derived from the effective eddy current resistance and the effective hysteresis resistance. The effective eddy current and hysteresis resistances are expressed as $((1-s)/s)R_e$ and $(1-s)R_h$, respectively, where s is the slip of the motor. In the sub-synchronous mode of operation, both the loss component and the effective load component of the eddy current resistance and the hysteresis resistance exist in the rotor, and results in high I^2R losses in the rotor. At synchronous speed, the eddy current resistance and the hysteresis loss component vanish and the torque produced by the motor is due to combinations of the permanent magnet and the hysteresis effects. The total developed electromagnetic torque at synchronous speed is the summation of the magnet alignment torque, reluctance torque and the hysteresis torque. The hysteresis IPM motor can synchronize larger load torques than the conventional squirrel cage line start IPM motor because of the additional hysteresis torque.

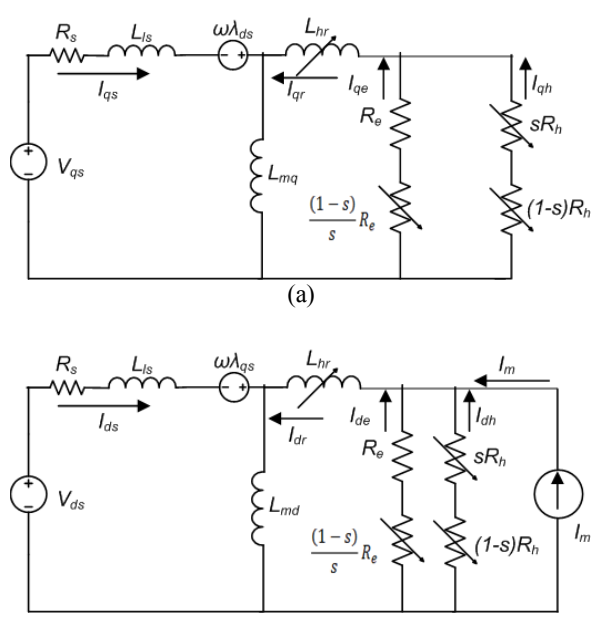

Figure 3. Electrical equivalent circuits of a hysteresis IPM motor: (a) *q*-axis and (b) *d*-axis

The *q-d* axis equations of the motor are derived from the equivalent circuits and are expressed as,

$$\begin{bmatrix} V_{qs} \\ V_{ds} \\ V_0 \end{bmatrix} = \frac{2}{3}\begin{bmatrix} \cos\theta_r & \cos(\theta_r - \frac{2\pi}{3}) & \cos(\theta_r + \frac{2\pi}{3}) \\ \sin\theta_r & \sin(\theta_r - \frac{2\pi}{3}) & \sin(\theta_r + \frac{2\pi}{3}) \\ \frac{1}{2} & \frac{1}{2} & \frac{1}{2} \end{bmatrix}\begin{bmatrix} V_a \\ V_b \\ V_c \end{bmatrix} \quad (9)$$

$$\theta_r = \int_0^t \omega_{rm}(t)dt + \theta_r(0) \quad (10)$$

$$V_{qs} = R_s I_{qs} + \frac{d\lambda_{qs}}{dt} + \omega_r \lambda_{ds} \quad (10)$$

$$V_{ds} = R_s I_{ds} + \frac{d\lambda_{ds}}{dt} - \omega_r \lambda_{qs} \quad (11)$$

$$V_{qr} = 0 = R_r I_{qr} + \frac{d\lambda_{qr}}{dt} \quad (12)$$

$$V_{dr} = 0 = R_r I_{dr} + \frac{d\lambda_{dr}}{dt} \quad (13)$$

$$\lambda_{qs} = I_{qs}(L_{mq} + L_{ls}) + L_{mq}(I_{qe} + I_{qh}) \quad (14)$$

$$\lambda_{ds} = I_{ds}(L_{md} + L_{ls}) + L_{md}(I_{de} + I_{dh} + I_m) \quad (15)$$

$$\lambda_{qr} = (I_{qe} + I_{qh})(L_{hr} + L_{mq}) + L_{mq} I_{qs} \quad (16)$$

$$\lambda_{dr} = (I_{de} + I_{dh})(L_{hr} + L_{md}) + L_{md} I_{ds} + L_{md} I_m \quad (17)$$

$$R_r = \frac{\frac{R_e}{s} * R_h}{\frac{R_e}{s} + R_h} = \frac{1}{\frac{1}{R_h} + \frac{s}{R_e}} \quad (18)$$

$$T_e = \frac{3}{2} p(\lambda_{ds} I_{qs} - \lambda_{qs} I_{ds}) \quad (19)$$

where R_s is the stator phase resistance, L_{ls} is the per phase stator leakage inductance, L_{mq} and L_{md} are the *q-d* axis magnetizing inductances, respectively and ω_r is the electrical angular frequency of the rotor. V_{qs} and V_{ds} are the *q-d* axis stator voltages, V_{qr} and V_{dr} are the *q-d* axis rotor induced voltages, θ_r is the rotor position, λ_{qs} and λ_{ds} are the *q-d* axis stator flux linkages, λ_{qr} and λ_{dr} are the *q-d* axis rotor flux linkages, R_r is the total equivalent rotor resistance and T_e is the developed electromagnetic torque.

III. Finite Element Modeling of Hysteresis IPM Motors

Figure 1 illustrates one quarter of a 2D hysteresis interior permanent magnet motor finite element model which is developed in ANSYS Maxwell 2D, based on the geometric symmetry and electrical symmetry of the motor. The model is discretized into small triangular elements. All the triangles are assembled together by an adaptive mesh technique. In two dimensional magnetic field solutions, the vectors have only one component in the z-direction. The magnetic vector potential, A_z in each element is approximated using a second order quadratic polynomial [13]. Magnetic transient solver is

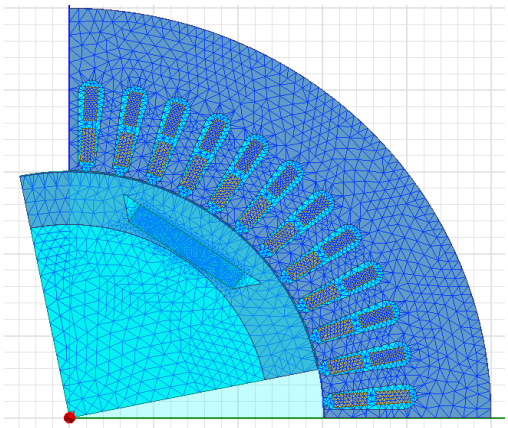

Figure 4. Finite element model of a hysteresis IPM motor

used to analyze the magnetic fields, energy, torque, losses, speed, currents and flux of the hysteresis IPM motor model using time stepping finite element analysis. In time stepping FEA, the desired vector field is computed at various time steps of a solution over a specified time period [13]. The time dependent magnetic equation which is used by the Maxwell magnetic transient solver is given by [13],

$$\nabla \times \upsilon \nabla \times A = J_s - \sigma \nabla V + \nabla \times H_c + \sigma v \times \nabla \times A \qquad (5)$$

where H_c is the coercivity of the permanent magnet, v is the velocity of the rotor, A is the magnetic vector potential, V is the electrical potential, υ is the reluctivity and J_s is the source current density. The excitation is set up as a balanced three phase ac voltage sources and the conductors are assumed to be stranded. The boundary condition of the model is chosen as the odd symmetry boundary which capitalizes the geometric and electrical symmetry of a model in order to reduce the computational time. In the odd symmetry boundary, the signs of the magnetic/ electric fields on one side of a symmetry plane are the opposite of those on the other side of the plane [13].The magnetic transient solver computes the magnetic vector potential in the z-direction A_z. The magnetic field intensity H and the magnetic flux density B are derived from A_z using the Maxwell's equations.

The magnetic flux distribution is displayed in Fig. 5. Fig. 6 illustrates the magnetic flux density. The flux is radial in the airgap and travels circumferentially inside the hysteresis ring.

IV. Transient Performance Analysis

The transient run-up responses of a 3-phase 4-pole 208V 2.5kW hysteresis IPM motor for different loads are shown in Fig. 7. The motor is run by a 3-phase Δ-connected 208V 60Hz balanced ac supply. The motor starts smoothly with some rotor oscillations at the low speed because of the magnet brake torque. The motor overcomes the maximum magnet brake torque with the help of high hysteresis torque and eddy current torque, and ramps up towards the synchronous speed. The developed instantaneous electromagnetic torque is illustrated in Fig. 8. The hysteresis IPM motor has a starting torque. The developed torque is comprised of an average asynchronous torque and a pulsating torque. The average asynchronous torque combines the hysteresis torque, the eddy current torque and the magnet brake torque. Due to the presence of permanent magnet acting as a current source in the rotor, there is a pulsating torque superimposed on the average

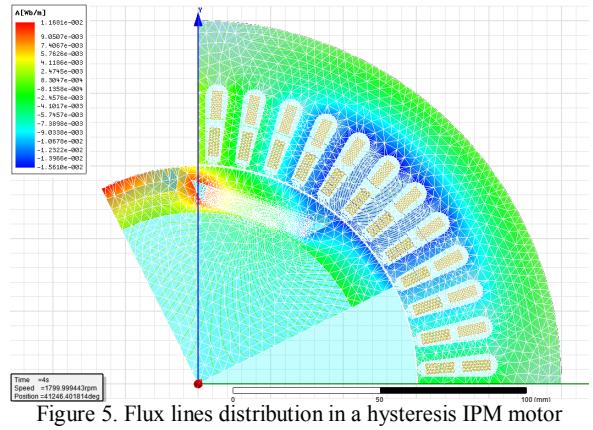

Figure 5. Flux lines distribution in a hysteresis IPM motor

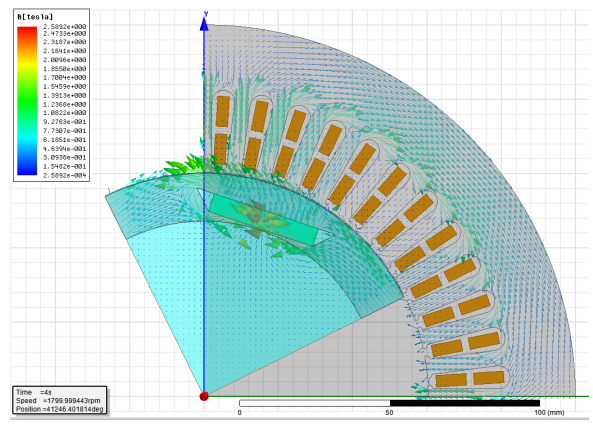

Figure 6. Flux density inside a hysteresis IPM motor

asynchronous torque. The pulsating torque assists the motor to a fast acceleration towards the synchronous speed. During the period of synchronization, the torque pulsation dies out and turns into a part of the synchronous torque. The eddy current torque also vanishes when the slip approaches zero. The magnet brake torque reverses its role and becomes a constituent member of the synchronous torque. The stator phase current for rated load is illustrated in Fig. 9. The starting current is only 2.5 times higher than the steady state rated current which is a significant improvement of conventional line start IPM motors [14]. In Fig. 10, the torque vs. speed trajectories for different loads are depicted. Because of the interaction between the permanent magnet flux and the currents inside the hysteresis ring, the line start hysteresis IPM motor suffers from a few number of torque reversals at low speed. Before reaching the synchronization, there is a series of slow pole-slips which appears in Fig. 10 as almost elliptical. The final synchronization trajectory follows a spiral that originates at the synchronous speed. The load torque was changed suddenly from no load to full rated load torque at t=2s. The rotor goes through some speed overshoots and undershoots for a short time and becomes synchronized again. Both the electromagnetic torque and the phase currents have gone through some oscillations for a very short time before reaching to higher steady state values. The motor starts with a constant hysteresis lag angle but goes though cyclic oscillations during the synchronization period before reaching to a steady state value. As the load torque becomes higher, the lag angle increases which results in a higher torque. Fig. 11 shows the constant flux linkages in phase A of the motor.

VI. CONCLUSION

This paper presents the modeling and transient finite element analysis of a hysteresis interior permanent magnet (IPM) motor. *d-q* axis equivalent circuits have been developed in this paper considering both the eddy currents and the hysteresis phenomena in the rotor. Finite element transient analysis results of a hysteresis IPM motor are presented and explained in this paper. The simulation results exhibit that the proposed hysteresis IPM motor has good self-starting and synchronization capabilities.

***Abstract*—This paper describes the development of a prototype of a microcontroller-based phase angle controlled single-phase AC voltage controller that can efficiently control AC voltage and also accommodates soft start capability for single-phase induction motors. The output voltage of the controller is regulated to maintain a desired fixed RMS value and provide stabilized output by implementing a feedback control system. One microcontroller generates PWM signals in synchronism with the supply voltage to control the firing angle of thyristors while a second microcontroller remains dedicated for measuring the RMS value of the output voltage and sending that to the main microcontroller for the purpose of feedback control. The provision for soft starting of a load is also incorporated into this prototype.**

***Index Terms*—AC voltage controller, Automatic voltage regulation, Soft start**

I. Introduction

PWM-based AC voltage controllers are widely used in UPS and high power flexible AC transmission systems. This varying voltage output is used for dimming street lights, varying heating temperature in homes and industry, speed control of fans and winding machines and many other applications. These systems need switching elements which can bear high voltage.

Frequently, high power MOSFETS are used as the switching element. Their advantage is that they generate less lower-order harmonics. They have the physical limitation of maximum blocking voltage; excessive heating is also an issue for MOSFET based controllers. Amongst other options, an anti-parallel pair of SCRs has the advantage over a TRIAC in controlling highly inductive loads. Although TRIACs have the advantage of a comparatively simpler gate circuit, TRIACs have lower *dv/dt* ratings than SCRs and are available in only small ratings. Moreover, the reliability of a SCR is more than that of a TRIAC [1].

SCR is a reliable solution when it comes to AC voltage control at high power as they are available in higher ratings. However, SCR based system can only be controlled by phase angle control method. This method generates more harmonic distortions [2]. Moreover synchronization with AC supply is necessary when the control mechanism is provided by microcontrollers. The gating circuit required is relatively more complex.

The provision of feedback allows output voltage to be stable and maintain the same RMS value of voltage while there is change in the supply voltage [3]. The gain of the error signal of the feedback control system can be varied to obtain a slower or faster response of the system thus allowing soft start.

II. Overview Of The Design

The development of the prototype is mainly composed of several stages of design consideration: 1) anti-parallel SCR-based voltage controller, 2) Gate-drive circuitry for SCRs, 3) PWM generation through microcontroller, 4) Phase and frequency detection, 5) RMS value calculation for feedback and 6) Input-output Interfacing.

The functional block diagram of the system is shown in Fig. 1.

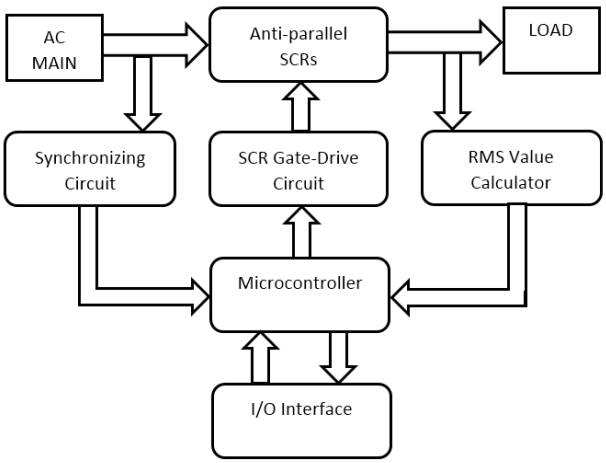

Fig. 1 Functional block diagram of the voltage controller

III. Hardware Implementation

A. Voltage Control Mechanism

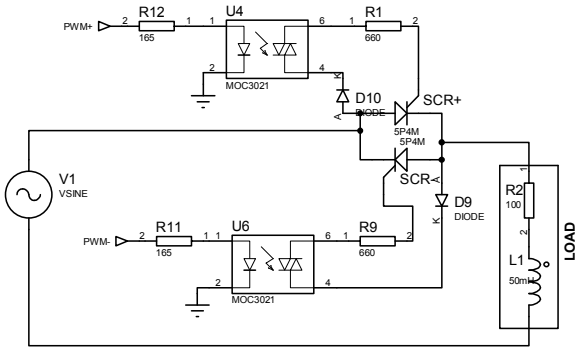

Fig. 2 The main circuit diagram for the prototype

A pair of anti-parallel SCRs is used as the switching device for controlling the AC voltage. The circuit diagram of the SCR based voltage control circuit is shown in Fig. 2. Due to the nature of the connection the two cathodes of the two SCRs corresponds to two different nodes. Thus each gate pulse must

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

be isolated from each other. This is achieved through optical coupling provided by MOC3021 optocouplers [4]. The mechanism is shown in Fig. 3.

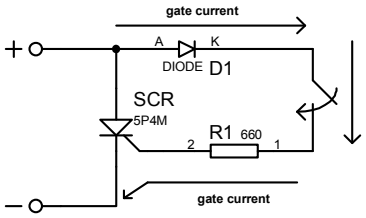

Fig. 3 Path of gate current when optocoupler is turned on

B. Synchronization

The PWM signals must match accurately in phase and frequency with the AC supply line. Even a very small deviation in frequency can gradually lead to the PWM signals becoming out of phase with the supply. A modified zero crossing detector is used for the purpose of synchronization. The circuit diagram is shown in Fig. 4.

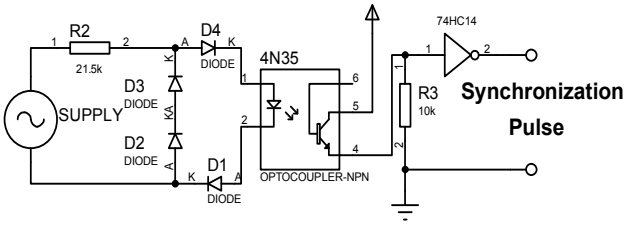

Fig. 4 Synchronization circuit, a modified zero crossing detector

The final output of this circuit is a PWM signal which should ideally have a logic level 0 at the positive half cycle and logic level 1 at the negative half cycle. However due to the presence of resistance in the input circuit the signal mark (logic level 1) starts a little earlier than the start of negative half cycle and ends a little later (by the same amount of time) than the end of the negative half cycle. The timing is shown in Fig. 5.

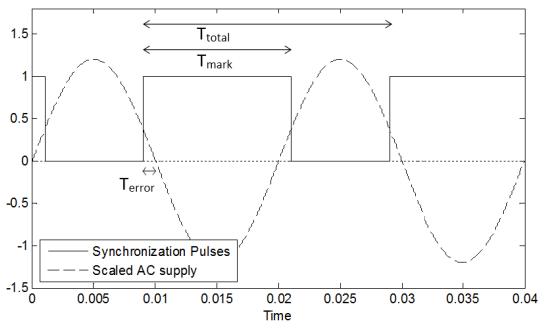

Fig. 5 Timing diagram of synchronization pulses

The error in time can be calculated by the equation (1) which is based on the relative positions of the AC supply and the synchronization pulses.

$$T_{error} = \frac{T_{mark} - T_{total}/2}{2} \quad (1)$$

T_{mark} and T_{total} is calculated using one of the timer resources available in the microcontroller and T_{error} is obtained from the above equation. T_{total} is also the period of the AC supply. Thus both frequency and phase information is obtained.

C. PWM Generation

To control the SCRs the PWM signals must fulfil certain criteria: 1) The PWM signals must be inverted (space comes before mark), 2) The frequency of the PWM must match exactly with the supply, 3) The phase information of the supply must be available and 4) The PWM frequencies must be twice the frequency of the AC supply.

An AVR microcontroller, ATmega32, was used for the purpose of PWM generation [5]. Even though it is possible to drive the two SCRs with the same PWM signal, a slight mismatch in timing can result in unwanted triggering in the next half cycle. Two PWMs working in an interleaved manner eliminates the risk of such triggering. Thus during the positive half cycle the PWM controlling the reverse SCR is set to be zero and during the negative half cycle the PWM controlling the forward SCR is set to zero. Fig. 6 shows the two PWM signal generated and the resultant output voltage alongside the supply voltage.

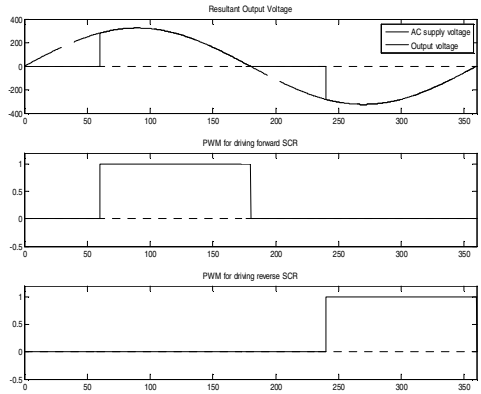

Fig. 6 PWM control signals

D. RMS Value Calculation:

The RMS value of the output cannot be determined by simply dividing the peak value by √2 due to the output voltage being a distorted sinusoidal wave [6]. In order to calculate the RMS value of the output voltage we have used another microcontroller, AVR ATmega8 [7]. This is due to the consideration that the burden of the excess calculation required for this step might hamper the time sensitive operation of the main microcontroller. If the output voltage is sampled over a full cycle of the supply voltage and N samples are obtained, the RMS value is calculated by the following equation.

$$V_{rms} = \sqrt{\frac{\sum_{i=1}^{N} V_i^2}{N}} \quad (2)$$

However since the analogue to digital converter of the AVR microcontroller only allows the conversion of positive voltages, the symmetric nature of the output is exploited and the output is sampled in one half cycle only. The result is then fed to the main microcontroller for the purpose of feedback.

E. Input/output Interface

For the provision of manual input to set the reference voltage value we have used a variable resistor. A 16x2 LCD module is interfaced for displaying various data related to the operation. The reference voltage value and the resultant output voltage are displayed on the LCD display. The frequency of

the supply voltage respective to the clock of the microcontroller is also displayed.

IV. Algorithm And Execution

When the device is started up it automatically measures the value of T_{total} and T_{error}. From Fig. 5 it is apparent that the rising edge of the synchronization pulse arrives at T_{error} time earlier than the end of the positive half cycle. Thus every rising edge means that there T_{error} time left until the negative clock cycle begins. If T_{PWM} is the time starting from the beginning of the PWM cycle then on every positive edge T_{PWM} should be equal to $(T_{total}/2-T_{error})$.

The two PWMs necessary are not generated separately. Rather, the same PWM is fed through two different pins of the microcontroller to deliver them to the respective SCR drive circuit at the appropriate time. After the end of each PWM cycle the pins are swapped. The flow chart of the synchronization process is shown in the Fig. 7.

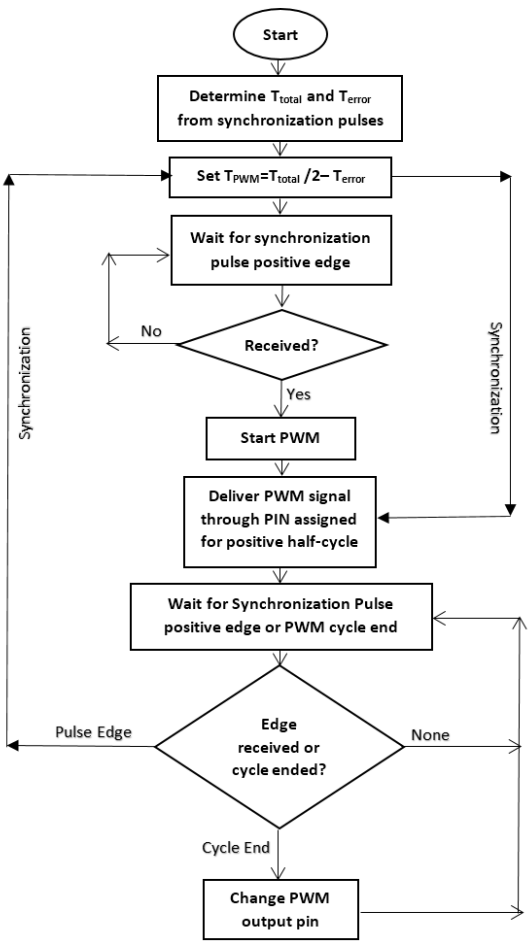

Fig. 7 Flow chart of re-synchronization

The target output voltage value is updated continuously. The target output voltage is determined by the manual input reference and the value of the output voltage obtained from feedback. A voltage error V_e(or V_{ep}) is calculated as,

$$V_e = V_{ref} - V_{out} \quad (3)$$

The error is not utilized directly rather a PID controller is implemented. The proportional, differential and the integral part of the error is calculated and each assigned a gain K_P, K_D and K_I respectively. The total error is also subjected to an overall gain of K. The new target output voltage is thus determined as,

$$V_{target} = V_{ref} + K * V_{etotal} \quad (4)$$

The value of the target firing angle required to achieve the particular value of RMS output voltage V_{target} is determined. For this purpose a look-up table of 64 data point is stored in the microcontroller. For any point that does not match with the desired value linear interpolation is used. The target duty cycle D is thus obtained from the target firing angle. Fig. 8 shows the flowchart for determining target duty cycle.

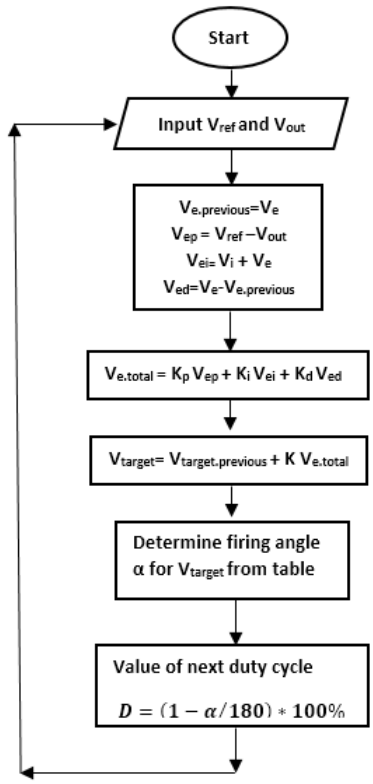

Fig. 8 Flow chart of duty cycle updating

V. Results and discussions

Theprototype was tested with pure resistive loads. Fig. 9 shows an input-output relationship where the input is given as the firing angle. The expected output is also plotted in the figure.

In Fig. 10 the output power is plotted with varying duty cycle. The relationship is non-linear in nature as the relationship between the voltage and the duty cycle. Due to almost a fixed amount of power loss of the operating circuit the efficiency of the device is very low when the power output is comparable to this small loss of power. The efficiency approaches unity as the load is increased and is in the range of any practical load. Fig. 11 shows the change of efficiency with change of output power.

Fig. 12, 13 and 14 shows the output power spectrum for 90˚, 120˚and 150˚ firing angles respectively. The contribution of harmonics towards the total power of the output is visibly high for the last two firing angles. So the preferred zone of operation should be firing angles less than or equal 90˚.

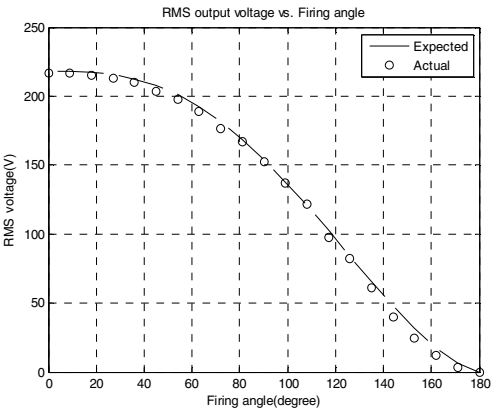

Fig. 9 RMS output voltage vs. firing angle

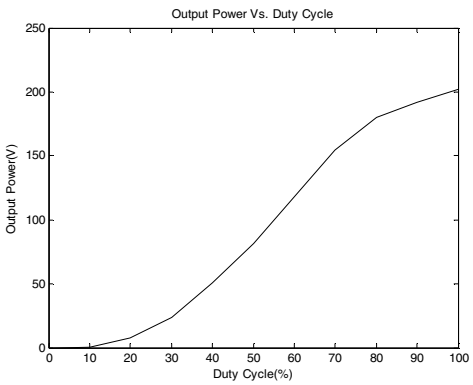

Fig. 10 Output power vs. duty cycle

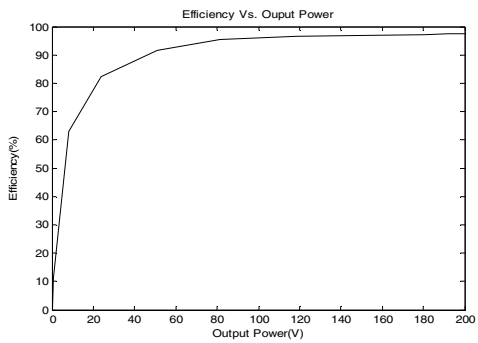

Fig. 11 Efficiency vs. output power

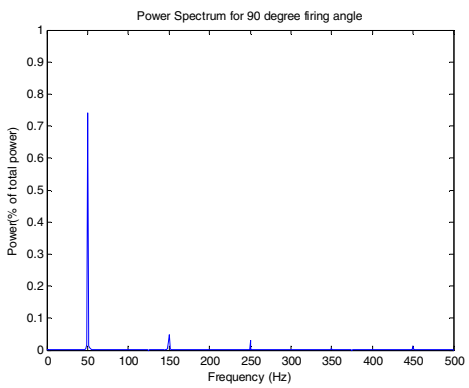

Fig. 12 Power spectrum for 90˚ firing angle

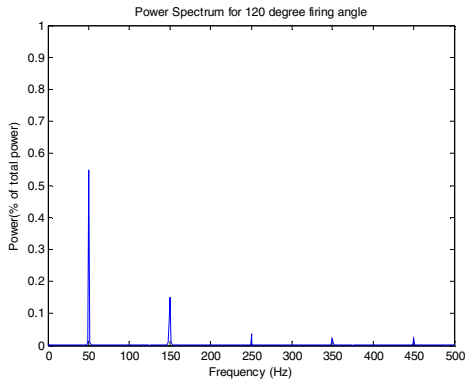

Fig. 13 Power spectrum for 120˚ firing angle

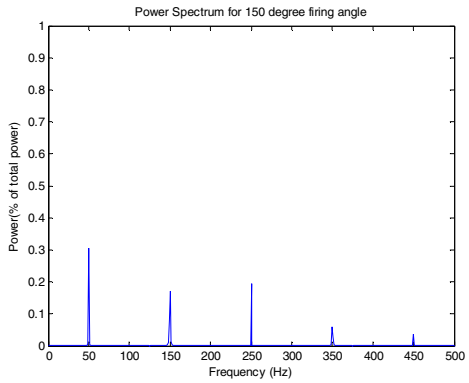

Fig. 14 Power spectrum for 150˚ firing angle

CONCLUSIONS

The feasibility and effectiveness of the proposed project is evaluated with simulation studies and practical real-time implementation. A microcontroller-based design can play a key role to increase its efficiency. Microcontroller based intelligent control allows the device to be more adaptive to different situations and is capable of responding to automation. Moreover, the device can be extended to work in a high power environment by simply replacing the SCR pair with a couple of high power SCRs. Filtering techniques could be applied to improve the design to reduce the harmonic content. However the presence of lower order harmonics makes the filtering difficult. Alternatively an adaptive range selector could be implemented that forces the firing angle to be less than 90^0 by reducing the input voltage by selecting from multiple transformers when necessary.

Abstract—**The concept of green and clean energy sources is the major concern for the researchers in the field of renewable and sustainable energy. Fuel cells are considered to be a promising source of electrical power but the stability of the output voltage is a question yet to be answered. In this paper a fuel cell generation model is shown as well as two stability control schemes (DVR and D-STATCOM) have been implemented in the time domain simulation of MATLAB/ SIMULINK. The comparison of these two schemes is also given for the analysis of the feasibility of the better scheme. The control schemes are analyzed mathematically and simulation is done to determine the stability of the system. A comprehensive analysis of harmonic characteristics is also shown for both the control schemes.**

Index Terms— green energy, fuel cells, DVR, D-STATCOM, MATLAB

I. INTRODUCTION

Power quality problems are of different types. One of the power quality problems is voltage sag that causes the voltage level instable in the transmission line [1]. Voltage sag can occur at any instant of time, with amplitudes ranging from 10%-90% and a duration for lasting half a cycle to one minute.

Another major problem is the fault case. These problems are minimized by DVR (dynamic voltage restorer), D-STATCOM (distribution static compensator) which are the most popular schemes to improve power system stability. These devices are based on voltage source converter principle.

Fuel cells are new sources of electrical energy. The energy produced from fuel cells is not stable. As it is a dc source it has to be converted to ac using inverter control strategy. Previously, fuel cell voltage converted to ac using inverter control strategy has been analyzed [2]. Power quality problem for this system has to be considered too. Symmetrical and Unsymmetrical faults may appear at any time and cause the instable condition which may make the system further worse. Previously, a comprehensive method for voltage stabilization scheme with DVR has been adopted [3]. By means of D-STATCOM a cost effective method is also approached. Separate Energy storage devices (SESD) based DVR is introduced and voltage sag is evaluated for a fuel cell system recently [4]. During different fault conditions how the fuel cell inverter system behaves also have been shown [5]. But the comparison of these two schemes for a fuel cell model has not been reported yet. In this paper, voltage sag is minimized using both DVR and D-STATCOM.

II. FUEL CELL MODEL

A. Principle

Fuel cells convert chemical energy of fuel into electrical energy. The fuel cell used for modeling is termed as Proton exchange membrane fuel cell (PEMFC). In fig. 1 the schematic diagram of PEM fuel cell is given. It is fed with hydrogen and air. There are few assumptions in the modeling. The electrode channels are assumed to be small enough that the pressure drop across them is negligible. The ratio of pressures between the inside and outside of the electrode channels is large enough to assume choked flow. The temperature of the fuel cell is stable. The gases are assumed to be ideal [6].

The typical anode and cathode reactions for a hydrogen fuel cell can be described as follows:

In the anode section, hydrogen gas oxidizes releasing electrons and creating H^+ ions.

Anode equation:

$$2H_2 = 4H^+ + 4e^- \tag{1}$$

At the cathode, oxygen reacts with electrons from the electrodes and H^+ ions from the electrolyte and form water. Here water is the waste product and taken out from the cell.

Cathode equation:

$$O_2 + 4e^- + 4H^+ = 2H_2O \tag{2}$$

$$O_2 + 2H_2 = 2H_2O + heat + electricity \tag{3}$$

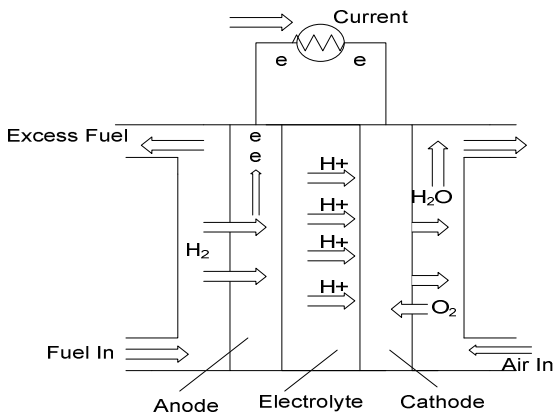

Fig. 1. Fuel Cell schematic diagram

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

B. Fuel Cell Model

The simplified model represents a particular fuel cell stack operating at nominal conditions of temperature and pressure. The parameters of the equivalent circuit can be modified based on the polarization curve obtained from the manufacturer datasheet. The tuning parameters of the simplified model are the value of the voltage at 0 and 1 A, the nominal and the maximum operating points. A diode is used to prevent the flow of negative current into the stack.

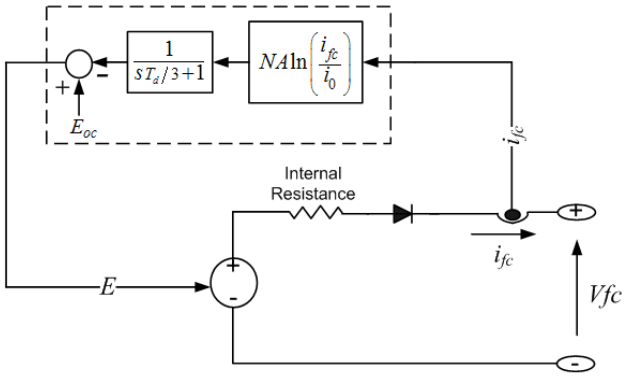

Fig. 2. Simplified model of a PEM Fuel Cell

The detailed model represents a particular fuel cell stack when the parameters such as pressures, temperature, compositions and flow rates of fuel and air vary. voltage (E_{oc}), the exchange current (i_0) and the Tafel slope (A). E_{oc}, i_0 and A are modified as follows:

$$E_{oc}=K_c E_n \tag{4}$$

$$i_0=\frac{zFk\,(p_{H_2}+p_{O_2})}{Rh}e^{\frac{-\Delta G}{RT}} \tag{5}$$

$$A=\frac{RT}{z\alpha F} \tag{6}$$

Where

R = 8.3145 J/(mol K)

F = 96485 A s/mol

z = Number of moving electrons

E_n = Nernst voltage, which is the thermodynamics voltage of the cells and depends on the temperatures and partial pressures of reactants and products inside the stack (V)

α = Charge transfer coefficient, which depends on the type of electrodes and catalysts used

P_{H2} = Partial pressure of hydrogen inside the stack (atm)

P_{O2} = Partial pressure of oxygen inside the stack (atm)

k = Boltzmann's constant = 1.38×10^{-23} J/K

h = Planck's constant = 6.626×10^{-34} J s

ΔG = Size of the activation barrier which depends on the type of electrode and catalyst used

T = Temperature of operation (K)

K_c = Voltage constant at nominal condition of operation

III. DVR Control Strategy

The basic structure of a DVR (Dynamic voltage restorer) is shown in Fig.3.

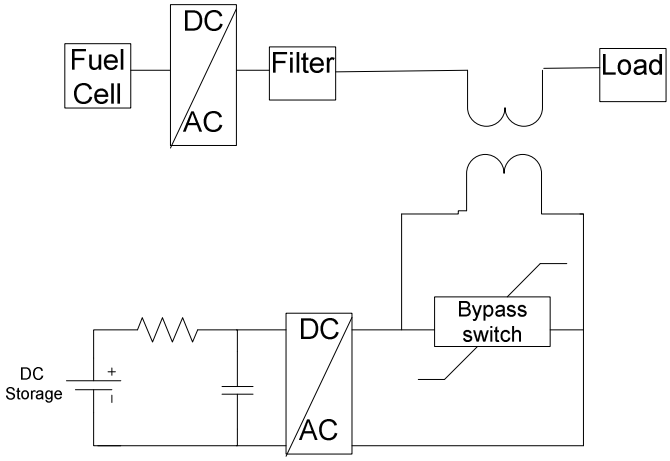

Fig.3. Basic Structure of Dynamic Voltage Restorer

Voltage injection transformers are used in DVR for voltage injection purpose. In a three-phase system, either three single-phase transformer units or one three phase transformer unit can be used. DVR has a large DC capacitor to ensure stiff DC voltage input to inverter. An Inverter system is used to convert dc storage into ac form [7]. Voltage source inverter (VSI) of low voltage and high current with step up injection transformer is used for this purpose in the DVR compensation technique. Filters are used to convert the inverted PWM waveform into a sinusoidal waveform. This is achieved by eliminating the unwanted harmonic components generated VSI action. Higher orders harmonic components distort the compensated output voltage. By-pass switch is used to protect the inverter from high currents in the presence of faulty conditions. Energy storage unit is responsible for energy storage in DC form. Flywheels, batteries, superconducting magnetic energy storage (SMES) and super capacitors can be used as energy storage devices.

A. Simulation result

In test case scenario, voltage is maintained at 1 per unit during stable operation. When the fault is applied voltage drops in case of system without DVR. But the system with DVR shows stable operation during this fault. So fuel cell voltage stability is enhanced using DVR strategy.

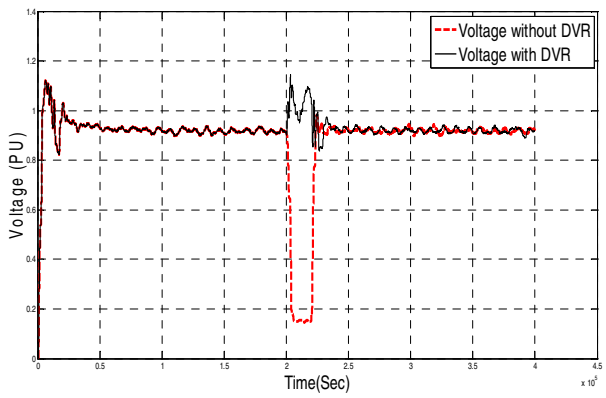

Fig. 4. Per Unit Fuel cell output voltage (ac)

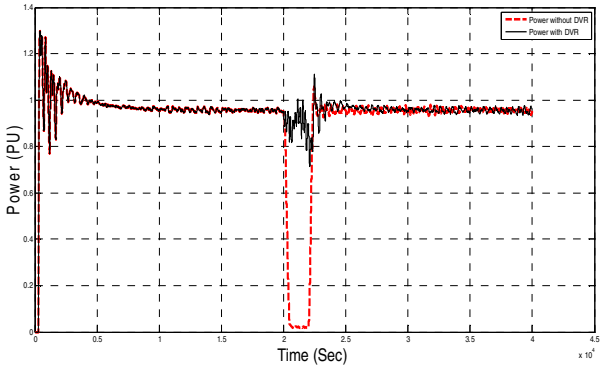

Fig. 5. Per Unit Fuel cell output power (ac)

IV. D-STATCOM CONTROL STRATEGY

A D-STATCOM (Distribution Static Compensator) consists of a dc energy storage unit, a two stage voltage source converter, a coupling transformer connected in shunt with the distribution network. The voltage source converter is essentially a dc to ac converter which converts the dc voltage of the energy storage device to three phase ac voltage. These ac voltages are in phase and coupled with the ac system through a coupling transformer [8].

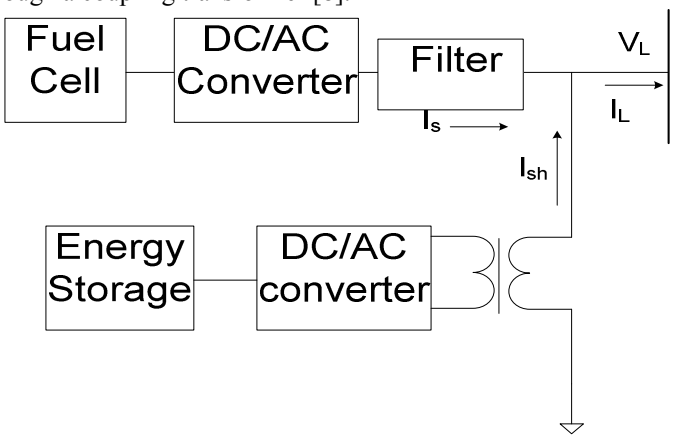

Fig. 6. D-STATCOM acting on the ac system

The shunt current I_{sh} corrects the voltage sags by adjusting the voltage drop across the system impedance Z_{th}. The shunt current in fig. 6 can be written as-

$$I_{sh} = I_L - I_s = \frac{V_{th} - V_L}{Z_{th}} \tag{7}$$

$$I_{sh}\angle\eta = I_L\angle -\theta - \frac{V_{th}}{Z_{th}}\angle(\partial - \beta) + \frac{V_L}{Z_{th}}\angle -\beta \tag{8}$$

The complex power injected from the D-STATCOM can be written as-

$$S_{sh} = V_L I_{sh}^* \tag{9}$$

The control scheme for the D-STATCOM follows the same principle as for DVR. When the shunt current I_{sh} is kept in quadrature with V_L, the desired voltage correction can be achieved without injecting any active power into the system. On the other hand, when the value of I_{sh} is minimized, the same voltage correction can be achieved with minimum apparent power injection into the system [8].

B. Simulation result

In test case scenario, voltage is maintained at 1 pu during stable operation. When the fault is applied the voltage drops in case of system without D-STATCOM. But the system with D-STATCOM shows stable operation during this fault. Although there exist some fluctuations in voltage level due to circuit breaker operation, it can be reduced using other protection schemes. So fuel cell voltage stability is enhanced using D-STATCOM strategy. In each case voltage and power recovery during fault condition using D-STATCOM are demonstrated by fig 7-10 respectively.

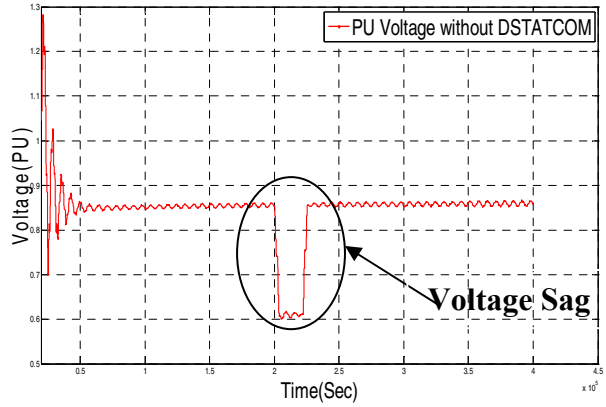

Fig. 7. Per Unit Fuel cell output voltage (ac) without D-STATCOM

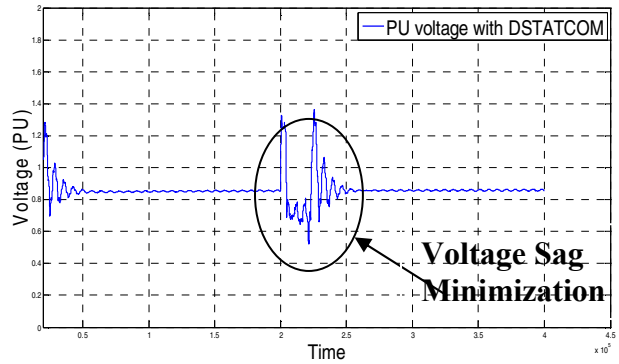

Fig. 8. Per Unit Fuel cell output voltage (ac) with D-STATCOM

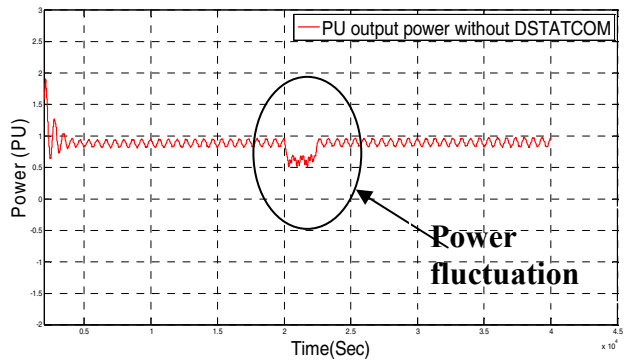

Fig. 9. Per Unit Fuel cell output power without D-STATCOM

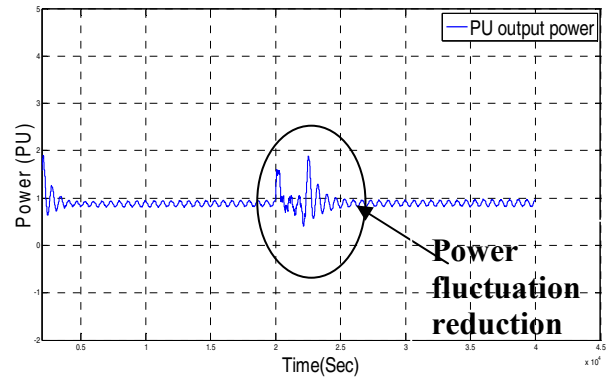

Fig. 10. Per Unit Fuel cell output power with D-STATCOM

V. COMPARATIVE HARMONIC ANALYSIS

THD is defined as the RMS value of the waveform remaining when the fundamental is removed. A perfect sine wave is 100%. Harmonic distortion is caused by the introduction of waveforms at frequencies in multiplies of the fundamental. If the fundamental frequency is 50 Hz then the 5th harmonic is 5x the fundamental frequency =250 Hz. Total harmonic distortion is the measure of the closeness to the sine wave. THD (total harmonic distortion) can be expressed by the following equation [9]

$$THD = \frac{\left[\sum (\text{Amplitudes of All Harmonics})^2\right]^{\frac{1}{2}}}{\text{Amplitude of Fundamental Harmonic}} \quad (10)$$

So, harmonic distortion is simply the ratio of the amplitude of the harmonic to the fundamental one.

At different DVR voltage the THD is calculated in harmonics order. At 1KV DVR dc storage voltage the THD is found to be 19.96%. For an increased dc storage voltage THD was also increased accordingly. The following figure shows the THD for DVR at 1KV.

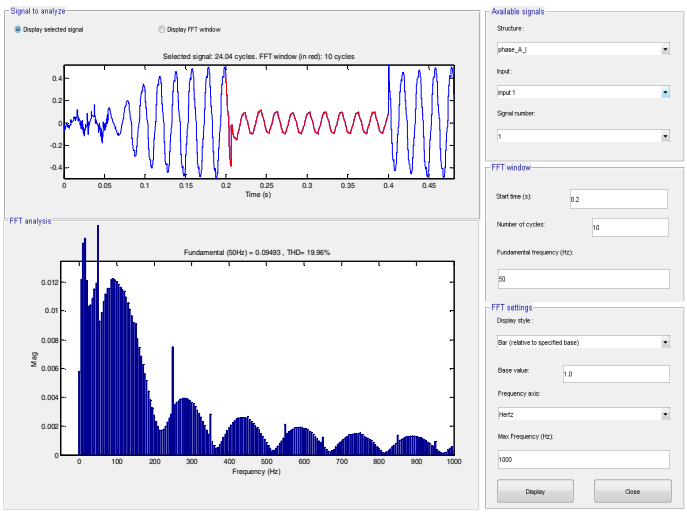

Fig.11. THD in Harmonics Order for DVR

For D-STATCOM the same procedure is followed. In case of D-STATCOM THD is found to be 15.53%. From the harmonic analysis it is shown that better THD has been found when D-STATCOM is used.

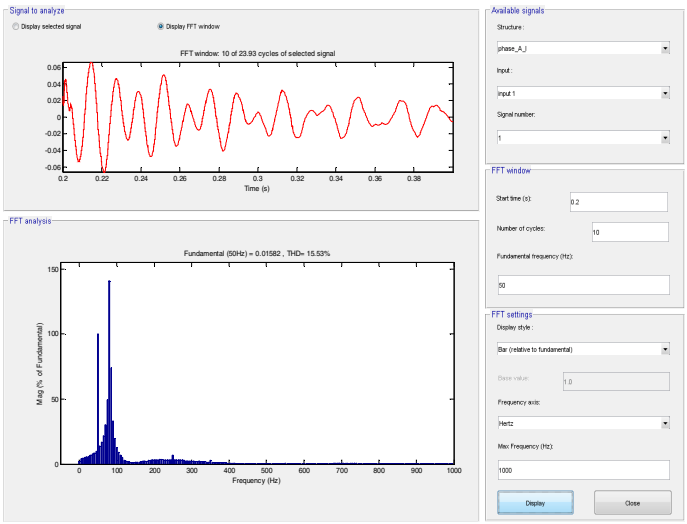

Fig.12. THD in Harmonics Order for D-STATCOM

THD is to be decreased to a certain level in order to decrease the pick current hence decreasing the power loss of the system. This is an important factor to be considered. LCL filter generally decrease the THD which is a scope of the future work.

VI. CONCLUSIONS

Both DVR and D-STATCOM are very effective stabilization schemes to reduce the voltage sags, voltage dips etc. The reduction of voltage sags and power injection to the system depends on the dc rating of the energy storage devices for both DVR and D-STATCOM. But from the simulation it is seen that D-STATCOM requires more active power injection to the system than DVR. D-STATCOM is also more costly stabilization scheme than DVR. DVR has more capabilities to regulate the voltage. There are other methods in FACTS devices such as FFS fundamental frequency switching methods. But PWM based method is better than these methods. Among the PWM methods, performance of DVR is found to be more superior to D-STATCOM considering all the facts.

***Abstract*—This study proposes a new circuit consisting of a Vienna rectifier and a single phase two stage inverter. The inverter consists with a combination of sinusoidal pulse width modulation (SPWM) and a square wave along with grid synchronization condition. The simulation work of this circuit has been done using PSIM. The new technique revealed that the low ripple, low THD below 0.1%, low cost and simple control providing a improved power factor of above 0.94.**

Keywords—Vienna Rectifier, Single phase two stage Inverter, Power Factor, Power electronics.

I. INTRODUCTION

The process of increasing the power factor without changing the loads or altering the voltage or the current to the original load is known as power factor improvement [1]. Among the rectifier topologies, VENNA rectifier[2-4] is an attractive choice for power factor improvement because its switch voltage stress is one half of the total output voltage so that fast switches such as MOSFETs can be used.The Vienna rectifier is useful wherever six switch converters are used for achieving sinusoidal mains current and controlled output voltage, when no energy feedback from load into the mains is required. The Vienna rectifier comprises a semiconductor switch in each phase leg of 1- phase Diode Bridge. It is a highly efficient method of high current, single-phase AC/DC conversion and is very useful for achieving unity power factor correction.[5].There are many processes to improve power factor. Vienna rectifier and Buck-Boost converter can improve the power factor of a three phase circuit [6]. Harmonics have a negative effect in theoperation of the electrical system and therefore, anincreasing attention is paid to their generation and control [7-8]. So, the study of Total Harmonic Distortion (THD)is important. Single phase two stage highly efficient inverter provides low harmonics, low cost, high efficiency, low THD and simple control [9]. To improve efficiency and noise performance, we have proposed the single phase two stage inverter instead of using Buck-Boost Converter.

II. VIENNA RECTIFIER

VIENNA rectifier is a three-switch rectifier which gives the DC output given in Fig.1. For controlling the rectifier it only need three switches rather five floating switches of other rectifiers. This switching system gives it more convenience to implement.

But in comparing this with single switch controlling is still complex. But the input current distortion of this rectifier is about 8.2% which is significantly less than the single switching and also than H-bridge and two switch implementation [10]. Basically the VIENNA rectifier works as a two-switch boost rectifier. One of the switches works at line frequency and two switches switched at high frequency. In 60° control block one switch is permanently on.

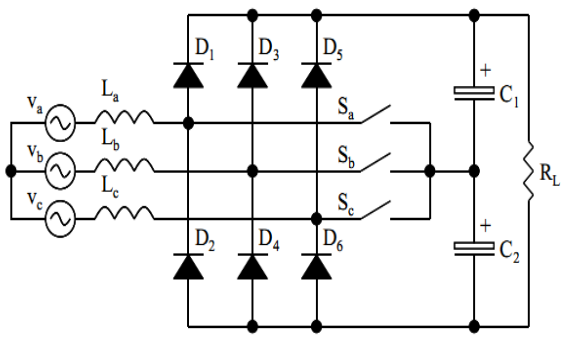

Fig.1. Vienna Rectifier

VIENNA rectifier can be explained as two independent boost rectifiers, one for boosting C1 and the other for boosting C2. Thus it can be seen that the minimum boost voltage over C1 and C2 will be the maximum line-to-line voltage of the input.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

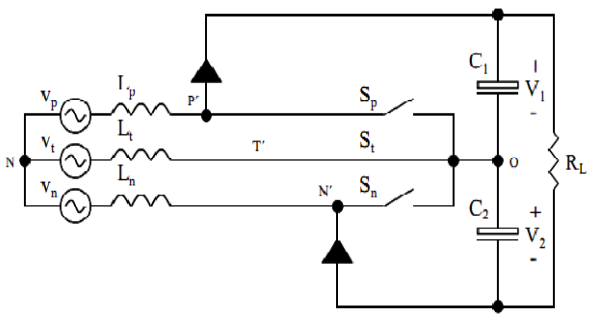

Fig.2. Equivalent circuit of VIENNA rectifier (60° control block) [11]

The equivalent representation of VIENNA rectifier for a 60° control block in one switch "on" condition is shown in the Fig.2. VIENNA rectifier has lower switch and diode currents than all of the other dual-boost rectifiers [12].For switch losses and diode losses it has the same harmonic distortion like others. But an extra convenience of the VIENNA rectifier is that modules are available having all the power stage bridge leg p, n and t-subscript denotes parts associated with the positive rail, parts associated with the negative rail and parts associated with a transitional period respectively. The small-signal model is derived for a negative duty cycle which is larger than the positive duty cycle, $d_N>d_P$. Then the process is repeated for the positive duty cycle which is larger than the negative duty cycle, $d_P>d_N$. The common parts of two switch cycle off periods $(1-d_N)$ and
$(1-d_P)$ can be associated.

III. DESIGN AND SIMULATION OF THE INVERTER:

This inverter power circuit design consists of a pair of two parallel MOSFET gates [9]. In conventional inverters only one type of switching technique is used. This design instead uses a combination of SPWM and square wave to reduce the switching loss by reducing the switching frequency.The sine wave is sampled from power grid by using transformer that steps down voltage from 220V to 5V.A high frequency triangle wave of 10 KHz frequency is used. Then the two signals are passed through a comparator to produce the SPWM signal.A square wave signal is used as the line frequency and is in phase with the SPWM.The square wave is transmitted through a NOT gate to produce a signal that is 180 degree out of phase of the original signal. The inverter requires four switching signals since it has four MOSFET switches [9].To create four signals an AND operation is performed between two sets of square wave signals and the SPWM. The four sets of switching signals can be categorizedin two groups. The first group contains MOSFETs Q_1 & Q_2while the second group contains MOSFETs Q_3 & Q_4. The gatepulses for switching of MOSFETs.

IV. SYSTEM MODEL

Fig.4 represents the model of a R-L load using single phase Vienna rectifier and single phase two stage highly efficient inverter.The Vienna Rectifier in which the input 30V p-p ac voltage is rectified dc voltage. The MOSFET are triggered using a Square pulse of 30V. The single phase two stage inverter, where the MOSFETs are triggered using a triangular pulse of 12V.We also use a L-C filter to minimize the distortion. The last part of this circuit is the R-L load.

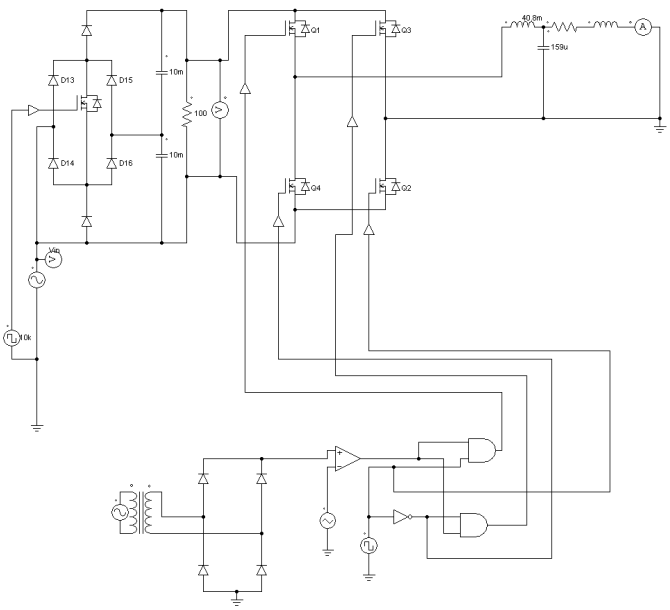

Fig.4. Schematic diagram of a Vienna rectifier connected to a single phase two stage highly efficient inverter for simulation in PSIM.

V. SIMULATION RESULT

Fig.5 shows the input voltage which is 30v p-p. Fig.6 exposes the output of Vienna.It revealed that the output is distorted and is difficult to measure the voltage. Fig.6and Fig.7showthe triggering pulses of Inverter and Vienna rectifier respectively. Fig.9 shows output current of the inverter. It contains ripple. To minimize this distortion we use a L-C filter. Then we get a almost ripple free current curve of the inverter in Fig.10. Same scenery has been achieved in the case of voltage. Fig.11 reveals a distorted voltage of the inverter before using filter while a almost pure sinusoidal voltage curve is achieved in Fig.12 after using the L-C filter. L-C filter is available in market at low cost. So, it is cost effective. L-C filter can be handled easily. So, it also provides simple control of the circuit.

VI. PERFORMANCE ANALYSIS

A vienna rectifier is useful to improve the power factor. The MOSFET switch controls the current by controlling the magnetization of the inductor. Switched on charges in the inductor, drives the current through the bidirectional switch. Deactivating the switch increases the current to bypass the switch and flow through the freewheeling diodes. This results in a negative voltage across the inductor and drains it. This describes the ability of the topology to control the current in phase with the mains voltage (Power Factor Improvement capability). Here a vienna rectifier is also used. So, an improved power factor of 0.9411 has been achieved. The output current and voltage of the single phase two stage inverter have been pure sinusoidal after using L-C filter. Before that there was ripple. It is also observed that the output power is sent at an angle of 45 degrees with total harmonic distortion of less than 0.1%.

VII. CONCLUSION

In this paper we have studied the model of a R-L load achieving low THD, low cost, improved power factor and a simple control. To fulfill the purpose we used a Vienna rectifier and a single phase two stage inverter. By analyzing the simulation result we got a power factor of above 0.94.The simulation result also shows that the Inverter produces a high quality ripple free sinusoidal AC curve with a voltage THD below 0.1% which is very much lower than IEEE 519 standard. So, the new circuit providing low cost, simple control, low THD, low ripple and improved power factormight be the application of modern power electronic system.

Abstract—**Due to high switching frequency and modulation strategy, neutral point clamped (NPC) inverter generates varying common mode voltage as well as leakage current in PV and wind turbine system. This leakage current causes electrical hazard, THD at the output voltage, EMI and ultimate pollution at the output power. To reduce this varying common mode voltage and leakage current, this paper proposes a Split Inductor based Neutral Point Clamped (SINPC) inverter with improved modulation technique. The proposed inverter can reduce common mode voltage and suppress leakage current comprehensively. In order to verify the effectiveness of the SINPC inverter with improved modulation, simulation has been carried out in PSIM software. Finally, the output wave shape of reduced common mode voltage and leakage current ensures the effectivity of the proposed circuit.**

***Index Terms*— Split Inductor NPC, common mode voltage, leakage current.**

I. Introduction

Voltage source inverters are widely used in renewable power processing stage like in photovoltaic (PV) system, wind turbine, fuel cell etc. Pulse width modulation (PWM), space vector modulation (SVM) etc. is the standard approaches to operate the inverter switches in order to generate the required high quality output voltage. But the switching frequency of the inverter in these techniques is usually very high. So due to this high switching frequency, some problems have been occurred in inverters connected with the PV systems or wind turbine. Among them, leakage current generation is one of the frequent problems usually observed in transformer less PV systems [1]-[4]. Due to the absence of the transformer, there is a galvanic connection between power grid and solar cell array. Not only that, there are stray capacitors to ground formed by the surface of the PV array. So when high frequency switching occurs, a varying common mode voltage will be generated in this system which creates a dangerous leakage current through the stray capacitance between the PV array and the ground. This leakage current cause's electrical hazard increases the total harmonic distortion (THD) and ultimate pollutes the output power of the inverter circuit. This problem not only occurs in transformer less PV system but also in DFIG based wind turbine where back-to-back PWM converter is used [3]-[7]. So our main target is to reduce this varying common mode voltage and leakage current which is generated during high frequency switching of the neutral point clamped (NPC) inverter.

In NPC inverter, Space Vector Modulation (SVM) is usually used to generate the output voltage. In this technique, a varying common mode voltage levels are being generated at different switching stages. If some of the harmful switching stages can be eliminated during the modulation period, then a minimize common mode voltage as well as leakage current can be achieved. In [4], some effort has been given to do that but in this work, the technique is implemented in a conventional NPC Inverter. So the varying common mode voltage still bears a very high magnitude (more than 500V peak to peak for 1200V DC input). In our paper we proposed a split Inductor based Neutral point clamped (SINPC) Inverter instead of conventional NPC inverter which reduces the varying common mode voltage comprehensively at the improved modulation technique. In addition to that, split inductor concept of the proposed inverter generates low leakage current in the system. In order to prove the effectiveness of proposed circuit, simulation has been carried out which has been demonstrated at the simulation part.

II. Common mode voltage And circuit Analysis

Fig.1 (a) shows the conventional NPC inverter and Fig 1(b) shows the proposed SINPC inverter for reduced common mode voltage at improved modulation Technique. L_{1a}, L_{1b},L_{2a},L_{2b},L_{3a} and L_{3b} are the split inductors in Fig.1(b).

From the figure, we can express the common mode voltage in mathematical form. The instantaneous common mode voltage -

$$V_{CM} = \frac{V_{ao} + V_{bo} + V_{co}}{3} \tag{1}$$

Where V_{ao},V_{bo},V_{co} are the instantaneous leg voltages of the inverter.

This varying common mode voltage creates a leakage current which flows through the capacitive element in a transformer less PV systems. For equal inductance, the magnitude of the leakage current is calculated as follows-

$$I_{leakagecurrent} = \frac{V_{CM}}{Z} \tag{2}$$

Where Z is the combined impedance of C_{PV} and equivalent inductance of the circuit. The equivalent common mode model is described in[3].

III. Improved Modulation Technique

A very common SVM technique for three-level NPC inverter generates 27 switching states which is illustrated in Fig 3 and sum up at TABLE I [4]. In the table, a three digit number represents the switching stages of leg a, b and c. "0" means two upper switches of the leg is tuned off , "-1" means two lower switches are turned off, and "1" means first upper switch and last lower switch is off. It is evident from the table that, applying these vector generates $\pm V_{dc}/6$, $\pm V_{dc}/3$, $\pm V_{dc}/2$,0 common mode voltage which is varying in nature. The switching vectors which have been divided in to six two-level hexagons is shown in Fig 3.It is interesting in hexagon's figure that in each sector two or three vectors generating the same reference vector but leads to different common mode voltage. Like, $\pm V_{dc}/2(V_{14},V_{16},V_{22},V_4,V_{10},V_{12})$ or $\pm V_{dc}/3(V_1,V_3,V_9,V_{17},V_{23},V_{25})$ are the two vectors set creating the same reference vector but generating different common mode voltage. In order to minimize the variation in common mode voltage, we used the first switching vectors set in switching pattern. In addition to that V_0, V_{26} are the Zero switching vectors which produce $\pm V_{dc}/2$ common mode voltage but V_{13} is the another one which produce zero common mode voltage. We used V_{13} as zero switching vector. After eliminating these vectors, the six hexagon switching patterns now produce the common mode voltage only zero and $\pm V_{dc}/6$. So these help to reduce the variation of common mode voltage as well as leakage current. Now the switching patterns according to the improved modulation technique (which is discussed) are summarised in Fig.2 from Hex1 to Hex6.

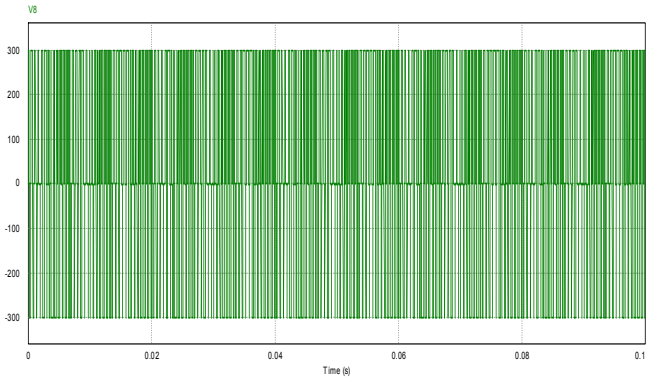
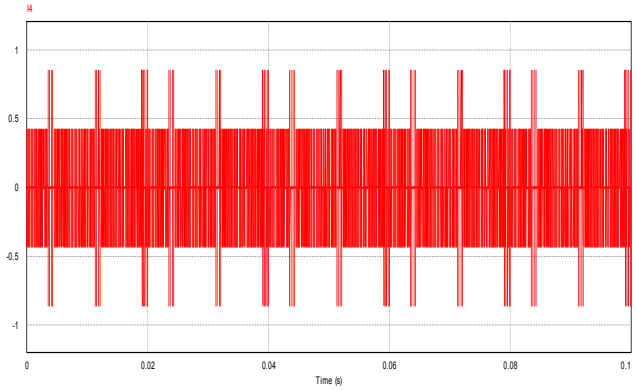
IV. Simulations and Performance Appraisal

In this section, conventional NPC inverter and proposed SINPC inverter are simulated to display the validation of the proposal of reducing Vcm and leakage current. The switching pulse for 12 individual MOSFETs of both circuits is generated according to the aforementioned improved modulation technique. The simulation parameters are, Input DC voltage=1200V, Split inductor= 4mH, Cpv=0.1uF, Output voltage frequency=50Hz. The PV array was simulated with a DC voltage source and the values of split inductors for three phases are considered equal. The simulated Vcm and leakage current curves for conventional NPC inverter are depicted in Fig.5. It exhibits that Vcm has peak to peak 600V



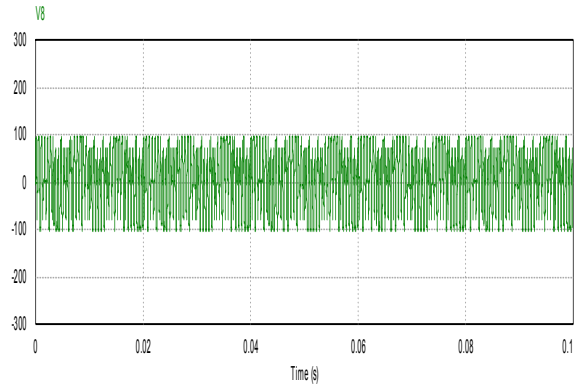
(a)



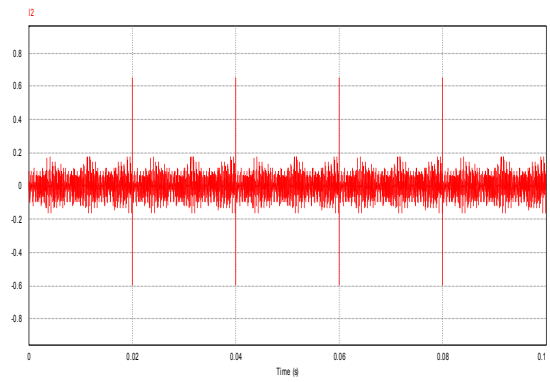
(b)

Fig.5 (a) Vcm of conventional NPC inverter (b) leakage Current

amplitude with large variation which is good enough to generate high leakage current. The measured leakage current through Cpv at this stage is 800mA. Similar analysis has been performed for SINPC inverter. Simulated results are presented in Fig.6 where it is noticed that the value of Vcm and leakage current reduced remarkably. Vcm falls down to 200V peak to peak where the leakage current becomes300mA. The comparison of the two curves validates the effectiveness of the proposed circuit. We have taken the output voltage wave shape across the load displayed in Fig.7(a). The FFT analysis of the proposed SINPC inverter and conventional NPC inverter has shown in Fig.7(b) and Fig.7(c) respectively. It is evident from the figure that SINPC inverter generates less harmonics (THD 0.176%) compare to conventional NPC inverter (1.23%)



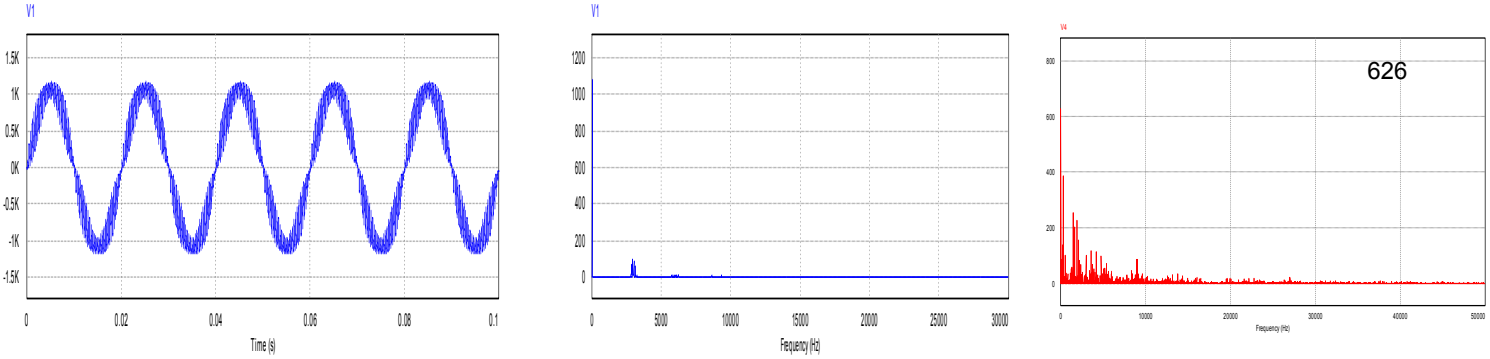
(a)



(b)

Fig.6 (a) Vcm of SINPC inverter (b) Leakage current

In the proposed SINPC Inverter,the value of split inductor is a pivotal parameter to reduce the Vcm and leakage current.So,we have measured the Vcm and leakage current by



(a) (b) (c)

Fig. 7 (a) Output voltage of SINPC inverter (b) FFT analysis of output voltage of SINPC inverter (c) FFT analysis of conventional NPC inverter

varying the split inductor value which is demonstrated in Fig.8 , Fig.9 and also sum up in TABLE II. It exhibits that the higher value of split inductor generates lower Vcm as well as lower leakage current. But larger values of split inductors will increase the overall inverter size, weight and loss. So we need to obtain an optimum value of split inductors which will be discussed elsewhere.

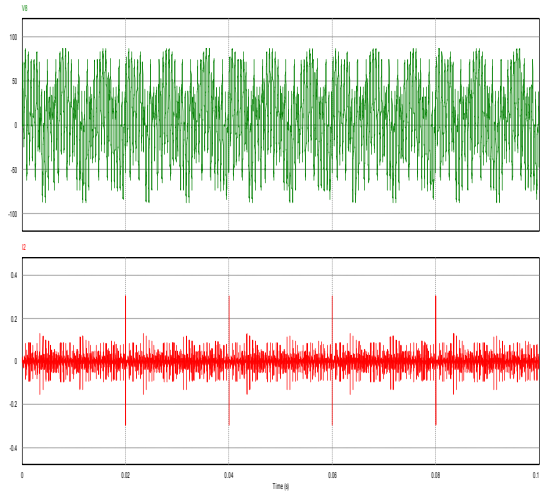


Fig. 8 Vcm and Leakage Current for 10mH Split Inductor

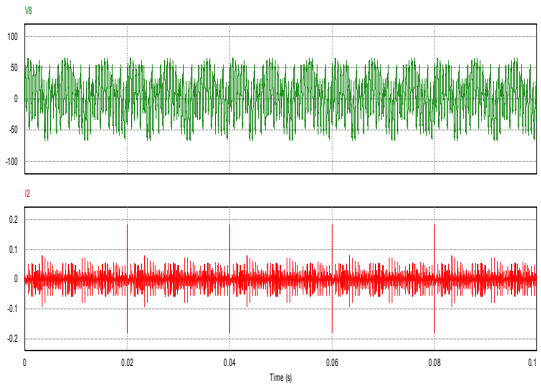

Fig. 9 Vcm and Leakage Current for 20mH Split Inductor

TABLE II. VCM AND LEAKAGE CURRENT VARIATION WITH SPLIT INDUCTANCE

Split Inductor Value	Common Mode Voltage (peak to peak)	Leakage Current (peak to peak)
4mH	200V(almost)	300mA(almost)
10mH	160V(almost)	200mA(almost)
20mH	120V(almost)	120mA(almost)

V. CONCLUSIONS

Variable common mode voltage Vcm as well as leakage current reduction strategy has been proposed in this paper. Based on the previous analysis we have observed that, Vcm usually depends upon the modulation technique and circuitry configuration. So we have applied a new modulation technique in a new split inductor based NPC inverter. Our analysis shows that due to the use of split inductors, the Vcm and leakage current reduce comprehensively compare to the conventional NPC inverter. The simulation shows that the new SINPC inverter also generates less higher order harmonics. So where the system is burdened with varying Vcm or leakage current problem, SINPC inverter with this improved modulation technique can resolve it adroitly.

*ymdsalahu2@gmail.com

Abstract—**This paper demonstrates the lightning surge response of a reduced scale four parallel vertical conductor model of tower for power systems including the effects of ground plane and without ground plane. Tower surge responses are analysed using Numerical Electromagnetic Code (NEC-2). Different types of model tower configuration are considered to determine, which will provide suitable structure of tower design for lightning. Besides, voltage, current and surge impedance are also evaluated to observe the lighting phenomena for the design of protective equipments so save our daily used sophisticated electronic equipments.**

Index Terms— **Lightning Surge, Method of Moment (MoM), Surge Impedance, Vertical Conductor, NEC-2.**

I. Introduction

Lightning is one of the most significant sources of overvoltages in overhead transmission lines. Transmission line faults caused by lightning strikes give serious damages, such as a massive blackout and instant voltage drop, on electric power systems. Therefore, the rational lightning protection measures should be adopted for ensuring a stable electric power system. Analysis of lightning surges is important for power systems, since lightning strokes on transmission towers, shield wires and phase conductors may cause insulation flashover which may lead interruption of continuous power transmission.

Several studies on surge analysis of the transmission lines have been carried out to evaluate the effect of the lightning protection measures and to estimate the lightning outrage rates [1]-[3] There are many works that have been devoted to the analysis of lightning surges on transmission towers. Experimental studies on this subject have usually been carried out in Japan and measured results have become an important base for computer simulations [4]. In experimental work done by Kawai surge response of transmission tower has been measured [1]. Later Ishii performed experiments on a full scale tower with phase conductors and ground wires [2] and as a result of these experiments a multistory tower model has been proposed for multiconductor analysis in EMTP. Series of experiments later have been continued on a different tower configuration [3] [4] to generalize the results obtained in previous works. On the other hand, in the area of numerical developments, Almeida and Correia De Barros [5] used finite element method for the EMTP simulation. Later Ishii and Baba [6] analyzed a large scale UHV transmission tower using moment method by solving electric field equations directly, and in their study the effect of slant elements, horizontal elements and crossarm has been investigated. Using the same method, they also investigated lightning surge characteristics of a transmission line comprising a tower, a shield wire and phase conductors with the help of computer program NEC-2 [7]. Next, in one of the works tower body and crossarms are modeled in details using short lines sections [8]. Recently, Mozumi et al. analyzed archorn voltages of a simulated 500 kV twin-circuit line [9]. In this paper, lightning surges on reduced scale four parallel conductor model a transmission tower are analysed using the numerical solution of the electric field integral equations used in NEC-2 are obtained.

For the present analysis, the (NEC-2) is employed. It is a widely used three-dimensional (3-D) electromagnetic modelling code based on the MoM in the frequency domain, and is particularly effective in analyzing the electromagnetic response of antennas or of other metallic structures composed of thin wires. A vertical conductor system needs to be decomposed into thin wire elements, and the position, orientation and the radius of each element constitute the input data, along with the description of the source and frequency to be analysed. In the analysis, all the elements in the systems are treated as perfect conductors. To solve the time varying electromagnetic response, Fourier transform and inverse Fourier transform are used. The study in this paper precedes the work done to obtain the surge characteristics of reduced scale model of tower struck by lightning with the help of NEC-2 in case of direct and indirect stroke.

II. Theoretical Formula of Surge Impedance

There is a theoretical formula of surge impedance [10] of a vertical conductor, in case with ground plane and without ground plane. Suppose that lightning surge strike on the vertical conductor whose height is h and radius is r. Then the surge current wave is reflected at the ground of the perfect conductor and returns to the top of the vertical conductor. Introducing the current reflectivity $\beta = 1$ and the magnetic field reflectivity $\gamma(\gamma_i, \gamma_r) = 0$, the theoretical formula of surge impedance which is very close to the well-known empirical formula of Dr. Hara, is obtained as follows:

$$Z = 60\left\{ln\left(\frac{h}{2r}\right) - \frac{1}{4}\right\} = 60\left\{ln\left(\frac{2\sqrt{2}\,h}{r}\right) - 1.983\right\} \quad (1)$$

Equation (1) gives the surge impedance of the vertical conductor just after the occurrence of the reflection of the traveling wave propagation down from the top of the structure. However if it is considered that $\beta = \gamma_i = \gamma_r = 1$, the potential $V(t)$ generated in the vertical conductor at h became,

$$V(t) = \frac{c\mu_0 I_0}{2\pi}\left\{ln\frac{(ct + 2r)}{2r} - \frac{ct}{2(ct + r)}\right\}$$

The above equation can be modified by substituting $ct = 2h$, where c is the velocity of light and assuming $h \gg r$ as follows:

$$Z = 60\left\{ln\left(\frac{h}{r}\right) - \frac{1}{2}\right\} = 60\left\{ln\left(\frac{2\sqrt{2}\,h}{r}\right) - 1.540\right\} \quad (2)$$

On the other hand, if there is no ground, the following formula is induced

$$V(t) = \int_0^{ct} (-E_i.dl) = \frac{c\mu_0 I_0}{2\pi}\left\{ln\frac{(ct+2r)}{2r} - \frac{ct}{2(ct+r)}\right\}$$

Substituting $ct = 2h$ and assuming $h \gg r$ in the above equation, we get

$$Z = 60\left\{ln\left(\frac{h}{r}\right) - \frac{1}{2}\right\} = 60\left\{ln\left(\frac{2\sqrt{2}\,h}{r}\right) - 1.540\right\} \quad (3)$$

This formula given by equation (2) is the same as equation (3). This is suitable for calculating the value of surge impedance single vertical conductor in case of with and without ground plane.

III. Surge Simulation of Reduced Scale Model

Lightning is responsible for severe electromagnetic stress in electric and electronic systems that frequently result in damages or operational outages. The evaluation of such a stress is very important for lightning protection. So in this research, lightning surge response for four parallel conductor model as reduced scale model of transmission tower has been taken into account. The surge impedance obtained from four parallel conductors is analyzed for both cases with ground plane and without ground plane.

Fig.1 shows the structures subjected to analysis. The single vertical conductor is shown in Fig. 1(a). The four parallel vertical conductor's model of a tower is shown in Fig.1 (b), which has a radius of 16.5 mm and 404 mm apart. A steep-front current having a rise time of 5 ns was injected into a current lead wire as shown in Fig.2. In Fig.2 the injected ramp also compared with the computed current at the input terminal. For the numerical analysis, the conductor system needs to be modeled with segments according to the modeling guidelines stated in the preceding chapter. It is not difficult to satisfy recommended conditions except the following one: $0.001\lambda < \Delta L < 0.1\lambda$ This requirement is too severe to be satisfied exactly, since the wider frequency range is needed here to investigate the transient characteristics of such a system. However the author found the following condition yielding reasonable computation results by trial and error process. Frequency range: 1.5625 MHz to 0.8000 GHz with 1.5625 MHz increment step and Segment length: 0.202 m to 0.300 m. This frequency range corresponds to the time range of 0 to 640ns with 1.25ns Increments.

A. *With Ground Plane*

The following Fig.3 shows the arrangement of the four parallel conductor's models to be analysed with ground case. To evaluate the voltage of the top of a structure, 10-kΩ resistance was inserted between the top of a structure and the end of the voltage measuring wire and the waveform of the current flowing through the resistance was calculated. The system of structures under the numerical analysis was postulated to be on the perfectly conducting ground. This postulation is used throughout in this thesis. Fig.4 shows the computed waveforms of the voltage and the current at the top of the four parallel conductors

If a travelling wave propagates along the tower at the velocity of light the reflected wave from the ground should return to the tower top after the round-trip time of a travelling

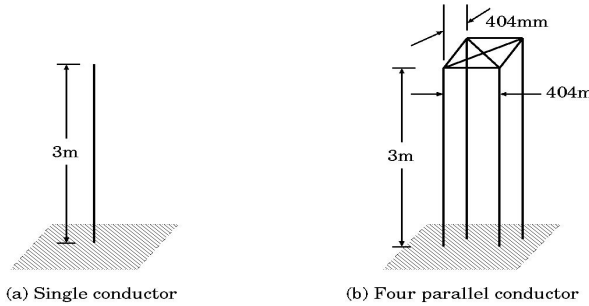

Fig.1 Structure subjected to analysis

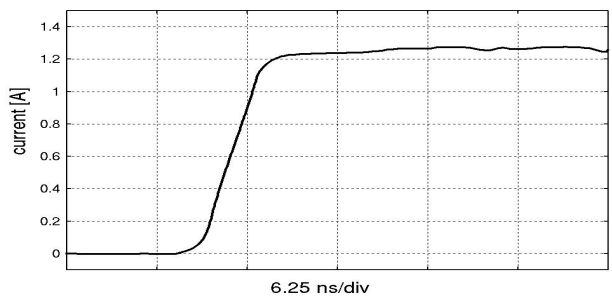
(a) Voltage waveform



(b) current waveform

Fig.4 NEC-2 results of voltage at the top and current waveforms of the four parallel conductors with ground plane case.

return to the tower top after the round-trip time of a travelling wave in the tower which is 20 ns for this structure as shown in Fig.3. But form the computed result it is seen that voltage waveforms reach their peaks about 17 ns after the beginning which indicates that a negative voltage wave arrives at the top before the arrival of the reflected wave from the ground.

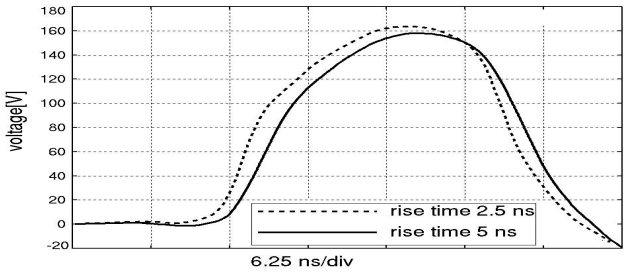


Fig.5 NEC-2 results of voltage waveforms at the top of the four parallel conductors with ground plane case for different rise time.

This phenomenon is due to the electromagnetic field of TEM mode illuminating the structure, i.e., the electromagnetic wave associated with a travelling wave in the current lead wire arrives at the structure foot simultaneously with the arrival at the top of a structure and a negative voltage wave is induced at the structure foot before the occurrence of the reflection of the travelling wave propagating down from the top of the structure. This induced wave is observed in the current waveform as shown in Fig.4 (b).

The analysis was carried out for different rise time as shown in Fig.5, which were 5 ns and 2.5 ns respectively. From the output it is seen that for small rise time the voltage of the structure at the top reaches the peak value earlier than other.

B. *Without Ground Plane*

The following Fig.6 (a), (b) and (c) show the arrangement of the four parallel conductor model to be analyzed without ground cases. On the other hand from numerical analysis by NEC-2 the computed waveforms of the voltage and the current at the top of the four parallel conductors are obtained as shown in Figs.7, 8 and 9. The rise time was set to be 5 ns as shown in the following Figs. In Fig.7 and 8, the voltage waveform rises exponentially and reaches their peak after 21 ns, which shows that in this case the electromagnetic wave propagates along the conductor with the velocity of light. Then it decreases downward as the reflection comes from the ground. But in Fig.9 the voltage waveform rises abnormally and reaches its peak after 25 ns, which is not similar to the other cases. As the output for structure of Figs.6 (a) and (b) show the characteristics like single vertical conductor so this structure is suitable for analysis and design. On the other hand, structure of Fig.6(c) is not suitable for design purposes.

IV. Surge Impedance of the Simulated Model

The tower surge impedances are defined as the ratio of the instantaneous values of the voltage to the current at the moment of voltage peak. The computed tower surge impedance's using NEC-2 is summarized in TABLE I.

The difference of the surge impedance's depends on the arrangement that can be explained by the electric field associated with the steep-front currents flowing in the current lead wire, the voltage measuring wire or earth wire and the vertical conductor or tower. With vertically applied input or without ground plane case, the positive surge current from the pulse generator flowing into the vertical conductor and the negative current propagating up the vertical current lead wire produce the strong upward electric field. This makes the injected current split more into the voltage measuring wire and less into the vertical conductor. On the other hand, a strong horizontal electric field is produced by the negative current into the horizontal current lead wire. This makes the

V. CONCLUSIONS

The surge characteristics obtained in this research are most likely to be the same as electromagnetic phenomena of lightning. These results can be used to estimate the tower surge impedance of the standard arrangement with a vertical current lead wire and horizontal voltage measuring wire as well as with ground plane in case of four parallel vertical conductor models. From the analysis Figs.6 (a) and 6 (b) as the models are recommended. This analysis will help us to configure the structure of control building and high tech building when highly sophisticated instruments and electronic equipments are installed.

Aberrant Amplification of Torsional Oscillating Torques in Turbine-Generator Shaft Due to Multiple EAF Operation

Md. Minarul Islam*, A. Hasib Chowdhury
Department of EEE, Bangladesh University of Engineering and Technology
Dhaka-1205, Bangladesh
*minarbuet@gmail.com

Abstract-**Electric arc furnace (EAF) acts as a source of sub-synchronous frequencies (SSFs) in the electrical network. If these SSFs lead to resonance, respective matched torsional modes of turbine-generator (T-G) shaft are excited causing torsional oscillating torques (TOTs) amplification. This may lead to gear damage, shaft fatigue lifetime reduction, severe damages to T-G shaft. This paper presents an assessment of TOTs amplification due to multiple EAF operations at the same PCC. The EAFs have been modeled using mathematical model of the electric arc, where resistances of EAFs varied deterministically in frequency range of 1.2-45.5 Hz to comport with realistic EAF. TOTs have been measured with/without resonant excitation of torsional modes. Eigenvalue analysis and FFT technique have been used to analyse torsional torques.**

Index Terms- **Electric arc furnace, sub-synchronous resonance, torsional oscillating torques, shaft fatigue**

I. Introduction

The dominant frequencies of torsional oscillating torques (TOTs) among masses of turbine-generator (T-G) shaft are in subsynchronous range [1]. Among the electrical loads, electric arc furnace (EAF) comports as a blatant source of subsynchronous frequencies (SSFs) [2]-[5] and may induce pulsating components in the air-gap torque of synchronous machine through which TOTs are amplified during torsional resonance (TR). The consequential torsional stress on T-G unit depends on EAF actions and how it is connected to grid, characteristics of T-G and utility power system.

Higher frequency components in air-gap torque have dominant effects on smaller components such as turbine blades and lower frequency components stimulate the TOTs in main shaft sections [6]. The random property of arc melting process and control system contribute to thermal and electrical dynamics which may affect supply system adversely [7]. In [8], Robert et el. discussed unusual power oscillations which were observed at two power plants located near large EAF.

Torsional amplification can lead to gear damage, shaft fatigue lifetime reduction, severe damages to T-G shaft [2]. Although the shaft could withstand most severe impact due to three-phase fault, it still can not guarantee long-term safety operations even under normal operating conditions if there occurs TR [3]. Mechanical failures have been consistently reported due to machine air-gap torques supplied by PWM drives [2]. The first and second T-G shafts failure due to subsynchronous resonance (SSR) were experienced at the Mohave plant in sourthern California [9].

Evidently, the impact on the torsional torque due to operation of multiple numbers of EAFs at same point of common coupling (PCC) or at close electrical proximity has not been reported in details yet. This paper presents an assessment of TOTs amplification and find out its severity due to operation of multiple EAFs at the same PCC.

II. Component Modeling

The major components such as EAF and air-gap torque of synchronous generator is presented in this section.

A. Electric Arc Furnace

A precise model for three-phase EAF is required to analyse its characteristics including SSFs. Due to nonstationary stochastic characteristics of steel making process using electric arc, it is very difficult to model EAF load appropriately. Furthermore, there are many external factors such as melting stage, scrap materials, electrode position, electrode arm control, the supply system voltage and impedance, which affect operation of EAF [10]. It is therefore desired to include all these factors in designing a model which can resemble realistic EAF. Hence, a dynamic model based on the principle of energy conservation of electric arc [11] has been considered for this simulation. The relationships between supplied current to furnace lead, i, arc radius, r, and arc voltage, v, can be expressed by the following equations:

$$C_1 r^n + C_2 r \frac{dr}{dt} = \frac{C_3}{r^{m+2}} i^2 \quad (1)$$

$$v = \frac{C_3}{r^{m+2}} i \quad (2)$$

Where C_1, C_2, C_3 are constants.

Fig. 1 shows V-I characteristic of electric arc which has been obtained by MATLAB simulation using equations (1) and (2), and this resembles to characteristic of realistic EAF.

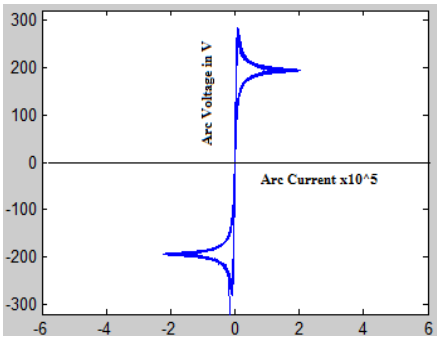

Fig. 1. Simulated V-I characteristic

Fig. 2 shows the simulation output of current waveform in phase-a at the primary side of furnace transformer. The waveform is modulated which can be expressed by the following equation.

$$i_a(t) = \sqrt{2} I_{rms} [1 + \sum I_n \sin(2\pi f_n t + \phi_n)] \sin(2\pi f_s t + \beta) \quad (3)$$

where, f_s is system fundamental frequency, I_n and f_n are amplitude and frequency of modulating current, and β is angle between feeder voltage and current.

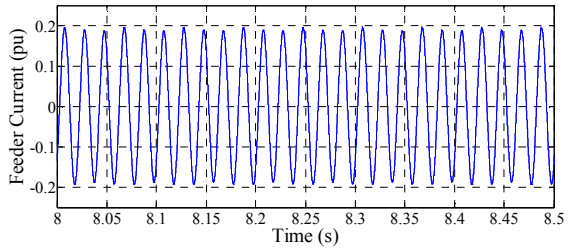

Fig. 2. Feeder current i_a at the primary side of furnace transformer

The frequency spectrum of the modulating current gives f_s+f_n and f_s-f_n, which are defined as super- and sub-synchronous frequencies, respectively. This current may disturb generator stator current which cause perturbation in air-gap torque. If SSR occurs, a large subsynchronous current may result from a small voltage induced by rotor oscillations. A rotor torque corresponding to this current enhances the rotor oscillation. If this torque become larger than mechanical damping, the coupled electromechanical system will experience increasing oscillations.

A. Air-Gap Torque of Synchronous Generator

The air-gap torque of synchronous generator, in *dq0* reference frame, can be expressed by the following equation.

$$T_e = \psi_d i_q - \psi_q i_d \tag{4}$$

where, $i_d = f(i_a, i_b, i_c)$, $i_q = f(i_a, i_b, i_c)$, $\psi_d = f(i_d, i_{fd}, i_{kd}, L)$, $\psi_q = f(i_q, i_{kq}, L)$, L includes leakage, self and mutual inductances. So it is seen that the air-gap torque is function of *dq*-axis flux linkages and currents. At synchronous operation, *dq*-axis parameters appeares as constant i.e. no change in T_e. But if there are any changes or disturbances in those parameters, T_e will be disturbed resulting in perturbation in TOTs.

III. Assessment of Torsional Mode Amplification

A test system consisting of steam turbine driven generator connected to an infinite bus and EAFs has been used for simulations (Fig. 3). In this paper, both single and multiple EAF operation has been considered. The T-G shaft consists of five masses: high presure (HP), intermediate presure (IP), and two low presure (LP_A and LP_B) turbine sections and the generator rotor section. The TOT signals are obtained by first using MATLAB Simulink. Torsional mode frequencies of the T-G system are then obatained by both, eigenvalue analysis of the system and FFT analysis of TOT signals.

B. Description of The Test System

The physical parameters of T-G shaft are given in [9]. The synchronous generator is rated as 3000 rpm, 2-pole, 24 kV, 555 MVA. A static exciter has been used with the generator. The electrical parameters in pu, based on rated value of the synchronous generator, are given in [9]. The generator is supplying power to the network via a step-up transformer (24kV/132kV, 555 MVA) through a transmission line of length 50 km. The 132 kV bus also supplies power to an EAF, located at 8 km distance from PCC, through a 132kV/24kV transformer.

Other transformers, one rated as 24kV/11kV, 200 MVA, three-phase and another rated as 11kV/.5kV, 50 MVA, 3 single phase units are also installed in furnace feeder line to step down voltage to furnace operating value. The impedances of the three-phase and single-phase transformers have been chosen as 0.008+j0.13 pu and 0.0006+j0.13 pu, respectively. Components of impedance- positive siquence: resistance (0.01165 ohm/km), inductance (0.8679 mH/km), capacitance (13.41 nF/km)-and zero sequence: resistance (0.2676 ohm/km), inductance (3.008 mH/km), capacitance (8.57 nF/km) have been used for transmission line.

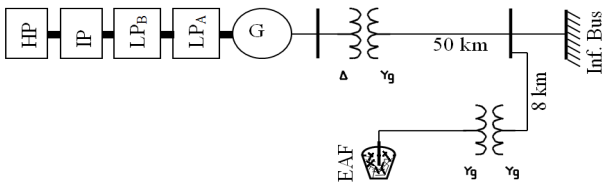

Fig. 3. Single line diagram of the test system

C. Determination of Torsional Mode Frequencies

The T-G system, shown in Fig. 3, can be represented by a simple lumped-mass model [9]. The equations of rotating motion of any rotor masses can be expressed by the following general formulae:

$$2H_j \frac{d\Delta\omega_j}{dt} = T_j + K_{j,j+1}(\delta_{j+1} - \delta_j) - K_{j-1,j}(\delta_j - \delta_{j-1}) - D_j(\Delta\omega_j) \tag{5}$$

$$\frac{d\delta_j}{dt} = \omega_0 \Delta\omega_j \tag{6}$$

where, j=1 to 5. $T_1 = -T_e$, $T_2 = T_{LPA}$, $T_3 = T_{LPB}$, $T_4 = T_{IP}$, $T_5 = T_{HP}$, H = mass inertia, K = rigidity coefficient, D = damping factor, ω = shaft speed, δ = rotor angle.

Equations (5) and (6) are linearized and expressed in state-space form for the eigenvalue analysis. For small disturbance, the change in electromagnetic torque can be expressed as $\Delta T_e = K_s \Delta\delta_1$, where K_s is the synchronizing torqe coefficient. The mechanical torques developed by the turbine section are assumed to be constant. Arranging the linearized equations in matrix from gives:

$$\begin{bmatrix} \Delta\dot{\omega}_i \\ \Delta\dot{\delta}_i \end{bmatrix} = \boldsymbol{A} \begin{bmatrix} \Delta\omega_i \\ \Delta\delta_i \end{bmatrix} \tag{7}$$

where $\boldsymbol{A}$ is the state matrix and function of H, D, K, K_s. The state variables are speed deviations $\Delta\omega_i$ and rotor angle deviation $\Delta\delta_i$, with i = 1 to 5. The eigenvalues of $\boldsymbol{A}$ are calculated. The imaginary part of eiginevalues gives the torsional mode frequency. Table I presents torsional modes and their frequencies.

TABLE I
Mode Frequencies and Torsional Modes

Eigenvalues λ	Mode Frequency (Hz)	Torsional Mode
$\lambda_{1,2}$ = -0.6931652 ± 285.44842383i	45.4	4
$\lambda_{3,4}$ = -0.5566807 ± 196.73304251i	31.3	3
$\lambda_{5,6}$ = -0.6441085 ± 156.21256768i	24.9	2
$\lambda_{7,8}$ = -0.3551595 ± 105.42518046i	16.8	1
$\lambda_{9,10}$ = -0.4069221 ± 3.4898816350i	0.55	0 (system mode)

As the T-G shaft has five masses, there are five modes of torsional oscillation. The mode frequencies are 0.55, 16.8, 24.9, 31.3 and 45.4 Hz. The mode frequencies can also be obtained from the FFT analysis of TOT signals as shown in Fig. 4. It is seen from Fig. 4 that the torsional mode frequencies are 1.2, 16.8, 24.9, 31.3, 45.4 Hz which are almost the same as obtained from eigenvalue analysis technique.

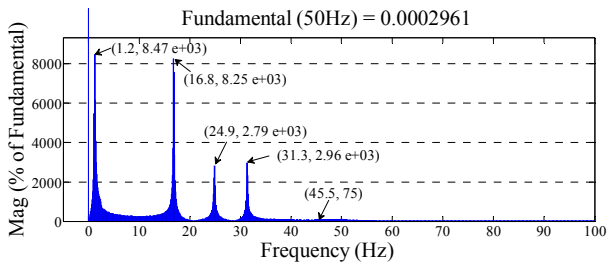

Fig. 4. FFT of torsional oscillating torque between generator and LP_A section

D. Simulation and Results

During the sinusoidal variation of arc resistance a 16.8 Hz signal along 60% modulation index is used simulation.

1)Arc Resistance and Voltage: Due to movement of electrodes and melting of scraps, the arc length changes which cause change in arc resistance. From Fig. 5 it is seen that arc voltage increases precipitately from its zero crossing point to arc ignition voltage, which signposts that the equivalent circuit of EAF comports as an open circuit.

A small leakage current flows through the foamy slag which presumed a constant high resistance implicated by the impulses in Fig. 5(a). When the arc is established, a transient process emerges in the voltage waveform at the beginning of arc melting process. The arc voltage drops exponentially from ignition voltage to a constant value. During arc established period, the electrodes and scraps are short circuited which results in almost zero resistance. After melting scraps the arc is extinguished and the arc voltage drops to arc extinction voltage.

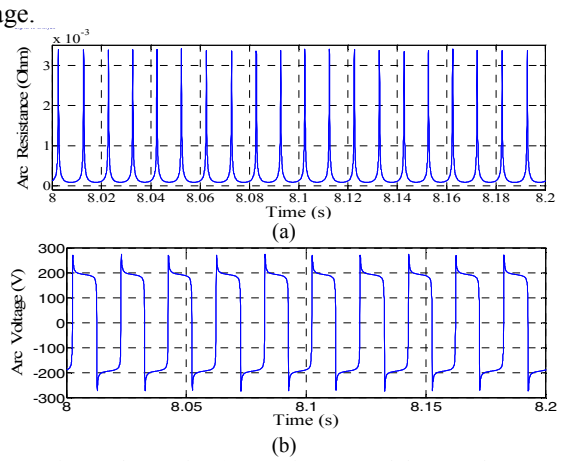

Fig. 5. Changes in (a) arc resistance, and (b) arc voltage

2)Feeder Current: The FFT of the feeder current, shown in Fig. 2, is presented in Fig. 6. It shows that the two frequencies 33.2 Hz and 66.8 Hz are present in feeder current waveforms. These frequencies are present because a 16.8 Hz signal was impregnated during resistance modulation.

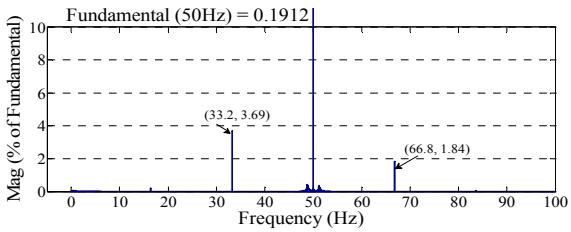

Fig. 6. FFT of i_a near furnace transformer

3) Analysis of Air-gap Torque: Fig. 7 shows air gap torques without/with resonance when there is EAF in the system. Fig. 7(a) shows a small variation of air-gap torque when there is no resonance. Fig. 7(b) shows amplification of this small variation of torque during resonance. This amplification is the result of perturbation of *d*-and *q*-axis current component due to operation of EAF in the system. The EAF produces a subsychronous current of frequency 16.8 Hz which perturb the air-gap torque.

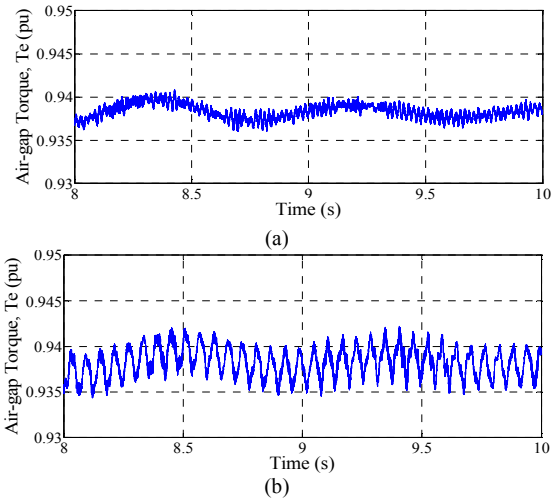

Fig. 7. Air-gap torque (T_e) (a) no resonance, (b) at resonance

4) Analysis of Torsional Torque Amplification: Fig. 8 shows the torsional torque transmission between generator and LP_A section of the turbine without/with resonance when there is an EAF in the power system. From Fig. 8(a), it is seen that the torsional torque reach to a steady value after 8 seconds of starting generator. But if the EAF produces any frequency equal or close to torsional mode frequency, the TOT between generator and LP_A mass is amplified as shown in Fig. 8(b).

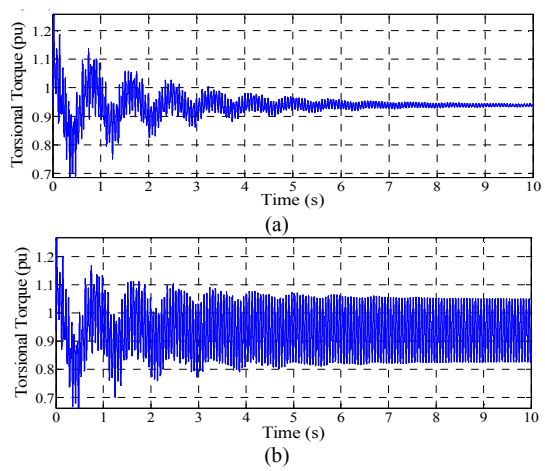

Fig. 8. Torsional torque (a) no resonance, (b) at resonance

E. Quantification of Torsional Torque

A paradigm of calculating amplified TOTs for a single EAF operation using FFT analysis has been expounded in Table II. Here, torque at 16.8 Hz resonance due to EAF has been compared with torque at non-resonance. It is seen that due to resonance, the TOT between generator and LP_A section of turbine is amplified by 4.57 times.

TABLE II
EXCITATION OF TORSIONAL MODE 1

Torque without EAF (pu)	Torque with EAF but resonance (pu)	Torque with EAF at resonance (pu)	Torque amplification
0.02443	a = 0.02533	b = 0.11569	b/a = 4.57

For the assessment of TOT amplification due to multiple EAF operation, for all EAFs, arc resistances have been adapted in such a way that the EAFs portray as current sources of frequencies in the range of 1.2-45.5 Hz, worst case conditions have been considered. TOT amplifications have been compared and shown in Fig. 9. For example, TOT amplification due to resonant excitation of two EAFs at same PCC is almost double to that of one EAF at PCC. As the number of EAFs increase at PCC there cause increased amplification of TOTs at T-G shaft.

Table III presents TOTs amplification with EAFs at PCC. It is seen that the average amplified TOT due to resonant excitation of mode 1 is 8.63 times of its non-resonant TOT. The average torque amplifications of mode 2, 3 and 4 are 12.3, 14.5 and 29.8 respectively. It seen that if one mode is excited it does not affect other modes.

The TOT amplifications due to one EAF at PCC have been compared with that of multiple EAFs at the same PCC in Table IV. From Table IV, it is seen that the TOT amplification, due to resonant excitation of two EAFs at same PCC, is almost double to that of one EAF at PCC. As the number of EAFs increase there cause increased amplification of TOTs.

	One	Two	Three	Four	Five
0	1.24	1.46	1.64	1.83	2.01
1	4.55	8.63	12.42	15.86	19.48
2	6.8	12.3	17.04	22.1	26.71
3	7.4	14.5	19.65	24.61	29.82
4	16.3	29.8	41.46	50.08	58.98

Fig. 9 shows average amplified TOTs (torque ratios resonant to norresonant) due to operation of multiple EAFs. From the trends of the graph in Fig. 9, the torque ratio of a torsional mode due to operation of any number of EAF at the same PCC can be approximated. For example, if N_{eaf}= 8, then the torque ratio corresponding to mode 3 can be calculated using equation as follows:

$$T_{ratio(m3)} = 0.1833N^3_{eaf} - 1.9336N^2_{eaf} + 11.523N_{eaf} - 2.354$$
$$= 0.1833\times8^3 - 1.9336\times8^2 + 11.523\times8 - 2.354 = 59.97$$

This value indicates that mode 3 will be amplified by 59.97 times of its non-resonant TOT if 8 EAFs are connected to the same PCC and mode 3 is excited. From the analysis, it is deducible that the more the EAFs added to the same PCC and if resonant excitation occurs, the larger the amplitude of oscillation of TOT occurs.

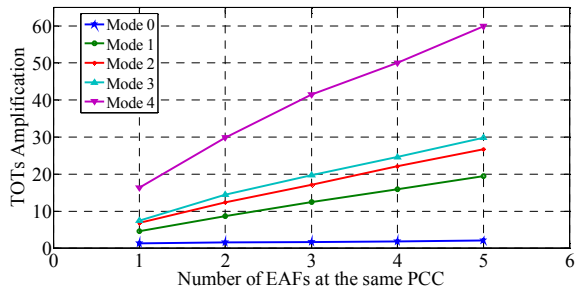

Fig. 9. TOTs amplification due to multiple EAFs at same PCC

IV. CONCLUSION

Subsynchronous frequencies engendered by EAF load stimulate torsional resonance in T-G shaft. Therefore, TOTs are amplified aberrantly which may induce abnormal torsional stress to the shaft system. It may reduce fatigue-life and even cause severe damages to T-G shaft. This paper presents a detailed assessment of impacts of multiple EAF operation at same PCC on nearby T-G system. It has been found that large amplification of TOTs occur when higher modes are excited. It has also been observed that the TOTs increase non-linearly to higher magnitude due to multiple EAF operation at the same PCC. During torsional excitation, TOTs absorb energy. Calculation of the amount of this energy and investigation of its source should be studied in future.

Vulnerable Operation of Turbine-Generator Due to EAF Loads in Bangladesh Power System

A. Hasib Chowdhury, Md. Minarul Islam*

Department of EEE, Bangladesh University of Engineering and Technology
Dhaka-1205, Bangladesh
*minarbuet@gmail.com

Abstract—**Steel mills in Bangladesh are concentrated in the Chittagong region. Some of these steel mills are installing electric arc furnace (EAF). EAFs generate sub-synchronous frequencies (SSFs) which may pose threat to nearby turbine-generator shaft by causing torsional resonance (TR). This paper presents an investigation into TR due to EAF operation in the Chittagong region of Bangladesh Power System (BPS). Multiple AC EAFs installed in two steel mills in close proximity has been considered. In the mathematical model of the EAF, electric arc resistances are varied deterministically in the frequency range of 1.2-45.5 Hz to meet the characteristics of realistic EAF. FFT technique has been used to find the torsional mode frequencies of the T-G shaft. Simulations show considerable TOTs amplification due to EAF operation. Simulations show possible T-G shaft damage in the Raozan and Shikalbaha power plants in the long run.**

Index Terms—**Electric Arc Furnace, Air-gap torque, Torsional resonance, Shaft fatigue, Bangladesh power system**

I. Introduction

The electric arc furnaces (EAF) may cause power quality problems in subsynchronous frequency (SSF) range, which is most prone to induce pulsating components in the air-gap torque of synchronous machine and through which the torsional oscillating torques (TOTs) are amplified during torsional resonance (TR) [1]-[4]. The TR imposes considerable stress on turbine shaft and blades [2]. The magnitude of torsional resonance depends on the proximity of stimulating frequency and natural frequency, on the magnitude and duration of the excitation and on the damping of the excited natural mode. Higher frequency components in air-gap torque have dominant effects on small components such as turbine blades and lower frequency components stimulate the TOTs in the main shaft sections [5]. Furthermore, unbalanced currents produced from EAF can contribute to generator rotor heating [3], [4].

TOTs amplification can lead to gear damage, shaft fatigue lifetime reduction, severe damages to turbine-generator (T-G) shaft [1]. The first and second T-G shafts failure due to TR were experienced at the Mohave plant in sourthern California [7]. Hence, interaction among EAF, other rotating electrical loads and T-G unit needs to be investigated with great importance.

Steel mills in Bangladesh are installing EAFs for better quality and larger quantity of steel production. The impact of steel mills, operation with EAF loads, on generating unit in Bangladesh Power System (BPS) has not been studied in details and reported yet. This paper presents the assessment of the impact of EAF operation on multi-stage T-G shaft in the Chittagong region of BPS. The TOT amplifications are quantified and its severity due to operation of additional EAFs are calculated.

II. Component Modelling

The major components such as electric arc furnace and air-gap torque of synchronous generator are modeled in this section.

A. Electric Arc Furnace

A precise model for three-phase arc furnace is required to analyse its characteristics. Because of its unpredictatable characteristics, it is very difficult to model EAF load appropriately. Different EAF models are available [8]-[9] and among them a dynamic model based on the principle of energy conservation of electric arc has been considered for the simulation of EAF. This model, described in [9], is expressed by equations (1) and (2), where i is EAF load current, v is arc voltage, r is arc radius, and C_1, C_2, C_3 are constants.

$$C_1 r^n + C_2 r \frac{dr}{dt} = \frac{C_3}{r^{m+2}} i^2 \tag{1}$$

$$v = \frac{C_3}{r^{m+2}} i \tag{2}$$

Fig. 1 shows the simulation output of current waveform in phase-a at the primary side of the furnace transformer. The waveform is modulated and can be expressed by,

$$i_a(t) = \sqrt{2} I_{rms}[1 + \sum I_n \sin(2\pi f_n t + \phi_n)]\sin(2\pi f_s t + \beta) \tag{3}$$

where, f_s is system fundamental frequency, I_n is amplitude of modulating current, f_n is frequency of the modulating current, β is angle between EAF feeder voltage and current. The frequency f_n could randomly spread all over the subsynchronous range. The frequency spectrum of the current gives f_s+f_n and f_s-f_n, which are defined as super and SSFs respectively. These frequencies spread all over the network. Hence an EAF can be considered as current source with SSFs. This current may disturb the stator current that may cause perturbation in generator air-gap torque.

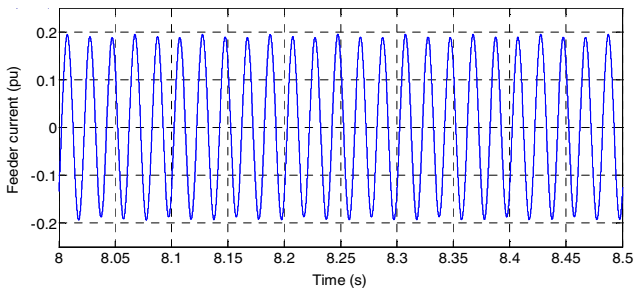

Fig. 1. Feeder current i_a at the primary side of furnace transformer

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

B. Air-Gap Torque of Synchronous Generator

The air-gap torque of synchronous generator, in *dq0* reference frame, can be expressed by equation (4).

$$T_e = \psi_d i_q - \psi_q i_d \tag{4}$$

where,

$$i_d = f(i_a, i_b, i_c)$$
$$i_q = f(i_a, i_b, i_c)$$
$$\psi_d = f(i_d, i_{fd}, i_{kd}, L)$$
$$\psi_q = f(i_q, i_{kq}, L)$$

L includes leakage, self and mutual inductances. Hence, air-gap torque is function of *dq*-axis flux linkages and currents. At synchronous operation, *dq*-axis parameters appeares as constant and results in no change in T_e. But if there are any changes or disturbances in those parameters, T_e will be disturbed which will result in perturbation in TOTs.

III. Application Area In BPS

A. Steel Mills in Chittagong

There are many steel mills in Chittagong region listed in Table I with their electrical load capacity. It is seen that three steel mills are using EAFs. Among them, BSRM and MKSBSL are using AC EAFs. To see the impacts on T-G shaft, two AC EAFs have been modeled for simulation. BSRM closer to Raozan power plant, is connected to grid at Hathazari bus and MKSBSL closer to Sikalbaha power plant, is connected to grid at Modern bus.

TABLE I
List Of Steel Mills In Chittagong Region

Steel mill name	Voltage level at PCC (kV)	Furnace type	Furnace load (MW)
H-steel	132	Induction + ladle	33
Sitalpur	132	Induction	10
BSRM	230	EAF + Ladle	87+19
MKSBSL	132	EAF + Ladle	13.6
Abul Khair	230	DC EAF + Ladle	140 + 24
Modern	132	Induction	30

B. Description of BPS Application Area

Fig. 2 shows the BPS grid network in the Chittagong region. There are three large power stations, namely Kaptai Hydro, Raozan Steam Turbine and Sikalbaha Steam and Gas Turbine Power Plants. Following assumptions/simplification have been made for the simulation.

- Two generating units at Raozan considered as a single unit of equal capacity.
- Two units at Sikalbaha considered as a single unit of equal capacity.
- Five units at Kaptai considered as one equivalent unit of equal capacity. Since impact of SSF in the slow speed water turbine is nominal, no investigation is carried out for these units.
- The physical parameters, *H*, *K* and *D* of T-G units, shown in Table II, are taken from different sources and IEEE(R) benchmark for SSR study [11].
- Five stages, HP, IP, LP_B, LP_A and generator, are considered for generating units at Raozan and Sikalbaha.
- Fixed excitation is considered for steam T-G units and controlled excitation is considered for hydro-T-G units.

IV. SIMULATION RESULTS

The impact of EAF loads on generating units at Raozan and Sikalbaha power plants have been investigated. For the purpose of analysis, EAFs have been considered to produce SSFs equal to torsional mode frequencies.

A. Torsional Mode Frequencies of T-G Shaft

FFT has been used to compute modes and its frequencies of TOT signals. As an example, FFT of torque signals between IP-HP section has been shown in Fig. 3 from which it is seen that the torsional mode frequencies are 14, 20.7, 26.1 and 37.9 Hz which are termed as mode 1, 2, 3 and 4 respectively.

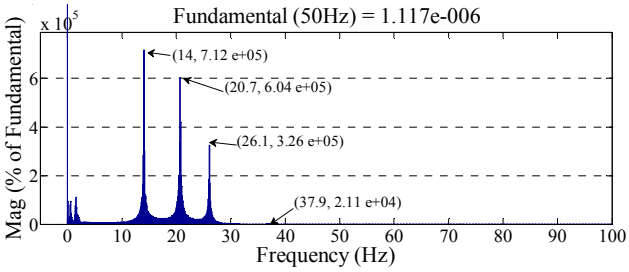

Fig. 3. FFT of torsional torque between IP-HP section in Raozan plant

B. Air-gap Torque

Fig. 4 shows FFTs of air-gap torque with EAF in the system. If the SSFs present in air-gap torque match frequencies of torsional mode, TOTs will be amplified. For the impact analysis, signals of SSFs such as 14, 20.7, 26.1 Hz have been generated by EAFs. Fig. 4 shows the presence of those frequencies in the air-gap torque.

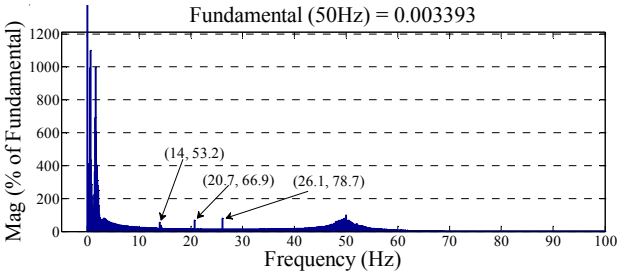

Fig. 4. FFT of air-gap torque with EAF in the system

C. Torsional Torques

Resonant excitation of torsional modes and the amplification of TOTs in the IP-HP section at Raozan and Shikalbaha plants are presented. Figs. 5(a) and 6(a) show that torsional torque transmitted between IP-HP sections of T-G shaft, when EAFs cause no TR, reach an almost steady value after some time of starting generator. On the other hand, Figs. 5(b) and 6(b) show the transmitted torque between IP-HP sections when EAFs cause TR. It is seen that amplitudes of TOTs are amplified abberently and that amplification at Raozan plant is greater than that at Shikalbaha plant. TOTs amplifiation in other sections of the T-G shaft show the same characteristics.

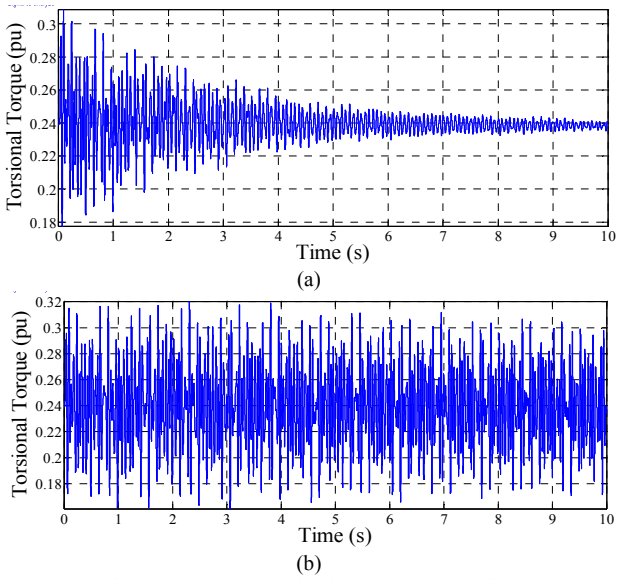

Fig. 5. Torsional torque in IP-HP section in Raozan power plant (a) no resonance (b) at resonance

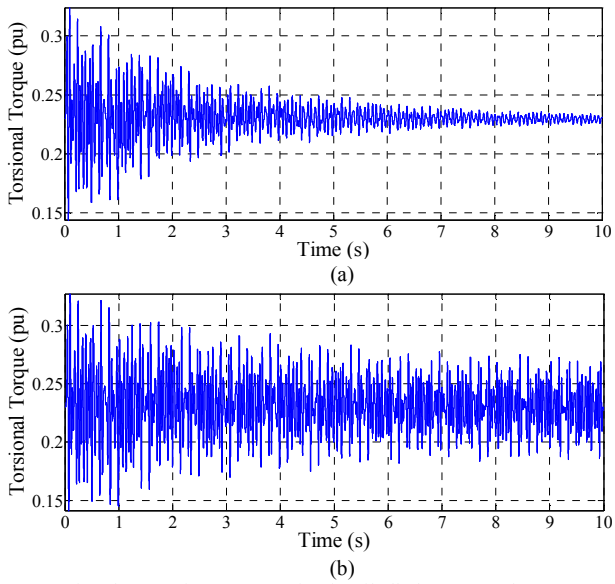

Fig. 6. Torsional torque in IP-HP section in Sikalbaha power plant (a) no resonance (b) at resonance

V. QUANTIFICATION OF TORSIONAL TORQUE

A. Torque Amplification with Existing EAFs

Magnitude of torsional torques have been quantified using FFT of TOT signals. Then, torsional torques at resonance have been compared with that of torques at nonresonance. Table VI and VII show the amount of torsional torque amplification due to TR at Raozan and Sikalbaha plants, respectively.

TABLE VI
TOTS AMPLIFICATION IN RAOZAN PLANT WITH EXISTING EAFS

Mode / Torque ratio between sections	0	1	2	3	4
HP-IP	.999	2.75	4.26	5.20	.923
IP-LP_B	1.00	2.75	4.26	5.21	.936
LP_B-LP_A	.998	2.76	4.16	5.21	1.34
LP_A-Gen	.999	2.75	4.26	5.19	.779

TABLE VII
TOTs AMPLIFICATION IN SIKALBAHA WITH EXISTING EAFs

Mode / Torque ratio between sections	0	1	2	3	4
HP-IP	.998	2.35	2.52	2.54	1.02
IP-LP_B	1.00	2.35	2.52	2.53	.778
LP_B-LP_A	.996	2.35	2.47	2.55	1.37
LP_A-Gen	.996	2.35	2.52	2.54	.262

From Table VI, it is seen, for example, that the amount of average amplified TOT due to resonant excitation of mode 2 is 4.26 times of its non-resonant TOT. From Table VII, it is seen that mode 2 is amplified, on an average, 2.52 times of its non-resonant value.

B. Torque Amplification with Additional EAFs

Considering future installations, four AC EAFs of equal capacity (100 MVA each) with similar characteristics have been assumed to be connected to the grid of BPS-Chittagong region: one at Abul Khair, one at Modern and the other two at Khulsi grid. TOTs at resonance are compared with that at nonresonance. Table VIII and IX show the amount of TOT amplification due to TR at Raozan and Sikalbaha plants, respectively.

TABLE VIII
TOTS AMPLIFICATION IN RAOZAN POWER PLANT WITH ADDITIONAL EAFS

Mode / Torque ratio between sections	0	1	2	3	4
HP-IP	1.0	5.74	8.66	10	1.09
IP-LP_B	1.0	5.83	8.70	10	1.13
LP_B-LP_A	1.0	5.81	8.43	10	2.44
LP_A-Gen	1.0	5.79	8.64	9.98	2.77

TABLE IX
TOTs AMPLIFICATION IN SIKALBAHA WITH ADDITIONAL EAFs

Mode / Torque ratio between sections	0	1	2	3	4
HP-IP	1.01	5.98	8.41	10	1.14
IP-LP_B	1.0	5.97	8.40	10	1.11
LP_B-LP_A	1.0	5.98	8.35	10	2.11
LP_A-Gen	1.0	5.98	8.37	10	2.25

Table VIII shows that when mode 3 is excited the TOT is amplified 10 times of its non-resonant value. Table IX shows similar amount of TOTs amplification in the T-G shaft at Sikalbaha plant. It can be seen that higher the mode is excited, higher the amplification occurs. TOT amplification with additional EAFs has been compared with that of existing EAFs in Table X which shows TOTs with additional EAFs are greater.

TABLE X
COMPARISON OF TOTS AMPLIFICATION BETWEEN SYSTEMS WITH ADDITIONAL EAFS AND EXISTING EAFS

Power plant	Mode	Torque amplification at present	Torque amplification with additional EAFs	Torque increment (%)
Raozan	1	2.7525	5.7925	110.5
	2	4.2350	8.6075	103.3
	3	5.2025	9.9950	92.1
Sikalbaha	1	2.3500	5.9775	154.4
	2	2.5075	8.3825	234.3
	3	2.5400	10.0000	293.7

If there are no protection schemes, the shaft of the T-G units at Raozan and Sikalbaha may not be broken/cracked immediately due to torsional resonance but will lose fatigue life. In the long run, the shaft system may get damaged.

VI. CONCLUSION

Electric arc furnaces in BPS are operating without prior study of their impact on T-G unit. EAF cause TR in T-G shaft. This paper focused on identification of occurance of TR. The three torsional modes of all generators at Raozan and Sikalbaha plants were excited by the simultaneous operation of EAFs. It is observed that the T-Gs in the Raozan plant faces a greater impact than those at Sikalbaha plant. Impacts of simultaneous operation of aditional EAFs in the region is also observed. Since the physical parameters of the turbines are not available and the data used in simulation are collected from different sources, the actual torsional mode frequencies in BPS may be different. To find the actual mode frequencies, acurate parameters of turbine section are required. The SSFs produced by EAFs may also be obtained from the field measurement data. Since there are no TR protection schemes in the BPS at present, it can be presumed that the T-G shafts at Raozan and Sikalbaha power plants may not get broken/cracked immediately due to TR, but will lose their fatigue life. In the long run, the shaft systems may get damaged.

Abstract— **Reliability of power transmission corridor is of great importance for the reliability of the bulk power system. Any intermediate substation in the transmission corridor affects its reliability. Studies have been done on reliability of substation in isolation but its effect on transmission corridor has not been studied. Studies on transmission line reliability have also been carried out, but they focused on system connectivity neglecting reaction of system protection. This paper studies the reliability of a transmission corridor with intermediate substation having different configurations. Event tree analysis has been adopted for the purpose. The effect of substation configuration on reliability of the transmission corridor, both qualitatively and quantitatively, is analysed and compared.**

Index Terms—**Transmission corridor reliability, Substation configuration, Protection failure.**

I. Introduction

The main objective of a power system is to satisfy the load requirement continuously with reasonable assurance of quality. The ability to provide power continuously is ascertained by the term reliability. Generally power is generated at one place and then transmitted through transmission corridor to another place. Needs may arise to break in the transmission corridor and feed an intermediate substation. In that case the reliability of the transmission corridor will depend on the intermediate substation reliability. Whenever a fault occurs in a substation, the protection system isolates the faulty part. But there is a possibility that protection system may fail to react properly. As a result this protection failure may lead to cascading failures of the other components in the substation and eventually fault will propagate to the transmission corridor which will result in transmission failure through the corridor. In most of the traditional reliability studies, the assumption of protection systems being perfect, makes the analysis and calculations much easier, but may lead to unrealistic results. Reality has shown that failures of the protection can lead to serious outages of the substation [1] and protection failures have critical impact on the reliability of power system [2]. Therefore, the reliability of the corridor with protection failures in the substations is a major concern. Two main types of protection failures can happen [3]. One type of failure is the protection system's failure. This type of failure mainly refers to the situation where the protection system fails to see the fault within its operating zone or it fails to give a tripping signal to the circuit breakers. The other type of protection failure is that the circuit breaker cannot respond to the command in time.

This paper studies the effects of intermediate substation configuration subjected to protection failure on the reliability of power transmission corridor. It is assumed that the initial fault occurs on the transmission line/cable connected in the substation or the initial fault occurs on the substation components. It is further assumed that the protection system of the substation fails to operate properly. Different methods have been presented for the reliability assessment of power systems with protection failures. In this paper, the main method that is used to study the reliability of transmission corridor with intermediate substation is inspired by paper [3] and [4], which is the event tree.

II. Reliability of Power Transmission Corridor

A. Transmission Corridor Model

A power transmission corridor generally transmits electricity from a generation rich area to a load rich area. It may consist of overhead transmission line or underground cables or both. Transmission corridor with double circuit line has greater reliability. Bulk consumers generally prefer to get electricity from nearest part of the grid through line in line out (LILO) connection to avoid requiring long radial transmission lines. Any substation added to a transmission corridor also affects its reliability. A general arrangement of a single circuit LILO connection is shown in Fig. 1.

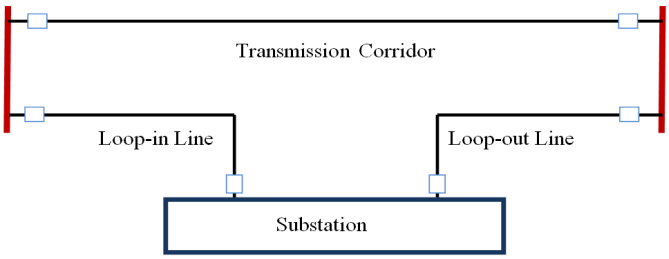

Fig. 1 Single circuit LILO connection with the consumer substation.

B. Technique to Assess Transmission Corridor Reliability

The reliability of a power system has two different aspects: system adequacy and system security [5]. System adequacy is assessed by static reliability, while system security is assessed by dynamic reliability. Most of the studies about power system reliability, are in the static reliability field, i.e. they only consider the connectivity of the system and does not consider disturbances such as load fluctuation and component outages exist in real world [6].

The post-fault phenomena in a substation are dynamic and are usually involved with the connectivity between the energy source and the load. These post-fault phenomena can be very complex depending on the system structure. To involve the system dynamic behaviour, such as the protection system response after a component failure, dynamic reliability evaluation must be applied [6].

There are two steps in dynamic reliability assessment technique. The first step is to select the state and the second

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

step involves calculating the state probability. These are explained below.

1) State Selection: State commonly refers to either the present condition of a system or entity, or to a governed entity. Effect of a unit on system reliability depends on its capacity and the probability of residing in each state. The states of a unit can be classified as shown in Fig. 2.

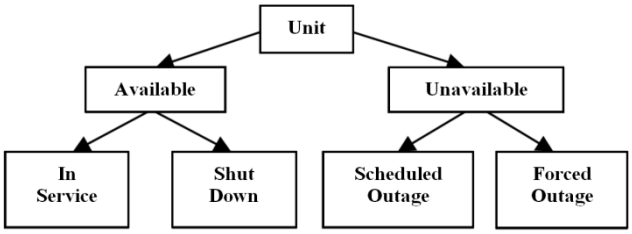

Fig. 2 Power system unit states.

There are two approaches of state selection: state enumeration and Monte Carlo simulation. State enumeration is more effective for a system with a relatively small number of components and/or low failure probabilities of components [7]. It involves- (a) enumeration of contingencies, including both circuit outages and unit outages, and (b) enumeration of electric load levels according to a specified electric load model. The objective of contingency enumeration is to identify the contingencies which may lead to unavailability [7].

The unavailability of a component is given by [8],

$$U = \frac{f \times MTTR}{8760} \tag{1}$$

where f is failure frequency and $MTTR$ is mean time to repair. A zone comprises of more than one component, failure in one or more components will cause the same effect. So, the components can be considered as series connected and unavailability of a zone comprised of such components can be calculated by [8],

$$U(unit) = \sum U(component) - \prod U(component) \tag{2}$$

2) State Probability Calculation: There are two main methods of probability calculation. They are fault tree analysis (FTA) and event tree analysis (ETA). FTA can build a diagram of all the elements that may contribute to a system failure, and then trace back the groups of elements that will necessarily lead to the system's undesired situation [9]. In the FTA, end result is the analysis starting point. Here, event is first defined for which causes are to be resolved. Causes are the starting points. Event is resolved into its immediate and causal event. Starting event is related to the causal events using appropriate Boolean logic. Stepwise resolution proceeds in this manner until primary causes are identified. Being an inductive analytical diagram, the event tree presents the system possible outcomes after the injection of an initiating event. In ETA initiating event such as loss or component failure is first defined which can have undesired consequences. Subsequent events are identified which define possible progressions of the initiating event. It displays sequence progression, end states and sequence dependencies across time. When applying the FTA in the reliability evaluation of power systems, it is mostly focused on the connectivity of the system, which is static reliability. For the reliability evaluation that includes protection failures, ETA offers a better solution.

III. Reliability of Transmission Corridor for Different Substation Configuration

A. The Considered System

In this paper three different substation configurations are considered for reliability evaluation of power transmission corridor with a single circuit LILO connection. The substation configurations are: 4/3 circuit breakers substation, one and a half circuit breakers substation and typical double busbar substation. The substation has six feeders, among which three at transmission voltage level and three fed by step down transformer. The system with three different substation configurations is shown Figs. 3 to 5.

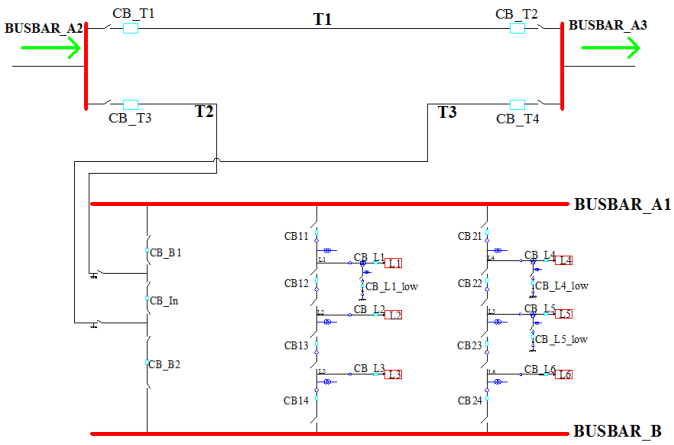

Fig. 3 Transmission corridor with intermediate 4/3 circuit breaker substation.

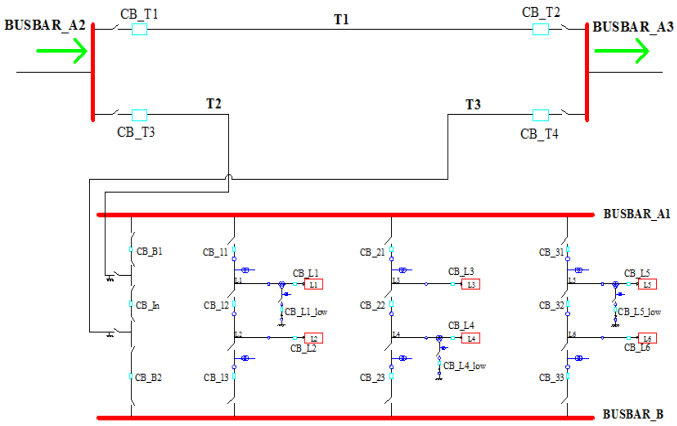

Fig. 4 Transmission corridor with intermediate one and a half circuit breaker substation.

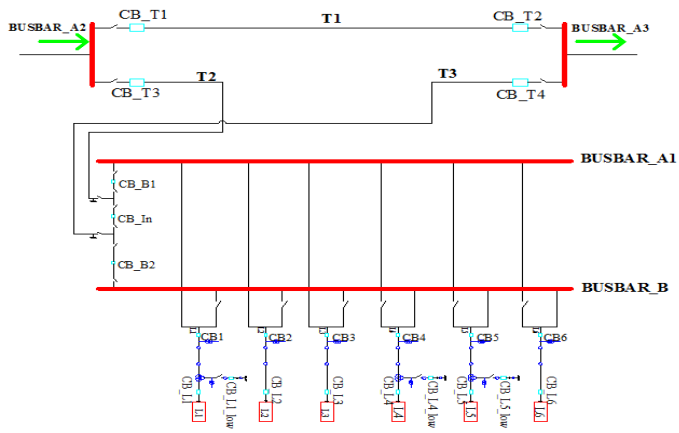

Fig. 5 Transmission corridor with intermediate typical double busbar circuit breaker substation.

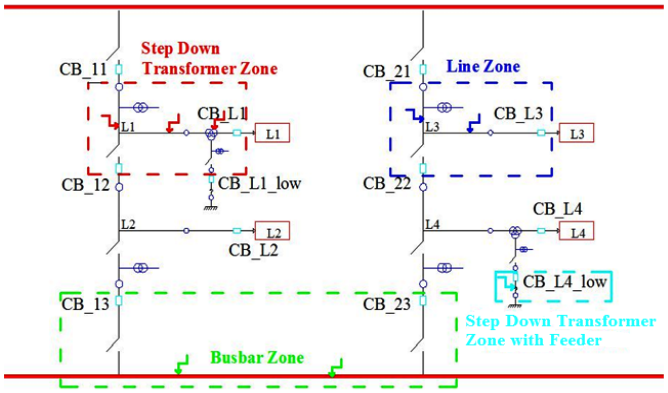
B. Zone Division

Differential protection, distance protection and the busbar protection in a substation coordinate with each other to ensure overall system protection. Which of these protection systems reacts to a fault mainly depends on the fault location. The whole substation is divided into eleven zones. These eleven zones can be further classified into four types of zone: step down transformer zone, line zone, step down transformer zone with feeder and busbar zone. These four zones are shown in Fig.6 for one and a half circuit breaker substation.



ig. 6 Zone division for one and a half circuit breaker configuration.

C. Initiating Event Calculation

To calculate the resulting probabilities i.e. unavailability from the event tree, the unavailability of the initiating events must be calculated first. This can be done by using state enumeration. The failure statistics of different components of a substation used in this paper are listed in the Table I.

TABLE I
FAILURE STATISTICS OF DIFFERENT COMPONENT OF SUBSTATION

Component	Failure Frequency	Mean Time to Repair (Hour)
Overhead line	0.0031/km	8
Cable (including joints)	0.0063/km	600
Circuit breaker	0.003/comp.	24
Disconnecting/Earthing switch	0.003/comp.	8
Busbar	0.003/comp.	2
Transformer	0.05/comp.	24
Instrument transformer	0.0002/comp.	24
Surge arrestor	0.001/comp.	2
Compensating coil	0.004/comp.	3

The unavailability of a component is calculated using Eq. (1). Each substation zone consists of several components fail and failure of the components that are located in the same protection zone will cause the same effect. The unavailability calculation for L1 zone of one and a half circuit breaker substation system using Eq. (2) is shown in Table II.

TABLE II
UNAVAILABILITY CALCULATION FOR L1 ZONE

Zone Construction	Zone Data	Components Unavailability	Zone's Unavailability
CT	4	0.000000548	3.79057E-04
PT	2	0.000000548	
DS	2	0.00000274	
L1 Cable	0.5 km	0.000432	
Transformer	1	0.000137	
L1 150KV Line	0.3 km	0.00000283	
Circuit Breaker	2	0.00000822	

The unavailability of zones for the three substation configurations considered in the paper is presented in Table III.

TABLE III
UNAVAILABILITY OF ZONES FOR DIFFERENT SUBSTATION CONFIGURATION

Fault Zone	4/3 Configuration	One and a Half Configuration	Typical Configuration
L1	0.000379057	0.000379057	0.000367549
L1_Low	0.000010138	0.000010138	0.000010138
L2	0.008663564	0.008652604	0.008649864
L3	0.008661372	0.008661372	0.008649864
L4	0.000379057	0.000370289	0.000367549
L4_Low	0.000010138	0.000145768	0.000010138
L5	0.000381249	0.000379057	0.000367549
L5_Low	0.000010138	0.000010138	0.000010138
L6	0.008652604	0.008652604	0.008649864
Busbar A1	0.000033565	0.000044525	0.000033565
Busbar B	0.000033565	0.000044525	0.000044525

D. Event Tree Calculation

Event tree can be calculated using the unavailability value of the initiating event as input to the first stage which is the primary protection. The primary protection system and each circuit breaker associated with all protection stages are considered to have 0.999 and 0.9985 availability, respectively, under the condition that a fault has occurred in the system first. For each stage, success and failure is found by multiplying initiating event of that stage with the availability and unavailability of that stage, respectively. The event tree calculation for unavailability of transmission corridor with an intermediate substation having one and a half circuit breaker configuration for initiating fault at L1 zone is presented in Table IV followed by a description of the calculation process for Table IV.

TABLE IV
EVENT TREE FOR L1 ZONE OF ONE AND A HALF CONFIGURATION

Initiating Event	Protection		Success	Failure
	Availability	Unavailability		
Primary Protection				
3.79057E-04	0.999	0.001	3.78678 E-04	3.79057 E-07
Primary protection CBs (CB_11,CB_12,CB_L1,CB_L1_low)				
3.78678 E-04	0.994013487	0.005986513	3.76411 E-04	2.26696 E-06
Backup protection_1 CBs (CB_B1,CB_21,CB_31,CB_13,CB_L2)				
3.79057E-07	0.992522466	0.007477534	3.76222 E-07	2.83441 E-09
Backup protection_2 CBs (CB_22, CB_L3, CB_32, CB_L5, CB_L5_low, CB_T3, CB_B2, CB_23,CB_33,CB_In)				
2.83441E-9	0.985100846	0.014899154	2.79218 E-09	4.22303 E-11
Backup protection_3 CBs (CB_L4, CB_L4_low, CB_L6, CB_T4, CB_T1)				
4.22303E-11	0.992522466	.007477533725	4.19145 E-11	3.15778 E-13

When a fault occurs in the L1 zone, the unavailability of that zone initiates event tree and the primary protection to react. If it succeeds to react, its success initiates tripping of its associated circuit breakers CB_11, CB_12, CB_L1, CB_L1_low. If primary protection fails to operate then its failure initiates tripping of backup protection_1 circuit breakers CB_B1, CB_21, CB_31, CB_13, CB_L2. If any of

these circuit breakers fails to operate then their failure initiates backup protection_2 circuit breakers CB_22, CB_L3, CB_32, CB_L5, CB_L5_low, CB_T3, CB_B2, CB_23, CB_33, CB_In to trip. Again if any of these circuit breakers also fails then their failure initiates tripping of backup protection_3 circuit breakers CB_L4, CB_L4_low, CB_L6, CB_T4, CB_T1. Failure of a circuit breaker at this stage will lead to the fault reaching the transmission corridor and a stop in the power flow through the corridor. The failure value of the last stage is the unavailability of the transmission corridor for fault in L1 zone. Neighbouring substations are assumed to be perfect in this calculation.

Proceeding in this manner, the unavailability of the power transmission corridor for fault in each zone for all three substation configuration is calculated and presented in Table V. The last row of Table V presents transmission corridor total unavailability for the different substation configurations. Fig. 7 presents a comparison of transmission corridor unavailability for zone wise failure for all three substation configurations.

TABLE V
TRANSMISSION CORRIDOR UNAVAILABILITY WITH ZONE WISE FAILURE FOR DIFFERENT SUBSTATION CONFIGURATION

Zone	Unavailability for		
	4/3 Configuration	One and a Half Configuration	Typical Configuration
L1	2.479416E-13	3.157787E-13	4.442332E-14
L1_low	3.969823E-17	3.794823E-17	1.280807E-17
L2	2.771437E-14	5.769424E-12	1.305839E-12
L3	1.710548E-11	7.613844E-12	1.305839E-12
L4	2.656516E-13	3.698920E-13	5.548754E-14
L4_low	3.192428E-17	5.892843E-16	4.588047E-18
L5	9.153855E-16	3.157787E-13	5.548754E-14

Busbar A1	4.782894E-12	9.883873E-12	4.782894E-12
Busbar B	3.592550E-12	9.785035E-12	2.091223E-12
Total	3.108029E-11	4.269762E-11	1.120705E-11

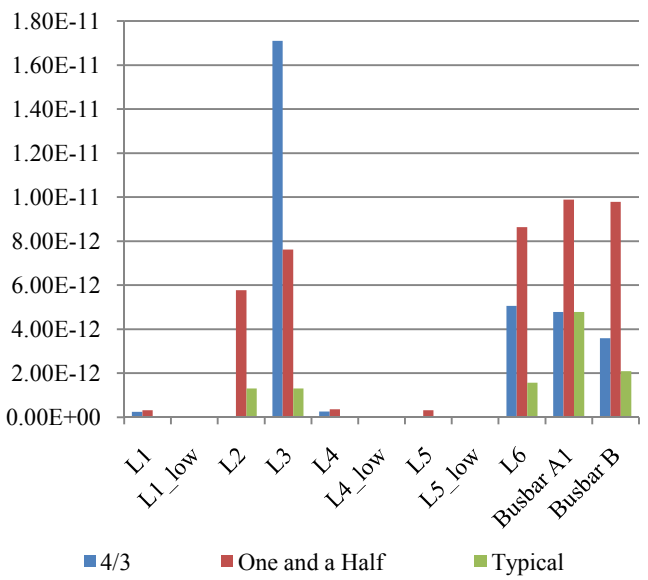

Fig. 7 Transmission corridor unavailability for zone wise failure for different substation configuration

From Table V and Fig. 7 it can be seen that for 4/3 system fault in L3 zone has the highest value of unavailability. But for most of the zones 3/2 substation configuration has the highest unavailability and typical substation configuration the lowest. It can be seen from the last row of Table V that typical substation configuration has the lowest total unavailability. That means if a fault occurs in the substation zone, the transmission corridor will be less venerable to the fault for intermediate substation having typical configuration. This is because in typical substation configuration there are less stages of protection and as a result number of associated circuit breaker is also less.

IV. CONCLUSIONS

In this paper, effect of different intermediate substation configurations on reliability of power transmission corridor subject to protection failure in the substation has been studied. Event tree analysis is used for unavailability calculation. In general, being an inductive graphical method, event tree analysis combines the calculation with system principles perfectly. The effects of substation configuration on reliability of the transmission corridor obtained both qualitatively and quantitatively.

It is observed that for greater reliability of a transmission corridor with intermediate substation typical substation configuration is the best choice. Moreover, typical substation is simple in design, cost effective and convenient to operate. There are scopes of further work including calculating the effects on power transmission corridor's reliability for different combination of circuit breaker failure for each stage of protection for both single and double LILO connection with an intermediate substation.

Abstract— **Electric arc furnaces (EAF) are very large electrical loads and they cause voltage flicker problem in the power system due to their non-linear and random electrical characteristics. Voltage flicker (cyclic and stochastic) causes annoying sensation experienced by human eye and is a very important power quality parameter. In this paper, a Matlab-Simulink based flicker severity analysis module has been proposed to analyse voltage flicker in the network under multiple EAF operation fed from a substation. In this module a new system-modelling strategy is proposed. The power system is modelled and simulated in Simulink and instantaneous voltage data is analysed by a separate Matlab program. With this module, a power system containing two parallel EAFs is modelled and simulated and the short-term flicker severity index of voltage at point of common coupling is calculated. This new module can be used very effectively to estimate the flicker of any system having multiple arc furnaces that are fed from a substation.**

Index Terms—**Electric arc furnace, voltage flicker, power quality, short term flicker severity**

I. Introduction

Voltage flicker is one of the important parameters of power quality and the only one based on human perception. Annoying sensation is experienced by human eye due to light flickering in lamps caused by rapid voltage fluctuations. Voltage flicker can be classified into two types- cyclic flicker and non-cyclic flicker. Cyclic flicker results from periodic voltage fluctuations whereas non-cyclic flicker involves random variations of power system voltage [1]. Potential flicker sources are- electric arc furnaces (EAFs), arc welders, start-up of large motors, compressors, power electronics devices and all rapidly-changing loads in general. Their impact is dependent on their power and location of connection to the network.

By far the largest flicker sources are EAFs which are usually connected to high voltage network. Operation of EAF imposes a serious strain to power supply network with its rapidly changing and highly irregular power consumption. Extensive studies on EAF has revealed that voltage variations as low as 0.5% in the frequency range of 6-10 Hz can cause objectionable light 'flicker' in ordinary incandescent lamps [2,3,4]. The flicker produced by EAFs depends on many different factors which may vary randomly, and exact prediction of flicker is, therefore, very difficult. Before connecting an EAF into the grid, its effect on the power system is thus difficult to estimate and consequently voltage flicker problems become unavoidable, if mitigation measures are not adopted. In most standard power system simulation software, EAF model for flicker study is not available. In this case, mathematical equations that model the behaviour of EAF and other components of the power system as accurately as possible are needed to forecast flicker in the system. There are several models of EAF described in literature for flicker study [2,5,6,8]. These models can be used to simulate the approximate real-time operating condition.

In this paper, a new flicker analysis module has been presented and a system-modelling technique has been developed to analyse flicker in a power system under multiple EAFs fed from a substation. The work is done in Simulink and Matlab. For flicker analysis, arc resistance model of the EAF has been adopted from [2]. Both cyclic and non-cyclic flicker are modelled by sinusoidal and stochastic modulation of arc resistance in the EAF. The simulation of the power system is conducted for ten minutes and voltage at the point of common coupling (PCC) is recorded at a sampling frequency of 5 kHz. The voltage data is then feed into a Matlab program which calculates short-term flicker severity (P_{st}) according to IEC flickermeter standard. Lastly, P_{st} for both cyclic and non-cyclic flicker phenomena are compared. The steps are shown in Fig.1.

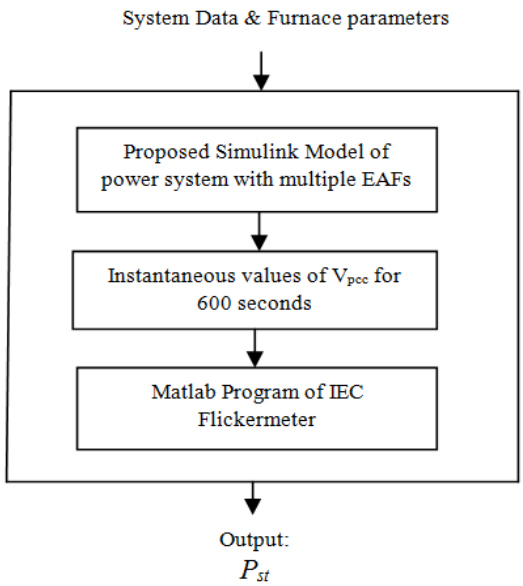

Fig. 1 Block diagram of proposed module

II. Voltage Flicker

Power system voltage varies over time due to perturbations that occur in the processes of electricity generation, transmission and distribution. Interaction of electrical loads with the network causes further deterioration of the electrical power quality. High power loads that draw fluctuating current, such as large motor drives and arc furnaces, cause low

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

frequency voltage variations i.e. voltage flicker. A voltage flicker waveform can be expressed as,

$$v(t) = \sqrt{2}\, V_{RMS}\left[1 + \frac{1}{2}\sum_n \Delta V_n \sin(2\pi f_n t + \phi_n)\right]\sin(2\pi f_s t) \quad (1)$$

Voltage flicker causes fluctuation in brightness of light sources which can cause significant physiological discomfort, physical and psychological tiredness, and even pathological effects for human beings. Flicker also causes problems with the stability of electrical devices and electronic circuits.

III. IEC FLICKERMETER

Flicker severity is expressed in terms of two parameters: short term flicker severity P_{st} and long term flicker severity P_{lt} [3]. Short term flicker severity (P_{st}) is determined by analysing the voltage at the point of common coupling. According to IEC standard 61000-4-15, which is accepted as the international standard on measuring flicker, the flickermeter is divided into 2 parts [3]:

- Task 1: Simulation of lamp-eye-brain response which is realized with the signal processing techniques such as filtering, squaring, and re-sampling
- Task 2: Statistical data evaluation of flicker level selected by CPF (cumulative probability function) as the standard defines.

Fig. 2 shows the block diagram of the IEC flickermeter. The process to calculate P_{st} is not simple and the statistical procedure is inevitable when calculating P_{st}. From the resulting momentary value of flicker the short term flicker value P_{st} is generated in the last block of Fig. 1 according to a statistical process over a predefined observation interval. Long term flicker P_{lt} is calculated as the cubic average of several P_{st} values.

The observation intervals and limiting values for P_{st} and P_{lt} as specified in IEC 61000-3-3 is presented in Table I [3].

TABLE I
ALLOWED LIMIT ON FLICKER SEVERITY VALUES

Value	Observation Interval	Limiting Value
P_{st}	10 min	1.0
P_{lt}	2 h	0.65

IV. ELECTRIC ARC FURNACE MODEL FOR FLICKER STUDY

The actual V-I characteristics and its piecewise linear model of an arc furnace is shown in Fig. 3. The arc ignition voltage V_{ig} and the arc ignition voltage V_{ex} are determined by the arc length during arc furnace operation [2]. Figure 2 shows actual EAF operating characteristics in solid line and approximate operating conditions in dotted line.

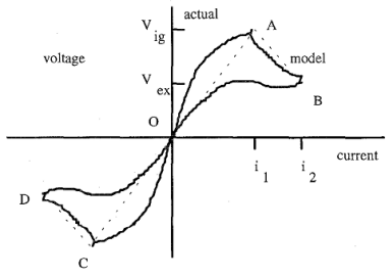

Fig. 3 Actual and piece-wise linear approximation of v-i characteristic of an arc furnace load [1]

Let R_1 and R_2 be the slopes of the lines OA and AB. Then the relationship between arc voltage and current for one cycle, according to [2,6] can be expressed as -

$$R_1 = \frac{V_{ig}}{i_1} \quad (2)$$

$$R_1 = \frac{V_{ig}^2}{P + \frac{V_{ig}^2}{R_2} - \frac{V_{ex}^2}{R_2}} \quad (3)$$

$$R_2 = \frac{V_{ex} - V_{ig}}{i_2 - i_1} \quad (4)$$

$$v(t) = \begin{cases} R_1 i(t); & 0 \le |i(t)| \le i_1 \\ R_2 i(t) + V_{ig}(1 - \frac{R_2}{R_1}); & i_1 \langle |i(t)| \langle i_2 \end{cases} \quad (5)$$

Figure 4 shows the simulated V-I characteristic of the model. As mentioned in [2], quantities V_{ig}, V_{ex}, R_2 are assumed not to change with load operating conditions and V-I characteristics are made dependent on the operating condition, P, of the arc furnace load.

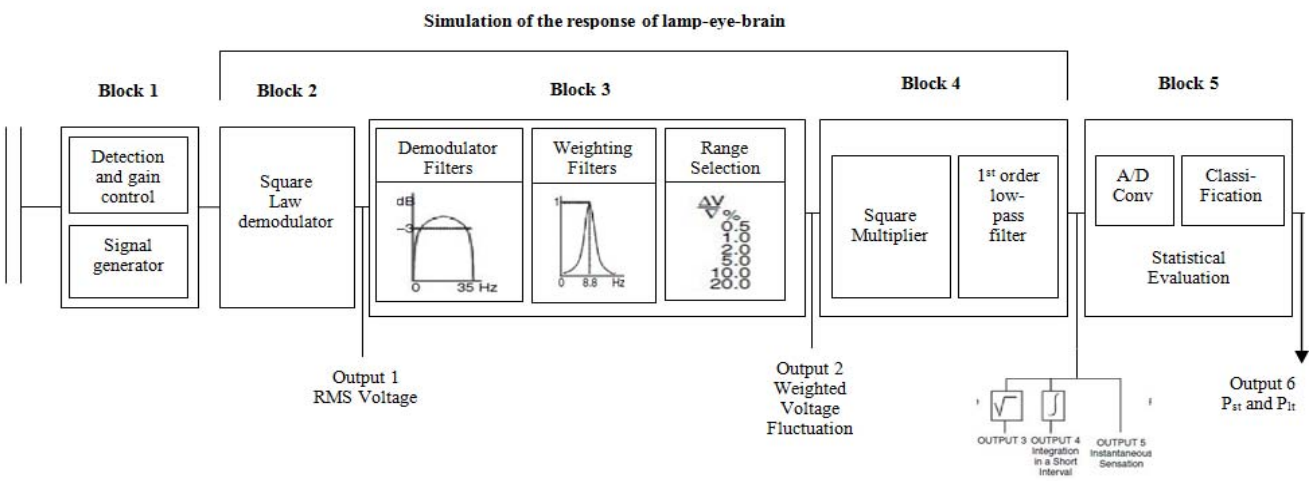

Fig. 2 Block diagram of the IEC flickermeter

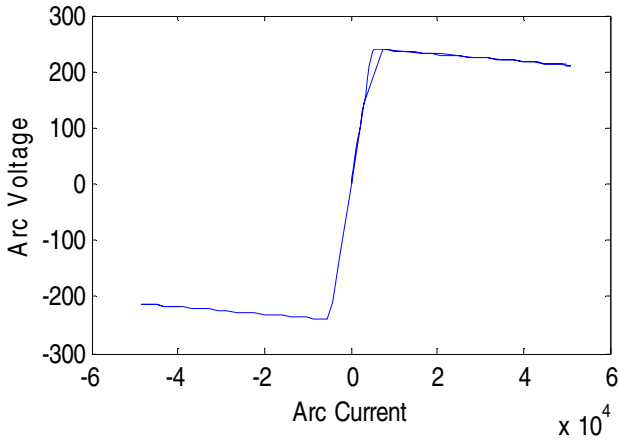

Fig. 4 Simulated V-I characteristic of the model

To analyze flicker generated by an arc furnace, the dynamic arc furnace model is needed. To generate the dynamic behaviour of the arc furnace using different models, the slope of the V-I curve in figure 4 should be changed. The change can be sinusoidal or stochastic. Stochastic modulation is done by superimposing the arc resistance of the EAF with band-limited noise of 5-12 Hz and sinusoidal modulation is done by modulating a sine wave of frequency 8.5 Hz multiplied by a "modulation index" on the constant value of arc resistance.

The arc resistance in the case of sinusoidal variation and in the case of band limited white noise variation are defined by Eqs. (6) and (7), respectively-

$$R_2(t) = R_2[1 + m\sin(\omega_f t)] \tag{6}$$

$$R_2(t) = R_2 + BLW \tag{7}$$

Where R_2 is a constant obtained from Eq. (2), ω_f is the flicker frequency, m is the modulation index and BLW is the band-limited (4-14 Hz) white noise with zero mean. The modulated value, $R_2(t)$ is such that the total input power requirement of the arc furnace is satisfied.

V. Proposed System Modelling Strategy

The power system under consideration is depicted in Fig. 5. It contains two arc furnaces, fed from a common substation transformer. The system equations for the system shown in Fig. 4 are given in equations (8) to (11).

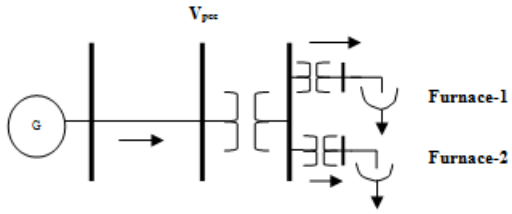

Fig. 5 Test System

$$V_{pcc} = V_1 + I_{arc,1} Z_{t1} \tag{8}$$

$$V_{pcc} = V_2 + I_{arc,1} Z_{t2} \tag{9}$$

$$I = I_{arc,1} + I_{arc,2} \tag{10}$$

$$V_{source} = V_{pcc} + IZ_s \tag{11}$$

This system of mathematical equations can be modeled in a block building fashion as shown in Fig. 6,where $Z_{t,1}$ & $Z_{t,2}$ are summation of line and transformer impedance of furnace-1 and furnace-2 respectively. Z_s is the Thevenin impedance at the source bus of the power system.

The unique aspect of the proposed model is that if the furnaces are located in nearby but different areas from the feeding point, then the change in impedance can be easily incorporated in the impedances indicated by $Z_{t,1}$ and $Z_{t,2}$.

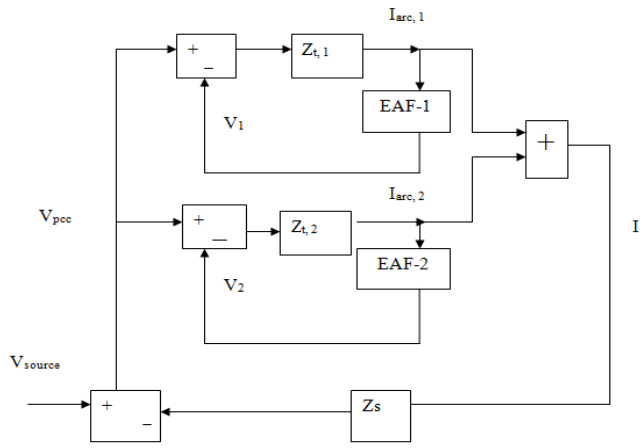

Fig. 6 Mathematical modelling of the Test System

Now, if a power system contains N EAFs fed from a substation, it can be accurately modeled and simulated by the proposed technique as shown in Fig. 7.

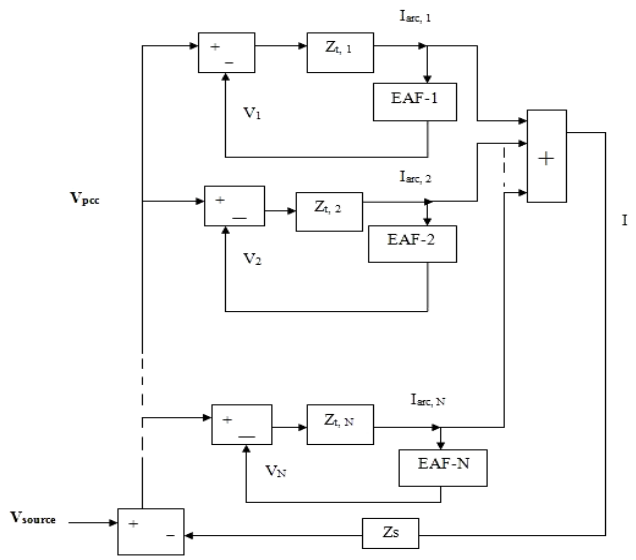

Fig. 7 Mathematical modelling of test system with N number of EAFs

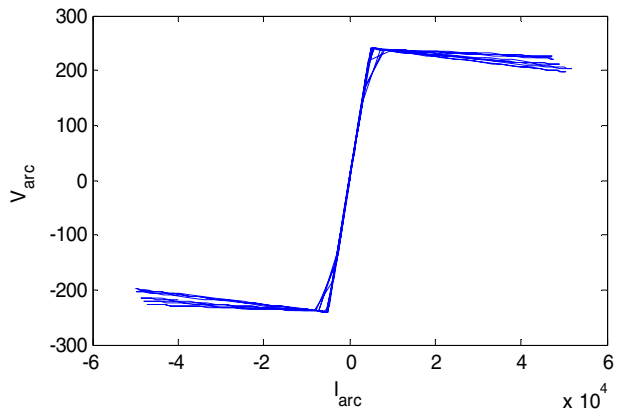
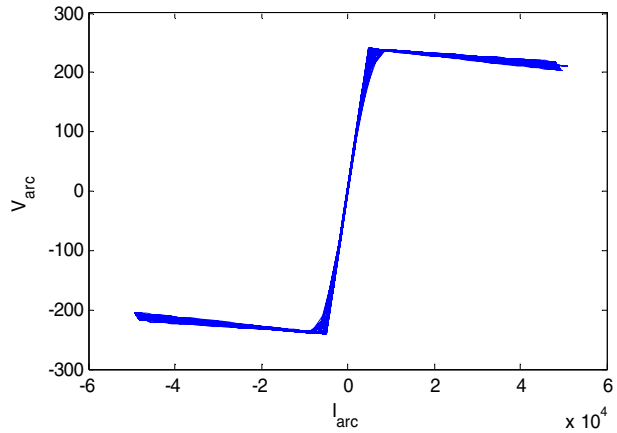
VI. Simulation Results

The test system as shown Fig. 4 is simulated. The furnace parameters (V_{ig}, V_{ex}, i_1, i_2) are adopted and calculated according to Eqs. (2) to (4). Both the furnaces are assumed to have identical parameters and same power rating (87 MW). However, the system model can accommodate furnaces with different power ratings. The source impedance Z_s is 1.056e-4+j7.8e-4 ohms and impedance of each furnace transformer is taken 7.701e-4+j6.1398e-3 ohms (referred to the secondary of the furnace transformers). The simulation voltage data at PCC (V_{pcc}) is recorded and the acquired V_{pcc} data is then analysed in a Matlab program for P_{st} estimation [7]. Figures 8(a) and 8(b) show the dynamic V-I curve of the EAF under sinusoidal and stochastic modulation of the arc resistance, respectively. Figures 9(a) and 9(b) show the envelopes of the voltage at PCC with two EAFs operating simultaneously with sinusoidal and stochastic modulation of the arc resistance, respectively.

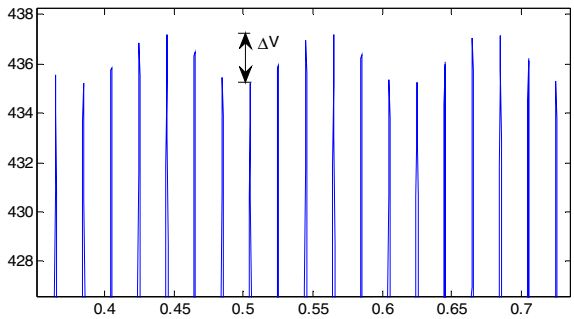


(a)

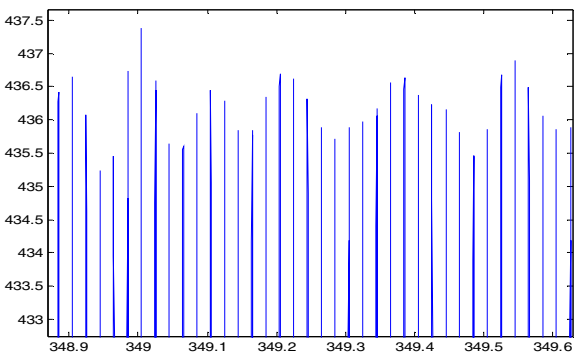


(b)

Fig. 8 Dynamic V-I curve of the EAF with arc resistance modulated (a) sinusoidally, (b) stochastically



(a)



(b)

Fig. 9 Envelope of V_{pcc} during simultaneous operation of two EAFs under (a) sinusoidal and (b) stochastic modulation of R_2

The instantaneous voltage at PCC is sampled at 5 kHz. The short term flicker severity (P_{st}) is then calculated using the flickermeter and listed in Table II.

TABLE II
SHORT TERM FLICKER SEVERITY

Furnace model	P_{st}
Sinusoidal modulation	3.3641
Stochastic modulation	1.5289

The simulation result shows that sinusoidal flicker results in higher P_{st} value than the stochastic modulation, which is in agreement with [9]. In addition, P_{st} value exceeds the limiting value of 1.0 in both cases, which indicates voltage flicker at the PCC will be perceptible to human eye.

VII. CONCLUSION

A new flicker analysis module along with a new system-modeling technique for flicker study in a power system containing multiple EAFs has been proposed. Together with the module, a representative power system has been modeled to analyze both sinusoidal and stochastic flicker in the system. IEC standard flickermeter has been used to estimate short term flicker severity index (P_{st}) of voltage at PCC. Dynamic V-I characteristics of EAF has been plotted along with voltage waveform at PCC and P_{st} obtained for both sinusoidal and stochastic flicker has been compared. It is evident that the module developed in this paper can be easily applied to predict voltage flicker in any power system under multiple electric arc furnace operation when the furnaces are fed from the same substation. A greater detailed model of EAF would give a more accurate result.

Abstract— **Human eye is susceptible to rapid voltage fluctuations of power system, which is termed as 'voltage flicker'. Voltage flicker causes psycho-physical discomfort to humans. It is quantified by short term flicker severity index (P_{st}) according to IEC standards. Electric arc furnaces (EAF) are one of the main flicker sources in the power system. In this paper, voltage flicker caused by the operation of both single and multiple EAFs on the power system has been considered. A comparative analysis of flicker phenomena has been made by estimating P_{st} under variations of several modelling parameters and operating conditions.**

Index Terms— **Electric arc furnace, voltage flicker, power quality, short term flicker severity, band limited white noise**

I. Introduction

Power system voltage is subjected to rapid change or fluctuation due to the occurrence of disturbances in operating conditions. Voltage change is defined as a deviation in the R.M.S. voltage value with respect to a steady-state value averaged over some period of time [1]. The voltage deviations may or may not be periodical. When the fluctuations in voltage are subjected to luminosity and human eye comfort, the term 'flicker' is used and voltage flicker is classified into two types in the literature- cyclic flicker and non-cyclic flicker respectively, depending on the deviation type of voltage [2]. Flicker severity is a parameter used to quantify the intensity of flickering. Several severity indices exist in literature, and among these, short term flicker severity (P_{st}) is widely used.

In a power system, the most threatening flicker sources are electric arc furnaces (EAF). With its rapidly changing and highly irregular power-consumption characteristics, the flicker produced by electric arc furnaces deteriorates power quality of the network. Moreover, amount of flicker in the power system can vary with MW ratings, electrode geometry and thermodynamics of the EAFs. Hence, in this paper, a comparative approach is undertaken to observe flicker in the power system under several operating conditions such as- variation of number of furnaces in the system, variation of MW ratings of EAFs, relative change of the length of electrodes during arcing periods etc. For the purpose of the study, EAFs have been modelled as a source of both cyclic and non-cyclic flicker in the system. Flicker severity P_{st} has been calculated for all cases. The resultant values are then compared with allowed limits and conclusions drawn.

II. Flicker Injection by Electric Arc Furnaces

Electric arc furnace converts electrical energy to thermal energy creating arc and are widely used for smelting and refining metal scraps. As current drawn during the arcing period is extremely high (in the order of 10^4 A), the temperature rises to above 2000^0C which is enough for melting steels.

During EAF operation arcing is accomplished continuously. Electrodes are scrolled up and down in each period of arcing to vary arc length. Owing to irregular shaping of metal scraps, presence of non-homogeneity and impurities within phases and non uniformity of temperature inside furnace chamber, variation in arc length takes place from cycle to cycle of arc period. This complex metallurgical process is responsible for non-linearity in arc current which in turn, causes fluctuation in voltage at PCC and eventually leads to perceptible flicker sensation.

III. Flicker Severity and its Estimation

Flicker is basically characterized by two parameters obtained by means of the flicker measurement apparatus namely, short term flicker severity (P_{st}) and long term flicker severity (P_{lt}).

A. Short Term Flicker Severity

A unit of short term flicker severity, P_{st}, corresponds to the severity limit that should not be exceeded in order not to create malaise for an observer. P_{st} is obtained from $s(t)$ through a series of statistical evaluations as shown in Fig. 1 [5].

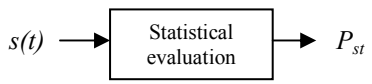

Fig. 1 Statistical analysis for P_{st} evaluation

B. Long Term Flicker Severity

The long term flicker severity, P_{lt}, is deduced from 12 consecutive values of P_{st} by Eq. (1).

$$P_{lt} = \sqrt[3]{\frac{\sum_{i=1}^{12} P_{st,i}^3}{12}} \quad (1)$$

The observation intervals and the limiting values for P_{st} and P_{lt} specified in the standard IEC 61000-3-3 [3] are presented in Table I.

TABLE I
Allowed Limit on Flicker Severity Values

Value	Observation Interval	Limiting Value
P_{st}	10 min	1.0
P_{lt}	2 h	0.65

C. Prediction of Flicker in Cyclic Flicker Phenomenon

Cyclic flicker results from periodic fluctuation of R.M.S voltage at the frequency sensitive to human perception at the point of interest. This variation may be sinusoidal, rectangular,

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

triangular etc. depending on the behavior of loads connected to system. For being periodic variation some direct equations to approximate P_{st} in cyclic flicker phenomenon have been proposed in literature.

From instantaneous flicker: In occurrence of sinusoidal fluctuation of system voltage short term flicker severity is approximated directly from instantaneous flicker sensation [4] by Eq. (2).

$$P_{st} = \sqrt{0.5096 * S_{\max}} \tag{2}$$

Where S_{max} is the maximum value of $s(t)$.

From relative voltage change: This method can be applied for rectangular voltage changes with the same magnitude and regularly distributed in time [1]. In this method P_{st} is given by

$$P_{st} = d/d_0 \tag{3}$$

where, d is relative percentage voltage change and d_0 indicates that for unity of flicker severity.

Analytical method: This method is presented in IEC 61000-3-3 [3]. It is based on calculating the flicker time, t_f, which is a magnitude with a time dimension describing the flicker impression caused by a single voltage variation. The expression of P_{st} appears as shown in Eq. (4).

$$P_{st} = \left(\frac{\Sigma t_f}{T_p}\right)^{\frac{1}{3.2}} \tag{4}$$

D. Estimation of P_{st} In Multiple EAF Operation

When two or more electric arc furnaces are operated simultaneously in a power network the cumulative P_{st} at PCC can be estimated using Eq. (5) [5].

$$P_{st,total} = \sqrt[n]{\sum_{i=1}^{m} P_{st,i}^{n}} \tag{5}$$

Where $P_{st,i}$ indicates the flicker severity due to single operation of each furnaces and n represents flicker summation factor, and it varies between 1 to 4 [6]. As the factor, n becomes smaller cumulative flicker severity at PCC becomes larger [5].

In case of parallel operation of identical EAFs (having same rating and modulation parameter), the summation factor can be determined directly using Eq. (6).

$$n = \frac{\ln(m)}{\ln(P_{st\,cum}) - \ln(P_{st\,ind})} \tag{6}$$

Where, m stands for number of furnaces, $P_{st,ind}$ denotes flicker severity due to standalone operation of each furnace.

IV. Electrical Arc Furnace Model for Flicker Study

The EAF is modelled as resistive load with different slopes during pre-arcing and arcing period for flicker analysis [7]. Hence, the EAF model appears as a piece-wise linear model. Fig. 2 shows actual EAF operating characteristics in solid line and approximate operating conditions in dotted line.

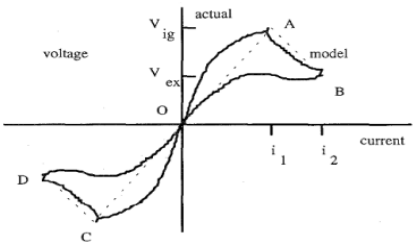

Fig. 2 Actual and piece-wise linear approximation of V-I characteristic of an arc furnace load [7]

Assuming R_1 and R_2 to be the slopes of the lines OA and AB in Fig. 2, the relationship between arc voltage and current for one cycle, is determined according to [7,8]. As voltage flicker occurs due to variation of arc length and since resistance is proportional to length of a conductor, the flicker phenomenon is simulated by varying R_2, where R_2 represents arc resistance during arcing period.

In case of cyclic flicker, fluctuation of sinusoidal system voltage is periodic, and this phenomenon is modelled by sinusoidal modulation of R_2 at flicker frequency [8]. For simulating non-cyclic flicker R_2 is varied by stochastic modulation. It is obtained by adding a band limited (5-12 Hz) Gaussian noise of zero mean with R_2 [7].

V. Test System and Modelling Parameters

In a practical system, EAFs are connected to a PCC through furnace transformers. During simulation EAFs are connected with a test system shown in Fig. 3.

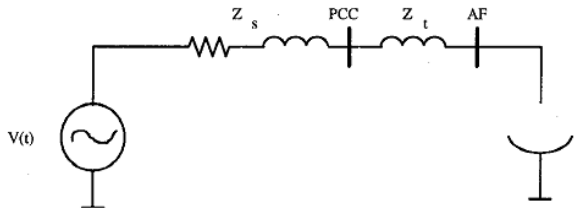

Fig. 3. A representative system for simulation [8]

In Fig. 3, Z_s includes source and transmission line impedance and Z_t accounts for the impedance of transformer. The selection of Z_t depends on the power ratings of EAFs.

For simulating the phenomena of multiple EAF operation and further comparison, two EAFs of different rating are selected. Single phase power in MW is chosen for each rating. EAF-1 is rated 29 MW and that of EAF-2 is 47 MW.

Modulation parameter plays a vital role both in cyclic and non-cyclic flicker. Choice of this parameter should be such that P_{arc} never exceeds the EAF rated power during furnace operation [7]. To investigate the effect of cyclic flicker, sinusoidal fluctuation of V_{pcc} has been considered as it occurs in most cases. In this phenomenon modulation index, m is considered to be that parameter. The value of allowable modulation index depends on system parameters.

Modulation parameter for stochastic flicker simulation is titled on power of random noise as it incorporates noise variance. Maximum allowable noise power increases with decreasing ratings of EAF. The reason lies in steeper V-I characteristics in smaller furnaces during arcing period.

VI. Results And Analysis

Simulations of the test system give the maximum allowable value of m to be 0.5 for all cases of cyclic flicker. Maximum allowable noise estimated for EAF-1 and EAF-2 is about $5.7\text{x}10^{-10}$ and $2.2\text{x}10^{-10}$, respectively. Simulation results and observations are presented in this section.

A. Variation of P_{st} With Rating of Furnaces

Simulating the representative system with single EAF short term flicker severity index is calculated for different power ratings. The result is tabulated in Table II.

It can be seen from Table II that for a fixed modulating index and modulation frequency P_{st} is larger for the furnace of higher rating. Flicker severity for non-cyclic flicker also shows similar trend.

TABLE II
VARIATION OF P_{ST} WITH EAF RATING

Furnace rating (MW)	P_{st}
29	1.9919
47	3.6751

B. Comparison of Furnace Rating with Modulation Index

For cyclic flicker a distinct feature is observed from Table III, and that is, allowable variation rate of arc length for keeping P_{st} under acceptable limit is to be reduced if an EAF of higher rating is to be used. It has been observed from simulations that similar comments can be made for parallel operation of EAFs.

TABLE III
VARIATION OF MAXIMUM VALUE OF m WITH EAF RATING

Furnace rating (MW)	Maximum value of m
29	0.25
47	0.144

C. Effect of P_{st} On Modulating Frequency

Human eye sensitivity is maximum when frequency of light flickering from incandescent lamp is between 6 Hz to 10 Hz. Variation in P_{st} with different frequencies in the flicker range is shown in Fig. 4. Furnace rated at 47 MW is chosen for the comparison and modulation index is taken as 0.5. It has been observed, as shown in Fig. 4, that P_{st} is maximum for a modulation frequency of 8.8 Hz.

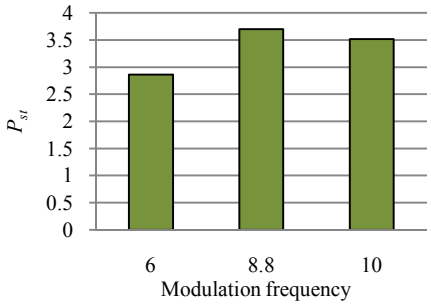

Fig. 4 Variation in P_{st} with different modulation frequencies

D. Effect On P_{st} Due to Multiple EAF Operation

Simultaneous operation of multiple arc furnaces in close proximity in a power system network causes greater severity in flicker phenomenon at PCC.

1) Sinusoidal Flicker Severity

Figure 5 gives a perceptible comparison to realise cyclic flicker severity at grid voltage owing to simultaneous operation of two EAFs over their individual operation. Flicker severity is also illustrated if ratings of EAFs connected in parallel were different.

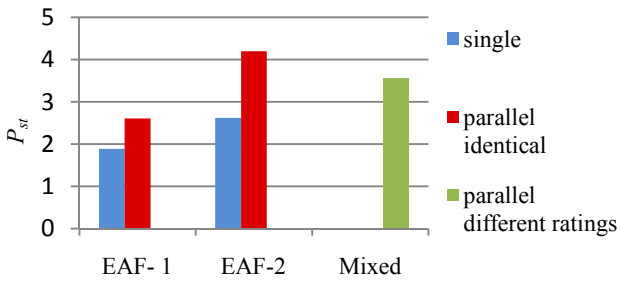

Fig. 5 Cyclic flicker severity at PCC for single and two EAFs operation

For all cases modulation index and the frequency of fluctuation is kept constant as 0.4 and 8.5 Hz respectively. Using equations (5) and (6) summation factor n for parallel EAF operation are found 1.94, 1.468 and 1.54, respectively. It implies that cumulative flicker level at PCC is more severe when two identical EAFs of smaller rating are operated simultaneously.

2) Stochastic Flicker Severity

Table IV presents the change in P_{st} due to parallel operation of two identical furnaces over their operation alone. Noise power is kept constant at maximum value for emphasizing this effect in particular. It can be seen that for single EAF operation P_{st} is within acceptable range, but it is not so for parallel operation. It is also observed that for multiple EAF operation Eq. (5) is satisfied but flicker summation factor is not fixed.

TABLE IV
P_{st} VALUES FOR SINGLE AND PARALLEL EAF OPERATION

EAF operation	P_{st}
Single	0.9371
Parallel	1.5289

E. Variation of Modulating Index in Parallel EAFs

In parallel operation of two identical EAFs, each having ratings of 29 MW, variation of modulation index m results in significant conclusion. This effect is shown in Table V.

TABLE V
EFFECT OF MODULATION INDEX ON P_{ST}

Modulation index		P_{st}
m_1	m_2	
0.145	0.145	0.9850
0.10	0.20	1.0189
0.05	0.24	0.9843

It can also be seen from Table V, from the first and last data rows, that the summation of m_1 and m_2 is constant for a given value of P_{st}. This property can be taken into account while installing a second EAF in a region in close proximity to the first EAF having identical rating. It is also notable that this rule doesn't follow if the ratings of the two EAFs are different.

F. Validation of Thumb Rule in Cyclic Flicker

Table VI reveals that the thumb rule depicted in Eq. (2) is applicable for all cases of cyclic flickers and it is not violated even for operation of multiple EAFs.

TABLE VI
P_{ST} AND $S(T)_{MAX}$ UNDER DIFFERENT OPERATING CONDITIONS

Furnace operation	m_1	m_2	P_{st}	S_{max}
Single EAF-1	0.4		1.5887	4.983
Parallel : two EAF-1	0.5	0.3	2.6973	14.3688
Single EAF-2	0.1		0.8951	1.5824
Parallel: one EAF-1 and one EAF-2	.5	.1	2.0487	8.2828

G. Effect Of Background Noise Power on Flicker Severity

P_{st} values against different background noise powers for parallel EAF operation are recorded in Fig. 6. The increasing nature of P_{st} with incremental noise power is obtained as

expected. Similar trends are observed for operation of single EAF of different ratings.

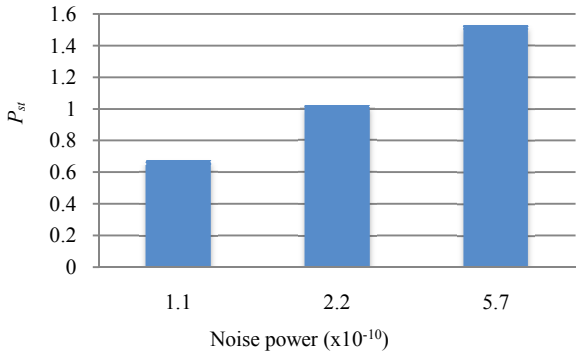

Fig. 6 Effect of background noise power on P_{st}

H. Flicker Severity Ratio of Single and Multiple EAF Operation

P_{st} ratio for parallel operation of two EAFs and their isolated operation is calculated and plotted against the corresponding modulating parameter *m,* for both sinusoidal and stochastic flicker phenomenon in Fig. 7. For multiple EAF operation the modulation parameter is considered same in each furnace.

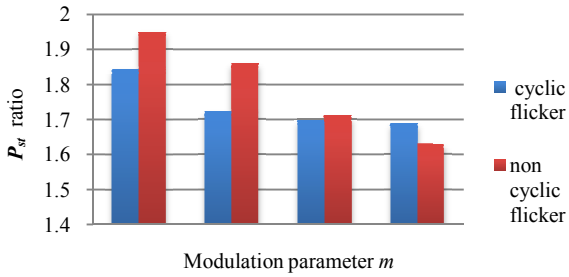

Fig. 7 P_{st} ratio for parallel and single EAF operation and for different modulation parameter *m*

Figure 7 shows that as the modulation parameter is increased, flicker ratio diminishes. It reveals that at lower rate of relative variation of arc length voltage flicker due to parallel operation of EAFs becomes prominent. The figure also indicates that in case of cyclic flicker the P_{st} ratio becomes less sensitive to variation of *m* at higher modulation indices. But for stochastic or non cyclic flicker such conclusions can't be drawn readily.

VII. CONCLUSION

In the paper flicker severity due to EAF operation has been discussed for both cyclic and non-cyclic flicker phenomena to make effective comparison between them. The effect of P_{st} on furnace ratings has been observed both for single and parallel operation of arc furnaces. Moreover, the effect of modulation index, modulation frequency and noise power on acceptable flicker limit has been depicted. It has been observed that relative variation of arc length is to be decreased for higher ratings of EAF for reliable operation. In case of parallel operation of identical EAFs, the cumulative level at PCC is more severe with smaller ratings than that of higher ratings. It is also remarkable that individual modulation indices have little effects on allowable P_{st} in sinusoidal flicker if the summation fulfils the condition. Comparison between cyclic and non-cyclic flicker reveals that the former is more threatening to power system than the other. For non cyclic flicker it is observed that no thumb rule is exactly satisfied.

Dhaka-1205, Bangladesh
*iqbalbuet18@gmail.com

***Abstract*— Determination of the reliability of a substation is important as it helps locate weak points that may be contributing to overall power system unreliability. This paper evaluates reliability of 230 kV grid substations in Bangladesh subject to protection failures. The problem belongs to the dynamic reliability evaluation field. Event tree analysis is used as the main method. Fault tree analysis is used to get the input of the event tree. Reliability of five grid substations are calculated. Ishurdi grid substation is found to have a mean time to failure of only six months, which will affect seriously the design and safety of the proposed nuclear power station at Rooppur sited closely nearby.**

***Index Terms*—Substation reliability, protection failure, event trees, Bangladesh power system**

I. Introduction

While one of the strongest points in a power system is the grid substation, it still contains weak points or points of failure that would lead to loss of load. Therefore, determining the reliability of a substation is important as it can help locate weak points that may be contributing to overall system unreliability.

The reliability of substation is dependent mainly on three factors: incorrect design, incorrect installation and service deterioration that leads to protection failure [1]. Several methodologies and computational models have been developed to evaluate the substations reliability. Most of the studies focus on the substation connectivity. The reaction of protection system is fully neglected. These methods use the minimum cut set technique to select the failure modes of the substation arrangements and classify them in outage categories. Mostly used methods are fault tree analysis (FTA) [2,3], event tree analysis (ETA) [2,3], Monte Carlo simulation and state enumeration [4,5]. Which method is to be used depends on the field of evaluation. To study the static reliability FTA, Monte Carlo simulation and state enumeration are used frequently. To evaluate the dynamic reliability ETA and sequential Monte Carlo are used.

This paper evaluates reliability of 230kV grid substations in Bangladesh power system subjected to protection failures. The reliability problem belongs to the dynamic reliability evaluation field. Design and installation mistakes are ignored and only the service deterioration is considered. Two types of protection failures are taken into account: protection system failures and associated circuit breaker (CB) failures. In this paper ETA is combined with FTA. ETA is the main method used and FTA is applied to get the input of the event tree [6,7].

II. Methodology

To reduce the number of event trees elements, components in the same protection zone are combined into one unit. When one or more than one of the components in a zone fails, the protection system will react. Consequently, FTA is needed to calculate the unavailability of this 'unit'. The result will be the initiating event probability for the ETA.

In ETA there are four states that occur based on the functionality of primary protection, CBs and back up protection [8].

State 1: When both the primary protection and CBs function well, there is no protection failure, and the fault will be cleared successfully

State 2: If the primary protection sees the fault, but the associated CBs fail, the CB failure function will be activated and trips the CBs next to the firstly associated ones.

State 3: When the primary protection fails, but the back-up protection works successfully, the fault will be cleared after a time delay.

State 4: When the primary protection and the back-up protection fail; the chance is so small that it is not considered. In this paper back-up CBs are assumed to be perfect.

When the events are independent of each other, the event trees can be calculated simply with the products of the probabilities along the tree branch. Thus the probability of any of the four states can be calculated by multiplying the probability of each event along the tree branch,

$$P(state1) = U(ini) \times A(pri) \times A(CB) \quad (1)$$

where $U(ini)$ is the unavailability of the initial event, $A(pri)$ is the availability of primary protection and $A(CB)$ is the availability of circuit breaker.

If the input data of the initiating event changed from its unavailability to its failure frequency while keeping the conditional probabilities of a protection failure and a circuit CB failure, the output of the tree will also change to a failure frequency,

$$P(state1) = f(ini) \times A(pri) \times A(CB) \quad (2)$$

where $f(ini)$ is the failure frequency of the initial event.

The concept pairs of reliability/failure probability and availability/unavailability are more or less the same. The parameters used in this paper are availability/unavailability.

Several assumptions are made first before analyzing the reliability of the substations.

- Components considered having a chance to fail: bus bar, CB, disconnecting switch, step-up and step-down transformers, current transformer, voltage transformer, overhead lines and cables connected to substation.
- Earthing switches and surge arrestors inside substation do not have a significant effect on the substation reliability and are neglected.
- Back-up protection systems and the back-up circuit breakers are assumed to be perfect.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

- Neighboring substations are assumed to be perfect.

A. *Effect of Substation Reliability On Respective Lines*

To realize the effect of reliability of a substation on respective lines consider a substation 'S/S 1' as shown in Fig. 1. The neighboring substation is 'S/S 2' which is assumed to be perfect. That is, 'S/S 2' is assumed to consist of CBs that will never fail.

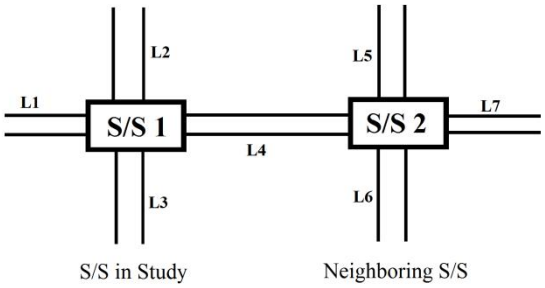

Fig. 1 Effect of substation reliability on respective Lines.

If 'S/S 1' fails then lines 1, 2, 3, and 4 are affected. Hence, reliability assessment of S/S 1 actually determines the unavailability (*U*), failure frequency (*f*), mean time to failure (*MTTF*) and mean time to repair (*MTTR*) of lines 1, 2, 3, and 4. These are reliability indices that are related to each other by Eqs. (3) and (4).

$$U = \frac{f \times MTTR}{8760} \tag{3}$$

$$f = \frac{1}{MTTR + MTTF} \tag{4}$$

In Eq. (3) MTTR is measured in hours, but in Eq. (4), both, MTTR and MTTF, are calculated in years.

B. *Reliability Input Data*

Failure statistics of different grid substation components including data for CBs, current transformer, potential transformer, and other switchgear components are not available for Bangladesh power system (BPS) network. Hence, the data from different sources are used [8,9]. Transmission line lengths and substation configuration data are taken from the Power Grid Company of Bangladesh (PGCB), the grid operator in Bangladesh.

III. Reliability Evaluation of BPS Grid Substations

There are a total of 104 grid substations in BPS. Among them 1 substation is of 400 kV HVDC, 17 substations are of 230/132 kV and 86 substations are of 132/33 kV [10]. In this paper reliability evaluation of five 230/132 kV substation is presented. These are Hasnabad, Hathazari, Ishurdi, Haripur and Rampura 230 kV grid substations. Detailed analysis is presented for the Hasnabad 230 kV grid substation.

Differential protection, distance protection and busbar protection coordinate with each other in a substation. Which of these protection systems reacts to a fault mainly depends on fault location. For the components that are within one protection zone, the effects on the protection will be the same. Therefore, the whole substation is divided into several zones. Hasnabad 230 kV grid substation has three types of zones.

1) *Bus bar Zone:* When the initiating fault is located in the zone of the busbar protection, as shown in Fig. 2, the busbar protection should react first, and trip the CBs: 808B, 818B, 828B and 838B. If any of these CBs fail, the CB failure function will be activated, and trip 805B, AT-1, 815B, AB-1, 825B, AB-2, 835B and AT-3. There is no back-up protection within the substation. If the busbar protection fails, the fault will not be seen by the distance protection within this substation. It will be the distance protection from the nearby substation that clears the fault. Therefore, the whole substation is assumed to be down.

The event tree for a fault within busbar 2 zone is shown in Fig. 3. When both the primary protection (busbar protection) and the associated CBs react successfully, there will be no lines isolated. When primary protection works successfully, but one of the associated CBs fails to trip, the next level of CBs will be tripped by the CB failure function. Line AT-1, Aminbazar-1, Aminbazar-2, AT-3 will be isolated in this case. If the busbar protection fails to see the busbar fault, the whole substation will be down. The situation where both primary and back-up protection fails is neglected, since back-up protection is assumed to be perfect in this study.

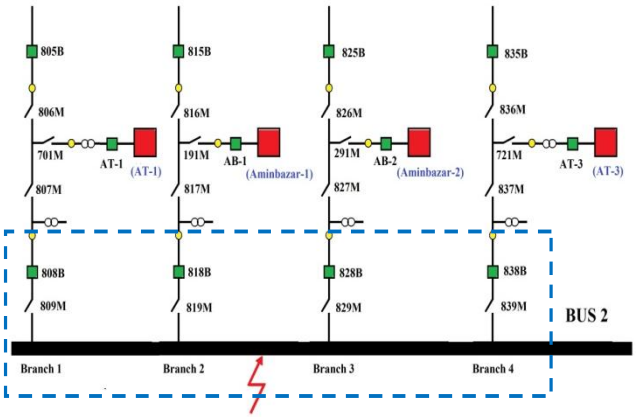

Fig. 2 Bus bar zone of Hasnabad 230 kV grid substation

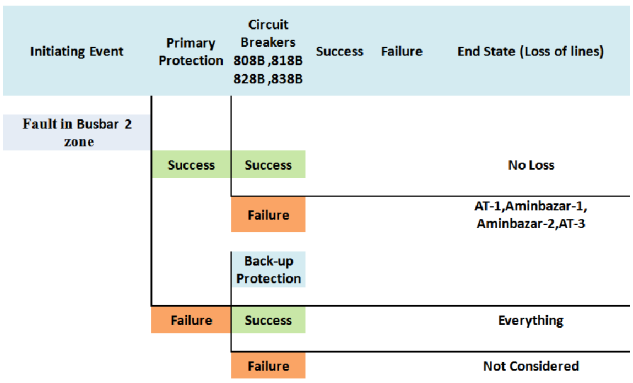

Fig. 3 Event tree for a fault in bus bar 2 zone of Hasnabad S/S

2) *Line Zone:* In Fig. 4, a fault occurring within a line zone is shown. When a fault occurs on the line, the field differential protection should react first. If the initiating fault is a line fault, line differential protection is the primary protection. Since the protection system for those two faults will trip the same CBs, they do not have a different effect on the reliability study. Therefore, these two zones are combined into a single line zone.

The event tree for a fault within Aminbazar-1 zone is shown in Fig. 5. In this case, the primary differential protection should react and trip CBs 815B, AB-1 and 818B and only Aminbazar-1 will be isolated. If one of the CBs fails, the CB failure function will trip 808B, 828B, 838B, 812B, MG-2 and Aminbazar-1, Meghnaghat-2 will be isolated. When differential protection fails to see the fault, the distance protection on the line should react, and trip 815B, AB-1 and 818B. Only Aminbazar-1 will be isolated in this case.

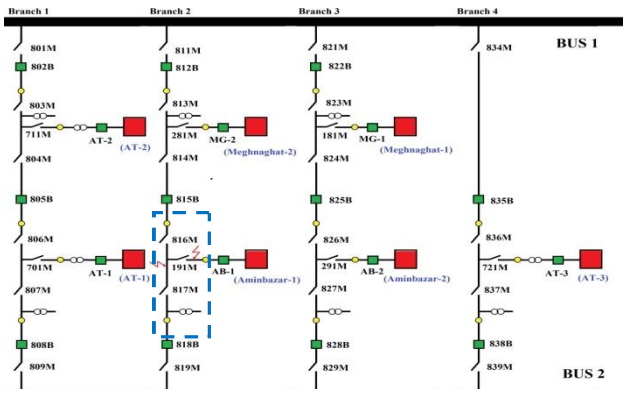

Fig. 4 Line zone of Hasnabad 230 kV grid substation

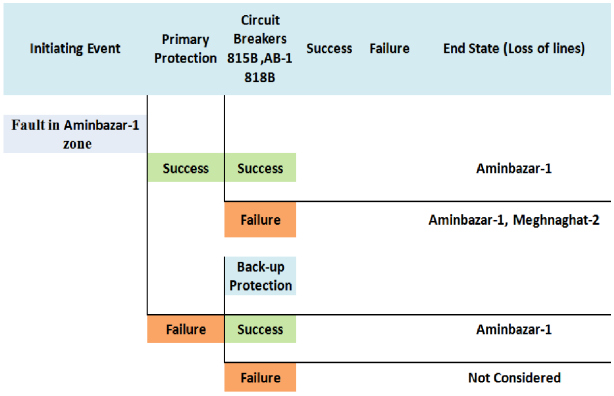

Fig. 5 Event tree for a fault in Aminbazar-1 zone of Hasnabad S/S

3) *Step-down Transformer Zone:* The step-down transformer zone is shown in Fig 6. If the fault is located on the line, field differential will react first. If the fault is a line fault, line differential protection is the primary protection. A fault lying in the transformer zone is protected by the transformer field differential protection. These different types of primary protection systems will trip the same CBs. Therefore, the three different zones are combined into one.

The event tree for the fault within the AT-1 zone is shown in Fig. 7. If an initiating fault occurs within this zone, the primary differential protection will trip 805B, AT-1, 808B and only AT-1 will be isolated. If one of those CBs fails, 818B, 828B, 838B, 802B, AT-2 will be tripped by the CB failure function. Both AT-1 and AT-2 will be isolated. When the primary protection fails, the distance protection should react and isolate AT-1.

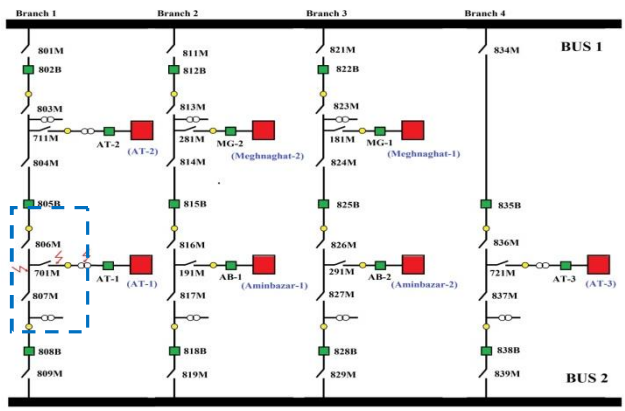

Fig. 6 Step-down transformer zone of Hasnabad 230 kV grid substation

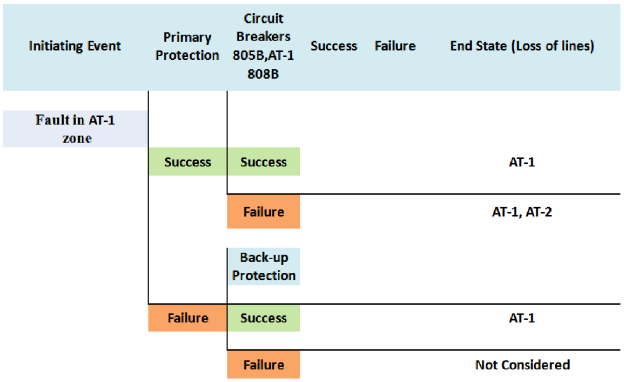

Fig. 7 Event tree for a fault in AT-1 zone

IV. Results And Analysis

To calculate the resulting probabilities and failure frequencies from the event tree, the unavailability and failure frequency of the initiating events is calculated first. This is done by using a small fault tree. When one or more than one of the components within a zone fails, this zone is regarded as failed. As such, every zone can be regarded as a small series connected system and its reliability can be calculated. The zone reliability for the Hasnabad grid substation is presented in Table I. These are the output of FTA and used as the input to ETA.

TABLE I
Zone Reliability

Zone name	Zone's failure frequency	Zone's unavailability
Aminbazar-1	0.0626	0.000058652
Aminbazar-2	0.0626	0.000058652
Meghnaghat-1	0.0668	0.000062124
Meghnaghat-2	0.0668	0.000062124
AT-1	0.06388	0.000364261
AT-2	0.06368	0.000363713
AT-3	0.06388	0.000364261
Busbar 1	0.015	0.000011645
Busbar 2	0.015	0.000011645

The event trees can be calculated using the method introduced in section III. By adding the failure statistics of the same end states, the frequency and probability of losing lines can be calculated. The results are presented in Table II.

TABLE II
Specific Line Failure Statistics

Lost line	Unavailability	Failure frequency	Mean time to failure (Year)	Mean time to repair (Hr)
Aminbazar1	6.06E-05	0.063	15.79	8.39
Aminbazar2	6.06E-05	0.063	15.79	8.39
Meghnaghat1	6.41E-05	0.067	14.81	8.32
Meghnaghat2	6.41E-05	0.067	14.81	8.32
AT1	3.68E-04	0.064	15.48	49.87
AT2	3.67E-04	0.064	15.52	49.95
AT3	3.64E-04	0.064	15.59	49.81

The unavailability and failure frequency of a line represents the probability/frequency that this line is isolated from the substation due to any component's fault. These are calculated using the event trees. The dominant component in reliability evaluation is the transmission line or cable. The longer the line, the greater the chance that a line fault occurs.

Meghnaghat1 and Meghnaghat2 have the longest transmission lines: 26 km. So their failure frequency is the highest. The MTTF represents the average time it takes before the specific line/generator is isolated due to a component's fault. The MTTR represents the average time it takes to locate and repair the fault, and then put the specific line back into operation.

A summary of the five 230 kV grid substations in terms of the most reliable zone and the zone of highest possibility to fail for each substation is presented in Table III. The zone which has highest MTTF or lowest failure frequency is the most reliable zone and the zone which have lowest MTTF or highest failure frequency has the highest failure possibility.

TABLE III
RELIABILITY OF ZONES OF RESPECTIVE SUBSTATIONS

Substation	Most Reliable zone	Most unreliable zone
Hasnabad	Aminbazar1, Aminbazar2	Meghnaghat1, Meghnaghat2
Hathazari	Raojan1, Raojan2	Comilla1
Ishwardi	T3	Ghorashal1, Ghorashal2
Haripur	Siddhirganj	Rampura1
Rampura	MT3	Ghorashal1

Figures 8(a) to 8(c) present the overall unavailability, failure frequency and MTTF, respectively, of the five grid substations.

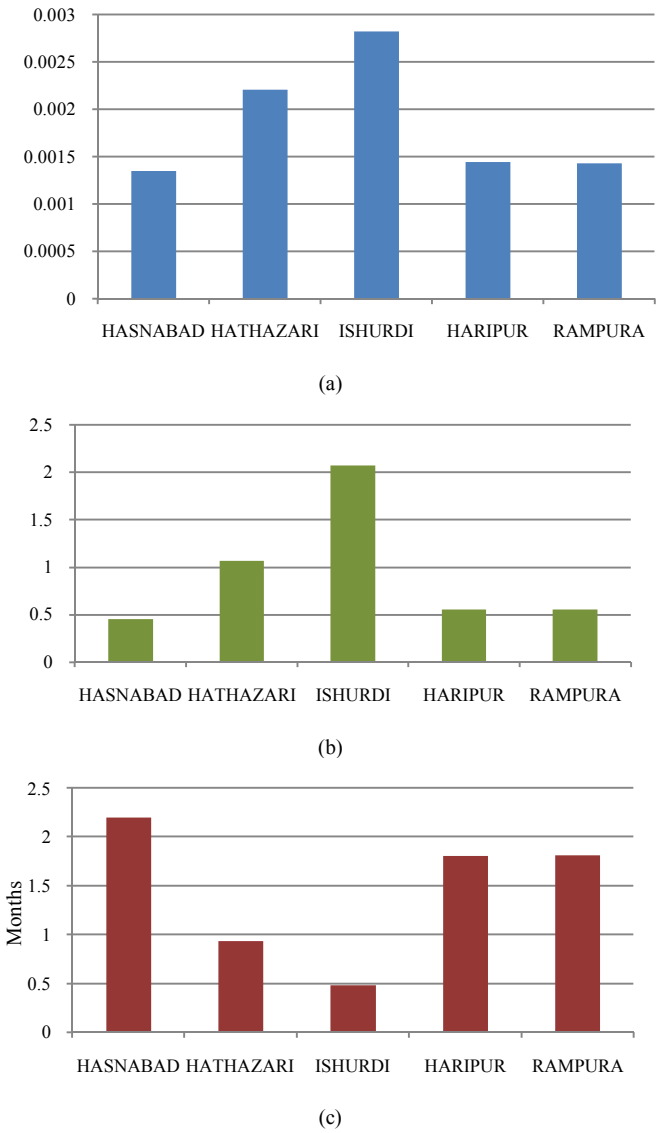

Fig. 8 Reliability indices for different grid substations: (a) unavailability, (b) failure frequency, (c) mean time to failure

The overall unavailability and failure frequency is calculated by adding up the unavailability and failure frequency of different zones. Then MTTF is calculated by Eqs. (3) and (4). It can be seen that the Ishurdi 230 kV grid substation has the highest unavailability of almost 0.003, followed by Hathhazari with an unavailability a little over 0.002. Hasnabad, Haripur and Rampura, all within or near the capital city of Dhaka, have similar level of unavailability of less than 0.0015. Hasnabad grid substation has the lowest failure frequency and the highest MTTF.

Ishurdi grid substation is the most vulnerable with the highest failure frequency of more than two failures a year and the lowest mean time to failure of a little less than six months. This will seriously affect the design and operational safety of the proposed nuclear power station at Rooppur sited closely nearby.

V. CONCLUSIONS

The reliability of five different 230kV substations of Bangladesh is analyzed and their unavailability, failure frequency and mean time to failure compared. The study will help to assume the ability of BPS grid substations to be connected to challenging energy sources like nuclear power plants. Throughout the analysis, it has been observed that the dominant component in reliability evaluation of a system is the transformers and line/cable, because their failure frequency is large and the lines with similar parameters and locations have similar failure statistics. In this paper, all the components within the substation are assumed to be operating properly, which means that maintenance is not considered. Maintenance may be included in future studies.

Abstract— **Today's mainstream flexible electronics research is geared towards replacing silicon either totally, by having organic devices on organic substrates, or partially, by transferring inorganic devices onto organic substrates. In this work, we present a pragmatic approach combining the desired flexibility of organic substrates and the ultra-high integration density, inherent in silicon semiconductor industry, to transform bulk/inflexible silicon into an ultra-thin mono-crystalline fabric. We also show the effectiveness of this approach in achieving fully flexible electronic systems. Furthermore, we provide a progress report on fabricating various memory devices on flexible silicon fabric and insights for completely flexible memory modules on silicon fabric.**

***Index Terms*— flexible electronics; mono-crystalline silicon; semiconductor industry; memory devices; electronic systems.**

I. Introduction

As new horizons and applications arise for flexible electronics, the opportunity for flexible systems enhances [1-9]. Applications ranging from biomedical to consumer electronics impose some specifications to be met in this new electronics generation, such as high flexibility, reliability, performance, and integration density. Great progress and milestones have already been achieved through different approaches utilizing polymeric substrates and polymeric devices [10-17]. However, there are many challenges along the way involving low carrier mobility, thermal instability, low integration density, etc. Other approaches exist, such as utilizing expensive silicon on insulator (SOI) or unorthodox silicon (111) wafers and peeling off the thin silicon nano-ribbons with or with-out devices [18-19]. This solves the thermal budget limitations partially (if the devices are already fabricated) and low performance associated with organic electronics but at the expense of the higher costs and limited integration density.

To this end, we provide a pragmatic approach to complement current research which transforms bulk silicon into a flexible fabric hosting devices [20-27]. Our approach follows an etch-protect-release-recycle process to peel off an ultra-thin flexible sheet with pre-fabricated devices from low cost bulk mono-crystalline silicon (100), commonly used in the semiconductor industry. This process capitalizes on the complementary metal oxide semiconductor (CMOS) technology as opposed to replace it while keeping the cost checked.

Furthermore, we utilize our demonstrated process to build up various device components required for building flexible memory modules, essential elements in all electronic systems. This is a necessary step towards taking flexible electronics research into demonstration of completely flexible stand-alone electronics systems.

This work is organized as follows; Section II discusses our generic transformative process for creating flexible Si fabrics; Section III provides review of the various demonstrated devices on flexible fabric required for building a flexible memory module; Section IV is for conclusions and insights related to the future of flexible electronics research.

II. Transforming Bulk Silicon Into a Flexible Ultra-Thin Semi-Transparent Silicon Fabric

To transform bulk devices into flexible ones, we have two approaches. The first is the "device first" approach where we build the devices on bulk then peel off a thin Si fabric containing the devices. The second is the "device last" approach where the thin silicon fabric is peeled off with only the edges acting as anchors to tie it to the wafer while device building processing steps are performed. The detailed process for each approach is as follows:

A. Device first approach

Fig. 1 shows the schematic for the process; starting with 1, a) showing a Si/hard mask (SiO_2 in our case)/ device stack. Then, etching deep trenches ("release holes") throughout the whole stack and deep into the Si up to the desired fabric thickness (Fig. 1, b) using photolithographic techniques and deep reactive ion etching. Next, using spacer formation technique a conformal atomic layer deposition (ALD) layer is deposited everywhere then vertically etched leaving only sidewalls protection (Fig. 1, c, d). Finally, the sample is put in XeF_2 for isotropic etching of Si from the bottom of release holes (only exposed Si area) until the etched regions merge, enabling the release of the thin device containing fabric (Fig. 1, d). Fig. 1, e shows a top view after the final step.

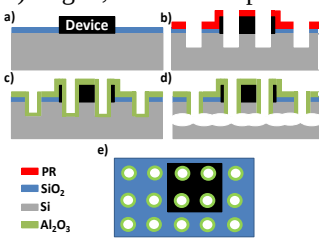

Fig. 1 Process flow fort the "device first" transformational approach.

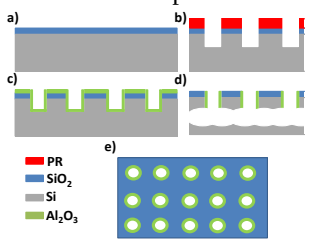

Fig. 2 Process flow fort the "device last" transformational approach.

B. Device last approach

Fig. 2 shows the fabric release process after which the devices can be built in the traditional way on the already flexible fabric.

Both approaches have associated perks compared to aforementioned techniques using polymeric devices or expensive inorganic substrate in terms of performance and cost. Performance wise, the devices are silicon based built on silicon using traditional optimized semiconductor processes that outperform organic electronics. Cost effectiveness comes from the fact that the wafers are mono-crystalline silicon (100) compared to the less common silicon (111) and the 10x more expensive SOI wafers. Moreover, the recyclability of the remaining bulk wafer after the removal of the top thin layer renders this solution more economical. On the other hand, the release holes network in this work consumes 19.6% (10 µm holes, 20 µm pitch, and 100 x 100 μm^2 devices) of chip area. This is still acceptable with respect to the international technology roadmap for semiconductors (ITRS) projections showing that 20% of active chip area will still be consumed with shallow trench isolation (STI) even with extreme scaling [28]. The pros and cons of the device first vs. the device last approaches are as follows. The device first approach follows standard CMOS processes until the devices are completely built, then release holes are etched-protected then the thin fabric containing devices is released. This makes it easier to handle during device fabrication and enables testing the bulk devices for functionality before and after flexing for comparison. However, this comes at the expense of fabricated devices passing extra processing steps (RIE, DRIE, ALD-300°C and XeF_2 gas for extended durations). On the other hand, the device last approach spares the devices the extra steps after their fabrication at the expense of more delicate handling constraints, relatively non planar released fabric, and the inability of probing bulk devices before flexing. Packaging of these devices can be done using SU-8 (an epoxy based polymer used in microelectronic applications) which possess chemical and thermal stability and excellent flexibility up to 75 µm thickness [29].

III. Review of Various Memory Components Built on Flexible Silicon Fabric and Performance Assessment

Using the two flexing approaches, various memory components (DRAM, ReRAM, FeRAM) were built on the flexible Si fabric. DRAM is composed of an array of memory cells hosting a select/access transistor and a stored charge in a capacitor representing bits (digital ‘0’ or ‘1’). DRAM has a volatile nature, i.e. loses information when no power is supplied, and has a small foot print due to its simple cell structure. ReRAM is an emerging non-volatile memory technology where resistance of material is dependent on the history of applied voltage. It has simple structure like DRAM but does not require continuous power supply to store the data and has fast switching capability. FeRAM is similar to ReRAM but it is a more mature technology (commercially available) where material polarization depends on the history of applied voltage. FeRAM has desirable low power operation, extended data retention periods, and survives millions of read/write cycles.

Memory arrays account for the majority of transistors (select/access transistors) in a CMOS system on chip. Therefore, MOSCAPs (basic gate stack of MOS transistors) is an essential memory component that needs to be assessed when addressing the roadmap towards flexible memory.

A. Dynamic random access memory (DRAM)

The DRAM is the volatile fast component of memory modules. Using the “device last” approach, metal/insulator/metal capacitors (MIMCAPs), basic building block of DRAMs and the structure suggested by technology roadmap for 65 nm DRAM nodes and below [30], were built. Fig. 3 shows the observed increase in normalized capacitance per unit planar area for released devices versus unreleased (details can be found in [21]). This observation indicates that the released devices can be used to build a flexible and denser DRAM relative to ones utilizing bulk devices.

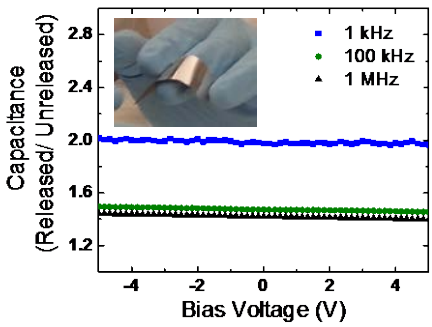

Fig. 3 Improvement in capacitance per unit planar area of released devices.

B. Resistive random access memory (ReRAM)

Conceptualized in 1971 by L. Chua and realized in 2008 in HP labs, memristors research has been gaining momentum especially as an alternative non-volatile memory (NVM) to CMOS based flash which is approaching scaling limits [31, 32]. This is mainly due to their simple structure and fast switching.The same MIMCAPs stack showed resistive switching at higher voltages which can be explained by a phenomenon similar to a soft breakdown after which the material is able to recover when applied voltage polarity is reversed. Figure 4 shows the memristive effect in MIM stack for bulk (unreleased) and flexible (released devices). The plot shows that there is no discernible degradation due to the flexing process as the curves overlap throughout the sweeping regime.

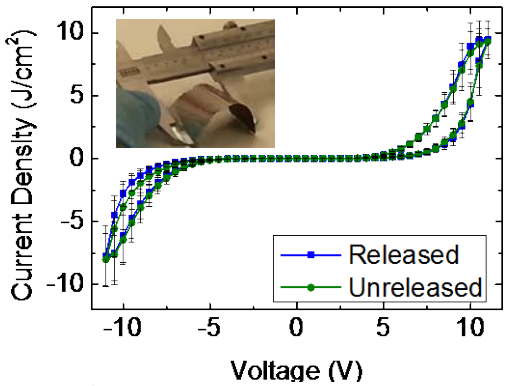

Fig. 4 Flexible and inflexible memristive devices observed hysteresis loops.

C. Ferroelectric random access memory (FeRAM)

Another form of NVM is FeRAM -- matured technology and widely available. Using the most widely used ferroelectric material, lead zirconium titanate (PZT), prepared using sol-gel technique, FeRAM cells were fabricated. Fig. 5 shows the fabrication process followed, which is simpler and different from our previous approach but a necessary step before performing our more elaborate flexing process. First, the

SiO_2/Si is sputtered with Pt electrode (Fig. 5, b). Then, PZT first layer was spun at 1500 rpm for 35 seconds, followed by a pyrolysis bake at 300 °C for 5 minutes; this is repeated for 4 layers (~280 nm) followed by a final anneal at 650°C for 30 minutes. Then, a Ti adhesion layer and Pt top electrode are sputtered and patterned. Finally, the top side of the sample is protected with photoresist and sample is flipped and etched using DRIE to make a thin Si sheet. The goal of this study is to make sure FeRAM devices will still function on a bent flexible Si fabric.

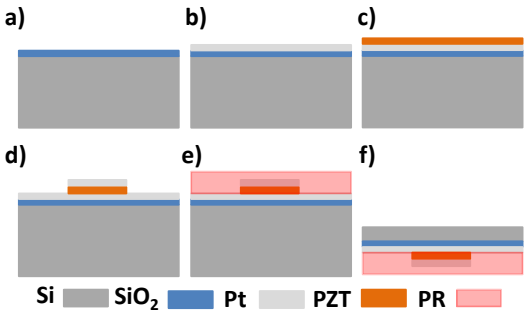

Fig. 5 Fabricating PZT FeRAM devices.

Figure 6 shows the P-E hysteresis loop for functioning bulk, flexible and bent at 10 mm bending radius ferroelectric devices.

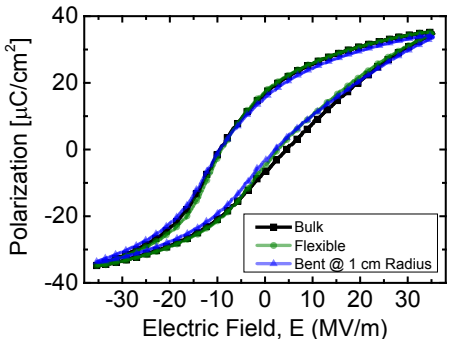

Fig. 6 P-E Hysteresis curves for bulk, flexible, and bent ferroelectric devices.

D. MOSCAPs

Transistors are essential elements in memory modules due to their significant role in crossbars arrays architecture [33, 34]. Select transistors are used to select the row and column of the cell to be read from or written into. Metal oxide semiconductor capacitors (MOSCAPs) are used to study the gate stack and predict the effects of various anomalies in these transistors.

State-of the art high-κ MOSCAPs were built on bulk wafer and then released using our "device first" approach. Figure 7, a) shows the C-V plot for bulk and flexible devices at different frequencies, indicating frequency imposed limitations. From the plot we observe that there is more frequency dispersion in the released devices which can be attributed to the release holes network passing through the active area of the devices. This can be avoided by scaling down active areas and varying the spaces between holes. This is still an area of improvement for our Si based flexible memory modules to function at high frequencies.

Transistors reliability is another area of concern and has been assessed for our MOSCAPs. Figure 7, b) shows the time dependent dielectric breakdown plot for released MOSCAPs. These plots are used to extrapolate the safe operational voltage of the devices that would pass the 10 years lifetime benchmark (industry standard). The lifetime projections showed 20% decrease in safe operation voltage for flexible devices versus unreleased. However, the minimum safe voltage was 5 V which is acceptable as today's ICs aim at 1 V supplies.

Furthermore, we have studied the effect of bending on the leakage current and the breakdown voltage of the devices (depicted in Figure 8). Figure 8, a) shows that the devices can survive up to 7 days while bent at 10 mm bending radius (0.125% nominal strain) if the operational voltage is below 85% of breakdown voltage. On the other hand, Figure 8, b) shows that the number of bending cycles has a fast degradation effect on the value of breakdown voltage of the devices. Hence, these devices would be more suitable for applications where they remain bent or conformal to a non-planar surface than an environment where it is repetitively bent and unbent (detailed discussion on mechanical reliability of flexible MOSCAPs can be found in Ref. [35]).

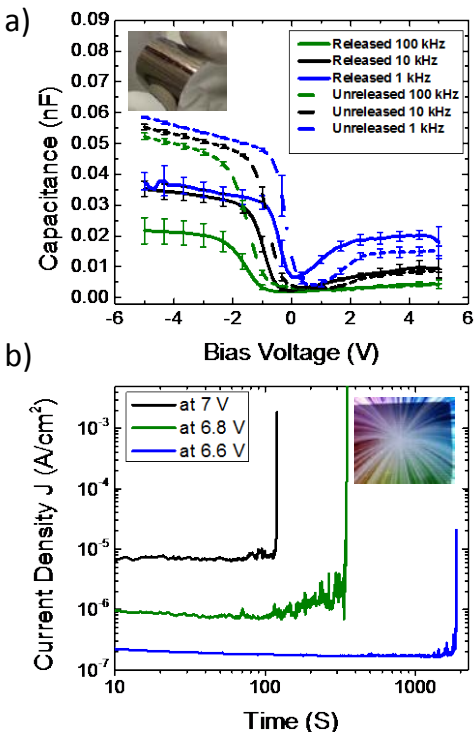

Fig. 7 MOSCAP plots, a) C-V plot for flexible and inflexible devices, b) time dependent dielectric breakdown study of flexible devices on Si fabric, inset showing semi-transparency of flexible silicon fabric.

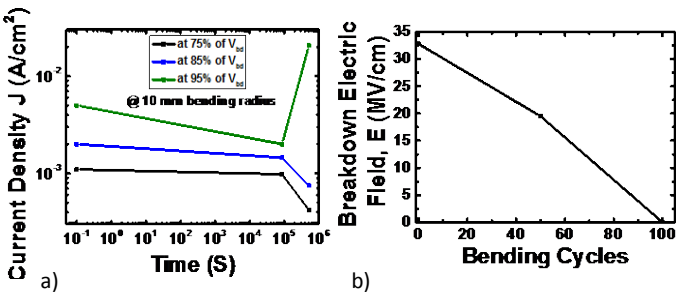

Fig. 8 Leakage plot as a function of bending time (a), and breakdown plot as a function of bending cycles (b).

IV. Conclusions

We have demonstrated a CMOS compatible low cost process to transform any traditional electronics into flexible and semi-transparent one. Using that generic batch process,

we have made all necessary elements required for silicon based fully flexible memory modules. Devices include DRAM cells, NVM cells (memristive and ferroelectric), and MOSCAPs to study the gate stack of select transistors to be used in crossbars arrays architectures, all built on thin flexible silicon fabric. This is an important step forward towards achieving completely flexible stand-alone electronic modules while capitalizing on the perks associated with the well-established silicon based semiconductor industry.

ACKNOWLEDGEMENTS

This work was supported by KAUST Office of Competitive Research Fund (OCRF) Competitive Research Grant CRG-1-2012-HUS-008. The authors would like to thank Mohammed Y. Al-Nassar for sharing his valuable knowledge of PZT film deposition conditions, and Mohammed A. Zidan for the invaluable discussions on resistive memory cells.

***Abstract*—Ballistic performance of nanoscale InGaSb and InAsSb XOI n-FET is compared using non equilibrium greens function (NEGF) method. The simulation results demonstrate that the ballistic performance is opposite to what is expected if the devices were long channel MOSFET. Although InAsSb possesses higher bulk electron mobility, but in ballistic regime, InGaSb gives higher drain current along with better subthreshold characteristic and reduced threshold voltage, if the off state current for both material is made equal.**

Keywords—XOI;NEGF;Ballistic transport; InGaSb;InAsSb (key words)

I. INTRODUCTION

On demand of performance improvement and increased integration density, Gate-length of the Silicon MOSFETs has reduced from 10 µm to 22 nm in last 40 years, and it is now approaching its physical limit [1-3]. These ultra scaled devices suffer from various adverse effects including short channel and hot electron effects, parasitic capacitance, leakage current, transistor isolation etc. Getting rid of bulk silicon (Si) structure in which channel had been formed by inversion layer, a layer of single crystalline Si is laid over insulator. This Si layer serves as channel and the silicon-on-insulator (SOI) structure has drastically improved the device performance by suppressing these adverse effects [4,5]. Performance of this device could further be improved by replacing Si from the channel with a material having better electron transport properties. This would allow reduction in operating voltage without compromising the switching speed. Therefore, further downscaling may be feasible [6].

Group III-V compound semiconductors exhibit outstanding electronic, including high electron mobility, high peak saturation velocity [7,8]. Additionally, III-V semiconductors have a mature and large industry for solid-state lighting and transceivers for optical communications [8]. Therefore, integration of III-V semiconductors on Si platform would now be the 'royal road' for achieving high performance low power device fabrication. With that aim, in analogy to SOI, n-type InAs FETs were experimentally demonstrated on Si/SiO_2 substrate [9] and the structure is termed as "XOI" to represent compound semiconductor-on-insulator platform. Due to similar device structure, XOI also offers all the advantages of SOI. Specially, the suppression of short channel effect (SCE) makes the XOI a promising technology for sub-100-nm node and beyond [10].

But performance of a device in this ultra scaled dimension can be very different since the dominating factors are not the same. InAsSb long channel MOS shows better performance than that of InGaSb due to higher electron mobility [8, 11]. However, when the channel length goes to sub 100nm regime the electronic transport is ballistic. As a result, the drain current is determined by the density of states of the channel material as well as the electron velocity through the channel [12, 13]. In this paper, the performances of InAsSb and InGaSb XOI FETs are investigated using non equilibrium greens function (NEGF) method. It is found that InGaSb XOI FET shows better performance than that of InAsSb in all aspect.

II. QUANTUM BALLISTIC SIMULATION

A. Device structure

The device structure studied here is shown in fig. 1. Table-1 lists the numerical parameters used for the simulation. Two well established theories are there to study the ballistic performance namely "Top of the barrier (TOB)" model and "Non equilibrium Greens function (NEGF)". We used NEGF mode space approach in effective mass approximation in the environment of silvaco's Atlas device simulation tool.

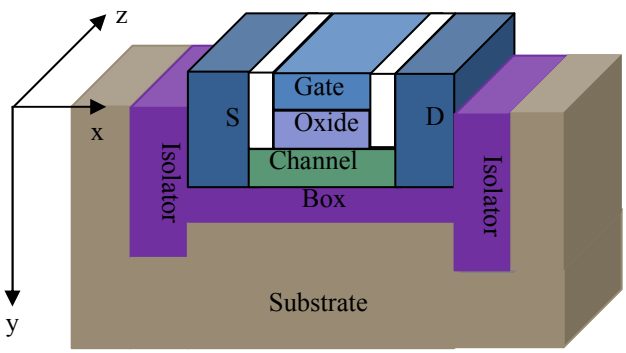

Fig. 1. XOI device structure under study. Detail of physical and material parameters are given in Table I.

TABLE I. PARAMETERS USED IN THE SIMULATION OF THE DEVICE STRUCTURE SHOWN IN FIG. 1.

Parameter name	*Value*	*Description*
ε_{ins}	22	HfO_2 as gate oxide
t_{body}	3nm	It is the thickness of the channel. $In_{0.3}Ga_{0.7}Sb$ and $InAs_{0.7}Sb_{0.3}$ as channel material
t_{ins}	2.82 nm	Thickness of HfO_2 gate oxide, EOT = 0.5 nm
N_{body}	P type, $10^{15}/cm^{-3}$	Doping at the channel region laid right bellow the gate oxide.
N_{SD}	N type, $10^{20}/cm^{-3}$	Rest of the channel region, i,e region where N_{body} is not used.
L_{SD}	5nm	This is the extension of channel from that covered by gate oxide.
L_G	15nm	Channel region covered by gate oxide.
Φ_{metal}	4.1eV and 4.92073 eV	InGaSb and InAsSb XOI FETs respectively

B. NEGF theory

The NEGF method provides a rigorous formalism for quantum transport in nanoscale devices [13]. In this quantum modeling, schrodinger equation is solved using open boundary condition in the source and drain region (through which electron can come into or leave from the region under study). And it is solved self-consistently with the Poisson's equations to obtain the energy level, charge and current distribution [14].

NEGF are solved using two approaches namely real space and mode space method. Simulation in real space method is computationally very much costly. In case of the device where quantum confinement is strong (double gate MOS or XOI FET) the mode space approach can be used. The Hamiltonian in these device structures is separated in longitudinal and transverse directions; as a result, it greatly reduces the computational burden. Moreover, in the devices where the cross-section does not change, the sub-bands are not quantum-mechanically coupled to each other; the transport equations become essentially 1D for each sub-band that leads to use the uncoupled mode space approach [15]. The transformation of a real space effective mass Hamiltonian H_0 to a mode space is done by taking a matrix element between m^{th} and n^{th} wave functions of kth and l^{th} slices

$$H^{MS}_{mnkl} = < \psi^{k}_{m(y)} | H_0 | \psi^{l}_{n(y)} > \quad (1)$$

The transport equation in mode space is

$$\left(E - H^{MS}_{mnkl} - \Sigma^{R}_{S} - \Sigma^{R}_{D}\right) G^{R} = I \quad (2)$$

Here, E is the energy of carrier, Σ^{R}_{S} and Σ^{R}_{D} are retarded self energies carrying information about source and drain respectively, H_0 contains the information of the channel, and G^R is the retarded greens function, I is the identity matrix. After solving the above equations for each energy level, current density is calculated by [15]

$$J_x(x_i, y_j) = -\frac{2e}{hL_z\Delta_x} \sum_{k_z\sigma} \sum_{mn} \int Re(t_{i+1ijj} G^{<}_{mnii+1}\, \psi^{i}_{m}(y_j)\, \psi^{*i+1}_{n}(y_j) \frac{dE}{2\pi} \quad (3)$$

III. RESULT AND DISCUSSION

In our simulation, source and drain doping concentration is taken to be $10^{20}/cm^3$, and this doping is done throughout the region marked by L_{SD} in figure-1. Von Neumann boundary conditions for potential are used because the ballistic carrier do not create voltage drop near source and drain contact. Moreover the potential in source and drain are allowed to float, because the carrier may reflect backward and hence the total carrier concentrations in the contact can change with bias.

Figure-2 shows a comparison of I_D-V_G characteristics of InGaSb and InAsSb XOI FETs plotted at V_D=0.05V. The body thickness of the device is 3nm. Wave function penetration in the oxide region is also taken into account. To compare the performance, first the off current of the devices are made equal by tuning the gate metal work function, Φ_{metal}. It is clear from the figure that, the drain current, for InGaSb is higher than that for InAsSb at each gate bias. It is because, when device size shrinks down to the ballistic limit, carrier goes through the channel facing negligibly small or no scattering. Since current is defined as the amount of charge transferred per unit time, the ballistic current is simply determined by two factors, i) how much charge is there in the channel moving, ii) the transit time of the carrier through the channel [12]. The second factor also means the current is proportional to the carrier velocity. But the travelling carrier can have different allowed velocities through the channel, and to find the total current, summation of the currents given by each allowed velocities are to be taken. In another sense, integral over the entire energy range of travelling carriers must be taken when current components are expressed in terms of energy.

Amount of carrier in the channel depends on the density of states (DOS). For InGaSb and InAsSb materials the effective density of states are evaluated using linear interpolation from the values experimentally measured for the binaries [16], and found to be 1.93×10^{17} and 1.05×10^{17}, respectively.

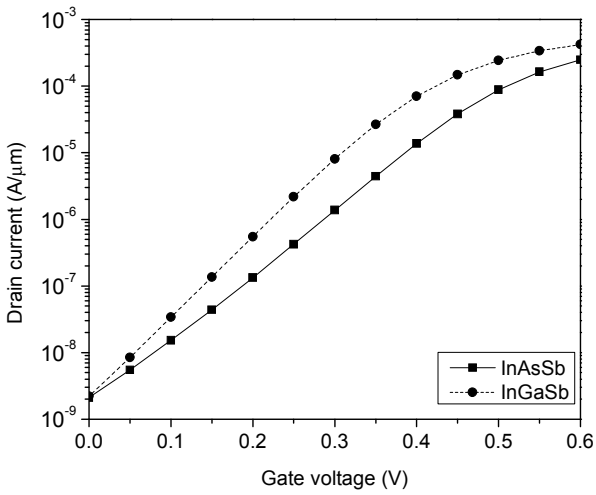

Fig. 2. I_D-V_G characteristics of 15nm InGaSb and InAsSb XOI nFETs. The structure of the devices is shown in fig.1.

Again, any heavier particle tends to move slowly, i,e the velocity of electron is inversely proportional to the effective mass (m^*). More accurately speaking, it is proportional to the inverse of square root of m^* for a given energy of travelling electron. The m^* for both materials are also calculated by linear interpolation and found to be m^*=0.039 and 0.026, for InGaSb and InAsSb respectively.
Therefore the ratio of effective DOS to m^* would indicate the amount of current through the device. This ratio for InGaSb is found to be 1.225 times higher than that of InAsSb. That is why InGaSb XOI FET gives higher current than InAsSb XOI FET.

Not only higher drain current, the I_D-V_G characteristic in fig. 2 also shows the drain current for InGaSb increases more sharply than InAsSb. This behaviour could be easily understood from semiclassical "Top of the barrier" or TOB model of ballistic transport. The highest point of electronic potential (band diagram) in the channle is called the "Top of the barrier", which is evaluated from self consistent electrostatics. According to this model, the drain current is given by [17]

$$I_D = \frac{W2q}{h}\int_{E_c}^{\infty}\sqrt{\frac{2m^*E}{\pi\hbar}}[f(E) - f(E - qV_d)]dE \quad (4)$$

Here, W is the width of the device, f(E) is the fermi function with respect to the chemical potential at the source, f(E-qV_d) is the fermi function with respect to drain chemical potential. E_C is the position of "TOB", and the above integral gives the on state current. Integral of the same equation, using the limit from negative infinity to "TOB" determines the subthreshold current, which is mainly leackage or tunnelling of carrier from source to drain [18]. That is why position of TOB actually determinces the subthreshold as well as off state current. This position of TOB is tuned by tuning gate metal work function Φ_{metal} to get same I_{OFF} for both material.

Equation (4) show that the drain current is proportional to the

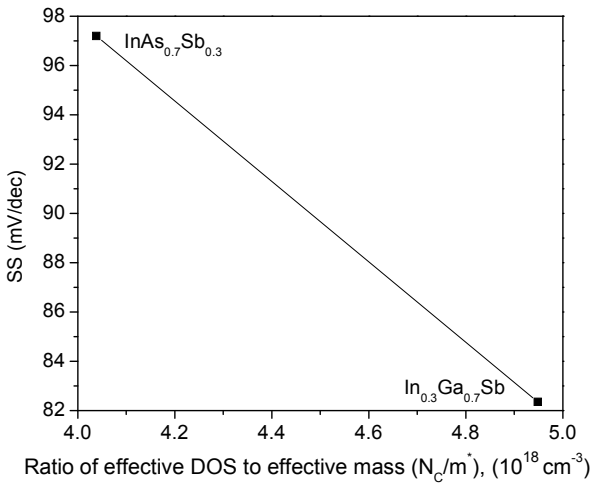

Fig. 3. Variation of Subthreshold slope (SS) with the ratio of effective DOS (density of states) to m^* (effective mass).

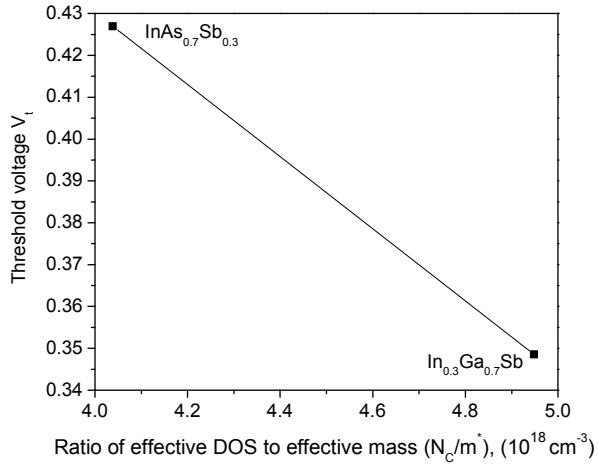

Fig. 4. Variation of threshold voltage with the ratio of effective density of states to effective mass. The workfunction the gate metal is tuned to give the same off current for InGaSb and InAsSb materials.

square root of the effective mass. Further, the rate of change of current with respect to gate bias also has similar proportionality relation. Since, InGaSb possess slightly higher effective mass, current increases much sharply leading to lower subthreshold slope (SS), and finally saturates at a higher value in case of InGaSb XOI FET. Fig. 3 shows the SS is reduced from 97.186 to 82.351 for changing the material from InAsSb to InGaSb.

Figure 4 shows the variation of threshold voltage of InGaSb and InAsSb XOI nFETs as a function of the ratio of effective density of states to effective mass. The threshold voltages are determined by substucting half of the applied drain bias from the point on voltage axis where the highest slope of the I-V curve cuts. It is found that InGaSb gives lower threshold voltage than InAsSb. The threshold voltage as well as the off current of the device depends on the barrier height at zero gate biases. This barrier height can be controlled by the work function of the gate metal. It is important that, we tuned the work function of the gate contact to make the off current equal for both cases so that other parameters can be compared.

IV. CONCLUSION

In this paper, we studied the ballistic performance of InAsSb and InGaSb XOI nFETs. The performance of the devices is compared for 15nm channel with 2.82 nm oxide thickness (0.5 nm EOT) using NEGF method. The source and drain regions are taken to be heavily doped (10^{20}/cm^3) and the channel is very lightly p type doped which can be considered as intrinsic. Gate metal work function is tuned to make the off state current equal for both of the material and the wave function penetration to the oxide is also taken into account. Source drain contacts are allowed to float to treat the carrier reflection accurately. We found that, in ballistic regime, the performance is opposite to what is expected for long channel MOSFET. InAsSb possess relatively higher bulk electron mobility, but in ballistic regime, InGaSb XOI FET gives higher drain current for all positive gate bias. With increased on state current, InGaSb also gives lower threshold voltage (V_T) and

subthreshold slope (SS). The study reveal that InGaSb would be the suitable material for low power high speed logic nanoscale FETs.

Influence of band parameter of gate dielectrics on the ballistic performance at same EOT

Md. Nur Kutubul Alam, Muhammad Shaffatul Islam, Md. Raifqul Islam
Department of Electrical and Electronic Engineering
Khulna University of Engineering & Technology
Khulna-9203, Bangladesh
alamjhilam@gmail.com

***Abstract*— Different high-k dielectrics have been supposed to provide same device performance if their physical thickness are not equal but equivalent, called "Equivalent oxide thickness" (EOT). For ultra thin body (UTB) devices like XOI, despite of EOT, conduction band offset (ΔE_C) at gate oxide-channel interface dominates the ballistic performance. In case of $In_{0.3}Ga_{0.7}Sb$ XOI nFET using Al_2O_3 and HfO_2 with 0.5 nm EOT, we show the threshold voltage decreases and the subthreshold slope (SS) increases with increase in ΔE_C.**

Keywords—XOI; NEGF; Ballistic transport; InGaSb; High K; gate dielectric.

I. INTRODUCTION

Transistors are now approaching to their physical limit since their size has been reduced from 10 µm to 22 nm in last four decades for the search of better performance [1-3]. At this extremely scaled size, various adverse effects like short channel and hot electron effects, parasitic capacitance, leakage current, problem of transistor isolation etc. arises. To solve these problems, silicon-on-insulator (SOI) structure has been adopted which drastically improved the device performance by suppressing these adverse effects [4,5]. Replacement of Si from the channel with III-V materials would further allow the lowering of operating voltage without sacrificing device performance due to their better transport properties [6,7 (Kuniharu, Nainani)]. That is why, taking the advantage of available process technology [8], n-type InAs FETs were experimentally demonstrated on Si/SiO_2 substrate by Javey et. al [9] and the structure is termed as "XOI" to represent compound semiconductor-on-insulator platform.

Not only the device architecture, but also the gate dielectric used is also a major issue. With decreasing gate length, area under gate dielectric decreases causing the oxide capacitance (C_{ox}) to decrease. That is why to maintain the control over channel, oxide thickness is needed to be decreased and thereby keeping required level of C_{ox}, I_{ON} and to control the threshold voltage roll off. In case of bulk Si MOSFET, thickness of gate oxide (SiO_2) is reduced over the years from 300nm for 10µm gate length (L_G) to 1.2nm for 65nm L_G. But use of that thin SiO_2 brings reliability issues due to high leakage current, dielectric breakdown, reduced channel mobility and so on [10,11]. One solution to this is replacement of SiO_2 with a material having higher dielectric constant. High-k material can be grown physically thicker and still providing the same oxide capacitance (C_{ox}) as thin SiO_2 does. In that case the thickness of high-K material is equivalent to the thickness of SiO_2, which is termed as "Equivalent oxide thickness", or "EOT". The thick high-k dielectric then offers required control over the channel with significant reduction in leakage current [11]. It has also been expected for different high-K material having different dielectric constant, if their EOT is the same, they would give same C_{ox} and therefore provide same device performance.

But in this study we found that for ultra thin body (UTB) devices like XOI, not the EOT solely control the device performance, but the band parameters like conduction band offset (ΔE_C) between gate dielectric and channel material has a great influence on the ballistic I-V characteristics. Using Non equilibrium Greens function (NEGF) method, we studied the ballistic performance of $In_{0.3}Ga_{0.7}Sb$ XOI nFET using Al_2O_3 and HfO_2 as gate oxide. In both cases, we used 0.5nm EOT. Wave function penetration to the oxide has also been taken into account. It is found that the threshold voltage decreases and the subthreshold swing (SS) increases with the higher value of ΔE_C. All other parameters affecting I-V characteristics (e,g gate metal work function) has been kept same in both cases.

II. QUANTUM BALLISTIC SIMULATION

A. Device structure

The device structure studied here is shown in fig. 1. Table-1 lists the numerical parameters used for the simulation. Two well established theories are there to study the ballistic performance namely "Top of the barrier (TOB)" model and "Non equilibrium Greens function (NEGF)". We used NEGF method in mode space approach with effective mass approximation in the environment of silvaco's Atlas device simulation tool.

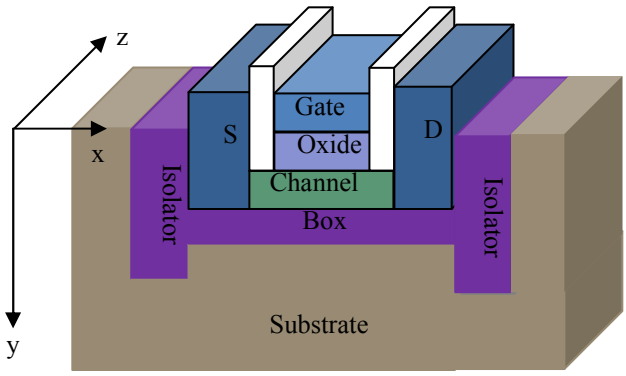

Fig. 1. XOI device structure under study. Detail of physical and material parameters are given in Table I.

TABLE I. PARAMETERS USED IN THE SIMULATION OF THE DEVICE STRUCTURE SHOWN IN FIG. 1.

Parameter name	***Value***	***Description***
ε_{ins}	22	HfO_2 as gate oxide
t_{body}	3nm	It is the thickness of the channel. $In_{0.3}Ga_{0.7}Sb$ and $InAs_{0.7}Sb_{0.3}$ as channel material
t_{ins}	2.82 nm	Thickness of HfO_2 gate oxide, EOT = 0.5nm
N_{body}	P type, $10^{15}/cm^{-3}$	Channel region laid right bellow the gate oxide.
N_{SD}	N type, $10^{20}/cm^{-3}$	Rest of the channel region, i,e region where N_{body} is not used.
L_{SD}	5nm	This is the extension of channel from that covered by gate oxide.
L_G	15nm	Channel region covered by gate oxide.

B. *NEGF theory*

The NEGF method provides a rigorous formalism for quantum transport in nanoscale devices [12]. In this quantum modeling, schrodinger equation is solved using open boundary condition in the source and drain region (through which electron can come into or leave from the region under study). And it is solved self-consistently with the Poisson's equations to obtain the energy level, charge and current distribution [13].

NEGF are solved using two approaches namely real space and mode space method. Simulation in real space method is computationally very much costly. In case of the device where quantum confinement is strong (double gate MOS or XOI FET) the mode space approach can be used. The Hamiltonian in these device structures is separated in longitudinal and transverse directions; as a result, it greatly reduces the computational burden. Moreover, in the devices where the cross-section does not change, the sub-bands are not quantum-mechanically coupled to each other; the transport equations become essentially 1D for each sub-band that leads to use the uncoupled mode space approach [14]. The transformation of a real space effective mass Hamiltonian H_0 to a mode space is done by taking a matrix element between m^{th} and n^{th} wave functions of kth and l^{th} slices

$$H_{mnkl}^{MS} = < \psi_{m(y)}^{k} | H_0 | \psi_{n(y)}^{l} > \quad (1)$$

The transport equation in mode space is

$$\left(E - H_{mnkl}^{MS} - \Sigma_S^R - \Sigma_D^R\right) G^R = I \quad (2)$$

Here, E is the energy of carrier, Σ_S^R and Σ_D^R are retarded self energies carrying information about source and drain respectively, H_0 contains the information of the channel, and G^R is the retarded greens function, I is the identity matrix. After solving the above equations for each energy level, current density is calculated by [14]

$$J_x(x_i, y_j) = -\frac{2e}{hL_z\Delta_x} \sum_{k_z\sigma} \sum_{mn} \int Re(t_{i+1ijj} G_{mnii+1}^{<} \psi_m^i(y_j) \psi_n^{*i+1}(y_j) \frac{dE}{2\pi} \quad (3)$$

III. RESULT AND DISCUSSION

In our simulation, source and drain doping concentration is taken to be $10^{20}/cm^3$, with zero gate underlap. Von Neumann boundary conditions for potential are used because the ballistic carrier do not create voltage drop near source and drain contact. Moreover the potential in source and drain are allowed to float, because the carrier may reflect backward and hence the total carrier concentrations in the contact can change with bias.

The I_D-V_G characteristic of the InGaSb XOI FET for two gate dielectrics is shown in Fig. 2. It is obtained at V_D=0.05V. The body thickness of the device is 3nm. Wave function penetration in the oxide region is also taken into account. It is found that for HfO_2, the drain current is lower than that for Al_2O_3, although they have same EOT. Generally if two gate oxides have the same EOT, the same oxide capacitance, and thereby same electrostatic control over the channel and hence identical device performance is expected. But in case of XOI structure, the deviation is found because of conduction band discontinuity (ΔE_C) between the oxide and the channel.

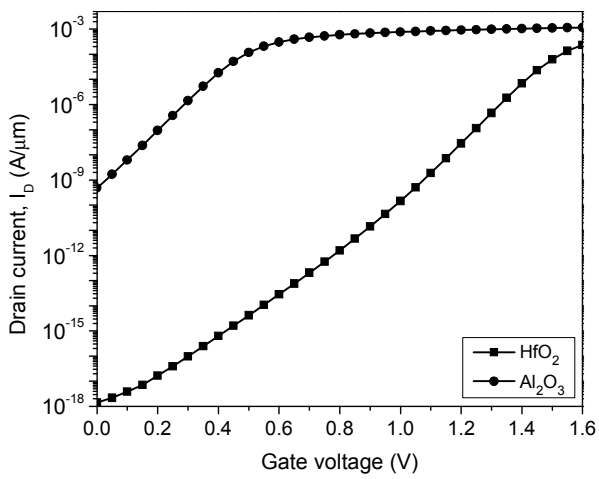

Fig. 2. I_D-V_G characteristics of 15nm InGaSb XOI nFETs using Al_2O_3 and HfO_2 as gate oxide. The structure of the devices is shown in fig. 1.

The ballistic current through any device depends on the fermi level at the source contact as well as on the highest value of conduction band along the channel, which is called "Top of the barrier" or TOB. If TOB lies above the fermi level at the source, it effectively blocs any current conduction. But if it lies bellow the source fermi level, then it modulates the current through the device.

In our simulation, fermi level at the source is kept fixed at zero eV. When the gate metal work function (Φ_{metal}) is kept fixed which is greater than 4 eV in our study, lower ΔE_C implies the higher difference between Fermi level at the source contact and the TOB at the channel. That further implies lowest number of energy states are available for conduction at every gate bias. Since lower number of states available for conduction leads to lower drain current, lower conduction band offset between oxide and channel leads to lower drain current, provided that Φ_{metal} is kept fixed. For $In_{0.3}Ga_{0.7}Sb$ channel, $\Delta E_C(Al_2O_3)$ = 2.88eV and $\Delta E_C(HfO_2)$ = 1.76eV [15]. That is why HfO_2 is giving lower drain current despite of same EOT.

Since the TOB is situated at different level for zero gate bias, we carried out the simulate for a wide range of gate bias to ensure the turn on of both devices. But in real life application both devices could be operated at a much less bias range by tuning the gate work function. The I-V curve shown in fig. 2 for HfO_2 can be shifted to the left by reducing Φ_{metal} used for HfO_2 based device. And, if it were choosen to be 1.12eV less than that used for Al_2O_3 based device (since $\Delta E_C\{Al_2O_3\}$-$\Delta E_C\{HfO_2\}$=1.12 eV), the two curves will be at closest position. To understand the effect of ΔE_C only, other influential factors like Φ_{metal} are so choosen that causes the energy band inside the oxide to start from the same maximum height.

Fig. 3 shows the change in subthreshold slope (SS) as a function of ΔE_C between oxide and the channel. It is found that the subthreshold slope decreases with decreasing ΔE_C.

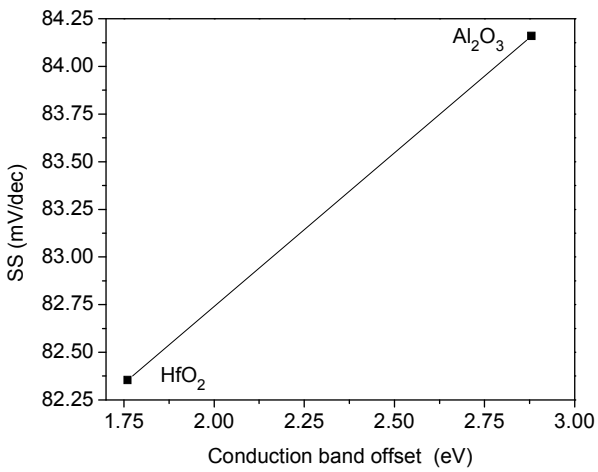

Fig. 3. Variation of Subthreshold slope (SS) for the use of HfO_2 and Al_2O_3 as gate oxide on InGaSb XOI nFET.

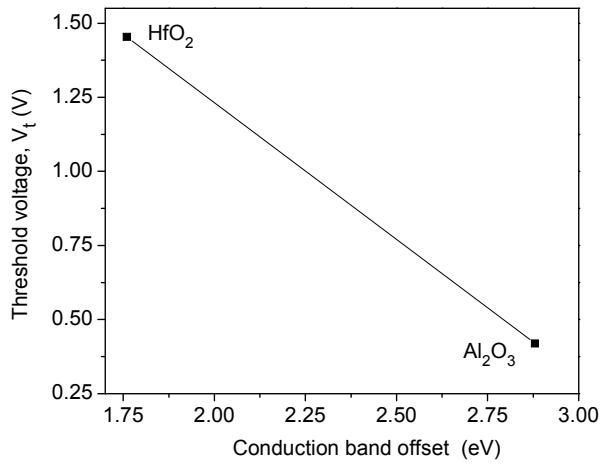

Fig. 4. Variation of threshold for the use of HfO_2 and Al_2O_3 as gate oxide on InGaSb XOI nFET.

The lower SS implies the sharp change of drain current with gate bias and the better electrostatic control of gate over the channel. Better control of gate also indicates the lower influence of drain voltage on I-V characteristic and hence supressed short channel effect (SCE), like drain induced barrier lowering.

Fig. 4 shows the variation of threshold voltage as a function of ΔE_C between oxide and the channel. It shows the threshold voltage decreases with increasing ΔE_C. For HfO_2 gate oxide, the threshold voltage found in our case is 1.454V, which is not acceptable any way. But it can be brought very close to zero by gate work function engineering, so it is not a problem at all. Our study reveals a great impact of ΔE_C on the SS and the threshold voltage.

IV. CONCLUSION

We analyzed the influence of conduction band offset, ΔE_C between the gate oxide and the channel on the performance of $In_{0.3}Ga_{0.7}Sb$-on-insulator or the XOI FET. We took Al_2O_3 and HfO_2 as gate oxides having 0.5 nm of equivalent oxide thickness for each case. The ballistic performance of the device is computed by NEGF method. The source and drain regions are taken to be heavily doped($10^{20}/cm^3$) and the channel is left undoped. Gate metal work functions are so chosen that the energy band at the gate metal-oxide interface lies at 2.92eV at zero gate bias. Wave function penetration to the oxide is also taken into account. Source drain contacts are allowed to float to treat the carrier reflection accurately. We found that the drain current increases with increase in ΔE_C. Also the threshold voltage (V_T) decreases and SS increases with increasing ΔE_C. SS of the device under study goes bellow 90mV/dec for both cases. So both of the design are acceptable for logic application. Although we get lower drain current for HfO_2 because of its lower ΔE_C with the InGaSb channel, it can be controlled by tuning the gate metal work function. That is why the overall performance of HfO_2 is better since it gives lower SS.

Abstract—**In this paper, impact of device & process parameter variation on quantum ballistic Current-Voltage (I-V) characteristics of a surface channel, High K stack gate Quantum Well MOSFET is simulated. Physical device parameters like channel thickness, gate dielectric thickness and process parameters like doping density have direct effects on quantum ballistic current. We use mode space approach with NEGF formalism to simulate Current-Voltage (I-V) characteristics. Short Channel effects (SCE) are studied from the simulation for these variations. Observed effect is scaling dielectric & channel thickness results in better subthreshold slope & Drain induced barrier lowering at the cost of On-current. By increasing doping concentration, ballistic current can be improved. However with increasing doping density, SCE effects are compromised.**

I. Introduction

Si CMOS has reached almost bottleneck because of practical & fundamental considerations [1], [2]. So, new and alternate device structures and device materials are in great demand for research purposes. III-V materials and their associated device structures [3] have emerged as potential candidates. Because they can be used for low power, high frequency operations. III-V materials are mostly direct bandgap materials, have higher mobility due to smaller effective masses. Performance of III-V MOSFET is superior to Si counterpart. A 55nm Quantum Well device structure that is surface channel with high K stack as gate dielectric has been reported in recent literature [4]. Effect of various device and process parameters like doping density, channel thickness, gate dielectric thickness on ballistic performance of the device structure is observed in this paper. The simulation approach is evolved from Nanomos 2.5[5]. III-V HEMT device structures have simulated with same approach [6]. We follow the same approach for the quantum ballistic simulation of the structure in [4].

II. Device Structure And Simulation Approach

We developed a device simulator to characterize the device in Fig. 1. The device has 5nm delta-doped n type $In_{0.52}Al_{0.48}As$ layer separated from channel by 1nm $In_{0.52}Al_{0.48}As$ spacer. High-k stack consists of 0.5nm Al_2O_3 & 6.5nm HfO_2. In real devices, the current flow is two- dimensional from the raised source to the drain through the doped heterostructure stack.

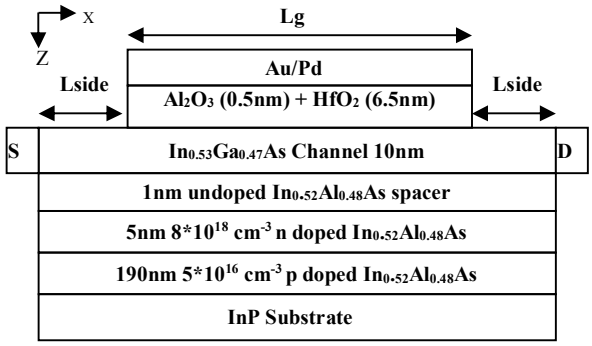

Fig. 1. Rectangular intrinsic simulation region where quantum ballistic transport dominates, used in this study.

Rather than attempting to simulate the contacts and the associated metal semiconductor contact resistance, we placed ideal contacts at the two ends of the channel to simplify the structure. Although this approach does neglect some practical aspects of device operation like source access issue, source starvation etc. it provides us with an upper level projection of device performance.

Fig. 1 shows the rectangular 'intrinsic' simulation region used in this study. Here, Lg refers to the gate length; Lside refers to the distance from gate to n+ layer edge of the device. To maintain numerical stability we have considered length of Lside region to be equal of Lg. The total simulation region is divided into *Nx*Nz* number of nodes, where *Nx* and *Nz* refers to the total number of nodes in X and Z direction. The 2D simulation starts by solving the Poisson equation with the charge from an initial flat band as the guess potential. The updated potential leads to a new set of spatial charge distribution. This process is repeated until desired convergence is achieved. The ballistic current is then readily calculated with the NEGF formalism in mode space for each subband. For current calculation, we consider 2 subbands in the QW channel. The Poisson equation is solved using proper boundary conditions applying a non-linear algorithm [7]. In this approach, the carrier concentration $n_{m,n}$ at node [m, n] is expressed in terms of the to-be-solved potential $V_{m,n}$ and the quasi-Fermi potential energy, Fn[8]:

$$n_{m,n} = N_C \Im_{1/2}\left[\frac{(F_n)_{m,n}+qV_{m,n}}{k_B T}\right] \quad (1)$$

Where $\Im_{1/2}$ stands for the Fermi-Dirac integral of order ½ and N_C is the effective density of states. The quasi-Fermi potential is pre-calculated from the input potential and charge density:

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

$$(F_n)_{m,n} = -q(V_{old})_{m,n} + k_B T \Im_{1/2}^{-1}\left(\frac{n_{m,n}}{N_C}\right) \quad (2)$$

We can obtain the charge distribution by solving the 1D effective mass Schrödinger equation along the Z directed slice in the 2D discretization mesh

$$-\frac{h^2}{2m_z^*}\frac{d^2}{dz^2}\Psi_i(x,z) - qV(x,z)\Psi_i(x,z) = E_i(x)\Psi_i(x,z) \quad (3)$$

Where, m_z^* is the electron effective mass in the z direction, $\Psi_i(x,z)$ and $E_i(x)$ are the wavefunction and Eigen energy for subband i at slice x. Using an uncoupled mode space approach, we divide this 2D problem into two 1D problems. We find out the total number of subbands in the quantum well channel and calculate charge density in each of these subbands using NEGF formalism. If a is the grid spacing in X direction, using the Green's function formalism [9], the 2D charge density matrix of mode i is obtained as

$$n_{2D} = \int_0^\infty \frac{1}{a\hbar}\sqrt{\frac{m_y^* k_B T}{2\pi^3}}\left[\Im_{-1/2}(\mu_S - E_l)A_S + \Im_{-1/2}(\mu_D - E_l)A_D\right]dE_l \quad (4)$$

Where

$$A_S = G\Gamma_S G^+, \qquad A_D = G\Gamma_D G^+$$

are the spectral density functions due to source/drain contacts [10]. Γ_S and Γ_D are self energy terms for source & drain. Physically this term determines the electron exchange rates between the source/drain reservoirs and the active device region. But in general it can be viewed as the measure of interaction strength due to any perturbation source. Although the device itself may be in non-equilibrium state, electrons are injected from the equilibrium source/drain reservoirs. G is the retarded green function [7]. The 3D charge density at slice x can be obtained by multiplying $n_{2D}(x)$ by the wavefunction probability and summing for all the subbands:

$$n(x,z) = \sum_i n_{2D}(x,i)|\Psi_i(x,z)|^2 \quad (5)$$

Once self-consistency is achieved, the intrinsic ballistic current is calculated as

$$I_D = \int_0^\infty \frac{q}{\hbar^2}\sqrt{\frac{m_y^* k_B T}{2\pi^3}}\left[\Im_{-1/2}(\mu_S - E_l) - \Im_{-1/2}(\mu_D - E_l)\right]T_{SD}(E_l)dE_l \quad (6)$$

Where, $T_{SD}(E_l)$ is the transmission coefficient as a function of the longitudinal energy calculated from the Green's function.

III. Results & Discussions

A. Effect of Channel thickness

Fig. 2 shows the effect of channel thickness variation on intrinsic Id-Vd characteristics for the 55nm gate length device structure. The figure shows Id-Vd characteristics for 3 different channel layer thicknesses: 9nm, 10nm, 11nm. Here gate voltage varies from 0.6V to 1.4V in step of 0.4V and drain voltage varies from 0.0V to 1V.From Fig. 2 it is observed that, as we increase channel thickness, the drain

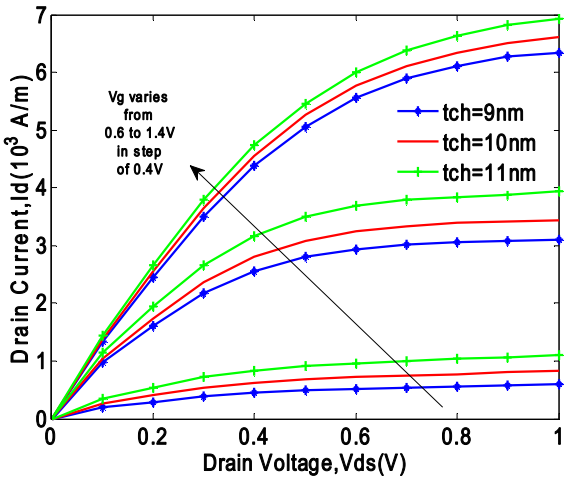

Fig. 2. Id-Vds characteristics for different channel thickness conditions

current increases. Increasing channel thickness allows accumulation of more carriers in the channel. Fig. 3 shows Id-Vg characteristics (log scale) for various channel widths at a drain bias of 0.5 volt. The logId-Vg characteristics give us an idea of the subthreshold performance of the device. Higher channel thickness leads to higher current in subthreshold region and therefore subthreshold swing (SS) and drain induced barrier lowering (DIBL) parameters increase.

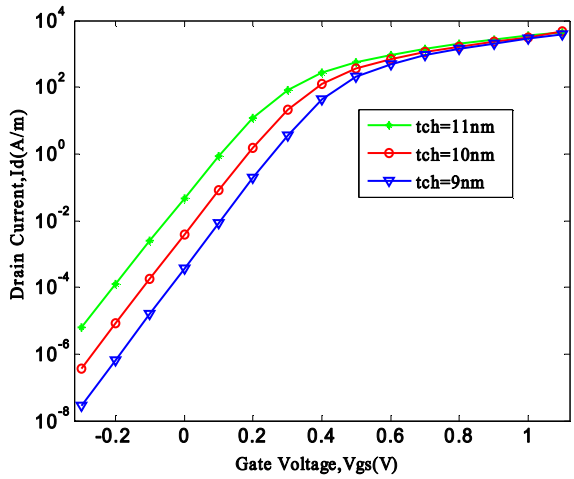

Fig.3. Id-Vgs characteristics for different channel thickness conditions (log scale). Vd=0.5V

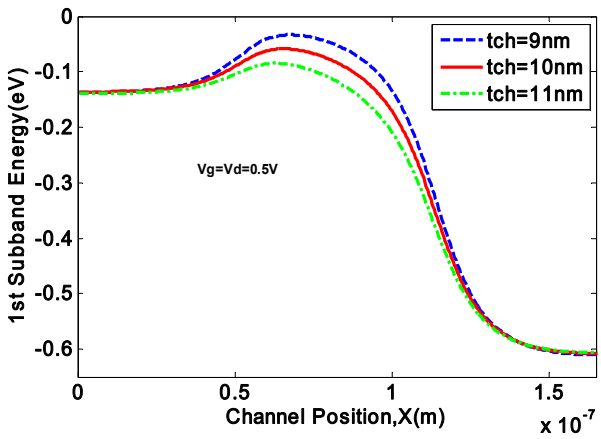

Fig. 4. 1st subband energy at different Channel thickness conditions.

Fig. 4 shows the potential barrier lowering in the channel with higher channel thickness which also supports higher drain current at increased channel thickness.

B. Effect of Gate Oxide thickness

Fig. 5 shows intrinsic I_d-V_d characteristics for the 55nm device under variable oxide thickness condition. As the oxide thickness increases, the drain current increases. This phenomenon may be attributed to 2D electrostatics inside the device and the weakening control of gate voltage over the energy barrier in the channel for the device. As oxide thickness is increased, for the same applied gate bias, the voltage drop across oxide increases and therefore control of gate voltage over the potential barrier in the channel weakens. So DIBL effect becomes more prominent in the channel region. This leads to an increase in the drain current in the ballistic regime. The barrier lowering effect can be observed from the Fig. 6. In this figure we show the 1st subband energy in the channel of the device.

Fig. 7 presents I_d-V_{gs} characteristics for the device (log scale). For higher oxide thickness, drain current increases more rapidly with increasing gate voltage which is due to greater lowering of the potential barrier in the channel at higher oxide thickness. At sub threshold region, device with higher oxide thickness shows shallower slope and therefore higher SS. Due to weaker gate control over the potential barrier, the device with higher oxide thickness would show degraded DIBL effects compared to the device with lower oxide thickness.

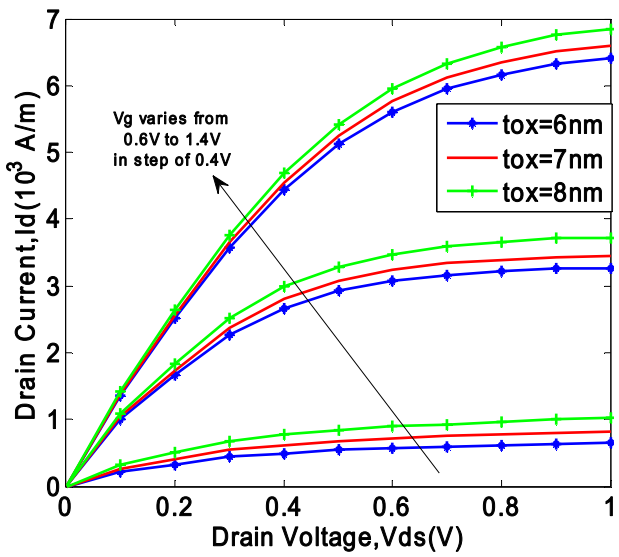

Fig. 5. Id-Vd characteristics for the device structure at different oxide thickness

C. Effect of Doping Concentration

Fig. 8 shows the I_d-V_d characteristics of the quantum well structure at different doping concentration of the 5 nm n type high doped region. As we increase the doping concentration, current in the channel increases. This phenomena can be explained from the fact that carrier in the channel is supplied from the nearby high n doped region. As we modulate the channel potential barrier by gate voltage, more and more carriers are injected into the channel from the high doped region. A higher doping concentration in the high doped region means it can supply greater amount of charge in the

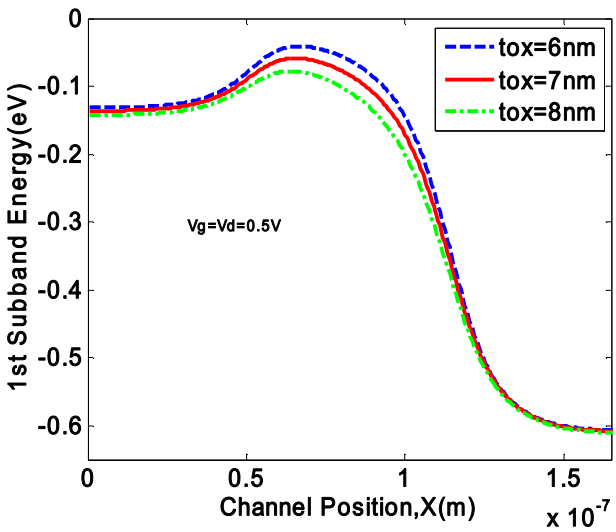

Fig. 6 1st subband energy at different Oxide thickness conditions. At Vg=Vd=0.5V

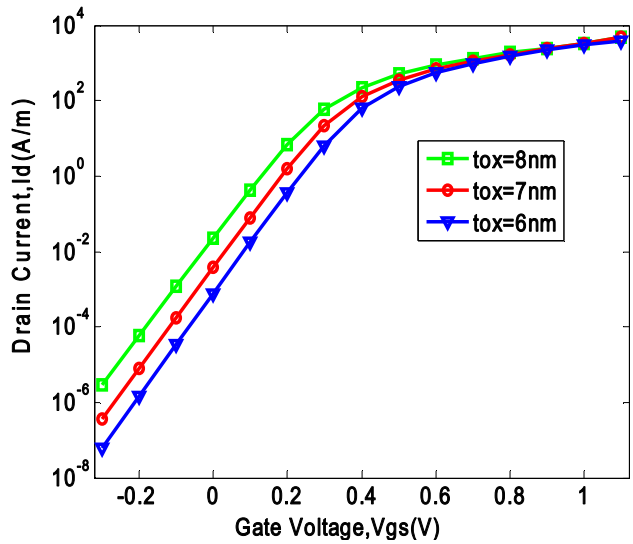

Fig. 7. Id-Vgs characteristics for different oxide thickness conditions (log scale). Vd=0.5V

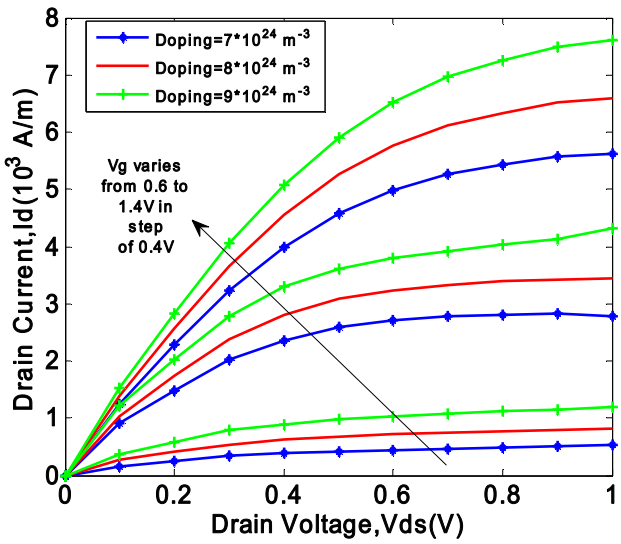

Fig. 8. Id-Vd characteristics for the device structure at different Doping concentrations.

channel for a given gate and drain bias. A higher carrier density in the channel eventually results in greater lowering of the potential barrier in the channel as evident from Fig. 9. It results in higher drain current as observed from Fig. 8.

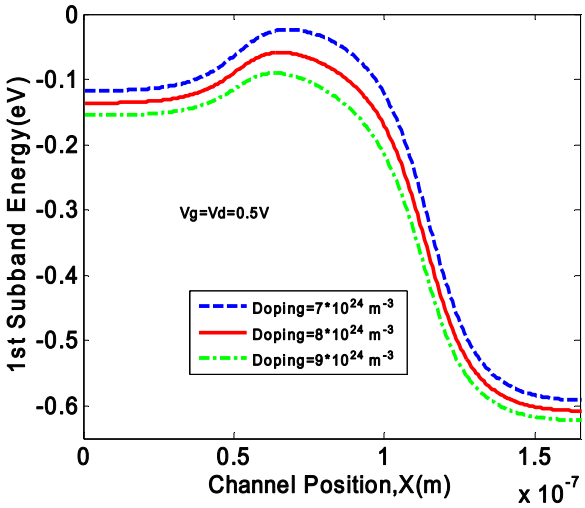

Fig. 9. 1st subband energy at different Doping Concentration. At Vg=Vd=0.5V

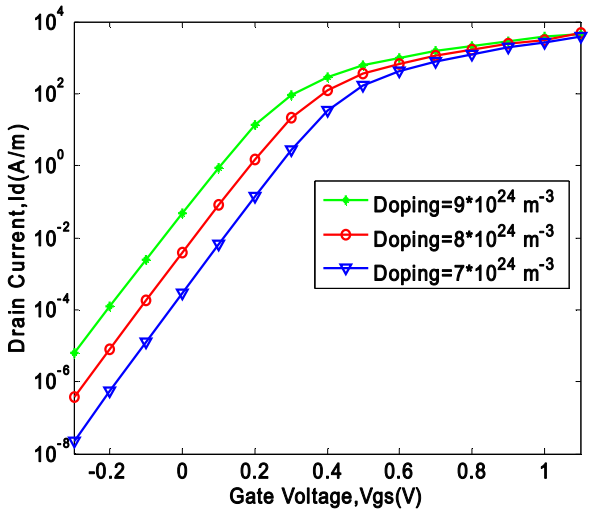

Fig. 10. Id-Vgs characteristics for different doping concentration conditions (log scale). Vd=0.5V

The Log I_d-V_{gs} characteristics have been shown in of Fig 10. It is observed from the figure that a higher doping concentration results in higher change in drain current with gate bias which is due to the same reason explained before. At sub threshold region, device with higher doping concentration shows shallower slope and therefore higher SS. Also increasing doping concentration lowers threshold voltage as observed from the Fig. 10.

IV. Conclusions

In this work, we report simulation result for physical & process parameter variation on quantum ballistic current for a 55 nm InGaAs surface channel quantum well MOSFET. Among these three parameters, process parameter (Doping concentration) produced more observable result. Reducing InGaAs channel improves short channel performance of the device, but we get a compromised ballistic On-current. Since these quantum ballistic current is usually 2-3 times the experimental one, we didn't measure accurate values of SS swing & DIBL. However we captured the trend on SCE effects with this scaling. Increasing gate dielectric material thickness improves ballistic device performance but leads to degraded short channel performance. Doping density, as expected, results in higher on-current.

***Abstract*— In this work, quantum ballistic simulation study of a novel III-V $In_{0.7}Ga_{0.3}As/InAs/In_{0.7}Ga_{0.3}As$ Quantum Well MOSFET is presented. To simulate the device in quantum ballistic regime, nonequilibrium Green's function formalism has been used. 2D Poisson and Schrodinger equations are solved in self-consistent manner taking into account 2D electrostatics and other quantum mechanical effects. Strong carrier confinement in the $In_{0.7}Ga_{0.3}As/InAs/In_{0.7}Ga_{0.3}As$ quantum well allows the application of efficient mode space approach in quantum ballistic simulation. Simulation results for the QW device with 30 nm gate length are reported. At the same time, effect of gate length variation on the quantum ballistic characteristics is explored.**

***Index Terms*—Quantum Well MOSFET, Delta Doping, III-V Semiconductors, Ballistic Transport, 2D Electrostatics**.

I. Introduction

With tremendous improvement in lithography and scaling technology, smart optimization, Moore's law [1] had gone unabated for the last four decades [2]. However, scaling of planar silicon CMOS transistors is reaching its fundamental limits due to various practical limitations [3]. Scaling of planar MOSFET structures brings a number of challenges like increased short channel effects, increased gate leakage and off-state leakage, increased power dissipation etc. With excellent carrier transport properties and improved 'on' state performance over silicon, III-V compound semiconductors like: GaAs, InGaAs and InAs and their associated devices structures have emerged as potential candidates for high speed, low power logic operations [4]. III-V quantum well device structures with extremely scaled high-k gate dielectric material exhibit excellent 'on' state performance and are considered suitable for future low power logic implementation. A novel III-V quantum well device that incorporates a thin pure InAs sub-channel and extremely scaled HfO_2 dielectric material has been reported in recent literature [5]. This paper focuses on the quantum ballistic simulation study of the device structure reported in [5]. The effect of gate length scaling on ballistic performance is also explored and presented.

II. Device Structure and Simulation Approach

In this work, we simulate a simplified form of the device structure reported in [5]. Here the channel consists of high mobility $In_{0.7}Ga_{0.3}As/InAs/In_{0.7}Ga_{0.3}As$ materials. A 1 nm Si δ-doped layer is placed just 5 nm below the bottom $In_{0.7}Ga_{0.3}As$ channel layer. High-k material HfO_2 is used as gate dielectric. To improve interface properties and reduce

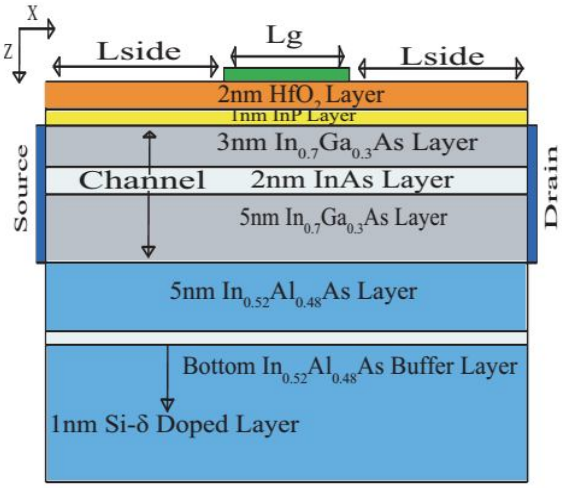

Fig. 1 Rectangular intrinsic simulation region where quantum ballistic transport is expected to dominate, used in this study. Simulation region is similar to the region applied in [7].

interface scattering, 1 nm InP layer is placed just beneath the gate oxide layer. The bottom $In_{0.52}Al_{0.48}As$ buffer layer is over 300 nm thick. Fig. 1 shows the simplified intrinsic simulation region used in this study. In real HEMT or QW MOSFET devices , the current flow usually takes place from raised drain through heterostructure stack, laterally through the channel and then through the raised source contact [7]. However, ideal contacts are considered at two ends of the channel. We hereby only simulate the region where ballistic transport is expected to dominate. In Fig. 1, Lg refers to the gate length, Lside refers to the distance from gate to n^+ edge of the device. The total simulation region is divided into N_x * N_z number of nodes, where N_x and N_z refers to the total number of nodes in X and Z direction. However, the bottom $In_{0.52}Al_{0.48}As$ layer is about 300 nm thick. To reduce total number of nodes, we apply uniform grid spacing up to a certain distance along Z direction where more accurate results are required. After that, we apply nonuniform grid spacing. At the same time, to maintain numerical stability we have considered length of Lside region to be 44 nm. The doping in the Si δ-doped region is kept at $1\sim2\times10^{12}$ cm^{-2}.

The simulation approach used in this study evolves from nanoMOS2.5 [6]. Similar simulation approach had already been applied for simulation study of III-V HEMTs [7], [8]. In this approach, 2D Poisson equation is solved using Finite Difference Method (FDM) method with proper boundary conditions by applying a nonlinear algorithm [9]. Charge distribution is obtained by solving the 1D effective mass

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Schrodinger equation along the Z directed slice in the 2D discretization mesh:

$$-\frac{\hbar^2}{2m^*}\frac{d^2}{dz^2}\Psi_i(x,z)-qV(x,z)\Psi_i(x,z)=E_i(x)\Psi_i(x,z)$$

where m^* is the electron effective mass in the Z direction, $\Psi_i(x,z)$ and $E_i(x)$ are the wavefunction and eigenenergy for subband i at slice x. Strong confinement of carriers in the $In_{0.7}Ga_{0.3}As/InAs/In_{0.7}Ga_{0.3}As$ quantum well allows the implementation of uncoupled mode space approach in simulation that divides this 2D problem into two 1D problems. The total number of subbands in the $In_{0.7}Ga_{0.3}As/InAs/In_{0.7}Ga_{0.3}As$ quantum well is determined and carrier density in the channel is determined using NEGF formalism [10]. The 2D carrier density for mode i is obtained as:

$$n_{2D}(x,i)=\int_0^\infty \frac{1}{a\hbar}\sqrt{\frac{m_y^* k_B T}{2\pi^3}}$$
$$[\Im_{-1/2}(\mu_S-E_l)A_S+\Im_{-1/2}(\mu_D-E_l)A_D]dE_l$$

where,

$$A_S=G\Gamma_S G^+ \qquad and \qquad A_D=G\Gamma_D G^+$$

are the spectral density functions for source and drain contacts respectively [10], G is the retarded Green's function and a is the grid spacing in X direction. Using the wavefunction profiles obtained from the solution of Schrodinger equation along Z direction, a spatial charge distribution profile is obtained and used for the solution of Poisson equation:

$$n(x,z)=\sum_i n_{2D}(x,i)\left|\Psi_i(x,z)\right|^2$$

Once self-consistency is achieved, the intrinsic ballistic current is calculated as:

$$I_D=\int_0^\infty \frac{q}{\hbar^2}\sqrt{\frac{m_y^* k_B T}{2\pi^3}}$$
$$[\Im_{-1/2}(\mu_S-E_l)-\Im_{-1/2}(\mu_D-E_l)]T_{SD}(E_l)dE_l$$

And

$$T_{SD}(E_l)=trace(\Gamma_S G\Gamma_D G^+)$$

where $T_{SD}(E_l)$ is the transmission coefficient from the source to drain contact as a function of the longitudinal energy calculated from the Green's function [10].

III. Results and Discussion

Fig. 2 shows the conduction band profile and the normalized wavefunction for the 1st subband along gate confinement direction for a bias condition Vg=0.3V and Vd=0.5V. From this figure, we can observe that the carrier wavefunction is well confined in the $In_{0.7}Ga_{0.3}As/InAs/In_{0.7}Ga_{0.3}As$ quantum well which validates the application of mode space approach. Fig. 3 shows the 1st subband profile in the channel as a function of gate bias voltage at Vd=0.5V. With increased gate bias, the top of the barrier energy is lowered which leads to the injection of more carriers from the source contact. In this simulation, two subbands in the $In_{0.7}Ga_{0.3}As/InAs/In_{0.7}Ga_{0.3}As$ quantum well are considered. Fig. 4 shows the 1st subband profile in the channel at Vg=0.2V and at different intrinsic drain bias voltages. The figure reveals a slight lowering of the top of the barrier energy with increasing drain bias. At the same time, subband

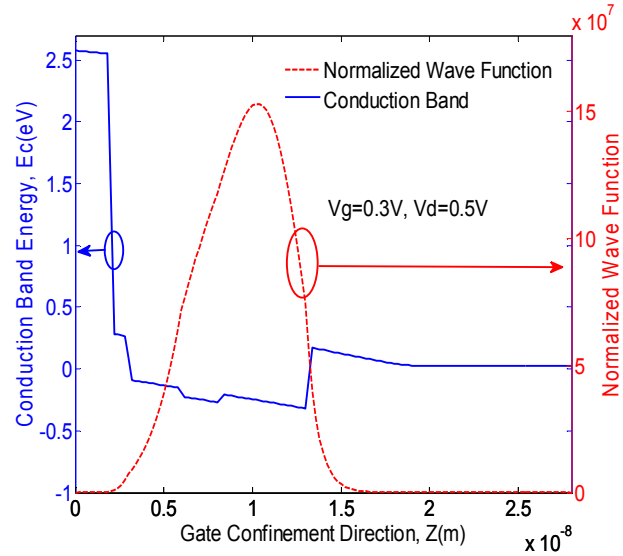

Fig. 2 Normalized wavefunction and the conduction band profile along the gate confinement direction for the 1st subband at Vd=0.5V and Vg=0.3V.

energy at the drain contact end also decreases with increasing drain bias voltage. Fig. 5 shows the 1st subband profile along with transmission coefficient obtained from simulation at Vg=0.2V and Vd=0.5V. As seen from the figure, transmission coefficient does not show an entirely step like nature. The figure also reveals that, the transmission coefficient rises to a value of 1 at just about the top of the barrier energy. At the same time, due to the consideration of two subbands in the quantum well, the combined transmission coefficient reaches a value of 2 as seen from the inset figure at the bottom left corner. Fig. 6 shows the energy resolved current density for the 1st subband obtained from simulation. This figure reveals contribution of carrier at different energies to the overall current density of the device. From this figure, it can be seen that carriers having energies above the top of the barrier energy, contribute to the overall current density. Fig. 6 also reveals a little fraction of under the barrier transport which may be attributed to the transmission coefficient not having an abrupt step like nature.

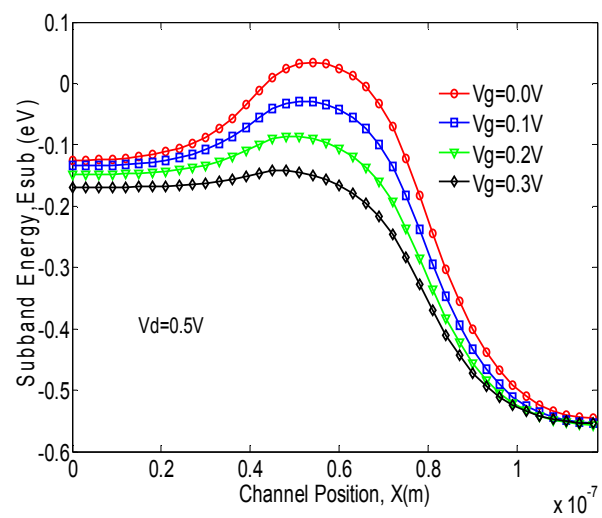

Fig. 3 1st subband profile in the channel at different intrinsic gate bias conditions for an intrinsic drain bias voltage of Vd=0.5V. With increasing gate voltage the energy barrier height between the source and the channel is lowered which leads to the injection of more carriers into the channel.

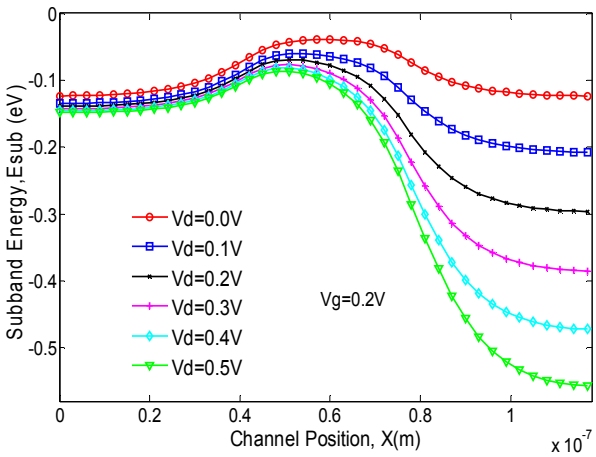

Fig. 4 1st subband profile in the channel at different intrinsic drain bias conditions for an intrinsic gate bias voltage of Vg=0.2V. With increasing drain voltage a slight lowering of the energy barrier height between the source and the channel can be seen.

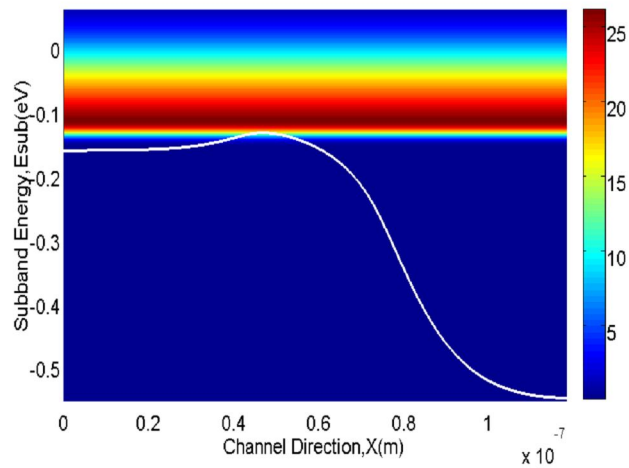

Fig. 6 Energy resolved current density for 1st subband at Vg=0.3V and Vd=0.5V. Carriers with energy higher than top of the energy barrier contribute to total ballistic current. Some under the barrier conduction is also observed.

Fig. 7 shows the intrinsic Id-Vd characteristics for the simulated device structure with Vg varying in 0.05V step. With increasing gate bias conditions, intrinsic drain current increases. MOSFETs operate by modulating the energy barrier between the source and the channel [11]. With increasing gate bias voltage, this energy barrier height is lowered which leads to injection of more carriers from the source and therefore increased energy separation between the source fermi energy level and the top of the barrier energy. This phenomenon leads to an increase in the drain current with increased gate bias voltage. Short channel effects and 2D electrostatic effects are also observed as the drain current gradually increases with increasing drain bias voltage. At Vg=0.4V and Vd=0.5V the simulated intrinsic current is about 2.5 times of the reported experimental results [5]. This discrepancy may be attributed to disregarding scattering effects which becomes significant at high gate bias conditions. Fig. 8 shows the intrinsic Id-Vg characteristics for the simulated device with 30 nm gate length. Here, we present Id-Vg characteristics for two drain bias voltages. The figure also shows the Id-Vg characteristics in log scale.

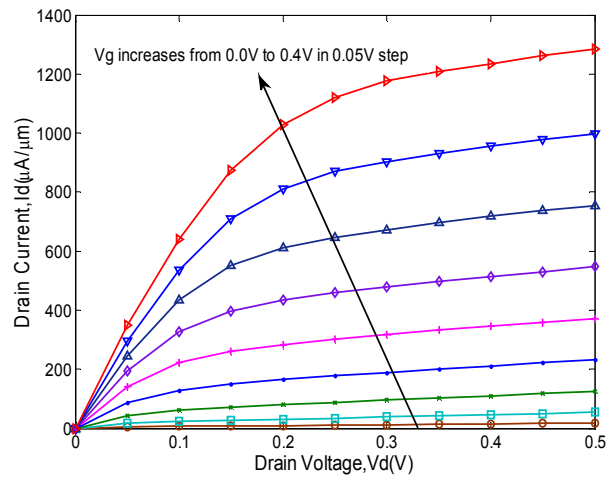

Fig. 7 Intrinsic Id-Vd characteristics for the simulated device structure at different gate bias conditions.

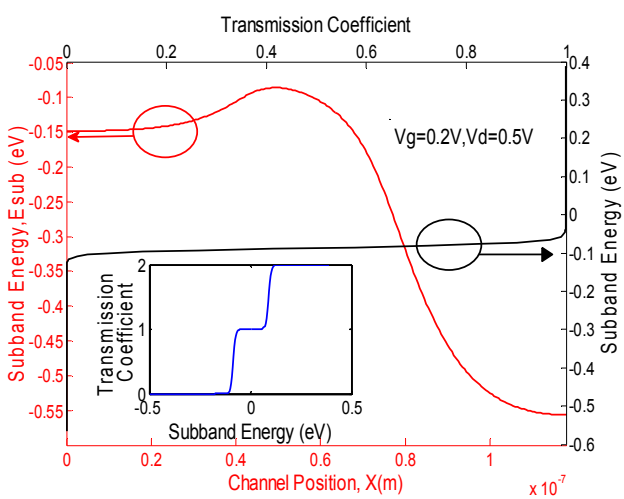

Fig. 5 1st subband energy profile along with transmission coefficient for intrinsic gate bias of 0.2V and drain bias 0.5V. The inset figure at bottom left shows transmission coefficient for 1st and 2nd subband combined at same bias.

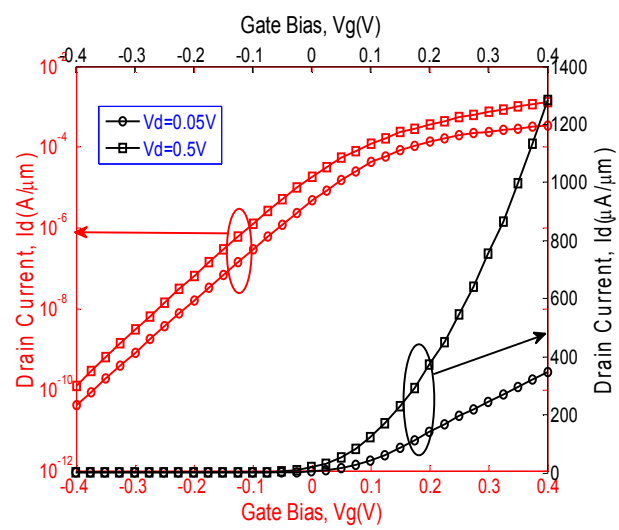

Fig. 8 Intrinsic Id-Vg and logId-Vg characteristics for the simulated device structure at two intrinsic drain bias conditions.

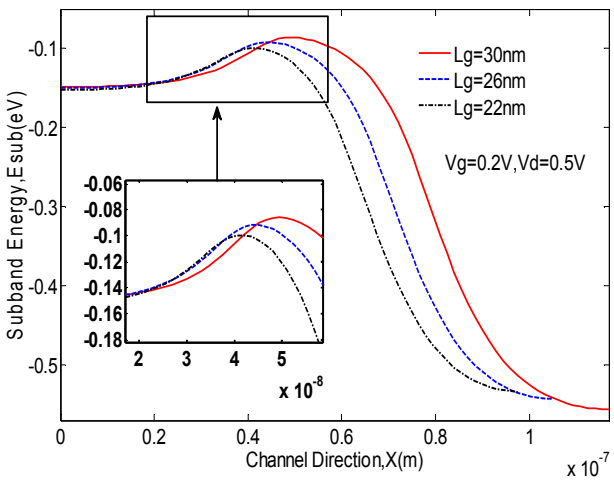

Fig. 9 1st subband energy profile at different gate length conditions at Vg=0.2V and Vd=0.5V. The lowering of the energy barrier between the source and the channel can be observed from these profiles.

Fig. 9 shows the effect of gate length on the 1st subband energy profiles in the channel at Vg=0.2V and Vd=0.5V. The figure reveals a slight lowering of the energy barrier height between source and the channel with decreasing gate length. This lowering of energy barrier increases the difference between source fermi energy and top of the barrier energy and therefore drain current increases.

Fig. 10 shows the intrinsic Id-Vd characteristics at three different gate length conditions. The figure reveals an increment in drain current with gate length scaling. The separation between the intrinsic Id-Vd curves is more observable at high drain bias regime which suggests increasing short channel effects with gate length scaling. Fig. 11 shows the effect of gate length scaling on the intrinsic Id-Vg characteristics in both normal and log scale at Vd=0.5V. From this figure, we see that device with lower gate length has a higher subthreshold current. Also, it can be observed that Subthreshold Swing (SS) increases and threshold voltage decreases with gate length scaling.

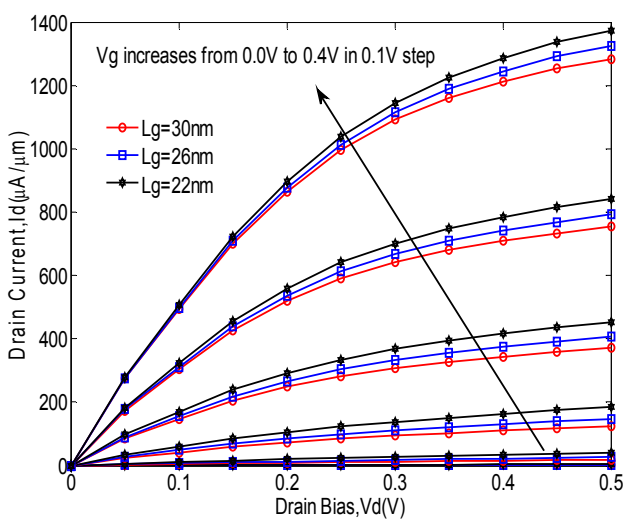

Fig. 10 Intrinsic Id-Vd characteristics at different gate length conditions for the simulated device structure. Vg varies from 0.0V to 0.4V in 0.1V step. Scaling results in increased drain current. At the same time degraded short channel performance can also be observed from the figure.

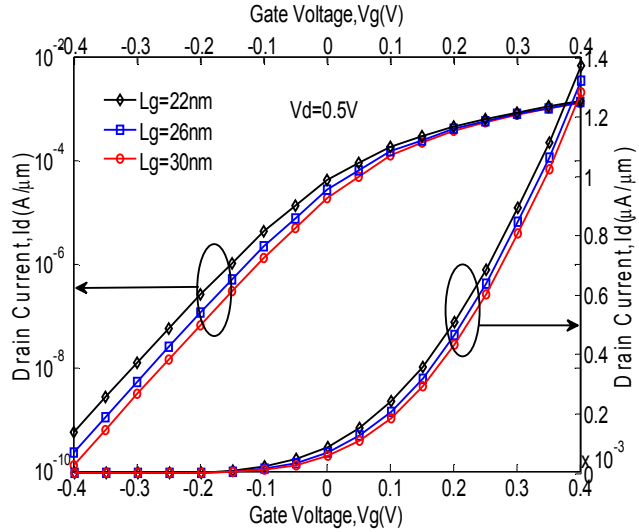

Fig. 11 Intrinsic Id-Vg and logId-Vg characteristics at different gate length conditions at intrinsic drain bias Vd=0.5V. Drain current in subthreshold region increases with decreasing gate length. Increment in Subthreshold Swing (SS) with gate length scaling can be observed as well.

IV. Conclusion

In this work, we report quantum ballistic simulation results of a novel 30 nm quantum well device using mode space approach. The quantum ballistic current is calculated using NEGF formalism. The simulated intrinsic ballistic current overshoots experimentally reported values [5] as scattering is not considered in quantum ballistic simulation. The effect of gate length scaling on the ballistic device operation and subthreshold operation is studied and presented. Scaling of gate length improves quantum ballistic current. However, simulation also reveals lowering of threshold voltage, degraded short channel performance with gate length scaling.

Abstract— **We demonstrate the integration of nanowires to design gate-all-around field-effect-transistors (GAA-FETs) in the shape of horizontally aligned 3-dimensional semiconductor nano-bridges. The transistors exhibited a high on/off-current ratio, low sub-threshold swing and very low off-currents. In addition to designing low-voltage non-volatile memory cells, the photosensitivity of the FETs is employed to demonstrate several analog and digital applications such as electro-optical OR gate circuit elements and frequency doublers. Based on this approach, nanowires with high mobility can be integrated on Si platform to enable the next generation high performance nanowire FETs.**

***Index Terms*—transistors, nanowires, 3D FETs**

I. Introduction

Field effect transistors (FETs) enabled by one-dimensional nanowires grown by synthetic *bottom-up* methods have attracted attention because they are expected to present a pathway to overcome the roadblocks to Moore's law and can enable gate-all-around (GAA) transistors. However, lack of reproducibility in their growth, alignment into arrays, and contact formation to enable scalable fabrication of transistors is challenging. As a practical way of overcoming the obstacles for the integration of nanowire FETs, in-place growth techniques have been proposed [1-3]. Amongst them, fabrication of nanowire bridges is particularly attractive because it allows for direct growth of crystallographically aligned nanowires on pre-patterned semiconductor electrodes as well as their electrically and metallurgically robust linkages to the electrodes (as shown in Fig. 1) [3-6]. For FETs, the bridged nanowires are then designated as channels, and source/drain electrodes can be readily patterned along with the pre-patterned electrodes. Consequently, compared to any other methods, this route provides much simpler and more practical ways for preparing aligned nanowires and further fabricating FETs.

Here, we demonstrate GAA-FETs based on horizontally aligned nano-bridges with a high on/off-current ratio, low sub-threshold swing and very low off-currents. In addition to designing low-voltage non-volatile memory cells, the photosensitivity of the 3-dimensional (3D) FETs is employed to demonstrate several analog and digital applications.

II. GAA-FET Fabrication

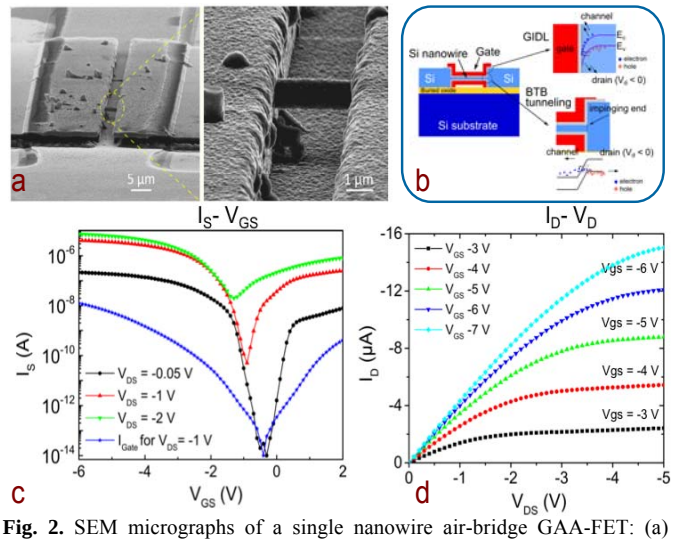

Fig. 2. SEM micrographs of a single nanowire air-bridge GAA-FET: (a) Bird's-eye view and zoomed-in view of the nanowire channel. The nanowire channel is suspended between two electrodes and surrounded by polysilicon gate electrodes. (b) Schematics showing device cross-section and band-diagram. (c) Measured current (I_S) -voltage (V_{GS}) for three drain voltages (V_{DS}). (d) Output characteristics (I_D-V_{DS}), collected from a nanowire channel GAA-FET with a 3 μm long and 120 nm thick channel.

To fabricate an array of integrated FETs, silicon source/drain electrodes, were patterned on p^+-(110) silicon (5×10^{18} cm^{-3}) in SOI, using KOH solutions or reactive ion etching (RIE) after photolithography. On the sidewall surfaces, photolithography was carried out to create small openings,

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

where nanowires are expected to grow. In those openings, the poly-L-lysine was treated and then gold colloids (200 nm, from Sigma Aldrich), as a catalyst to aid nanowire growth, were deposited. Consecutively, the substrates were cleaned with acetone, a piranha solution (H_2SO_4:H_2O_2=2:1), HF acid, and DI water. Silicon nanowires were grown using a cold-wall CVD tool (First Nano®) with SiH_4, B_2H_6, HCl, and H_2 gases. Growth temperature and pressure were respectively 575°C and 13 torr. Diameters and lengths of nanowires were determined by sizes of gold nanoparticles and growth time, respectively. Gold tips and impurities along silicon nanowire surfaces were removed using a gold etchant TFA without damaging the nanowires prior to additional processes. Detailed procedures for creating nanowire bridges are presented in Ref 14c. For creating GAA-FETs, the nanowire bridges, were oxidized at 900°C for 10 min to grow 10 nm thick gate oxide. On the oxidized nanowires, p+ polysilicon was conformally deposited and delineated to the gate electrodes using photolithography and wet etching. For the fabricating flash memory cells, on the other hand, tunneling barrier layers of SiO_2 (2 nm)/Si_3N_4 (3 nm)/SiO_2 (2 nm), a charge trap layer of HfO_2 (5 nm), and a blocking layer of Al_2O_3 (15 nm) were sequentially deposited on nanowire bridges. The detailed deposition scheme and structural analysis of the tunneling barrier are presented elsewhere [6, 7]. Using the lift-off technique, platinum thin film pads were fabricated to create Ohmic contacts on the silicon electrodes.

In our nano-bridge enabled FETs, we synthesized lateral bridging nanowires with both Ti and Au catalysts in between two vertical walls of a trench [6, 8-12]. Fig. 2a illustrates Au-nucleated Si nanowires growing laterally from one (111)-oriented trench face toward the opposing face. To form functioning devices such as FETs or memory, the electrodes must be isolated from each other, from electrodes of other devices, and from the substrate, which might contain other electronic components. For Si nanowire devices, the electrical and thermal isolation can be provided by forming the electrodes from the heavily doped, (110)-oriented, top silicon layer of a silicon-on-insulator (SOI) structure, in which a thin layer of SiO_2 separates the Si device layer from the mechanically supporting underlying Si wafer, as schematically illustrated in Fig. 2a. Removing the entire thickness of the top silicon layer between the electrodes provides the necessary electrical isolation (Fig. 2b). Metal catalyzed nanowires are grown and bridged between two isolated electrodes in the same method as described above.

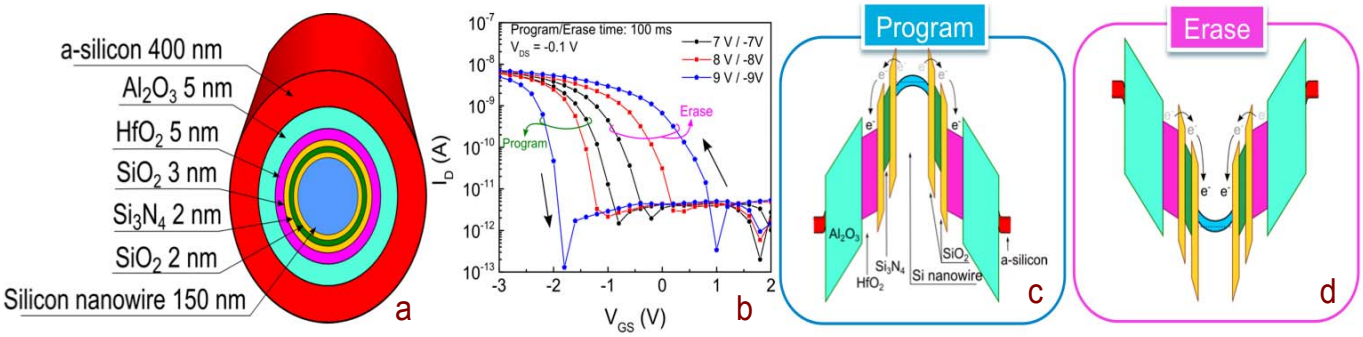

Fig. 3. (a) Schematic diagram of the nanowire channel with tunneling barriers, trap layers and the gate in a VARIOT type nanowire air-bridge memory cell. (b) Semi-logarithmic plot of current ($|I_D|$) versus V_{GS} after program and erase operations. For ±7 V, ±8 V, and ±9 V sweeps at V_{DS}= -0.1 V, memory window range increases from 0.5 V to 1.3 V and to 2.7 V, respectively; arrows represent sweep/hysteresis direction. III. Device Characterization

GAA-FET Based Memory and Logic: To demonstrate a proof-of-concept device, we fabricated an array of GAA-FETs with Si nanowire air-bridged channels, grown by VLS technique. The horizontally aligned nanowire air-bridges led to the integration of a GAA-FET array without rigorous processes for aligning and contacting the nanowires. The devices exhibited excellent performance including high on/off-current ratios, low sub-threshold swings and off-current, as shown in Fig. 3. Statistical evaluation on electrical properties of the GAA-FETs confirmed that our fabrication method possesses a promising capability of integrating any number of nanowire FET devices. In addition, the demonstration of the low voltage operational VARIOT type non-volatile memory cells reveals that our device fabrication scheme has high versatility to prepare other functional nanodevices beyond FETs.

Demonstration of GAA Phototransistors for Electro-optical OR Gate Circuit and Frequency Doubler Applications: We also demonstrated photosensitive 3-D silicon nanobridge GAA-FETs integrated in an array using a high-throughput fabrication technique, as shown in Fig. 4. Off-current of the nanobridge GAA-FET increases by as high as three orders of magnitude with wide-spectral illumination. The device also showed phototransistors characteristics in which output current was linearly modulated with the incident illumination. Photosensitive off-current of the GAA-FET allowed for the successful demonstration of digital and analog applications, such as an electro-optical OR gate circuit and an illumination-enabled frequency doubler. When they are associated with more photosensitive compound semiconductor nanowires such InP and GaN, the nanobridge GAA-FETs can be exploited for realizing high performance multifunctional devices including optoelectronic transceivers as well as sensors, as is proposed in this proposal.

In order to address the challenges in continued scaling of CMOS and increase their performances, one proposed solution is to introduce a new channel material in which charge carriers travel at a much higher velocity than those in silicon. This would allow a reduction in voltage without a loss of speed or other performance and this is why attention is turning to III–V compound semiconductors. Such materials are attractive because of their high electron mobility,

exceptional thermal and chemical stability, high electrical endurance, very high reliability and high-quality interface with gate dielectrics. Currently silicon transistors are going through new gate architectures, channel materials and switching mechanisms. The trend in transistor scaling has already led to a change in gate structure from two dimensions (2D) to three (3D), to avoid the issues in miniaturization such as high off-state leakage current and the short-channel effect.

Compared to the conventional planar gate FETs, multiple gate FETs—such as tri-gate, pi-gate, Ω-gate, and surrounding gate FETs—have improved controllability over the channel in such a way that they effectively suppress the off-current. Owing to enhanced gate controllability, multiple gate FETs aid in low power consumption and downscaling of CMOS devices. The idea of gate-all-around (GAA) transistors, in which the gates are wrapped around nanowire channels, provide the best possible electrostatic gate control [6]. At present, planar, fin architectures using III–V materials are being explored as alternative fast channels on silicon (Si). Although Si is widely used as the channel materials in such devices when devices are designed on Si wafers, using other materials such as InP or GaN channels on silicon, however, has not been widely investigated because of difficulties in integrating free-standing III-V nanostructures on silicon.

If we were to deposit III-V layers directly on Si, the layers will not be continuous and will grow as widely separated nano-dots. However, researchers have shown that even with large lattice mismatch with Si, small cross-section allows the growth of III-V nanowires on a Si surface, accommodating this lattice mismatch [11,13]. Transistors enabled by one-dimensional nanowires have attracted attention because they are expected to present a pathway to overcome the roadblocks to Moore's law and can enable gate-all-around transistors. However, lack of reproducibility in their growth, alignment into arrays, and contact formation to enable scalable fabrication of transistors is challenging.

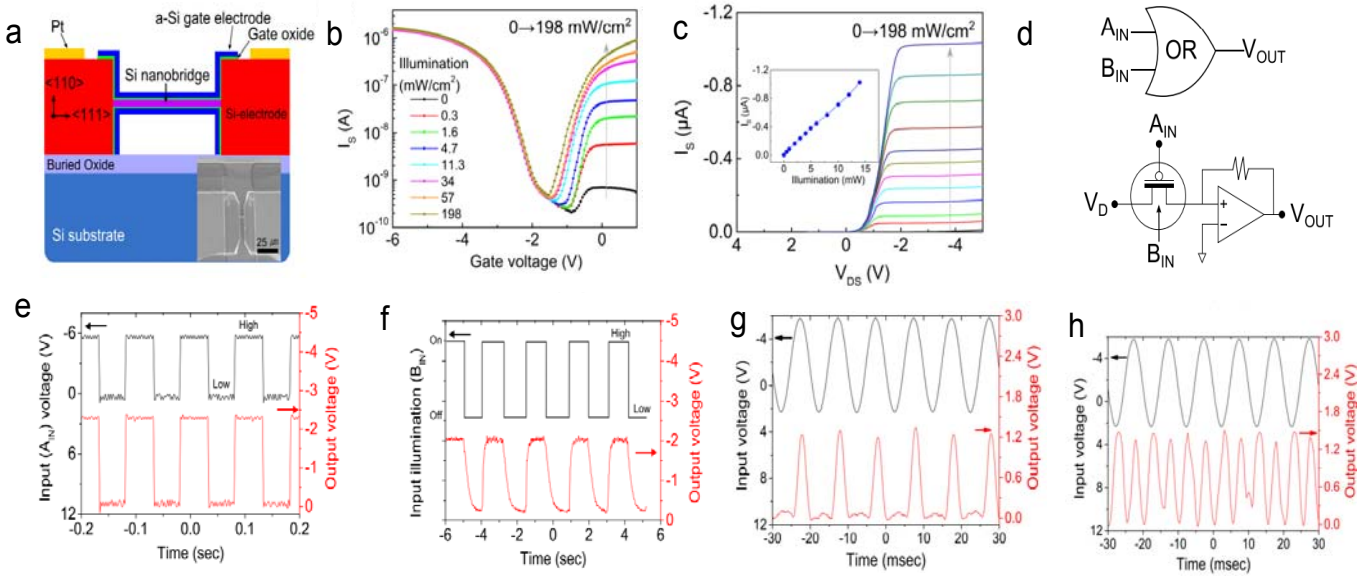

Fig. 4. (a) A 2D schematic diagram of a Si nano-bridge GAA-phototransistor and its SEM micrograph shown in the inset. (b) Measured I_S-V_{GS} curves with illumination of different intensities from 0-198 mW/cm^2. (c) Output characteristics (I_S-V_{DS}) with photo-gating. The inset in (c) shows a linear increase of photocurrent collected for V_{DS} = -2.5 V with increasing illumination intensities. Note that while the off-current in (b) drastically increases with illumination, the on-current increases by 10 %, and subthreshold slopes and threshold voltages remain unaffected by illumination. (d) Symbolic representation of an electro-optical OR gate and its circuit diagram. (e-f) Ouput voltages with an electrical input (A_{IN}) (e) in dark and optical input (B_{IN}) (f) with low A_{IN}. It should be noted that a discernable delay in the fall-time of the output pulses are caused by the latent light from the tungsten-halogen bulb. Illumination-regulating frequency doubling characteristics of the circuit illustrated in Figure e-f. Input and output voltages measured (g) without illumination and (h) with illumination intensity of 190 mW/cm^2. Fast-Fourier-transform (FFT) of output signals of (g) and (h) show that the input signal of 100 Hz is doubled to the output of 200 Hz.

IV. Conclusions

In conclusion, an array of GAA-FETs with Si nano-bridge channels grown via a high-throughput *bottom-up* (VLS) technique has been demonstrated. The horizontally aligned nano-bridges led to the integration of nanowire GAA-FETs without rigorous processes for aligning and contacting the nanowires. The devices exhibited high on/off-current ratios, low sub-threshold swings and off-current. Off-current of the nanobridge GAA-FET increases by three orders of magnitude with wide-spectral illumination. The device also showed phototransistors characteristics in which output current was linearly modulated with the incident illumination. Photosensitive off-current of the GAA-FET allowed for the demonstration of digital and analog applications, such as an electro-optical OR gate circuit and an illumination-enabled frequency doubler. When they are associated with more photosensitive compound semiconductor nanowires such as ZnO and InP, the nanobridge GAA-FETs can be exploited for realizing multifunctional devices including optoelectronic transceivers as well as sensors. Statistical evaluation on electrical properties of the GAA-FETs confirmed that the presented fabrication method possesses a promising capability of integrating nanowire FETs.

***Abstract*—Ballistic performance of nanoscale $In_{0.3}Ga_{0.7}Sb$ double gate n-MOSFET is studied for different gate oxides considering same Equivalent oxide thickness (EOT). Non equilibrium greens function method is utilized under the environment of well-known SILVACO's ATLAS device simulation package to carry out the simulation. Wave function penetration to the oxide is taken into account in the simulation. The results obtained from the simulation indicate that EOT is not solely control the device performance. Rather, a strong correlation is found between the I-V characteristics and the conduction band offset (ΔE_C) of the channel and dielectric materials. It is also found that the threshold voltage decreases and the subthreshold swing increases with the higher value of ΔE_C. It reveals that for nanoscale MOSFET design, another tunable variable is found to ensure best performance.**

I. INTRODUCTION

Owing to the matured process technology Si has been using as an attractive material for commercial device fabrication [1]. For the last 30 years [2], CMOS transistor has been drastically scaled down to meet up the demand of high speed computation. In recent years, further scaling down has become a challenging issue due to the physical limits [3] of Si-based MOS device technology. When the dimension of Si transistors are scaled downed to a certain limit, it causes short channel effects (SCEs), enhanced parasitic resistance, scattering at oxide-silicon interface and thereby degrade the device performance [4]. To overcome these limitations, III-V materials are being studied to replace Si from the channel and are expected to give better performance due to their superior transport properties [5].

According to ITRS roadmap III-V material will replace Si from the channel by 2018[6,7]. Among the III-V materials, InGaSb is a promising candidate for the channel of future MOSFET as it shows highest electron and hole mobilities [8]. Apart from the channel material, gate oxide of MOSFET is also a major issue. When the channel length of a device is scaled down, oxide thickness is also to be scaled to maintain the required level of C_{ox}, I_{ON} and to control the threshold voltage roll off, that is, to keep the control over the channel. Thickness of SiO_2, which is the preferred gate insulator for Si MOSFETs, is reduced over the years from 300nm for 10μm technology to 1.2nm for 65nm technology. When SiO_2 thickness is scaled down, key dielectric properties degrades and device suffers from high leakage current, dielectric breakdown, reduced channel mobility and so on [9,10]. These problems can be solved by replacing SiO_2 with a material having higher dielectric constant. High-k material can be grown physically thicker than SiO_2which has the same electrostatic effects that a thin SiO_2 of thickness equal to "Equivalent oxide thickness, EOT" has. The thick high-k dielectric offers required control over the channel with significant reduction in leakage current [10].

It is well established that to achieve the required control over the channel at the small length targeted by ITRS, multi gate device structure is necessary. Keeping all these issues in mind, in this paper, we studied the performance of $In_{0.3}Ga_{0.7}Sb$ double gate MOSFET for n-type operation considering two different dielectric materials Al_2O_3 and HfO_2 with same EOT of 1nm. The effects of conduction band offsets and gate oxides over current-voltage characteristics as well as related terms like subthreshold swing are investigated. Since drain current is normally calculated by quantum mechanical approaches in ballistic range, we used non equilibrium greens function (NEGF) to carry out the simulation.

II. QUANTUM BALLISTIC SIMULATION

A. Device structure

The proposed device structure is shown in figure-1 and the numerical parameters used in our study are summarized in Table-1. SILVACO's Atlas device simulation package is used to determine the ballistic performance of the device. We used NEGF mode space in effective mass approach.

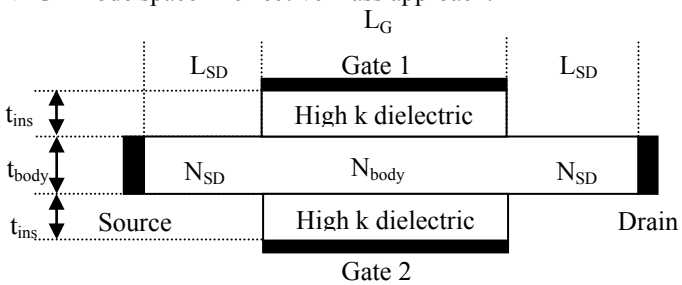

Fig. 1. Device structure of InGaSb double gate nMOSFET. Some the simulation parametersares are shown in TABLE I.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

TABLE I. PARAMETERS USED IN THE SIMULATION OF THE DEVICE STRUCTURE SHOWN IN FIG. 1.

Parameter	*Value*	*Description*
V_{dd}	0.05V	
ε_{ins}	9.3 (for Al_2O_3) 22 (for HfO_2)	Al_2O_3 and HfO_2 as gate oxide
t_{body}	3nm	$In_{0.3}Ga_{0.7}Sb$ channel
t_{ins}	2.385 nm (for Al_2O_3) 5.64nm (for HfO_2)	EOT=1nm for both oxide
N_{SD}	N type, $10^{20}/cm^{-3}$	Within the region L_{SD}
N_{body}	0	Within the region L_G
L_{SD}	5nm	
L_G	15nm	
Φ_{metal}	3.52eV	Gate metal workfunction

B. NEGF theory

The NEGF method provides a rigorous formalism for quantum transport in nanoscale devices [11]. This quantum modeling relies on self-consistent solution of Greens function and Poisson's equations to obtain the energy level, charge and current distribution [12]. The Greens function in fact is a modified schrodinger equation in which the quantum mechanical effect is introduced considering that electrons travel like wave or wave packet from source to drain through the channel.

NEGF are solved using two approaches namely real space and mode space. Simulation in real space method is computationally very much costly. In case of the device where quantum confinement is strong (double gate MOS or XOI FET) the mode space approach can be used. The Hamiltonian in this situation is separated in longitudinal and transverse directions; as a result, it greatly reduces the computational burden. Moreover, in a device structure where the cross-section does not change, the sub-bands are not quantum-mechanically coupled to each other; the transport equations become essentially 1D for each sub-band that leads to use the uncoupled mode space approach [13]. The transformation of a real space effective mass Hamiltonian H_0 to a mode space is done by taking a matrix element between m^{th} and n^{th} wave functions of kth and l^{th} slices

$$H^{MS}_{mnkl} = < \psi^{k}_{m(y)} | H_0 | \psi^{l}_{n(y)} >$$

The transport equation in mode space is

$$\left(E - H^{MS}_{mnkl} - \Sigma^R_S - \Sigma^R_D\right) G^R = I$$

Here, E is the energy of carrier, Σ^R_S and Σ^R_D are retarded self energies carrying information about source and drain respectively, $G^R(E)$is the retarded greens function. After solving the above equations for each energy level, current is calculated by [13]

$$J_x(x_i, y_j) = -\frac{2e}{hL_z\Delta_x}\sum_{k_z\sigma}.\sum_{mn}\int Re(t_{i+1ijj}G^{<}_{mnii+1}\,\psi^{i}_{m}(y_j)\,\psi^{*i+1}_{n}(y_j)\frac{dE}{2\pi}$$

III. RESULT AND DISCUSSION

In our simulation, source and drain doping concentration is taken to be $10^{20}/cm^3$, and this doping is done throughout the region marked by L_{SD} in figure-1. Von Neumann boundary conditions for potential are used because the ballistic carrier do not create voltage drop near source and drain contact. Moreover, the potential in source and drain are allowed to float, because the number of carrier reflected backward and hence the total carrier concentration in the contact can change with bias. The body thickness of the device is 3nm. Wave function penetration in the oxide region is also taken into account.

Figure-2 shows a comparison between the I_D-V_G characteristics plotted at V_D=0.05V for the double gate MOS device having two gate dielectrics. It is found that the drain current is higher for Al_2O_3 than that of HfO_2, although they have same EOT. Generally it is expected that if two oxides have the same EOT, they will provide same oxide capacitance, thereby same electrostatic control over the channel and hence identical device performance. But in case of double gate MOSFET, the deviation is found because of conduction band discontinuity (ΔE_C) between the oxide and the channel.

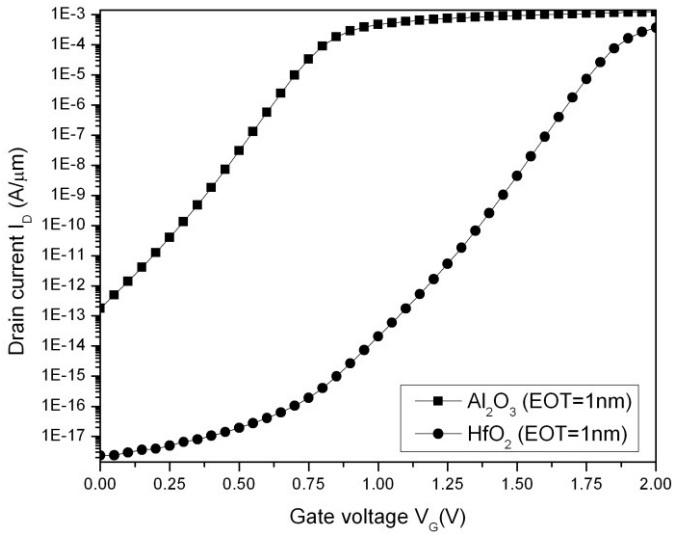

Fig. 2. I_D-V_G characteristics of double gate MOSFET for different gate dielectric material. The structure of the device is shown in fig-1

To understand the effect of ΔE_C, the conduction band diagram across and along the channel at V_D=0.05V and V_G=2V are estimated and plotted in figures 3 (a) and (b), respectively. It is clear that at very low gate bias, with keeping the gate metal work function (Φ_{metal}) fixed, lower ΔE_C implies the higher difference between the channel conduction band minima and Fermi level at the source contact, which is set at "zero". The opposite is found for high gate bias as shown in fig. 3(a). These band positions relative to source contact fermi level implies lowest number of energy states are available for conduction if ΔE_C gets lower. Since lower number conducting states leads to lower drain current, lower conduction band offset between oxide and channel leads to lower drain current,

provided that Φ_{metal} is kept fixed. For $In_{0.3}Ga_{0.7}Sb$ channel, $\Delta E_C(Al_2O_3)$ = 2.88eV and $\Delta E_C(HfO_2)$ = 1.76eV [14]. That is why HfO_2 is giving lower drain current despite of same EOT.

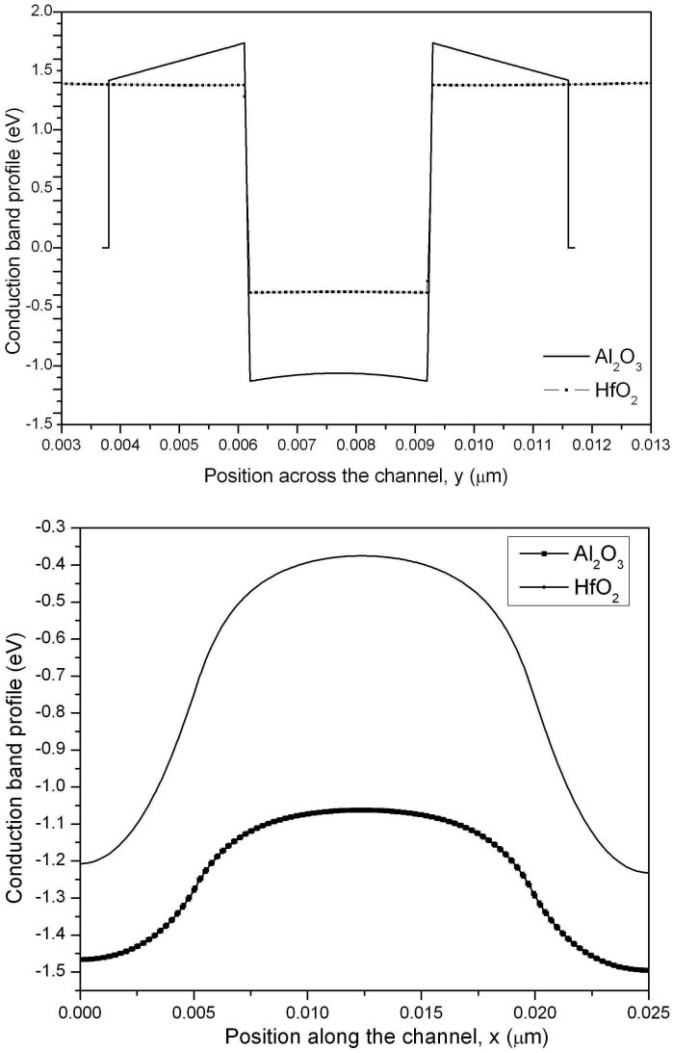

Fig. 3. Conduction band profile of the double gate MOSFET (a) across the channel (b) along the channel, at V_D=0.05V and V_G=2V.

It is also found in figure 3(b) that the conduction band profile does not start from the same position, not from zero level either for two different gate oxides. It is because in ballistic transport source and drain contacts are allowed to float to take into account any reflection of carrier during transport.

Since the threshold voltage can be tuned by tuning the gate metal work function (Φ_{metal}), the I-V curve for HfO_2 can be braught to the left by reducing Φ_{metal}. If Φ_{metal} for HfO_2 based device is choosen to be 1.12eV less than that used for Al_2O_3 device, the I-V curves will be at closest position, because $\Delta E_C(Al_2O_3)$-$\Delta E_C(HfO_2)$=1.12. But to compare the impact of ΔE_C only, all other device parameters need to be same.

Figure-4 shows the change in subthreshold swing (SS) as a function of ΔE_C between oxide and the channel. It is found that the subthreshold swing decreases with decreasing ΔE_C. Lower SS implies the sharp change of drain current with gate bias and the better electrostatic control of gate over the channel. Better control of the gate also indicates the lower influence of the drain voltage on I-V characteristic and hence supressed SCE, like drain induced barrier lowering. Theoriticaly the lowest possible SS at room temperature is 60mV/dec which means the best electrostaic control of MOSFET. In practice, SS bellow 90mV/dec is acceptable for logic application.

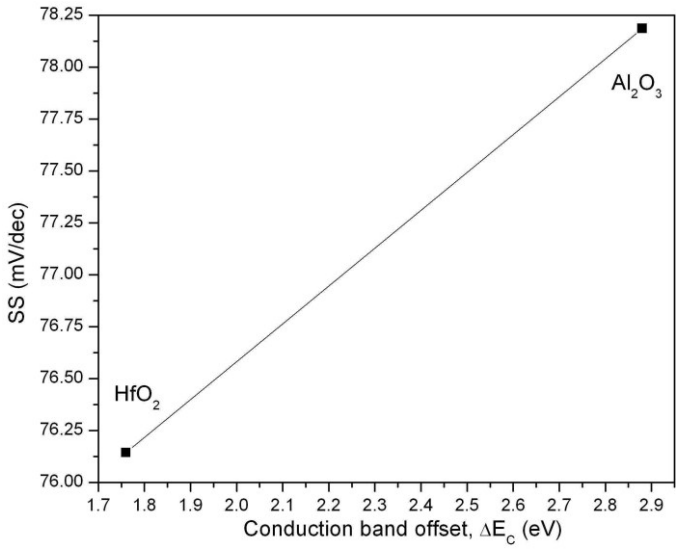

Fig. 4. Variation of subthreshold swing(SS) as function of gate oxidedielectric constant

IV. CONCLUSION

In this paper, we analyzed the influence of ΔE_C between the gate oxide and the channel on the performance of $In_{0.3}Ga_{0.7}Sb$ nanoscale double gate MOSFET. We took 15nm channel with Al_2O_3 and HfO_2 gate oxides having 1nm of equivalent oxide thickness and simulated the performance of the device by NEGF method. The source and drain regions are taken to be heavily doped($10^{20}/cm^3$) and the channel is left undoped. Effective gate metal work function is taken to be 3.52eV and the wave function penetration to the oxide is also taken into account. Source drain contacts are allowed to float to treat the carrier reflection accurately. We found that the drain current increases with increase in ΔE_C if the work function of the gate remains unchanged. Also the threshold voltage (V_T) decreases and SS increases with increasing ΔE_C. SS of the device under study goes bellow 90mV/dec for both case and it is a rule of thumb that SS bellow 90mv/dec is acceptable for logic application. Although we get lower drain current for HfO_2 because of its lower ΔE_C with InGaSb, it can be controlled by tuning the gate metal work function. That is why the overall performance of HfO_2 is better since it gives lower SS.

***Abstract*—Wavelets as one of the most important signal processing tools are widely used in biosignal research. The continuous wavelet transform based on an analog circuit implementation offers power-efficient real-time signal processing. This paper presents a complexity reduction method of an analog wavelet filter design. The Chebyshev polynomial with higher accuracy approximation is utilized in the wavelet design. In order to simplify the circuit implementation, the transfer function is transformed into the multiplication of biquads. For the proof-of-concept, a Mexican hat wavelet filter circuit is implemented as the multiplication of biquads. The measurement results show that the proposed design process offers higher accuracy approximation and less complex method for the implementation of analog wavelet transform circuit.**

***Index Terms*—Chebyshev approximation, continuous wavelet function, implantable system, Taylor's approximation.**

I. Introduction

Various types of biosignals originating from the human body are being extensively used for emerging clinical applications including but not limited to mind-driven rehabilitation, metabolic monitoring, seizure detection, etc[1]. Biosignals such as Electrocardiograph (ECG), Electroencephalograph (EEG) are typical examples of biosignals characterized by transients and non-stationarity such as spiking and small oscillation [2].

In order to process the vital physiologic phenomena in the biosignals, the need of a biopotential recording system is indispensable. The conventional biopotential recording system includes low-noise amplifier, filter, analog-to-digital converter and signal processing circuitry [3]. The signal processing unit as one of the most important parts in the biopotential recording system offers various types of signal analyses such as Fourier Transform, Hilbert Transform, and Continuous Wavelet Transform (CWT).

The CWT is considered as one of the most useful technique in signal processing that offers the localization in both time and frequency for transients, aperiodic and non-stationary signals. The CWT utilizes a wavelet function that acts as a low pass filter (Gaussian wavelet) or a bandpass filter (Mexican hat wavelet and Morlet wavelet). When a signal is applied to such a filter, the wavelet function facilitates the analysis of the frequency contents of the signal at any particular instance of time. For wavelets with different mother wavelet functions and dilation parameters, CWT provides time and frequency information of the input signal, which allows for noise reduction [4], spike detection [5], and seizure detection [6].

The conventional CWT is based on software which requires high data rate analog-to-digital (ADC) converter to minimize the loss of information in the biosignal. The high performance ADC usually has high power consumption. However, for applications requiring real-time processing, such as implanted or mobile biomedical devices, low-power consumption is a priority. Hence, the signal processing block should be implemented in hardware instead of software. Even in hardware-based implementation, analog circuits can offer reduced power consumption compared to equivalent digital circuits [7]. CWT based on an analog filter implementation offers a power-efficient real-time signal processing such as feature extraction and skip detection [8].

Various types of low-power analog CWTs are reported in the recent years - LC ladder, Gm-C filter [8], and log-domain filter structures based CWT [7]. The padé approximation and log-domain based CWT design offers less order of the approximation and low-power consumption [7]. The 7th order Taylor approximation and LC ladder with active inductor greatly decreases the power consumption and the circuit complexity.

This paper presents a method on the implementation of the CWT, with the motivation of reducing the complexity of the circuit implementation. A 4th order Chebyshev polynomial is used to increase the accuracy of the Fourier transform of the Mexican hat wavelet function. The transfer function of the wavelet is reconstructed into the multiplication of two biquad filters to further simplify the circuit implementation. For the proof of concept, a circuit implementation of Mexican hat wavelet based on the proposed method is tested. The results show that the proposed design process offers higher accuracy approximation and less complex method in analog wavelet transform circuit implementation.

In section II, a brief background of wavelet transformation and the method of Chebyshev approximation with different interval is explained. The analog circuit implementation of the wavelet function is shown in section III. Section IV shows the simulation and measurement results. Finally the conclusion is drawn in section V.

II. Continuous Wavelet Transform and Chebyshev Polynomial

A wavelet transform is considered as one of the most widely used mathematical function in signal processing. Wavelet analysis overcomes the inability of Fourier analysis to capture the transients of the time location specific features within a signal. Comparing with the method of Short Time Fourier Transform, wavelets can simultaneously provide the temporal and spectral information of a signal [9]. Wavelets have dilation

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

and location parameters, which result in functions that are localized in both time and frequency. The dilation parameter facilitates the wavelet function with a variable window width. In the low-frequency zone, the long time windows are used to get a finer low-frequency resolution whereas in the high frequency zone, the short time windows are used to get finer time information.

Wavelet transformation as a time-frequency analysis method can be performed in continuous time as well as in discrete time domain. The CWT can be defined as,

$$T(a,b) = \frac{1}{\sqrt{a}} \int_{-\infty}^{\infty} x(t)\psi^* \left(\frac{t-b}{a}\right) dt \tag{1}$$

where $\psi^*(t)$ is the complex conjugate of the mother wavelet function $\psi(t)$, a is the dilation parameter, and b is the location parameter of the wavelet.

The Gaussian function based mother wavelet (Gaussian wavelet and Mexican hat) are the popular choices for biosignal analysis. Therefore, in this paper we demonstrate a Mexican hat wavelet design. The Mexican hat wavelet is the second derivative of a Gaussian function, and the ideal impulse response is as shown in Fig. 1. The equation of Mexican hat in time domain can be expressed as,

$$\psi_t = \frac{2}{\sqrt{3\sigma}\pi^{\frac{1}{4}}} \left(1 - \frac{t^2}{\sigma^2}\right) e^{\frac{-t^2}{2\sigma^2}}. \tag{2}$$

where σ is the dilation factor. The corresponding Fourier transform of the Mexican hat wavelet is ,

$$H(j\omega) = \sqrt{\frac{8}{3}}\pi^{\frac{1}{4}}\sigma^{\frac{5}{2}}\omega^2 e^{\frac{-\sigma^2\omega^2}{2}}. \tag{3}$$

After substituting s into $j\omega$ in (3) and adding a delay $e^{-\tau s}$ into (3), the expression becomes,

$$H(s) = \frac{-\sqrt{\frac{8}{3}}\pi^{\frac{1}{4}}\sigma^{\frac{5}{2}}s^2}{e^{\tau s - \frac{-\sigma^2 s^2}{2}}}. \tag{4}$$

Since (4) has exponential term in the denominator, the transfer function cannot be realized into a standard form. Hence the exponential term needs to be expanded. The most common exponential expansion is Taylor using Maclaurin's series and Padé approximation. Maclaurin's series is easy to implement. However it is very accurate when σ is near zero, but becomes increasingly inaccurate when σ increases. The padé approximation offers less order of polynomial compared to Taylor, however it has higher complexity and unsuitability. To achieve the high accuracy approximation with less order, the Chebyshev polynomial expansion is used.

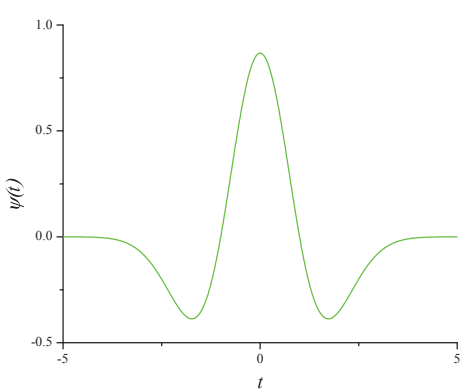

Fig. 1. The plot of ideal Mexican hat mother wavelet.

Chebyshev polynomials, named after Pafnuty Chebyshev, are a sequence of orthogonal polynomials that can be written as monic polynomials of nth degree whose deviation from zero is as small as possible. Using series based on orthogonal Chebyshev polynomials on approximating large systems of equations gives better results in terms of accuracy than the typical methods such as the mean square approximation or the Taylor approximation [10].

The recurrence relation of Chebyshev polynomials with arbitrary interval a can be found as,

$$\left.\begin{aligned} T_0(x) &= 1 \\ T_1(x) &= \frac{x}{a} \\ T_2(x) &= \frac{2x}{a}T_1(x) - T_0(x) \\ &\vdots \\ T_n(x) &= \frac{2x}{a}T_{n-1}(x) - T_{n-2}(x) \end{aligned}\right\} \quad for\ x \in [-a, a]. \tag{5}$$

The weight function $C_k(x)$ in the interval of $[-a, a]$ is,

$$C_k(x) = \int_{-a}^{a} W(x) \cdot T_n^2(x)\, dx$$
$$where \tag{6}$$
$$W(x) = \frac{1}{\sqrt{a^2 - x^2}}.$$

The coefficients of the Chebyshev polynomials corresponding to the function $f(x)$ can be found as,

$$c_{o_n} = \frac{1}{C_n(x)} \int_{-a}^{a} W(x) \cdot T_n(x) \cdot f(x)\, dx. \tag{7}$$

III. The Analog Continuous Wavelet Transform Implementation

The design procedure of the Continuous Wavelet Transform can be found in Fig. 2. The design steps involve selecting the mother wavelet, taking the Fourier transfer of the desired wavelet, adding delay, applying Chebyshev approximation, calculating the zeros and poles of the transfer function, reconstructing the transfer function, and finally implementing the resultant transfer function by using biquads.

To process the EEG signal, the low frequency Mexican hat wavelet is needed. With a dilation factor $\sigma = 0.2$ and delay $\tau = 0.8$, the center frequency of the wavelet is found to be 1 Hz. The filter order used represents a trade-off among the accurate approximation of the desired function, the circuit complexity and the power consumption. To optimize the performance and the circuit complexity, the 4th order approximation is used.

To compare the performance of the Chebyshev approximation, same order of the Taylor expansion is used to approximate the wavelet function. Fig. 3 shows the percentage error of the 4th order Chebyshev and the 4th order Taylor approximations of the denominator in (4) with $\sigma = 0.2$ and $\tau = 0.8$ in the interval of -3 to 3. The maximal error of Taylor approximation reaches to 40%, however the maximal error of Chebyshev approximation is only 6%.

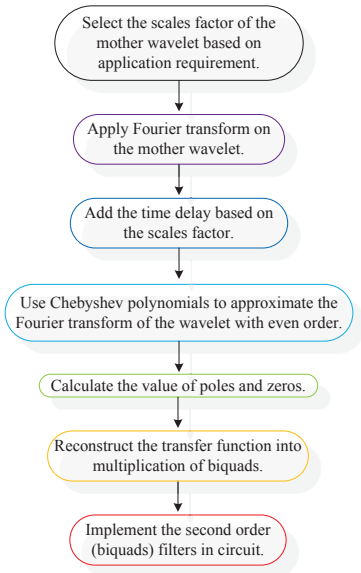

Fig. 2. The flow chart of the design procedure of the Continuous Wavelet Transform

The 4th order Chebyshev approximation of (4) with $\sigma = 0.2$ and $\tau = 0.8$ is as shown below,

$$H(s) = \frac{-0.0389s^2}{\begin{array}{l}0.011999853794280714727977842784763s^4 \\ +0.082948231213368508144515537331379s^3 \\ +0.296199087631179461112108776256 31s^2 \\ +0.769154217916028601932191636573 56s \\ +1.001894393842919726497764365547\end{array}}. \tag{8}$$

The approximated transfer function can be implemented by LC ladder, Gm-C, or log-domain structures. However, constructing a high order filter based on (8) is not obvious. Due to the complexity of higher order transfer function (such as the function in (8)) implementation in analog domain, a new transfer function has been reconstructed by using the values of poles and zeros of the transfer function. The values of four poles and two zeros can be calculated from (8). They are $s_1 = -2.91 - j0.71$, $s_2 = -2.91 + j0.71$, $s_3 = -0.551 - j3.011$, $s_4 = -0.551 + j3.011$, and $z_1 = z_2 = 0$. The reconstrudted transfer function can be rewritten as,

$$H(s) = \frac{s^2}{s^2 + 36.568138s + 354.208258} \cdot \frac{-0.0389}{s^2 + 6.92407s + 369.90179795}. \tag{9}$$

The new transfer function (9) indicates that the Mexican hat wavelet can be easily implemented by cascading a second-order high pass filter and a second-order low pass filter. The corresponding block diagram to the reconstructed transfer function is shown in Fig. 4. The first stage is a second-order high pass filter with two zeros at the origin. The second stage is a second-order low pass filter that generates the third and fourth poles for the system. The last stage is a normalized gain control stage. The first and the second stage can be implemented either by passive structures, such as LC ladder and RC filter, or by active structures, such as signle-amplifier biquad filter, butterworth biquad, and Sallen-Key circuits *et al*; and other MOSFET based structures, such as Gm-C filter and log-domain filter.

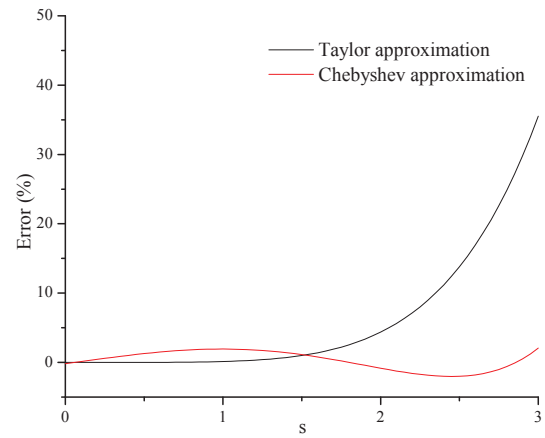

Fig. 3. The maximal error of Taylor approximation reaches to 40%, however the maximal error of Chebyshev approximation is only 6%.

IV. Simulation and Experimental Results

An OTA based 4th Mexican hat wavelet filter has been designed and simulated by Cadence. Due to very limited microchip fabrication facility, a proof-of-concept of the proposed method is implementation by using AD8044. The proposed method can be easily implemented by using three OPAMPs based units - a high pass filter, a low pass filter, and an inverting amplifier.

Fig. 5 is the impulse response of the Mexican hat wavelet measured by oscillator scope. The upper plot is the input impulse generated by function generator with an amplitude of 1 V, pulse width of 100 ms and delay of 500 ms . The lower plot is the output of the Mexican hat wavelet corresponding to the impulse signal with amplitude of 1.2 V.

Fig. 6 shows the comparison of measured result of the impulse response with the simulation result. Although the passive components have value variation and the mismatch, the measured results show the great similarity to the simulation result. The experimental result shows that the realization of the wavelet transform by using biquads structure has a great tolerance on components value variation.

V. Conclusion

This paper presented a method on the implementation of the continuous time wavelet transformation by using the biquads,

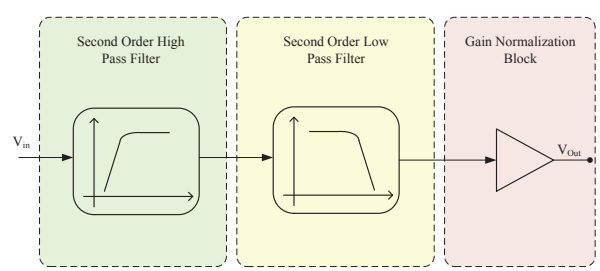

Fig. 4. The block diagram related to (9).

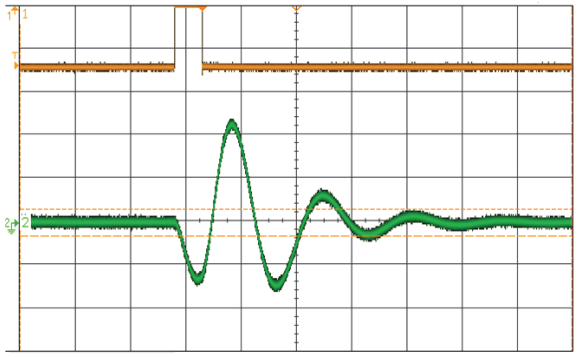

Fig. 5. The upper plot is the input impulse with amplitude of 1 V, 100 ms pulse width and 500 ms delay. The lower plot is the impulse response output of the Mexican hat wavelet.

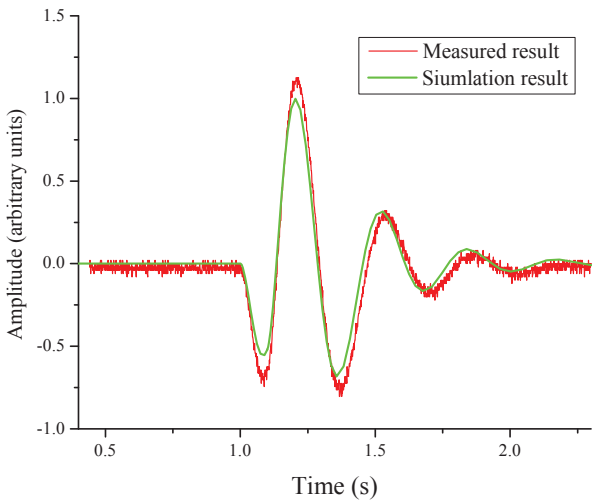

Fig. 6. The comparison of measured result of the impulse response versus the simulation results.

with the motivation of simplifying the circuit implementation. The Chebyshev approximation of Mexican hat wavelet shows better accuracy compared to Taylor expansion in 4th order. The maximal error of Taylor approximation reaches to 40%whereas the maximal error of Chebyshev approximation of the denominator is only 6%. A new transfer function has been reconstructed into the form of multiplication of biquads to simplify the circuit implementation of higher order transfer function. As a proof of concept, a circuit implementation of Mexican hat wavelet has been implemented. The experimental result and the simulation result show a close match. The proposed the method offers approximation with higher accuracy and easier way to implement the analog continuous wavelet transform circuit.

***Abstract*— Skin diseases are among the most common health problems worldwide. In this article we proposed a method that uses computer vision based techniques to detect various kinds of dermatological skin diseases. We have used different types of image processing algorithms for feature extraction and feed forward artificial neural network for training and testing purpose. The system works on two phases- first pre-process the colour skin images to extract significant features and later identifies the diseases. The system successfully detects 9 different types of dermatological skin diseases with an accuracy rate of 90%.**

***Index Terms*— Skin disease, artificial neural network, computer vision, clustering, dermatology.**

I. Introduction

Dermatology is the branch of medicine dealing with the hair, nails, skin and its diseases, It is a specialty with both medical and surgical aspects A dermatologist takes care of diseases, in the widest sense, and some cosmetic problems of the skin, scalp, hair, and nails. Human skin is one of the most unpredictable and difficult terrains to automatically synthesize and analyze due to its complexity of jaggedness, tone, presence of hair and other mitigating features. In a developing country like Bangladesh it is expensive for a large number of people to go to dermatologist for their skin disease problem. Every year a large number of populations in the developing countries like Bangladesh suffer due to different types of skin diseases. So, it is very necessary for both the patients and dermatologists to have an automated skin disease detection system especially in developing countries. Even though there have been several researches conducted to detect dermatological skin diseases using Computer Vision based techniques but almost every one worked for only 2-3 diseases. In our wok we have worked to detect 9 different types of skin diseases. They are Eczema, Acne, Leprosy, Psoriasis, Scabies, Foot Ulcer, Vitiligo, Tinea Corporis and Pityriasis Rosea. We have used 8 different types of algorithms for image pre-processing (YCbCr, grey image, sharpening filter, median filter, smooth filter, binary mask, histogram and sobel operator). Our system will take 10 different features from image pre-processing results and user inputs (liquid type, liquid colour, elevation, duration, feeling, gender, age). These features are used for training and testing purpose of our feed forward artificial neural networks (ANN). Using artificial neural networks (ANN) as knowledge base appears to be a promising method for diagnosis and possible treatment routines. In this article next we will discuss in brief about the related works regarding this topic, architecture, methodology, pre-processing algorithms and learning algorithm used in our proposed method. Then we will discuss about result and efficiency of our system.

II. Related Work

Detecting different types of skin diseases from colour image is a very challenging task in computer vision. Finding out different features from the colour skin images of the infected area of different skin diseases and detecting them with a high accuracy rate is the primary purpose of this research.

Researchers are working on several algorithms that can be used to detect different types of skin diseases. Kabari et al [6] crated a artificial neural networks system that predict diagnosis and routine treatment for skin diseases patients and their accuracy rate is *90%.* M. SHAMSUL et al [11] proposed an automated dermatological diagnostic system. They have used different pre-processing algorithms like ours and used feed forward back propagation artificial neural networks for training and testing purpose. Shuzlina et al [12] elaborates a prototype with back propagation neural network (BPNN) to assist the dermatologist accuracy rate was *91.2%.* Nidhal et al [15] proposed a psoriais diseases detection system using feed forward artificial neural networks. Nasir et al [2], Shang et al [7] and Nibaran et al [13] compared between different features of different types of algorithms. Hashim et al [1] used different matlab tools for image processing and Wahab et al [3] presented a texture classification system. Gerald et al [4] have introduced an approach that produces accurate overlays of thermal and visual medical images. Chang et al [8] proposed an automatic facial skin defects detection and recognition system with an accuracy rate of *98.0%.*

In this research similar approach like [6],[11] is used in order to detect different types of skin diseases from colour image. The main difference between their system and our system is, they have considered region of interest (ROI) as image extracted feature but we have considered average colour code of infected area, shape, and area size and also some inputs from user as features like elevation of the infected area, liquid colour, liquid type etc.

III. Architecture and Methodology

The system works on two phases- first pre-process the colour skin images to extract significant features and later identifies the diseases. At first we are using the colour skin images and then apply 8 different image processing algorithm on it to find some visual pattern and significant features like average colour code of infected area, infected area size in case of pixels and shape or edge detection of an infected area. Then we use user inputs like gender, age, duration, liquid type,

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

liquid colour, elevation and feeling. We train user input values along with colour skin image extracted features to train and test into a feed forward back propagation artificial neural network to identify the dermatological disease. Here we have shown the complete architecture of the system through a diagram.

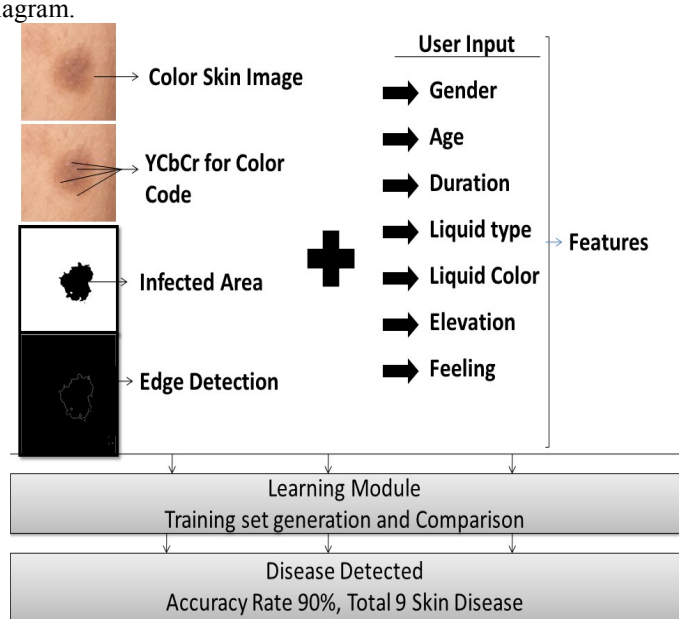

Figure 1: Complete Architecture of the system.

IV. Data Collection

Our first task was to collect necessary data's (image, information) of patients. For fulfilling this purpose we went to Sir Salimullah Medical College and Mitford Hospital, Dhaka, Bangladesh, Department of Dermatology. We took images of total 128 patients of 9 different diseases from the dermatology department.

Table 1: Data Collection Table

Disease Name	Number of Patients	Images taken
Eczema	7	28
Acne	25	152
Leprosy	5	24
Psoriasis	12	99
Scabies	40	277
Foot Ulcer	6	35
Vitiligo	15	62
Tinea Corporis	10	66

V. Pre-processing Algorithms

We pre-processed the images and trained the resulted images in our feed forward back-propagation neural network. Eight different types of algorithms were used, they are grey image, sharpening filter, median filter, smooth filter, binary mask, histogram, YCbCr and sobel operator. The algorithms were implemented sequentially.

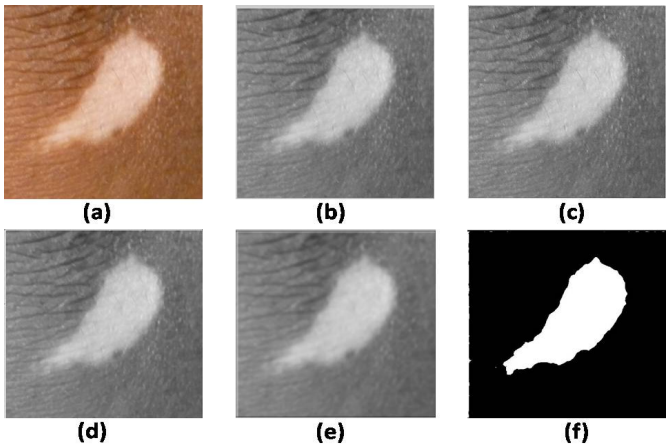

Figure 2: Result of Pre-processing algorithms. (a) Original Colour skin image, (b) Grey Scale image conversion, (c) sharpening filter, (d) Median filter, (e) Smooth Filter, (f) Binary Mask

The normal image of the infected area is converted into a greyscale image at first. Sharpening filter is applied to the greyscale image to get shaper details of the infected area. Median filter is used after sharpening filter to remove noise. We used 5*5 matrix here for median filter. Smoothing filter is applied after media filter. The idea of mean (smoothing) filtering is simply to replace each pixel value in an image with the mean ('average') value of its neighbours, including itself. Binary image was generated from the mean filtered image and distribution of colour of binary image was showed by histogram. YCbCr was used to extract average colour code of the infected area from the binary image. Sobel operator was applied to binary image to detect edge of the infected area.

Figure-2 shows the original colour skin image and results of implementing different algorithms.

VI. Feature Extraction

Two types of features were extracted are given below:

1. Features extracted from images (colour, area, edge)
2. Features extracted from user input (liquid type, liquid colour, elevation, duration, feeling, gender, age)

1. Features Extracted from Images

The first feature extracted from colour image is the colour code of the infected area of the skin. We used YCbCr algorithm to find out the colour code of the infected area from the binary image. The area or size of the infected skin is important to classify the disease. It is done by first getting the histogram graph of the binary image. After we get the histogram of the binary image we get to know the pixel of the whole area. Then we multiplied the area in pixel with the ratio of pixel to finally get the area or size of the infected skin in mm^2.

Detecting the edge of the infected area gives us the shape, as it is very important to detect the diseases. To detect the edge we have used sobel operator here. Binary mask splits the main infected area from the whole image and applying sobel

operator in the binary image gives us the shape of the area by detecting the edge.

2. Features Extracted from User Input:

The features we collected from patient's history are liquid type, liquid colour, elevation, duration, feeling, gender, age. Three different types of liquid type (blood, pus, watery) are considered. Liquid colour parameters for blood, pus and watery are red, yellowish/white and transparent respectively.

During data collection we measured elevation of the infected area for different diseases. The average approximate sizes of elevation for all diseases are 0.1cm-7cm depending on the situation expect leprosy patients because the elevation of infected area is very high for leprosy. We saw different types of feeling of patients for different diseases like itching, pain, burning sensation, numbness, headache, fever etc. Gender, age, duration these features are collected from normal patient's survey. A specialized dermatologist helped us to validate the survey we conducted on the patients.

VII. Learning Algorithm

We have used feed-forward back-propagation neural network training to perform this step. We validated and tested our system using the tenfold cross validation process. The virtue of using a cross validation technique is that there are no overlapping of the test data and training data, making the system testing results viable and dependable. We have trained our feed forward back-propagation neural network with 10 different features, 3 of them are extracted from the image pre-processing algorithms and 7 of them are from user inputs. In this system we have used 100 neurons in our hidden layer to get the best result from the system. Some sample feature values are given below that we have used in our input layer.

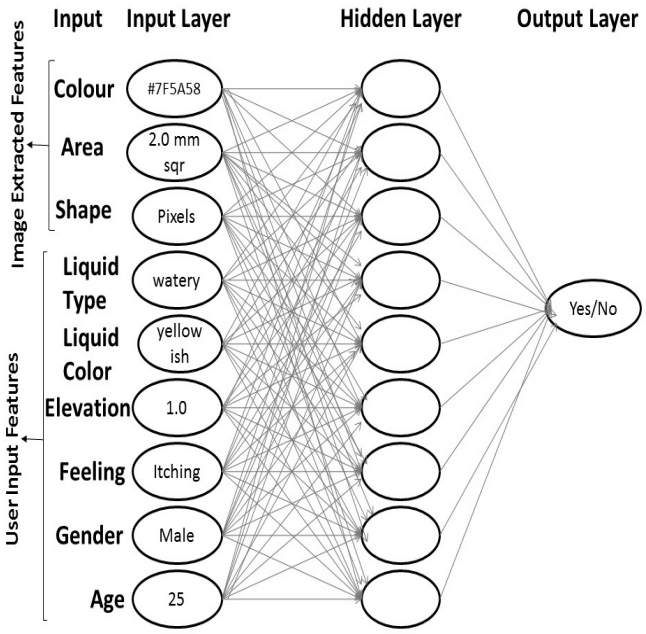

Figure 5: Feed forward back propagation artificial neural network diagram

In the figure-5 we can see that we have trained our feed-forward back-propagation neural network by 10 features. Features like colour, area, edge/shape are extracted from colour skin images and rest of the features like liquid type, liquid colour, elevation, feeling, gender, age are extracted from user input.

VIII. Result

In this research 775 colour skin images were used of 128 dermatological disease patients. The proposed system can successfully detect 9 different dermatological diseases with an accuracy of 90%. We have used 15 % of our colour skin images for testing purpose, 10% of images for validation purpose and 75% of images for training purpose. The supervised system works well than semi-supervised and unsupervised system. Detection rate of our supervised system is 90% where the detection rate of semi-supervised system is 88% and 85% for unsupervised system.

In the figure-6 we can see different detection rate for 9 different diseases. Detection rate of diseases that has low elevation in the infected area like foot ulcer, vitiligo and psoriasis are very high like 97%, 97% and 91%. Where the detection rate of diseases that has low elevation in the infected area are comparatively low which is between 85-88%. The whole processes of this proposed system starts with taking a colour skin image and pre-process the image by applying 8 different algorithms. Applying pre-processing algorithms we get three image extracted features which we use in our feed forward back-propagation neural network along with seven other user input features. Out of 9 dermatological diseases our system shows best accuracy rate for foot ulcer and vitiligo and our system did not perform according to our expectation for acne and tinea corporis.

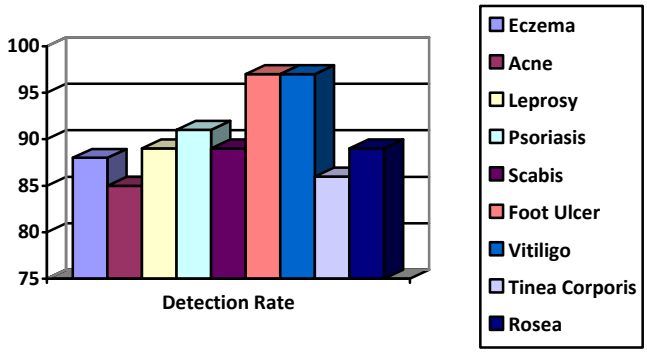

Figure 6: Detection rate of different skin diseases

In the Table- 3, we provided sample colour skin images of nine dermatological diseases, approximate elevation rate of each dermatological disease, total image used to train and test our system, successfully disease detected images and accuracy rate for each dermatological disease.

We can see that our system performed well for diseases that has low elevation in the infected area. For this type of disease images, system can generate binary image accurately and sobel operator can detect the shape of the infected area more precisely.

Table 3: Disease detection rate

Disease Name	Sample image	Elevation (cm)	Total image	Disease detected	Detection rate %
Eczema		0.1-0.3	28	23	88%

Acne		0.2-0.4	152	140	85%
Leprosy		1-7	24	20	89%
Psoriasis		0.1-0.2	99	90	91%
Scabies		0.15-0.25	277	246	89%
Foot Ulcer		NO	35	33	97%
Vitiligo		NO	62	60	97%
Tinea Corporis		0.1-0.2	66	52	86%
Rosea		NO	32	23	89%

IX. Conclusion

In this article we presented an automated system for detecting various kinds of skin diseases. At first it was not easy for us as we were trying to analyse human skin characteristics since human skin is one of the most difficult surface to analyse. It is unique and novel since our dataset was not acquired from secondary sources; rather it was a work of months of toil in an actual hospital of Bangladesh making the dataset a standard dataset which is completely new in perspective of Bangladesh. The system examines an image of infected human skin and detects the disease with an accuracy rate of 90%. We have tested a total number of 775 skin images for 9 diseases.

Acknowledgment

We are thankful to the Director Brig Dr. Zakir and Dr. Md. Masudul Hoque, Register, Dermatology & Veneriology Department of Sir Salimullah Medical College, Dhaka for helping us to collect Colour skin image data from the Medicine Department of the Hospital. We are also thankful to Adnan Firoze and M.Shamsul Arifin for giving their research data for testing our developed system.

Direct Strain Estimation for Ultrasound Elastography Using Peak Frequency Ratio of Radiofrequency Echo Signals

Abu Shahir Md. Khalid Hasan,* Raziur Rahman and Mohammad Ariful Haque
Department of Electrical and Electronic Engineering, Bangladesh University of Engineering Technology

*khalidhasan27@yahoo.com

***Abstract*—Ultrasound elastography is a medical imaging technique to visualize the tissue stiffness using a conventional ultrasound machine. To compute the elastogram, the radiofrequency echo signals are acquired before and after a small applied deformation. Then the local tissue displacement field is estimated by searching the peak of the cross-correlation function between small segments of pre- and post- deformation signals. Finally, the corresponding strain distribution is imaged by differentiating the displacement field. However, the pre- and post- signals are not exactly the shifted versions of one another and hence the displacement estimation is inaccurate and the resulting strain image is highly noisy. In this paper, we propose a novel technique to estimate the strain image from the ratios of the peak frequencies of the pre- and post- deformation signals. Unlike other time/frequency domain reported schemes, our proposed technique does not use cross-correlation or any other similarity measures and directly estimate the strain in the power spectral density domain. Simulation experiments are conducted at various strain conditions and the results show that the proposed method can be an effective and computationally efficient algorithm for ultrasound elastography.**

***Index Terms*—Elastography, Strain Estimation, Power Spectrum Density, Peak Frequency Ratio**

I. Introduction

Tissue stiffness is utilized by clinicians for centuries to aid clinical diagnosis. Ultrasound Elastography is a sophisticated non-invasive alternative technique to estimate tissue stiffness. Measurement of biological tissue stiffness/elasticity is done for the purpose of pathological diagnosis as tissue stiffness or relative strain contains vital information for detection and classification of tumors in different organs such as breast [1], prostate [2], thyroid [3] and liver [4]. Normal tissue and benign tumors are typically elastic or soft and can be compressed easily by applied stress whereas malignant tumors are just about inelastic. A number of algorithms have been developed to estimate the strain distribution in elastography which have different image quality and numerical efficiency. The objective of our work is to get an improved strain image with a computationally efficient algorithm.

Strain imaging methods developed so far can be broadly classified into two groups: gradient based strain estimation and direct strain estimation. In the gradient based methods, strain image is generated from the derivative of the displacement field. The displacement can be estimated in various ways, namely time-domain cross-correlation [5], the phase root seeking (PRS) techniques. In the PRS method [6-7], the displacement/time-shift is calculated by seeking the phase-root of the zero-lag cross-correlation between the corresponding analytic pre-and post-compression windowed RF signals. The gradient based method by nature has the deficit of high noise corruption [8] and therefore may result in poor signal-to-noise ratio (SNR) strain image. Moreover, due to internal tissue compression, post-compressed RF echo signal can't be exact delayed or shifted version of pre-compressed signal [9]. To reduce the effect of this compression, temporal stretching [10] by an appropriate factor is performed on the post-compressed RF signal. Though the stretching operation improves the SNR of the strain image, the performance of the technique is highly dependent on proper choice of the stretching factor. On the other hand, in direct strain estimation method [9], the post-compressed signal is stretched by an interpolation technique and cross-correlated with the pre-compressed RF signal. The stretching factor is varied iteratively until the cross-correlation coefficient is maximized. The strain image obtained from direct method is superior to that of the gradient based method, but due to multiple stretching and matching, the former one requires significantly greater amount of computation.

In this paper, a novel ratio-based elastography method is proposed where strain is estimated by the ratio of peak frequencies of the pre- and post-compressed signals in the power spectrum density (PSD) domain. The ratio-based method has the advantage of computational efficiency as no temporal stretching and cross-correlation operation are required. The auto-correlation operation of pre- and post-compressed signals for obtaining the PSD reduces noise and increases robustness of the technique. Moreover, an adaptive search window is used to find the corresponding frequency peaks of the pre- and post-compressed signals that further improves the strain estimation accuracy. Simulation results show that the proposed technique produces better strain image as compared to the conventional PRS method.

II. Signal Model

The echo of ultrasound RF signals, as shown in Fig. 1, corresponding to pre- and post-compressed tissue can be modeled as

$$y_1(t) = x_1(t) + v_1(t) = x(t) * p(t) + v_1(t) \quad (1)$$

$$y_2(t) = x_2(t) + v_2(t) = x(t/a) * p(t) + v_2(t) \quad (2)$$

where $x(t)$ is the 1-D scattering function of the elastic target and $p(t)$ is the impulse response of the ultrasonic system [11]. Here, $v_1(t)$ and $v_2(t)$ are uncorrelated noise signal, $y_1(t)$ and $y_2(t)$ are the pre- and post-compression RF echo signals, respectively, and '*' indicates the convolution operation. Here

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

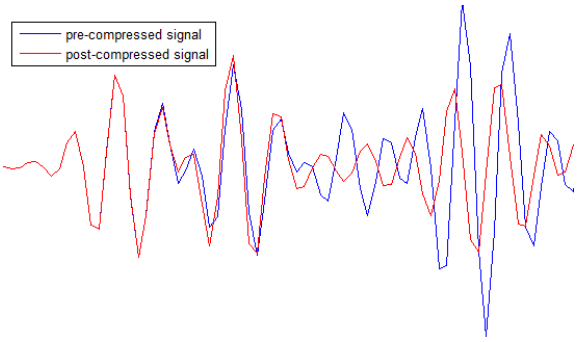

Fig. 1. Pre- and post-compressed signal in the time domain

the post-compressed signal is modeled as scaled version of the pre-compressed signal with compression factor $1/a$. The strain can be estimated as

$$s = 1 - a \tag{3}$$

where $a \leq 1$ and $s \ll 1$. Our objective is to estimate s utilizing the pre- and post-compressed signals $y_1(t)$ and $y_2(t)$.

III. Proposed Peak Frequency Ratio-based Strain Imaging Method

A. Principle of operation

In our proposed method, we estimate strain from the pre- and post-compressed signals in the PSD domain. In order to estimate the PSD, we need autocorrelation operation followed by Discrete Fourier Transform (DFT) of the pre- and post-compressed signals. The auto correlation of the pre-compression RF echo signals can be expressed as

$$r_{y_1y_1}(\tau) = r_{x_1x_1}(\tau) + r_{x_1v_1}(\tau) + r_{v_1x_1}(\tau) + r_{v_1v_1}(\tau) \tag{4}$$

Now auto correlation of pre-compressed elastic target is

$$\begin{aligned} r_{x_1x_1}(\tau) &= x_1(\tau) * x_1(-\tau) \\ &= [x(\tau) * p(\tau)] * [x(-\tau) * p(-\tau)] \\ &= [x(\tau) * x(-\tau)] * [p(\tau) * p(-\tau)] \\ &= r_{xx}(\tau) * r_{pp}(\tau) \end{aligned} \tag{5}$$

Since the pre-compressed signal and the noise are uncorrelated, the cross correlation between these two signals can be approximated to zero. Again, the auto correlation of the noise signal is a delta function. Therefore, equation (4) can be rewritten as

$$r_{y_1y_1}(\tau) = r_{xx}(\tau) * r_{pp}(\tau) + \delta(\tau) \tag{6}$$

Using the Wiener-Khintchine Theorem, the PSD of the pre-compressed RF echo can be expressed as

$$S_{y_1y_1}(\omega) = S_{xx}(\omega)S_{pp}(\omega) + U(\omega) \tag{7}$$

Similarly, the auto correlation and power spectral density of post-compressed RF echo is expressed as

$$r_{y_2y_2}(\tau) = r_{xx}(\tau/a) * r_{pp}(\tau) + \delta(\tau) \tag{8}$$

$$S_{y_2y_2}(\omega) = aS_{xx}(a\omega)S_{pp}(\omega) + U(\omega) \tag{9}$$

Comparing equation (7) and (9), it is seen that the frequencies of the post compressed echo are expanded with the ratio of the inverse of the compression factor. Now, the ratio of peak frequencies of the pre- and post-compressed PDS can estimate the strain distribution of the pathological tissue. The

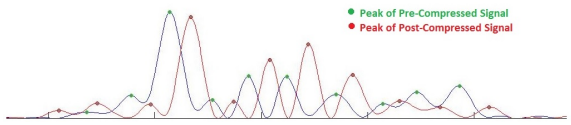

Fig. 2. Peaks of Pre and Post-compressed Signal.

importance of autocorrelation can also be observed from above equations where the noises have become an unit function. As a result, it will have a little effect on peak determination of the pre- and post- compression spectrum.

B. Ratio Estimation

Fig. 2 presents a typical PSD of small segments of pre- and post-compressed signals. The peak frequencies are indicated in the figure. The compression factor can be estimated from the ratio of the adjacent peak frequencies of the pre- and post-compressed signals. In our work, we have estimated the inverse of the compression factor using all the peak frequencies as follows:

$$\hat{a} = \frac{1}{N}\sum_{i=1}^{N}\frac{\omega_{post(i)}}{\omega_{pre(i)}} \tag{10}$$

where N is number of peaks in the PSD of the selected window block. ω_{pre} and ω_{post} represent the frequencies of the peaks of the pre- and post-compressed PSD, respectively. We have calculated the strain from the estimated $\hat{a}$. For better accuracy, only the peaks over a certain threshold magnitude has been chosen to estimate the strain distribution. There are two irregular cases for finding peaks in the pre- and post-compressed signals. In the first case, for one peak in pre-compressed signal, there are more than one peaks in post-compressed signal. Then, the first post-peak is used for corresponding pre-peak. In other case, where more than one pre-peaks are found for one post-peak, last pre peak is used to calculate the ratio.

C. Adaptive Search Window for Finding the Corresponding Peak Frequencies

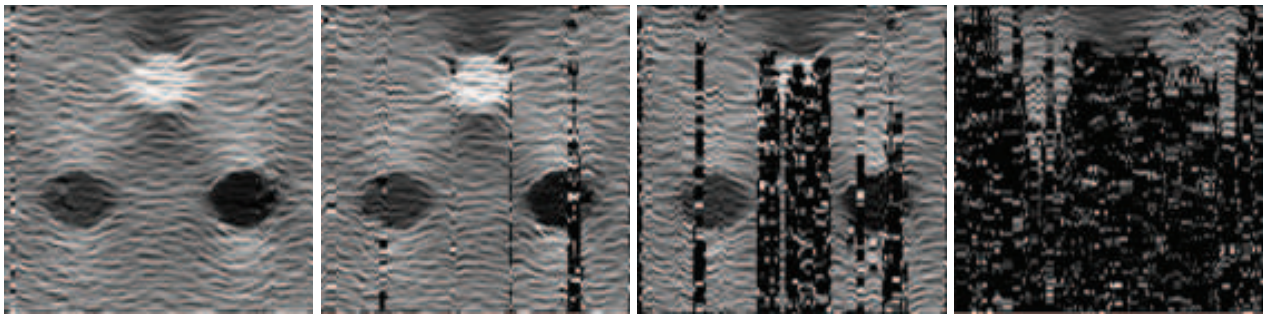
In order to estimate $\hat{a}$ in equation (10), we need to know the corresponding peak frequencies of pre- and post-compressed signals. To find the corresponding expanded peaks of the pre-compressed signal in the post-compressed spectrum, we have to set a frequency range. For example, if pre-peak is in frequency ω_k, then the frequency range to find its post-peak is set as

$$\omega_k \leq \omega \leq \omega_k * a_{rr}. \tag{11}$$

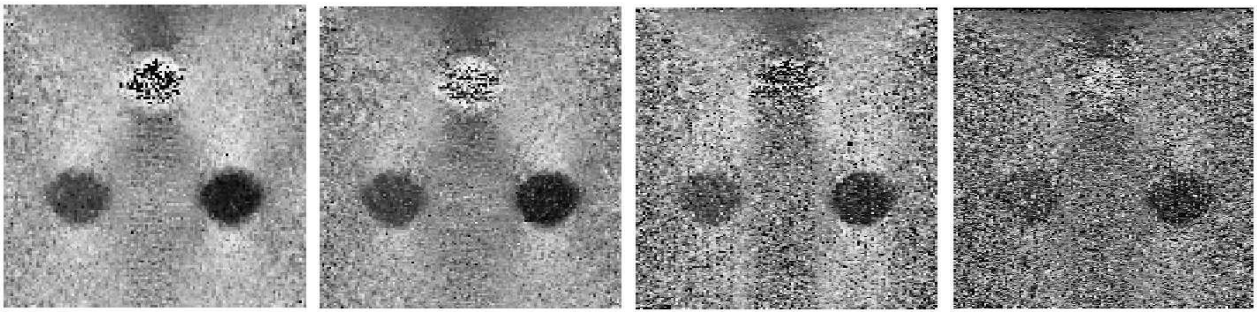
Here, a_{rr} refers to search window range to find the peak. At low strain, a fixed a_{rr} can be used. However, at high strain, the fixed range does not work. We have developed an adaptive algorithm for automatic detection of the search window range as follows:

$$a_{rr(k)} = \frac{1}{3}\sum_{i=0}^{2} a_{rr(k-1-i)} + \left(\frac{a_{rs}}{m} - 1\right). \tag{12}$$

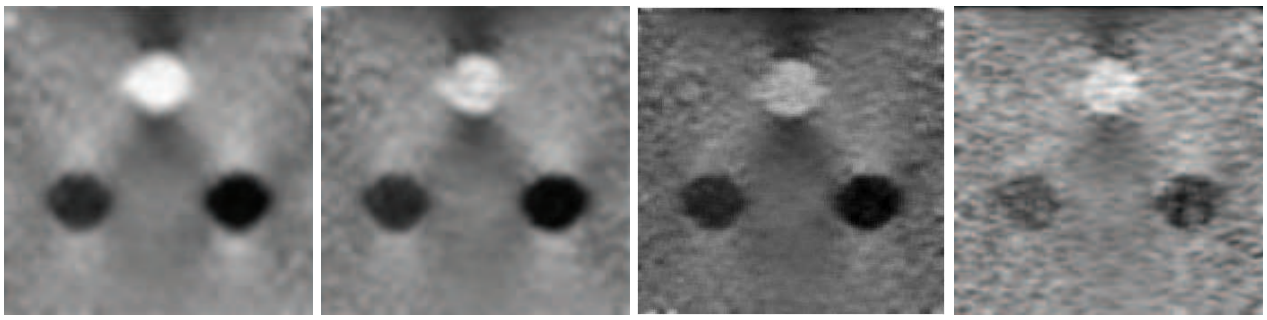
Here, $a_{rr}(k)$ refers to the adaptive range for the kth window block, m is the total number of blocks processed so far and a_{rs} is the sum of estimated ratios of the m blocks. Here, the first part of equation (12) accounts for the variation of range depending on recent estimates of a_{rr} and the second part



(a) Phase Root Seeking



(b) Estimated Strain from Ratio of Peak Frequencies in Fixed Frequency Range



(c) Proposed Peak Frequency Ratio-based Strain Imaging Method

Fig. 3. Strain images of the FEM simulation phantom generated by different methods for 2,3,4 and 6 percent compression.

provides an extra boundary based on the cumulative average value of estimated a_{rr}.

D. High Compression offset for search window range

When the applied deformation is very high, the corresponding post-peaks may go beyond the search window range obtained from equation (12). Therefore, an offset is added to the adaptive search window range, when high compression ratio is detected. By incorporating this offset value, the strain image can be generated for as high as 6% deformation. The modified equation can be simply stated as

$$a_{rr(k)} = \frac{1}{3}\sum_{i=0}^{2}\hat{a}_{k-1-i} + \left(\frac{\hat{a}_{rs}}{m} - 1\right) + HCO \qquad (13)$$

where HCO is the high compression offset. Finally the obtained strain image is smoothed using a Gaussian filter kernel.

IV. Result

In this section, we present simulation results to evaluate the performance of our proposed peak frequency ratio based strain imaging method. We also compare the results with that of the PRS method [7]. A rectangular phantom of dimension $40mm \times 40mm$ was used for the study. The phantom was simulated using finite element model (FEM) simulation software ANSYS (ANSYS, Inc., Canonsburg, PA) and Field II [12]. An ultrasound RF data were generated by Field II simulation program (10 MHz transducer center frequency and 1.5 mm beam width). The total number of samples and scan-lines were 26749 and 128, respectively.

Fig. 3 presents the strain images obtained using our proposed and PRS methods at different applied compressions. The elastograms in Fig. 3(a) are generated by the PRS method. The method works well for low strain, but for higher strain, strain estimation deteriorates significantly. In Fig. 3(b) and (c), strain images are shown for the proposed ratio-based method considering fixed and variable search window, respectively. For fixed search window method, strain estimation has been improved compared to the PRS method, thought the image is quite noisy at higher strain. Fig. 4 explains the reason of this noisy strain image. It is seen that with increasing strain, the frequency distance between pre and post peaks increases. Now if a predetermined fixed search window is used, some post peaks may go beyond the search window, especially at higher strain. As a result, the strain estimation is erroneous and the image gets noisy. The problem is overcome using an

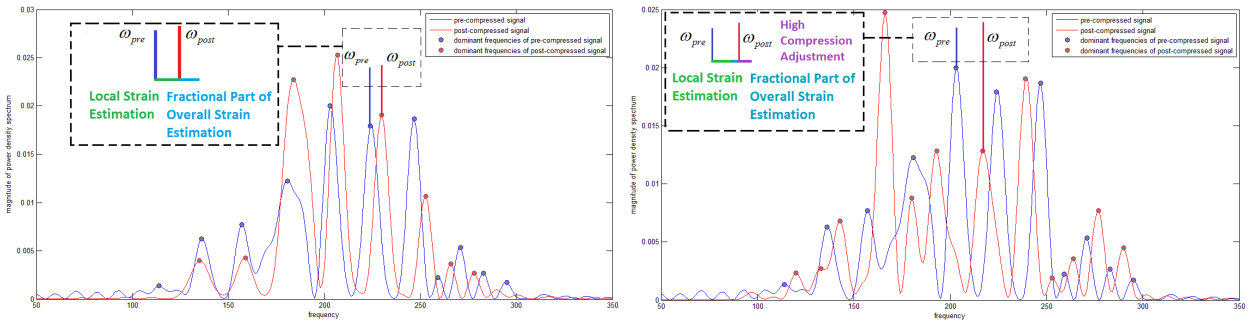


Fig. 4. Power Density Spectrum of a block of data for 2 and 6 %.

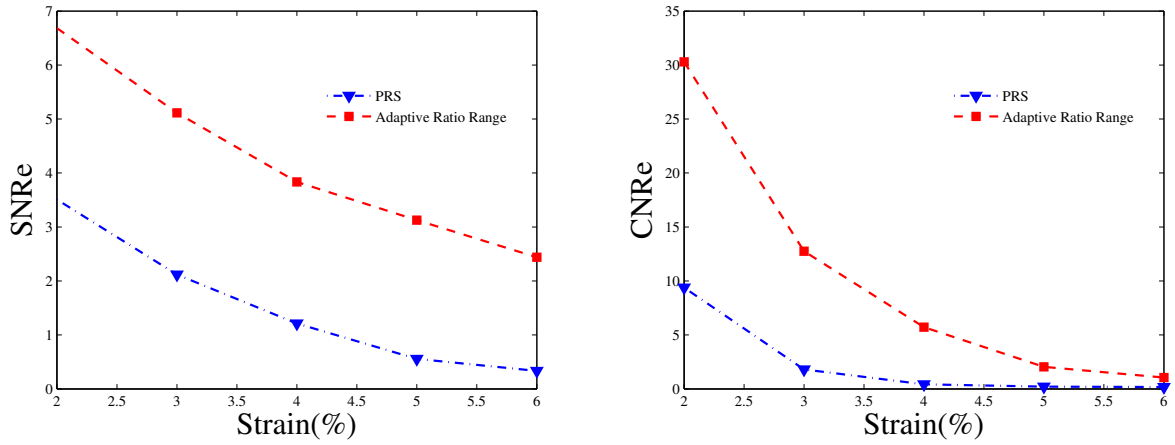

Fig. 5. Performance Comparison of Different Methods using Numerical performance Metrics for FEM simulation Data(a)SNRe vs. Applied Strain (b)CNRe vs. Applied Strain.

adaptive search window along with a high compression offset as shown in Figure 3(c). Now, the strain estimation works quite well for up to 6 % applied strain.

The quantitative performances of the proposed and PRS methods were evaluated by estimating the elastographic signal-to-noise ratio (SNRe)[13] and elastographic contrast-to-noise ratio (CNRe)[14] from the obtained strain images. The results are presented in Fig. 5 for 2% to 6% applied strain. It is observed that the proposed method performs significantly better than the PRS methods in terms of SNRe and CNRe.

V. CONCLUSION

In this paper, a novel algorithm for elastography has been proposed to estimate strain distribution using ratio of dominant frequencies of pre- and post-compressed signals. The technique does not require any cross-correlation and/or temporal stretching operations like any other reported techniques. As a result, it is computationally efficient. Simulation results show that the propose technique provides better strain image compared to the conventional gradient based technique.

Bessel K-Form Parameters in the Dual Tree Complex Wavelet Transform Domain for the Detection of Epilepsy and Seizure

Anindya Bijoy Das* and Mohammed Imamul Hassan Bhuiyan
Department of Electrical and Electronic Engineering(Bangladesh University of Engineering and Technology, Bangladesh)
Email: *anindya149@yahoo.com

***Abstract*—In this paper, a statistical analysis of EEG signals is carried out in the dual tree complex wavelet transform (DT-CWT) domain. It is shown that Bessel k-form(BKF) pdf can suitably model the DT-CWT sub-bands and the BKF parameters in various DT-CWT sub-bands can discriminate various types of EEG data effectively. Next these parameters are utilized by the SVM-based classifiers to classify the EEG data. The classification performance is studied for three clinically relevant cases including healthy vs seizure, non-seizure vs seizure and inter-ictal vs ictal recordings. The proposed method provides 100% accuracy with 100% sensitivity and 100% specificity in all the cases. In addition, in comparison to several state-of-the-art algorithms, the proposed method has also been shown to be computationally fast.**

***Index Terms*—Electroencephalogram(EEG), Seizure, Dual Tree Complex Wavelet Transform(DT-CWT), Bessel K-Form(BKF), Support Vector Machine(SVM).**

I. Introduction

About 1% of the world's population are affected with epilepsy, which is characterized with recurrent seizures [1]. It has serious health implications as well as involve economic loss since it may cause injury, sometimes death and constricts the work capacity of epileptic patients. Traditionally, epilepsy diagnosis for seizure detection is carried out by electroencephalographers, highly trained professionals, who observe long term records, hours to days, even weeks of electroencephalogram(EEG) signals. Obviously, this is an expensive and time-consuming process and may be prone to error due to its subjective nature. Thus, automated detection of seizures from EEG signals can assist the electroencephalographers in this respect by relieving off this laborious job of monitoring EEG signals. In additon, it may provide solutions for therapeutic devices such as the cranially implanted neuro-stimulators, such as Responsive neuro-stimulators(RNS) [2].

Among various algorithms in the literature, the time-frequency-based ones ([3]- [9]) have been shown to be highly promising for automatic detection of seizures. One of the main reasons behind the success of these methods may be the brain dynamics being spread over a number of time-frequency EEG sub-bands [5]. The Dual Tree Complex Wavelet Transform (DT-CWT) has been recently introduced as a highly efficient time-frequency transform having improved directionality, limited redundancy, shift invariance and less computational-complexity [10]- [11]. It is shown in [8] and [9] that the higher order statistical moments in the dual tree complex wavelet transform(DT-CWT) sub-bands can discriminate and classify the EEG data into various classes such as seizure and non-seizure. The higher-order moments can be obtained using the underlying probability density function (pdf) that can model the statistics of the data accurately. The first objective of this paper is to investigate whether the Bessel K-Form (BKF) is a suitable pdf to model the DT-CWT sub-bands of EEG data and to see whether its parameters can discriminate the EEG data. The motivation for using the BKF pdf arises from its ability to model the heavy-tailed statistics of non-linear data effectively [12]- [13]. The second goal is to develop Support Vector Machine (SVM)-based classifiers to effectively classify the EEG signals wherein the BKF parameters extracted from the various DT-CWT sub-bands are utilized as features. The analysis is carried out using a publicly available benchmark EEG database [14], [15]. The performance of the SVM-based classifiers is studied for a number of clinically relevant classification cases and compared to that of several other algorithms available in the EEG literature.

II. Dual Tree Complex Wavelet Transform

In this Section, a brief introduction of the DT-CWT is provided. Traditional Discrete wavelet transform(DWT) offers good time-frequency localization. However, it is not redundant, lacks shift-invariance and gives directional information only in three directions. The undecimated wavelet transform(UWT), albeit shift-invariant, has similar directional information and is computationally expensive. The DT-CWT provides a reasonable solution in this respect. It is shift invariant while being only 2^d times redundant for a d-dimensional signal as of the DWT and offers directional information in six directions, thus being more efficient in time frequency localization of signal features. The DT-CWT has two DWT trees. The first tree represents the real part of the complex coefficients. whereas the second represents the imaginary parts.

Several wavelet functions are available in the literature [10]. In this paper, the Farras wavelets [16] are employed for performing DT-CWT decomposition.Fig. 1 shows the plots of two sample EEG segments for eight seconds from the datasets D (top left) and E (top right) in the first row and the plots of the corresponding first level DT-CWT coefficients in the second and the third row.

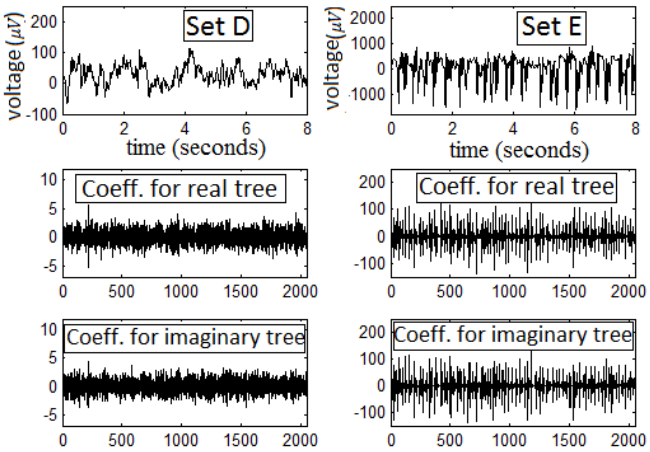

Fig. 1. Sample EEG Signals and the corresponding DT-CWT coefficients

III. Analysis of EEG in DT-CWT domain

The EEG database used in this paper has a considerable volume with the collection of five different types of recordings (Sets A, B, C, D and E) providing the statistical significance of the analysis. The database has been widely used in the EEG literature ([3]- [9]). The sampling frequency of this EEG database is 173.61 Hz, and thus, the highest frequency component is 86.8 Hz. But, the frequency range of an EEG signal spans over 0 to 60 Hz. Thus, the frequencies greater than 60 Hz may be considered as noise [5] and those are removed by using a 6th order Butter-worth filter.

Next, the band-limited signals are subjected to a 4 level DT-CWT decomposition. After four levels of decomposition of a signal **x**(0-60 Hz), the components z4 (0-4 Hz), y4 (4-8 Hz), y3 (8-15 Hz), y2 (15-30 Hz), and y1 (30-60 Hz) are obtained [8]. Reconstructions of these five components using the inverse DT-CWT approximately correspond to the five physiological EEG sub-bands delta, theta, alpha, beta, and gamma respectively [5]. Since, each DT-CWT coefficient has two parts, real and imaginary, the 4-level decomposition yields ten sub-bands in total (five for real and five for imaginary). The DT-CWT coefficients for any sub-band are characterized with higher order statistical moments such as variance, skewness and kurtosis. The dispersion, asymmetry and peakedness of a data-set are well described by these moments. These higher-order moments of the data can be obtained using the under-lying probability density function (pdf) that can model the statistics of the data accurately. Thus, it might be interesting to see whether the parameters of that suitable pdf can be used to differentiate EEG data. In this paper, the Bessel k-form (BKF) pdf is proposed as a suitable prior for modeling the EEG data in the DT-CWT domain. The BKF pdf is unimodal and symmetric around the mode (the mode necessarily not being zero). The BKF pdf is expressed as:

$$f(x) = \frac{1}{\sqrt{\pi}\Gamma(p)} \left(\frac{c}{2}\right)^{-\frac{p}{2}-\frac{1}{4}} \left|\frac{x}{2}\right|^{p-\frac{1}{2}} K_{p-\frac{1}{2}} \left(\sqrt{\frac{2}{c}}|x|\right) \quad (1)$$

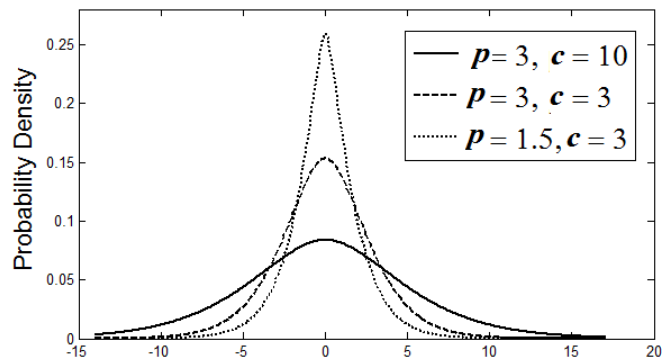

Fig. 2. Changes in shape of the BKF pdf for various values of its parameters

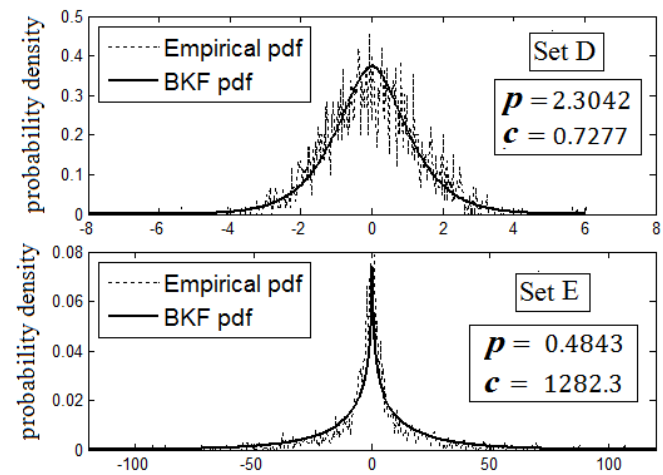

Fig. 3. Plots of the empirical pdf with the BKF pdf for the sub-band (y1,1) of two sample EEG signals along with the values of respective BKF parameters

where K_v is the modified Bessel function of the second kind of order v, and p and c are the BKF parameters where $p, c > 0$. For a BKF pdf, p controls the peakedness of the pdf and c controls the dispersion. Fig. 2 shows the plots of the pdf for various values of the parameters p and c. The values of the parameters p and c are estimated [12] from the different EEG sub-bands using the following equations-

$$p = \frac{3}{kurtosis(x) - 3} \quad (2)$$

$$c = \frac{variance(x)}{p} \quad (3)$$

Fig. 3 shows the plots of the empirical pdfs and the corresponding BKF pdfs of the y1 sub-band (from the real tree) for two sample EEG signals from Set D and Set E. It is seen that the BKF pdfs fit the empirical ones quite well.

For analysis, the parameters p and c are estimated from all the DT-CWT sub-bands of 100 data segments for each of the five sets. Table I provides the corresponding p-values obtained from the ANOVA analysis. Note that, the real and imaginary trees are indicated by tree 1 and 2, respectively. For example, (z4,1) means the z4 sub-band (0-4 Hz) of the real tree or (y3,2) means the y3 sub-band (8-15 Hz) of the imaginary tree.

TABLE I
P-VALUES FOR ANOVA ANALYSIS FOR THE BKF PARAMETERS

Signals	p-values for p	p-values for c
Band-limited	0.2386	0.0014
(y1,1)	0.4609	1.3456e-15
(y1,2)	0.2674	8.6940e-18
(y2,1)	0.5713	1.0294e-30
(y2,2)	0.3521	4.2977e-30
(y3,1)	0.4972	2.0112e-19
(y3,2)	0.4298	2.2076e-19
(y4,1)	0.5132	2.2392e-04
(y4,2)	0.2835	1.6270e-07
(z4,1)	0.8919	2.1929e-05
(z4,2)	0.4678	4.1029e-04

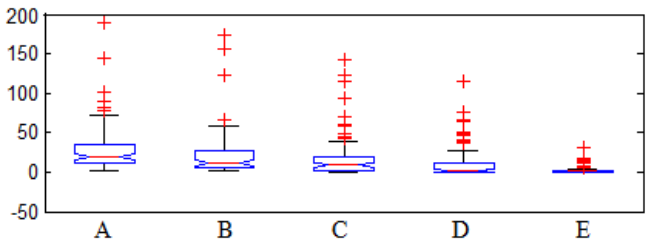

Fig. 4. Box plots for p for the real tree of y1 sub-bands

It is seen from Table I that the p-values for c are smaller than those for p in all the cases which indicates a better discrimination capability of c than p to classify the EEG data into different classes. However, the p-values for the band-limited segments are not significantly small enough to distinguish among the EEG data. Among the box plots, in Fig. 5, there is a more obvious and precise indication than in Fig. 4 for the discrimination of the seizure recordings (Set E) from the non-seizure ones (Sets A,B,C and D) which also confirms the superior discrimination capability of the parameter c over p. Thus, the BKF parameter, c, extracted from the DT-CWT sub-bands may be used as the features in the classifier for discriminating the EEG signals.

IV. THE PROPOSED SVM-BASED CLASSIFICATION

In this Section, the proposed classification procedures are described. In this paper, Support Vector Machine (SVM), proposed by Vapnik [17], is used for classifying various types of EEG signals. It is based on statistical learning theory

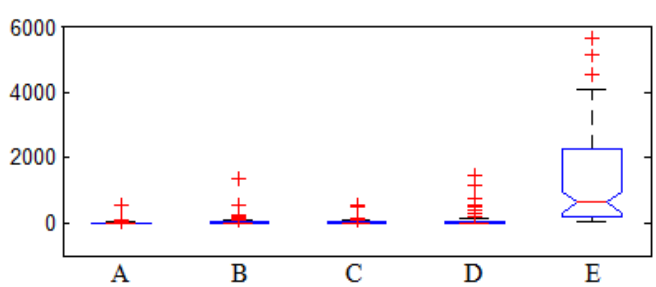

Fig. 5. Box plots for c for the real tree of y1 sub-bands

where the nonlinear separable samples are projected onto a higher dimensional space using kernel functions. Subsequently, the classification is performed by locating the optimal separating hyper-plane in the projected space. The various kernel functions are studied empirically and the radial-basis function(RBF) kernel provides the best result.

In order to perform feature extraction from an EEG record, each data-set is first divided into 16 non-overlapping segments due to the non-stationary nature of EEG data [3]. As there are 100 EEG data-sets from each of the Sets A,B,C,D and E, 500×16=8000 segments are generated in total. After that, the BKF parameter, c is calculated from each of the DT-CWT sub-bands for all the segments. For example, Set E has 100×16=1600 segments, giving 1600×10=16000 sub-bands, thus 16000 values of c are obtained for Set E. Finally, for a particular set, half of the segments chosen randomly are used for training, the rest half for testing in a SVM classifier.

For the five sets of EEG records described earlier, three different cases of classification problems are considered. The cases are chosen based on their clinical relevance and their widely use in various papers in the literature. In Case I, Set A and Set E are classified into the healthy and seizure classes respectively. For Case II, Set D and Set E are classified into the inter-ictal and ictal classes, respectively. It separates the ictal recordings from the inter-ictal ones which is related to the detection of the onset of seizures. In Case III, segments from Sets A, B, C and D are combined together to form the non-seizure class and Set E is classified seizure class.

The performance criteria of the proposed classification method in classifying different types of EEG data are-

$$Sensitivity = \frac{TP}{TP+FN} \times 100\% \tag{4}$$

$$Specificity = \frac{TN}{TN+FP} \times 100\% \tag{5}$$

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \times 100\% \tag{6}$$

where TP, TN, FP and FN stand for true positive, true negative, false positive and false negative events, respectively [3].

The performance of the proposed method is first studied using the features from band-limited (BL) EEG signals only, and a particular DT-CWT sub-band. Table II shows the performance(per) for all the classification cases in terms of sensitivity (sen), specificity (spec) and accuracy (acc) using the BKF parameter c estimated from different sub-bands and band-limited segments. It is seen that in almost all the cases the high frequency sub-bands like y1 or y2 provide better performances than the low frequency ones like y4 or z4. Next, Table III shows the performance for the combinations of features from different sub-bands. It is seen that 100% accuracy is achieved along with 100% sensitivity and 100% specificity for all three cases using features from y1 to z4 sub-bands. As DT-CWT consists of two trees which indicates that for sub-band level, two values of c are obtained. Thus, when $5 \times 2 = 10$ features are utilized, it provides 100% accuracy for

all the cases. However, for Case I, six features from sub-bands y1,y2 and y3 also provide 100% accuracy.

TABLE II
PERFORMANCE FOR VARIOUS CASES USING FEATURES FROM BAND-LIMITED SIGNAL AND A SINGLE SUB-BAND

Cases	Per	Names of the Used Segments					
		BL	y1	y2	y3	y4	z4
Case I A,E	Sen	89.56	91.13	96.81	93.63	86.88	88.13

	Acc	99.3	98.225	96.0250	**100**

TABLE IV
COMPARISON OF CLASSIFICATION PERFORMANCE OBTAINED FOR VARIOUS ALGORITHMS

Cases	Methods	Classifier	No. of Features	Acc(%)
Case I	Tzallas [4], (2007)	ANN	16	100
	Fathima [6], (2011)	Lin. Classifier	3	96.9
	Alam [3], (2013)	ANN	3	100
	Proposed	SVM	6	**100**
Case II	Liang [7], (2010)	SVM	16	98.74
	Alam [3], (2013)	ANN	3	100
	Proposed	SVM	10	**100**
Case III	Tzallas [4], (2007)	ANN	16	97.73
	Liang [7], (2010)	SVM	16	98.51
	Alam [3], (2013)	ANN	3	100
	Proposed	SVM	10	**100**

The performance of the proposed classifier is compared with that of several existing methods in Table IV. Along with providing 100% accuracy, the proposed method is also computationally fast. It is implemented in MATLAB in a desktop computer with a core-to-duo processor of 2.66 GHz and 2 GB RAM. The proposed method requires 0.003∼0.005 seconds to extract features. On the contrary, the method of [3] needs 0.2∼0.6 seconds. The method in [4] requires 3.8∼4.09 seconds to extract features from a 23.6 seconds segment.

V. CONCLUSION

In this paper, EEG signals have been analyzed in the DT-CWT domain and the suitability of using the BKF pdf to model the DT-CWT sub-bands has been explored. It has been shown that the BKF parameters can discriminate the EEG data. SVM-based classifiers have been developed to classify EEG signals using BKF parameters computed from the DT-CWT sub-bands. For three classification cases, the proposed SVM-classifiers have been shown to provide 100% accuracy, sensitivity and specificity. Furthermore, the proposed method is computationally faster in comparison to several state-of-the-art algorithms. However, to confirm the use of the proposed method for clinical applications, experiments with long-term EEG recordings are necessary. It is expected that the proposed classifier would demonstrate similar performance since it employs the underlying statistics of EEG signals in time-frequency domain and thus, the high variability of background and seizure characteristics is avoided.

***Abstract*—In this paper, we propose automated image processing method for mammogram image analysis to enhance the classification of malignant and benign clustered micro calcifications. Mini-Mias, one of the most renowned mammogram dataset, is used for our experiment. Region of interest (ROI) is selected using connected component labeling method. Shape and textural features are computed and used in five different classifiers to validate the correctness of labeling method usage for this specific research. Experimental results show that Random Forest and Bagging classifier can produce best classification accuracy among them. We used Receiver operating characteristic (ROC) analysis to asses and differentiate the classification performance from different methods. Random Forest and Bagging, both classifiers provide more than 99% accuracy.**

***Index Terms*—Connected Component Labeling, Breast Cancer Detection, Mammogram Analysis, Image Processing**

I. Introduction

Breast cancer is one of the prevalent diseases observed among the women and the incident rate is in upward trend in recent years. There are several ways to identify breast cancer using the images from the radiologists. According to the physicians and past researchers, mammography is the most effective technique to detect this cancer at early stage. There are some research on this issue focusing on CAD (Computer Aided Diagnosis), mammogram, ultrasound and MRI (Magnetic Resonance Imaging) and clinical prototypes are built as well to improve the diagnostic performance. In this paper, we extract region of interest from Mini-Mias database and compute several features to use as feature vector for classifiers. In our approach, we apply connected component labeling to find the ROI from each mammogram and construct a feature extractor to collect features from them.

The following is a brief analysis of other contemporary research on classification of micro calcification from mammograms. Solka et al. [1] emphasized on the high dimensional features through two techniques, namely, dimensionality reduction and discriminant analysis. They used different version of contrast, smoothness, edge strength, gradient, moment, compactness, shape, and average grey level moment as features for the breast images. Later they performed Fisher Linear Discriminant (FLD) and Principal Component Analysis (PCA) to reduce dimensionality and followed Bayesian approach for classification. They show that FLD performs better than PCA while classification. Hung et al. [2] mentioned neural network to diagnose breast cancer in more depth using resampling techniques like bootstrap.They focus on building an integrative approach to build neural network models to resolve the issues of model selection, feature selection and function approximation. Their goal was to produce more accurate classification for posterior probabilities. Giger et al. [3] explained the necessity of the CAD technologies for determining the cancer indication. She mentioned three techniques, MRI, Mammography and Ultrasound and explained the comparison among them in brief. Their observation concludes that Mammogram data analysis provides better indication about the cancer detection method. Haddadnia et al. [4] used both statistical and thermal features to diagnose the breast cancer from medical infrared images. They calculated mean, variance, skewness, kurtosis and entropy to form a combinatorial model with the help of artificial neural network and genetic algorithm. It was mentioned that thermal pattern and kurtosis are the main parameters for diagnosing breast cancer form medical imaging.

Hassanien et al. [5] showed various machine intelligence techniques to diagnose breast cancer from medical images. They used type-II fuzzy algorithm to improve the quality of MRI images and then performed segmentation using pulse coupled neural networks to extract region of interests. Finally, wavelet transformation was performed on those regions to get the original information to process via support vector machine and decide whether they represent cancer or not. Huang et al. [6] used vessel analysis in 3D power doppler ultrasound images of 113 solid breast masses. Vessel analysis estimates the difference between blood vessels of tumor and non tumor areas. Six features including volume of vessels, vascularity index in normal tissue, and vascularity index in surrounding region of the tumor within 2 cm were measured; later neural network was applied to classify the tumors. The receiver operating characteristic (ROC) curve analysis was used to evaluate the performance. Lee et al. [7] proposed an efficient classifier with feature selection based on fuzzy entropy for pattern classification which was formulated from Shanon entropy.They performed their experiment in Iris and Wisconsin Breast Cancer Diagnostic Database(WBCDB).

The rest of the paper is organized as follows: A brief

discussion on region of interest (ROI) selection method, mathematical formulation, and description on connected component technique and its application in our research is presented in section II. Performance evaluation and results are discussed in section IV. Finally, section V concludes and suggests future direction of our research.

Fig. 1. (a) Raw X-ray mammogram from MiniMias Dataset (image number mdb029.pgm). (b) Generalized marking of the objects detected by the connected component labeling algorithm.

II. ROI Selection Using Connected Component

In this paper, the mammogram image [8] classification is separated in two groups with seven classes, i.e., an image can be either clustered with micro-calcification or not. These two classes are known as malignant and benign by the radiologists. It is not obvious that a breast tissue with malignant micro-calcification is sure to have some cancer in it.

The first step is to preprocess the mammogram images which is the raw image data from the X-ray machine. The image contains additional data(mammogram date, difference in background and foreground due to the imbalance of the light rays, shade, spots etc.) that can be put aside while detecting the lesion grand. But the question comes how computers can ignore these noise? To begin, let vector $x_i^j \subset R^N$ denote the set of points for different objects within an image. In addition, i and j refers number of objects and pixel values within each objects those are not null and have distance less or equal to some predefined threshold.

$$x_i^j = \{1, \ldots, j\} \tag{1}$$

Most of the previous work was performed with the help of image cropping using tools like Adobe Photoshop that can invalidate useful pixel values while conversion from one format to another. Thus, we avoid using those methods to resize the image. In general, it is evident from the mammogram images that the largest area covered must preserve the breast gland. So, our aim is to look for the available objects within the image first, which makes the problem into an object detection problem. If we look into Fig.1 (b), it is noticeable that the yellow marks are showing different smaller objects within the image area. White letters within the textual part are treated individually while leaving them out in the preprocessing step, but it is shown in a group for the simplicity. Additionally, the images are considered to be black and white for this experiment.

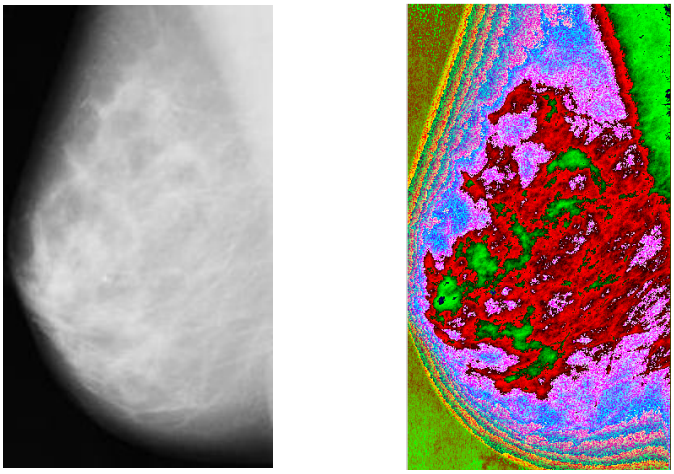
Mammograms are taken from different angles to ensure that no area from the tissue is being abandoned, later the X-ray film is examined by specialists for further verification. Now, our aim is to simulate the specialists verification knowledge through CAD (Computer Aided Diagnosis) systems.

Before going in detail, first we should know what connected sets determine? Mathematically, A region $R \subset S$ is defined as connected under $c(s)$ if for all $s, r \in R$, there exists a sequence of M pixels, $s_1, \ldots, s_M$ such that $s_1 \in c(s), s_2 \in c(s_1), \ldots, s_M \in c(s_{M-1}), r \in c(s_M)$. Which mean there must be a connected path from s to r. Now, as we are concerned about grayscale image which has values between 0 to 255 in each pixel, we can start from any pixel which has value 0 (black pixel treated as background) and start to grow each connected set. Additionally, we chose the neighborhood system to select the nearest pixels for region growing purpose. Usually, there are two neighborhood systems, i.e., 4-point neighborhood and 8-point neighborhood method denoted as N_4 and N_8 respectively.[9]

	N	
W	S_0	E
	S	

NW	N	NE
W	S_1	E
SW	S	SE

Fig. 2. Demonstration of neighborhoods of a pixel. S_0 is at the center when 4-point neighborhood is considered. S_1 is the central pixel surrounded by eight neighboring pixels. The four neighborhood of $N_4(x, y)$ of pixel (x, y) is surrounded with pixels $(x-1, y), (x+1, y), (x, y+1), (x, y-1)$. Similarly, $N_8(x, y)$ of pixel (x, y) includes with neighboring pixels of $(x-1, y), (x-1, y+1), (x-1, y-1), (x+1, y), (x+1, y+1), (x+1, y-1), (x, y+1), (x, y-1)$. N,E,W,S and other four derived values denotes the side of the center pixel.



(a) (b)

Fig. 3. (a) Cropped image without removing any pixel information from the region of interest. (b) Colormap applied for better visualization of abnormal tissue image in the ROI.

8-points neighborhood pixel method is suitable for use in RGB images where objects have different combination of colors and the pixels values vary too much in general. On the contrary, gray scale images can have only values between 0 to 255 and most dominant colors are black and white, thus the difference between white and black sectors are very much prevalent to distinguish. As a result 4-point neighborhood method works well to determine the connected objects with

ease, but there is some relation with the threshold value which has to be checked each time the region is grown [10] from the source S_0 (Fig.2). Now we can formulate that the connected set, $c(s) = \{r \in \delta_s : |S_r - P_s| < Th\}$, where, r is the pixel position to be tested, δ_s is the set of neighboring pixels, $S_r - P_s$ refers to the distance between pixel r and each neighbors, and Th is the threshold value that can not be crossed. However, two or more objects may overlap in some scenarios, which can be difficult to differentiate for gray scale images compared to RGB ones. Connected component algorithm can well identify the presence of the overlapping objects by computing the intensities of the color level, but it is not easy in our case as the black color is considered to be the background and the only important values for pixels are those which are non zero values.

III. Description of Mammogram Dataset and Feature Selection

A. Mammogram Data Set

We performed our experiment using a dataset prepared by the Department of Physics at the Royal Marsden Hospital of London, UK and it is popular by its name Mini-Mias mammogram repository [11]. The data contains 322 images of 161 patients, each one having left and right mammograms. All the images size were adjusted by padding zeroes (black background) to make 1024×1024 pixels. Each image is accompanied with some predefined information, i.e., center of the image, radius, coordinate start location etc. It was also mentioned whether calcification is present centrally or in a scattered manner. Normal and benign classes are mentioned along with other six abnormality types. The origin of the abnormality is provided with their axis values and the radius of the calcification spread. For example, the calcification origin is at (500,200) and the radius is given as 312, which means the abnormality is approximately spread around the point (500,200) with the radius of 312 pixel units.

B. Feature Extraction and Processing

For automated classification, we used total ten features of both shape and texture category and saved in a vector. For example, if an image, A has radius, r and center, c as features, then the feature vector of image A is $V(A) =< r, c >$. The features extracted from the processed mammograms are variance, standard deviation, median, mode, average gray scale value, average contrast, smoothness, skewness, uniformity, and entropy. The first four features are statistical measures and the latter six are texture features. Average gray-scale value is computed from the first moment which gives the idea about the distribution of the gray-level pixels. Average contrast is measured by the standard deviation σ, which is the square root of the second moment. Smoothness [12] provides the approximating function to capture significant patterns from the pixel data by removing the noise. We used the below equation for smoothing purpose.

$$R = 1 - \frac{1}{1 + \sigma^2} \tag{2}$$

Skewness can be positive, negative or both to quantify the bias of the random variable (here pixel) from the ideal viewpoint.[13] It is measured using the third moment. Equation 3 shows the correspondence among third central moment (μ_3), mean (μ), standard deviation (σ), and the expectation operator (E).

$$\gamma_1 = E\left[\left(\frac{X-\mu}{\sigma}\right)^3\right] = \frac{\mu_3}{\sigma^3} = \frac{E[(X-\mu)^3]}{(E[(X-\mu)^2])^{3/2}} \tag{3}$$

Uniformity of the mammogram measures the sum of the squared relative frequencies p_i of the gray-scale values and it is maximum when image remain constant. Entropy E measures the predictability using Equation 4.

$$E = p_i \log_2 p_i \tag{4}$$

We masked [14] the original mammograms after processing them using connected component algorithm in order to compute these features for further classification. As discussed in the next section, several classifiers were run to identify the classification accuracy parameters using the feature vector.

IV. Evaluation

Statistical and texture features were extracted from the Mini-Mias dataset using Matlab programs. Microcalcification detection was performed using decision tree, bagging, decision table, and locally weighted learning classifier available in the Weka Machine Learning Algorithms Toolkit [15]. This experiment was evaluated using 10-fold cross validation for the classifiers to split the input feature vector into both training and testing set.

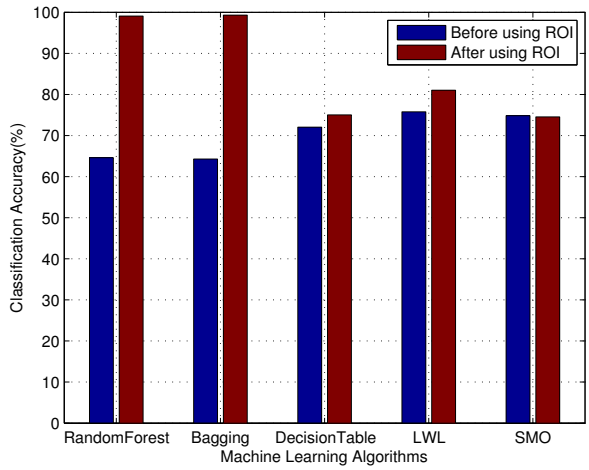


Fig. 4. Classification accuracy and type of the algorithms used with the data vectors extracted from the processed mammograms. Random Forest and Bagging provides similar accuracy both before and after the usage of labeling.

A. Results and Discussion

Classifiers were tested with several configuration using the dataset containing 322 samples from the MiniMias. Experimental result shows that Bagging [16] and Random Forest [17] classifier provides the maximum accuracy (Fig. 4) among the chosen five algorithms. Random Forest is of type decision tree classifier, which uses multiple decision trees at the training time and the mode class among them becomes the desired output class (99.06% accuracy). Random forest of 10 trees, each constructed while considering 5 random features and the out of bag error was 0.3571. Bagging was used with 100% bag size, J48 pruned tree, and seed value of 1.00. It provides 99.37%

TABLE I. TP (True Positive), FP (False Positive) and ROC (Receiver Operating Curve) values shows strong class label detection. (Sample shown for Bagging classifier)

TP Rate	FP Rate	ROC Area	Class
1.00	0.00	1.00	CIRC
1.00	0.017	1.00	NORM
0.929	0.00	1.00	MISC
1.00	0.00	1.00	ASYM
1.00	0.00	1.00	ARCH
1.00	0.00	1.00	SPIC
0.96	0.00	1.00	CALC
0.994	0.011	1.00	Weighted Avg.

accuracy for the classification. Particularly, Bagging classifier reduces the variance among the output class using sampling with replacement. Locally weighted learning (LWL) algorithm used decision stump as classifier, Linear nearest neighbor as neighbor search algorithm, and the value for KNN weighted function as 1 to select all the neighboring values (80.43% accuracy). Decision table majority classifier used leave-one-out cross validation method, forward best first search, and RMSE (Root mean squared error) as evaluation measure. SMO (Sequential Minimal Optimization) used Polykernel as kernel function along with 0.001 as tolerance parameter and provided 74.53% accuracy.

Table I shows the ROC (Receiver operating characteristics) [18], TP (True positive), and FP (False positive) values for each of the classes for Bagging classifier. The weighted ROC value is 1.00, which means the maximum accurate performance is achieved with this classification. TP rate and FP rate helps perceive the misclassification error rate of the classifier. For example, let there are two classes of A, B and TP rate of 0.8 and 0.9 respectively (FP rate is 0.2 and 0.1 as it is the complement of TP rate). So, it means 80% of class A data is picked as class A and the rest 20% is misclassified as class B. Thus, higher value of TP rate for a particular class defines higher classification accuracy. (TP and FP rate ranges between 0 and 1)

On the other hand, we can notice significant improvement of classification accuracy for both Random Forest and Bagging classifier when compared with non-connected component labelled mammograms. One of the major reason for this improvement is normalizing the frequency distribution of the pixels, which is ensured by the labeling operation. Additionally, all the four classifier provides better result than before, except SMO which shows a bit less. SMO uses Support vector machine (SVM), which is best known for classification of noisy data of two class. In our experiment, six classes were present and there were some overlapping of feaures of different classes that can make the classification task confusing for SVM.

Table I shows seven different class labels provided in the dataset, which can further be narrowed down to two class problem (Normal and Abnormal) [19]. These six other classes, except normal category, defines different type of malignant tissue growth within breast gland.

V. Conclusions

Using regression model and decision tree can enhance the classification accuracy in great detail, compared to other algorithms for this specific mammogram classification research. However, our major goal was to augment the mammography image processing to collect the desired region from them, which in the end helps exposing the abnormality or severity of breast cancer via computer aided applications. Thus, we had to go through the classification process as well to prove that the detection accuracy improves if our ROI selection method is followed. This experiment was performed using 10-fold cross validation with labeled dataset.We will use larger dataset and narrow down the seven class problem into two class classification problem using layered architecture in our future research. The first layer will separate the seven classes. The second class will leave *Normal* category intact and run the classification on the rest six classes. We will use our method on separate testing and training data as well, which can surely help diagnose early stage cancer identification.

***Abstract*—In this paper, an efficient scheme is proposed for classification of electroencephalogram (EEG) data in to different motor imagery (MI) tasks based on empirical mode decomposition (EMD). The EEG data recorded from each channel is first decomposed into a set of intrinsic mode functions (IMFs) by using the EMD analysis. In view of extracting discriminative information from the EEG signals corresponding to different MI tasks, we propose to utilize the entropy of band-limited IMF. Instead of considering all IMFs or first few IMFs, in the proposed method only the first IMF is chosen because of its low variance. In order to reduce the dimension of the feature vector consisting of entropy values from all channels, principal component analysis is performed. For the purpose of classification, train and test datasets are formed as per leave one out cross validation scheme and then linear discriminant analysis (LDA) is carried out. Simulation is performed on publicly available MI dataset IVa of BCI Competition-III to classify the MI data in to two classes, namely right hand and right foot MI tasks. It is observed that the proposed classification scheme not only offers significant reduction in feature dimensionality but also provides satisfactory classification accuracy.**

I. Introduction

Electroencephalography (EEG) has become the most popular and widely studied non-invasive brain-computer interface (BCI) due to its excellent temporal resolution, usability and low setup costs. EEG-based BCIs use electrical brain activity in assisting, augmenting, and repairing human cognitive functions. The greatest challenge in BCI systems is to correctly and efficiently identify different EEG signals of different motor imagery (MI) tasks. Recently, MI EEG signal classification has received much attention by several researchers [1]-[4]. With the ease of availability of high quality low cost EEG leads, one major concern now-a-days is the huge amount of data to be handled in case of multi-lead EEG signal analysis. Different spatial filters can be used for EEG channel reduction, where a major drawback is the manual selection of regularized parameter. For example, sparse spatial filter optimization method, introduced in [1], can offer EEG channel reduction at the expense of manual parameter selection. Similarly, the regularized common spatial pattern (CSP) algorithm, reported in [2], involves two regularization parameters which are not selected optimally. Four different approaches for MI task classification using EEG signals are proposed in [3] based on CSP which itself is very sensitive to noise and often over fits with small training sets. The regularization and aggregation techniques introduced in [4] solve the parameter determination problem by cross-validation method but only in a small sample setting. In [5], least squares support vector machine (LS-SVM) based clustering technique is proposed for feature extraction but the parameters are not selected optimally. Although a high level of cross validation accuracy is reported in this method, a prior knowledge on the class labels is assumed to be available during cross-correlation based feature extraction. Considering the non-stationary nature of EEG signal, empirical mode decomposition (EMD) is also applied for EEG analysis in different applications [6]-[8]. Recently in [8], the potential of EMD analysis in MI data handling is discussed with a note that relevant features must be carefully selected for getting better accuracy.

The objective of this paper is to develop a robust classification scheme based on EMD analysis of the EEG signal corresponding to different MI tasks. The EMD operation is first performed on EEG data of each channel to obtain a set of intrinsic mode functions (IMFs). Next, the entropy of band pass filtered first IMF of each channel data is computed and a feature vector is formed. Because of a large number of channels, the feature dimension becomes large and thus PCA based dimension reduction is performed. Finally, linear discriminant analysis is carried out for classifying the EEG data into two MI tasks. Performance of the proposed method is validated by using a publicly available MI EEG dataset IVa [9]-[10] of BCI Competition III.

II. Data Acquisition

In this paper, most widely used publicly available EEG dataset IVa of BCI Competition III is considered for the purpose of classification [9]-[10]. This dataset was recorded from five healthy subjects labeled aa, al, av, aw, and ay. In this dataset, EEG signals from 118 electrodes were collected based on the international 10/20 system. There were 280 trials for each subject, namely 140 trials for each task per subject. During the each trial, each subject was required to perform either of the two (right hand and right foot for IVa) MI tasks for 3.5 seconds. The down-sampled data at 100 Hz is generally used although the original sampling rate was 1000 Hz. Duration of the recording of the MI task is 3.5 seconds.

III. Proposed Method

A. Empirical Mode Decomposition (EMD)

The EMD is a time-frequency analysis tool for nonlinear and nonstationary signals [6]-[7]. It is a fully data driven technique

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

with which any complicated data set can be decomposed into a finite and often small number of intrinsic mode functions (IMF). A function is considered to be an IMF if it satisfies two conditions; first, in the whole data set, the number of local extrema and that of zero crossings must be equal to each other or different by at most one and second, at any point, the mean value of the envelope defined by the local maxima and that defined by the local minima should be zero. The systematic approach to decompose the data $x[n]$ into IMFs, known as the "sifting" process, can be briefly summarized as follows [7]:

- Identify all local extrema of the signal. Next, interpolate maxima to define an upper envelope E_U and interpolate minima to define a lower envelope E_L. Set $h_1[n] = x[n] - m_1$; $m_1 = \{E_L[n] + E_U[n]\}/2$.
- Iterate on h_1 until a stopping criterion is satisfied. Upon stopping one has an IMF C_1. The extraction of subsequent IMFs works by iterating on $r_1 = x - C_1$ and so on until an outer loop stopping criterion is satisfied. The result is $x[n] = C_1 + C_2 + \ldots\ldots + C_N + r_N$.
- Let after w cycles of operation, $h_w[n] = h_{w-1}[n] - m_w$ becomes an IMF. Repeating the above process for L times, L no. of IMFs is obtained along with the final residue $r_L[t]$. A popular stopping criteria for the sifting process is to have the value of standard difference (SD) within a threshold as:

$$SD = \sum_{n=1}^{N} \frac{\left|h_{w-1}[n] - h_w[n]\right|^2}{h_w[n]^2}, \qquad (1)$$

where w and $w-1$ are index terms indicating two consecutive sifting processes. Thus the decomposition process is stopped since $r_L[n]$ becomes a monotonic function from which no more IMF can be extracted. To this end, for L level of decomposition, $x[n]$ can be reconstructed as

$$x[n] = \sum_{k=1}^{L} c_k[n] + r_L[n] \qquad (2)$$

Here $c_1, c_2, \ldots, c_L$ represent the IMFs. In this work, EEG data of each channel is decomposed into 8 IMFs.

For the purpose of feature extraction, it would be very difficult to consider all IMFs, which will not only increase the computational burden but also reduce the feature consistency. In many cases, first few IMFs are chosen. However, in this paper, it is decided to consider only one of the eight IMFs. For the purpose of analysis, first, the variance of the IMF data pattern is measured. In Fig. 1(a), the variance of the first and second IMFs are plotted for different trials considering a fixed channel (chammel no. 1). In a similar way in Fig. 1(b), the variance of the first and second IMFs are plotted for different channels considering a fixed trial (trial no. 1). In Fig. 1(c), variation of energy over different trials for a fixed channel is shown for the first three IMFs. It can be clearly observed that the variance of the first IMF is is lower in most of the cases in comparison to that of the second IMF and its energy is also comparatively lower. Hence, in the proposed method only the first IMF is considered for feature extraction.

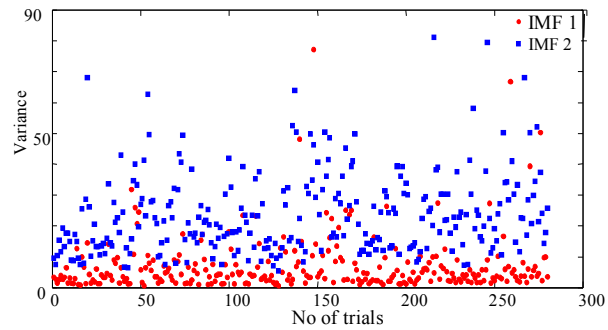

Fig. 1(a). Variance of the first and second IMFs over different trials for a fixed channel.

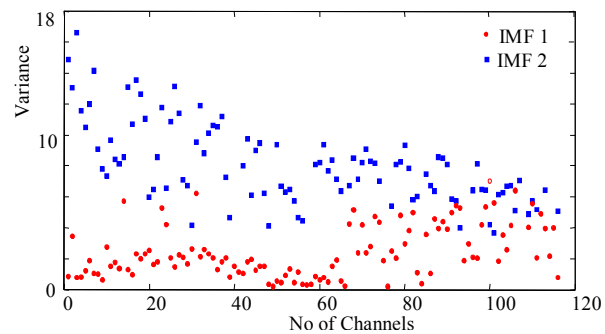

Fig. 1(b). Variance of the first and second IMFs over different channels for a fixed trial.

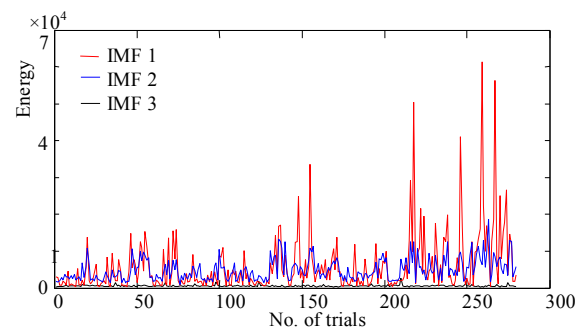

Fig 1(c). Variation of energy over different trials for fixed channel for first three IMFs.

Next the frequency content of the first IMF is investigated. In low frequency region, it is very difficult to discriminate the data for two different MI tasks. Alternatively, it is expected to find more distinguishable characteristics in the high frequency region for the first IMF. It is to be mentioned that such a scenario may not be true for other IMFs. Hence, the first IMF is band limited using a high pass filter. The frequency spectra of a sample first IMF is shown without and with band limitation in Figs. 2(a) and 2(b), respectively. It is observed that the spectra exhibit more distinguishable information in the high frequency range as expected.

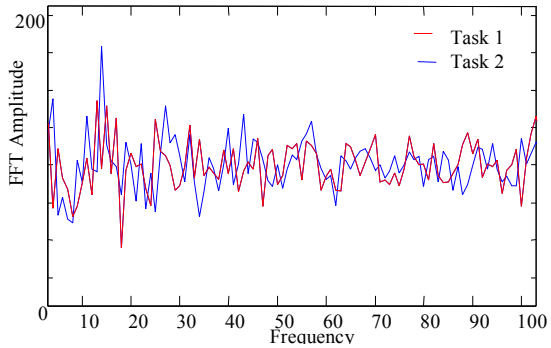

Fig. 2(a). Frequency spectra corresponding to the first IMF of two tasks without using band limiting operation.

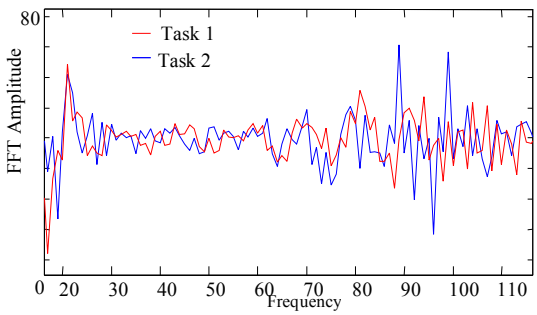

Fig. 2(b). Frequency spectra corresponding to the first IMF of two tasks after band limiting operation.

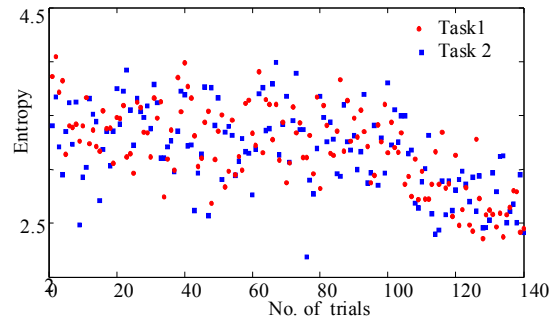

Fig 3(a). Variation of entropy values over different trials for fixed channel (channel 1).

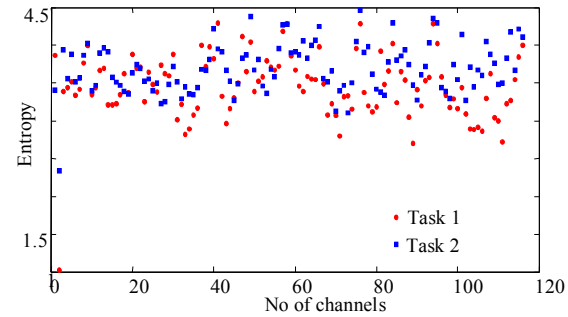

Fig 3(b). Variation of entropy values over different channels for fixed trial (trial 1).

B. Proposed Feature: Entropy of Band-limited IMF

Entropy of a discrete random variable X with (N+1) number of possible values $\{x_0, x_1, x_2, \ldots, x_N\}$ is defined as

$$H(X) = E(I(X)), \tag{3}$$

where $E(.)$ denotes the expectation operator and $I(X)$ represents the information content. For a particular value x_i of X, the information content can be expressed as

$$I(X) = -\log_2(p(x_i)), \tag{4}$$

where $p(x_i)$ denotes the probability of occurrence of x_i. Using (4), the entropy in (3) can be rewritten as

$$H(X) = -\sum_{i=0}^{N} p(x_i) \times \log_2(p(x_i)). \tag{5}$$

Here $p(x_i)=n_i/N$ and where n_i is the number of occurrence of coefficients in a bin in proximity of x_i value among the N number of values, i.e. $\sum_i n_i=N$. In the proposed method, entropy of the band limited first IMF is considered as feature. In Fig. 3(a), variation of entropy values over different trials for a fixed channel (channel no. 1) is shown. Next in Fig. 3(b), variation of entropy values over different channels for a fixed trial (trial no. 1) is presented. From these figures, it is difficult to comment on the quality of the extracted feature. In order to improve the feature quality, instead of considering the entire duration of an IMF in entropy calculation, we propose to compute entropy in a small duration. The band limited first IMF is windowed into 10 overlapping frames with 50% overlap and the entropy is calculated in each window. An average value of entropy over then frames is considered as a desired feature. It is observed that instead of computing entropy once on the whole duration, computing it in all small windows and then considering the average value significantly enhances the feature quality. Entropy values obtained from all the channels are used to form the desired feature vector.

C. Dimensionality Reduction Using PCA

As in the feature vector, entropy values from all channel are considered, the feature dimension becomes large. Next, principal component analysis (PCA) is carried on to reduce the feature dimension. The PCA is a very well-known and efficient orthogonal linear transformation [11]. It transforms the original p-dimensional feature vector into the L-dimensional linear subspace spanned by the leading eigenvectors of the covariance matrix of feature vector in each cluster ($L<p$). PCA is theoretically the optimum transform for given data in the least square sense. For a data matrix $\mathbf{X}^T$ with zero empirical mean, PCA transformation is given by

$$\mathbf{Y}^T=\mathbf{X}^T\mathbf{W}=\mathbf{V}\mathbf{\Sigma}^T \tag{6}$$

where the matrix $\mathbf{\Sigma}$ is a $m\times n$ diagonal matrix with nonnegative real numbers on the diagonal and $\mathbf{W}\mathbf{\Sigma}\mathbf{V}^T$ is the singular value decomposition of $\mathbf{X}$. Implementation of PCA on the derived feature space not only reduces the feature dimension it also helps in obtaining better feature characteristics. In order to demonstrate the effectiveness of using the PCA, feature values corresponding to two tasks obtained after performing the PCA are shown in Fig. 4. It can be observed that the proposed features after performing PCA exhibit better separability between the two tasks.

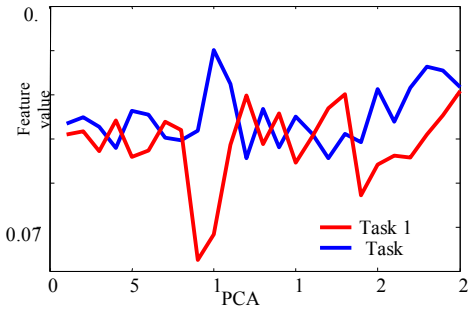

Fig 4. Comparison of feature values obtained after PCA.

D. Classification

In the proposed method, linear discriminant analysis (LDA) is used to classify the testing EEG signals among two different classes (tasks). In LDA, the objective function is based on determining a projection direction **w** to maximize the Fisher's discriminant defined as

$$J(\mathbf{w}) = \frac{\mathbf{w}^T \mathbf{S}_b \mathbf{w}}{\mathbf{w}^T \mathbf{S}_w \mathbf{w}} \tag{7}$$

where $\mathbf{S}_w$ and $\mathbf{S}_b$ are within- and between-class scatter matrices, respectively [12]. Classification performance is measured using leave-one-out cross validation where the test is performed for all 280 datasets (both training and testing) for each subject.

IV. Simulation Results

For the purpose of testing with MI EEg data, sample values are first imported into EEGLAB GUI [13]. A reference electrode TP10 is chosen during data import. Without a reference electrode, it is possible that minimum level of 40 dB noise is accumulated in channel information [13], [14]. Typical references in the EEG recording are TP10, Cz or channel on the nose tip. EEGLAB is also used to separate frames of two classes from a jumbled dataset. In the band limiting operation on the first IMF, high frequency band is selected as 70-120 Hz. After PCA the feature dimension is reduced to 20. Finally, features obtained after PCA is used in the LDA to classify the two tasks via leave one out cross validation. Accuracy is measured based on the correctly identified number of trials among all 280 trials. In Table I, comparative results of the classification accuracy are presented for dataset IVa for the five subjects as well as the overall mean accuracy [1], [14]. It is clearly observed that the performance of the proposed method is significantly better in cases of subject av and aw, which is very promising in subject specific applications. However, the performance in case of subject al is relatively poor and needs further investigation. Overall the proposed methodology provides competitive average classification accuracy compared to all the reported algorithms.

V. Conclusion

A simple but efficient MI classification scheme is developed based on EMD analysis. It is found that use of only the first IMF can provide satisfactory classification performance when entropy of the band-limited IMF is considered as the feature. Because of considering only the entropy value of the selected IMF, the feature dimension is drastically reduced. Moreover, use of PCA provides further control on feature dimension reduction as well as significant improvement in the derived feature quality. Because of the quality of the extracted features, even simple LDA based classifier can provide satisfactory classification performance. It is observed that the proposed entropy based method offers a very satisfactory classification performance for all subjects in comparison to some of the existing methods.

TABLE I. PERFORMANCE COMPARISON OF DIFFERENT METHODS

Method	**Classification Accuracy (%)**					
	aa	**al**	**av**	**aw**	**ay**	***Average***

***Abstract*—This paper features the spatial characteristics of the brain towards brain-computer interface (BCI) research. A study on motor imagery (MI) based BCI has been carried out and important implications are identified. Common Spatial Pattern (CSP) is applied to the EEG signals before proceeding to the classification. The primary focus of this research is to utilize the spatial dynamics of the brain to develop BCI with reduced number of electrodes which contribute to the motor imagery tasks with optimal impact. It is observed that computational cost can be reduced drastically by selecting channels from specific regions of interests (ROIs) of the brain without compromising the classification accuracy making BCI efficient. Here, we have reported the best classification accuracies 72.5% and 97.1% which are achieved for two subjects ('av' and 'ay', respectively, in the dataset IVa in the BCI competition III) using less number of electrodes.**

***Index Terms*—Brain Computer Interface (BCI), Motor Imagery (MI), Electroencephalogram (EEG), Common Spatial Pattern (CSP), Brain Dynamics.**

I. Introduction

The research on brain-computer interface (BCI) has got significant pace in its way lately. The objective of BCI is to develop a sophisticated system that allows people to communicate with computer without stimulating any muscles. The BCI system enables physically disabled people, e.g., having Tetraplegia, to communicate with computer or to control artificial limb. Also, there are other applications of BCI such as lie detection, brain fingerprinting, mode assessment and mind control, etc. There are few techniques of signal acquisition such as functional magnetic resonance imaging (fMRI), magnetoencephalogram (MEG), electroencephalogram (EEG), electrocorticogram (ECoG), etc., which may be used in BCI. The fMRI and the MEG are brain imaging techniques which give good spatial resolution but poor temporal resolution. The EEG is the recording of the electrical activity of the brain recorded from the scalp using noninvasive electrode montages. The EEG gives good spatial and temporal features. The ECoG is also a process of acquiring signal from the brain by placing the electrodes directly on the exposed brain surface. However, ECoG needs invasive surgery to place electrode montages in exposed brain surface.

The EEG based BCI is very popular due to its cost efficiency and non-invasive signal acquisition process. In this paper, we have used EEG signal as response from the brain for motor imagery (MI) tasks. In the development of BCI, motor imagery tasks (MI) are proved to be very effective. According to the Jeannerod (1994, 1995), brain's response to the conscious motor imagery (MI) task is functionally equivalent to the brain's response to the preparation of the unconscious motor execution (ME) [1]. In this paper, we have studied the classification of event related EEG pattern for motor imagery (MI) tasks. The BCI research trend based on motor imagery (MI) task is reported in [2]-[5]. The EEG signal needs to be properly preprocessed to implement BCI system. It is quite challenging as EEG signal is highly nonlinear in nature. We have applied the common spatial pattern (CSP) filter as a preprocessing technique. The CSP is very popular method in BCI field as it is used in many of the previous works [2]-[5]. We have validated our proposed algorithm using both CSP and Regularized Common Spatial Pattern (RCSP). The RCSP is more robust as it can reduce the effect of outliers [5]. The outliers are the patterns deviated from the general pattern of the data. In [2], the RCSP with aggregation is proposed for small sample settings. A few modified CSP algorithms are also described in [3]. It is observed that both CSP and RCSP algorithms have been proven to be very effective in increasing the classification accuracy.

The goal of the proposed experiment is for finding a way to employ less number of electrodes in BCI system without compromising accuracy so that the computational cost can be reduced. We have demonstrated a comparative study concerning number of electrodes as well as the computational cost in BCI system. Our experiment attributes to computational latencies which is distinctive from the orthodox BCI literatures. In our experiment, we have proposed to consider the spatial brain dynamics effectively. The experiments in previous literatures have emphasized on the classification in different settings, e.g., in the presence of outliers [5], in case of small training trials set [2] or comparison between the potentiality of multiple preprocessing methods [3], etc. Although our experiment aims to classification problem for BCI, we have emphasized a great deal on the spatial dynamics of the brain to minimize the number of electrodes as well as the computational cost. An approach to important channel (actual EEG montage) selection is proposed in [4] based on CSP features. In [4], the CSP is applied to the EEG data and optimal channels (after CSP is applied) for different classes are used to correlate with the actual EEG montages. Thus, the actual EEG electrodes are selected for BCI purpose which have more discriminative features for two classes. In contrast, we have proposed to simply use the spatial brain dynamics to reduce the number of electrodes used rather to consider statistical features provided by CSP as proposed in [4].

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

II. Channel Selection Featuring Brain Dynamics

The BCI research tends to be collaborative. Engagement of different fields such as Neuroscience, Mathematics, Statistics, and Engineering, etc., is necessary for BCI development. In this paper, we have utilized the spatial dynamics (i.e., knowledge of Neuroscience) of the brain to sort out electrodes which have optimal impact for the specific task. Though the CSP gives best channels for different classes irrespective of actual EEG montages, the spatial dynamics can give idea about the suitable electrode montages. The assumption behind this study is that the channels placed on the specific brain regions where the impact of the event related EEGs are mostly significant, will help the algorithm to give optimal performance with less computation.

There is significant number of works studying spatial areas activated during motor imagery (MI) tasks. In [1], the general concepts about motor imagery task (MI) are explained elaborately. An investigation based on fMRI has been carried out in [6] and specific regions are reported during motor imagery (MI) task. Also, source activation in different brain areas is shown in [7]. These studies show some regions frequently activated during MI. The specific areas are Primary Motor Cortex (M1), Supplementary Motor Area (SMA) and Premotor Cortex (PMC) [1]. These areas are also reported in [6] as well. According to the source activation shown in [7], lateral PMC is mostly activated during MI. Besides, there are significant activation in SMA and parietal lobe during MI.

III. The Dataset and The Experiment Overview

To evaluate the proposed algorithm, we have used the dataset IVa from the BCI Competition III [8]. The data was recorded from five healthy subjects while sitting on a comfortable chair with arms resting on armrests. The signal was recorded using 118 channels (Extended 10/20 System) at a sampling rate of 1 KHz. We have used the data which are downsampled to 100 Hz. The subjects were given visual cues to perform each of three MI tasks (left hand, right hand and right foot). The data is provided for only two classes (right hand and right foot). The data consists of 280 trials for each subject. Each trial consists of 3.5s of recording for any of the two classes.

We split our experiment into four cases listed in Table I considering the dataset described earlier. Each case deals with electrodes from specific regions. In Case-I, we have evaluated the data using all the available electrodes (118 channels). In Case-II, we choose 18 electrodes from the specific regions reported in [1]-[7] in the left hemisphere. In the Case-III, we choose 18 electrodes from the motor area in both hemispheres. Finally in Case-IV, we choose only 9 electrodes from the sensorimotor areas in left hemisphere which is mostly activated during MI as shown in [1]-[7]. In the last section, we consider the following assumptions featuring the spatial dynamics of the brain:

(a) The left hemisphere of the brain controls the movements in the right part of the body.
(b) The source activation during the MI is mostly in the sensorimotor (i.e. M1, SMA, PMC etc.) areas [1]-[7].

IV. Spatial Filtering Method

In this paper, we have applied CSP and RCSP as preprocessing techniques. The CSP gives a projection matrix which is used to transform the EEG data linearly into a space in which the maximal discriminative features between two classes are seen. In case of RCSP, regularization of different parameters are introduced and we can get better accuracies by tuning the parameters. The motivation behind studying RCSP is that its robustness to outliers [5] as well as its performance in small sample settings [2]. The following sections describe briefly CSP and RCSP[2].

TABLE I
Study Of Spatial Brain Areas

Case	No. Of Channels	Spatial Brain Areas
I	118	Whole Brain
II	18	Sensorimotor Areas + Parietal Lobe (Left Hemisphere)
III	18	Sensorimotor Areas (Both Hemisphere)
IV	9	Sensorimotor Areas (Left Hemisphere)

A. Sample Based Covariance Matrix Estimation For CSP

At first, the CSP method was applied to EEG regarding MI hand movements by Ramoser in [9]. CSP is very sensitive to outliers and artefact as reported in [2] and [5]. As EEG signals have very challenging SNR, more robust methods are needed to improve performance. We use RCSP which is more robust compared to CSP [2], [5].

EEG signal is represented by $\mathbf{E}$ and of size $N \times P$, where N is the number of channels and P is the number of samples per trial. In traditional CSP algorithm, the sample based covariance matrix estimation is required. The sample covariance matrix of a trial $\mathbf{E}$ is normalized with the total variance as [2], [9].

$$\mathbf{S} = \frac{\mathbf{E}\mathbf{E}^T}{\text{trace}\left[\mathbf{E}\mathbf{E}^T\right]} \tag{1}$$

where ^{T} denotes the transpose of a matrix.

Considering M trials are available for training in each class for a subject, indexed by m as $\mathbf{E}_{(\mathbf{c},\mathbf{m})}, m = 1, 2, ..., M$

$$\bar{\mathbf{S}}_c = \frac{1}{M}\sum_{m=1}^{M}\mathbf{S}_{(\mathbf{c},\mathbf{m})} \tag{2}$$

where $c \in \{1, 2\}$ represents either of the two classes of the trial depending on the MI task for the right hand or right foot movement.

The discriminative spatial patterns in CSP are calculated based on this sample based covariance matrix estimation based on (2). The next section will introduce regularization in CSP.

B. Covariance Matrix Estimation With Regularization

Regularization works by biasing the covariance estimation away from their sample based values towards more physically plausible values, which reduces the variance of the sample based estimates while tending to increase bias [2]. This is done using one or more regularization parameters (i.e., β and γ in this paper).

Now, the regularized average spatial covariance matrix for each class is defined as

$$\widehat{\sum}_c(\beta,\gamma) = (1-\gamma)\widehat{\mathbf{\Omega}}_c(\beta) + \frac{\gamma}{N}\text{trace}\left[\widehat{\mathbf{\Omega}}_c(\beta)\right]\cdot\mathbf{I} \tag{3}$$

Here, β and γ are the two regularization parameters ($0 \leq \beta, \gamma \leq 1$) and $\mathbf{I}$ is an identity matrix. $\widehat{\mathbf{\Omega}}_c(\beta)$ is comprised of

covariance matrix for the trials from the specific subjects as well as generic trials and given by

$$\widehat{\mathbf{\Omega}}_c(\beta) = \frac{(1-\beta).\mathbf{S}_c + \beta.\widehat{\mathbf{S}}_c}{(1-\beta).M + \beta.\widehat{M}} \tag{4}$$

In that case, $\mathbf{S}_c$ is the sum of the sample covariance matrices for all M training trials for class c :

$$\mathbf{S}_c = \sum_{m=1}^{M} \mathbf{S}_{(c,m)} \tag{5}$$

Also, $\widehat{\mathbf{S}}_c$ is the sum of the sample covariance matrices for $\widehat{M}$ generic training trials with covariance matrix $\mathbf{E}_{(c,\hat{m})}$ for class c:

$$\widehat{\mathbf{S}}_c = \sum_{\hat{m}=1}^{\widehat{M}} \mathbf{S}_{(\mathbf{c},\hat{\mathbf{m}})} \tag{6}$$

Here, $\mathbf{S}_c$ and $\widehat{\mathbf{S}}_c$ are normalized and analogous to the sample covariance matrix mentioned in (1). The objective of $\widehat{\mathbf{S}}_c$ is to reduce the variance in the covariance matrix estimation and may produce more reliable results.

The regularization parameter β controls the shrinkage of the training samples covariance matrix estimate to the pooled estimate. The other regularization parameter γ controls the degree of shrinkage towards a multiple of the identity matrix, with the average eigenvalue of $\hat{\mathbf{\Omega}}_\mathbf{c}(\beta)$ as the multiplier. This second shrinkage has the effect of decreasing the larger eigenvalues while increasing the smaller ones. Actually, this works well in case of small training samples set as in [2].

C. Feature Extraction In RCSP

The regularized composite spatial covariance is formed and factorized as [2]

$$\widehat{\sum}(\beta,\gamma) = \widehat{\sum}_1(\beta,\gamma) + \widehat{\sum}_2(\beta,\gamma) = \widehat{\mathbf{U}}\widehat{\wedge}\widehat{\mathbf{U}}^T \tag{7}$$

Here, $\widehat{\mathbf{U}}$ denotes the matrix eigenvectors and $\widehat{\wedge}$ denotes the diagonal matrix of corresponding eigenvalues. The eigenvalues are assumed to be sorted in descending order throughout this paper [2], [9].

Finally, the projection matrix is formed as [2]

$$\widehat{\mathbf{W}} = \widehat{\mathbf{B}}^T\widehat{\wedge}^{-1/2}\widehat{\mathbf{U}}^T \tag{8}$$

where $\widehat{\mathbf{B}}$ denotes the matrix of eigenvectors for the whitened spatial covariance matrix and defined as

$$\widehat{\mathbf{B}} = \widehat{\wedge}^{-1/2}\widehat{\mathbf{U}}^T\widehat{\sum}_c(\beta,\gamma)\widehat{\mathbf{U}}\widehat{\wedge}^{-1/2} \tag{9}$$

In RCSP, an input trial E is projected as [2]

$$\widehat{\mathbf{X}} = \widehat{\mathbf{W}}^T\mathbf{E} \tag{10}$$

To get the most discriminative features for both classes, the optimal channels are to be selected from the leftmost and rightmost channels. For example, the first channel represents the most distinguished features for class 1 and the last channel represents the most distinguished features for class 2. As channel selection converges to the central channel of the $\widehat{\mathbf{X}}$, the features becomes poor which may hardly distinguish different classes. It is to be noted that, RCSP becomes traditional CSP when $\beta = \gamma = 0$.

V. Experimental Design And Validation

In this section, we will discuss the experimental steps and elaborate the parameters' specific values which we have used in this study.

A. Experimental Design

The experimental flow of the proposed study is described in Fig.1. We have used N channels as described in Table I. At first, the set of signals are bandpass filtered to get rid of the low frequency artifacts such as eyeblinks. Then, we have applied spatial filtering to increase the classification accuracy. From channels containing filtered signals, we select 4 optimal channels, i.e., first two channels for class 1 and the last two channels for class 2. After selecting 4 optimal channels, we have extracted subband energy and subband entropy from all the four optimal channels. Afterwards, the features are used for classification. We have used Neural Network (NN) as classifier.

B. Validation Of Proposed Method

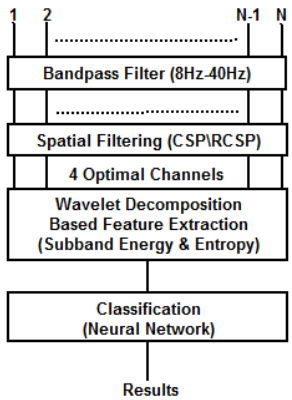

Fig. 1. Block Diagram Of Our Proposed Algorithm

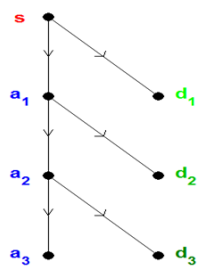

Fig. 2. Wavelet Decomposition Tree Upto Level 3

In this experimental study, we have proposed the spatial dynamics to be studied to minimize the number of channels as well as computational cost. We have used 120 trials for the training phase, 60 trials for the validation phase and 100 trials for the testing phase. For each trial, we have taken 3secs of data after 0.5secs of the visual cues. The experiment is divided into four *cases* as described in Table I. First, the data is band pass filtered from 8-40Hz using Butterworth filter of order 10. The Butterworth filter is used as it has magnitude response which is almost flat in the pass band. Second, the data is preprocessed using CSP or RCSP as discussed in the previous section. The first and last two channels are selected which show optimal variances for class 1 and class 2, respectively.

Then, wavelet based subband energy and subband entropy (Shannon Entropy) are extracted as features. The signals are decomposed up to level 3 using wavelet transform as shown in Fig. 2. Thus, each of the four channels is decomposed into four subbands. In each of the subbands, energy and Shannon entropy have been calculated. Finally, Neural Network is used as classifier. We have used a two layer feed forward network with 12 hidden neurons at the hidden node. This setup is applied to the all four *cases* as in Table I. In this experiment, we have used different combination of values of β and γ as follows

$\beta = (0, 0.001, 0.01, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9)$

$\gamma = (0, 0.01, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9)$

We have tested all possible combination of values from the above sets. These values are selected from previous experiments described in [2] and [3].

TABLE II
VALIDATION OF PROPOSED ALGORITHM : CLASSIFICATION ACCURACIES

Case	Method	aa	al	aw	av	ay	Avg.
I	CSP	83.6%	97.9%	93.2%	70.4%	91.8%	87.38%
	RCSP	86.8%	97.9%	95.7%	70.4%	92.9%	88.78%
II	CSP	80.4%	96.1%	92.5%	66.8%	89.3%	85.02%
	RCSP	85.4%	97.1%	93.2%	70.7%	93.6%	88%
III	CSP	81.1%	95.7%	92.5%	67.9%	93.2%	86.08%
	RCSP	87.1%	96.4%	93.6%	70%	93.9%	88.2%
IV	CSP	82.9%	94.6%	87.1%	71.8%	93.9%	86.06%
	RCSP	85.4%	94.3%	88.2%	72.5%	97.1%	87.5%

The results for all four *cases* under this study are shown in Table II. It is observed that the performance of the proposed method varies across different subjects. This is due to the fact that the quality of the signal regarding MI depends on the subjects' ability to simulate MI task in brain. In this experiment, the best result is 97.9% for subject 'al' in Case-I and the worst result is 66.8% for subject 'av' in Case-II. In Case-IV, we have the best results for subjects 'av' and 'ay' which are 72.5% and 97.1% respectively although we have used only 9 selective channels. For the subjects 'aa', 'al', and 'aw', the best results are 87.1% (Case-III), 97.9% (Case-I) and 95.7% (Case-I), respectively. But, these best results for subjects 'aa' and 'al' are comparable with the results reported in Case-IV. Only for subject 'aw', the difference between the best result and the result from Case-IV is a little high. However, if we look at the average results for different subjects, we can easily notice that the best average result is 88.78% (Case-I) and the average result for Case-IV is 87.5%. These are quite comparable results although we have reduced the number of electrodes significantly. Therefore, we can conclude that we can reduce the computational cost by engaging spatial brain dynamics in BCI development. The computational latencies of all four cases are reported in Table III. The difference between the studies are the number of channels (electrodes) which are used to verify the proposed algorithm. Therefore, we have accounted for the computational latencies between the input of the bandpass filter and the output of the spatial filter as shown in Fig. 1. The remaining computational complexities are quite equivalent as in Fig. 1. The subject specific computational latencies are shown in Table III. In each of the cases, the computational latencies are observed 10 times (i.e, 10 simulation runs for each). Then, we have calculated the average over all the 10 runs. Also, the averages for each of the studies are shown in Table III. The average computational latency in Case-I is significantly higher compared to the average computational latency of Case-IV. Therefore, it is feasible to implement an BCI system with less number of electrodes without compromising performance significantly. In this way, computational cost can be reduced drastically by selecting channels from specific Regions Of Interests (ROIs) of the brain.

TABLE III
COMPUTATIONAL LATENCIES (IN SECS): COMPARISON BETWEEN STUDIES

	Study 1	Study 2	Study 3	Study 4
aa	22.33	4.56	4.39	2.89
al	20.80	4.26	4.21	2.76
aw	20.98	4.41	4.18	2.75
av	22.03	4.21	4.21	2.73
ay	20.61	4.32	4.19	2.73
Avg.	21.35	4.35	4.24	2.77

This experiment has been performed in a personal workstation with the following configurations: CPU-2.5GHz, RAM-4GB, Windows 7 Home Premium, MATLAB 2013b.

VI. FUTURE DEVELOPMENT

In this experimental study, we have studied spatial brain dynamics and have tried to correlate these facts with BCI development. This paper presents the significance of the spatial dynamics which contributes to reducing the computational cost in BCI system. We have considered previous literature based on the spatial reasoning of the brain during MI tasks. But, the fact is that the brain dynamics varies a lot from subject to subject. Thus, subject specific brain dynamics may play important role in subject specific BCI development. To do this, employment of both the brain imaging techniques (i.e., fMRI) and the EEG is necessary. In that case, it is possible to extract useful spatial information by studying on the source activation areas during MI (i.e., by analyzing the the fMRI images for specific subject). Based on this, EEGs from few selected channels can be employed to extract features resulting in reduction in the computational complexities in BCI.

Abstract— **Quality analysis of biomass is an important parameter to use it as an effective energy source. It is necessary to understand because the performance and efficiency of biomass based power plant machineries are interrelated with biomass quality. In this paper, the efficiency of biomass utilization has been realized from quality perspective. Moreover, biomass quality variation has been analysed with respect to different weather conditions.**

***Index Terms*—Biomass, biomass quality, power generation, NCV, EMC.**

I. Introduction

Every year the whole world produces about hundreds of tons of biomass in various forms lending itself a popular source of energy after coal, oil and natural gas. The most obvious benefit of biomass based energy is that it is a renewable source and also environment friendly. Worldwide biomass ranks fourth as an energy resource, providing approximately 14% of the world's energy. In developing countries like Bangladesh, it can be as high as 35% of the primary energy supply [1]. Quality control and analysis of the biomass material are essential to both the home heat generator and large industrial users. Biomass has different characteristics and understanding the composition of it can help to decide which conversion technique will be best for power generation. Biomass quality also changes with seasonal variation. So, it is another important factor to be considered in the case of energy extraction process from biomass.

In this paper, biomass characteristics with its chemical composition have been presented. Moreover, the comparison between biomass and fossil fuel has been discussed on the basis of their function as fuel. For the analysis of biomass quality, Equilibrium Moisture Content (EMC) of woody biomass has been calculated by using an empirical equation which is an approximation of the relationship among EMC, temperature and relative humidity. However, seasonal quality variation and corresponding efficiency of biomass energy source have been obtained by analysing the yearly weather variation in Dhaka, Bangladesh.

II. Biomass as Energy Source

The fundamental process by which energy is stored in biomass is photosynthesis. It is the process where light energy from the sun is captured and stored in the chemical bonds of the tissues of living plants [2]. The photosynthetic efficiency is the fraction of light energy converted into chemical energy during photosynthesis in plants and algae. Photosynthesis can be described by the simplified chemical reaction-

$$H_2O + CO_2 + \text{energy} \rightarrow C_6H_{12}O_6 + O_2$$

$C_6H_{12}O_6$ represents carbohydrates such as sugars, cellulose and lignin [3].

Biomass energy can be converted into different forms of energy like chemical, mechanical or electrical .The process of converting energy varies from biomass type and specific properties like moisture and ash content of biomass. Net Calorific Value (NCV) or Lower Heating Value (LHV) of biomass changes significantly with the variation of moisture content in it [4]. When biomass is converted thermally in the presence of excess amounts of air (combustion), the total energy released in the form of heat is called its heating value or calorific value. Generally, biomass has heating value ranging from 15 MJ/kg to 25 MJ/kg [5]. Fig. 1 shows the variation of NCV of some biomass samples with the change in moisture content where NCV decreases with the increase of moisture content.

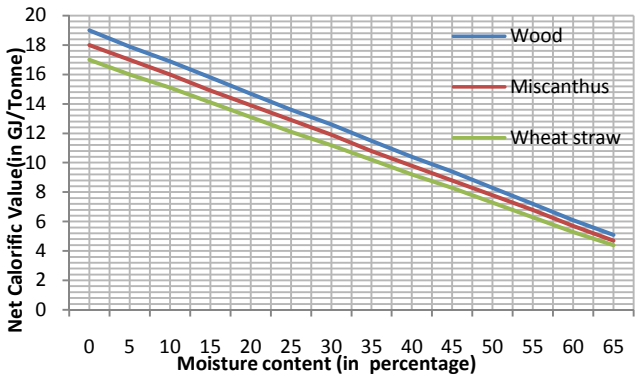

Fig. 1 Calorific value vs. moisture content of some typical biomass.

III. Chemical Composition of Biomass

Biomass is carbon based and composed of a mixture of organic molecules containing hydrogen, usually including atoms of oxygen, often nitrogen. It also contains small quantities of other atoms, including alkali, alkaline earth and heavy metals [6]. Table I contains general chemical composition of biomass in percentage weight (dry condition) [7].

TABLE I
General Chemical Composition of Biomass

Element	Weight (%)
Carbon	44-51
Hydrogen	5.5-6.7
Oxygen	41-50
Nitrogen	0.12-0.6
Sulfur and Others	0-0.2

Biomass differs from coal (solid fossil fuel) in many important ways, including the organic, inorganic, energy content and physical properties. Relative to coal, biomass

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

generally has less carbon, more oxygen, more silica and potassium, less aluminium and iron, lower heating value, higher moisture content and lower density and friability [8]. Fig. 2 shows the comparison of chemical composition between biomass and coal.

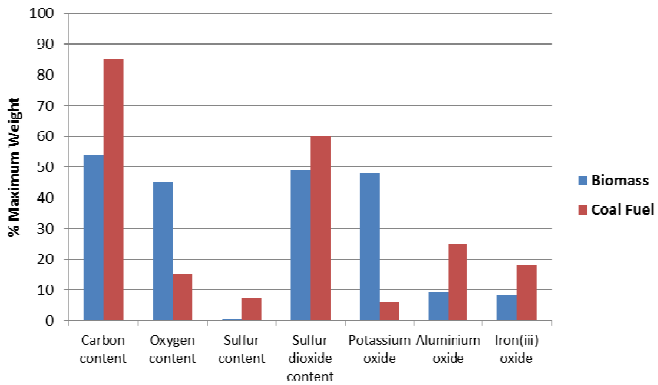

Fig. 2 Chemical composition comparison between biomass and coal.

IV. Quality Analysis

Biomass qualities are affected by mainly two factors. These are internal or structural factors and external or environmental factors.

A. Internal Factors

Internal factors of biomass are mainly the constitutional factors such as fixed carbon, volatile substances, ash content, water content etc.

B. External Factors

For biomass quality analysis external factors are the most important parameters to be considered. Among the external factors, moisture content is the important one. Moisture content can be determined by two methods [9].

1) Wet basis: In the case of wet basis calculation,

$$Moisture\ content = \frac{Mass\ of\ water\ in\ the\ biomass}{Total\ mass\ of\ biomass} \times 100\%.$$

2) Dry basis: In the case of dry basis calculation,

$$Moisture\ content = \frac{Mass\ of\ water\ in\ the\ biomass}{Total\ mass\ of\ biomass\ without\ water} \times 100\%.$$

Moisture content of biomass largely depends on temperature and humidity variation of the environment. The moisture content of wood is directly related to the humidity and temperature of the surrounding air. The Equilibrium Moisture Content (EMC) occurs when the wood has reached a water content equilibrium with its environment and is no longer gaining or losing moisture. The EMC value of biomass in different seasons of the year is necessary to realize the efficiency of biomass utilization. EMC can be calculated by using the Hailwood-Horrobin equation [10],

$$EMC\ (\%) = \frac{1800}{W}\left[\frac{kh}{1-kh} + \frac{klh + 2k^2lmh^2}{1 + klh + k^2lmh^2}\right] \quad (1)$$

Where, h = Relative humidity (fractional), T = Temperature (in degree Fahrenheit), $W = 330 + 0.452T + 0.00415T^2$, $k = 0.791 + 4.63 \times 10^{-4}\ T - 8.44 \times 10^{-7}T^2$, $l = 6.34 + 7.75 \times 10^{-4}\ T - 9.35 \times 10^{-5}T^2$, $m = 1.09 + 2.84 \times 10^{-2}\ T - 9.04 \times 10^{-5}T^2$.

Using (1), EMC (%) vs. temperature for different values of humidity has been plotted by MATLAB R2008a software.

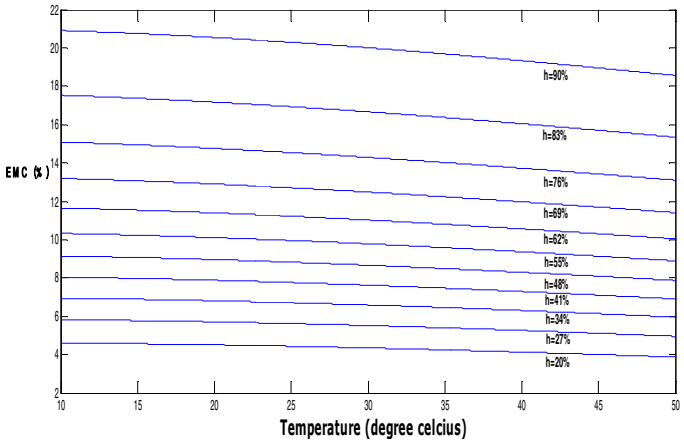

Fig. 3 EMC (%) vs. temperature graph for different humidity.

Using the graph of Fig. 3, EMC (%) value fluctuation due to temperature and humidity variation of different months (year 2013) of Dhaka, Bangladesh has been determined. Fig. 4 shows the EMC (%) fluctuation graphically.

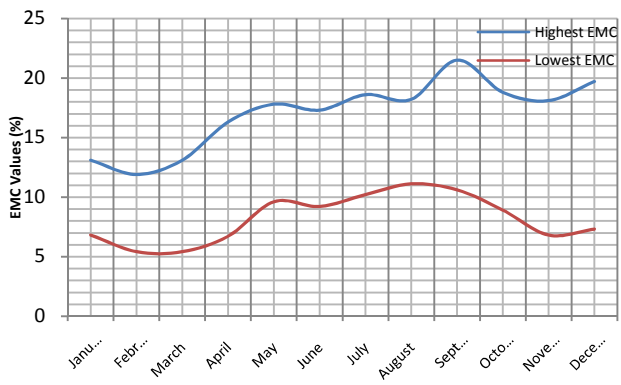

Fig. 4 EMC (%) values vs. different months.

From Fig. 4 it is observed that, EMC (%) value falls from the month of January and reaches its bottom at the month of March. After that, from March to May its shows increasing behaviour of EMC (%). During the period of May to August it becomes almost constant. In the mid of September to October EMC (%) value shows abrupt behaviour and reaches its peak value. From October to November its decreasing rate is similar to the month of January to February.

In biomass based power generation, total system efficiency depends on EMC (%) of biomass. If EMC (%) increases, NCV of biomass decreases (Fig. 1) as well as the efficiency of power generating components like boiler, turbine etc. From the analysis of Fig. 4 it has been found that, probability of high efficient operation is greater at the month of February-March than any other months throughout the year. It has been also found that lower efficiency occurs at the month of September-October.

As it is observed that, efficiency is higher at a particular time in a year whereas lower at other periods, so for ensuring continuous power flow from biomass based power plant, sufficient amount of backup power should be provided at the period of lower efficiency and less backup is needed at the time of higher efficiency.

V. Conclusions

Biomass quality analysis should be done at priori before using it as fuel in the power generation system because the efficiency of energy extraction from biomass depends on its quality. From the study, it has been found that efficiency of biomass energy source is high at specific period of year and low at the remaining time. For this reason, the weather condition should be kept in mind for the utilization of biomass as energy source.

Abstract—**In this paper a new technique is proposed to improve the performance of the linear permanent magnet generator (LPMG) which is basically a point absorber. This paper also represents analysis, design and simulation of a LPMG for improvement of oceanic wave energy conversion (WEC). Different output voltage, current and power waveforms of the conventional and proposed LPMG are analyzed, simulated and compared by MATLAB software by constructing mathematical models of WEC, LPMG and output stage. Various parameters like magnitude, wavelength and phase of oceanic wave are observed to make proper simulation by changing different parameters. It is applicable almost all of the point absorbers and offers the great advantage to get relatively more even power distribution which is a major concern for WEC.**

Index Terms—**Linear generator, point absorber, oceanic wave energy, translator.**

I. Introduction

In recent years WECs are the centre of attention in the renewable energy field because it has the feature of very high energy density. The wave energy resource is substantial, and the total resource around the world is estimated 10 TW in the open sea, which is comparable to the world's total power consumption [1]. Different types of WEC devices have been proposed for development, such as Archimedes Wave Swing (AWS), Oscillating Water Column (OWC), Pelamis structure, Wave Dragon, Mighty Whale etc. ([2]–[4]). Ocean power technology companies own the commercial product based on a point-capture wave power generation system with AWS submerged under the water for power generation [5]. Traditional wave power generation methods have the disadvantages of complex and expensive system structures and are hard to maintain and possess low transformation efficiency ([6], [7]). Hence, the generated electricity from such systems is not cost-effective. The AWS consists of a hollow cylinder and a lid fixed on the sea-bottom filled with air, called floater as shown in Fig.1(a). The floater moves in the vertical direction. When the wave comes, the floater sinks because of increase of the weight of the water above, while the pressure of the air in the cylinder increases and vice-versa. In a power buoy, from the reciprocating motion of the floater moved linearly, the wave energy is extracted that convert the wave energy to electrical energy. A point absorber is a floating structure with components that move relative to each other due to wave action utilizing the rise and fall of the wave height at a single point for energy conversion as shown in Fig.1(b). The measurement of power buoy and accessories are given here as an example and need to be varied according to different situation. The relative up and down bobbing motion caused by passing waves is used to drive electromechanical or hydraulic energy converters to generate power. Internal construction of a conventional LPMG is shown in Fig.1(c).

At present, research studies on direct-drive methods have been carried out by direct capture of wave energy as it is proved to be more efficient compared to the traditional generators ([7]–[10]). The LPMGs are employed to directly transform the low speed mechanical energy into electricity, thus eliminating intermediate mechanical translators, a crank or linkage etc. or converters. Although the LPMGs have relatively large force-to-volume ratio and own high efficiency, the involvement of LPMGs results in complicated winding scheme or sophisticated arrangement and assembly of LPMGs [11].

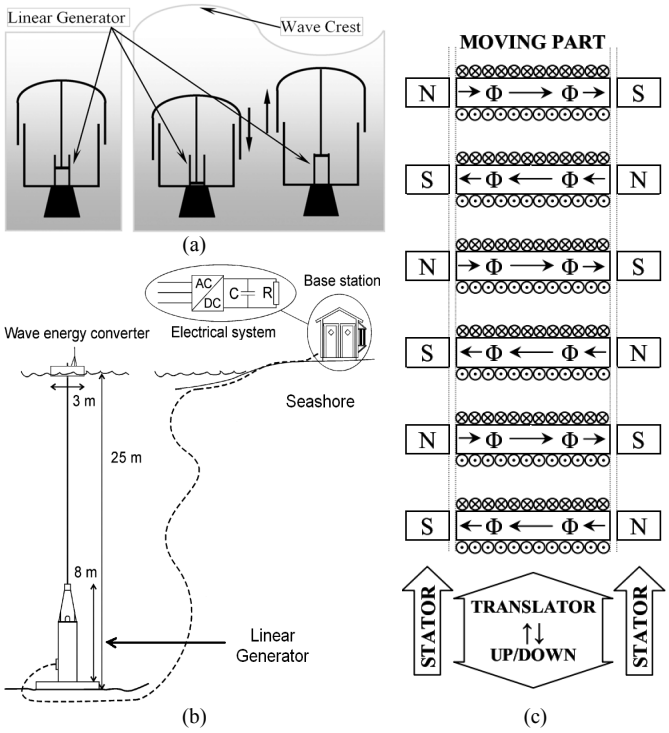

Fig. 1(a) LPMG shown in an AWS configuration, (b) LPMG mounted with power buoy, (c) LPMG internal construction.

In the latest report from the International Energy Agency (IEA), 81 different wave energy projects including linear generator (LG) and WEC were examined and out of them 13 were estimated to have reached the stage of having a full- or near-full-scale prototype at sea [12].

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

II. Conventional Linear Generators

Different internal construction of conventional LPMGs are shown in Fig.2(a–c). When a magnet moves in relation to an electromagnetic coil, this changes the magnetic flux passing through the coil, and thus induces the flow of an electric current. Like rotary generators it essentially contains stator and translator which works similar as rotor. The translator and the stator can either have the same vertical length as shown in Fig.1(c) that mean the active surface will vary during cycle of motion or one of them can exceed the other in vertical length as shown in Fig. 2(c). If the surplus in length is equal to the pitch length the active surface will be constant.

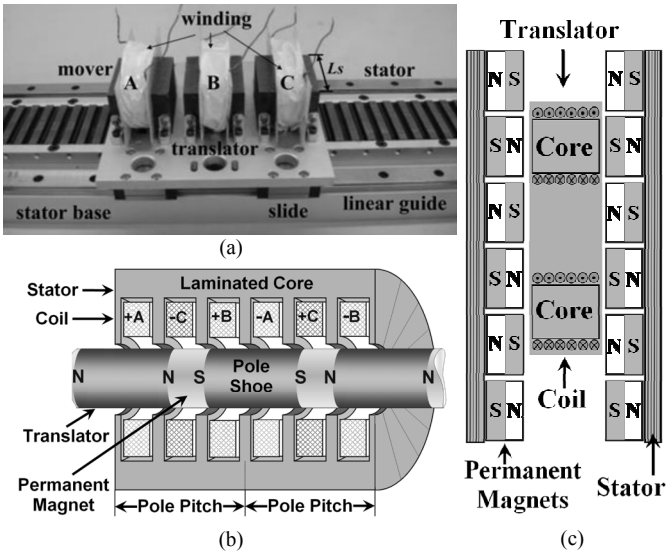

Fig. 2(a) Conventional flux switching LPMG, (b) Conventional tubular LPMG, and (c) Conventional LPMG with longer stator.

However, the longer translator has some advantages on longer stator though both of these give similar output waveforms. A practical output waveform of electrical power is shown in Fig.3 for an example [12].

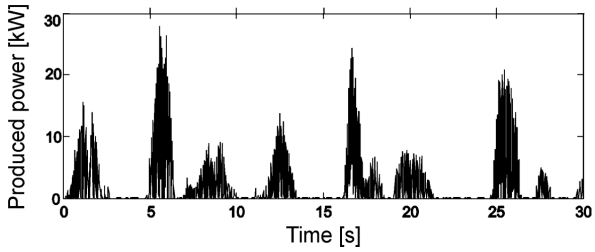

Fig. 3 Electrical power output of a conventional LPMG.

All conventional LPMGs produced discontinuous output power. From Fig.3 it is clear that it gives negligible output power from 2 to 3 seconds approximately in each cycle.

III. Model of WEC and LPMG

The up and down movement produced by an ideal wave can be approximated by a sine function, resulting a cosine-shaped speed variation, with maximum speeds reaching up to 2m/sec, depending on the sea state. The speeds are usually between 0.5m/sec to 1m/sec. The linear generator should be chosen considering these speed values and the working conditions. The induced voltage is found according to Faraday's law of electromagnetic induction as given in (1)

$$E = -N\frac{d\overline{\Phi}}{dt} \tag{1}$$

Here E is induced voltage in the coil, N is turn number of wire in coil and $\overline{\Phi}$ is average flux passing through coil. As vertical wave displacement is very similar to sinusoidal function, assuming sinusoidal wave the vertical displacement of wave and velocity can be expressed as given in (2) and (3) respectively.

$$y(t) = H_m \sin\left(\frac{2\pi}{T}t \pm \theta_i\right) \tag{2}$$

$$v(t) = H_m \frac{2\pi}{T}\cos\left(\frac{2\pi}{T}t \pm \theta_i\right) \tag{3}$$

Here $y(t)$ and $v(t)$ represents position or displacement of wave and velocity respectively. H_m, θ_i and T represents height, phase angle and period of oceanic wave respectively. In this model H_m, θ_i and T can be varied to get wide range of input variable.

The proposed LPMG is consisted of a possible special new translator as shown in Fig.4(a) and a stator with windings. Flux switching method is used for generation of electricity. According to Fig.4(b) when translator moves at a particular time it aligns at position-1 and flux direction is upward through first pole shoe. At position-2 the flux direction is reversed as it is downward through the same pole shoe. All the cases vertical velocity of any type of translator mounted with floater or something like that is very low at the two ends, hence generating negligible amount of electricity as shown in Fig.3 as an example as the output power is proportional to speed or velocity. A new design of pole shoes so far is also implemented which is able to increase rate of change of flux with proper mounting with translator, thus generate more electrical power even with low velocity because although the displacement per unit time is low two consecutive translator tips are closer near both ends compared to the regular distance around the middle position.

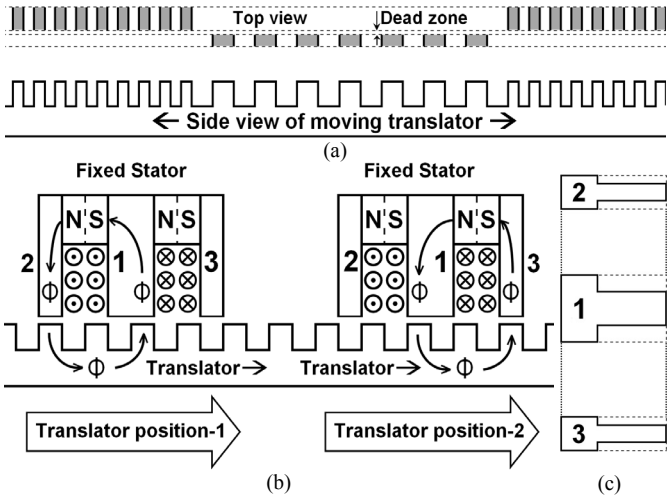

Fig. 4(a) Top view and side view of the proposed translator, (b) Direction change of flux in stator when position is changed, and (c) Bottom view of proposed pole tips of stator.

The Proposed LPMG block diagram of model is shown in Fig.5. Different parameters of wave energy like wave length, height, phase, reaction force, cogging force, friction is considered which can be given as preset value or it can be varied during simulation. Variables can be changed during simulation using function with preset value or can be given in the model by another function named "Random" connected with some other blocks that can produce random height and wavelength of wave energy to produce more realistic outputs.

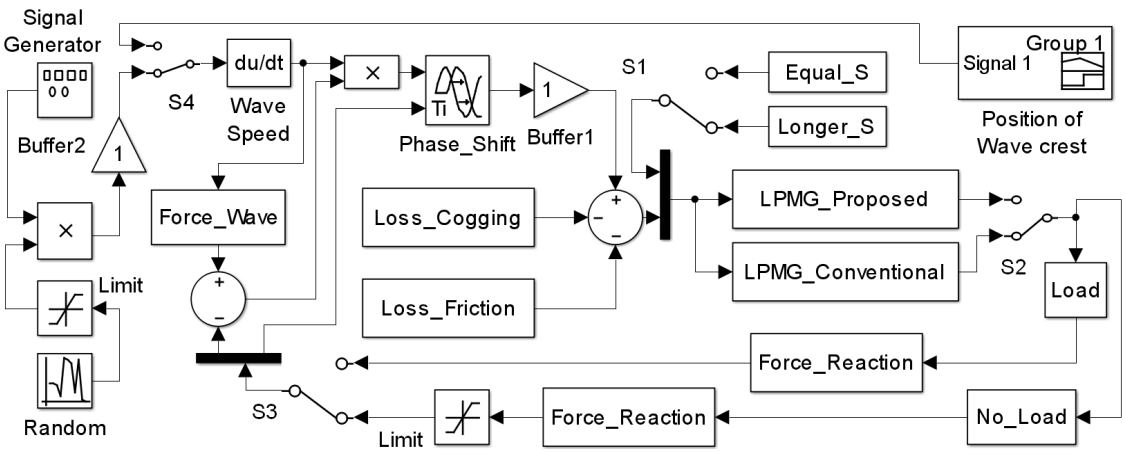

Fig. 5 Block diagram of simulation model of the conventional and proposed WEC and LPMG.

IV. SIMULATIONS

In the simulation model cogging force, core loss and frictional loss is considered as the function of velocity with some coefficients. Reaction force and loading effect depends on floater, output electrical power and current mainly. Selector switches S1 to S4 are used in this model to increase its flexibility and multimode selection purpose. For an example, equal stator and longer stator mode can be selected by S1 represented as Equal_S and Longer_S respectively. Fig.6 represents vertical oceanic wave displacement and velocity which are the inputs for the conventional and proposed model according to (2) and (3). Fig.7 shows the voltage and current waveforms of a conventional LPMG and Fig.8 shows the same for the proposed LPMG for a given resistive load. Fig.9 shows generated voltage of a conventional LPMG with respect to magnetic flux density represented as B in tesla. As flux density varies from 0 to 1.2 wb/m^2 according to the model parameters which is much less compared to voltage scale so, it is zoomed to 100 times so that is can be easily visualize in the same scale of voltage. Fig.10 shows generated voltage versus B for the proposed LPMG. Fig.11 and Fig.12 represents phase and magnitude of no load and full load voltage waveforms of a conventional and the proposed LPMG respectively. Full load voltage is less than no load voltage not only for the regulation of LPMG but also for the reaction force created by the wave, hence there is some phase difference. The output electrical power of a conventional and the proposed LPMG is shown in Fig.13 and Fig.14 respectively for equal translator length and the same are shown in Fig.15 and Fig.16 respectively for longer translator length than stator where the pitch length is equal or greater than wave amplitude. It is clear that average output electrical power is more in the proposed LPMG and also the ripple factor is significantly low than the conventional LPMG. Fig.7 to Fig.16 are cropped from 0 to 10 second from full simulation time of 20 and 40 second to easily visualize and compare the waveform, peak values and phases.

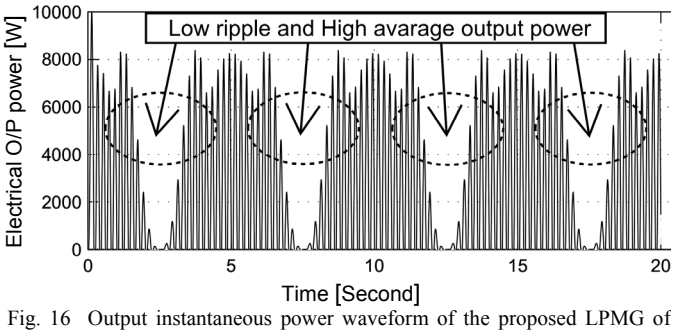

Fig. 16 Output instantaneous power waveform of the proposed LPMG of longer length of translator than stator.

V. Conclusions

Though in commercial LPMG multiple windings are used, in this model comparison of only one winding for both the conventional and proposed one is explained but it can also simulate multiple coil windings. Generally all of the LPMG connected to grid is at first connected to power converter to make a dc power then supply ac electrical power to grid by means of a power inverter with additional devices. As all of the conventional LPMG produces negligible electrical power for long interval of time in each half cycle of wave energy so, it is not possible to supply an acceptable level of constant real power to grid without electrical storage with large capacity because of the high fluctuating electrical power. This major drawback of all the LPMG is reduced in a great extent with the proposed design which can extract electrical power from wave energy while the vertical velocity of wave is low.

Power Generating Slabs: Lost energy conversion of human locomotive force into electrical energy

* Rajesh Kumar Datta, [1], Sazid Rahman[2]

***Abstract*— In the world of modern technology, newer sources of energy and new methods of power generation are two important area of interest for researchers and engineers. Recently a new method is established to generate power from the lost energy of a human during his/her locomotive period. A piezoelectric sensor based costly product is available in some developed countries which can generate power from human locomotive force, but it is not suitable for countries like Bangladesh where power demand is very high but economy is not highly developed. In this paper we will explain the design and construction method of a "Power Generating Slab" which can be used to generate power by establishing anywhere of the walking zone of human (roads, stairs, pavements, dais etc). This is done in a low cost process with locally available equipments (micro-generator, iron plate, rack pinion gear, free-wheeling system, spring etc). These slabs can easily sustain human weight when people walk along them. With a small deformation of spring, the weight (mechanical energy) of a human body is converted into electrical energy by rotating a micro-generator with the help of a 'rotating shaft' coupled with it. From each foot step almost 10V-12V is generated. This energy is stored in a rechargeable battery which can be used as a power source to drive loads. Assembly of some power generating slabs can give better result. This is a method which is reusable and it will run for a longer period.**

***Index Terms*— Power Generating Slab, Mechanical force, Locomotive force, Foot step, Electrical energy.**

I. Introduction

Lost energy conversion of human locomotive force into electrical energy is a relevant and important proposal of power production for highly populated countries of the world. For a healthy human being, walking is the most common activity in daily life. During the movement of a person, energy is lost in the form of impact or vibration on the walking surface. [4] We can convert this lost energy in the usable form of power. The method we have implemented to make "Power Generating Slab" needs some simple mechanical set ups. These slabs can be embedded in the places where there are continuous rush of people; like roads, footpaths, railway platform, stairs etc. When any person will step on the top plate of the slab, the body weight will compress the springs under the slab and the top plate will dip down a little bit. This small downward displacement of the top plate will rotate a micro generator's shaft fitted at the bottom plate and produce electrical energy. When the person will take off his foot from the slab, the springs will regain the position of the top plate. This produced electrical energy will be stored to use later. More human movement will generate more power from these slabs. In overcrowded countries like Bangladesh this methodology will be very much efficient and helpful to reduce power crisis.

II. Design Principle of Power Generating Slabs

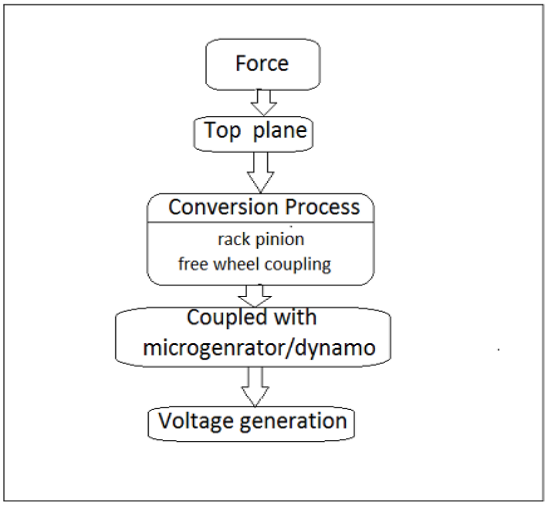

Fig 1: Block diagram of Power Generating Slab

III. Construction and Specification

Top Plane:

This is the upper portion of the slab. In our design we have made this portion with the iron plate. It can be built with other materials too. The main condition of this plate is to sustain the weight of any person walking along it. Footsteps will work as mechanical force.

Length: 50cm, Width: 30cm, Material: Iron

Fig 2 : Top Plane

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Rack and pinion:

This part of the device is attached with the top plate. The mechanical force is converted into a rotational force with the help of rack and pinion. Starting point of rack is welded with the iron plate and the bottom is attached with a pinion along with a shaft.

Length (Rack): 18cm, Radius (Pinion): 03cm

Fig 3: Rack

Fig 4: Pinion

Springs:

Below the top plane layer there are 4 helical springs [5]. These springs are one of the most important parts of this design. When the top plate is loaded with human foot step these springs are distorted slightly and when the load is removed they recover their original shape. This displacement does not make any discomfort in the human walking zone.

Spring type: Helical, Number of springs: 04, Length: 3cm, Maximum weight tested: 90 kg, Maximum displacement: 1cm.

Fig 5: Helical Spring

Shaft with freewheeling bearing:

A shaft is coupled with the pinion and the gear mechanism. The shaft is clamped between the iron frame works. And the freewheeling type bearings are attached on the shaft. The free-wheeling bearings rotate only in one direction.

Length: 50cm

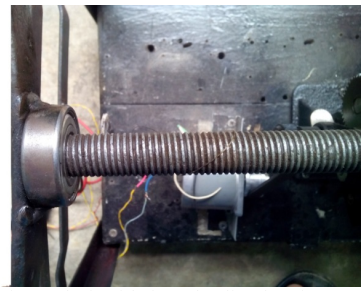

Fig 6: Shaft with freewheeling bearing

Gear mechanism:

This mechanism can be used in many different forms. The arrangement we have used for our device is attached with the shaft with the help of sprocket arrangement. There is a smaller output shaft in this mechanism which converts the total applied force into the rotational force.

Sprocket diameter: 12.5cm

Fig 7: Coupling system with Sprocket

Fig 8: Gear arrangements

Micro- Generator (dynamo):

In this slab we have used a 12V, 0.7A dynamo as micro generator. A dynamo, another form of electrical generator produces direct current. This dc current is produced with the help of a commutator. In dynamo there are rotating coils and a magnetic field. When the shaft of the dynamo rotates with the help of any external force a pulsating direct current is produced because of Faraday's law of induction[3].The constant magnetic field is provided by a stator and a set of armature turn in that magnetic field. When the armature cuts the magnetic field, an alternating electric current is induced in the wire. Commutator works like a rotary switch. Connection of the windings is reversed to the external circuit by the commutator when the direction of the potential reverses. As a result the direction of the output current remains always same. Thus pulsating direct current is produced instead of alternating current from the dynamo.

Fig 9: Coupled dynamo with a belt

Total mechanical setup:

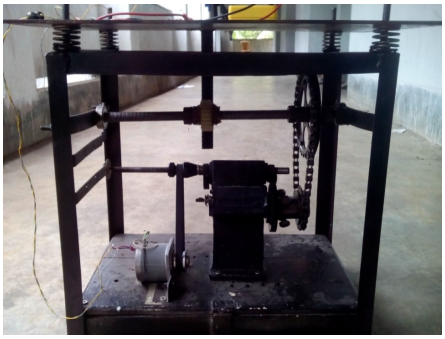

Fig 10: Power Generating Slab

Output:
Maximum voltage in one foot step: 12v

Voltage type: Pure dc

Fig 11: Output Voltage

IV. Charging Arrangements

The produced energy from the slab must be stored in a rechargeable battery. So a charge controller is needed at the output of the slab. For charging of a battery we have used a constant voltage method. The voltage level produces from slab varies time to time. So a charge controller is needed to keep a constant voltage to charge a battery. The controller we have used can charge a battery at a constant voltage of about 13.8V. The voltage that is generated from the human foot step is firstly stored in a capacitor. This capacitor can be of any value as much as desired. The charge controller circuit keep the voltage constant at the output. This helps to charge a battery properly. When the battery is fully charged, charge controller does not pass any voltage to the battery terminal.

V. DATA

Number footsteps	Average power/foot step		
	Capacitor voltage	current	Average Power/foot step
5	32V dc	0.7A dc	4.48 Watt
10	61V dc	0.7A	4.27 Watt
15	85Vdc	0.7A	3.96 Watt

This data table shows the relationship between the number of footsteps and average produced power. This observation is done with a person of 60kg weight.

.

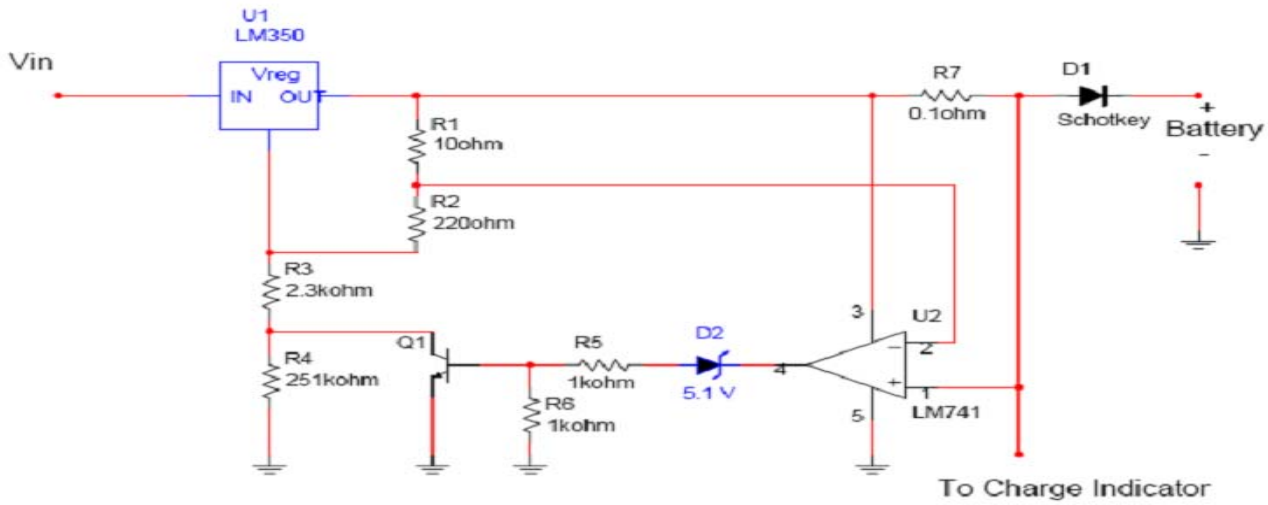

Fig 12: Charge controller circuit [1]

V. RELATION BETWEEN FORCE AND VOLTAGE

The relation between mechanical force and electrical voltage is proportional in these slabs. The force is applied in the form of human weight. More the weight is applied, more the voltage is generated. The force strength is depended on the spring's strength. Springs consume the mechanical energy obeying Hook's Law in their elasticity limit

$$F = -kx$$

Where

x is the displacement of springs from its normal length.

F is the resulting force vector, the magnitude and direction of the restoring force the spring exerts.

k is the spring constant , a constant that depends on the spring's material and construction[7].

This force **F** is applied to the freewheeling bearing which produces a rotational energy. The amount of energy stored in a flywheel is proportional to the square of its rotational speed.

$$E_k = \frac{1}{2} I \omega^2$$

Where,

ω is the angular velocity

I is the moment of inertia of the mass about the centre of rotation. [8]

Thus the rotational energy is converted into electrical energy with dynamo rotation.

So, the relation is actually

Force ∞ rotational energy ∞voltage

VI. ADVANTAGES

1. Lower cost.
2. Can be made with locally available materials.
3. Power can be generated in many forms.
4. Easy construction.

VII. APPLICATIONS

1. For emergency backup power.
2. To run small electrical equipments at the time of load shedding.
3. Street light
4. For charging purpose.
5. Different ways of applications like stairs, classroom daises, parks etc.

VIII. DIFFERENCE WITH EXISTING SYSTEM

The existing system in market is based on the piezoelectric sensor which is a costly material. So the price of the total device is very high ([2], [6]). And the materials to make the slab are not available in all places. In our method, we have used the materials which are easily available in all places and the mechanical system can be easily made in workshops. Our design can be reused and if any kind of hamper is occurred it can be easily solved. The flooring system is a prime concern of this project. We have successfully made the system in which the flooring will not be a discomfort to walk.

IX. CONCLUSION

In modern world the demand of renewable energy is increasing rapidly. Power generating slab doesn't need any fuel to produce power. It just uses the energy that is lost by a human during walking. These slabs can be helpful in reducing power crisis. If these slabs are produced industrially and further research is done on materials and the design, the efficiency will be a lot better. Then these slabs can be viewed as a next promising source of generating power.

Abstract—**The rapid depletion of fossil fuel resources and environmental concern has given awareness on generation of renewable energy resources. Among the various renewable resources, wind energy seems to be promising solution to provide reliable power supply with improved system efficiency. As wind turbine output is proportional to the cube of wind speed, the wind turbine generator output fluctuates due to wind speed variation. This study investigates the influences of a new pitch controller & governor control system model on frequency of power system, when variable load has been considered. It is observed that system frequency can be maintained in acceptable level by using newly designed pitch controller & governor control system when several interconnected synchronous generators (SGs) are operated in different governor control modes with high wind power penetration, when the total capacity of SGs is considered as 100 MVA. Real wind speed data have been considered for this study. PSCAD/EMTDC software is used for simulation analyses.**

Index Terms—**Wind turbine; new pitch controller; variable load; system frequency; wind power capacity; governor control system model.**

I. Introduction

Global energy consumption has increased by leaps and bounds to improve our living standards. But it is a matter of great regret that, the world has limited amount of fossil fuel and nuclear power resources ([1], [2]). So, the growth of wind energy around the world in recent years has been consistently impressive.

In the conventional operation of wind power generators, when the wind speed is between the rated speed and the cut out speed, the wind power generator output is controlled at the rated value by a pitch control system [3]. On the other hand, when the wind speed is between the cut in speed and the rated speed, the blade pitch angle is maintained constant (= 0 deg), in general for the wind turbine to capture the maximum power from the wind turbine [4]. If the power capacity of wind generators becomes large, wind generator output can have an influence on the power system frequency ([5]-[8]).

From the previous study ([1], [3], [4]), it is seen that when single SG or several SGs are connected with networks, only governor control system model & conventional pitch controller cannot maintain the power system frequency to the desired level and severe situation occurs when wind power penetration becomes 10% of the total capacity. But this study investigates the influence of a new modified pitch controller & governor control system and it is observed that system frequency can be maintained in acceptable range when several interconnected SGs are operated with different governor control modes where the load is considered variable and wind power capacity is 10% of the total capacity.

In [5] the authors applied a new pitch control system where the reference power is considered variable. Thus the frequency can be controlled up to a certain limit of wind generator capacity by losing some amount of energy. However, in our study energy can be the same, which is more economical. In fact voltage can not be controlled by their pitch control system.

As the wind power penetration increases day by day, this study plays a vital role for power system application. It is seen from the study that the modified pitch control and governor control system model can maintain the frequency as well as voltage in acceptable limit with high wind power penetration. As a result, energy storage devices can be avoided which reduce the total cost of the system.

II. Model System For Simulation Analysis

The model system used in the simulation analysis is shown in Fig. 1. The model system consists of five wind generators (IG), a hydropower generator, HG (a salient pole synchronous generator, SG1), two thermal power generators, TG (cylindrical type synchronous generators, SG2 and SG3), a nuclear power generator, NG (a cylindrical type synchronous generator, SG4) and three loads. SG1 and SG3 are operated under load frequency control (LFC), SG2 is under governor-free (GF) control and SG4 is under load limit (LL) operation [9] which are all clearly indicated in the figure below.

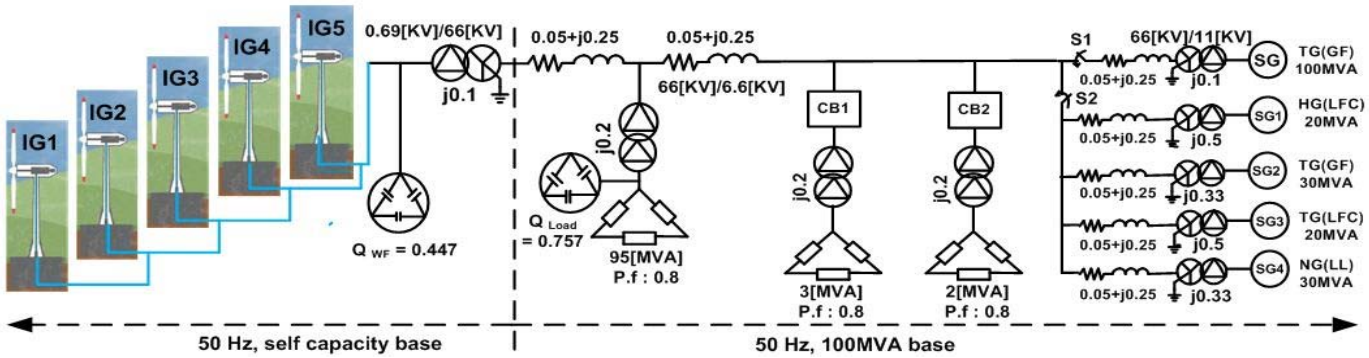

Fig. 1 Model circuit.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Q_{WF} and Q_{Load} are capacitor banks where Q_{WF} is used at the terminal of IG to compensate the reactive power demand of wind generator at steady state. The value of the capacitor is chosen so that the p.f. becomes unity, when the wind generator operated in the rated condition. On the other hand, Q_{Load} is used at the terminal of load to compensate the voltage drop by the impedance of transmission lines. Here circuit breakers CB1 and CB2 are used to control the load as a variable load. Core saturations of induction generator and synchronous generators are not considered for simplicity. The initial power flow and initial conditions are taken from [3].

III. Synchronous Generator Model

A. Governor for Hydro and Thermal Generators[3]

The governor models used in the simulation analyses are shown in Fig. 2 and Fig. 3 respectively. The values of 65M and 77M of different SGs are shown in Table I. Where, Sg: the revolution speed deviation (pu); 65M: the initial output (pu); 77M: the load limit (65M + rated MW output × PLM (%)); PLM: the spare governor operation (%); Pm: the turbine output (pu). PLM for SG2 is set 5% and for SG4 PLM is set 20% because the nuclear generator output (SG4) is controlled constantly (LL, load limit operation).

For governor-free (GF) operation, When PLM > 0

65M = the initial output (pu)

77M = 65M + rated MW output × PLM (%)

For load limit (LL) operation, When PLM < 0

65M = 77M + rated MW output × PLM (%)

77M = the initial output (Pu)

Sg is set zero for SG1 and SG3 because these generators are operated under LFC to control frequency fluctuations with a relatively long period.

B. Load Frequency Control Mode [4]

In the Load Frequency Control (LFC) model, the output power signal is sent to each power plant when the frequency deviation is detected in the power system. After that, governor output value (65M) of each power plant has changed by LFC signals and then the output of power plant is also changed. The LFC model is taken from [4].

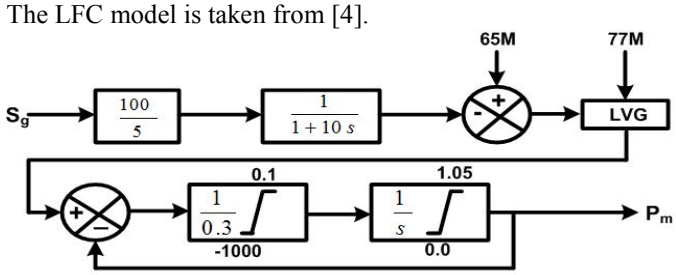

Fig. 2 Model of hydro governor.

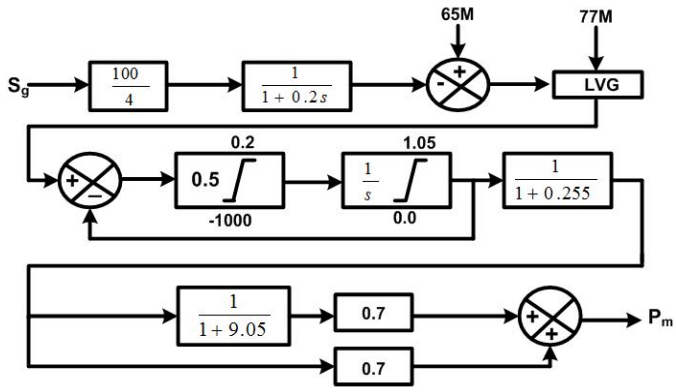

Fig. 3 Model of thermal governor.

TABLE I
Values of 65M and 77M for Multiple Generators

SG1 (Hydro)		
Frequency Control	65M	77M
LFC	LFC signal	1
SG3 (Thermal)		
Frequency Control	65M	77M
LFC	LFC signal	1
SG2 (Thermal)		
Frequency Control	65M	77M
GF	Starting Value=0.653 Running adjustment If f > 50.2 then 65M = 0.70 If f < 49.8 then 65M = 0.62	0.767
SG4 (Nuclear)		
Frequency Control	65M	77M
LL	0.96	0.80

IV. Modified Pitch Controller

The newly designed pitch controller is shown in Fig. 4 and its purpose is to maintain the output power of the wind generator at rated level by controlling the blade pitch angle of turbine blade when the wind speed is over the rated speed. Generally, the blade pitch operation system is complicated, but this paper simulates the pitch operation system by using a first order time delay system with time constant T_w = 5 sec. In addition, the pitch angle can not be changed instantly due to the rotational inertia of blade and mechanical limitations. Therefore, the rate of change of pitch angle is limited to 10 degrees per second in the simulations. Also this controller can detect the frequency levels whether it is beyond or bellow the acceptable level. Thus this controller can also generate new pitch angle for the wind turbine if the frequency is beyond the acceptable level. Beside this, the modified pitch controller can adjust the initial input to the thermal governor i.e. 65M (shown in Fig. 2 and Table I) by comparing the following (1) and (2) to maintain frequency to the desired acceptable range. The comparator and control circuit as shown in Fig. 5 is used to adjust the initial input i.e. 65M for the governor with the addition to pitch controller.

If f > 50.2 then 65M = 0.70 (1)

Or If f < 49.8 then 65M = 0.62 (2)

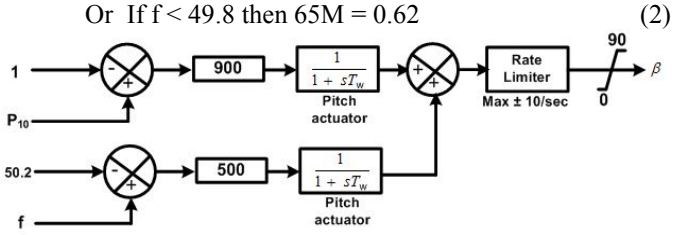

Fig. 4 Modified pitch control system.

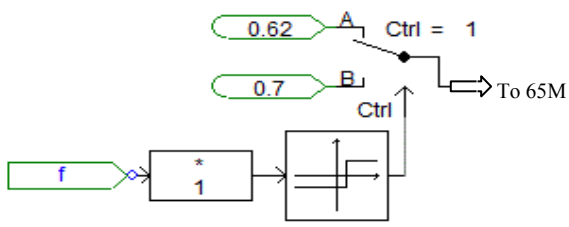

Fig. 5 PSCAD control box.

V. Simulation Analyses

In this paper, simulation analyses have been compared by using both conventional and newly designed pitch controller and the analyses have been carried out to investigate the performance of the new pitch controller & governor control system with high wind power penetration using real wind speed data, which are measured in Hokkaido Island, Japan. Simulation combination shows in Table II. In this study, it is considered that five wind generators experience different five wind data as shown in Fig. 6. The simulation analyses have been performed by using PSCAD/EMTDC [10].

TABLE II
Simulation Pattern

No. of Cases	SG	Rating (MVA)	Total Capacity (MVA)
Case 1	TG(GF)	100	100
Case 2	HG(LFC) TG(GF) TG(LFC) NG(LL)	20 30 20 30	100

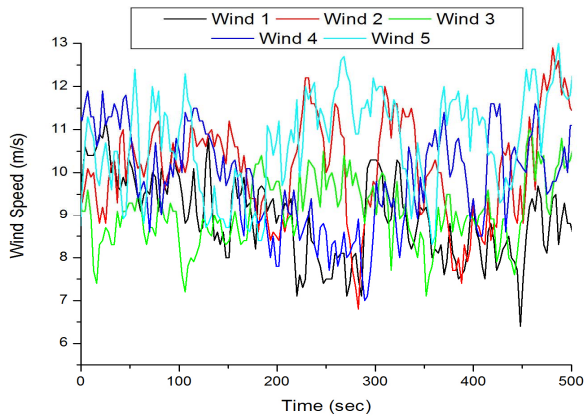

Fig. 6 Wind speed data.

Fig. 7 shows the grid voltage, where the fluctuation is comparatively less for modified pitch controller then conventional pitch controller. Fig. 8 shows the total load that varies between 74MW to 80 MW and Fig. 9 represents the synchronous generator power output which fluctuates more at the time of load change. From Fig. 10 it is seen that when modified pitch controller is used, frequency fluctuation is comparatively less but energy remains almost the same (from Fig. 11) and the variation of pitch angle for wind 5 corresponds to IG5 is shown in Fig. 12.

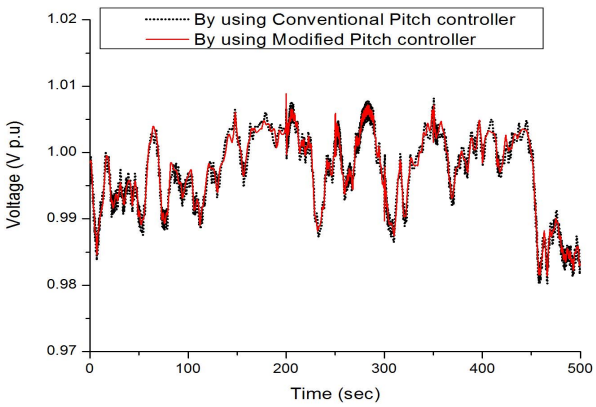

Fig. 13 Response of output voltage [case 2].

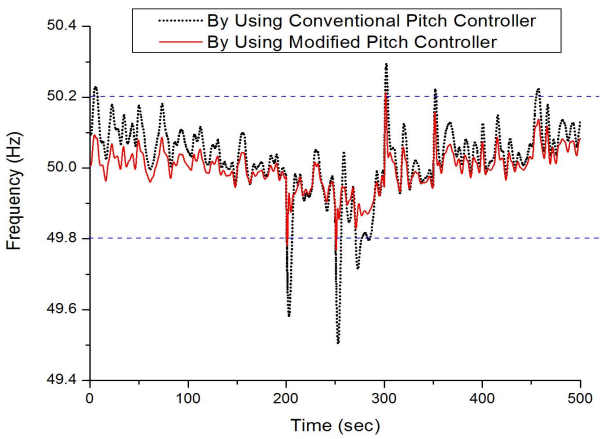

Fig. 14 Response of output frequency [case 2].

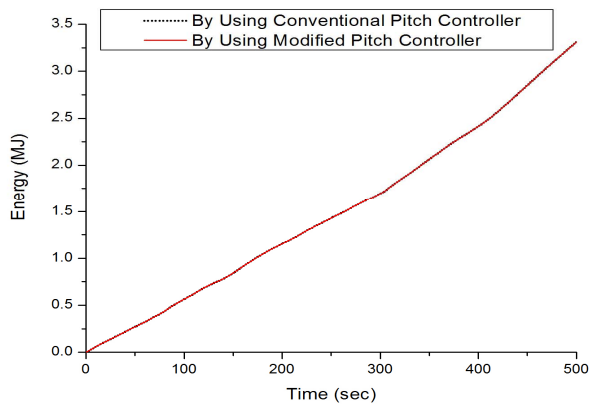

Fig. 15 Response of output Energy [case 2].

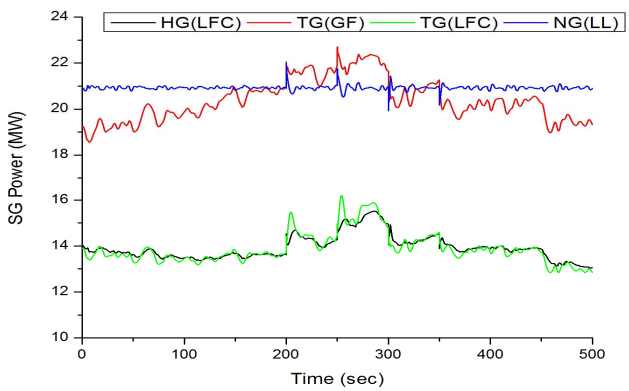

Fig. 16 Response of SGs real power [case 2].

Fig. 13 and Fig. 14 represent the output voltage and frequency which fluctuate less without any energy loss (from Fig. 15) when modified pitch controller is used. The outputs of four SGs are shown in Fig. 16.

VI. Conclusions

A permissible range of power system frequency deviation provided by the most of the developed countries is within ± 0.2 [Hz]. As frequency is one of the measures to determine the quality of electric power, this study focuses on the influences of a modified pitch controller and governor control system model when variable load and different types of governor control system are considered. It is confirmed from the above simulation results that the modified pitch control and governor control system are able to maintain the frequency fluctuations within acceptable level when high wind penetration is considered. It is also cleared that the newly designed control system can maintain frequency without any loss of energy. Thus energy storage device can be neglected.

Abstract—**A hybrid energy system consists of two or more renewable or conventional energy sources used together to provide efficient power supply. In this paper, a new and evolving hybrid power system has been designed by integrating different types of biomass and diesel. This system can ensure an uninterrupted power generation irrespective of the weather condition and supply of biomass. This system can also ensure maximum utilization of biomass energy sources which will reduce the dependency on the limited fossil fuels like oil and coal those are environmentally harmful.**

***Index Terms*—Hybrid power system, biomass, diesel, renewable diesel.**

I. Introduction

Hybrid energy technology is the latest innovation in the field of energy sector which is often done either to reduce the cost of generating electricity from fossil fuels or to provide backup for a renewable energy system that ensures continuity of power supply when the renewable energy source fluctuates. Hybrid energy usually consists of one conventional energy source and another would be renewable energy source like solar photovoltaic, wind, biomass, hydro etc.

However, a lot of requirements have to be considered first for the implementation of hybrid system. The most important factors are time, location and power demand. Location associates information about climate, energy sources availability and environment conditions. This information is very important to decide what kind of renewable source can be chosen [1]. Biomass-diesel combination can be a very effective choice because biomass is an easily available, eco-friendly renewable source of energy and it does not vary considerably with the change of weather, temperature or season. Moreover, it can address limitations in terms of fuel flexibility, efficiency, reliability, emissions and economics. In this paper, the proposed biomass – diesel hybrid system design is more applicable where different types of biomass are available and can easily be processed. This can emerge as a pragmatic solution to the energy crisis for any agricultural and overpopulated countries where amount of solid waste generation is abundant.

II. Energy Sources

There are mainly two types of energy sources, non-renewable energy sources and renewable energy sources.

A. Non-renewable Energy Sources

Non-renewable energy sources are not replaced or replaced very slowly by natural processes such as oil, coal and coal derivatives, natural gas, diesel and radioactive atoms (uranium). Most of them dispose great amount of green-house gases while burning and responsible for global warming and climatic change.

B. Renewable Energy Sources

Renewable energy is generally defined as energy that comes from resources which are continually replenished on a human timescale such as sunlight, wind, rain, tides, waves, biomass and geothermal heat [2]. Biomass is a renewable source of energy because the waste residues will always exist in terms of scrap wood, mill residuals or forest resources. As plants use atmospheric CO_2 in the process of photosynthesis which completes the carbon cycle, so it is renewable. The carbohydrate produced by photosynthesis is in fact the source of biomass.

III. Biomass Quality Analysis

Quality analysis of biomass is an important parameter to use it as an effective energy source. Biomass qualities are affected by mainly two factors- internal factors and external factors.

A. Internal Factors

Internal factors are the constitutional factors that affect the variation of biomass heating value radically. These are fixed carbon, volatile substances, ash content and water content.

Composition of twenty different biomass samples has been observed which can be used as fuel for the power generation [3], [4].

TABLE I
Different Types of Biomass and Their Composition

Biomass Type	Fixed Carbon (%)	Water Content (%)	Ash Content (%)	Volatile Matter (%)
1.Wood(dry)	14.5	7.8	0.2	77.5
2.Sugarcane	11.1	10.4	1.9	76.6
3.Coconut shells	22.0	4.4	3.1	70.5
4.Musturd husk	22.0	5.6	3.9	68.5
5.Bamboo whole	15.2	13.0	0.8	71.0
6.Wheat straw	16.3	10.1	6.4	67.2
7.Rice straw	14.4	7.6	18.6	59.4
8.Rice husks	17.2	10.6	16.1	56.1
9.Miscanthus grass	14.0	11.4	2.7	71.9
10.Buffalo gourd	12.3	10.0	4.2	73.5
11.Eucalyptus bark	15.1	12.0	4.2	68.7
12.Wood residue	12.2	26.4	4.0	57.4
13.Sawdust	9.3	34.9	0.7	55.1
14.Fir mill residue	6.5	62.9	0.2	30.4
15.Forest residue	7.3	56.8	1.4	34.5
16.Furniture waste	11.8	12.1	3.2	72.9
17.Wood agri-residue	12.7	30.3	2.3	54.7
18.Biomass mixture	16.5	8.8	11.4	63.3
19.Mixed waste paper	6.8	8.8	7.6	76.8
20.Land-clear wood	7.0	49.2	8.4	35.4

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

B. External Factors

Extensive care should be taken for external factors. Among these external factors, moisture content is the important one. Most boilers are designed to operate with fuel of limited moisture range. If the fuel is used outside this range, the boiler will either operate inefficiently leading to increased emissions or trip out the control system and fail to function at all. It is very important to find out the specification of correct moisture content range of boiler from the manufacturer. In the case of purchasing wood fuel by weight, moisture content is critical parameter to know how much are paying for energy [5].

Based on biomass quality analysis and availability of sources, biomass can be classified into four categories-

1) Biomass Type-1: Biomass having moisture content less than 30% has been classified as Biomass Type-1.

2) Biomass Type-2: Biomass having internal moisture content more than 30% has been classified as Biomass Type-2.

3) Biomass Type-3: All types of sewage and human or animal waste that are used to produce biogas have been classified as Biomass Type-3. Biogas is produced by anaerobic digestion with anaerobic bacteria or fermentation of biodegradable materials such as manure, sewage, municipal waste etc. It is primarily methane (CH_4) and carbon dioxide (CO_2) and may have small amounts of hydrogen sulphide (H_2S), moisture and siloxanes [6]. The gases methane, hydrogen and carbon monoxide (CO) can be combusted or oxidized with oxygen. This energy release allows biogas to be used as a fuel.

4) Biomass Type-4: Special type of biomass which can produce renewable diesel has been classified as Biomass Type-4. It can be produced either by Engineered Bacteria (*Escherichia coli*) or by Hydropyrolysis [7]. This green diesel can be used alone or blended with petrodiesel in any proportions as fuel.

TABLE II
BIOMASS CLASSIFICATION FOR HYBRID SYSTEM DESIGN

Biomass Type	Description	Examples
1	moisture content less than 30%	wood, wheat straw, rice husk, coconut shell, sugarcane etc.
2	moisture content more than 30%	sawdust, fir mill residue, forest residue, agricultural residue, land clearing wood etc.
3	sewage, human or animal waste	cow dung, poultry litter etc.
4	producing green diesel	vegetable oil, animal fat (algae, jatropha etc.)

Fig. 1 shows the scatter-diagram of different biomass samples where some lies in Biomass Type-1 zone and other in Biomass Type-2 zone.

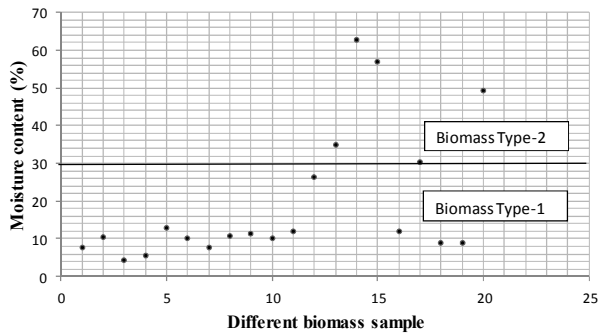

Fig. 1 Scatter-diagram of different biomass samples.

IV. DESCRIPTION OF THE DESIGN

Fig. 2 shows the design of a hybrid power system where different components have been integrated to produce electricity from biomass and diesel with reliability and efficiency.

Biomass Type-1 which is readily combustible is provided into the combustion unit with sufficient air supply. On the

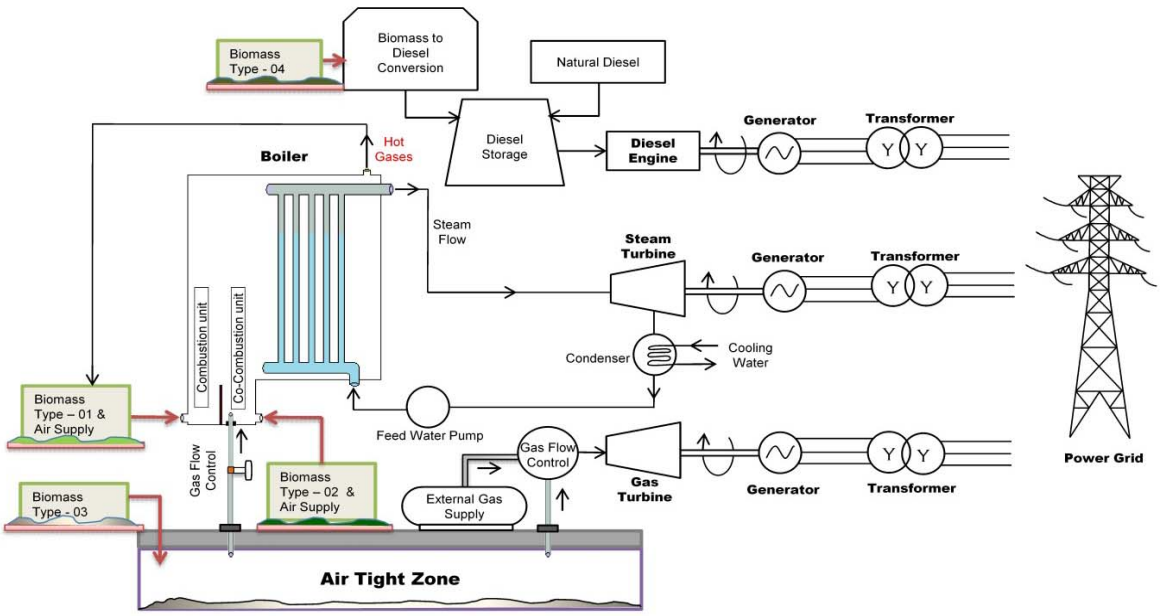

Fig.2 Biomass-diesel hybrid power system design.

other hand, Biomass Type-2 and biogas from airtight dome are provided into the co-combustion unit with sufficient air supply. In air tight zone, biogas is produced using Biomass Type -3 by anaerobic digestion process or fermentation. Biogas produced in this zone is supplied to both co-combustion unit and gas turbine via gas flow control valves.

Due to biomass quality variation, heat generation rate in co-combustion chamber differs significantly. To maintain constant heat generation in co-combustion unit, a valve senses temperature and pressure of the chamber and allows the effective flow rate of gas using the feedback. Another valve is interfaced between air tight zone and gas turbine. An external gas supply is also connected to the control valve to ensure necessary flow rate of gas in the gas turbine.

Steam from boiler is used to drive the steam turbine. A condenser is used for the purpose of condensing the exhaust steam from the turbine to reuse in the cycle and to maximize turbine efficiency by maintaining proper vacuum. A pump is used to feed the condensed water into the steam boiler. Moreover, the exhaust hot gases from the boiler unit are utilized for drying up Biomass Type-1 hence reducing the inherent external moisture content in it.

To ensure scheduled power supply to the power grid, a diesel backup system has been introduced in the design. Biomass Type-4 is used to produce diesel known as 'renewable diesel' by different bio-chemical processes. It is both non-toxic and renewable as it essentially comes from plants and animals which can be replenished through farming and recycling.

Other conventional components of power generation system are- generator, transformer, diesel engine, control unit etc.

V. Conclusions

The proposed hybrid design presented in this paper is less susceptible to weather variation than solar and wind based power system because solar energy is always dependent on intensity of day light whereas wind energy varies significantly with seasonal variation. The integration of the presented hybrid system with solar or wind power system can provide a cost effective solution throughout the year. Moreover, as the hybrid power system contains conventional components like boiler, turbine, generator etc., it is easy to implement practically.

Design and Optimal Cost Analysis of Hybrid Power System for Kutubdia Island of Bangladesh

Amit Kumar Sikder,[1,*] Nishat Anjum Khan,[1] and Aminul Hoque[1]
[1] Department of Electrical and Electronic Engineering, Bangladesh University of Engineering and Technology, Dhaka-1205, Bangladesh
[*] amitkumarsikder@gmail.com

Abstract— **Hybrid power system is the newest idea of utilizing renewable energy resources for generating electricity. Power generation largely depends on fossil fuel and as the total amount of reserved fossil fuel is decreasing we have to search for new resources for power generation. Hybrid power system usually demonstrates lower cost of production and higher reliability than the power system only using one renewable source. Geographically, Bangladesh is situated in an area having many renewable resources. Utilization of these resources could help to minimize the power crisis of Bangladesh. As Bangladesh has a large coastal area, we can have moderate wind speed and tidal wave throughout the year. A hybrid power system utilizing wind and tidal energy will be effective to generate power in the coastal areas. This paper shows the design and optimal cost analysis of a hybrid power system using wind and tidal energy in the Kutubdia island of Bangladesh.**

Index Terms—**Hybrid power, Optimal cost, Energy resources, Operating cost.**

I. Introduction

Bangladesh is a developing country having a population over 160 million [1]. The total demand of electricity is increasing with time and energy crisis have become a severe problem for Bangladesh. Total demand of electricity has been raised to over 7000 MW. The electricity demand is increasing day by day which is also expected to be doubled within 2020 [2]. Only 31.2% of the total population is connected to grid electricity (80% of urban and 23% of rural households), with the vast majority being deprived of a power supply [3, 4].The main source of power generation is using natural gas. But the total reserve of gas is decreasing. So, the search for new source of energy is essential in the context of Bangladesh.

.

Hybrid Power Generation, as the name implies, combine two or more mode of power generation together usually using renewable technologies. Hybrid power systems are designed for the generation of electrical power. They are generally independent of large centralized electric grids and are used in remote areas. Hybrid systems by definition contain a number of power generation devices such as wind turbines, photovoltaic, micro-hydro and/or fossil fuel generators. Hybrid power systems range from small systems designed for one or several homes to very large ones for remote island grids or large communities.

Geographically, Bangladesh is situated between 20.30 and 26.38° north latitude and 88.04 and 92.44° east longitude. In the southern portion of the country, the Bay of Bengal is situated which is a big source of tidal energy. We have many rivers flowing over the country and meet the Bay of Bengal. In these outfalls, tidal height and tidal flow both are high and suitable for harnessing energy. Wind flow is also reasonable in these coastal areas of Bangladesh. So, it is feasible to implement a hybrid power system in the coastal area of Bangladesh. Implementation of hybrid power system in the coastal area could solve energy crisis to some extent.

II. Energy Resources for Hybrid System

To design an optimal hybrid energy system it is important to select suitable energy resources. Bangladesh is blessed with many renewable energy resources and since Kutubdia is in the coastal region, so tidal and wind resources are selected for this work as there is availability of high tidal range and wind velocity. The optimal design is performed with the HOMER (Hybrid Optimization Model for Electric renewables) software and economic system is obtained to find the feasibility of our proposed system.

A. Wind Resources

The wind velocity over Bangladesh differ from 3m/s to 9 m/s at different height during month March to September and according to Bangladesh Metrological Department (BMD) the wind speed is high during March to September monsoon and low during October to February in Bangladesh [5]. Kutubdia is a coastal area along the line of Bay of Bengal. In the area near Bay there is enough wind speed to produce electricity commercially. The wind speed data at Kutubdia is collected from LGED [6] at height 20m. Figure 1 shows the monthly average wind speed at Kutubdia over a year.

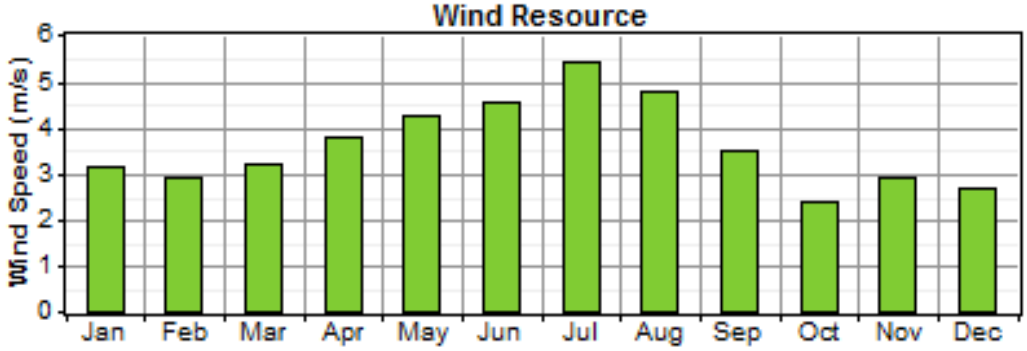

Figure 1: Wind speed variation per month.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

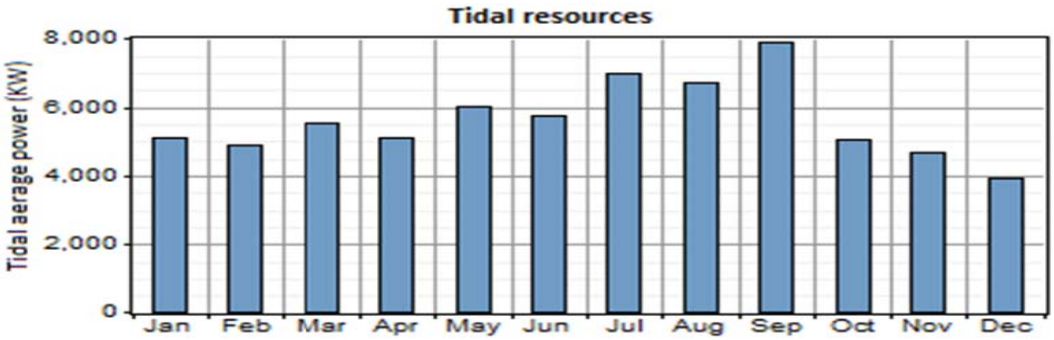

Figure 2: Average tidal power per month.

Wind energy is a special kind of kinetic energy in air as it flows. The power extracted by wind energy can be calculated by $P=1/2\rho AV^3$ formula [7]. Where, A is the area perpendicular to direction of flow (m^2), V is the wind velocity (m/s) and ρ is the air density (kg/m^3). Only a part of this power can be extracted. Under ideal condition maximum power that can be extracted is 59.3% of available power [5]. For wind speed calculation the weibull (k) constant, autocorrelation factor, diurnal pattern strength and hour of peak wind speed is needed in HOMER. For the selected site k is considered 2.17, autocorrelation measures the randomness of the wind which is considered 0.914. Diurnal pattern measures how strongly wind speed depends on the time of the day. This is considered 0.161 and hour of peak wind speed is considered 15 hours which considered the time of the day to be windiest on average throughout the year.

B. Tidal Resources

The energy extracted from the tides can be obtained from both the vertical water movements associated with the rise and fall of the tides. Potential energy or the kinetic energy which is the result of the roughly horizontal water motions termed as tidal currents. For these reasons tidal power harnessing technology can be categorized into two main types, tidal barrages and tidal current turbines [8]. Tidal barrages technology is selected for our designed system. For tidal barrage system we can extract energy from tide by two processes, one way tidal generation and two way tidal generation system [8, 9].

Two way generation system is selected for this proposed project, since the average output power getting from this system is more than one way generation system. The total power for two way power generation is $\eta \times 0.113\ AR^2$ [10]. Where, A is the basin area (m^2), R is the tidal range (m) and η is the efficiency of the turbine. Figure 2 shows the monthly averaged tidal power at Kutubdia over a year.

III. Design of Hybrid System

A hybrid energy system for Kutubdia is designed where tidal and wind power generation is combined with diesel generator. Diesel generator has been chosen because of its availability and its low cost comparing to other generator in Bangladesh. A hybrid system consists of primary energy sources which work with parallel to the secondary energy units. HOMER has been used to optimize the best efficient system for Kutubdia considering different load and tidal-wind and diesel combination. Figure 3 shows a design of hybrid system as implemented in HOMER.

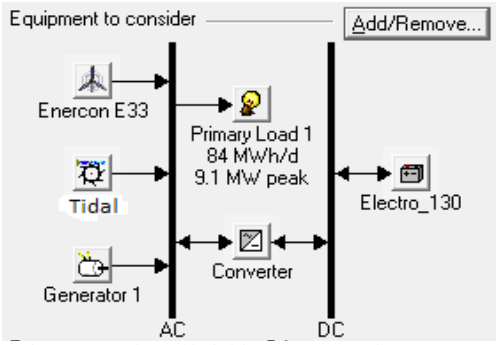

Figure 3: Design of hybrid power system in HOMER.

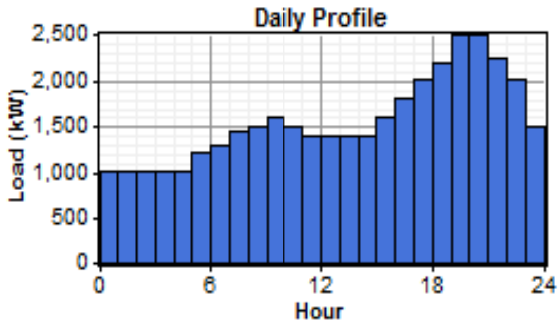
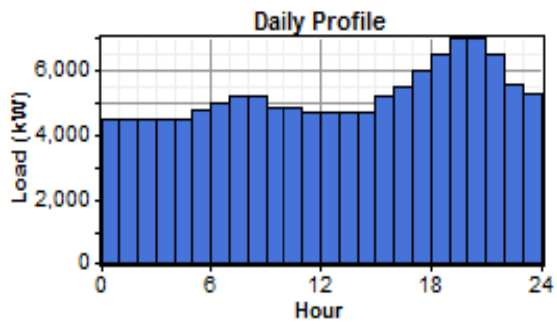
A. Electric Load Profile

An electrical load profile is the basis for design of hybrid energy system in HOMER. Load profile is actually the determination of electric load in an area according to a definite time period. Kutubdia is a coastal area of Bangladesh. The density of population is 580.6/km^2 and total population is around 150000 [11]. Each household is considered to consume 3 energy efficient bulbs (20W), 2 ceiling fans (60W). [12] The daily average uses of bulbs and fans are 8-9 hours and 12-13 hours respectively during the summer time and it varies from summer to winter. The total family is assumed 35000 and the load profile for January (winter) and May (summer) is shown in Figure 4



(a)



(b)

Figure 4: Load profile for winter (a) and summer (b)

B. Wind Turbine

The average wind speed in Kutubdia is measured 3.637m/s at 20 m height. From this we can measure wind speed at 50m which is 4.61m/s [13]. this velocity differs from summer to winter so cut in speed of wind turbine should be around 3m/s. Enercon E48 is suitable for low wind velocity and its cut in speed is 2.5m/s at height 50. Its rated power is 880KW AC and works in 50Hz which is suitable for Bangladesh. Enercon offers 15 years comprehensive operation and maintenance warranty reducing risk during the wind turbine operation [14]. The installation cost of Enercon E48 is $500000 and it offers most cost effective project even at site of difficult access. The lifetime of Enercon E48 is considered 25 years [14].

C. Tidal Turbine

In HOMER there is no block for tidal turbine, so the hydro block is modeled in such a way that it works as a tidal turbine block. For this the available head is assumed 101.9m, the designed maximum flow rate is assumed 4500L/s and efficiency is considered 100% so that the steam flow rate is equal to the tidal output power.

D. Diesel Generator

Diesel generator is used for the backup generation for this design of hybrid system. Diesel generator is worked in parallel with wind and tidal energy system to increase the efficiency. The installation cost of diesel generator is $18000 with operating cost $0.5/hr and minimum load 30% is provided by generator. The price of diesel is used $0.85.

E. Converter and Battery

A converter is used for AC-DC converter. $310 is considered for the cost of 2kW converter and efficiency is assumed 75%. The operating and maintenance cost is assumed $50/yr and lifetime for a converter is considered 15 years. Since in Bangladesh maximum rated capacity is 130-150Ah so a battery named electro_130 is created in HOMER with nominal capacity 130Ah and operating voltage 12 volt which has maximum energy storage 1.56kwh. The cost is considered $190 for per battery.

IV. Simulation Result and Analysis

The designed hybrid system will provide power to all the people in Kutubdia throughout year. Simulated result of HOMER gives an optimized result to meet the load demand in Kutubdia.

A. Optimization Result

The optimization result in homer is based on COE (cost of energy). The leveled COE for the best feasible result is $0.054/kWh, the total NPC (Net Present Cost) is $21,186,998 and operating cost is $84,062/yr. The detailed optimization cost for best possible combination of tidal-wind-diesel is shown in Figure 5 and Table I.

B. Simulation Result

The optimization result getting from HOMER simulation gives the best possible combination of energy resources to meet the demand. The optimized combination of tidal-wind-diesel is 22% of wind, 78% of tidal and very few of diesel generator which is near to 0%. Figure 6 shows the contribution of energy resources in the total power supply.

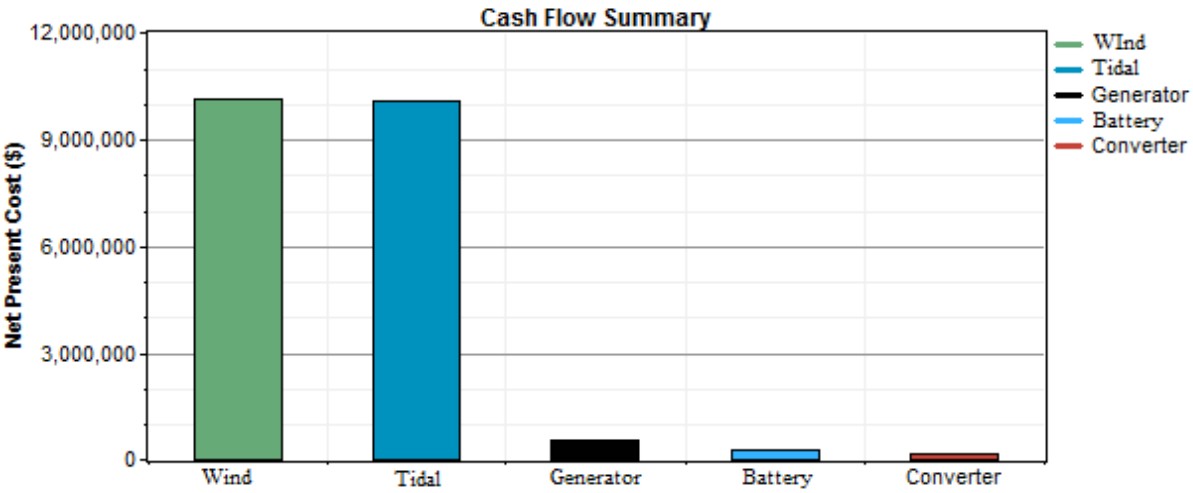


Figure 5: Cash flow bar chart

TABLE I. Optimizing Cost of Hybrid Power Designed System

Energy component	Initial Capital($)	Replacement ($)	Operating and Maintenance Cost($)	Fuel Cost ($)	Total cost ($)
Wind turbine	10,000,000	0	127,834	0	10,127,835
Tidal	10,000,000	0	63,917	0	10,063,917
Diesel Generator	5,400	1,831	1,685	556,198	564,498
Battery	76,000	122,083	76,700	0	274,784
Converter	31,000	61,042	63,917	0	155,959

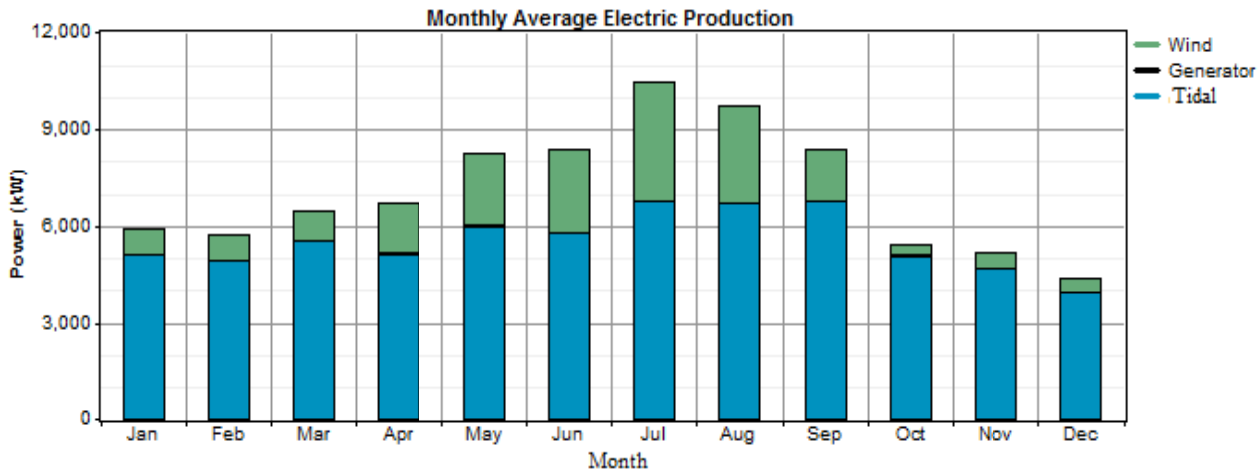

Figure 6: Monthly average power generation in the designed system

C. *Environmental Analysis*

Due to the reduction of fuel consumption the proposed design of hybrid system reduces the gas emission. The emission of the gases is calculated by HOMER software are given in Table II

TABLE II. ENVIRONMENTAL EFFECTS ON HYBRID POWER DESIGNED SYSTEM

Pollutant	**Emission (kg/yr)**
Carbon dioxide	134,794
Carbon monoxide	333
Unburned hydrocarbons	36.9
Particulate matter	25.1
Sulfur dioxide	271
Nitrogen oxides	2,969

V. CONCLUSION

Bangladesh is blessed with renewable resources and using it in power generation can be really effective in solving energy crisis of the country. The remote coastal areas which are not connected in the national grid can be supplied with electricity by implementing hybrid power system. Due to high diesel cost only diesel based power generation is not economically feasible. At the same time due to the intermittent nature of renewable sources and high initial cost of renewable energy technology, large scale power generation with only tidal or wind turbine is not economically feasible. So, a hybrid power system with more than one renewable energy source is economically suitable and sustainable system. According to the simulation results the projected hybrid system is economically feasible as decentralized or grid interactive system. We can install such power system for harnessing energy from renewable sources.

Abstract—**In recent years, several accidents in pioneer gas processing industries led industries to put emphasis on real-time fault detection. Neural Network (NN) based fault (abnormal situation) detection technique played an important role in monitoring industrial safety. In this work, an attempt has been made to study the fault detection of Brahmanbaria gas processing plant using multi layered feed forward NN based system. NN based fault detection system is trained, validated and tested using data generated using the dynamic model. Preliminary results show that NN based method is able to detect the faults of Brahmanbaria Gas processing plant for fewer no of faults.**[*]

Index Terms— **Neural Network, Fault detection, GasProcessing Plant, Industrial Safety Management.**

I. Introduction

Natural gas (NG) plays an important role in different sectors such as power generation sector, fertilizer, industrial and commercial sector in Bangladesh [1-2]. There are many gas producing fields in Bangladesh. Although process safety technology has been gradually implemented over the years, several accidents happened in gas field industry in Bangladesh like BGFCL, Nikko, Occidental, Tullow, and Chevron. Massive blowout took place in Occidental and the similar incident happened at Tengratila by Nikko. Major gas leakage was found in Titas Gas Field (BGFCL) [3-5]. Still, the process plants face difficulties due to lack of proper monitoring. Bangura gas plant was shut down for lacking proper monitoring [3-5] and the Bibiyana gas plant was shut down to repair a leaking gasket. Large gas processing plant consists of thousands of measurements, hundreds or thousands of controllers and many recycle streams. To reduce the frequency and consequences of accidents of chemical process operation, classical methods for fault detection are implemented. However, classical methods for fault detection in industries depend on human supervision and expertise. Again, operator of modern plant is saturated by alarm of supervisory control and data acquisition (SCADA) and Distributed control system (DCS) and difficult to manage the multiple fault simultaneously. Therefore, the above incidents clearly show the necessity of pro-active real time techniques for fault detection. A number of real-time monitoring techniques for chemical and petrochemical processes, such as extended kalman filter, signed diagraph, qualitative simulation, statistical method and neural network has been suggested in literature [6-12]. The use Neural Networks (NNs), in all aspects of process engineering activities, such as modeling, design, optimization and fault diagnosis, error detection, data reconciliation etc. has been considerably increased in recent years [8,11,12]. To the best of our knowledge, there has been no work reported in literature on using NN based fault detection system for gas processing plants in Bangladesh.

In this work, the steady state model of Brahmanbaria gas processing plant is developed using Aspen HYSYS and is validated using real plant data. Then, the dynamic model of the plant is developed from steady state model to understand the real plant behaviour and plant disturbances. Finally, an attempt has been made to study the fault detection of Brahmanbaria gas processing plant using NN based system. Early malfunction of liquid control valve in the plant is distinguished by using NN based Fault detection system from various parameters.

II. Brahmanbaria Gas Process Plant

Aspen HYSYS is user friendly software for simulation of chemical plants and oil refineries [13]. In this process (Fig.1) gas steam from air cooler flows through two phase vertical separator where, liquid separates from the gas. The overhead product gas passing through gas-gas exchanger, the gas goes to another two phase vertical separator where the bottom liquid product goes to liquid storage tank preheated by steam heater. The heavier hydrocarbon collected in the liquid storage tank is pumped to a distillation column with twenty trays.

III. Neural Network Fault Detection Scheme

Any non-linear relationship between input and output of a system can be captured effectively using NNs. NNs are consist of a large number of primitive computational elements called neuron. NN based fault detection are based on classification of historic process knowledge. The development of the NN based system involves selecting suitable architecture to differentiate between the fault of the process with the normal condition. The steps of NN based fault detection system in this work is shown in Fig. 2 and Fig. 3. NN is trained, validated and tested are similar to stated as [10] is shown in Fig. 4 and Fig. 5. Historic data of 10 key variables which affects the different mode of operations (types of faults and normal) is fed to the input layer and mode of operations fed to the output layer of the NN. NN is trained, validated and tested using dynamic data. Several multi layered feedforward neural networks with varying configurations and Levenberg Marquardt back propagation algorithm are also employed in the training and testing process of the to obtain optimum neural network architecture.

IV. Results And Discussion

Table I shows the design specification of the Brahmanbaria Gas processing Plant Model (Fig. 1) within Aspen HYSYS. 1700 sample data for key parameters from the normal situation to each type of faults are simulated using Aspen HYSYS simulator. The key data (Table III) of different normal operation mode using Aspen HYSYS simulator are shown in chart forms from Fig. 6 and sample fault (Table II) in the process plant generated using dynamic model are shown in chart forms from Fig. .7. However, visually distinguished such data pattern is quite difficult.

Those data for each key parameters are monitored by NN based fault detection system and fed to neural network input layer (Table III). Types of Operation Mode/Disturbance Criteria (Table II) is integrated with Output layer Neuron of NN based system. Neuron of output layer for each states value equal to 1 and for absent of the states value equal to 0 (Table IV). Data sets are sorted to avoid uneven distribution. All data are scaled to the symmetrical range of -1 to +l.

TABLE I

TABLE III
TYPES OF OPERATION MODE/DISTURBANCE CRITERIA

Different states (normal and abnormal) and Output layer Neuron	**Operation Mode/Disturbance Criteria**		
	Normal operation	Tower valve open	Tower valve close
		VLV-203 & 304 open	VLV-203 & 304 close

TABLE IV
NN ARCHITECTURE FOR DIFFERENT CONDITIONS

Condition	**Normal**	**Abnormal**			
		Tower valve open	**Tower valve close**	**VLV-203 & 304 open**	**VLV-203 & 304 close**
NN output layer	$\begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}$	$\begin{bmatrix}0\\1\\0\\0\\0\end{bmatrix}$	$\begin{bmatrix}0\\0\\1\\0\\0\end{bmatrix}$	$\begin{bmatrix}0\\0\\0\\1\\0\end{bmatrix}$	$\begin{bmatrix}0\\0\\0\\0\\1\end{bmatrix}$

Training of NN Fault detection system is shown in Fig. 8. The statistical regression plots of (Fig. 9 to Fig. 10) between predicted and target data of different operation mode are plotted. Network architecture is updated until the regression value is almost close to 1. Optimum network is found for this work with 9 neurons in hidden layer.

However, If the setpoint of normal operation is changed whose response is not similar to the training pattern network, NN fault detection might detect as normal operation. Hyperbolic tangent functions are used in the input and hidden nodes. Linear functions are used in the hidden layer and output nodes.

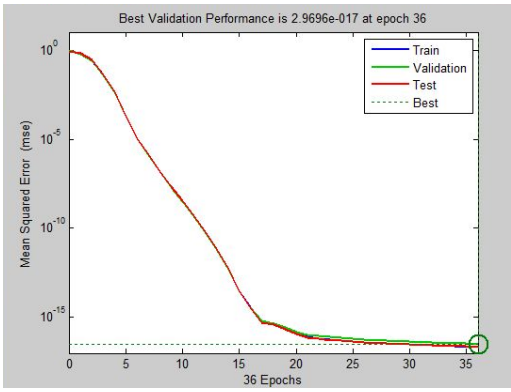

Fig. 8 Training of NN Fault detection system

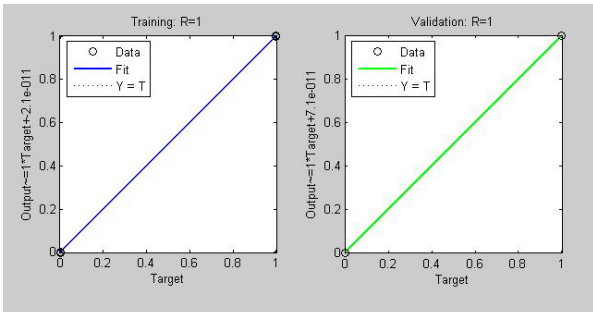

Fig. 9 Regression analysis of NN predicted data with Fault

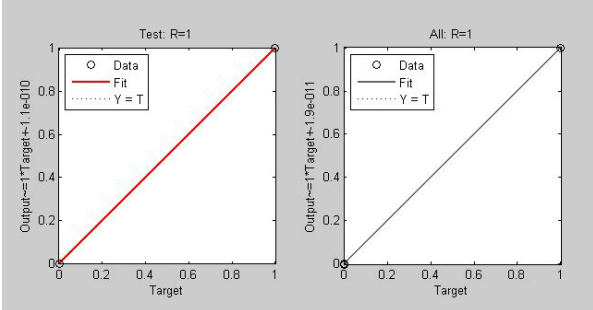

Fig. 10 Regression analysis of NN predicted data with Fault

Predictions by optimum NN within the training range follow the expected trends and it is within the engineering accuracy (Fig. 11 and Table V). This probe that optimum network able to predict types of fault (here liquid control valve failure for product quality loses) even when the network is with new inputs (test data).

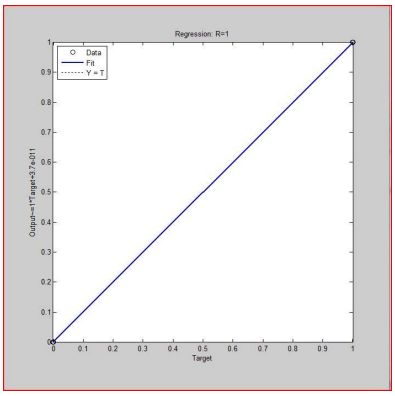

Fig. 11 Regression analysis of NN predicted test data

V. Conclusions

The priority of fault detection is increasing. Brahmanbaria Gas Plant behaviour and disturbances are studied using HYSYS dynamic model. Disturbance data are shown in chart form. A feedforward NN based fault detection was developed to identify the fault (disturbance) and no fault (normal) in plant operation. The NN based fault detection system was be trained, validated and tested using the dynamic model data. preliminary results show that NN based fault detection able to identify realistic fault output.

Authors believe that, NN based fault detection will help to avoid accident events and productivity losses in Gas processing industry in Bangladesh and help operators to identify and monitor multiple fault in real-time.

Interconnected Systems with "Mixed" Passivity and Negative-Imaginary Properties: A Stability Analysis in Discrete-time

Md. Arifur Rahman*, Abdullah Al Mamun, Sajal K. Das
Department of Electrical and Computer Engineering, National University of Singapore, Singapore
Email: *a0092557@nus.edu.sg

***Abstract*—This paper briefly presents a stability analysis of interconnected systems with mixed passivity and negative-imaginary properties in discrete-time. These results are analogous to previously established continuous-time case. As discretization of the system or discrete-time design is an important issue for control system design, this paper provides a base for discretization of "mixed" system with passivity and negative imaginary properties. Numerical example and simulation results demonstrate the effectiveness of the proposed analysis.**

***Keywords*—Passivity, Negative-imaginary, Stability**

I. Introduction

The passivity theorem and Negative-imaginary theorem are important the results in the theory of stability of input-output systems. Passivity theorem states that the negative feedback interconnection between two stable linear time invariant systems is stable when both systems are passive and one of them is strictly passive with finite gain [1], [2]. According to Negative-imaginary theorem, the positive feedback interconnection between two systems where one system is negative-imaginary and other system is strictly negative-imaginary is stable if and only if the DC loop gain is less than one [3], [4].

However, it is often seen that many practical systems do not always belong to the specific class over the whole interval of frequency [5]-[8]. There are many systems which belong to a mixed class with different properties at different frequency intervals. For example, Fig. 1 shows the experimental frequency response of a PZT micro-actuator ([15], [16]) where it can be observed that the system is not purely passive or negative-imaginary for the whole frequency range, but it is a "mixed" system.

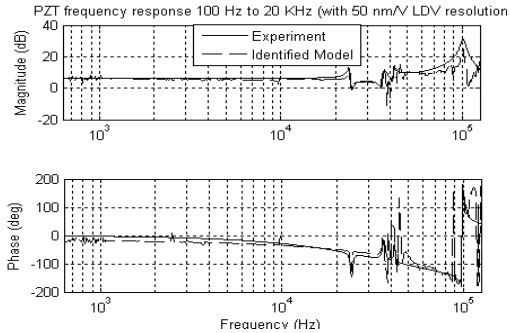

Fig. 1: experimental frequency response of a PZT micro-actuator

Many other systems may have "mixed" passivity and small-gain properties [5], [6] or "mixed" negative-imaginary and small-gain [7] properties. An unconditional stability analysis for systems with a "mixed" passivity and small-gain properties using negative-feedback is presented in [5] whereas [8] shows conditional stability between systems with "mixed" negative-imaginary and small-gain properties using positive feedback. Small-gain stability analysis can be applied and implemented to any kind of "mixed" system where the system does not hold only negative-imaginary or passivity property. The small-gain theorem states that the feedback interconnection of two stable systems is stable if the product of the gain of the systems at each frequency is less than one [1]. However, the use of the small-gain theorem makes the controller gain low which leads to low level of damping of the structures resonant modes in vibration control applications.

Nowadays, engineers or researcher rarely work with continuous-time systems in the industry or in the academic labs. In order to implement the control design for high speed system through some RTI tool like dSPACE, a discrete-time representation of the system must be required. Thus, it is to be established whether discrete-time systems inherit fundamental properties of the continuous-time systems from which they are derived. System discretization has currently become an issue of importance once again, and several papers [9]–[14] have recently appeared on this topic, particularly in the switched systems community. The purpose of this paper is to lay the foundation for future studies concerning the discretization of "mixed" systems with passivity and negative-imaginary properties and establishing a stability analysis in discrete-time for this types of mixed systems.

The rest of the paper is organized as follows. Section 2 presents the mathematical definitions of passivity; negative-imaginary and "mixed" properties and also highlights some preliminary results. Feedback stability analysis is presented in section 3. Section 4 demonstrates the numerical example and simulation results and section 5 presents the summary of the paper in conclusion.

II. Mathematical Definitions and Preliminary Results

Considering $y = xe^{j\theta}$ is a complex number where $x = |y|$ and $\theta = \angle y$ and assuming that $\theta = \omega T_s$ where T_s and ω are the sampling interval in seconds and signal frequency in rad/sec respectively.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Passivity and Negative Passivity **: (i)** A bounded-input bounded-output (BIBO) stable, discrete-time system with square, proper, real-rational transfer function matrix $G(z)$ is said to be input-output strictly passive over $[-m,-n]\cup[m,n]$ if there exists $\alpha,\beta\geq 0$ such that

$$-\alpha G^*(e^{j\theta})G(e^{j\theta})+G^*(e^{j\theta})+G(e^{j\theta})-\beta I\geq 0 \quad (1)$$

for all $\theta\in[-m,-n]\cup[m,n]$ where $0\leq m\leq n\leq\pi$.
(ii) A BIBO stable, discrete-time system with square, proper, real-rational transfer function matrix $H(z)$ is said to be input-output strictly negative passive over $[-m,-n]\cup[m,n]$ if there exists $\alpha,\beta\geq 0$ such that

$$-\alpha H^*(e^{j\theta})H(e^{j\theta})-H^*(e^{j\theta})-H(e^{j\theta})-\beta I\geq 0 \quad (2)$$

for all $\theta\in[-m,-n]\cup[m,n]$ where $0\leq m\leq n\leq\pi$.
The systems $G(z)$ and $H(z)$ are called input strictly passive and input strictly negative passive respectively if (1) and (2) are satisfied respectively for $\alpha=0$; output strictly passive and output strictly negative passive respectively if (1) and (2) are satisfied respectively for $\beta=0$; and passive and negative passive respectively if (1) and (2) are satisfied respectively for $\alpha=\beta=0$.
Negative Imaginary (NI)**:** A BIBO stable, discrete-time system with square, proper, real-rational transfer function matrix $G(z)$ is said to be input-output strictly negative-imaginary over $[-m,-n]\cup[m,n]$ if there exists $\alpha,\beta\geq 0$ such that

$$-\alpha\theta^2G^*(e^{j\theta})G(e^{j\theta})+j\theta G(e^{j\theta})-j\theta G(e^{j\theta})-\beta\geq 0 \quad (3)$$

for all $\theta\in[-m,-n]\cup[m,n]$ where $0\leq m\leq n\leq\pi$.
The system $G(z)$ is called input strictly negative-imaginary and input strictly negative passive respectively if (3) is satisfied respectively for $\alpha=0$; output strictly negative-imaginary if (3) is satisfied for $\beta=0$; and negative-imaginary if (3) is satisfied for $\alpha=\beta=0$.
"Mixed" NI and Passivity or Negative Passivity**: (i)** A BIBO stable, discrete-time system with square, proper, real-rational transfer function matrix $G(z)$ is said to have the "mixed" passivity and negative-imaginary properties if for each frequency $\theta\in[-\pi,\pi]$, there exists $\alpha,\beta\geq 0$ such that either a) $-\alpha G^*(e^{j\theta})G(e^{j\theta})+G^*(e^{j\theta})+G(e^{j\theta})-\beta I\geq 0$ or b) $-\delta\theta^2G^*(e^{j\theta})G(e^{j\theta})+j\theta G(e^{j\theta})-j\theta G(e^{j\theta})-\rho I\geq 0$ or both where $\alpha,\beta,\delta,\rho\geq 0$
(ii) A BIBO stable, discrete-time system with square, proper, real-rational transfer function matrix $G(z)$ is said to have the "mixed" negative passivity and negative-imaginary properties if for each frequency $\theta\in[-\pi,\pi]$, there exists $\alpha,\beta\geq 0$ such that either a) $-\alpha G^*(e^{j\theta})G(e^{j\theta})-G^*(e^{j\theta})-G(e^{j\theta})-\beta I\geq 0$ or b) $-\delta\theta^2G^*(e^{j\theta})G(e^{j\theta})+j\theta G(e^{j\theta})-j\theta G(e^{j\theta})-\rho I\geq 0$ or both where $\alpha,\beta,\delta,\rho\geq 0$
Let us now consider the following example from [17]

$$M(s)=\frac{10s}{s^3+10.02s^2+256.2s=2560} \quad (4)$$

M(s) is a system with "mixed" negative-imaginary and passivity properties [17], [18]. Now using zero-order hold discretization method $M(s)$ is discretized to $M_1(z)$ and $M_2(z)$ for sampling time $T=0.02$ sec and $T=0.2$ sec respectively.

$$M_1(z)=\frac{0.0019z^2-0.00012z-0.0017}{z^3=2.717z^2+2.554z-0.8184} \quad (5)$$

And

$$M_2(z)=\frac{0.0307z^2+0.00011z-0.0319}{z^3+1.857z^2+0.7263z-0.1348} \quad (6)$$

The nyquist plots in Fig. 3 shows that $M_1(z)$ is a discrete-time system with "mixed" passivity and negative-imaginary properties where $M_2(z)$ is a discrete-time system with "mixed" passivity, negative passivity and negative-imaginary properties. $M_1(z)$ holds the same properties as the $M(s)$ where $M_2(z)$ fails to preserve the same properties after discretization. Thus discretization may change the properties of a system from its continuous-time case.
Now some preliminary results are presented to establish the main results

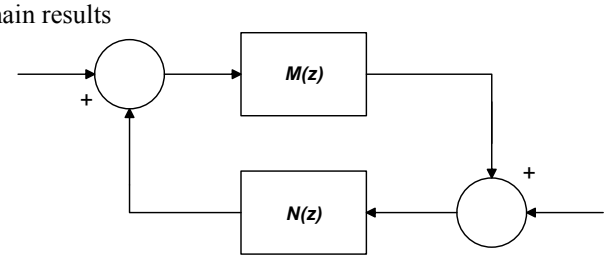

Fig. 2: Interconnection of system with positive feedback

Theorem 1**:** *According to [19], in discrete-time if $M(z)$ and $N(z)$ are strictly proper, real-rational transfer function matrices, then feedback interconnection of Figure 2 is stable if the nyquist plot of $\det[I-M(e^{j\theta})N(e^{j\theta})]$ for $-\pi\leq\theta\leq\pi$ does not make any encirclements of the origin.*

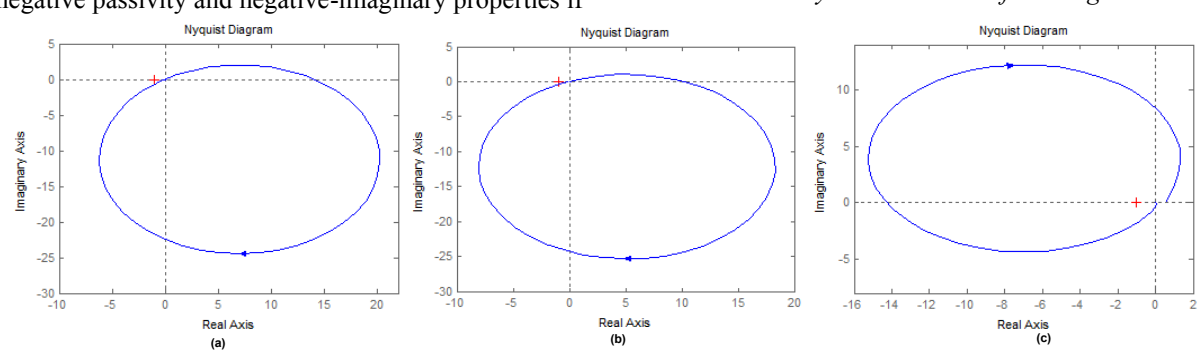

Fig. 3: For positive frequencies (a) Nyquist diagram of $M(s)$, (b) nyquist diagram of $M_1(z)$, and nyquist diagram of $M_2(z)$

The nyquist plot of $\det[I - M(e^{j\theta})N(e^{j\theta})]$ is included in the group of nyquist plots of $\det[I - \frac{1}{\Upsilon}M(e^{j\theta})N(e^{j\theta})]$, where $\Upsilon \in [1, \infty)$. Suppose the nyquist plot of $\det[I - \frac{1}{\Upsilon}M(e^{j\theta})N(e^{j\theta})]$ encircles the origin at least once which means that if Υ is continuously decreased from a large value towards 1, then there must be at least one Υ_0 and one θ_0 for which $\det[I - \frac{1}{\Upsilon}M(e^{j\theta})N(e^{j\theta})]$=0. Therefore, to avoid the encirclement of the origin, the sufficient condition is that for all $\Upsilon \in [1, \infty)$ and all $\theta \in [-\pi, \pi]$, $det[I - \frac{1}{\Upsilon}M[I - \frac{1}{\Upsilon}M(e^{j\theta})$ $N(e^{j\theta})] \neq 0$.

***Lemma 2*:** Suppose that $M(z)$ and $N(z)$ are BIBO stable, square, strictly proper, real-rational transfer function matrices. At some $\theta_0 \in [-\pi, \pi]$, if $M^*(e^{j\theta_0}) + M(e^{j\theta_0}) > 0$ and $-N^*(e^{j\theta_0}) - N(e^{j\theta_0}) \geq 0$, then $\det[I - M(e^{j\theta_0})N(e^{j\theta_0})] \neq 0$.

Proof: Since $M^*(e^{j\theta_0}) + M(e^{j\theta_0}) > 0$ and $-N^*(e^{j\theta_0}) - N(e^{j\theta_0}) \geq 0$, hence real parts of $\lambda_i[M(e^{j\theta})] > 0$ and real parts of $\lambda_i[-N(e^{j\theta})] \geq 0$, where $\lambda_i[.]$ denotes the ith eigen value [20]. Therefore $M(e^{j\theta})$ is nonsingular. Since $M^*(e^{j\theta_0}) + M(e^{j\theta_0})$ and $M^{-*}(e^{j\theta_0}) + M^{-1}(e^{j\theta_0})$ are Hermitian congruent [21], hence $M^{-*}(e^{j\theta_0}) + M^{-1}(e^{j\theta_0}) > 0$ which therefore implies that $M^{-*}(e^{j\theta_0}) - N^*(e^{j\theta_0}) + M^{-1}(e^{j\theta_0}) - N(e^{j\theta_0}) > 0$. Therefore, real parts of $\lambda_i[M^{-1}(e^{j\theta_0}) - N(e^{j\theta_0})] > 0$ for all λ_i and $det[M^{-1}(e^{j\theta_0}) - N(e^{j\theta_0})] \neq 0$ which entails that $det[I - M(e^{j\theta_0})N(e^{j\theta_0})] \neq 0$. Since $det[I - M(e^{j\theta_0})N(e^{j\theta_0})] = \det[M(e^{j\theta_0})\det[M^{-1}(e^{j\theta_0}) - N(e^{j\theta_0})]]$, $M(e^{j\theta_0})$ is nonsingular.

***Lemma 3*:** Suppose that $M(z)$ and $N(z)$ are BIBO stable, square, strictly proper, real-rational transfer function matrices. At some $\theta_0 \in [-\pi, \pi]$, if $j\left(M(e^{j\theta_0}) - M^*(e^{j\theta_0})\right) > 0$ and $j\left(N(e^{j\theta_0}) - N^*(e^{j\theta_0})\right) > 0$ then $\det[I - M(e^{j\theta_0})N(e^{j\theta_0})] \neq 0$

Proof: The two suppositions can be written as $jM(e^{j\theta_0}) + (jM(e^{j\theta_0})^* > 0$ and $\left(jN(e^{j\theta_0})\right)^{-1} + \left(jN(e^{j\theta_0})\right)^{-*} > 0$. Hence, $\det[I - M(e^{j\theta_0})N(e^{j\theta_0})] = \det[I + (jM(e^{j\theta_0}))$ $(jN(e^{j\theta_0}))] = \det[(jM(e^{j\theta_0}) + (jN(e^{j\theta_0})^{-1}]$ $\det[(jN(e^{j\theta_0})] \neq 0$.

III. Feedback Stability

***Theorem 4*:** If $M(z)$ and $N(z)$ are BIBO stable, square, strictly proper, real-rational transfer function matrices, then for the feedback interconnected system in Fig. 2, the interconnected system is finite-gain stable if there exists there sets of frequency range: (i) $\boldsymbol{\varphi_{NI}}$, a set consists of $\theta \in [-\pi, \pi]$ over which both $M(z)$ and $N(z)$ have negative-imaginary property (ii) $\boldsymbol{\varphi_{P-NP}}$, a set consists of $\theta \in [-\pi, \pi]$ over which $M(z)$ has passivity property and $N(z)$ has negative passivity property (iii) $\boldsymbol{\varphi_{NP-P}}$, a set of consists of $\theta \in [-\pi, \pi]$ over which $M(z)$ has negative passivity property and $N(z)$ has passivity property.

Proof: The proof can be divided into two parts: (a) For $M(z)$ and $N(z)$ belong to set $\boldsymbol{\varphi_{NI}}$, it is to be shown that $\det[I - \frac{1}{\Upsilon}M(e^{j\theta_0})N(e^{j\theta_0}) \neq 0$ all $\Upsilon \in [1, \infty)$ (b) For $M(z)$ and $N(z)$ belong to set $\boldsymbol{\varphi_{P-NP}}$ or $\boldsymbol{\varphi_{NP-P}}$, it is to be shown that $\det[I - \frac{1}{\Upsilon}M(e^{j\theta_0})N(e^{j\theta_0}) \neq 0$ all $\Upsilon \in [1, \infty)$.

(a) Since $M(z)$ and $N(z)$ belong to set $\boldsymbol{\varphi_{NI}}$, there exists $\alpha_i, \beta_i > 0$, such that $-\alpha_1\theta^2 M^*(e^{j\theta})M(e^{j\theta}) + j\theta M(e^{j\theta}) - j\theta M(e^{j\theta}) - \beta_1 \geq 0$ and $-\alpha_2\theta^2 N^*(e^{j\theta})N(e^{j\theta}) + j\theta N(e^{j\theta}) - j\theta N(e^{j\theta}) - \beta_2 \geq 0$ respectively, which entails that $j\theta\left(M(e^{j\theta_0}) - M^*(e^{j\theta_0})\right) > 0$ and $j\theta\left(N(e^{j\theta_0}) - N^*(e^{j\theta_0})\right) > 0$. Therefore, $\frac{1}{\sqrt{g}}j\theta\left(M(e^{j\theta_0}) - M^*(e^{j\theta_0})\right) > 0$, for $g > 0$. Hence, according to Lemma 3, $\det[I - \frac{1}{\Upsilon}M(e^{j\theta_0})N(e^{j\theta_0}) \neq 0$.

(b) Let us consider $M(z)$ and $N(z)$ belong to set $\boldsymbol{\varphi_{P-NP}}$, then there exists $\alpha_i, \beta_i > 0$ such that $-\alpha_1 M^*(e^{j\theta})M(e^{j\theta}) + M^*(e^{j\theta}) + M(e^{j\theta}) - \beta_1 I \geq 0$ and $-\alpha_2 N^*(e^{j\theta})N(e^{j\theta}) - N^*(e^{j\theta}) - N(e^{j\theta}) - \beta_2 I \geq 0$ respectively which implies that $M^*(e^{j\theta_0}) + M(e^{j\theta_0}) > 0$ and $-N^*(e^{j\theta_0}) - N(e^{j\theta_0}) \geq 0$. Therefore, $\frac{1}{\sqrt{g}}M^*(e^{j\theta_0}) + \frac{1}{\sqrt{g}}M(e^{j\theta_0}) > 0$ and $-\frac{1}{\sqrt{g}}N^*(e^{j\theta_0}) - \frac{1}{\sqrt{g}}N(e^{j\theta_0}) \geq 0$, for $g > 0$. Hence from Lemma 2, $\det[I - \frac{1}{\Upsilon}M(e^{j\theta_0})N(e^{j\theta_0}) \neq 0$. If, $M(z)$ and $N(z)$ belong to set $\boldsymbol{\varphi_{NP-P}}$, the above proof is vice versa.

IV. Numerical Example and Simulation

We consider the transfer function models $M_1(z)$ in (5) and let us consider another continuous time system as follows:

$$N(s) = \frac{0.1s^2 + 0.2s}{s^3 + 10.02s^2 + 356.2s + 3560}$$

Now using the sampling interval 0.02 sec we discretize the above model

$$N_1(z) = \frac{0.0018z^2 - 0.003542z + 0.001734}{z^3 - 2.678z^2 + 2.522z - 0.8184}$$

The nyquist plot of $N_1(z)$ is shown in Fig. 5(a). If we see the properties of $M_1(z)$ and $N_1(z)$ from Fig. 3(b) and Fig. 5(a), then we can summarize as shown in Fig. 4. Three frequency regions are here. In the first region, $N_1(z)$ has the negative passivity property where $M_1(z)$ has passivity property, in the second region both $M_1(z)$ and $N_1(z)$ have negative-imaginary property and $M_1(z)$ has negative passivity property where $N_1(z)$ has passivity property in the third region. Therefore positive feedback interconnection of $M_1(z)$ and $N_1(z)$ is stable. Step response (Fig. 5(b)) of the closed-loop interconnected system also confirms the stability.

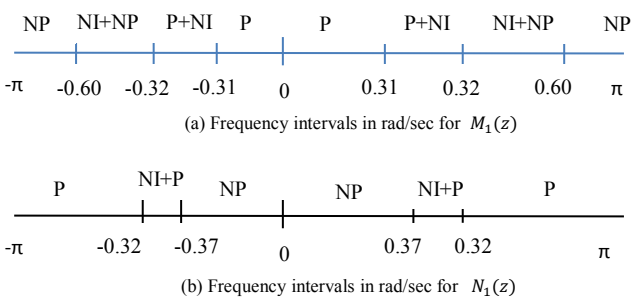

Fig. 4: Frequency intervals (NI: Negative-imaginary, P: Passivity, NP: negative passivity)

V. Conclusion

This paper proves the stability of discrete-time interconnected systems with mixed passivity and negative-imaginary properties. Discretization method may change the properties of the system than from its continuous-time case. Therefore Finite-gain stability theorem is proposed here in discrete time for system with "mixed" negative–imaginary and passivity properties. Numerical example and simulation validates the theorem.

***Abstract*—The extensive use of sensor networks in detection and surveillance systems has made optimal sensor deployment a key issue. A lot of sensor deployment techniques have been devised. While a number of mobile sensor networks consider the presence of obstacles and other terrain features in the region of interest, most static sensor networks either consider an idealistic basic terrain model or model the obstacles as straight lines. The aim of this paper is to extend upon a previously proposed optimal sensor deployment technique and incorporate into it a more realistic terrain model. This paper considers only those terrain features which can be modeled by convex polygons. Optimal sensor deployment together with a realistic terrain model makes sensor deployment more practical and robust. Simulation results show that the the number of sensors, their locations and the node density change in presence of obstacles.**

***Index Terms*—Sensor deployment, Optimal control, Realistic terrain**

I. Introduction

Sensor networks are essential for the design and implementation of detection and surveillance systems. Applications of sensor networks include military, environmental, medical, industrial and even home applications. There are many aspects of a sensor network. An important and interesting one is that of sensor deployment. Sensor deployment is the intelligent positioning of sensor nodes in the region of interest (*RoI*) to detect or monitor a physical phenomenon referred to as the *target*. The *RoI* is the area where the target is likely to be detected and monitored.

The issue of sensor deployment has been extensively studied and a number of deployment techniques have been devised. The focus of these techniques is coverage as well as connectivity. A number of computational geometry based deployment techniques has appeared in literature. In [1] the deployment of both static and mobile sensors is considered using a deployment technique called *Bidding Protocol*. The initial deployment is random. Static nodes calculate coverage holes and place *bids* proportional to it. A mobile node has a *base price* proportional to the coverage hole it leaves when it moves. If a *bid* is higher than the *base price*, the mobile sensor moves to heal that coverage hole. In [2], a technique called *The Minimax Algorithm* is used to deploy mobile sensors.The initial deployment is random. The aim is to move a sensor to a point called *Minimax point*. The variance of distances from *Minimax point* to Voronoi vertices is minimum. This means a better coverage within the detection radius of the sensor.

Deployment techniques based on *Virtual Forces, (VF)* also appear in literature. In [3], it is suggested that a sensor is subject to three virtual forces: an attractive force exerted by preferential areas, a repulsive force exerted by obstacles and a force (attractive/repulsive) exerted by neighboring sensors. The initial deployment is random. If the coverage is inadequate, the *Virtual Forces Algorithm (VFA)* is executed by the cluster head to find the net force on each sensor and their new locations. When the threshold coverage is obtained, the cluster head communicates the final positions resulting in a one-time redeployment. In [4], *VFA* is modified on the basis that the original *VFA* leaves coverage holes even after convergence. It is stated that the forces exerted on a sensor by its neighbors cancel each other so that the sensor reaches equilibrium even though some area still remains uncovered. It is proposed that only forces exerted by the *adjacent sensors* should be considered instead of neighboring sensors. The sensors which are connected in Delaunay triangulation of the initial random deployment are defined as *adjacent sensors*.

In [5], a grid based *RoI* with exponential sensing model is considered. The overall miss probability due to a new sensor is calculated for all the candidate grid points. The sensor is deployed at a grid point with minimum overall miss probability according to the algorithm *MIN_MISS* which considers uniform detection requirements. In [6], it is shown that the logarithmic collective miss probability for the grid points is Linear Shift Invariant (LSI). The sensor deployment problem is formulated as an integer linear programming problem which is NP-hard. The sensors are deployed using a heuristic algorithm *DIFF_DEPLOY* which can be used for both uniform and differentiated detection requirements.

In [7] a control theoretic approach is used to solve the sensor deployment problem. By using the concept of control theory and optimization, the optimal locations of the sensors are found. Optimal sensor deployment is minimalistic in nature as it ensures the use of minimum number of sensors. Minimum number of sensors means minimized cost, reduced computation and communication and less sensor management issues (such as replacing faulty ones) while still providing threshold coverage. Minimum number of sensors also ensures that the sensor network is stealthy (if necessary) and that additional sensors can be deployed only for increased reliability.

Among the mobile sensor networks, *VFA* considers the presence of obstacles. Among the static sensor networks, [5]-[7] consider obstacles. However, these obstacles are modeled by straight lines parallel to either of the axis. The effect of obstacles of different shapes on routing protocols is considered in [8]. In [9], the effect of obstacles having the shape of

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

polygons on both coverage and connectivity is considered.

In this paper, the work in [7] is extended and the effect of *two dimensional (2D)* obstacles on sensor deployment and coverage is studied. The algorithms presented in [7] is modified and simulated. The original algorithms ensure optimal deployment. Modification to these algorithms does not compromise optimality. Rather the effects of a more realistic terrain model is incorporated into it.

II. System Model

A. Modeling the Sensor

A probabilistic sensor detection model is used. More specifically the exponential detection model is used:

$$p_{detect}(t,s) = \begin{cases} e^{-\alpha d(t,s)} & \text{if } d(t,s) \leq r_d \\ 0 & \text{if } d(t,s) > r_d \end{cases} \quad (1)$$

Here r_d is the sensing range and α is a parameter which depends on the sensor. These factors can be found out from experiments. The distance between the target(t) and the sensor(s) is denoted by $d(t,s)$. Both $d(t,s)$ and r_d are measured in units of grid points. It is assumed that the sensors follow the line-of-sight (LOS) principle.

B. Modeling the RoI and Terrain

The *RoI* is modeled as a $2D$ grid of points denoted by $\mathcal{G}$. There are N_x points along one axis and N_y along the other giving a total of $N_x \times N_y$ points. Terrain in its simplest sense means the features of an area. In our case, it means the features of the *RoI*. It includes natural features such as vegetation, forest, water bodies, hilly areas, rocks, uneven surfaces and so on. It also includes man made structures such as buildings and walls. For indoors walls, furniture and other equipments can be considered as terrain features.

A basic terrain model assumes a plain *RoI*. That is a flat, open and unobstructed *RoI*. A basic terrain model is ideal for sensor deployment. However, in reality there may be obstacles present in the *RoI* and so deploying sensors assuming a basic terrain model is not appropriate. If the terrain features are known beforehand then that knowledge should be used to modify the sensor deployment accordingly. In this paper, knowledge about the terrain will be incorporated with existing deployment algorithms. Since the *RoI* is *2D* so only those terrain features which can be modeled by *2D* obstacles are considered. The *2D* obstacles in turn are modeled by convex polygons. Obstacles of other shapes can be approximated using convex polygons.

C. Problem Formulation and Solution

The problem formulation is stated as: To find the location of sensors in an *RoI* with a realistic terrain model such that the effective squared error (eSE) is minimized after each sensor deployment. The eSE is the square of the error between the achieved and required overall logarithmic miss probabilities (logarithmic miss probability is defined as logarithm of (1-detection probability)) at those grid points for which achievement is less than the requirement. The problem formulation is similar to that stated in [7]. The modification in this paper is that a more realistic terrain model is used by taking into account *2D* obstacles.

In [7], the formulated problem is solved by a control theoretic approach. The sensor deployment problem is at first converted to a control theory problem, specifically as a linear-quadratic regulator (LQR). The maximum value of the control vector in the k_{th} step is the location of the k_{th} sensor. The solution is based on the concept of dynamic optimization. The optimality conditions are found out using method of Lagrange multipliers and then applying discrete Karush-Kuhn-Tucker (KKT) conditions. Finally, the optimal solution is found by the sweep method. In this paper, the same solution procedure is used. The mathematical equations used for problem formulation and solution are given in [7] and not repeated here due to page limitation. The relevant terms used in this paper are defined in Table I.

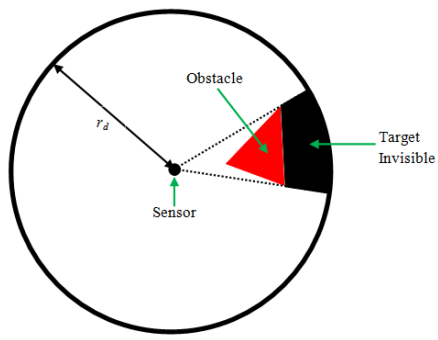

Fig. 1. The presence of an obstacle limits visibility of the sensor

TABLE I
NOTATIONS

$\mathbf{B}$	Node detection model ($N_xN_y \times N_xN_y$)
$\mathbf{p}_d^{req}$ / $\mathbf{p}_m^{req}$	Detection probability requirement vector / Miss probability requirement vector ($N_xN_y \times 1$)
$\mathbf{m}_{req}(= \ln(\mathbf{p}_m^{req}))$	Logarithmic miss probability requirement vector ($N_xN_y \times 1$)
$\mathbf{D}$	Deployment vector ($N_xN_y \times 1$)
$\mathbf{u}_k$	Control vector at the k_{th} step ($N_xN_y \times 1$)
$\mathbf{x}_k$	Difference between achieved and required overall logarithmic miss probabilities after k_{th} sensor deployment ($N_xN_y \times 1$)
$\mathbf{G}_k$	Feedback gain matrix for k_{th} step ($N_xN_y \times N_xN_y$)
$\mathbf{R}$, $\mathbf{Q}$, $\mathbf{Q_f}$	Diagonal weighting matrices ($N_xN_y \times N_xN_y$)

III. Deployment Algorithm

In [7], two deployment algorithms are proposed and simulated. These are the *Optimal Control Based Algorithm* (it will be referred to as *Optimal_Control* henceforth) and *Max_Deficiency*.

In *Optimal_Control*, the optimal location of the sensor is found out from the equation:

$$\mathbf{u}_k = -\mathbf{G}_k\mathbf{x}_k \quad (2)$$

The index corresponding to the maximum value of the control vector $\mathbf{u}_k$ gives the optimal location of the k_{th} sensor. Here $\mathbf{x}_k$ is the difference or error between achieved and required overall logarithmic miss probabilities and $\mathbf{G}_k$ is the feedback gain matrix given by the sweep method. In *Max_Deficiency*, a sensor is deployed at the grid point where the difference between the the required and achieved detection probability is maximum. The difference between required and achieved detection probability is referred to as *deficiency*. In this paper, the two algorithms are modified to deploy sensors in a more

realistic terrain. The modifications to the two algorithms are now discussed.

A. Optimal_Control

The original algorithm appears in [7]. The modifications are made to the inputs of the algorithm. These include matrix $\mathbf{B}$, column vectors $\mathbf{p}_d^{req}$/$\mathbf{p}_m^{req}$ and matrices $\mathbf{R}$, $\mathbf{Q}$ and $\mathbf{Q_f}$.

1) Matrix $\mathbf{B}$*:* The matrix $\mathbf{B}$ is the node detection model. The individual elements can be written as $b(r,c)$. If a sensor is at (i,j), target is at at (x,y) then $b(r,c) = \ln(1 - p_{detect})$ where p_{detect} is given by (1), $r = (x-1)N_y + y$ and $c = (i-1)N_y + j$.

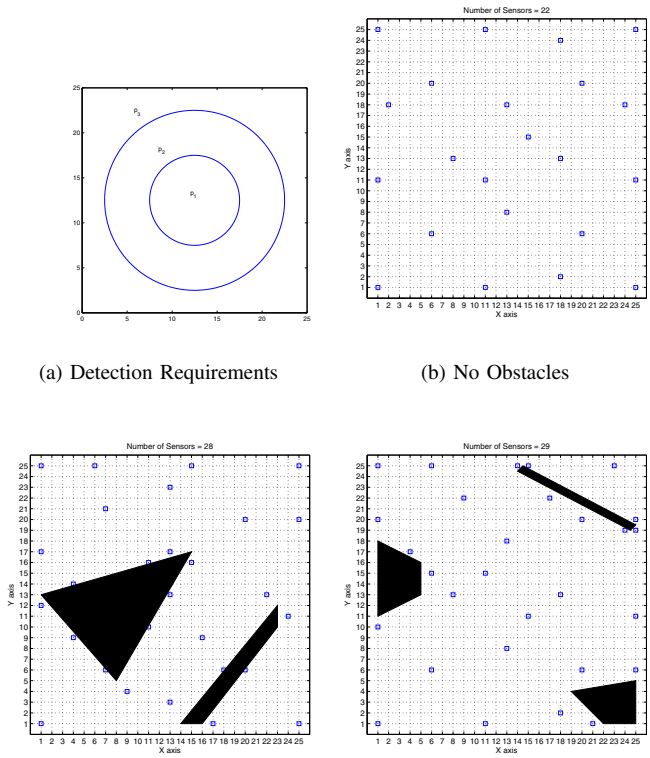
The effect of obstacles is shown in Fig. 1. The sensors are assumed to work on the LOS principle. A target is detected if it is within the the detection radius r_d and LOS exits with the sensor. In the absence of obstacles, targets at all grid points within the detection range are detected according to (1). In the presence of obstacles, if a target is at any grid points beyond the obstacle (such as the shaded region in Fig. 1), LOS does not exist and the target is *invisible* to the sensor. For multiple obstacles, more grid points will become *invisible* to the sensor. Hence for these points p_{detect} becomes zero making the corresponding entries of $\mathbf{B}$ zero as well. Also obstacles themselves occupy grid points in the *RoI*. These grid points are referred to as *inaccessible* points. It is assumed that neither the sensor nor the target can be placed at these grid points. Thus, the corresponding entries in $\mathbf{B}$ are set to zero.

2) Column vectors $\mathbf{p}_d^{req}$*,* $\mathbf{p}_m^{req}$ *and* $\mathbf{m}_{req}$*:* The value of $\mathbf{p}_d^{req}$/$\mathbf{p}_m^{req}$ is specified by the user. The following modifications are made: $\mathbf{p}_d^{req}(inaccessible) = 0$ and $\mathbf{p}_m^{req}(inaccessible) = 1$ leading to $\mathbf{m}_{req}(inaccessible) = 0$. It is assumed that the *inaccessible* points will not be monitored and so there is no need to have any detection requirements for these points.

Algorithm 1 Modification to the Algorithm

% The target (t) is at (x,y), the sensor (s) is at (i,j) and the set of grid points occupied by the obstacles is *inaccessible*
% Modification to matrix $\mathbf{B}$
if $(i,j) \in$ *inaccessible* $||$ $(x,y) \in$ *inaccessible* **then**
  $b(r,c) = 0$
else if $d(t,s) \leq r_d$ && *LOS exists between t and s* **then**
  $b(r,c) = \ln(1 - p_{detect})$ % where p_{detect} is given by (1)
else
  $b(r,c) = 0$
end if
% Modification to column vectors $\mathbf{p}_d^{req}$, $\mathbf{p}_m^{req}$ and $\mathbf{m}_{req}$
$\mathbf{p}_d^{req}(inaccessible) = 0$
$\mathbf{p}_m^{req}(inaccessible) = 1$, $\mathbf{m}_{req}(inaccessible) = 0$
% Modification to matrices $\mathbf{R}$, $\mathbf{Q}$ and $\mathbf{Q_f}$
$\mathbf{Q}(inaccessible) = \mathbf{Q_f}(inaccessible) = 0$
$\mathbf{R}(inaccessible)$ set to a large value

3) Matrices $\mathbf{R}$*,* $\mathbf{Q}$ *and* $\mathbf{Q_f}$*:* Matrices $\mathbf{R}$, $\mathbf{Q}$ and $\mathbf{Q_f}$ are diagonal weighting matrices. They are given by $\mathbf{R}(i) = (\mathbf{m}_{req}(i)/\mathbf{1}^T\mathbf{m}_{req})^{-1}$ and $\mathbf{Q}(i) = \mathbf{Q_f}(i) = (\mathbf{R}(i))^{-1}$. These weighting matrices ensure that the solution is biased towards grid points having higher detection requirements. Modification of $\mathbf{m}_{req}$ at the *inaccessible* points automatically modifies these weighting matrices such that $\mathbf{Q}(inaccessible) = \mathbf{Q_f}(inaccessible) = 0$ while $\mathbf{R}(inaccessible)$ is set to a large value. This reduces the bias towards the *inaccessible* points and hence sensor deployment on the available grid points is emphasized.



(a) Detection Requirements (b) No Obstacles

(c) Obstacle Set A (d) Obstacle Set B

Fig. 2. Simulation Profile and Sensor Deployment for First Experiment

For convenience, again the modification part to *Optimal_Control* algorithm is summarized in Algorithm 1.

The algorithm *Optimal_Control* comprises of two parts. First is the algorithm named *Sweep method* with inputs $\mathbf{B}$ and cost matrices $\mathbf{Q}$, $\mathbf{Q}_f$ and $\mathbf{R}$. In this paper, the *Sweep method* is executed and $\mathbf{G}_k$ are found out using modified $\mathbf{B}$, $\mathbf{Q}$, $\mathbf{Q}_f$ and $\mathbf{R}$. The second part is the actual deployment algorithm with inputs $\mathbf{B}$ and $\mathbf{p}_d^{req}$. In this paper, the deployment algorithm is carried out using modified $\mathbf{B}$ and $\mathbf{p}_d^{req}$ and sensor positions are determined from (2). As a result, the deployment vector $\mathbf{D}$ gives the optimal sensor positions taking into account the obstacles.

B. Max_Deficiency

The original algorithm appears in [7]. The inputs of the algorithm are matrix $\mathbf{B}$ and column vector $\mathbf{p}_d^{req}$. The modification to $\mathbf{B}$ and the column vector $\mathbf{p}_d^{req}$ are the same as that for *Optimal_Control*. Using modified inputs, the most *deficient* grid points in the presence of obstacles are found out and sensors are deployed according to deployment vector $\mathbf{D}$.

IV. Simulation Results

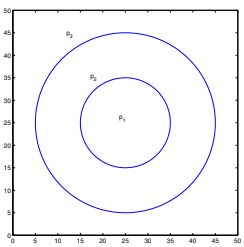
In this section, sensor deployment in presence of obstacles is compared to sensor deployment in a basic terrain model with no obstacles. The sensor parameters used are $\alpha = 0.2$ and $r_d = 7$.

In the first experiment, the effect of obstacles on sensor deployment by *Optimal_Control* is simulated. The *RoI* is modeled as a 25×25 grid. The detection requirements in

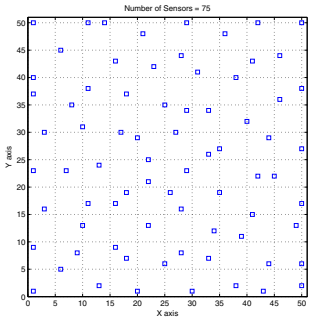
TABLE II
FIRST EXPERIMENT RESULTS

Detection Requirements	No Obstacles	Obstacle Set A	Obstacle Set B
$p_1 = 0.85, p_2 = 0.75, p_3 = 0.65$	22	28	29
$p_1 = 0.75, p_2 = 0.65, p_3 = 0.55$	21	24	25
$p_1 = 0.65, p_2 = 0.65, p_3 = 0.65$	17	22	25

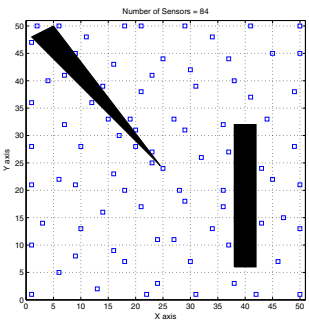
the *RoI* is given in Fig. 2(a). These detection requirements are specified by the user and can be varied. As an example, Fig.2 shows the sensor deployment for $p_1 = 0.85$, $p_2 = 0.75$ and $p_3 = 0.65$. In Fig. 2(b), a basic terrain model is assumed with no obstacles. The number of sensors deployed is 22. In Fig. 2(c) and Fig. 2(d), the presence of $2D$ obstacles are considered to model the features of the terrain. It is seen that both the number of sensors deployed and their locations in each case are different from the basic terrain model. For obstacle set A 28 sensors are needed and for obstacle set B 29 sensors are needed. One other observation is that the increased number of sensors are deployed over a smaller area. In the basic terrain model in Fig. 2(b), the sensors are deployed all over the *RoI* and provide coverage throughout. However, in Fig. 2(c) and Fig. 2(d) since the obstacles themselves occupy a certain amount of area the sensors are deployed over a reduced area. This means that the node density increases in the presence of obstacles. It can be observed in Fig. 2(c) and Fig. 2(d) that a greater number of nodes are deployed close to the obstacles. The detection requirements are varied and the number of sensors deployed recorded in Table II.



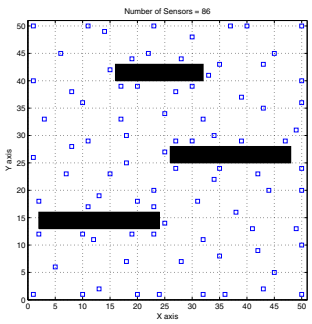
(a) Detection Requirements



(b) No Obstacles



(c) Obstacle Set A



(d) Obstacle Set B

Fig. 3. Simulation Profile and Sensor Deployment for Second Experiment

In the second experiment, the effect of obstacles on sensor deployment by *Max_Deficiency* is simulated. Due to the computational complexity of *Optimal_Control*, large grid sizes cannot be simulated. Since *Max_Deficiency* can simulate larger grid sizes, the *RoI* in the second experiment is a 50×50 grid. The detection requirements in the *RoI* is given in Fig. 3(a). As an example, Fig. 3 shows the sensor deployment for $p_1 = 0.85$, $p_2 = 0.75$ and $p_3 = 0.65$. In Fig. 3(b), a basic terrain model is assumed with no obstacles. The number of sensors deployed is 75. In the presence of obstacles, the number of sensors is 84 and 86 as shown in Fig. 3(c) and Fig. 3(d), respectively. Similar to the first experiment, the number of sensors, their locations and the node density are different compared to a basic terrain model. It is also observed that the node density increases in Fig. 3(c) and Fig. 3(d) with greater number of nodes deployed close to the edges of the obstacles. The detection requirements are varied and the number of sensors deployed recorded in Table III.

TABLE III
SECOND EXPERIMENT RESULTS

Detection Requirements	No Obstacles	Obstacle Set A	Obstacle Set B
$p_1 = 0.85, p_2 = 0.75, p_3 = 0.65$	75	84	86
$p_1 = 0.75, p_2 = 0.65, p_3 = 0.55$	66	73	69
$p_1 = 0.65, p_2 = 0.65, p_3 = 0.65$	69	72	72

V. CONCLUSION

In this paper, the problem of sensor deployment in a realistic terrain model is studied and simulated. The study of optimal sensor deployment proposed in a previous work is modified to take into account the terrain features of the *RoI*. The algorithms *Optimal_Control* and *Max_Deficiency* are modified and simulated. It is found that the number of sensors deployed are affected by presence of obstacles. The locations of the sensors in case of a realistic terrain model are found out. It is also seen that the node density increases over the *RoI* especially along the edges of the obstacles.

Abstract— **This paper proposes a robust control law for trajectory tracking problem of an n-link robot manipulator subjected to parametric uncertainty. The control law is derived based on Lyapunov theory, which guarantees asymptotic stability of the system. The upper bounds on the parametric uncertainties are determined with estimation law and an additional control input is updated according to the estimated value. The proposed methods improve tracking performance and provide less control effort with no chattering effect in control torques. The simulation results of 2-link robot manipulator are presented to validate the effectiveness of the proposed method.**

Index Terms: **Parametric uncertainty, Lyapunov's stability theorem, Bound estimation, Robust control.**

I. Introduction

In past two decades, the various optimal schemes have been developed to solve robotic manipulator problem [1]-[3]. Trajectory tracking problem is the most significant and fundamental task in control of robotic manipulator. The major source of uncertainty in robot manipulator is parametric uncertainty, which arises due to variations in payload and mass of links. The adaptive control approach proposed in [4] is very attractive to deal with the parametric uncertainty in robot manipulator. The novelty of the approach in [5] lies in the fact that uncertainty bounds information are necessary to derive the control law and the uniform ultimate boundedness of the tracking error depend only on the inertia parameters of robot manipulator. In [6], [7] a robust controller is designed based on estimation of upper bounds on parametric uncertainty, but in [7] priory knowledge about the upper bounds on parametric uncertainty is not required.

This paper is concerned with the design of a robust control law for trajectory tracking control of robot manipulator based on the approaches in [5] and [7]. The proposed method introduces an additional control input that uses the estimate of upper bounds of uncertainty; and the estimator is an exponential function of maximum singular value of a matrix that is related with the robot kinematics, inertia parameters and tracking error. The designed robust control law comprises with two terms, one act as a dynamic feed-forward to ensure robustness to the parametric uncertainty and the other acts as a simple PD feedback term to regulate the transient behavior. The proposed controllers significantly improve the tracking performance and also provide less control effort with no chattering effect in input torques.

II. Dynamic Model and Robust Control

An n-DOF robot manipulator is described by

$$M(q)\ddot{q}+C(q,\dot{q})\dot{q}+g(q)=\tau \text{ with } q\in\Re^n,\ \tau\in\Re^n \quad (1)$$

where $M(q)$ is $n\times n$ inertia matrix, the vector $C(q,\dot{q})\dot{q}$ represents centrifugal and coriolis forces, and $g(q)$ is the $(n\times 1)$ vector of gravitational forces. The above dynamic equation (1) is linearly parameterizable [5]

$$M(q)\ddot{q}+C(q,\dot{q})+g(q)=Y(q,\dot{q},\ddot{q})\theta=\tau \quad (2)$$

where θ is a constant $(px1)$ -dimensional vector of robot parameters and Y is an $(n\times p)$ matrix of known functions of the generalized coordinates and their higher derivatives.

It is assumed that $\exists$ an unknown bound on parametric uncertainty such that

$$\|\tilde{\theta}\|=\|\theta-\theta_0\|\le\rho \quad (3)$$

where θ_0 represents fixed robot parameters. In order to control dynamic behaviour of the system properly, we need to estimate ρ in an efficient manner. For any specific trajectory, $q_d,\dot{q}_d,\ddot{q}_d$ are desired position, velocity, acceleration and the corresponding position and velocity error are defined as $\tilde{q}=q-q_d$, $\dot{\tilde{q}}=\dot{q}-\dot{q}_d$. The following reference velocity and acceleration are defined as

$$\dot{q}_r=\dot{q}_d-\Lambda\tilde{q},\ \ \ddot{q}_r=\ddot{q}_d-\Lambda\dot{\tilde{q}} \quad (4)$$

and reference velocity error is given as

$$\sigma=\dot{q}-\dot{q}_r=\dot{\tilde{q}}+\Lambda\tilde{q} \quad (5)$$

The nominal control law τ_0 is expressed as

$$\tau_0=M_0(q)\ddot{q}_r+C_0(q,\dot{q})\dot{q}_r+g_0(q)-K\sigma=Y(q,\dot{q},\dot{q}_r,\ddot{q}_r)\theta_0-K\sigma \quad (6)$$

where the gain matrices K and Λ are positive definite diagonal matrices. Now, we define the control torque τ in terms of nominal control vector τ_0 as

$$\tau=\tau_0+Y(q,\dot{q},\dot{q}_r,\ddot{q}_r)u=Y(q,\dot{q},\dot{q}_r,\ddot{q}_r)(\theta_0+u)-K\sigma \quad (7)$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Where, u is an additional control input that is designed to achieve robustness to parametric uncertainty represented by $\tilde{\theta} = \theta - \theta_0$. From (7) and (1), after simplification we get,

$$M(q)\sigma + C(q,\dot{q})\sigma + K\sigma = Y(q,\dot{q},\dot{q}_r,\ddot{q}_r)(\tilde{\theta} + u) \quad (8)$$

Theorem 1: Consider the upper uncertainty bound ρ is known priori and if $\exists$ $\hat{\rho}(t)$ an estimate of ρ, and an additional control law $u(t) = -\beta\,\hat{\rho}(t)$ (where β is $(px1)$ dimensional unit vector) such that control law (7) stabilizes the closed-loop system as well as improves the performance of the tracking error when the estimator is designed as

$$\hat{\rho}(t) = \begin{cases} \dfrac{2\sigma^T Y\beta}{s_{\max}}\left(e^{(-1/2)\int s_{\max}\,dt} - e^{-\int s_{\max}\,dt}\right) + \rho & if\ \ s_{\max} > \varepsilon \\ \dfrac{2\sigma^T Y\beta}{\varepsilon}\left(e^{(-1/2)\int s_{\max}\,dt} - e^{-\int s_{\max}\,dt}\right) + \rho & if\ \ s_{\max} \le \varepsilon \end{cases}$$

where $s_{\max}$ = maximum singular value of $(Y^T\sigma\sigma^T Y)$ and $\tilde{\rho}(t) = \rho - \hat{\rho}(t)$.

Proof: Let the Lyapunov function as

$$V(\sigma, q, \tilde{\rho}(t)) = \frac{1}{2}\sigma^T M(q)\sigma + \frac{1}{2}\tilde{q}^T B\tilde{q} + \frac{1}{2}\tilde{\rho}(t)\psi(t)\tilde{\rho}(t) \quad (9)$$

where B is positive definite diagonal matrix and $\psi(t) > 0\,(scalar)$. The $\dot{V}(t)$ along the trajectories is

$$\dot{V} = \sigma^T M(q)\dot{\sigma} + \frac{1}{2}\sigma^T \dot{M}(q)\sigma + \tilde{q}^T B\dot{\tilde{q}} + \frac{1}{2}\tilde{\rho}(t)\dot{\psi}(t)\tilde{\rho}(t) + \tilde{\rho}(t)\psi(t)\dot{\tilde{\rho}}(t) \quad (10)$$

Using the skew-symmetric properties $\left[\dot{M}(q) - 2C(q,\dot{q})\right] = 0$, and assigning $(B - 2\Lambda K) = 0$, one can rewrite (10) as

$$\dot{V} = -\dot{\tilde{q}}^T K\dot{\tilde{q}} - \tilde{q}^T \Lambda K \Lambda\tilde{q} + \sigma^T Y(\tilde{\theta} + u(t)) + \frac{1}{2}\tilde{\rho}(t)\dot{\psi}(t)\tilde{\rho}(t) + \tilde{\rho}(t)\psi(t)\dot{\tilde{\rho}}(t) \quad (11)$$

With $\tilde{\theta} \le \beta \cdot \rho$ and $u(t) = -\beta \cdot \hat{\rho}(t)$, the above equation reduces to

$\dot{V} \le -\dot{\tilde{q}}^T K\dot{\tilde{q}} - \tilde{q}^T \Lambda K \Lambda\tilde{q} < 0$ (sin$ce\ K > 0$) if the rest of the part of (11) is assigned to zero i.e.

$$\sigma^T Y\beta + \dot{\psi}(t)(\rho - \hat{\rho}(t)) - \psi(t)\dot{\hat{\rho}}(t) = 0 \quad (12)$$

We defined $\psi(t)$ and its time derivative as follows

$$\psi(t) = e^{\int S_{\max}\,dt},\ \dot{\psi}(t) = S_{\max} e^{\int S_{\max}\,dt} \quad (13)$$

Substituting $\psi(t)$ and $\dot{\psi}(t)$ in (12) and subsequently multiplying both sides by $e^{(-1/2)\int S_{\max}\,dt}$ and rearranging, we get

$$\frac{d}{dt}\left[e^{(1/2)\int s_{\max}\,dt}\hat{\rho}(t)\right] = \sigma^T Y\beta \cdot e^{(-1/2)\int s_{\max}\,dt} + \frac{1}{2}s_{\max} \cdot e^{(1/2)\int s_{\max}\,dt}\rho \quad (14)$$

Integrating both sides of (14), and then multiplying the final expression by $e^{(-1/2)\int S_{\max}\,dt}$, we have

$$\hat{\rho}(t) = -\frac{2\sigma^T Y\beta}{s_{\max}} e^{-\int S_{\max}\,dt} + \rho + c \cdot e^{(-1/2)\int S_{\max}\,dt} \quad (15)$$

If we choose initial condition $\hat{\rho}(0) = \rho$, then integration constant is obtained as $c = \dfrac{2\sigma^T Y\beta}{s_{\max}}$ and (15) is rewritten as,

$$\hat{\rho}(t) = \frac{2\sigma^T Y\beta}{s_{\max}}\left(e^{(-1/2)\int s_{\max}\,dt} - e^{-\int s_{\max}\,dt}\right) + \rho$$

If the reference velocity tracking error ($\sigma = \dot{q} - \dot{q}_r = \dot{\tilde{q}} + \Lambda\tilde{q}$) approaches to zero, the corresponding value of $s_{\max}$ also approaches to zero. This problem may be eliminated using the modified estimation law as

$$\hat{\rho}(t) = \begin{cases} \dfrac{2\sigma^T Y\beta}{s_{\max}}\left(e^{(-1/2)\int s_{\max}\,dt} - e^{-\int s_{\max}\,dt}\right) + \rho & if\ \ s_{\max} > \varepsilon \\ \dfrac{2\sigma^T Y\beta}{\varepsilon}\left(e^{(-1/2)\int s_{\max}\,dt} - e^{-\int s_{\max}\,dt}\right) + \rho & if\ \ s_{\max} \le \varepsilon \end{cases} \quad (16)$$

where ε is small positive number.

Consequently, the additional control input is

$$u(t) = -\beta\,\hat{\rho}(t) \quad (17)$$

Noting $\hat{\rho}(t)$ is obtained in such way that (12) is satisfied, and substituting (17) in (11), we get $\dot{V} = -\dot{\tilde{q}}^T K\dot{\tilde{q}} - \tilde{q}^T \Lambda K \Lambda\tilde{q} < 0$. Hence, the closed-loop system is asymptotically stable and improves the tracking errors $\tilde{q}$ and $\dot{\tilde{q}}$ depending upon the choice of Λ. □

Remark-1: In the above proof if we choose different positive scalar function $\psi(t)$, we can get different estimation law. Now by choosing $\psi(t) = e^{\int \sigma^T Y\beta\,dt}$, we have derived different estimation law and controller is defined in following theorem.

Theorem 2: Let the upper uncertainty bound ρ is known priori and the estimate of ρ is defined as

$\hat{\rho}(t) = 2\left(e^{(-1/2)\int \sigma^T Y\beta\,dt} - e^{-\int \sigma^T Y\beta\,dt}\right) + \rho$, and the additional control input $u(t) = -\beta\,\hat{\rho}(t)$ ensure the asymptotic stability of the system and the trajectory tracking errors $\tilde{q}$ and $\dot{\tilde{q}}$ converge to zero.

Proof: Using $\psi(t) = e^{\int \sigma^T Y\beta\,dt}$, $\dot{\psi}(t) = \sigma^T Y\beta e^{\int \sigma^T Y\beta\,dt}$ and adopting the procedures given in theorem-1, one can prove the above theorem and details derivations are omitted.

Remark-2: Both the proposed theorems are the modified version of the algorithm described in [7]. It may be noted that the expressions for the uncertain bound ρ is modified to achieve improved tracking error as well as to get less input torque compared to the results obtained in [5] and [7].

III. DESIGN STRATEGY

In [5], the additional input is defined as

$$u = \begin{cases} -\rho\dfrac{Y^T\sigma}{\|Y^T\sigma\|} & \text{if } \|Y^T\sigma\| > \varepsilon;\ or\ -\rho\dfrac{Y^T\sigma}{\|Y^T\sigma\|} & \text{if } \|Y^T\sigma\| \le \varepsilon \end{cases} \quad (18)$$

where $\varepsilon > 0$ and the upper uncertainty bound is defined as

$$\rho = \left(\sum_{i=1}^{p} \rho_i^2 \right)^{1/2} \tag{19}$$

In previous section, derived additional control input $u(t)$ uses a scalar parameter $\hat{\rho}(t)$ as measure of uncertainty, but this may lead to excessive gains [5]. Assigning different gains to the each component of $u(t)$, one can modify the proposed estimation laws in both theorems if $\exists$ an upper bound on each parametric uncertainty as $\left|\tilde{\theta}_i\right| \le \rho_i, \quad i = 1, 2, \cdots, p.$

$$\hat{\rho}_i(t) = \begin{cases} \dfrac{2\sigma^T Y \beta}{s_{\max}} \left(e^{(-1/2)\int s_{\max}\,\mathrm{d}t} - e^{-\int s_{\max}\,\mathrm{d}t} \right) + \rho_i & if \;\; s_{\max} > \varepsilon_i \\ & ; \varepsilon_i > 0 \\ \dfrac{2\sigma^T Y \beta}{\varepsilon} \left(e^{(-1/2)\int s_{\max}\,\mathrm{d}t} - e^{-\int s_{\max}\,\mathrm{d}t} \right) + \rho_i & if \;\; s_{\max} \le \varepsilon_i \end{cases} \tag{20}$$

$$u_i(t) = -\beta \hat{\rho}_i(t) \tag{21}$$

Similarly, each component of estimation law in theorem-2 can also be modified as

$$\hat{\rho}_i(t) = 2\left(e^{(-1/2)\int \sigma^T Y \beta \mathrm{d}t} - e^{-\int \sigma^T Y \beta \mathrm{d}t} \right) + \rho_i; \; u_i(t) = -\beta \hat{\rho}_i(t) \tag{22}$$

If we don't have any priori knowledge about upper bound on uncertainty ρ then one can compute the proposed control law in theorem-1 as

$$\dot{\hat{\rho}}(t) = \left\{ \sigma^T Y \beta \left(2e^{-\int s_{\max}\,\mathrm{d}t} - e^{(-1/2)\int s_{\max}\,\mathrm{d}t} \right) \right. ; \; if \;\; s_{\max} > \varepsilon \;\; or \;\; 0 \;\; if \;\; s_{\max} \le \varepsilon$$

$$u(t) = -\beta\, \hat{\rho}(t) \tag{23}$$

Similarly, control law in theorem-2 can also be computed as

$$\dot{\hat{\rho}}(t) = \sigma^T Y \beta \left(2e^{-\int \sigma^T Y \beta \mathrm{d}t} - e^{(-1/2)\int \sigma^T Y \beta \mathrm{d}t} \right); \; u(t) = -\beta\, \hat{\rho}(t) \tag{24}$$

IV. Simulation Results

To show the effectiveness of the proposed controllers, a 2-link planar manipulator is considered in Fig.1. The matrices and vectors ($M(q)$, $C(q,\dot{q})$, $g(q)$ and $\tau = Y(q,\dot{q},\ddot{q})\theta;\; \theta \in \Re^6$) can be computed using the following parameters [6].

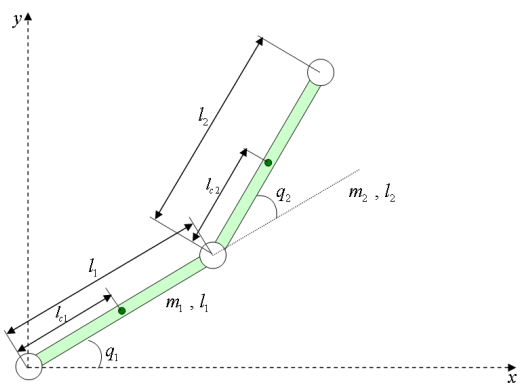

Fig.1. Two-link planar robot.

Using the values from Table I, we can get θ_i as shown in Table II.

TABLE I
Parameters of the Unloaded Arm

m_1	m_2	l_1	l_2	l_{c1}	l_{c2}	I_1	I_2
10	5	1	1	0.5	0.5	10/12	5/12

TABLE II
θ_i for the Unloaded Arm

θ_1	θ_2	θ_3	θ_4	θ_5	θ_6
8.33	1.67	2.5	5	5	2.5

TABLE III
Nominal Parameter Vector θ_0

θ_{01}	θ_{02}	θ_{03}	θ_{04}	θ_{05}	θ_{06}
13.33	8.96	8.75	5	10	8.75

TABLE IV
Uncertainty Bounds ρ_i

ρ_1	ρ_2	ρ_3	ρ_4	ρ_5	ρ_6
5	7.29	6.25	0	5	6.25

We assume that due to unknown load carried by second link of the robot, the parameters m_2 , l_{c2} and I_2 changes to $m_2 + \Delta m_2$, $l_{c2} + \Delta l_{c2}$ and $I_2 + \Delta I_2$, respectively. A robust controller is designed to ensure asymptotic stability and good tracking performance in presence of parametric uncertainties.

$$0 \le \Delta m_2 \le 10; \qquad 0 \le \Delta l_{c2} \le 0.5; \qquad 0 \le \Delta I_2 \le \frac{15}{12}.$$

The nominal parameter vector θ_0 , shown is in Table III, is obtained after choosing the mean value for the range of possible θ_i . Table IV shows uncertainty bounds ρ_i for each parameter, which is difference of Table III and Table II.

With the uncertainty range and nominal parameters θ_0 , it is possible to compute upper uncertainty ρ as

$$\rho = \left(\sum_{i=1}^{6} \rho_i^2 \right)^{1/2} = \left(\sum_{i=1}^{6} (\theta_{0i} - \theta_i)^2 \right)^{1/2} = 13.46$$

A 2-link robot manipulator is discretized with a sampling time (T) =0.005 sec. and desired trajectory for both the joints are considered as $q_d = 1 - \cos(at)$, $\dot{q}_d = a \sin(at)$ with $a = \dfrac{2\pi}{5}$. To illustrate the novelty of the proposed methods, results of [5] are compared with the proposed controllers stated in theorems 1 and 2. We have chosen $K = diag(75 \;\; 50)$ and $\Lambda = diag(40 \;\; 15)$ for all the controllers. Simulation results based on [5] are presented in Fig.2 where tracking error is about 9.9×10^{-3} rad. for joint-1, and 14.7×10^{-3} rad. for joint-2. The results obtained (in figs.3 and 4) based on theorems-1 and 2 are compared with that of [5]. It has been observed that the both the proposed methods ensure good tracking performance (using theorem-1 tracking error is observed about 2.7×10^{-5} rad. for joint-1, and 2.8×10^{-5} rad. for joint-2 (see Fig.3) whereas tracking error is about 3.1×10^{-5} rad. for joint-1, and 5.6×10^{-5} rad. for joint-2 when theorem-2 is employed (see Fig.4)) as well as require very less control torque compared to the results presented in [5]. Results based on proposed methods are also revealing better performance than that of [7]. Further, it may be noted that the chattering effect on the input torques is reduced to zero (see figs. 3 and 4).

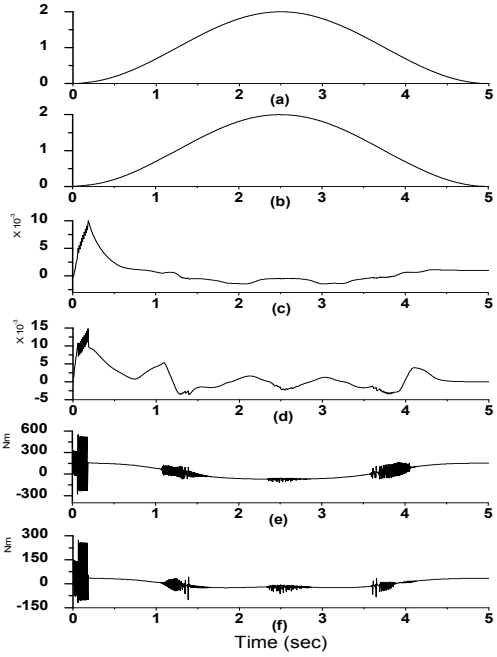

Fig.2. System response [5] when $\varepsilon = 0.1$: (a) Joint-1 position q_1 (b) Joint-2 position q_2 (c) Tracking error $\tilde{q}_1$, (d) Tracking error $\tilde{q}_2$, (e) Torque input τ_1 to joint 1, (f) Torque input τ_2 to joint 2.

V. CONCLUDING REMARKS

In this paper, two robust controllers for robot manipulator have been proposed by following the work of [5] and [7]. Stability analysis of such system is derived based on Laypunov function along with the estimated value of upper bounds on parametric uncertainty. Introducing new exponential functions yield improved parameter convergence rate of the proposed estimation laws and also ensure significant good tracking performance. It is also noticed that a reduction in torque magnitude with no chattering effect in input torques. The simulation results validate the effectiveness of the proposed designed techniques.

***Abstract*—This paper presents a design of PI type non-fragile controller for trajectory tracking and disturbance rejection of robot manipulators. The state equation of a robot manipulator is transformed to Canonical form and subsequently an error dynamic equation is obtained. Stability analysis and convergence of trajectory tracking error are investigated. Simulation results illustrating the performance of the proposed control algorithm for trajectary tracking of a robot manipulator with high precision tracking and improved convergence are presented.**

***Index Terms*—Canonical form, end effector, uncertainties,error dynamics,Riccatti equation, Optimal control.**

I. Introduction

In past two decades, the various optimal schemes have been developed to solve robotic manipulator problem [1]-[3]. Trajectory tracking problem is the most significant and fundamental task in control of robotic manipulator. The major source of uncertainty in robot manipulator is parametric uncertainty, which arises due to variations in payload and mass of links. With the increase in the order of such systems, the modeling of system has become a complicated issue and it is impossible to find an exact mathematical model of such systems. Imprecise Model of system leads to the devastating failure of controllers. A robust controller poses a challange for the control systems designers and it works even with actual system deviation from designed model. It is, therefore, quite important to design robust control strategies that ensure to track desire position in presence of uncertainties and payload variations and design techinques of such controllers can be found in [4]-[5].

This paper deals with the design of a non-fragile controller for trajectory tracking of an uncertain robot manipulator modifying control approach discussed in [6]. To control an such uncertain robot manipulator, one needs to deal with uncertainties involved in payload and friction. Our aim is to design a non-fragile controller by introducing the error equation in state space form, where the uncertainty is a function of state and its derivatives. It has been shown that the proposed trajectory tracking control algorithm improves the tracking performance compared with that of [6] in the presence of uncertainties in the system dynamics i.e. it demonstrates the movement of end effector tracks the desired trajectory in much less time in presence of disturbances in the control input channel.

II. Model Description and Problem Formulation

The dynamics of a robot manipulator is described by [6]

$$M(q)\ddot{q} + V(q,\dot{q}) + F(\dot{q}) + G(q) = \tau \tag{1}$$

where q consists of the joint positions, τ is the generalized forces, $M(q)$ the inertia matrix, $V(q,\dot{q})$ the coriolis/centripetal vector, $G(q)$ the gravity vector, and $F(\dot{q})$ the friction vector. Let

$$N(q,\dot{q}) = V(q,\dot{q}) + F(\dot{q}) + G(q)$$

There are uncertainties in $M(q)$ and $N(q,\dot{q})$ due to unknown load on the manipulator and unmodeled frictions and these are assumed to be bounded by the following equation.

$0 < M_{min}(q) \leq M(q) \leq M_0(q),\ \|N(q,\dot{q}) - N_0(q,\dot{q})\| \leq \eta_{max}(q,\dot{q})$ with $\eta_{max}(0,0) = 0$
Where, $M_{min}(q), M_0(q)$ and $\eta_{max}(q,\dot{q})$ are positive definite matrices and scalar quantity.

The objective of the proposed controller is to regulate the motion of robot manipulator with a view to track a desired trajectory $q_d(t)$, and also rejects the effect of disturbance on the system performance. The position and velocity error vector of n-link robot manipulator is defined as

$$\begin{aligned} e_{pi} &= q_i - q_{i,d} = x_i - x_{i,d} \\ e_{vi} &= \dot{q}_i - \dot{q}_{i,d} = \dot{x}_i - \dot{x}_{i,d}, \text{for } i = 1,2,3.....n. \end{aligned} \tag{2}$$

The dynamics of the error equation can be written as

$$\dot{e} = \begin{bmatrix} \dot{e}_{p(t)} \\ \dot{e}_{v(t)} \end{bmatrix} = \begin{bmatrix} 0 & I \\ 0 & 0 \end{bmatrix} \begin{bmatrix} \dot{e}_{p(t)} \\ \dot{e}_{v(t)} \end{bmatrix} + \begin{bmatrix} 0 \\ \ddot{q} \end{bmatrix} - \begin{bmatrix} 0 \\ \ddot{q}_d \end{bmatrix} \tag{3}$$

where $\dot{e}_p = [\dot{e}_{p1}, \dot{e}_{p2}.....\dot{e}_{pn}]^T$; $\dot{e}_v = [\dot{e}_{v1}, \dot{e}_{v2}.....\dot{e}_{vn}]^T$.
Using the expression $\ddot{q}$ from (1), one can rewrite the above equation as

$$\dot{e} = Ae + \begin{bmatrix} 0 \\ I \end{bmatrix} M(q)^{-1}[\tau - N(q,\dot{q})] - \begin{bmatrix} 0 \\ \ddot{q}_d \end{bmatrix} \tag{4}$$

where $B = [0^T \quad I]^T$. Now, the concept of inverse dynamics of an n-link robot manipulator is utilised to express the control law in the form

$$u(t) = M_0(q)^{-1}[\tau - N_0(q,\dot{q})] \tag{5}$$

where $u(t)$ represents a new control law. Using (5) in (4) and after some mathematical manipulations and simplification, one can obtain the following error vector expression.

$$\dot{e} = Ae + B(I + h(x))u(t) + Bf(x,\dot{x}) - B\ddot{q}_d \tag{6}$$

Where $h(x) = M(x)^{-1}M_0(x) - I \geq 0$ and $f(x,\dot{x}(t)) = M(x)^{-1}[N_0(x,\dot{x}) - N(x,\dot{x})]$
It may be noted that the error equation (6) is driven by the control input and the uncertainties $(h(x)\ and\ f(x,\dot{x}))$. Further, it may be noted that due to the special structures of A and B, a solution of non-fragile control problem can be formulated in simpler framework based on [6].

III. Proposed PI type non-fragile control strategy for a class of nonlinear systems

Let us introduce a new state vector defined by

$$z(t) = \int_0^t e_p(t)dt;\ \dot{z} = e_p(t) = [I\ \ 0]e(t) \tag{7}$$

where $e_p(t) = q(t) - q_d(t)$ and $q(t)$ is the actual position of n-link robot manipulator and $q_d(t)$ is the desired link position.

Augmenting (7) with (6), we get the final expression as

$$\begin{bmatrix} \dot{e} \\ \dot{z} \end{bmatrix} = \begin{bmatrix} A & 0 \\ C & 0 \end{bmatrix} \begin{bmatrix} e \\ z \end{bmatrix} + \begin{bmatrix} B \\ 0 \end{bmatrix} ((I + h(x))u + f(x, \dot{x})) - \ddot{q}_d) \tag{8}$$

One can rewrite (8) as

$$\dot{e_{au}} = \overline{A}e_{au} + \overline{B}(I + h(x))u(t) + \overline{B}f(x, \dot{x}) - \overline{B}\ddot{q}_d$$

where $e_{au} = [e^T\ z^T]^T$; $\bar{B} = [B^T\ \ 0^T]^T$ and $C = [I\ \ 0]_{n\times 2n}$. It is assumed that $f(x, \dot{x})$ is norm bounded by a known function, f_{max}. Our main goal is to design a linear robust controller $u(t) = -[K_1\ K_2]e_{au}$ based on minimizing quadratic performance index such that the system (8) is globally asymptotically stable for all admissive perturbation $f(x, \dot{x}(t))$ and uncertainties involved in input matrix $B(I+h(x))$. Control problem of such uncertain system described above can be solved with a non-fragile controller under some assumptions given below.

A. Design of Non-fragile Controller

Consider a class of nonlinear system (8) and each term associated with the expression is explained in the previous section.

It may be noted that the for all uncertainties involved in (8) can be bounded by a nonnegative function f_{max} and h_{max} such that $\|f(x, \dot{x})\| \leq f_{max}$ and $\|h(x)\| \leq h_{max}$. The formulation of proposed control strategy is quite different from the work of [6]-[7] and one can formulate the solution of non-fragile control problem into a standard linear quadratic control problem framework that will ensure asymptotic stablity of the closedloop system (8) for all uncertainties.

Recall the augmented system (8) and the corresponding linear feedback control law

$$u(t) = -Ke_{au}(t) = -(K_1e(t) + K_2z(t))$$

such that the performance index defined by the cost functional

$$J_{au} = \int_0^\infty (f^2{}_{max} + h^2{}_{max} + e_{au}(t)^TQe_{au}(t) + u(t)^Tu(t))dt \tag{9}$$

is minimised. It may be noted that the cost function consists of four terms. The first two terms stand for the cost of uncertainty compensation; third part for the cost of regulation; and $u(t)^Tu(t)$ for the cost of control effort. The stability analysis of the robust controlled system is derived by considering the theorem stated below.

Theorem 1: For the augmented system (8), there exists a control law $u(t)$ that minimizes a cost function (9) and simultaneously guarantees the stability analysis of the uncertain augmented system (8).

Proof: We need to design a control law $u(t) = u_0(t)$ such that the cost function for the augmented system (8) is minimised by bringing any initial error state $e(0) \neq 0$ to $e(\infty) = 0$. Based on the Hamilton-Jacobi- Bellman equation a condition is given below

$min_u[f^2{}_{max} + h^2_{max} + e^T_{au}Qe_{au} + u^Tu + (\frac{\partial V}{\partial e_{au}})^T(\overline{A}e_{au} + \overline{B}u - \overline{B}\ddot{q}_d)] = 0$ to derive the optimal control law. If $u = u_0$ is the solution to the control problem then,

$$f^2{}_{max} + h^2_{max} + e^T_{au}Qe_{au} + u^Tu + (\frac{\partial V}{\partial e_{au}})^T(\overline{A}e_{au} + \overline{B}u - \overline{B}\ddot{q}_d)] = 0 \tag{10}$$

Differentiating the above equation with respect to u_0, we get

$$2 * u_0^T + (\frac{\partial V}{\partial e_{au}})^T\overline{B} = 0 \tag{11}$$

We now show that the equilibrium point $e_{au} = 0$ of the augmented system (8) is globally asymptotically stable for all uncertainties. This can be proved by introducing a Lyapunov function defined as

$V(e_{au}(t)) > 0, e_{au}(t) \neq 0;\quad V(e_{au}(t)) = 0, e_{au}(t) = 0$ and subsequently we need to show that $\dot{V}(e_{au}(t)) \leq 0, e_{au}(t) \neq 0$ Now,

$$\begin{aligned} \dot{V}(e_{au}(t)) &= \left(\frac{\partial V(e_{au}(t))}{\partial e_{au}(t)}\right)^T \left(\frac{\partial e_{au}(t)}{\partial t}\right) \\ &= \left(\frac{\partial V(e_{au})}{\partial e_{au}}\right)^T [\overline{A}e_{au} + \overline{B}(u_0 + h(x)u_0) + \overline{B}f(x, \dot{x}) - \overline{B}\ddot{q}_d] \\ &= \left(\frac{\partial V(e_{au})}{\partial e_{au}}\right)^T [(\overline{A}e_{au} + \overline{B}u_0 - \overline{B}\ddot{q}_d) + \overline{B}h(x)u_0 + \overline{B}f(x, \dot{x})] \end{aligned} \tag{12}$$

Using (10) and (11) in (12) , we get

$$\begin{aligned} &= (-f^2_{max} - h^2_{max} - e^T_{au}Qe_{au} - u_0^Tu_0) \\ &-2u_0^Th(x)u_0 - 2u_0^Tf(x, \dot{x}) \\ &= -f^2{}_{max} - h^2_{max} + f^T(x)f(x) - (f(x) + u_0)^T(f(x) + u_0) \\ &-e^T_{au}Qe_{au} - 2u_0^Th(x)u_0 \\ &= -(f^2{}_{max} - f(x)^Tf(x)), \text{since } h(x) \geq 0 \end{aligned} \tag{13}$$

Thus, the conditions of local Lyapunov stability theorem are satisfied.

■

B. Design Steps for Implementing the Control Law

Systematic algorithmic steps to obtain the control law for the system (8) are given below:

Algorithmic steps:

Step-1: Transform the dynamic system (1) into the augmented error dynamic equation (8).

Step-2: The uncertainties $f(x, \dot{x})$ and $h(x)$ involved in (1) is bounded by the expression $f^T(x, \dot{x})f(x, \dot{x}) \leq f_{max} \leq x^T_{au}P_1x_{au} \leq e^T_{au}Pe_{au}$, and $h^T(x)h(x) \leq h_{max} \leq x^T_{au}P_2x_{au} \leq e^T_{au}\bar{P}e_{au}$, where $P_1,\ P_2 > 0,\ x_{au} = [x^T\ \dot{x}^T]^T; e_{au} = [e^T\ z^T]^T$

Note: $x^T_{au}P_1x_{au} \leq e^T_{au}Pe_{au}$, $x^TP_2x \leq e^T_{au}\bar{P}e_{au}$ and equality sign in both cases are valid when state tracks the desired trajectory perfectly.

Step-3: For the augmented system (8), find a feedback control law $u = u_0$ that minimises the cost function $\int_0^\infty (e^T_{au}Pe_{au} + e^T_{au}\bar{P}e_{au} + e^T_{au}Qe_{au} + u^Tu)dt$. Obtain W by solving the algebraic Riccati equation

$$\overline{A}^TW + W\overline{A}^T + (P + \bar{P} + Q) - W\overline{B}\overline{B}^TW = 0 \tag{14}$$

Note that the term $e_{au}^T(P+\bar{P})e_{au}$ is introduced in the performance index to compensate the effect of uncertainties involved in the system dynamics.

Step-4: The control law is computed using the relation $u_0 = -\overline{B}^T W e_{au} = -(K_1 e + K_2 Z)$. The designed control law can be applied in (1) to study trajectory performance and also to investigate the effectiveness of the proposed control algorithm.

IV. Simulations

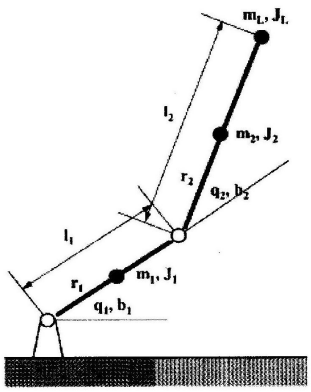

Fig. 1. A Two-link Robot Manipulator

Fig.1 shows a two-link rigid robotic manipulator [8] and its model parameters are given below: The robot manipulator has two joint variables, i.e two angles q_1 and q_2. The inertia matrix is

$$M(q) = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix} \tag{15}$$

Where

$$\begin{aligned} M_{11} &= J_1 + m_1 r_1^2 + J_2 + m_2(l_1^2 + r_2^2 + 2l_1 r_2 cosq_2) \\ &\quad + J_L + m_L(l_1^2 + l_2^2 + 2l_1 l_2 cosq_2) \\ M_{12} &= M_{21} = J_2 + m_2(r_2^2 + l_1 r_2 cosq_2) + J_L + m_L l_2^2 \\ M_{22} &= J_2 + m_2 r_2^2 + J_L + m_L l_2^2 \end{aligned} \tag{16}$$

The coriolis/centripetal vector is

$$V(q,\dot{q}) = \begin{bmatrix} V_1 & V_2 \end{bmatrix}$$

Where

$$\begin{aligned} V_1 &= (m_2 l_1 r_2 + m_l l_1 l_2)(\dot{q}_2^2 + 2\dot{q}_1\dot{q}_2)\, sinq_2 \\ V_2 &= (m_2 l_1 r_2 + m_l l_1 l_2)\dot{q}_2^2\, sinq_2 \end{aligned}$$

and assumed the gravity vector $G(q) = 0$

The friction vector is

$$F(q,\dot{q}) = \begin{bmatrix} b_1\dot{q}_1 \\ b_2\dot{q}_2 \end{bmatrix};$$

$$\text{Disturbance vector } d = \begin{bmatrix} 0.78 \\ 1.56 \end{bmatrix} \tag{17}$$

The constant matrices $\bar{A}$, $\bar{B}$ of the augmented system (see, e.g. in (8)) are already discussed in sections II and III. The following parameter values are considered for obtaining the simulation results.

$$m_1 = 0.41kg.;\ m_2 = 0.0985kg.;$$

$$J_1 = 72.6kgm/rad/sec.^2;\ J_2 = 19.4kgm/rad/s^2;$$

$$r_1 = 0.15m;\ r_2 = 0.08m; l_1 = 0.203m;$$

$$l_2 = 0.15m;\ b_1 = 0.236kgm/rad/sec.$$

$$b_2 = 0.59kgm/rad/sec.;\ m_L = 0.296\epsilon kg.;$$

$$J_L = 609.88\epsilon^2 kgm/rad/sec^2.$$

where $\epsilon \in [0,1]$' For trajectory tracking of two link robot manipulator the following initial data have been considered.

In this case, considering the augmented error dynamic equation (8), the associated quadratic bound for the the uncertainty terms $f(x,\dot{x})$ and $h(x)$ is computed combinely as

$$P^* = P + \bar{P} = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 2808 & 190 & 0 & 0 \\ 0 & 0 & 190 & 100 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

The augmented state weightimg matrix is selected as $Q = 5I_{6\times 6}$. Solving the augmented algebraic Riccati equation (14) of the error dynamic equation (8), we obtained the following PI type control strategy

$$\begin{aligned} u_1 &= -34.7e_{p1} - 1.0e_{p2} - 54.95e_{v1} - 2.75e_{v2} - 10z_1 \\ u_2 &= -e_{p1} - 20.16e_{p2} - 2.741e_{v1} - 15.26e_{v2} - 10z_2 \end{aligned}$$

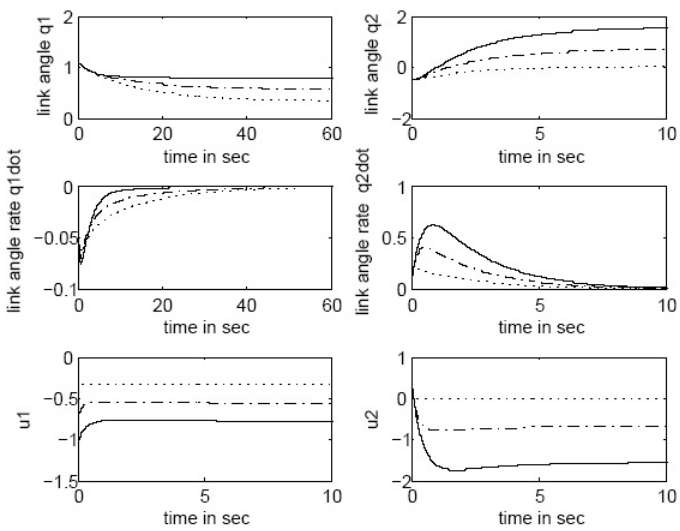

Fig. 2. Response based on [6] with disturbance $d = [0.78\ 1.56]^T$
$\cdots\cdots$ $m_L = 0$; $-\cdot-\cdot-$ $m_L = 0.15kg$; —— $m_L = 0.3kg$

Figs. 2 and 3 show the responses of two-link robot manipulator with changes in payload masses and constant external disturbances. It is obseved that the proposed method drives the link positions at the origin (i.e. $q_1 = q_2 = 0$). Figs. 4 and 5 depict the performance of the proposed controller for tracking a given trajectory $q_{d1}(t) = 1 + 0.1 * sin(2dt)$ and $q_{d2}(t) = 1 + 0.1 * sin(2dt)$ when the initial conditions $q_1 = 90^0$ and $q_2 = -60^0$ are considerd. Simulation results show that the proposed tracking controller appears to be

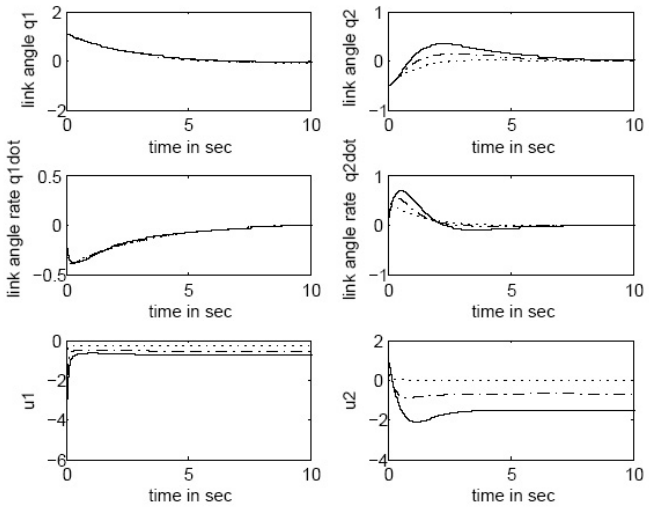

Fig. 3. Response of proposed method with disturbance $d = [0.78\ 1.56]^T$
$\cdots\cdots$ $m_L = 0$; $- \cdot - \cdot -$ $m_L = 0.15kg$; —— $m_L = 0.3kg$

useful to diminish the effects of payload uncertainties, external disturbances. The proposed controller outperforms than that of [6].

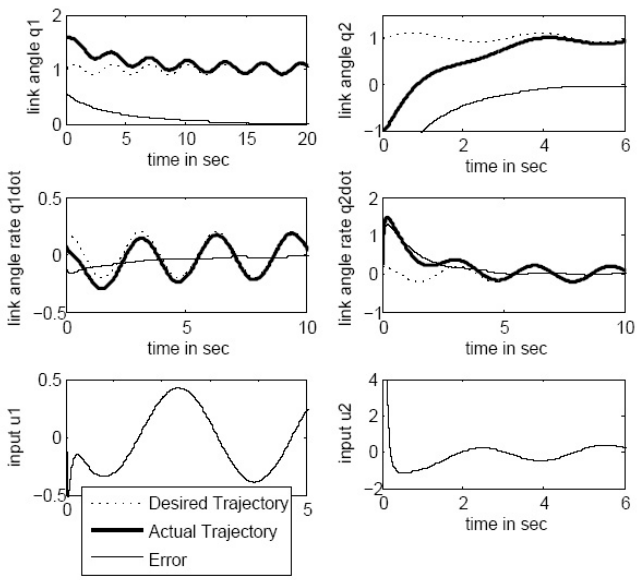

Fig. 4. Tracking response for m=0.3kg. based on the method of [6]

V. Concluding Remarks

A non-fragile controller is designed for an n-link robot manipulators based on an optimal controller approach. This control strategy can be used effectively (i) to move robot manipulator from any initial position to desired position $(q_d, \dot{q}_d) = (0, 0)$ with changes in payload masses and contant external disturbances, (ii) to track a desired trajectory. The proposed controller is designed in the framework of Lin et al. method [6] by introducing a new vector. In fact, this control law acts as a PI type non-fragile controller which is more effective in presence of constant disturbance and uncertainties. Figs 4 and 5 show that the output tracks the reference trajectory

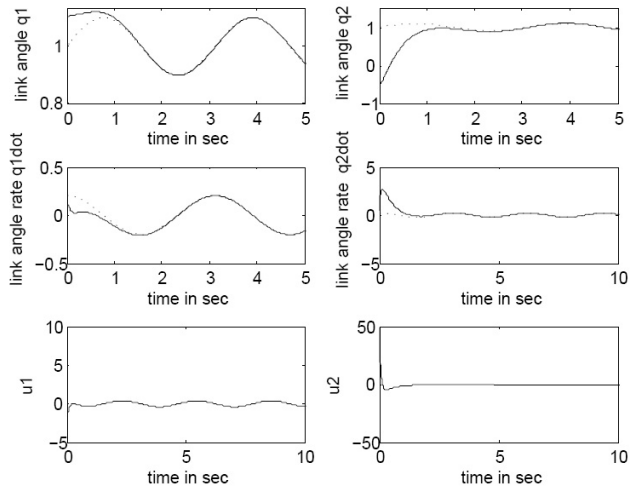

Fig. 5. Tracking response for m=0.3kg. with the proposed method
$\cdots\cdots$ Desired trajectory; ——— Actual trajectory

more perfectly and better results are obtained compared with that of Lin et al. [6] in presence of external disturbances and uncertainties in model.

***Abstract*—A computationally fast visual approach of autonomous robot localization with high degree of accuracy is demonstrated. Relative position and orientation of an autonomous robot with respect to a fixed reference point is determined by minimal processing of a monocular image employing projective geometry resulting in very low computational requirements. A three-layered sequential algorithm i.e. Detection–Pixel Level Analysis–Sub Pixel Accuracy, is used to speed up the process and to reduce computational bulk. The position co-ordinate of a point in a plane is obtained by analyzing the perspective projection of a reference structure on a monocular image perceived by a camera placed at that point. A chessboard pattern is suitably chosen as the reference structure which is placed at the origin of the plane.**

***Index Terms*—chessboard, localization, projective geometry, monocular vision, mobile robot, perspective view.**

I. Introduction

Localization is of fundamental importance in autonomy of a mobile robot [1]. In any environment where human involvement is hazardous such as in space or in some disaster-prone area where an autonomous robot is launched from a reference position, it would require a self-localization technique in order to track its reference so that it may return back to the original position. This necessitates a faster localization method which will run continuously without hampering the other processes running on the computer.

Various researches have been conducted on localization techniques utilizing different sensory inputs like laser range finders and sonar sensors. Substantial works have been done using vision as primary sensor, e.g. stereopsis uses two or more image capturing devices to obtain a depth map of its surroundings [2]. Some of these approaches especially stereo-matching algorithms require fairly high computational power to obtain nearly real-time data with appreciable level of accuracy. Again, these spatial sensors and image pairs for the stereo vision provide relative distance between the robot and some obstacle or boundary. So these methods are particularly useful in obstacle avoidance and path planning. Moreover, maintaining the relative spatial position of the two cameras used in the binocular vision is very difficult.

However, in many cases robot's location relative to a certain reference point at any instant of time might be of greater importance for path and action planning. For example, if a mobile robot is to explore a bounded region in space in the vicinity of a reference point or zone, availability of instantaneous spatial co-ordinates and information of its pose, orientation can greatly reduce its decision making complexities.

This paper presents such a method of robot localization which utilizes the geometry of a reference structure in a captured monocular image to obtain robot's position co-ordinates. A 4-by-4 chessboard with nine internal corner points is used as the reference structure providing an operational field of nearly 180°. Despite the broader 360° operational field of other localization techniques based on color-space image processing of 3D reference structures [3], the proposed approach is superior due to its relative insensitivity to varying light conditions and lesser processing requirements. Use of only one camera is another advantage of the proposed method. The mathematical treatment involved in this paper employs some basic rules of perspective projection which is a subset of projective geometry [4].

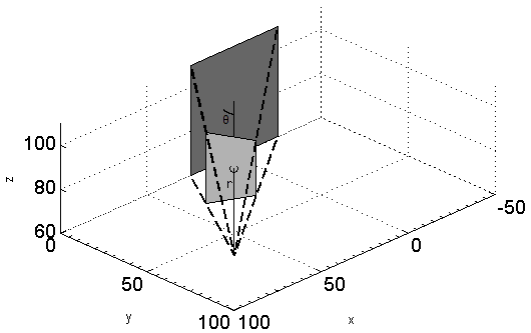

Fig. 1. Perspective view of a square-shaped reference placed at origin

II. Localization

The instantaneous co-ordinate of the robot is proposed to be estimated from the perspective view of a square placed at the origin of a horizontal plane. In order to analyze the perspective shape of the square perceived by a camera which is placed in that plane passing through the center of the reference square, identification of the four corners will suffice. From these four corners, the value of (r, θ) of the polar co-ordinate of the camera in Fig. 1 is to be calculated.

A. Reference Selection

While choosing a unique but easily detectable reference pattern, a number of procedures were adopted. The prime objective is to identify the four corners of the reference square structure placed at a dynamic environment in a reasonably short time.

At first, four colored-LEDs were chosen to be placed at the corners of the square, but the glowing LEDs appeared completely white in captured image which became indistinguishable from the background.

The next choice moves to four red circles having centers at the corners of a square which were detected using Hough

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Circle Transform [5]. Although HSV color space is quite suitable for detecting colored objects in an image than RGB, identification of color became very much sensitive to light [6].

The search for a reference having minimal sensitivity to ambient lighting conditions led to chessboard pattern. Due to inherent high contrast ratio of the checkerboard pattern, four corners pixel co-ordinates can be accurately detected. Its geometry also provides the scope to estimate errors in detection through self-referencing. Therefore, a 4-by-4 chessboard with nine internal corner points has been used.

B. Finding corners of a Chessboard

Chessboard corners can be detected using Moravec Corner Detection algorithm [7]. It tests each pixel in the image to see if a corner is present by considering how similar a patch centered on the pixel is, compared to the nearby largely overlapping patches.

The similarity is measured by taking the sum of squared differences (SSD) between the two patches. A lower number indicates more similarity. If the pixel is in a region of uniform intensity, then the nearby patches will look similar. If the pixel is on an edge, then nearby patches in a direction perpendicular to the edge will look quite different, but nearby patches in a direction parallel to the edge will result only in a small change. If the pixel is on a feature with variation in all directions, none of the nearby patches will look similar. The corner strength is defined as the smallest SSD between the patch and its neighbors (horizontal, vertical and on the two diagonals). If this number is locally maximal, a feature of interest is present.

Being anisotropic is one of the main problems with this operator as pointed out by Moravec i.e. if an edge is not in the direction of the neighbors, it will not be detected as an interest point. This problem is solved by using the Harris & Stephens [8] or Shi-Tomasi [9] Corner Detection algorithm.

Sub-pixel accuracy is also achieved by using The Förstner Corner Detector. To achieve an approximate solution, the Förstner algorithm solves for the point closest to all the tangent lines of the corner in a given image. This algorithm which provides a least-square solution, works by considering the fact that the gradients of the edges intersect at the point of interest.

C. Determination of polar co-ordinates

The derivation provided uses the pinhole camera approximation and assumes the center of the reference chessboard to be located at the principle point of the captured monocular image in order to avoid Barrel Distortion.

The center point E of a 4×4 chessboard with 3×3 internal corners at A through I is taken to be the origin of the XY plane.

If the nine corners of the chessboard is identified to be A' through I' in the image and O is supposed to be the location of the camera which is located at the left side (positive X direction) from the chessboard (Fig. 2) in the horizontal plane passing though the centre of the chessboard, then $A'G' \,||\, C'I'$ and $A'G' > C'I'$.

If the view angle of the camera with pixel resolution $W \times H$ is represented by ϕ, the vision angle subtended by the sides AG and CI of the square AGIC,

$$\theta_L = A'G' \times \phi/H \qquad \text{and} \qquad \theta_R = C'I' \times \phi/H \tag{1}$$

Now, the arc AG of the circle with a radius approximately equal to OD subtends an angle θ_L at the centre O whereas the arc CI of the circle with a radius approximately equal to OF subtends an angle θ_R at the centre.

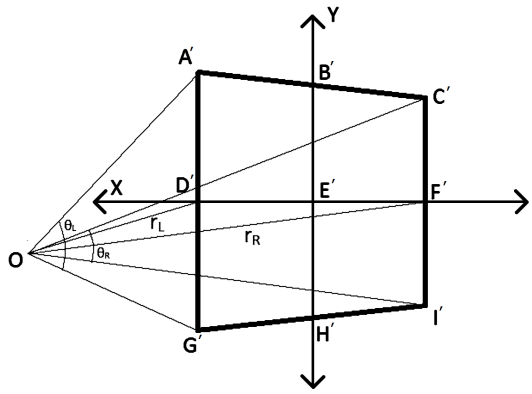

Fig. 2. Perspective view of the nine chessboard corners

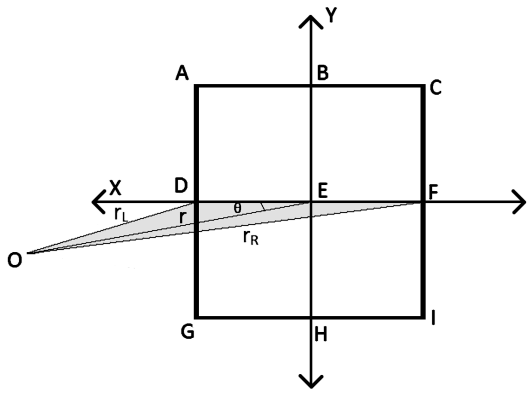

Fig. 3. Determination of polar co-ordinate using Apollonius' theorem

$$OD = AG/\theta_L \qquad \text{and} \qquad OF = CI/\theta_R \tag{2}$$

Let, the radii of the circles be OD = r_L & OF = r_R and the length of a side of the square AGIC in Fig. 3 be v, which can be measured prior to the execution i.e. $AG = CI = v$.

$$\therefore\ r_L = v/\theta_L \quad and \quad r_R = v/\theta_R \tag{3}$$

It is evident from Fig. 3, ODF forms a horizontal triangle of which OE is a median. Therefore, from Apollonius' theorem, (4) can be obtained.

$$OD^2 + OF^2 = 2(OE^2 + DE^2) \tag{4}$$

As, OE is the distance of the camera or robot from the origin (centre point of the reference) i.e. $OE = r$ and $DE = v/2$, (4) can be written as,

$$r = \sqrt{\frac{r_L^2 + r_R^2}{2} + \frac{v^2}{4}} \tag{5}$$

From the properties of a triangle, for $\triangle ODE$ in Fig. 3,

$$\cos\theta = \frac{DE^2 + OE^2 - OD^2}{2 \cdot DE \cdot OE}$$

$$\therefore\ \theta = \cos^{-1}\frac{r_L^2 + v^2/4 - r^2}{rv} \tag{6}$$

This polar co-ordinate (r, θ) can easily be converted to cartesian co-ordinate (x, y) where needed using (7).

$$x = r\cos\theta \quad and \quad y = r\sin\theta \tag{7}$$

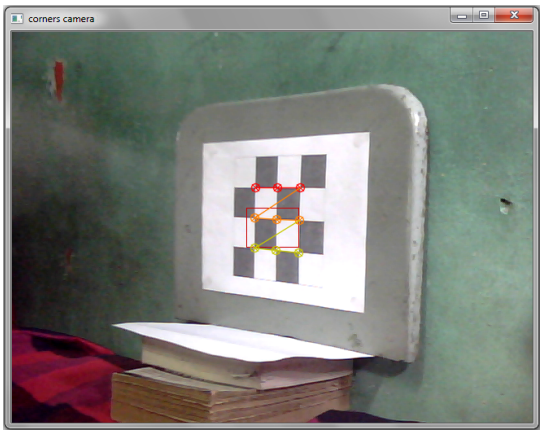

Fig. 4. Experimentation with detection of chessboard corners

TABLE I
COMPARISON BETWEEN CALCULATED AND ACTUAL MEASUREMENT

Actual reading		Calculated reading		Error percentage	
r (cm)	θ^o	r (cm)	θ^o	$\lvert\delta r\rvert$ (%)	$\lvert\delta\theta\rvert$ (%)
44.01	88.7	44.57	88.9	1.27	0.22

105.95	19.29	103.84	18.42	1.99	4.5
120.93	23.39	123.74	22.77	2.32	2.62

D. Limitations

The proposed theory assumes the projection plane of the camera and the plane of the reference pattern, both to be perpendicular to the XY plane. Inclination of either of the planes can cause the calculated co-ordinates to deviate from the actual values.

Although this method needs only four points and hence a 3-by-3 chessboard pattern should work fine, 9 internal corners are detected in this topology. However, as the shape of the chessboard is predefined, these 9 points can be used to generate a better estimation of the values of four required corners.

When the robot is in motion, the blurred image lacks the chessboard pattern. In order to avoid the motion blur, either the image is to be processed with Wiener filter [10] or a camera with much higher FPS (frames per second) should be used.

III. IMPLEMENTATION

To experimentally determine the accuracy of this localization scheme, a chessboard is printed and mounted on a vertical plane at a suitable height. An open source library, openCV 2.4.3 [11] is used in programming of the data collection program.

A. Program flow

The captured image is first checked for motion blur caused by the movement of the mobile robot using morphological filters [12] which is very fast irrespective of the presence of the chessboard in the field of view. The image is then put through chessboard corners finding algorithm [13] using adaptive threshold in order to enhance the compatibility in different lighting conditions. Although this function is a bit slower with no chessboard in the image, as the presence of the chessboard is confirmed by the previous function, the overall running time becomes quite low.

Once a chessboard pattern is detected anywhere in the image as shown in Fig. 4, the robot aligns the camera so that the center of chessboard reference is placed within a predefined region around the principle point of the image. The alignment is performed by successive rotation of a servo motor driven by the feedback from the position of the center of the chessboard in the image.

The image is then converted to gray scale and the corner positions are recalculated to sub-pixel accuracy [14] using Förstner corner detection algorithm.

The nine points are properly arranged and four corner points among them are used in calculation of the co-ordinate using (1), (3), (5) and (6) sequentially. Although the algorithm is robust enough, the corner detection exhibits some fluctuation especially in the inclined positions. Hence a moving average smoothing filter is used to stabilize the calculated values.

B. Data collection

Tests of the robot localization are performed using a chessboard with a dimension of 16.5 cm being the length of a side. Calibration procedures indicate that the field of view of the cameras is 33°. All of the experimental data are obtained using images of 640×480 pixels captured at a rate of 30 frames per second. The whole experiment is conducted in various lighting conditions and also in dynamic background.

The polar co-ordinates (r, θ) of the robot are calculated at different positions in such a way that for a certain value of θ there are 4 positions with different values of r. Thus 4 data are taken at each of the 4 different values of θ. These 16 data are analyzed to estimate the sensitivity of the system.

Table I shows the collected data which are tabulated at 4 different r with each value of θ on the horizontal plane. The calculated values are compared with the physically measured data and the percentages of errors are calculated using (8) and plotted to demonstrate the reliability of the scheme.

$$\delta r = \frac{r_{calc} - r_{actual}}{r_{actual}} \times 100\% \tag{8}$$

IV. RESULTS AND DISCUSSION

Fig. 5 shows that the error in calculation of r increases as the distance from reference increases. This restricts the upper bound of the distance. For this case, a chessboard of 16.5 cm could provide promising (more than 90% accurate) result up to a distance of 200 cm. However, a very close position (below 30 cm) cannot accommodate the full pattern in the image and hence calculation becomes impossible. These limits can be pushed further by increasing the size of the chessboard.

Another way of increasing the range of accurate measurement is to use dynamic zoom. When the size of the chessboard becomes very smaller in the image, the up sampling operation pushes the corner points further from each other and thus increases the accuracy of calculation to a great extent. Again

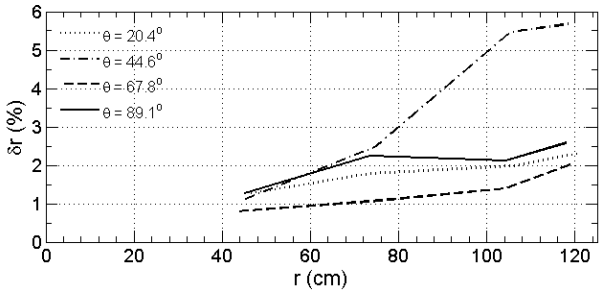

Fig. 5. Variation of δr at different θ

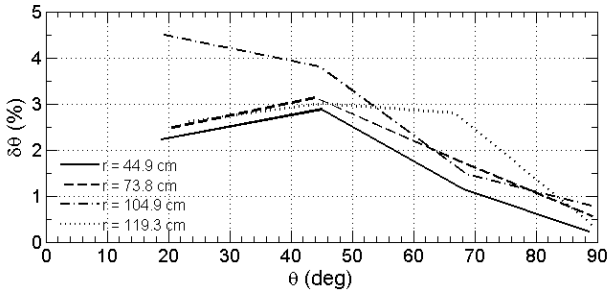

Fig. 6. Variation of $\delta\theta$ at different r

down sampling the image can help in the case when the chessboard is too large to be accommodated in the frame.

The error in calculation of $\delta\theta$ also shows a declining slope as actual θ increases in Fig. 6. As θ decreases, the increasing inclination causes the corners to be appeared very close to each other introducing an error in corner detection. Thus the method fails to measure accurate θ near the values 0° or 180°.

V. Future Development

The proposed scheme has a great possibility of further development in various aspects. As the scheme has a fairly low computational complexity, it can be implemented easily in FPGA technology to reduce the running time and to enhance hardware portability. With the advancement of autonomous vehicle technology, this topology can sufficiently enhance the robotic vision of the vehicle.

A. Three dimensional co-ordinate

As in case of the two-dimensional co-ordinate, the relative lengths of the two vertical sides in the perspective view of the square yielded the polar co-ordinate (r, θ). A more rigorous calculation including the relative lengths of all the four sides in the perspective view of the square will result in the spherical co-ordinate (r, ϕ, θ). This would find its application in localization of an aerial robot where the chessboard would be placed on the ground level.

B. Parallel processing

Parallel processing opens a huge door for further improvement. Parallel algorithm brings computational power efficiency. For parallel algorithms GPU is a very good choice, as they have quite high number of parallel processing cores e.g. 16-1536 cores as compared to CPU [15]. They also provide the opportunity for other expensive computation for decision making for a sophisticated autonomous robot with a number of objectives. Thus the technology of multipurpose robot can be advanced one step ahead by employing this developed scheme.

VI. Conclusions

The demonstrated scheme establishes a simple way of autonomous robot localization requiring minimal hardware and processing power. It provides a more pragmatic solution for autonomous localization in varying light conditions. With a fairly primitive camera, a minimum of 94% accuracy is achieved at measuring range. For terrestrial autonomous robotics application as well as outer-space applications, the proposed scheme provides sufficiently fast computation with substantial accuracy.

Abstract— **This paper presents the proposed control input converter (CiC) for robot leg's joint control with parallel actuation. The parallel actuation commonly used in heavy machine such as backhoe and bulldozer. This configuration performing muscle-based movement since the actuator attached becoming part of the frame. Therefore this particular switching mechanism is designed to translating a desired signal to the linear actuator from any close-loop control input. This simple algorithm is developed from the behavior study of the attached linear actuator motion on each crossed joint angle. The verification is done on actual leg of Quadruped Parallel Leg Actuation (QPAL) robot system by using a real-time target embedded system with focusing on foot motion for each leg and joint angle position error tracking from some angle inputs.**

***Keywords*—parallel actuation, control input converter, multi-joint leg.**

I. Introduction

In mechanical structure point of view various configurations have been introduced such as under-actuated leg, indirect actuated leg, flexible body and wheeled tips approaches. On the other hand, this research and development also involved on motion control, vision/image processing to increase its autonomy, dynamic and stable gait pattern, equilibrium center of body (CoB) control including walking algorithm design by mimicking legged life form living creatures. In the actuation mechanism in multi-limbs robot technology three approaches can be done either direct, parallel/indirect or hybrid mechanism in robot arm and leg design. Direct joint actuation or direct mechanism required sufficient torque to conduct both arm frames with sufficient shaft since major of attached motors contribute to the weight of the robot frame. It is different to the parallel actuation mechanism which is majorly configured as one of the frame structured with strong geared acting like a human muscle. This actuation mechanism is also configured to move leg/arm joint indirectly with limited rotational angles if compare to the direct drive mechanism.

On previous existed multi-legged robot, parallel actuation mechanism majorly applied on hydraulically driven robot design which is majorly used hydraulic cylinder/piston as its actuators such as MACANT[1], ROBOCLIMBER[2], TITAN-XI[3], BigDog[4] and COMET-IV[5]. These robots are focused on mega payload as its main characteristic to deal with the applications. Due to the current technology in electrical motor and actuation, medium and small scale high payload multi-legged robot is possible to be designed by using electrical linear actuator that function same as cylinder hydraulic actuator or servo pneumatics cylinder. Spidernaut from National Aeronautics and Space Administration (NASA) is an example of the large scale multi-legged robot that used parallel mechanism on its leg actuation. This robot has sophisticated indirect actuated leg configuration with 3 degree of freedom (DoF) which allows foot placement in space, but does not have a means of independently controlling the angle of the foot[6]. Furthermore, ADDAM from Kyushu Sangyo University, Japan also applied both indirect and direct actuation mechanism to perform human muscle-based movement for an endoskeleton leg. On its ankle, couple parallel actuation system is designed with adoption of couple parallel link mechanism with one linear actuator and 2-axis joint (cross revolute joint). Total of DoF for this robot is 12 consisting 4-DoF at ankles, 2-DoF at knees and 6-DoF at a hip[7].

Therefore this project has taken initiative to involve in this field by proposed a multipurpose medium duty Quadrupped robot system, namely Quadruped Parallel Leg Actuation (QPAL), with square shape body and 2-DoF indirect actuation and 1-DoF direct actuation of leg configuration using direct current (DC) linear actuator and DC brushed rotary motor respectively. Two revolute joints have been configured with linear actuators to realized closed-link mechanism in different way respectively. The issue will be taken here is to create a driven module to interface easily with the any close-loop control input for each leg's joint movement. The easiest configuration for error tracking on parallel actuation joint movement is to attach the encoder/potentiometer on the joint revolute point instead of estimating linear actuator's stroke movement. Another issue has come out on how to shoot the control input on the actuator driver correctly to achieve almost zero error tracking on joint angle movement. Therefore this research has proposed the control input converter (CiC) module that can be used to extract the control input in real-time legged robot system such as QPAL robot leg's configuration. The target of CiC implementation is to deal with the common and raw full-bridge DC motor driver and not for the advance driver. The research is done by verifying and validating the propose module in actual QPAL robot system with arbitrary angle inputs on each parallel actuation joints.

II. QPAL Robot System Configuration

Quadruped Parallel Leg Actuation (QPAL) is primarily concerned about the efficient structural and mechanic characteristics to deal with the medium payload application (4kg~6kg). As shown in Fig.1, the structure frame of QPAL was designed with a square shape and support polygon. The

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

research and development of this frame work are focused on several key issues that include parallel mechanism configuration design, drive and control technique. Moreover this robot also emphasized on common legged robot locomotion issues; impassable terrain, foot slippage, accidental collision, modeling errors and sensor errors [8].

QPAL was started designed and developed in July 2012 and targeted for medium payload applications such as firefighting extension system, mine detection, medium tunnel surveyor etc. With reference to the fundamental of biological insect legs such as crockroach, beatle and housefly as shown in Fig.2, the motions are made by the linear movement such as contraction and relaxation of furmur and tibia, and articulated with coxa as shoulder attached with the body [9]. Inspired with this configuration, QPAL's leg is designed by attaching linear actuators between shoulder and thigh (bended frame), and between thigh and shank frame as shown in Fig.2 respectively. The linear actuators positioned almost parallel with the links in order to make a bending movement like a muscles by performing extending and retracting as shown in Fig.3. One of the link is bended in order to achieve 90^0 bended position in offset mode as shown in Fig.3(b). This configuration allows large torque on each revolute joint from direct force on linear actuator piston[1].

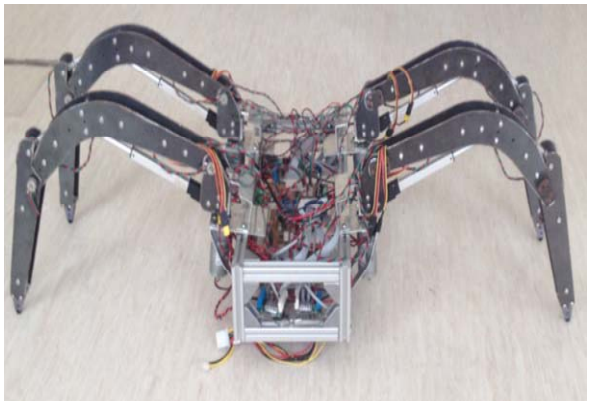

Fig. 1 QPAL robot system

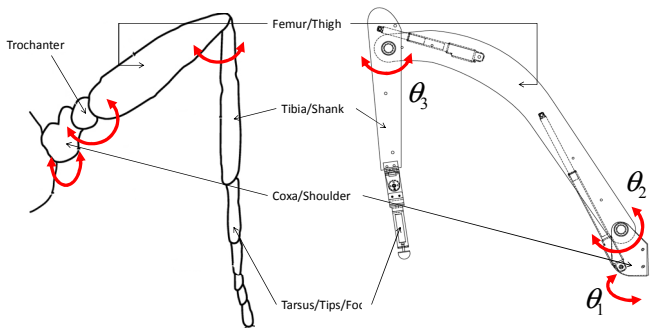

Fig. 2 QPAL's leg configuration that based on biological arthropod's leg

A customize single board named QBoard is designed and developed with extra inputs/outputs (I/Os) by applying digital multiplexer circuit to control each motor/actuator with minimizing the used of microcontroller I/Os as shown in Fig.4. This single board is specifically design for real-time control and monitoring for QPAL robot with up to 3-DoF/leg configuration. Extra detail specification about QPAL robot is tabulated in Table 1.

[1] Each linear actuator has maximum up to 23N of peak power point

Maximum A Linear Motor Speed [mm/s]	10~11	8 Unit
Maximum Total Torque/Leg [Nm]	80~90	4 Unit

III. CIC IN LEG'S CONTROL ARCHITECTURE

QPAL has been prepared with established and simulated control architecture as shown in Fig.5. Since parallel actuation mechanism is used on leg design, drive module becoming important part which is different from direct actuation mechanism. As shown in Fig.3 in Section II, drive module need to be designed according to the extending and retracting motion of a linear actuator to move two revolute joints θ_2 and θ_3. Therefore CiC is design with reference to the angle motion of thigh and shank joints flow mapped as shown in Table 2.

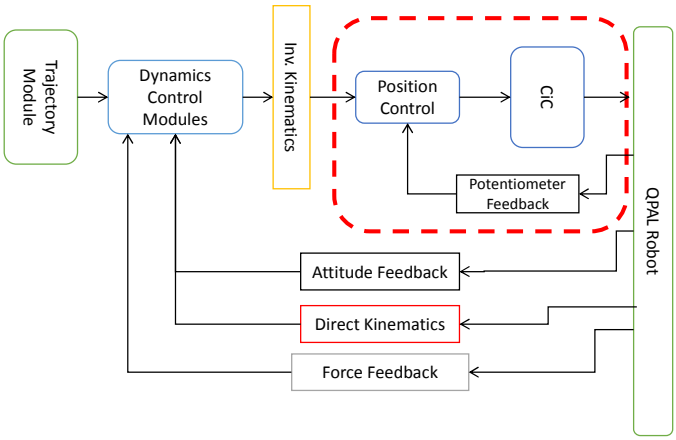

Fig. 5 Overall QPAL control architecture

TABLE II
TRUTH TABLE OF MOTIONS FOR LINEAR MOTOR LOGICAL DRIVE INPUT

θ_2	D_2	u	Actuator Function	θ_3	D_3	u	Actuator Function
0	0	0	Stop	0	0	0	Stop
↓	0	-	Retract	↑	0	+	Retract
↑	1	+	Extend	↓	1	-	Extend
0	X	0	Stop	0	X	0	Stop
↑ = angle increasing ↓ = angle decreasing X = no change							

D_2 and D_3 representing logical input (Bit 1=extending, Bit 0=retracting) for actuator poles control for θ_2 and θ_3 respectively. Moreover u is the control input from any designed control system. Thus to deal with the raw full-bridge driver, the CiC function is illustrated with the switching block as shown in Fig. 6.

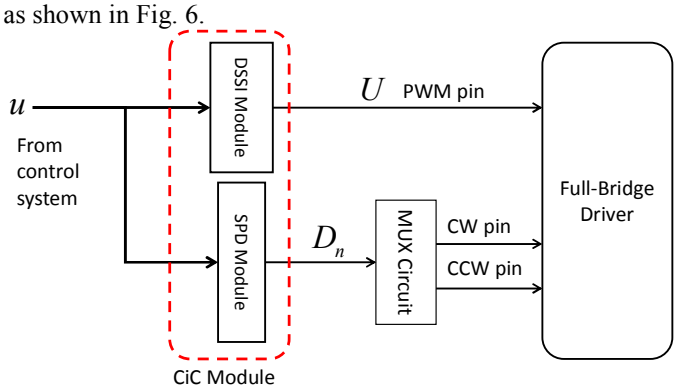

Fig. 6 CiC Module for single full-bridge driver control

The drive input pins of full-bridge driver or commonly known as pulse width modulation (PWM) pin, only accepting positive value signal, thus u need to be always in positive value. The Drive Signal Separator & Invertor (DSSI) module will play a main role here to detect the pole of u and invert this signal if u is in negative value and vice versa. On the other hand the u poles will be extracted as information for logical signal $\{1;0\}$ by Signal Pole Detector (SPD) module to the full-bridge driver via QBoard multiplexer circuit. The CiC also can be concluded in the form of equation as follows with $n = 2,3$;

$$U_n = \begin{cases} |u| & u > 0 \quad D_n = 1 \\ |u| & u < 0 \quad D_n = 0 \end{cases} \tag{1}$$

IV. EXPERIMENTAL AND RESULTS

In order to verify and validating the proposed CiC two experiments are done; analysis on the CiC output via simulation and experimental on a leg movements. Moreover this experiment is done by applying proportional, integral and derivative (PID) control on controlling the precision of joint angle movement for each leg. As shown in Fig. 7, the sample from simulation results (shank's joint angle movement) shows that CiC playing its role by inverting the negative u values from PID controller of poles and range of actuator motion is customized as different signal for retract and extend input respectively.

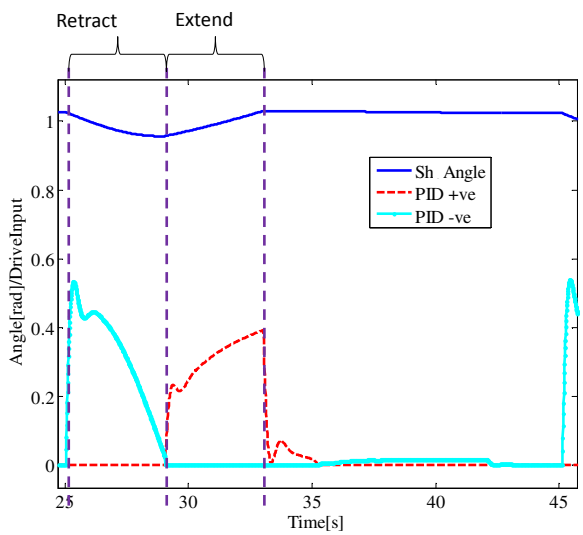

Fig. 7 Experiment results for shank angle input (sample for leg 3)

The verification works is further by moving the leg as shown in Fig.8 with some input. The QPAL robot system is prepared with real-time control structure that used hardware-in-loop concept between computer and QBoard unit in applying control architecture as shown in Fig.5. The function of CiC then is validated by showing stable movement angle as desired and error tracking can be control almost precise between 3-5% as shown in the sample results in Fig.9.

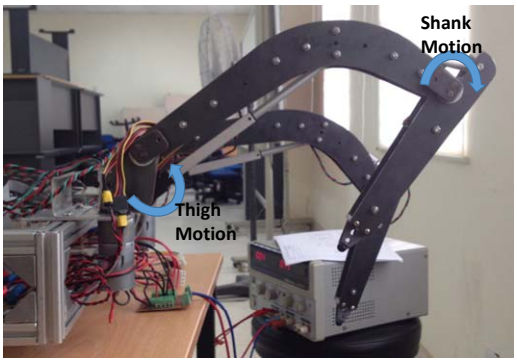

Fig. 8 Snap shot on leg movement of CiC validation (leg 2)

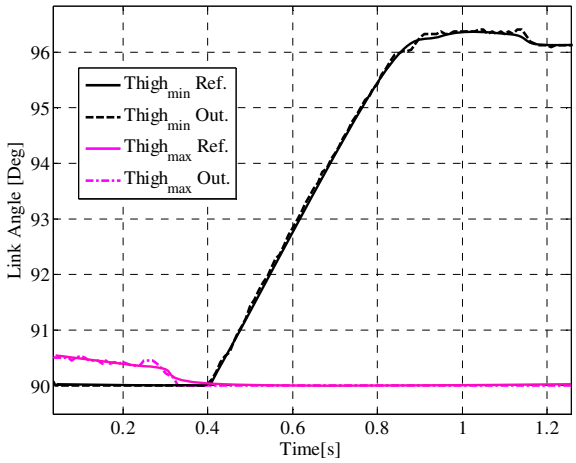

Fig. 9 Experiment results for thigh angle movement (sample for leg 2)

V. Conclusions

The simulation and experiment results show CiC able to stabilize the desired input that controlled via close-loop control such as PID controller for parallel actuation configuration of multi-DoF leg such QPAL robot. Furthermore the proposed DSSI and SPD shows stable inverting and switching operation to make PID control function such direct drive control on the targeted joint. The next progress will target on enhancing and simplifying the CiC module in some control system as adaptive element by considering the real-time hardware constraint and time response.

***Abstract*—A novel technique for increasing the detection range of a fully passive multiresonator based chipless RFID tag has been proposed using the diversity technique at the reader receiver. Analysis is carried out to find the signal to noise ratio at the output of the diversity receiver using maximal ratio combining (MRC) technique. Bit error rate (BER) is analyzed for Rayleigh fading over the channel. The analyzed approach gives a clear insight regarding the interrelationship between BER, detection ranges and reader received power with the application of receiver diversity and has given improved performance in detecting tag at a comparatively longer distance in different non line of sight (NLOS) environment.**

***Index Terms*—UWB, Chipless RFID, interrogator, tag, MRC.**

I. Introduction

Radio Frequency Identification (RFID) is a wireless data communication technology, which uses RF wave for communication between the reader and the tag [1]. The data carrying device is called a tag or a transponder. A reader or an interrogator is used to read and write the tag's information. [1]–[5]. RFID systems are classified as active and passive systems depending on whether the tags are powered up by their own power supply or by the RF energy provided by the interrogating signal. Passive tags can themselves be classified as chipped and chipless tags and are restricted to relatively small distances to the reader. Passive tags with chips are basically the conventional application specific integrated circuit (ASIC) RFID tags [3]. Passive tags without chips which is otherwise known as chipless RFID, are attractive because of their low cost and their ability to function at extreme temperature and high radiation level.

Thus far the research on chipless RFID mainly focuses on tag design, identification and short range localization [4]–[6]. However there had been numerous publications analyzing a reasonably big read range of a chipless tag [7]–[9]. In [7] the range of the ultra-wideband transmission system has been improved using rake receiver where the round trip distance is found to be less than $100m$. In [8] a general model for UWB channels has been presented that is valid for the high-frequency range (3-10 GHz) in a number of different environments as well as for the frequency. Here the maximum distance achieved is not more than $28m$.

In this paper an analytic approach is presented to improve the detection range of a chipless RFID UWB system using receive diversity in the reader with maximal ratio combining (MRC). Results are evaluated numerically for different indoor environmental conditions and improvement in increase in range is provided for different diversity conditions. The system model has been explained in section II, the analysis part has been explained in section III, in section IV the results are discussed and finally with a brief summary the concluding remarks are added in section V.

II. Proposed System Model

A. System Model of the Proposed Chipless RFID System

The system is composed of a reader (Interrogator) and a tag (Transponder) each equipped with an antenna serving the purpose of both transmitter and receiver simultaneously with the help of duplexers as shown in Fig. 1. When the interrogation signal from the reader reaches the tag, it is received using the receiving antenna of the tag and propagates further on towards the multiresonating circuit imprinted on the tag. The multiresonating circuit encodes data bits introducing attenuation and phase jumps at particular frequencies of the spectrum. After passing through the multiresonating circuit, the signal contains the unique spectral signature of the tag and is transmitted back to the reader receiver by the transmitting antenna of the tag [9].

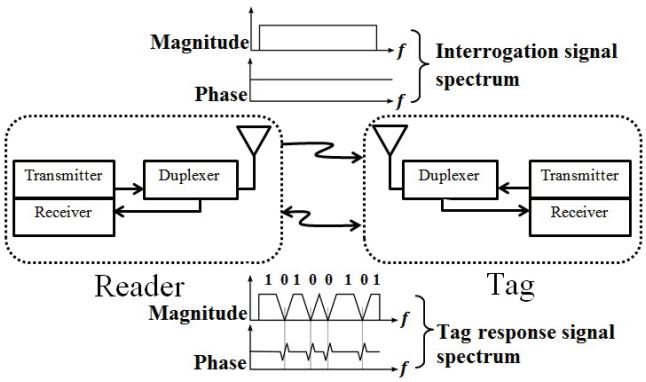

Fig. 1. System model

B. Reader Transmitter/Receiver Model Without Diversity

In the transmitter section of Fig. 2, the interrogator signal passes through a band pass filter (BPF) which acts as an input band limiting device. The band limited signal then goes through an up-converter which converts the frequency of the interrogating signal to a suitable frequency . The up-converted signal is then passed through the high power amplifier (HPA) that amplifies the modulated RF carrier to a suitable level.

On the receiver section of Fig. 2, the reader receives the low-level modulated RF carrier in the downlink frequency

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

spectrum. The low noise amplifier (LNA) is used to amplify the weak received band limited signals and improve the signal to noise ratio (SNR). RF is then reconverted to IF by the down-converter. The demodulator estimates which of the possible symbols was transmitted based on observation.

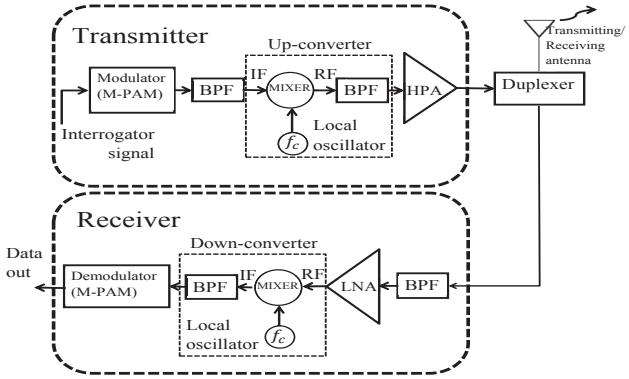

Fig. 2. Transmitter/Receiver block diagram of the proposed RFID reader

C. Reader Receiver Model Using Multiple Receiver With Maximal Ratio Combining (MRC)

In MRC, the combining technique assumes that the receiver is able to accurately estimate the amplitude fading $\alpha_l(t)$ and carrier phase distortion $\theta_l(t)$ for each diversity channel. With the knowledge of complex channel gains, $\alpha_l(t)e^{j\theta_l(t)}, l = 1, 2, ...L$, the receiver coherently demodulates the received signal from each branch. The phase distortion $\theta_l(t)$ of the received signal is removed from the lth branch by multiplying the signal component by $e^{-j\theta_l(t)}$ (Fig. 3). The coherently detected signal is then weighted by the corresponding amplitude gain, $\alpha_l(t)$. The weighted received signals from all the L branches are then summed together and applied to the decision device to achieve the best performance [10].

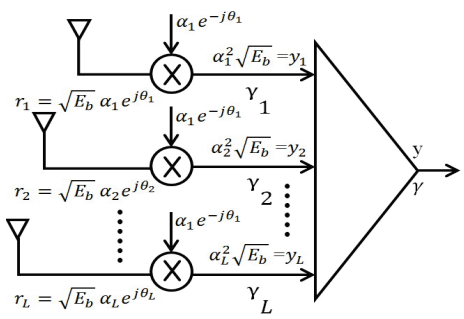

Fig. 3. Maximal ratio combining in the reader receiver end

III. Analysis

The transmitted PAM signal can be expressed as:

$$s(t) = \sqrt{2P_T}e^{j\omega_c t} \times a_i \tag{1}$$

where a_i represents the i-th symbol of the M-array PAM modulation and are given by, a_i=$\pm\frac{A}{2}$, $\pm\frac{3A}{2}$,.....$\pm\frac{(M-1)A}{2}$, M being even. The signal received by tag receiver is given by:

$$r(t) = s(t) \otimes g(t) + n(t) \tag{2}$$

The signal received by the reader receiver with $j - th$ antenna is given by:

$$\begin{aligned} y_j(t) &= r(t) \otimes h_j(t) + n_0(t) \\ &= s(t) \otimes g(t) \otimes h_j(t) + n(t) \end{aligned} \tag{3}$$

The output of the maximal ratio combiner is [11]:

$$\begin{aligned} y_0(t) &= \sum_{j=i}^{L} y_j(t) \otimes h_j^*(t) + n_0(t) \\ &= \sum_{j=i}^{L} s(t) \otimes g(t) \times |h_j(t)|^2(t) + n(t) \end{aligned} \tag{4}$$

$g(t)$ includes the effect of channel gain coefficient and $h_j(t)$ is the channel gain for tag to $j - th$ receiver. Frequency dependent path gain, $g(t)$ in a UWB environment neglecting the interdependence between the direction of the radiation and the directivity of the antennas is expressed as follows [8]:

$$G(f) = \frac{P_{RX}}{P_{TX}} = \frac{1}{2}.G_o.\eta_{TX}.\eta_{RX}.\frac{(\frac{f}{f_c})^{-2(k+1)}}{(\frac{d}{d_0})^n} \tag{5}$$

where, f_{min} = Minimum frequency, f_{max} = Maximum frequency, BW = Band Width, f_c= Reference frequency, d = Round trip distance in meter, d_0 = Reference distance, P_{TX} Transmit power, $G(f)$ = Path gain, P_{RX} = Receive power, G_0 = Path loss in the reference distance in dB, η_{TX} = Antenna transmit efficiency, η_{RX} = Antenna receive efficiency, k = Decaying factor, n = Path loss exponent. By furnishing all the necessary data in equation 5, P_{RX} is calculated. Thereafter, P_{RdBm} is calculated using the formula $P_{RdBm} = 30 + 10 \times log10(P_{RX})$

Probability Density Function in a Rayleigh fading environment using MRC technique is given as follows [10]:

$$P_r(\gamma) = \frac{(\gamma^{L-1}) \times exp^{-\left(\frac{\gamma}{\gamma_c}\right)}}{(L-1)! \times \gamma_c^L} \tag{6}$$

Here $\gamma_c = \frac{P_{RX} \times T_p}{N_0}$ (The average SNR per bit in each diversity channel), L = Receiving antenna, $T_p = \frac{1}{BW}$ (Time gap between two adjacent pulses), $N_0 = K \times T \times F$ (Noise power spectral density), $K = 1.3806488 \times 10^{-23}$ (Boltzmann Constant), T = Room temperature, F = Noise figure, γ = Overall signal to noise ratio [7]. By furnishing the data in equation 6, $P_r(\gamma)$ is calculated.

The bit error probability for an M-array PAM system is given as follows [7]:

$$P_b(\gamma) = \frac{M-1}{M} erfc\left(\sqrt{\frac{3c\gamma}{M^2-1}}\right) \tag{7}$$

Here, M = Alphabet size and c = Number of information bits carried by each symbol. By furnishing the data in equation 7, P_b is calculated.

The average bit error probability over a Rayleigh fading environment with diversity can be expressed as follows [10]:

$$BER = \int_0^\infty P_b(\gamma) \times p_r(\gamma)dx \tag{8}$$

IV. Results and Discussion

Following the analysis presented in section III, the bit error rate (BER) performance of an RFID network is evaluated numerically for different environmental condition as described bellow.

A. Indoor Residential Environment (Fixed Transmit Power)

These environments are critical for home networking, linking different appliances, as well as safety (fire, smoke) sensors

over a relatively small area. The building structures of residential environments are characterized by small units, with indoor walls of reasonable thickness [8]. Here the interrogator transmit power is assumed to be $200mW$. Other parameters are assumed as, $f_{min} = 3GHz$, $f_{max} = 10GHz$, $f_c = 5GHz$, $BW = 500MHz$, $n = 4.58$, $G_0 = -10dBm$, $d_0 = 1meter$, $\eta_{TX} = .80$, $\eta_{RX} = .20$ and $k = 1.53$. These parameters have already been used in previous analysis in a research work and have been accepted as standardized model by IEEE 802.15.4a. [8].

Fig. 4 depicts the plots of BER versus round trip distance in case of an indoor residential environment for different antenna diversity. From the plot it is clear that the BER increases with the increase of distance for a given number of antenna. It is further noticed that as the number of receiving antenna is increased, the achievable distance increases at the same BER. The achievable values of the round trip distance are plotted in Fig. 5 as a function of number of reader receiving antenna, L for several values of BER. It is noticed that, achievable distance is however smaller for lower BER values.

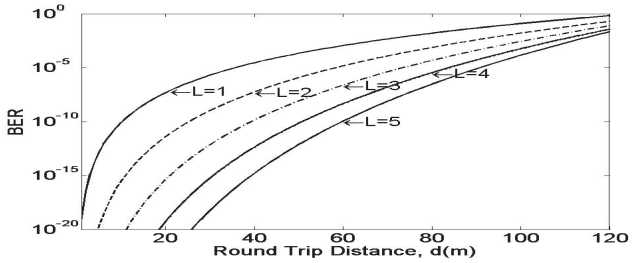

Fig. 4. Plots of BER versus round trip distance with fixed transmit power (Indoor residential NLOS environment)

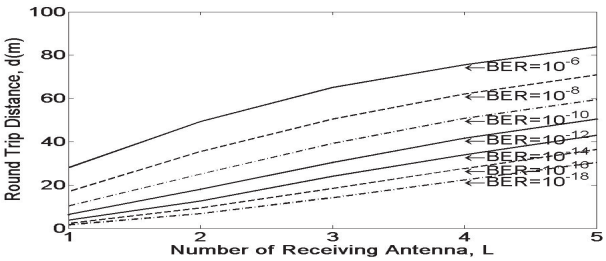

Fig. 5. Plots of round trip distance versus number of receiving antenna with fixed transmit power (Indoor residential NLOS environment)

The plots of BER versus power received by the reader receivers are shown in Fig. 6, for indoor residential environment with diversity in the receiver. It is noticed that the receiver sensitivity at a given BER improves with the increase of the number of receiving antenna at a given transmit power level. The required receiver sensitivity to attain a given BER are shown in Table I for different number of receiving antenna with a fixed transmit power. It is found that there is a significant improvement in receiver sensitivity due to receiver diversity.

B. Indoor Industrial Environment (Fixed Transmit Power)

This environment is characterized by larger enclosures (factory halls), filled with a large number of metallic reflectors and anticipated to lead to severe multipath. The parameters used here is similar to that followed in para IV-A except the value

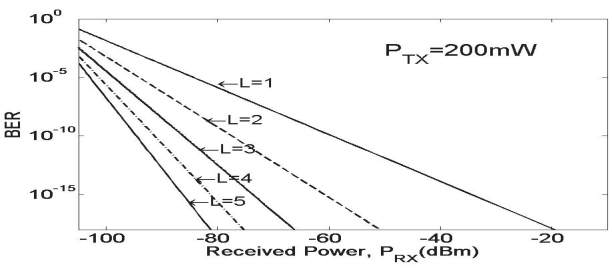

Fig. 6. Plots of BER versus received power with fixed transmit power (Indoor residential NLOS environment)

TABLE I
RECEIVER SENSITIVITY TO ATTAIN A GIVEN BER WITH FIXED TRANSMIT POWER AND DIFFERENT NUMBER OF ANTENNA (INDOOR RESIDENTIAL NLOS ENVIRONMENT)

BER	Received Power in dBm for different L				
	L=1	L=2	L=3	L=4	L=5
10^{-6}	-79.09	-90.59	-96.07	-98.85	-101.2
10^{-8}	-69.31	-83.94	-91.22	-95.26	-98.85
10^{-10}	-59.43	-77.3	-85.92	-91.31	-97.95
10^{-12}	-49.28	-71.05	-81.16	-87.27	-91.31
10^{-14}	-39.23	-63.83	-75.77	-83.14	-87.72
10^{-16}	-29.14	-57.28	-71.01	-79.09	-84.48
10^{-18}	-19.38	-50.72	-66.16	-75.37	-81.25

of path loss exponent, n and the decaying factor, k are assumed to be 2.15 and -1.427 respectively [8].

Fig. 7 and Fig. 8 shows performance similar to indoor residential environment except that the detection distance that can be achieved in case of indoor industrial environment for a particular BER is much higher compared to that achieved in case of indoor residential environment. It is due to the presence of a large number of metallic reflectors which leads to higher multipath propagation.

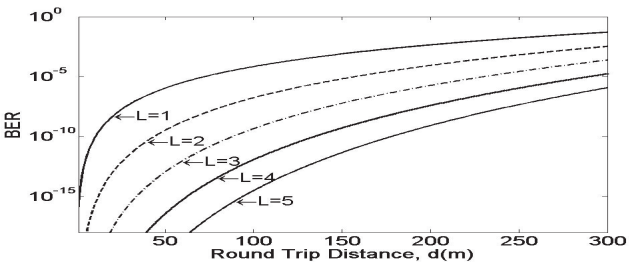

Fig. 7. Plots of BER versus round trip distance with fixed transmit power (Indoor industrial NLOS environment)

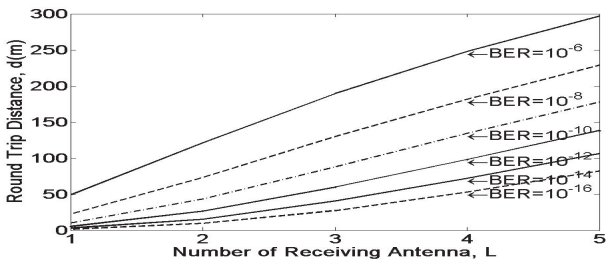

Fig. 8. Plots of round trip distance versus number of receiving antenna with fixed transmit power (Indoor industrial NLOS environment)

Fig 9 and Table II shows performance similar to indoor

residential environment except that at a given BER and at a fixed transmit power level, better improvement in receiver sensitivity is noticed with the increase of receiving antenna in case of indoor industrial environment compared to that noticed in case of indoor residential environment.

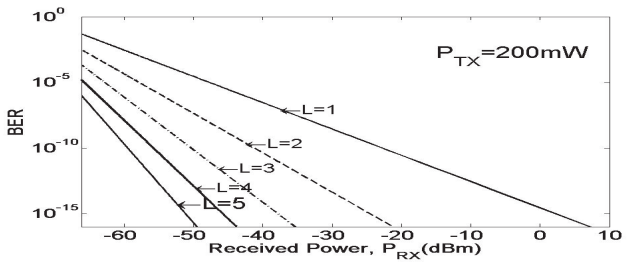

Fig. 9. Plots of BER versus received power with fixed transmit power (Indoor industrial NLOS environment)

TABLE II
RECEIVER SENSITIVITY TO ATTAIN A GIVEN BER WITH FIXED TRANSMIT POWER AND DIFFERENT NUMBER OF ANTENNA (INDOOR INDUSTRIAL NLOS ENVIRONMENT)

BER	**Received Power in dBm for different L**				
	L=1	**L=2**	**L=3**	**L=4**	**L=5**
10^{-6}	-42.71	-54.41	-60.26	-63.77	-66.12
10^{-8}	-32.7	-47.81	-55.16	-59.81	-62.76
10^{-10}	-24.94	-41.18	-50.33	-55.64	-59.58
10^{-12}	-12.63	-34.47	-45.34	-51.83	-56.11
10^{-14}	-2.76	-27.53	-39.98	-47.54	-52.98

C. Variable Power (Residential and Industrial Environment)

The plots of BER versus round trip distance for indoor industrial environment with 5 receiving antenna are shown in Fig. 10, with transmit power as a parameter. The plots indicate that for a given transmit power the BER increases as the distance is increased. It further indicates that for a given distance the value of BER decreases (BER improves) with the increase of transmitted power. The plots shown in Fig. 11 indicate the achievable round trip distance for a given BER as a function of transmit power. These plots clearly indicate that the maximum achievable distance is however lower at lower BER. The same phenomena it expected to happen in case of indoor residential model with inferior detection range. For example at $200mW$ transmit power the maximum achievable distance with 5 receiving antenna at a particular BER of 10^{-10} in case of indoor industrial environment as shown in Fig. 7 is $177.80m$ which is $59.54m$ in case of indoor residential model (Fig. 4). Similar inferiority in case of other transmit power levels $(40mW, 80mW, 120mW\ and\ 160mW)$ are expected to happen in case of indoor residential environment .

V. CONCLUSION

A low-cost novel architecture and a simple analysis method for detecting multiresonator-based chiplss RFID tags in UWB environment using MRC technique is presented where the transmit power has been kept within the limits of $40mW$ to $200mW$. The detection technique is analyzed for indoor residential and indoor industrial environment. It is found that the detection range can be increased significantly by increasing the number of receiving antenna at the reader receiver without

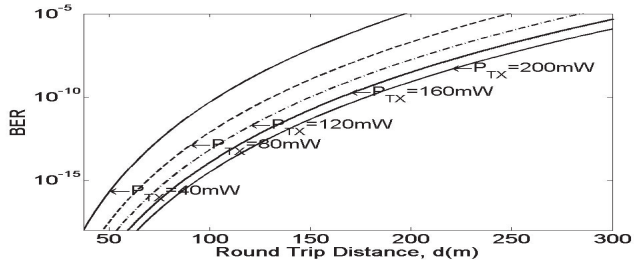

Fig. 10. Plots of distance versus BER with 5 receiving antenna (Indoor industrial NLOS environment-variable power)

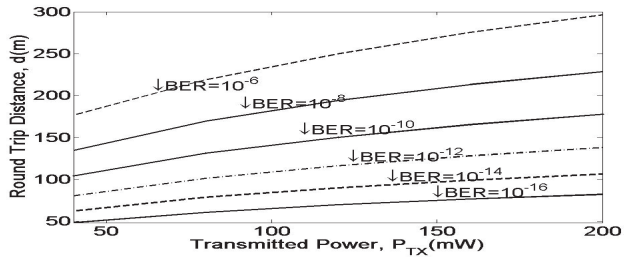

Fig. 11. Plots of transmitted power versus round trip distance with 5 receiving antenna (Indoor industrial NLOS environment-Variable power)

increasing the transmitting power. A comparative study between the two clearly indicates a better detection range for indoor industrial environment than the former one. Similar type of results can be evaluated in case of indoor office environment, outdoor environment, agricultural environment and body area network with certain changes in the parameters [8]. The proposed method not only offers an easy way to evaluate detection range but also allows the user to make certain reasonable assumptions regarding the appropriate scheme for achieving the best performance.

Abstract—**This paper provides a short overview on the state of the art in electromagnetic transduction based chipless RFID sensors. These types of sensors can be used for various applications including structural health monitoring, pressure, airflow and displacement detection, temperature, humidity, partial discharge monitoring and so on. A novel concept of high resolution crack sensing using super wideband antenna is also introduced here along with a brief review on airflow and partial discharge sensors.**

***Index Terms*—SWB Antenna, Airflow, Partial Discharge, Electromagnetic Transduction.**

I. Introduction

Radio Frequency Identification (RFID) is a wireless data capturing technology that utilizes radio frequency waves for extracting the identity of the remotely placed objects automatically. The RFID tag has the potential to replace the barcode on account of its manifold benefits, including its long reading range, non-line of sight reading as well as automated tracking and identification. The recent development of chipless RFID technology gives a new direction in the field of RF identification to address new markets such as items tracking where a unit cost comparable to those of optical barcode is an economic constraint. This technology doesn't embed any silicon ICs for the ID extraction and instead it uses the electromagnetic signature for data encoding which reduces the cost of the RFID tags to a level as low as the barcodes. [1] [2].

Sensors are a substantial part of multifaceted and sophisticated systems of contemporary technology. Sensors and associated measurement circuits pose a challenge towards the development of a low cost intelligent sensing system for which chipless RFID technology could offer an appropriate solution. Recent advancement in wireless sensor networks has paved the way to combine sensor and sensing technologies with RFID system. In addition to the automatic object identification, the RFID technology can monitor and share information about the surrounding environmental condition by using sensor enabled tags. Thus, an object which simultaneously provides its own condition and identification simplifies the total infrastructure and enhances the quality of the information. The passive chipless RFID sensors do not require any emitter integrated into the sensing unit. They are generally composed of integrated sensing components into the resonant circuits with lumped discrete elements such as inductors and capacitors as well as antennas or loops. The passive systems require energy from a reader device in order to be read, but the power levels can be very small. The reader is also utilized to analyse the backscattered signal by the sensing unit. [3] Such sensors are more adaptable to energy harvesting, has a simpler structure and more compatible with harsh environments. They are mostly suitable for applications that require sensing devices with low cost fabrication, small size and long term measurement ability. Chipless RFID tag sensors have huge potentials in retails, structural health monitoring, transportation, biotech, pharmaceuticals, security and surveillance.

Electromagnetic transduction based passive chipless RFID sensors convert the physical quantity into the variation of an EM descriptor. The modification of these descriptors by physical parameter to be measured is backscattered to the reader wirelessly where it is detected. This article presents a brief literature review on selected EM transduction based passive chipless RFID sensors as well as introduces a novel concept in crack sensing through the use of a super wide band antenna.

II. Classifications

The passive wireless sensors can be categorized into four different groups as shown in the following block diagram.

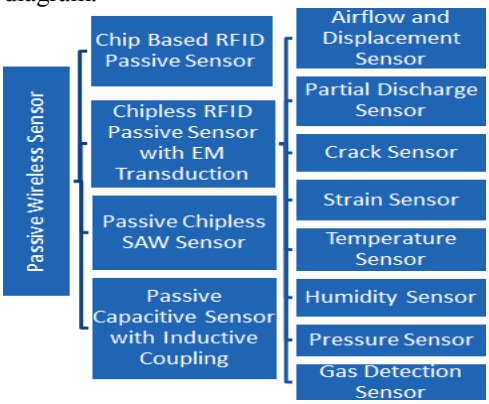

Fig. 1. Classification of Passive Wireless Sensors

The chip based RFID passive sensors can offer a very high accuracy depending upon the accuracy of the integrated transducer, however, its incompatibility with harsh environments and low interrogation distance has curtailed its application area to a very

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

limited range. The SAW sensor is the only commercially available chipless sensor but it has the disadvantage of being non-planar and having inconvenient fabrication process as well as low interrogation distance due to acoustic to EM wave conversion losses. The capacitive sensor has a high autonomy and simple technology but it also has a limited compatibility with harsh environment and requires a very low distance between the reader and sensor. The electromagnetic transduction based Chipless RFID sensors overcome these limitations and offer a pretty high interrogation distance. It can be operated at high frequencies which mean the sensors can be designed with a compact dimension. This type of sensor also meets the need for lightweight, flexible and durable wireless RFID enabled sensor nodes by enabling the use of a great choice of materials.

III. EM Transduction Principle Based Sensors

The electromagnetic transduction principle is used for the remote measurement of various kinds of physical parameters using micro-sensors requiring no active power supply and no signal processing circuitry. [4] When the sensor is placed into an environment to detect the variation or presence of a particular physical phenomenon, its RF parameter such as the resonance frequency or RF impedance is modified by that phenomenon. This modification is instigated by three key principles: the change in dimension or the variation of physical or electrical length a resonator, the modification of EM materials properties such as the variation of a resonator permittivity and the modification of RF coupling between a resonator and a microstructure.[5] Such modifications induces resistive or reactive variation of the system which influences the resonance frequency, impedance, quality factor and the radar cross section (RCS) level to provide a spectral signature containing information about the physical condition of the surrounding environment. The modified RF parameters are backscattered to a RFID reader to be analysed and measured. A wide variety of sensing properties can be addressed by Chipless RFID passive sensor with EM transduction as depicted in fig.1. This article briefly discusses about some of these properties as follows:

A. Airflow and Displacement Sensor

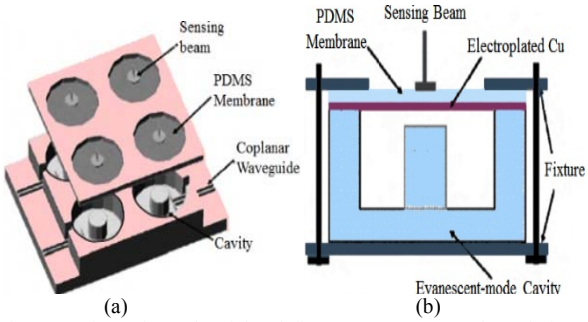

Fig. 2. Design schematic of the airflow sensor array: (a) lateral view, (b) cross-sectional view [6]

Zhao et al. has reported an airflow and displacement sensor based on RF evanescent mode cavity resonator in [6]. For a particular resonant frequency, the evanescent mode cavity resonators have a much smaller size compared to the rectangular or circular cavity resonator. Therefore, the sensitivity of the resonant frequency depending on the dimension of the cavity turns out to be more prominent in case of evanescent mode resonators. The proposed sensor has a rectangular or circular cavity with an electrically shorted centre post. When the air gap between the cavity and the post closes to zero, the parasitic capacitance increases which results in a sharp decrease in the resonance frequency. [6]

Fig.2 shows the schematic diagram of the airflow sensor where an elastic (PDMS) membrane is used to seal the cavity and a small sensing beam protrudes from the membrane surface which extends into the flow for effectively sensing the velocity of the airflow. These membrane and beam form the mechanical part of the sensor while the cavity and the coplanar waveguide (CPW) feeding structures constitute the RF part. The CPW feed is used to excite the resonator and it enables an easy integration of sensing elements with the antenna. [6]

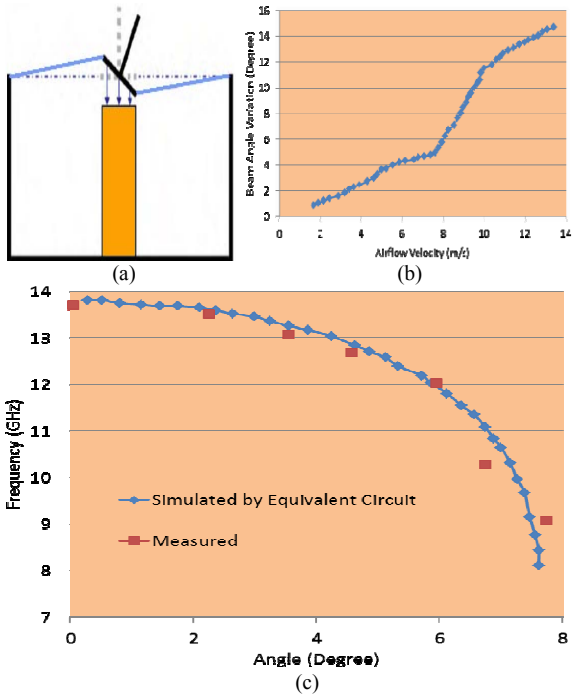

Fig.3 (a) Sensor Mechanism (b) Measured beam angle variation vs airflow velocity (c) Simulated and measured beam angle vs resonance frequency [6]

Fig. 3 (a) shows the operation principle of the reported sensor. If airflow is applied on the sensing beam, it gets deflected and hence changes the capacitance between the elastic membrane of the cavity and the top surface of the post. This in turn modifies the resonance frequency of the cavity resonator. The sensitivity of the sensor is expressed as:

$$S = S_{RF} \times S_{Mechanical}$$

$$\text{Where, } S_{RF} = \frac{\Delta f_r}{\Delta \theta_{beam}} \text{ and } S_{Mechanical} = \frac{\Delta \theta_{beam}}{\Delta v_{airflow}}$$

Fig. 3 (b) and (c) show the RF measurement plots for $S_{Mechanical}$ and S_{RF} respectively. The proposed sensor achieves an equivalent sensitivity of larger than 0.37 GHz/ (m/s) for the airflow velocity sensing. The sensitivity or dynamic range can be easily adjusted by controlling membrane thickness or sensing beam dimension in order to meet requirements of specific applications. The proposed sensor can also be used for the wireless sensing of normal directional displacement by using similar principles. [6] The fabricated displacement sensor is wirelessly interrogated by integrating an UWB antenna with the cavity resonator based sensor as well as two external reader antennas. A vertical force is applied to the sensing beam to generate a displacement. When the beam is displaced, a significant shift in the resonant frequency occurs.

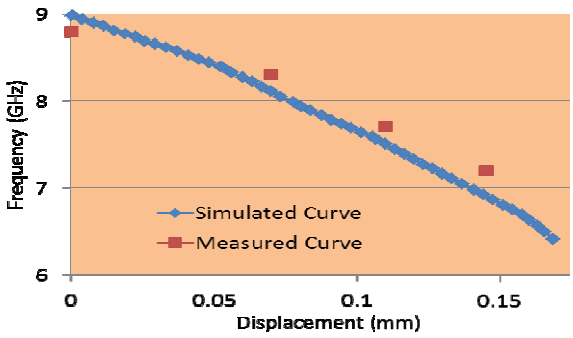

Fig. 4. Measured resonant frequency by wireless interrogation vs. beam displacement. [6]

Fig. 4 shows the resonance frequency versus vertical beam displacement and indicates a sensitivity of 16.7 MHz/µm. [6]

B. *Partial Discharge Sensor*

Electromagnetic transduction based chipless RFID sensors can be utilized for online monitoring of high voltage equipment in a switchyard without sacrificing reliability and capacity deployment. A partial discharge in HV equipment occurs when the electric field across a dielectric medium changes in such a way that a localized current is created. This current induces RF emission which is wirelessly captured and analysed for PD level and location detection [7]. A novel remote PD sensor is reported in [7], by the authors at the Monash University. It uses frequency modulation based technique for the detection of potential PD sources in a switchyard which reduces the reflection and multipath effect on source localization. This sensor consists of cascaded coplanar quarter wavelength tri section Stepped Impedance Resonators (SIR) that are coupled to a Microstrip line. The resonators act as band stop filters that modify the received UWB interrogation signal from the reader to provide with distinct frequency signatures to encode data as identification bits.

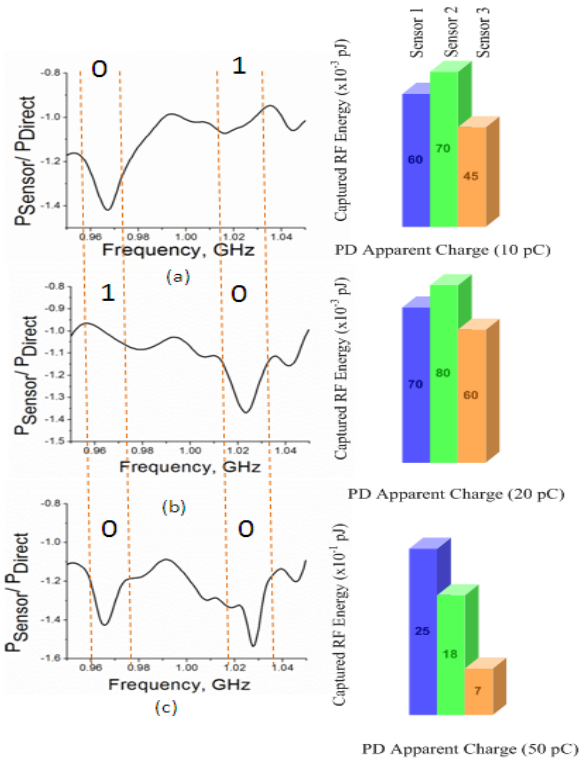

Fig. 5 Power spectrum for (a) sensor1, (b) sensor2 and (c) sensor3 having data ID 01, 10 and 00. (d) Measured RF energy for three sensors for PD apparent charge of 10, 20 and 50 pC.

Moreover, the sensor provides information about PD signal level by calculating cumulative energy. Three PD sensor operating between 950 -1050 MHz is developed using two SIR filters. The filters can encode data 0 and 1 depending on presence and absence of a resonance dip in frequency spectrum. Fig. 5 (a) - (c) shows the measured spectral response of sensor 1, sensor 2 and sensor 3 having encoded bits 01, 10 and 00. Also, Fig. 5 (d) shows measured cumulative energy for each sensor at various PD levels. For PD apparent charge 10, 20 and 50 pC, sensor 1 and sensor 2 have higher RF energy than sensor 3. This is due to the presence of both the filters in series resulting higher attenuation. However, in frequency spectral analysis the encoded data bits can be clearly identified.

C. *Crack Sensor*

In [8], it has been shown that a short duration UWB pulse which lasts only several nanoseconds can detect and localize a crack by utilizing a transmission line of few meters. The sensing system is established on the Time Domain Reflectometry (TDR) based chipless RFID technique. When an RF interrogating pulse from the reader reaches the sensor, a portion of it is immediately reflected back and another part is harnessed by the receiving antenna of the sensor which travels through the long transmission line segment until it experiences the abrupt termination of the transmission line. At this point the signal gets reflected

back towards the antenna of the sensor and ultimately gets retransmitted into the free space. These phenomena at the sensor instigate two prominent RF echoes: i.e. the initial reflection of the sensor antenna and the secondary retransmission of the harnessed energy. The time difference of arrival (TDOA) of these two echoes at the reader is determined by the length of the transmission line which in fact introduces a propagation delay to the secondary echo. In case of a structural failure, the sensor transmission line is ruptured which causes an open circuit termination at a shorter length. This premature termination of the transmission line changes the TDOA between the two echoes received at the reader and hence the TDOA can be used to determine the presence of a crack in the structure and also to localize it. [8]

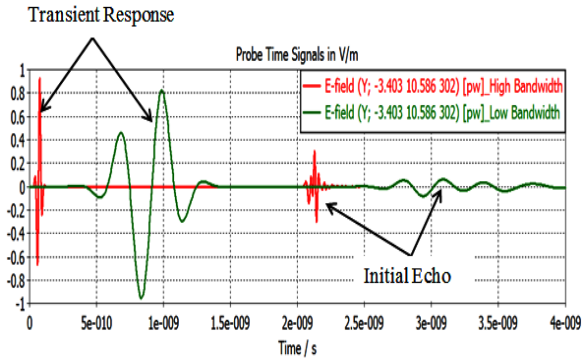

Fig. 6: Time domain response indicating potential application of the SWB antenna as high resolution sensor

A Super Wide Band (SWB) antenna based sensor can achieve more accurate localization of the crack by enabling extremely short SWB pulses. These short duration pulses also enable very high resolution estimation of distance to targets. If the crack is very near to the sensing antenna, it will not have enough time to be detected with the UWB sensors as the initial and secondary echo will be superimposed on each other. However, since the SWB sensors have shorter pulses, the initial reflection will be decayed before the arrival of secondary reflection which will give them enough time to detect the TDOA. For this type of sensors, the time domain antenna transients also decay extremely quickly to enhance the probabilities of clearly distinguishing both the echoes. Here, the SWB antenna is interrogated with a plane wave and the reflected signal is captured by a receiving probe. Fig. 6 shows the reflected time domain response at the probe. It depicts the comparison between the time domain signals of both UWB and SWB antennas. From fig. 6, it can be observed that for low bandwidth, the transient response and the initial echo is quite widespread in the time domain which indicate their longer duration for getting decayed. However, for higher bandwidth (SWB) the same antenna time domain responses get decayed very quickly and offer extremely short pulses. Thus the SWB sensor enables reflected signals to be detected more precisely and accurately since one pulse does not interfere the other.

IV. Conclusions

This paper presents a brief review on selected EM transduction based chipless RFID sensors along with the state of the art in this research field. A novel concept of crack sensing is also introduced here by using SWB technology. These sensors offer unlimited energy autonomy and consumes no power due to the absence of any embedded chip or battery. They are highly compatible with harsh environments like high temperature and high radiation level and offer a substantially higher reading distance compared to the other passive sensors. A wide range of materials can be used to design such sensors which enable them to be planar, lightweight and flexible. The printable structures and high frequency designs reduce the size and cost of these sensors significantly. Despite the enormous potential and exciting prospects, there exist a number of limitations in this technology in terms of security, networking, mass production and deployment, etc. This technology is still in its infancy and therefore, a huge room for improvement is present to bridge the gap between the transducer concept validations to actual sensor development with desired functionalities. Identifying smart materials with multi-sensing capabilities and their RF characterization as well sensor designs for various applications open a new research horizon in chipless RFID sensing technologies. Addressing these issues would be a revolutionary step towards the commercialization of EM based chipless sensors and pave the way for broadening the focus for applied research enabling the implementation of ambient intelligence.

***Abstract*— In this paper, a local phase correction method is proposed and demonstrated to effectively mitigate mode conversion in coupled transmission line bends leading to significant improvement in their high-speed performance. Signal loss and mode conversion improvements by more than 5 dB and 16 dB respectively at 50 GHz are reported for experimental prototypes. Good correlation has been established among analytical predictions, full-wave electromagnetic simulations and measurements.

***Index Terms*—Bend discontinuity, common mode filtering, common mode noise suppression, coupled lines, differential lines, high-speed routing, intra-pair skew, microwave discontinuity, mixed mode, mode conversion, phase correction, signal integrity, transmission line bends.**

I. Introduction

Raw signalling speeds in both wired and wireless communication networks have been steadily increasing to meet unrelenting demands for higher data bandwidth and throughput. As a result, high speed transmission lines are becoming essential in all levels of interconnection in a system. Of particular importance are coupled transmission lines used as differential lines which are most common in today's high speed systems, as they provide higher bandwidth and better immunity from noise and crosstalk. In order to achieve optimal performance with this type of differential lines, careful attention needs to be paid to every details of component placement and signal routing from early on in the design cycle. In a densely populated system board or component package or integrated circuit chip, turns and bends of signal lines are unavoidable. These turns and bends would eventually limit the bandwidth performance of a system employing coupled transmission lines [1], [2].

Coupled transmission lines support two modes of propagation, namely differential (odd) mode and common (even) mode. When a uniform coupled transmission line bends, conversion from one mode to another is inevitable. A purely differential mode before the bend will be transformed into a mixed mode, partly differential and partly common mode, after the bend. In a differential system, common mode is undesirable. Not only it takes energy away from the desired differential mode increasing the insertion loss as such, it also causes crosstalk, noise and electromagnetic interference.

In order to avoid bend related signal integrity issues in a differential channel, the first preference would always be to keep critical signal paths free of bends, i.e. route them in straight lines. However this is often not possible as the signal lines have to stay clear of many keep-out zones typically found in interface, fanout and connector access areas on boards and substrates. For signals that continue in the same direction, bends occur in pairs. If the coupled lines do not have modal dispersion, the bends in a pair compensate each other producing only minimal effects on signal propagation. However if the coupled lines exhibit modal dispersion, it would be shown later in this paper that the pair would no longer be fully compensating in nature and can cause significant deterioration of signals. For signals that do not continue in the same direction, some bends would always remain uncompensated. Therefore for a method to be universally effective in mitigating bend effects, it has to locally compensate each and every bend. A number of such schemes have been recently demonstrated to improve differential bend performance [3]-[5]. However there are practical challenges in implementing these methods in real systems.

In this paper, a novel and practical local phase correction method which mitigates detrimental mode conversion in a coupled line bend is presented. The working principle and effectiveness of the method will be illustrated first based on a simplified theory of mode conversion in single and double bends. A simple implementation will be considered next for proof-of-concept demonstration and experimental validation of full wave electromagnetic simulations and analytically computed results.

II. Simplified Theory of Mode conversion in coupled line bends

In order to gain fundamental insight into how mode conversion and associated signal degradation occur in coupled line bends, a theory is presented here with some simplifying assumptions. Fig. 1 delineates a structure consisting of a length of coupled lines with two bends, encountered often in routing of high speed signal lines. The individual bends are analyzed first following a similar approach as in [6].

The entire length in Fig 1 is divided into three segments of uniform coupled lines, between reference planes R_{in} and R_1, R_1' and R_2', R_2 and R_{out}. It is assumed that signal propagates in these uniform segments either as odd mode or even mode or as a linear combination of them. In the regions between R_1 and R_1' and between R_2' and R_2, only one of the constituent lines have non-zero lengths. This asymmetry causes intra-pair skew or equivalently excess phase in the line having the extra length. Multiplying the extra length by a phase constant, the excess phase ϕ in a single bend can be expressed as:

$$\phi = \frac{4\pi f k d}{c} \tan\frac{\alpha}{2} \tag{1}$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Where f is frequency, d is center-to-center distance between the lines or pitch, c is speed of light, α is the angle of the bend and k is equivalent to an effective index of refraction that is a function of the propagation constants of the coupled lines.

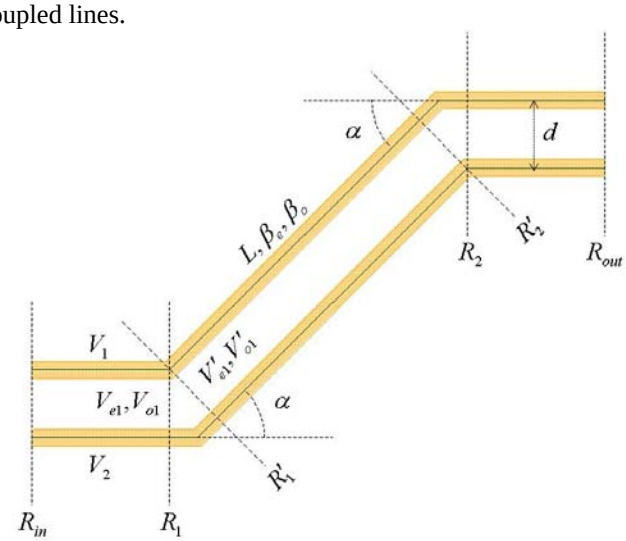

Fig. 1 Coupled lines with two bends. Reference lines are used to identify uniform segments of the lines and asymmetric regions in the bends.

Consider odd mode excitation at the input in Fig 1. The mode purity is maintained up to R_1 making terminal voltages equal and opposite in polarity there, i.e. $V_1 = -V_2 = V$. This is equivalent to the condition $V_{o1} = V$ and $V_{e1} = 0$, where V_{o1} and V_{e1} are odd and even mode voltages respectively. Although there is no even mode before the bend, the excess phase in the bend produces some even mode, V_{e1}' on the right of R_1' at the cost of reduced odd mode V_{o1}':

$$V_{e1}' = \frac{V}{2}(1 - e^{-j\phi}), \quad V_{o1}' = \frac{V}{2}\left(1 + e^{-j\phi}\right) \tag{2}$$

So the desired odd mode suffers insertion loss IL_S, and an undesired even mode of magnitude C_S gets excited due to mode conversion induced by excess phase in the bend. IL_S and C_S can be expressed in dB as:

$$IL_S = 20\log_{10}\left|\cos\frac{\phi}{2}\right|, \quad C_S = 20\log_{10}\left|\sin\frac{\phi}{2}\right| \tag{3}$$

The odd and even modes now propagate in segment 2 from R_1' to R_2' with their respective propagation constants, β_o and β_e. Each of these modes experiences insertion loss and mode conversion as it passes through the second bend. Cascading the effects of the first bend, mixed mode propagation in segment 2 and the second bend, the total insertion loss of desired odd mode, IL_T and mode conversion to even mode C_T in dB can be determined as:

$$IL_T = 10\log_{10}\left(\cos^2\frac{\Delta\beta L}{2} + \cos^2\phi\sin^2\frac{\Delta\beta L}{2}\right) \tag{4}$$

$$C_T = 20\log_{10}\left|\sin\phi\sin\frac{\Delta\beta L}{2}\right| \tag{5}$$

Where L is the length of segment 2, and $\Delta\beta = \beta_e - \beta_o$ represents modal dispersion.

Starting with even mode excitation at the input, it can be shown that (3)-(5) also hold in exact same forms. Therefore, IL_S and IL_T above represent the insertion loss of launched mode, odd or even, and C_S and C_T represent the conversion to the other mode. For mixed mode excitation, each launched mode can be treated separately and then superposed to obtain total insertion loss and mode conversion.

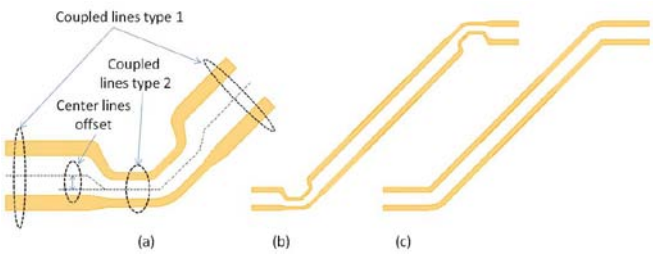

Fig. 2 (a) Proposed local phase correction method in coupled line bends, (b) coupled line with two phase corrected bends, (c) coupled line with regular bends having no phase correction

Several observations are worth noting from (3)-(5). First, for the trivial case of coupled lines with no bends, $\phi = 0$ and the launched mode suffers no insertion loss (0 dB) and no mode conversion ($-\infty$ dB). Second, for a single bend there would always be some insertion loss and mode conversion and their magnitude is a function of the pitch of the lines. Third, for a pair of bends separated by a uniform section of coupled lines as illustrated in Fig. 1, if the modal dispersion $\Delta\beta = 0$, signal suffers no insertion loss or degradation due to the bends. In this case, the bends are compensating each other. Fourth, if modal dispersion exists, even for compensating bends, there would be insertion loss and modal conversion and furthermore they would vary as a function of separation between the two bends. Last, both insertion loss and modal conversion are frequency dependent.

In the above analysis, impedance discontinuity at the bends and multiple reflections in the lines as a result of that are ignored. In addition, the odd and even modes are assumed to be perfectly terminated at both input and output ends. These are not too restrictive assumptions as a good design would always minimize impedance discontinuity at the bends and provide good terminations for all modes.

III. LOCAL PHASE CORRECTION METHOD TO MITIGATE MODE CONVERSION

Any strategy to mitigate mode conversion has to provide a means to eliminate, cancel or minimize the excess phase ϕ at the bends explained earlier. A straightforward way to minimize ϕ would be to use much smaller d, i.e. to use strongly coupled lines at the bends, since it will lead to smaller ϕ according to (1). A method that does just that is

demonstrated to improve bend performance recently [3]. However this approach requires a very small value of d and a long impedance matching taper, severely limiting its use in practical systems.

The method proposed in this paper is illustrated in Fig. 2(a). It works by modifying the construction of the coupled line in the bend area in a way such that physical lengths of the inner and outer lines are approximately equal. The modification essentially results in a narrower coupled line segment in the bend center with short transition areas on both sides connecting to incoming and outgoing lines. As can be seen in Fig. 2(a), the coupled line segment is placed slightly offset outward from the center line. This arrangement allows longer lengths for the inner line in the transition areas. By adjusting the offset, it is possible to equalize the lengths of the lines leading to a net zero excess phase. Although the reduced d in the bend area contributes to some degree to lower the excess phase, the majority of the correction comes from the introduction of the extra length of the inner line. The impedance discontinuity introduced is not too large to warrant separate impedance matching sections. The modified bend remains compact, its size being very similar to that of the original one. By judiciously choosing the parameters of the coupled lines as well as the shape of the small transition areas, good performance can be achieved.

IV. SIMULATION STUDIES

The proposed phase correction scheme lends itself to a variety of implementations based on substrate or board technology being used, dielectric and metal stack-up, material properties, fabrication capabilities and so on. In general, a good amount of design work would be involved in producing a phase corrected coupled line bend that meets often stringent specifications of a high-speed system. In order to keep this design work to a minimum, a simple yet fairly practical implementation is considered here with the goal of clearly demonstrating the effectiveness of the method. A single layer dielectric, with two metal layers, top and bottom, was used to construct the coupled line and the bends. Fig. 2(b) and 2(c) show the coupled lines with phase corrected bends and regular bends respectively. Only top metal patterns are shown. The bottom metal is a uniform pattern that serves as the ground plane for the coupled lines. Except for the bends, both types of lines have identical line widths and spacing with total lengths being approximately equal.

The coupled lines were analyzed as 4-port three dimensional structures using full wave electromagnetic simulations. A finite element based commercial software tool was used for this purpose. A frequency sweep from DC to 50 GHz was performed and results were obtained from the tool in the form of terminal scattering parameters. The scattering parameters were subsequently post-processed in a circuit simulator to first generate mixed mode scattering parameters and then compute insertion loss and mode conversion. In what follows, only results for the input differential excitation will be presented.

The differential insertion loss plots are shown in Fig 3. Significant signal degradation can be noticed at high frequencies for the coupled lines with regular bends. The loss is more than 6 dB at 50 GHz. In contrast, coupled lines with phase corrected bends have vastly improved loss performance exhibiting approximately 1 dB of loss at 50 GHz. The conversion from differential to common mode is presented in Fig. 4. As expected, a sharp reduction of mode conversion by as much as 16 dB at 50 GHz is observed for the phase corrected bends compared to regular bends.

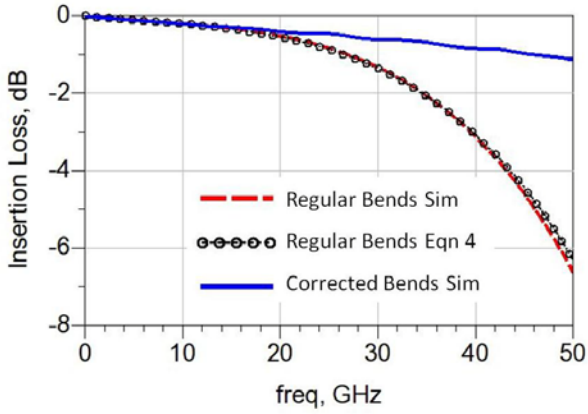

Fig. 3 Differential insertion loss for regular and phase corrected bends as a function of frequency. Results from both full wave electromagnetic simulations and analytical computations using (4) are plotted.

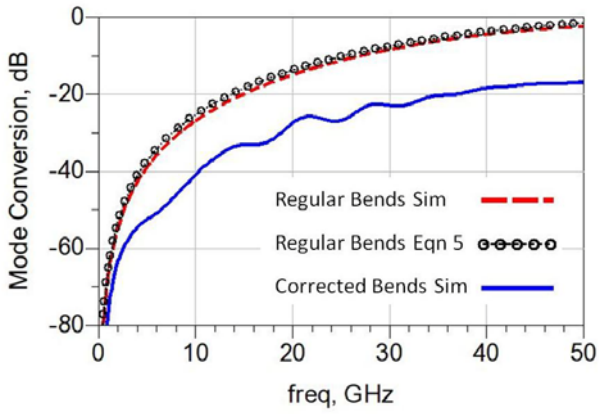

Fig. 4 Differential to common mode conversion for regular and phase corrected bends as a function of frequency. Results from both full wave electromagnetic simulations and analytical computations using (5) are plotted.

Also plotted in Fig. 3 and 4 are insertion loss and mode conversion computed analytically using (4) and (5) respectively for the coupled lines with regular bends. The analytical insertion loss also includes straight line losses, such as ohmic and dielectric losses, in addition to the loss due to bends given by (4). The straight line losses were computed from full wave electromagnetic simulation of straight coupled lines with identical line parameters and total lengths as was used in the case of the coupled lines with regular bends. The agreement between analytically computed values and those obtained from full wave electromagnetic simulations is excellent over a wide band from DC to 50 GHz.

V. EXPERIMENTAL DEMONSTRATION AND VALIDATION

Prototypes for both coupled lines with regular bends and with phase corrected bends shown in Fig. 2(b) and 2(c) were fabricated in a commercial substrate manufacturing house. In order to efficiently couple high frequency signals in and out of the coupled lines, launch structures compatible with GSGSG type on-wafer probing were integrated on both ends of the lines. Other features such as via shielding to quench substrate

mode excitations were also added on all sides of the coupled lines at a reasonable distance.

The measurements and characterization of the prototypes were performed in an on-wafer probing station equipped with a 4-port vector network analyzer (VNA). The scattering parameters obtained from the VNA were post-processed in a circuit simulator to compute differential insertion loss and mode conversion, which are plotted in Fig. 5 and 6. The corresponding plots from full electromagnetic simulation are overlaid in the same graph for comparison purposes. The agreement between measurement and simulation is almost perfect. A few spikes in the measured insertion loss data at high frequencies indicate slight coupling and resulting energy loss to substrate modes. With measured insertion loss improvement of 6 dB and mode conversion reduction of 16 dB at 50 GHz, the effectiveness of the local phase correction method is validated over a wide band.

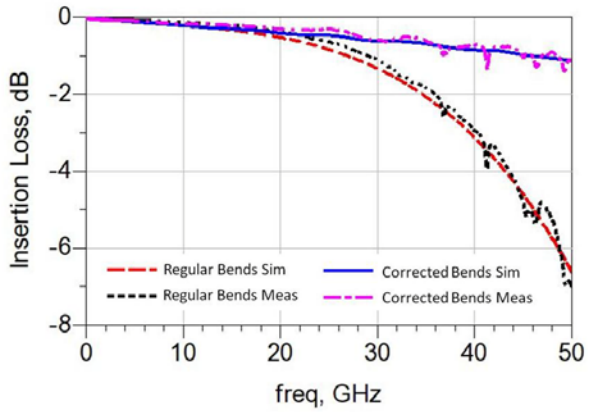

Fig. 5 Measured differential insertion loss for regular and phase corrected bends as a function of frequency. Results from full wave electromagnetic simulations are overlaid for comparison.

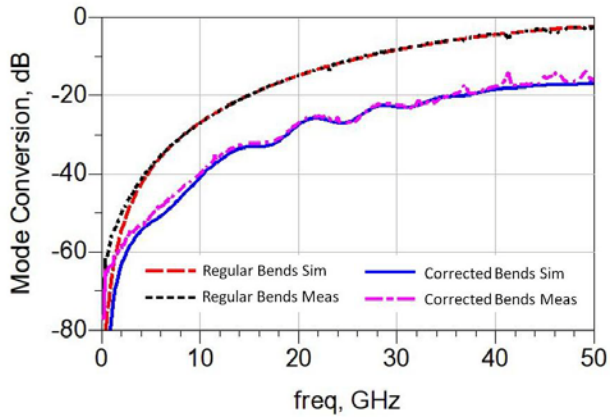

Fig. 6 Measured differential to common mode conversion for regular and phase corrected bends as a function of frequency. Results from full wave electromagnetic simulations are overlaid for comparison.

The simplified theory in section II predicted the insertion loss and mode conversion quite well over a wide band, even if it neglected one important factor, which is the impedance discontinuity caused by the bends. This vindicates the underlying assumption that the major contribution to signal degradation in coupled line bends comes from excess phase, not from impedance discontinuity. This is further confirmed by low return loss observed for the phase corrected bends as shown in Fig. 7. Although degraded somewhat compared to regular bends, the return loss of corrected bends stayed below -20 dB to 25 GHz and below -10 dB to 50 GHz, a level better than what is typically acceptable in high speed systems. The large discrepancy between simulation and measurements in Fig. 7 comes from inclusion of launch structures in experimental prototypes.

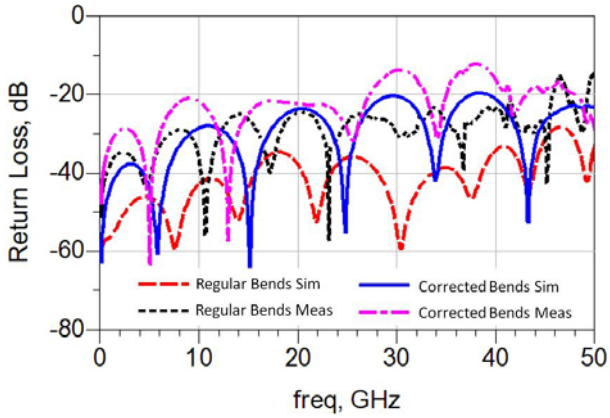

Fig. 7 Measured and simulated return loss characteristics for regular and phase corrected bends as a function of frequency.

VI. Conclusions

Signal degradation in coupled line bends is mainly attributed to mode conversion from excess phase in one of the constituent lines. A simplified analytical theory is first presented to quantify the signal degradation in a single or a pair of bends highlighting the importance of locally mitigating the bend effects. In this regard, a local phase correction method is proposed in which narrow coupled lines are offset placed inside the bends in such a way that leads to equal line lengths in the bend area. Proof-of-concept prototypes were built and characterized. The phase corrected bends yielded excellent performance over a wide frequency range from DC to 50 GHz. At 50 GHz, insertion loss and mode conversion improved by more than 5 dB and 16 dB respectively, while return loss performance remained acceptable. Measured characteristics correlated well with those obtained using full wave simulations, and the simplified analytical theory.

***Abstract*—In RADAR technology detection capability of radar is one of the most important factors. It depends on various parameters. Transmit power, wavelength, antenna gain, frequency, radar cross section area have effects on detection range of radar. Normal operation of radar may be hampered in presence of jammer. Jamming is usually referred to as an Electronic Countermeasure (ECM) which has an intention to disturb regular operation of radar. Range reduction factor of radar is decreased if there is a jammer. For this reason, the detection range of radar is also decreased. This paper has proposed a method to increase the detection capability of radar in presence of jammer by controlling radar effective temperature.**

Keywords*— *Antenna Gain, ECM, RCS, RRF, SNR

I. INTRODUCTION

Radar is an object-detection system that uses radio waves to determine the range, altitude, direction, or speed of objects. It can be used to detect aircraft, ships, spacecraft, guided missiles, motor vehicles, weather formations, and terrain. The usual noise that exists in a radar receiving system is partly of thermal origin and partly from other noise-generating processes. Most of these other processes produce noise which, within typical receiver bandwidths, has the same spectral and probabilistic nature as does thermal noise. Therefore it can all be lumped together and regarded as thermal noise. Radar jamming and deception is the intentional emission of radio frequency signals to interfere with the operation of a radar by saturating its receiver with noise or false information [1]. Jamming may be intentional, as with an electronic warfare tactic, or unintentional, as with friendly forces operating equipment that transmits using the same frequency range. Jamming is considered an active interference source, since it is initiated by elements outside the radar and in general unrelated to the radar signals. There are two types of radar jamming: Mechanical and Electronic jamming. Electronic jamming is a form of Electronic Warfare where jammers radiate interfering signals toward an enemy's radar, blocking the receiver with highly concentrated energy signals. The two main technique styles are noise techniques and repeater techniques. The three types of noise jamming are spot, sweep, and barrage. RADAR jamming decreases the range detection capability of radar. In this paper, we have discussed a method of increasing detection capability of radar in presence of jammer by controlling radar effective temperature.

II. SYSTEM MODEL

Let us consider a radar system whose detection range is 'R' in the absence of jamming. Then the signal to noise ratio at the output of the receiver will be,

$$(\mathrm{SNR})_o = \frac{P_t G^2 \lambda^2 \sigma}{(4\pi)^3 k T_e B F L R^4} \quad (1)$$

Where $'P_t'$ is called peak transmitted power, 'G' is the gain of the antenna, 'λ' is the wavelength, 'σ' is called Radar Cross Section(RCS), 'k' is the Boltzman's constant, $'T_e'$ is the effective noise temperature in degree Kelvin, 'B' is the Radar Operating Bandwidth, 'F' is the Noise Figure and 'L' is the radar losses [2, 3] .

The term Range Reduction Factor (RRF) refers to the reduction in the radar detection range due to jamming. More precisely, in the presence of jamming the effective radar detection range is,

$$Rdj = R \times RRF \quad (2)$$

Most jammers have a constant power output - that is, they always transmit the maximum available power of the transmitter (excepting desired ECM modulation). Some jammers also have a constant gain (linear) region [4, 5]. Usually these are coherent repeaters that can amplify a low level radar signal to a power that is below the level that results in maximum available (saturated) power output. At some radar to target range, the input signal is sufficiently high that the full jammer gain would exceed the maximum available power and the jammer ceases to be constant gain and becomes constant power [6].

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

In a constant gain jammer, the radar power received by the jammer,

$$10\log S_{Rj} = 10\log P_t + 10\log G_t - \alpha_{Tx} + 10\log G_{ja(Rx)}$$

(Factors in dB) (3)

The jammer constant gain power output is:

$$10\log P_{jCG} = 10\log S_{Rj} + 10\log \mathrm{G_{ja}} \quad (4)$$

By definition:

$$P_{jCG} \leq P_j \quad (5)$$

In the above equations, $'\mathrm{S_{Rj}}'$ is the Radar signal at the jammer input (receive antenna terminals), $'G_{ja(Rx)}'$ is the gain of the jammer receive antenna, $'G_t'$ *is* the gain of the jammer, $'\alpha_{Tx}'$ *is* the one-way free space loss from the radar to the target , $'P_{jCG}'$ *is* the jammer constant gain power output, $'P_j'$ *is* maximum jammer power output.

III. SIMULATION

For different effective temperature of RADAR, simulation has been carried out between range reduction factor and jammer peak power. Radar antenna gain of 45 dB, jammer antenna gain of 3 dB, frequency of 10 GHz, radar to jammer range of 750 km, radar operating bandwidth of 10 MHz have been used for simulation purpose.

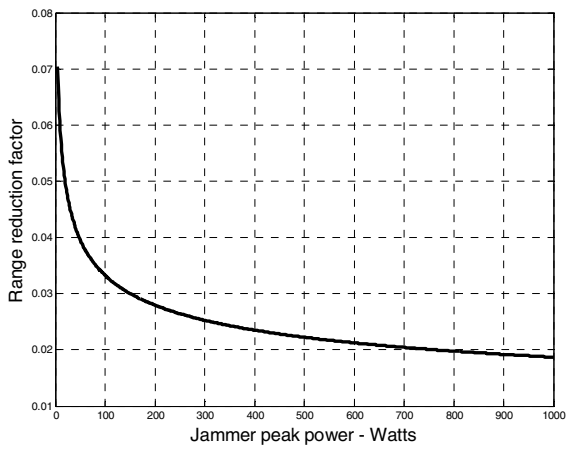

Figure 1. Relationship between range reduction factor and jammer peak power

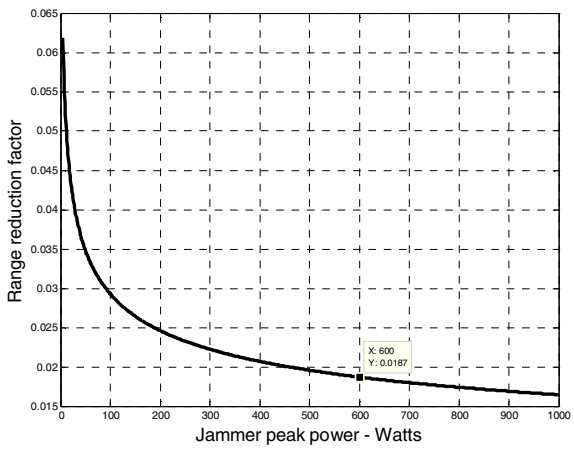
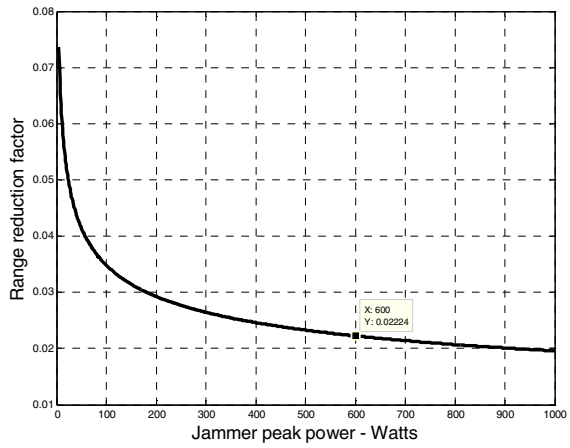
Figure 1 shows the curve which indicates the relationship between range reduction factor and jammer peak power. It is seen than increasing of jammer peak power reduces the radar range reduction factor. As a result radar detection capability decreases.

IV. RESULT AND DISCUSSION

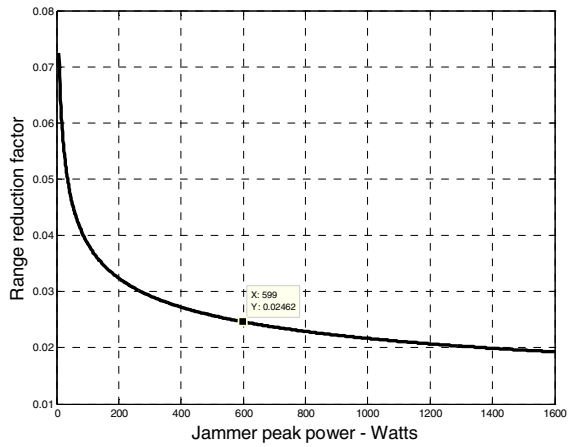
In this paper, the detection capability of radar in presence of jammer with different temperature has been compared. For different effective temperature of radar of a given jammer peak power, the range reduction factor is different. Simulation has been completed for 3 different temperatures of 300 K, 600 K, 900 K. The results have been shown in Figure 2.



(a)



(b)



(c)

Figure 2. Relationship betwwen RRF and jammer power (a) when temperature is 300K (b) temperature of 600 K (c) temperature of 900 K

Radar Effective Temperature In Kelvin	Range Reduction Factor (RRF) (Jammer peak power of 600 watt)
300 K	0.0187
600 K	0.0222
900 K	0.0246

Table 1: Value of RRF for various effective temperature of RADAR

From the above table it is clear that the effective temperature of radar has a great effect on range reduction factor in presence of jammer. When the effective temperature is lower, the range reduction factor (RRF) is lower. As a result the detection capability of radar is lower by equation (2). Increasing of temperature can improve the RRF as well as detection capability. Figure 2 shows when the effective temperature is minimum i.e. 300 K, the value of RRF is 0.0187. The value of RRF is improved to 0.0246 when the effective temperature is maximum i.e. 900 K. For all the above cases, jammer peak power is kept constant at 600 watt.

V. CONCLUSION

This paper presents a method for improvement of range reduction factor of radar in presence of jammer. Controlling the effective temperature play a very important role in this case. For a fixed jammer power the value of RRF will be improved if the effective temperature is increased. It is seen that the highest temperature can give the better value of RRF. As a result the detection range is higher though a jammer is present and performance of radar can be improved by this method. Adjustable higher effective temperature for implementation on radar may be a future work for this method.

***Abstract*—A simple algorithm for license plate reader for metropolitan cities in Bangladesh has been proposed in this paper. We have made use of a feature of Bangla script called "Matra" which joins the characters of a word together. Since the various words of a standard Bangladeshi license plate also have Matra, we have proposed a method where these words are segmented as single connected components and later recognized through template matching of words. There are also numbers and single letters in the number plate which are segmented and recognized as single characters. We have demonstrated that if we exploit the feature of Matra this way, the complexity of the algorithm is decreased, and the proposed system works smoothly for images taken under various conditions.**

***Index Terms*—license plate reader, template matching, connected component analysis, Bangla license plate, ANPR**

I. Introduction

Automatic Number Plate Recognition (ANPR) is an integral part of Intelligent Transport System (ITS). ANPR has become important due to its applicability in toll collection, crime prevention, traffic law implementation, travel-time measurements etc. In the metropolitan cities like Dhaka and Chittagong of Bangladesh, the importance of a fast and efficient algorithm in ANPR is explicit due to the increasing pressure of traffic.

The arrangement of different words and characters in the licence plates of metropolitan cities of Bangladesh, as regulated by BRTA (Bangladesh Road Transport Authority), was exploited in the algorithm to reduce complexity of the ANPR procedure. Again, a characteristic of Bangla script called "Matra" was also used to reduce steps of operations in the algorithm.

In this paper we approached ANPR from the standpoint of Binary Image Processing (BIP), primarily using the Connected Component Analysis (CCA) method, to segment entire words and single characters from the camera image after initial reduction of noise. Note that we could segment entire words as single connected components due to the presence of Matra. We used template matching technique, using correlation coefficient against a pre-recorded database, to recognize those segmented words and characters to provide the final output. Template matching has been named to be a suitable process for character recognition for single-font and not-rotated characters by [1] and [2]. The proposed algorithm is shown in Fig. 1.

This paper is organized as follows: section II discusses previous works done in the field. Section III gives a brief introduction to the various parts of a standard Bangladeshi license plate. Section IV describes the proposed method. Section V analyzes the results and compares them with previous works. Finally, we conclude the paper appreciating the previous researchers in the reference section.

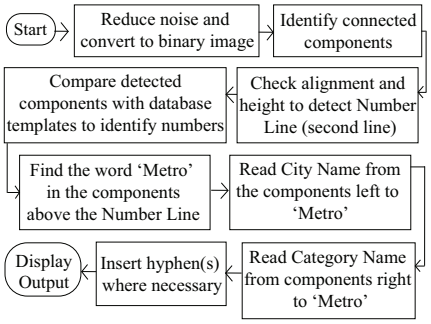

Fig. 1. Proposed Algorithm.

II. Related Works

Several methods have been proposed for Bangla ANPR, such as chain code and neural network [3], multi-layer feed forward network [4] and segmentation with adaptive threshold and artificial neural network [5]. A four layered back propagation neural network has been used in [6] and Tesseract based OCR has been employed in [7]. For license plates in other languages, [8] applied neural network for plate extraction and pattern matching for character recognition. A Gabor filter based technique has been used in [9]. Fuzzy logic for segmentation and feature based classification for character recognition has been applied by [10]. DTCNN has been shown to be applicable for license plate recognition in complex backgrounds in [11]. A multi-style recognition method has also been proposed by [12] using user-defined parameters. Connected component analysis in conjunction with probabilistic neural network has been used in [13]. Moreover, [14] has shown how correlation coefficients can be effectively exploited to dynamically vary the parameters for template matching. Word Image matching using Hausdorff distance has been shown to be effective for Chinese and English alphabets [15].

III. License Plate Properties in the Metropolitan Cities of Bangladesh

According to the regulations of BRTA, the registration number of license plates in the metropolitan cities has to be written in Bangla script painted on flat steel or aluminium plate of dimensions 524mm x 112mm for a car. The plates also must follow a specific colour code based on the type of the vehicle, the algorithm proposed here works independent of these color patterns.

The arrangement of different words and characters in a plate has a common pattern, as shown in Fig. 2:

- The first line contains the name of the vehicle registration area (which we referred to as "City Name"), the word

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

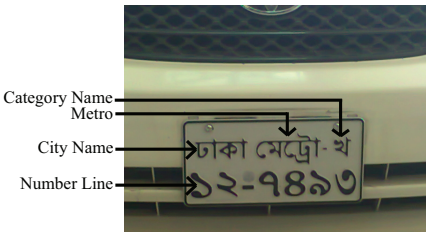

Fig. 2. A sample Bangla license plate.

"Metro" (a short form for "Metropolitan"), and after a hyphen a letter indicating vehicle category (which we referred to as "Category Name"). Here, the City Name could be "Dhaka" or "Chotto", Chotto being the short form of Chittagong. As "Category Name", thirty letters have been assigned which carry specific meanings.

- The second line (or "Number Line") contains six digits, the first two of which denote vehicle class number and the last four constitute unique vehicle registration number.

Interestingly, a characteristic of Bangla script called "Matra" comes into play here. Matra is a horizontal line at the upper part of many Bangla characters which join to make a continuous Matra when these characters combine to form a word. In the license plate, the word "Metro" and the City Name both have continuous Matra, which means if noise filtering does not damage the Matra, the words would appear as single connected components in the binary image. Therefore, we proposed detecting the word "Metro" and the City Name as whole words through template matching, which relieved the algorithm of the time consuming steps of splitting these words into characters for individual identification.

IV. Proposed System Architecture and Algorithm

The proposed system has three basic modules:

- Noise elimination and conversion to binary image.
- Segmentation of words and characters.
- Recognition of the segmented words and characters.

A. Noise Elimination and Conversion to Binary Image

The original image is resized to a height of 400 pixels with its aspect ratio unchanged, so that static filtering parameters could act upon the image successfully. The image is converted to grayscale and acted upon with median filtering to reduce small noises. Following that, a series of morphological operations, such as morphological erosion of the image, dilation of the same image and subtraction of the eroded and diluted versions result in the detection of the edges of words and single characters, as shown in Fig. 3. At this point, the characters and words in the image are contours of their original shapes.

We then perform the following 2D convolution operation to enhance the contrast of the image, resulting in Fig. 4:

$$P(x, y, z_{m+1}) = \int_{\delta D} W(x - x', y - y') P(x', y', z_m) dxdy \tag{1}$$

The image is then converted to binary and the contours of the characters and words are filled, which makes them solid again. The final binary image is shown in Fig. 5.

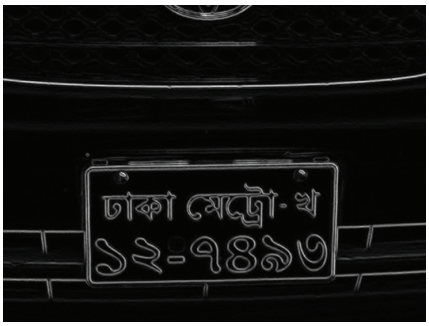

Fig. 3. Image after morphological operations.

Fig. 4. Image after convolution operation.

B. Segmentation of Characters and Words

Bounding boxes are formed around each of the connected components in the filtered binary image. Components with heights and widths below a threshold value of 10 pixels are discarded, which limits the algorithm's ability to detect too small characters but makes elimination of unwanted components easier.

We operate in two steps, the first of which reads the digits as single characters from the Second Line of the plate, and the second step reads the words and characters from the First Line.

To detect the 6 digits of the Second Line, we consider two criteria,

- The digits must be aligned,
- The digits must have similar heights.

A histogram is drawn with the upper-left corner ordinates of the connected components, as shown in Fig. 6. Components eliminated earlier do not appear in the histogram count. We take the average of ordinates of the components in the class with maximum elements. We add to that a small margin for error to determine a new range of acceptable ordinates

Fig. 5. Final binary image.

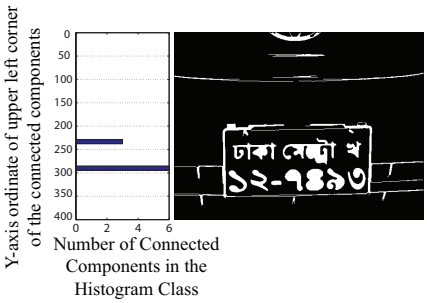

Fig. 6. Histogram showing distribution of connected objects.

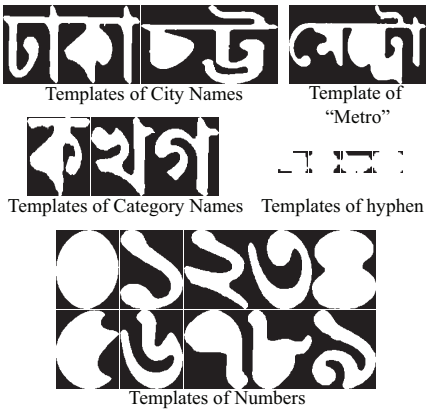

Fig. 7. Databases of City Names, Metro, Category Names, Hyphens and Numbers

and select obeying components to justify the first criterion of alignment. Then we check if these components indeed have same heights in order to justify the second criterion. This segmentation method is similar to the method proposed by [16]. We then send these selected components to the recognition module.

In the second step, we attempt to read the First Line of the plate. Here we consider the region directly above the number line and send the connected components within that region to the recognition module to locate the word "Metro". Once that has been identified, we return to the segmentation module to select the components on both sides of the word "Metro" whose upper left coordinates and heights are compatible to "Metro". The selected components to the left of "Metro" contain the City Name, and the ones to the right contain the Category Name. These segmented words and single characters are again sent to the recognition module.

C. Recognition of Segmented Characters and Words

We have formed separate and extensible databases of binary images, shown in Fig. 7, of the Bangla numbers 0-9; the words "Dhaka", "Chotto" as samples of City Name; the word "Metro"; and the letters "Ka", "Kha" and "Ga" as samples of Category Name.

From the first step of the segmentation module, segmented components of the second line are sent to the recognition module. This module first resizes the components to match the template image sizes, and then finds the 2D correlation coefficient of them against a database of the numbers 0-9, as per the following equation:

Dhaka Metro-Kha 12-7493

Fig. 8. Output for the sample in Fig. 2

$$r = \frac{\sum_m \sum_n (X_{mn} - \bar{X})(Y_{mn} - \bar{Y})}{\sqrt{(\sum_m \sum_n (X_{mn} - \bar{X})^2)(\sum_m \sum_n (Y_{mn} - \bar{Y})^2)}} \quad (2)$$

Here $\bar{X}$ and $\bar{Y}$ denotes the averages of the image matrices X_{mn} and Y_{mn} respectively. The digit which gives the highest value of r for a given image will be the digit represented by that component. This way, all the six digits from the second line are read.

From the second step of the segmentation module, the recognition module is called in two steps: first to recognize the word "Metro", then to recognize the city name and the category name. In all the cases, the module runs exactly like it did to recognize the digits, and uses appropriate database templates for recognizing different parts of the plate. The result is shown in Fig. 8.

V. Results and Analysis

The proposed system has been found to work very satisfactorily for samples that are not too noisy and not over-skewed. The results are shown in Fig. 8, Fig. 9, Fig. 10, Fig. 11, Fig. 12 and Fig.13, for images taken under various weather conditions and different spatial distances. The time performance, as measured on MATLAB r2014a software [20] running on Intel corei5 processor with 4.00GB of RAM is shown in Table. 1.

It is seen that the average recognition and execution time is comparable to generalized symmetry transform method proposed in [17] (1.3 seconds). The time and efficiency performance of the proposed system is comparable to other pattern matching algorithms, as in [18] and [19] (1.1 seconds). Moreover, it has been found that the system can work correctly for very low letter to image height ratio.

VI. Conclusions

In this paper, a method for Bangla license plate reader has been proposed, based on the segmentation algorithm for Albertan license plate proposed by [16], and it exploits features specific to the Bangla typography to reduce complexity. Template matching of single characters as well as of whole words has been applied in the connected components analysis. The database for templates can be easily extended to diversify the scope of the system. This method can deliver correct output within a reasonably short time, for images taken under various conditions.

Abstract— **Distributing equivalent programming problems among the students for evaluation is an inherent problem. To remove this inherent problem, weight measurement of computer programs is necessary. Although software is the outcome of human creative activity, cognitive informatics plays an important role in understanding its fundamental characteristics. In our research, a new software complexity measure based on cognitive weight of basic control structure has been proposed that reduce the limitations of existing measures. Primarily our aim is to build a question bank with programming problems. Our designed system will access the solution codes for finding out the weight of respective programming problem from the question bank by applying the proposed method. The method will find out the complexity according to our proposed cognitive weight model. It will facilitate the instructors distributing the programming problems among the students equivalently. Thus, the automatic complexity measurement will ensure the students obtaining equal problems for programming evaluation**

***Keywords*—Cognitive Weights, Basic Control Structures, Weight Measurement, Software Complexity**

I. INTRODUCTION

An important issue encountered in computer science and engineering in the field of programming problem distribution is to distribute the problem equivalently. In the last several years, there has been a great deal of interest in defining appropriate ways to measure the complexity of software [1]. There are different facets of software complexity, some of which have been computed using widely accepted metrics like cyclomatic complexity, data/information flow metrics, but very less attempts have been made to measure the cognitive aspect of the complexity [2]. The human mind's efforts needed for the comprehension of the source code reflect a different dimension of complexity, which is being measured in this paper [2]. Another issue encountered in software complexity analysis is the consideration of software as a human creative artefact and the development of a suitable measure that recognizes this fundamental characteristic. The existing measures for software complexity can be classified into two categories: the macro and the micro measures of software complexity [3]. In this paper, we have proposed a new method for measuring software complexity, which is based on the thinking capacity of Human brain. We have used cognitive weight to measure the complexity value of a program. The complexity measures based on cognitive informatics is in developing phase. Knowing that the basic control structures (BCS) such as sequence, branch and iteration are the basic logic building blocks of any program. Here we have developed a simple method for calculating the complexity of programs in terms of cognitive weights and showed an approach for the equal distribution of the programming problems to the students during examination has been provided. Sometimes at the time of examination, programming problems may not be distributed equally to the student. In that case some students find that the problem is very easy and other students complain that the problem is very complex to solve within limited time. So it is necessary to develop a complexity model to find out complexity value that can be used to identify problem equivalence. There are ways to find out the running time of algorithms, which can be used for the equal distribution of programs by comparing two different algorithms. But, it is very difficult to measure especially when there is no defined algorithm or the algorithm is too much large and complex. In Materials and Methods section, we have conducted a survey with various programming problems; various Cognitive Weights for various Basic Control Structures have been defined. Implementation section provided with our designed algorithm which will help us to find out the complexity of programming solution code and finally in Result and Discussion section, an approach for the equal distribution of the programming problems to the students during examination has been provided.

II. METHODS AND MATERIALS

In the section of programing courses evaluation programming problems are need to be solved within a limited time are to be distributed among students .variant students will be tested with miscellaneous programming problems. According to this motive, programming problems may not be equally distributed. As a result, some can find their problems easy and others can get problems which are comparatively complex. In this context, examines will not get the proper pronouncement. But it should not happen, our aim of study is to distribute the problem equally. For this reason, to minimize these problems there should have a question bank which will

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

contain various programming problems and solution with different complexities. There are various ways to compute run time complexity of an algorithm. Different well-known algorithms have also defined complexity value based on their run time. Programming problems can be distributed consequently to these values. In a specified boundary similar and approximately similar problems will be put. Same methods will be revolved for all problems on the questions bank. Problems within a specific boundary will be deliberated as analogous kinds of problems. In this exploration, we have built a new complexity model for measure complexity values of programming problems based on their solution codes. In this case, after selecting a problem respective solution code should be developed.

A. Cognitive Weights

To perceive a given program, we naturally concentrate on other architecture and basic control structures (BCSs) of the software [4]. BCSs are a set of essential flow control mechanisms that are used for building logical software architectures [4]–[5]. Three BCS are commonly identified: the sequential, branch, and iteration structures [6]. Although it can be proven that an iteration maybe represented by the combination of sequential and branch structures, it is convenient to keep iteration as an independent BCS. In addition, two advanced BCSs in system modelling, known as recursion and parallel, have been described by Hoare et al. [6]. Wang [4]–[5], [4] extended the above set of BCSs to cover function call and interrupt. We have used 13 Basic Control Structures: SEQUENTIAL, IF-THEN-ELSE, SWITCH, BREAK, CONTINUE, RETURN, FOR, WHILE, DO-WHILE, USER DEFINED FUNCTION (UDF), RECURSION, EXCEPTION HANDLING, and REPEAT-UNTIL.

Definition: The cognitive weight of software is the measurement of difficulty or comparative time and effort required for understanding a given piece of software modelled by a number of BCSs [3].

B. Data Collection and Observation

For finding out the cognitive weight, we have selected some programs each of them represents one control structure .Every program contains nearly same number of lines. We have not used two control structures, PARALLEL and INTERRUPT individually in this observation. Because, a program that describes this control structure contains other control structures used in the observation. During the survey, we gave 20 programs containing individual BCSs to different class of students at undergraduate level. After reading the problems, every student gave the result of the selected programs. They gave the result according to their thinking capacity of brain for individual BCS. All 20 students consider the initial fact of sequential statement containing weight 1.By observing the weight of sequential statement our selected 20 students gave the other BCS respective weight. These weight will help us to find out the average weight of individual BCS and later we will use this to find the complexity of any program. Maximum number of problems is taken from C for contest by Tamnun E Mursalin. We have chosen some common programs. Reason for choosing such common program for making problems relatively in a similar level (simple or complex). Following is a sample of a sequential statement program which we have used in our survey.

```
#include<stdio.h>
int main (void) {
int first,second,result;
printf("Enters two numbers: ");
scanf("%d %d",&first,&second);
result= first+second;
printf ("The two numbers are:%d %d\n ",first, second);
printf ("The Result is: %d", result);}
```

Survey results of Level 1 and 3 students are shown in Fig 1. Survey results of Level 2 and 4 students are shown in Fig 2. The results which we found by combining Fig 1 and Fig 2 data have been used to obtain the Cognitive Weight.

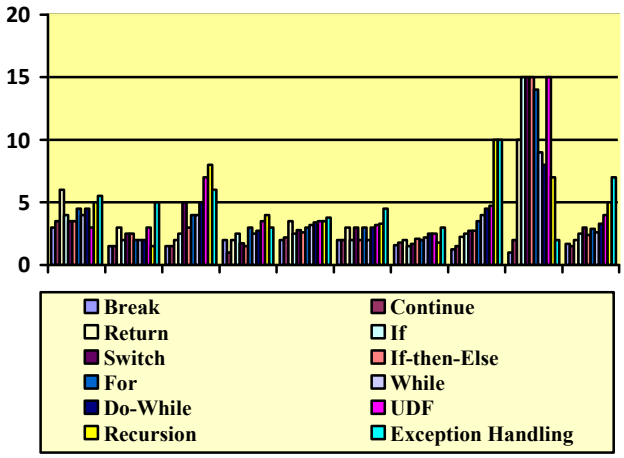

Fig 1: Graphical representation of Survey results of Level 1 and 3

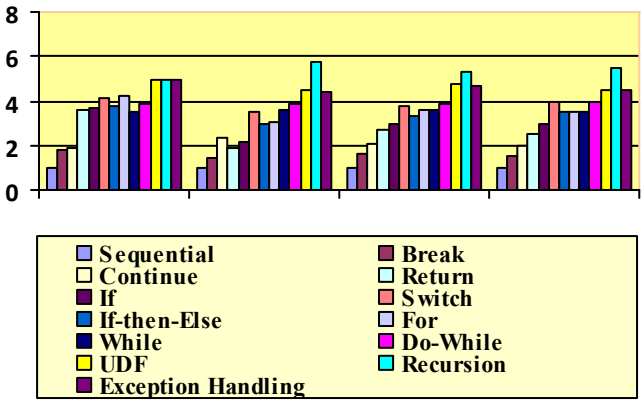

Fig 2: Graphical representation of Survey results of Level 2 and 4

We have divided the results in three Categories: a) When we get any value, x which satisfies 2 <= x <= 2.25 such as 2.24 then we consider this value as 2.b) When we get any value, y as 2.25 < y < 2.75 such as 2.41 then we consider it as 2.5 and c) When we get any value, z as 2.75 <= z <= 3.00 such as 2.76 then we consider it as 3. We have made a chart showing the comparison of our cognitive weight with others. In the chart, Cw means Cognitive Weights and Cw MSST represents our Cognitive Weight. Fig 3 shows how various cognitive weight of BCS varies with others developed cognitive weight.

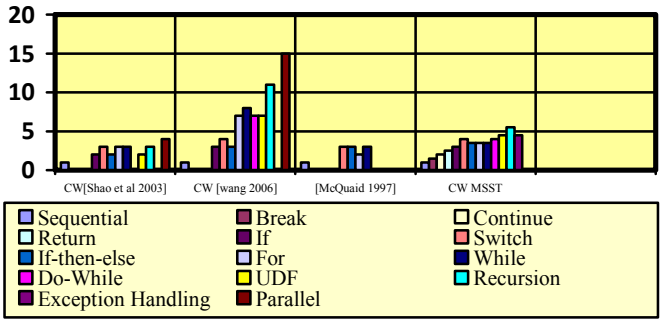

Fig 3: Comparison of Our Cognitive Weights with Others

It's quite clear that in comparison with others our survey result is unique and it do not interact with others measured value. In further work these values will help us to find out the complexity value of programs.

C. Complexity Model

In this section, we will show how our measured cognitive weights can be used to find out total weight or complexity, W_{bcs} of a given program. There are two different architectures for calculating Wbcs

- Either all the BCS's are in a linear layout. For this case, sum of the weights of all n BCS's are added

$$W_{linear}=\sum_{q=1}^{j} W_C(q) \ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Here, q = 1, 2,…,j

j = Number of linear BCSs

For example, we can consider the following Java code. Numbers in the right hand side indicates the weights of the respective BCSs.

```
1. public class SST{
2. public static void main (String args []){
 a.    Integer value_1 = 20;          1 }
 b.    Integer value_2 =10;           1 }
 c.    value_1 = value_1+ 5;          1 }      += 4
 d.System.out.println (value_1);      1
3.          }
4.          }
```

In the above program, line number 1 and 2 are common in Java code. Within the brackets, there are four (a-d) linear sequential statements. They are all independent i.e. they are not embedded in other BCSs. From the previous section, we have obtained the weights of various control structures, where the weight for sequential statements is 1. Therefore, total weight of this program will be, W_{linear}=1+1+1+1=4.

- Or some BCS's are embedded in others. For this case, cognitive weights of inner BCS's are multiplied with the weights of external BCS's.

$$W_{embedded}=\prod_{i-n}^{1} W_C(i) \ldots\ldots\ldots\ldots\ldots\ldots (2)$$

Here, i = n,……., 2, 1

n = Total number of BCSs in which the current BCS is embedded + 1

1 = Own weight

2 = Respective parent BCS of 1

3 = Respective parent BCS of 2

……..

n = Respective parent BCS of (n-1)

Parent Control Structure means the structure which encloses another control structure. For example, we can consider the following Java code:

```
1. public class SSTArray{
2. public static void main(String[]args){

Total Weight, W_{bcs} = 32.00

III. IMPLEMENTATION

In this section we will show how our designed system scan the programs and then give the weight of the programs. We have built our own method to measure the weight of programming problems. Implementing this task in real life is not so much easy. It's a hard task and we have done it by our own developed program. Our initial step is to measure the complexity of programs which not contain any embedded structure. Embedded structure means one BCS contain another BCS inside his structure. We are quite successful to do this by the help of our survey result which represent the cognitive weight of the respective BCS. Our goal is to access the database which is basically a question bank containing programs and then pick the set of problems from database for measuring the complexity of respective problems. Following figure showing how our designed system works in real life from set of input problems to complexity value of problems as output.

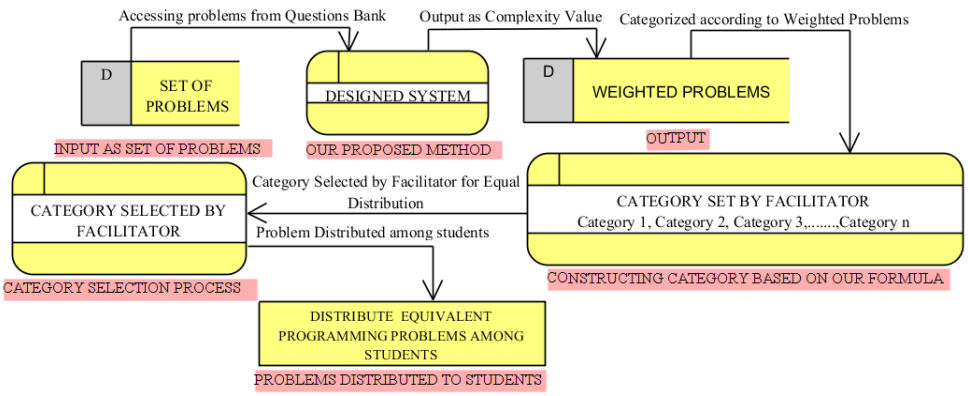

Fig 4: The Proposed System for Distributing Equivalent problems

We have built our own algorithm to find out the complexity value of programs. The following snippet of pseudo code of our program will tell how our system works for finding programs complexity values.

Input: A set of programs
Output: Calculated complexity of input programs
For each input character
IF
(Input stream==for)
THEN
Call class for ()
Complexity→ for-check ()
Index → return index

Pseudo code explained here is just only a part of our developed program and showing a few basic steps of operation.

IV. Result and Discussion

After the measurement of the complexity of some problems, we have concluded the result. We have got the complexity value of some problems. From the observation of the complexity values, we can say that, 1. For programs with increasing number of lines, the complexity increases gradually (without any exceptions). 2. If the number of linear BCSs is the same or approximately same, but one program contains BCSs of relatively higher weight, then this program will result in comparatively higher complexity value. 3. If the number of lines is the same, but one program contains BCSs which are more embedded, then this program will definitely result in high complexity value.

A. Distribution of Problems Based on Measured Complexity Value

For distributing similar types of problems to the students in the examination we have categorized the programs complexity according following formula where

L=Lowest Weight from a set of problems
H= Highest Weight from a set of problems
D=Difference between H & L
N=Number of category Facilitator Want
V=D/N
Category 1=L + V
Category 2=category 1+V
Category 3=category 2+V
……
Category N=category (N-1) +V

As a part of our thinking, now Facilitator can easily choose the category of problems according to complexity levels and can distributes the problems to the students equally.

B. Future Works

At this moment we are capable of finding out the complexity of programs only for linear structure with the help of our own designed system. Still we are working on this to improve the efficiency of our designed systems we will include the BCSs PARALLEL and INTERRUPT into our designed program in our later work.

V. Conclusion

We have designed a method and an algorithm to measure complexity of programming problems based on cognitive weights of Basic Control Structures. It is certain that this method will help a facilitator to distribute programming problems equally among the learners. It is found that measuring complexity based on cognitive weight is the most suitable measure, comparing with other existing measures, as problems are distributed to human not to the computer.

***Abstract*—Adaptive filters generally employed for estimation purposes require high computational power when it comes to real time estimation. Therefore, in this paper we propose a computationally light yet effective estimation algorithm based on state space model. Our algorithm has been employed successfully in linear and non linear state space model based estimation problems. We investigate few examples to demonstrate the novelty of our algorithm by comparison with few existing algorithms in presence of non Gaussian noise namely uniform noise. More specifically, the state space normalized least mean squares and the Kalman filter has been compared with our algorithm.**

***Index Terms*—SSLMF, SSNLMS, State Space Least Mean Fourth, State Estimation Algorithm**

I. Introduction

Advancements in computational speed, complexity and power efficiency of digital processors have assisted in adaptive filters gaining widespread acceptance and implementations in numerous fields. Adaptive filters provide an upper hand in comparison to conventional filters because of their ability to adapt by self adjusting filter parameters according to the optimization algorithm utilized ([1],[2]). Two of the most widely used adaptive filtering algorithms are the least mean squares (LMS) algorithm ([1],[2],[3]) and the recursive least squares (RLS) algorithm ([1],[2],[3]). The state space (SS) version of these algorithms have been developed and presented by Malik et al. ([4],[5],[6],[7]) and different analyses were presented.

Adaptive filters dealing with SS model of a system yields near true results compared to non model based systems because of the availability of prior knowledge of the states via the system model. Numerous adaptive filtering algorithms can be found in the literature addressing the problem of SS based models for example the very well known Kalman filter (KF) [8], which gives the linear optimal solution by calculating the Minimum Mean Square Error (MMSE). Using observations subject to noise and other disturbances, it optimally estimates the system parameters. In the domain of non linear filtering, we have the extended Kalman filter (EKF) [8], unscented Kalman filter (UKF) [9], cubature Kalman filter (CKF) [10], quadrature Kalman filter (QKF) [11] and many other variants of KF [8]. These non linear filtering algorithms are computationally computationally complex and therefore pose difficulties in real time filtering problems due to high computational requirement. In this paper we propose and investigate the state space least mean fourth (SSLMF) algorithm by defining a cost function $\mathbf{J}[k]$ and minimizing it. We also compare our performance with the existing state space normalized least mean square (SSNLMS) algorithm [4] and KF algorithm [8]. Our proposed algorithm is superior due to the fact that it requires lesser computations per iteration compared to the existing linear and non linear model based algorithms (KF, UKF, EKF, CKF, QKF, etc.). The performance of the algorithm in presence of non Gaussian noise namely uniform noise is investigated due to the fact that least mean fourth (LMF) algorithm performs better in non Gaussian noise environments [12].

The paper is organized as such, Section II of the paper introduces the State-Space model. Then in Section III the overview of the existing SSLNMS is presented following Section IV where the SSLMF algorithm is developed. Section V presents simulation and results of the comparison of and proposed algorithm keeping in view the mean square errors. And finally we conclude the paper in Section VI.

II. State-Space Model

We begin by defining the general state-space model of a linear time varying system.

$$\mathbf{x}[k+1] = \mathbf{A}[k]\mathbf{x}[k] + \mathbf{B}[k]\mathbf{u}[k] + \mathbf{w}[k], \tag{1a}$$
$$\mathbf{y}[k] = \mathbf{C}[k]\mathbf{x}[k] + \mathbf{D}[k]\mathbf{u}[k] + \mathbf{v}[k] \tag{1b}$$

where $\mathbf{x} \in \Re^n$ are the process states, $\mathbf{y} \in \Re^m$ are the measured outputs such that $m \leq n$. $\mathbf{A}[k]$ is the state transition matrix, $\mathbf{B}[k]$ is the input matrix, $\mathbf{u}[k]$ is the input vector where $\mathbf{u} \in \Re^p$, $\mathbf{w} \in \Re^n$ is the process noise vector and $\mathbf{v} \in \Re^m$ is the measurement noise vector. The matrix $\mathbf{C}[k]$ is the output matrix where $\mathbf{dim}[\mathbf{C}[k]] = m \times n$, $\mathbf{D}[k]$ is the feed through matrix with $\mathbf{dim}[\mathbf{D}[k]] = m \times p$. It is assumed that the above system is observable. A special case is the unforced (autonomous) linear time varying system, represented as

$$\mathbf{x}[k+1] = \mathbf{A}[k]\mathbf{x}[k] + \mathbf{w}[k], \tag{2a}$$
$$\mathbf{y}[k] = \mathbf{C}[k]\mathbf{x}[k] + \mathbf{v}[k] \tag{2b}$$

The state space representation for a non linear continuous time system is

$$\dot{\mathbf{x}} = f(\mathbf{x}, \mathbf{u}, \mathbf{w}), \tag{3a}$$
$$\mathbf{y} = h(\mathbf{x}, \mathbf{u}, \mathbf{v}) \tag{3b}$$

where f and h are non linear functions and the parameters are as defined before.

III. Overview of the existing SSNLMS

Considering the system described by equation (2). A model based adaptive estimation process can be divided into the

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

following two steps. Step 1, the time update which is given by

$$\bar{\mathbf{x}}[k] = \mathbf{A}[k-1]\hat{\mathbf{x}}[k-1] \tag{4}$$

Step 2, the measurement update which is given by

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] + \mathbf{K}[k]\varepsilon[k] \tag{5}$$

where

$$\varepsilon[k] = \mathbf{y}[k] - \bar{\mathbf{y}}[k] \tag{6}$$

here $\mathbf{y}[k]$ is as mentioned in (2), **K**[k] is the gain matrix and

$$\bar{\mathbf{y}}[k] = \mathbf{C}[k]\bar{\mathbf{x}}[k] \tag{7}$$

This is basically the structure employed in all Kalman Filtering techniques ([8],[9],[10],[11], etc.). In the case of SSNLMS [4] the gain matrix $\mathbf{K}[k]$ is derived as follows

$$\mathbf{e}[k] = \mathbf{y}[k] - \hat{\mathbf{y}}[k] = \varepsilon[k] - \mathbf{C}[k]\delta[k] \tag{8}$$

where

$$\delta[k] = \hat{\mathbf{x}}[k] - \bar{\mathbf{x}}[k] \tag{9}$$

Assuming $\mathbf{C}[k]$ is full rank, $\hat{\mathbf{x}}[k]$ is chosen such that $\mathbf{e}[k] = 0$ which implies the following

$$\varepsilon[k] = \mathbf{C}[k]\delta[k] \tag{10}$$

$\delta[k]$ is chosen as the minimum norm solution of the above equation which results in

$$\delta[k] = \mathbf{C}^T[k](\mathbf{C}[k]\mathbf{C}^T[k])^{-1}\varepsilon[k] \tag{11}$$

here

$$\mathbf{K}[k] = \mathbf{C}^T[k](\mathbf{C}[k]\mathbf{C}^T[k])^{-1} \tag{12}$$

The estimator equation from (9) and (11) is hence derived as

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] + \mathbf{C}^T[k](\mathbf{C}[k]\mathbf{C}^T[k])^{-1}\varepsilon[k] \tag{13}$$

This is termed in ([4],[5]) as the SSNLMS algorithm. However, to avoid the non invertible scenario of $(\mathbf{C}[k]\mathbf{C}^T[k])^{-1}$, a small value γ might be added to the term and hence the estimator can be represented as

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] + \mathbf{C}^T[k](\gamma + \mathbf{C}[k]\mathbf{C}^T[k])^{-1}\varepsilon[k] \tag{14}$$

The above estimator may be unstable and there are no known conditions for stability and hence convergence is not guaranteed. Therefore, a matrix **G** has been introduced in ([4],[5]) to overcome this problem. In ([4],[5]), it is claimed that the choice of this matrix **G** depends on the nature of the problem and one simple approach is to take **G** to be all zeros except for the first column to have non zero entries. In our investigation, we will consider the SSNLMS algorithm ([4],[5]) defined as

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] + \mu\mathbf{G}\mathbf{C}^T[k](\gamma + \mathbf{C}[k]\mathbf{C}^T[k])^{-1}\varepsilon[k] \tag{15}$$

μ is the step size parameter for quicker achievement of convergence.

IV. Derivation of SSLMF

Considering the class of adaptive filtering based on (5) which is employed in all KF techniques, this type of update equation can be generalized with the following update rule

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] - \mu\nabla\mathbf{J}[k] \tag{16}$$

where $\mathbf{J}[k]$ is the cost function to be minimized, $\nabla\mathbf{J}[k]$ is the gradient and μ is the step size parameter. To derive the SSLMF, we start by defining the cost function as

$$\mathbf{J}[k] = \mathbf{E}\left[\|\varepsilon[k]\|^4\right] \tag{17}$$

Minimizing the cost function $\mathbf{J}[k]$ with respect to the predicted states $\bar{\mathbf{x}}[k]$ result in

$$\nabla\mathbf{J}[k] = -4\|\varepsilon[k]\|^2\mathbf{C}^T[k]\varepsilon[k] \tag{18}$$

Equation (16) can therefore be written as

$$\hat{\mathbf{x}}[k] = \bar{\mathbf{x}}[k] + \mu\mathbf{G}\|\varepsilon[k]\|^2\mathbf{C}^T[k]\varepsilon[k] \tag{19}$$

which is our general estimator algorithm.Comparing equations (5) and (19) yields

$$\mathbf{K}[k] = \mu\mathbf{G}\|\varepsilon[k]\|^2\mathbf{C}^T[k] \tag{20}$$

Matrix **G** was imposed for the condition of controllability ([4],[5]) which is required due to the dynamics of the system where the algorithm is being applied.

V. Simulation Results & Discussion

Simulation results are presented here to validate the performance of the algorithm. We perform the estimation of the state parameters of a noisy sinusoid tracking problem, a real time trajectory tracking problem and the state parameters of a Van der poll oscillator ([4],[13]). These problems were investigated in the presence of uniform noise. The process and observation error covariance matrices were chosen to be similar to the noise covariances. An overview of the root mean square error (RMSE) of the output observations can be referred to in Table I. SSNLMS, KF, and SSLMF were compared. 100 simulations were performed while the estimation algorithms ran simultaneously.

A. Example 1. Tracking Sinusoids

In the first example we consider the system reported in ([4],[5]). More specifically we investigate a second order transversal filter with known frequency and unknown phase and amplitude of sinusoids which produces a 4th order system given by

$$\mathbf{A}[k] = \mathbf{diag}\left\{\begin{bmatrix}\cos(\omega_i T) & \sin(\omega_i T)\\ -\sin(\omega_i T) & \cos(\omega_i T)\end{bmatrix}\right\},\ i = 1,2 \tag{21a}$$

$$\mathbf{B}[k] = \begin{bmatrix}1 & 1 & 1 & 1\end{bmatrix}^T \tag{21b}$$

$$\mathbf{C}[k] = \begin{bmatrix}1 & 0 & 1 & 0\end{bmatrix} \tag{21c}$$

The ω_i's for this system are known and kept constant. For the purpose of our study, we have set the values of the frequencies ω_1, ω_2 to 0.5 and 0.25 respectively. The sampling time is considered as $T = 0.1s$ and μ for SSNLMS was taken as 0.05 whereas, μ for SSLMF was chosen as 300. The

observation is subject to uniform noise of covariance $\sigma^2 = 0.01^2$. The process noise was considered to be of covariance $\sigma^2 = 0.001^2$. The actual initial system states were considered to be $\mathbf{x}[0] = [0.1\ 0.1\ 0.1\ 0.1]^T$, and the initial estimate for tracking were chosen to be $\hat{\mathbf{x}}[0] = [0.15\ 0.2\ 0.05\ 0.16]^T$. The plot of observation and the mean square observation error are presented in Figure 1 and Figure 2 respectively. It is observed from Figure 1 that SSLMF performs better in terms of observation. A closer look at Figure 2 reveals that SSLMF maintains a lower level of observation error, while KF has the lowest. However, KF is computationally complex and thus state space least mean algorithms have an advantage due to their light computational requirement. Table I shows that the root mean square observation error for SSLMF is lower than that of SSNLMS and hence performed better than SSNLMS.

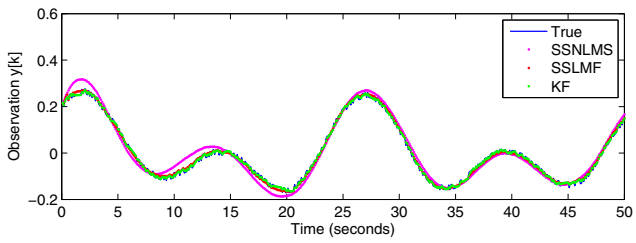

Fig. 1: Observation y[k].

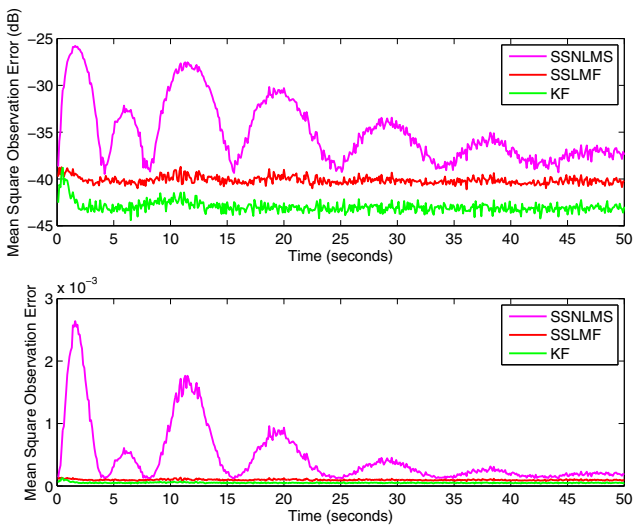

Fig. 2: Mean Square Observation Error y[k]

B. Example 2. Real time tracking

Considering the example of real time tracking ([8],[5]), the state space representation is as follows

$$\mathbf{x}[k+1] = \begin{bmatrix} 1 & T & T^2/2 \\ 0 & 1 & T \\ 0 & 0 & 1 \end{bmatrix} \mathbf{x}[k] \tag{22a}$$

$$y[k] = \begin{bmatrix} 1 & 0 & 0 \end{bmatrix} \mathbf{x}[k] \tag{22b}$$

The sampling time T is taken as 0.01s. The initial true state was considered as $\mathbf{x}[0] = [0.4\ 0.3\ 0.4]^T$ and the initial state for the estimation algorithms were chosen as $\hat{\mathbf{x}}[0] = [0.2\ 0.1\ 0.4]^T$. The observation was subject to uniform noise of covariance $\sigma^2 = 0.1^2$ and the process noise was considered to be of covariance $\sigma^2 = 0.01^2$. Figure 3 presents the observation plot while Figure 4 presents the mean square observation error. It was observed that both algorithms effectively estimate the states. However, SSLMF converges fast than SSNLMS which can be observed in 4. Referring to I, it can be confirmed that SSLMF performed better than SSNLMS.

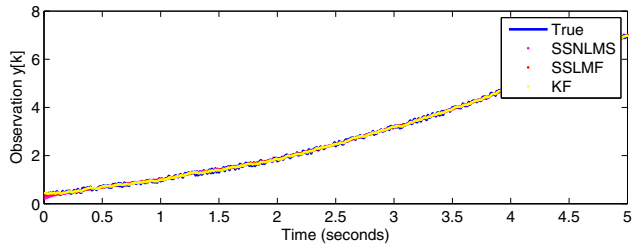

Fig. 3: Observation y[k]

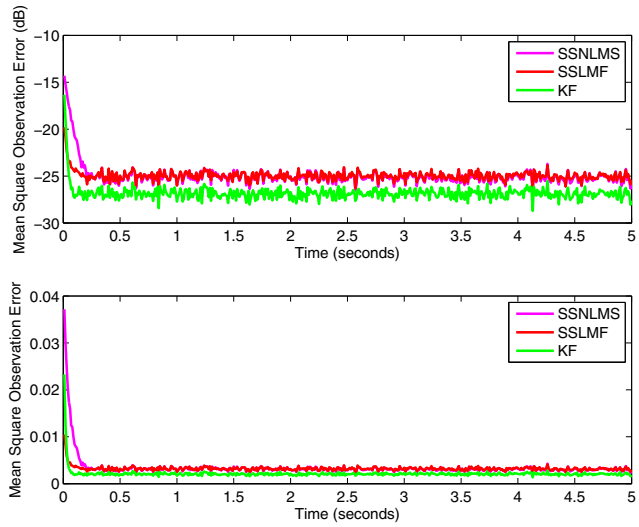

Fig. 4: Mean Square Observation Error y[k]

C. Example 3. Van der poll oscillator

In this example we consider the commonly used Van der poll oscillator which is a highly nonlinear system exhibiting both stable and unstable limit cycles [14]. We consider the case of stable limit cycle therefore, as time proceeds the system states converge to zero. The system is represented by the following differential equations ([13],[14])

$$\dot{x}_1 = -x_2 \tag{23a}$$

$$\dot{x}_2 = x_1 - \alpha(1 - {x_1}^2)x_2 \tag{23b}$$

here $\alpha = 0.2$ and the system has been discretized with a sampling time of 0.01s. The state space representation is as follows

$$\mathbf{x}'(t) = \begin{bmatrix} 0 & -1 \\ 1 & -\alpha(1 - x_1(t)^2) \end{bmatrix} \mathbf{x}(t) \tag{24a}$$

$$\mathbf{y}(t) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \mathbf{x}(t) \tag{24b}$$

μ for the SSNLMS was chosen as 0.1 and μ for SSLMF as 0.7. The observation was subject to uniform noise of covariance $\sigma^2 = 0.01^2$ and the process noise was considered to be of covariance $\sigma^2 = 0.001^2$. The system was simulated with initial system states to be $\mathbf{x}[0] = [1.4\ 0]^T$, and the initial estimate for the algorithms were chosen to be $\hat{\mathbf{x}}[0] = [1.3\ 0.2]^T$. The observations and the mean square observation error is presented in Figure 5 and Figure 6 respectively. It can be observed from I that the observation error remains lower

for SSLMF in comparison to SSNLMS. Moreover, SSLMF converges faster compared to SSNLMS.

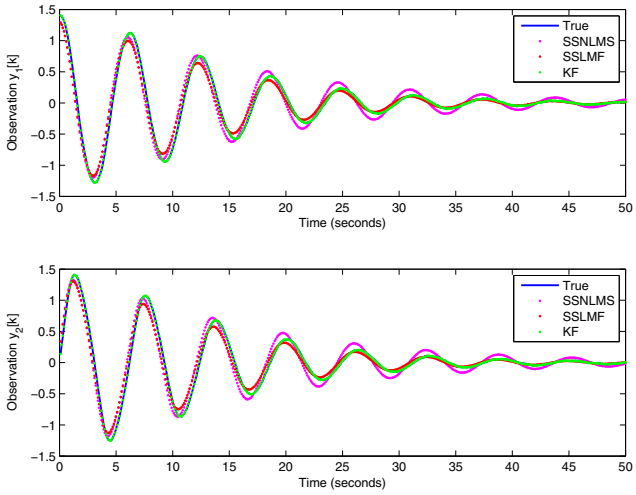

Fig. 5: Observation $y_1[k]$ and $y_2[k]$.

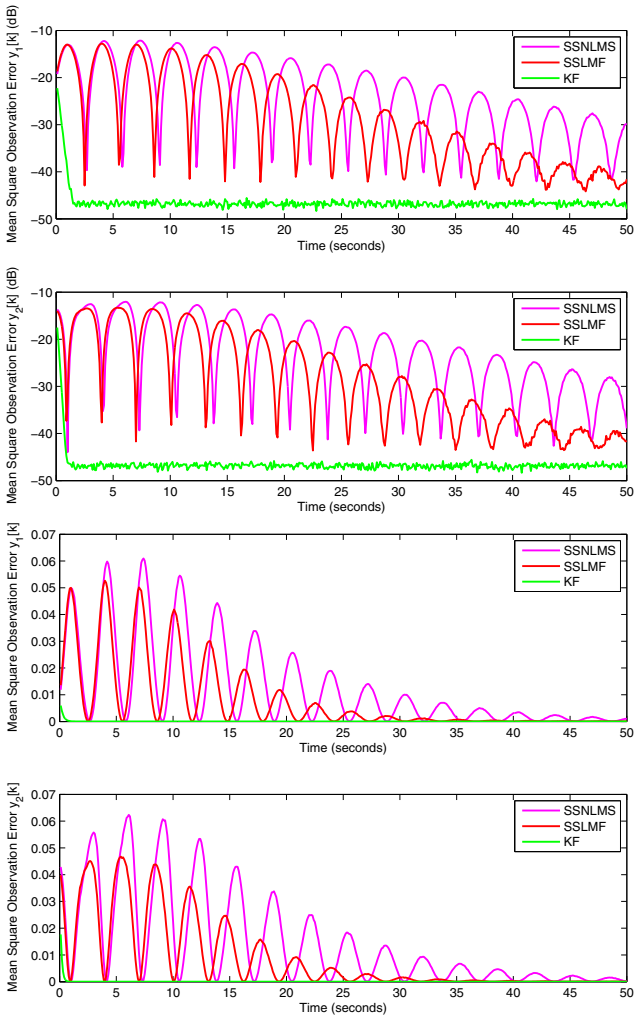

Fig. 6: Mean Square Observation Error for $y_1[k]$ and $y_2[k]$.

It is clear from the study that SSLMF indeed is a novel technique for estimation. Moreover, it is computationally very light when compared to other model based techniques like KF, EKF, UKF, etc. Our study reveals that SSLMF can be effectively utilized in non Gaussian noise environments.

TABLE I: Root Mean Square Error

		Root Mean Square Error		
		SSNLMS	SSLMF	KF
Example 1	Observation y	0.0215	0.0099	0.0071
Example 2	Observation y	0.0587	0.0566	0.0462
Example 3	Observation y_1	0.1108	0.0881	0.0073
	Observation y_2	0.1174	0.0911	0.0093

VI. Conclusion

In this paper the novel SSLMF algorithm has been proposed and investigated. The proposed algorithm is efficient and computationally light compared to existing model based linear and non linear estimation techniques (KF, EKF, UKF, etc.). Three different examples were investigated where SSLMF performed better than the SSNLMS and showed acceptable performance in comparison to KF keeping in mind the fact that KF is highly intensive in computation. For further studies SSLMF for Gussian noise environments can be proposed and investigated along with time varying step size parameters or hybrid algorithms for yet better results.

***Abstract*—Attitude plus velocity matching transfer alignment (TA) (Rapid Alignment Prototype RAP) algorithm has the advantage of faster convergence and it does not require pre - planned lengthy manoeuvre like velocity matching algorithm, which makes it best suited for tactical missions. For large initial misalignment angles, TA problem becomes nonlinear, for which, a conventional particle filter (CPF) based TA algorithm can be used to estimate misalignment. Time varying nature as well as dependencies on external parameters like sensor measurements of state transition matrix of TA problem, makes the system behavior unpredictable and hard to model. A CPF fails in this situation, due to its inability to capture complex nonlinearity associated with the system through system dynamics, due to sample impoverishment problem. Current work addresses this scenario and proposes an evolutionary strategy based algorithm, which performs effectively in such condition, by simulating varied system dynamics through generation of multiple support points. These algorithms are designed and tested for both perfectly modeled and perturbed systems. Simulation results are presented which shows the effectiveness of the proposed algorithm.**

***Index Terms*—particle filter, evolutionary strategy, attitude matching, system dynamics**

I. Introduction

Accurate initialization of navigation information of deliverable guided munitions (called daughters) from a moving platform (called mother), is a prerequisite for delivery of guided munitions. Transfer alignment (TA) is a process of such initialization and calibration of daughter inertial navigation system (INS). Measurements of mother and daughter INS differ due to the misalignment present between them and associated noise of daughter INS measurement. TA algorithm uses theis difference in measurements of mother and daughter INS to estimate their misalignment. A Kalman Filter (KF) is used as an estimator of misalignment and filter of noises associated with daughter INS measurement. Various TA algorithms have been studied in [1], [2].

Velocity matching TA algorithm uses the differences in velocity measurements provided by mother and daughter INS, and used extensively in case of in-flight TA algorithm. Although velocity matching provides optimal estimates of misalignment, it requires a preplanned large manoeuvre to excite inertial sensors of both mother and daughter, and thus, avoided in tactical missions, where faster convergence is of primary concern. Velocity plus attitude matching TA algorithm, also called Rapid Alignment Prototype (RAP) [3], considers differences of velocity as well as attitude in both mother and daughter and converges fast without requiring any large manoeuvre [4], [5].

Due to the failure of small angle approximation employed by the KF in the classical state space formulation, TA problem becomes nonlinear, if the initial misalignment is large. In such case, KF fails to estimate misalignment and some variant like unscented KF (UKF), extended KF (EKF) are used. Both UKF and EKF depend heavily on system models and also suffer from assumption of Gaussian white system as well as measurement noise statistics, which may not be the case in real time. Another approach of handling nonlinearity is particle filter (PF) which does not require these assumptions. Performance of PF based TA algorithms has been studied extensively [6], [7].

One problem associated with PF is sample impoverishment problem in which, only a few particles remain in the system after a few iterations, others being thrown away by the process of re-sampling. This loss of samples becomes a significant problem when the system model is not perfect. Factors such as external input like GPS measurements in the computation of time varying state transition matrix of TA problem, makes the system model erroneous. When CPF uses this erroneous system model to propagate its initially generated particles, it yields poor samples in the system. Upon resampling, some of these poor samples are retained in the system which in turn, affects overall performance of the filter.

To remedy this problem, evolutionary strategy based particle filter algorithm can be applied, which avoids the complex task like resampling of a CPF altogether. Description of such algorithm can be found in [8]. Initially generated N samples of this filter are supported by multiple support points in each pass and among these particle support combination, best N samples closest to measurements, are chosen. This redundant sample helps in avoiding re-sampling by retaining N particles in each pass.

Performance of such a filter named residual evolutionary particle filter (REPF) (named because it brings residual value closer to zero in all situations) has been studied for velocity matching TA algorithm [9]. For tactical flights where faster time of convergence with least possible manoeuvre is of primary concern, velocity plus attitude matching algorithm is preferred. Objective of current work is to investigate the performance of REPF based velocity plus attitude matching algorithm for in flight TA problem. A REPF based RAP algorithm is designed and its performance is compared with that of CPF. In normal situation, performance of the proposed algorithm is found at par with CPF both in terms of time and accuracy. However, simulation results shows that, REPF outperforms CPF in situation, when, system modeling is imperfect.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

Organization of the paper is as follows. After introduction, some basics of state space formulation of TA problem and the problem definition is given in the Section II. Proposed REPF based RAP algorithm is described in Section III. Computer simulation results are given in Section IV. Analysis of effectiveness of the proposed algorithm is discussed in Section V which is followed by conclusion in Section VI.

II. Background

RAP algorithm, has the advantage of faster convergence over only velocity matching TA, without using any large manoeuvre. For these reasons, RAP is preferred in tactical missions. Factor incorporating nonlinearity in the TA system is large initial misalignment, which entails nonlinear formulation of TA problem to be fit with some RAP based nonlinear filtering technique. Nonlinear error propagation equations for large misalignment angles involving large azimuth misalignment has been studied in [10], [11]. For the sake of simplicity in implementation avoiding complex computational loads, the linearized form of nonlinear TA problem described in [12], [13] can be used, which in discretized form, can be represented as follows:

$$\dot{X} = FX + G_w w \tag{1}$$

$$Y = HX + v \tag{2}$$

where, $X = [\delta V^T \ \psi_m^T \ \psi_a^T \ \bigtriangledown_s^{sT} \ \epsilon_s^{sT}]$ is the system state vector comprising of variables as described in Table I.

TABLE I
STATE VARIABLES

Parameters	Description
δV^T (3×1)	Velocity differences between mother and daughter INS
ψ_m^T (3×1)	Measurable time varying misalignment between mother and daughter INS
ψ_a^T (3×1)	Physical mislaignment between mother and daughter which need to be estimated
$\bigtriangledown_s^{sT}$ (3×1)	Accelerometer bias
ϵ_s^{sT} (3×1)	Gyroscopic drifts

F is the state transition matrix, constituted from nonlinear formulation of error propagation equations of sate variables like velocity, attitude as described in [13], [14] and given in Equation No. 3, each entry in the matrix having dimension 3×3. w and v are zero means Gaussian white noise for system and measurement respectively.

$$F = \begin{bmatrix} -(2\omega_{ie}^n + \omega_{en}^n)\times & -C_{s^*}^n f_s^s \times & C_{s^*}^n f_s^s \times & C_{s^*}^n & 0 \\ 0 & -\omega_{ns}^s \times & \omega_{ns}^s \times & I & I \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \tag{3}$$

Measurements used by the filter in this problem is constituted by the differences in velocities and attitudes of both mother and daughter INS, which is a linear function of the differences in measurements of these quantities from mother and daughter INS. Thus, the measurement sensitivity matrix H becomes time invariant, and measurement model can be represented in discretized form by

$$Y = HX + v$$

where, the measurement sensitivity matrix H of dimension 6×15, can be expressed as follows:

$$H = \begin{bmatrix} I & 0 & 0 & 0 & 0 \\ 0 & I & 0 & 0 & 0 \end{bmatrix}$$

A conventional KF applies small angle approximations in the computation of direction cosine matrix (DCM) for ease of computation, which fails in the case of large initial misalignment. A conventional particle filter (CPF) can handle nonlinearity effectively, but suffers from sample impoverishment problem (retention of a few initially generated samples, while omitting others). Moreover, the time varying nature of state transition matrix F due to use of measurements of mother and daughter INS in its computation, specifically in the computation of various DCMs and specific force (f_s^s), makes the system behavior unpredictable and hard to model perfectly, in real time. Such a nonlinear and time varying system cannot be handled by a CPF properly and calls for use of some variant.

III. Proposed Algorithm

The REPF algorithm is a evolutionary strategy based algorithm. The algorithm initially generates N number of particles with a known density and associated weights (equal to $1/N$ for each particles). These particles are then propagated through the system dynamics like CPF. Next, n ($n << N$) number of support points along with associated weights are generated for each particles, based on a known distribution. The system now have nXN particles and support points combination. From this, N best samples, closest to measurements are chosen for further computation, by applying some constant time sorting technique. This essentially avoids the complex and time consuming re-sampling technique required for CPF, and solves the sample impoverishment problem of CPF by retaining all N samples in every iteration.

Generation of n support points for N particles is similar to propagation of N particles through n different systems. This is comparable to multiple model adaptive estimation technique [15], and performs similar to CPF in normal condition (when system is modeled perfectly). Advantage of such filter can be found in situation when the knowledge about the system is inadequate. By generating n support points, REPF encompasses n different systems, among which, the one which provides samples closest to measurement, is selected for next iteration. Effectiveness of this approach has been established by applying it to the classical $2D$ tracking problem, and then applied to velocity matching TA problem in [9].

IV. Simulation Results

Results of computer based simulation is presented in this section in order to prove the effectiveness of the proposed algorithm.

A. Simulation Criteria

Parameters used in this work for the simulation purpose are shown in Table II

For both the filters, particles are initially generated from a known distribution with $\mathcal{N}(0, 0.1)$. System and measurement noises w and v are assumed to be white Gaussian with $\mathcal{N}(0, Q^2)$ and $\mathcal{N}(0, R^2)$ respectively. A regulator is designed which computationally corrects the misalignment and converts the estimation problem to zero tracking problem.

TABLE II
PARAMETERS USED IN SIMULATION RUNS

Parameters	Value
Initial Misalignment	$\psi_\alpha = 7^o$ $\psi_\beta = 8^o$ $\psi_\gamma = 9^o$
Gyro Drift	$3^o/hr$
Accelerometer Bias	$500\mu g$
System noise covariance $Q(15 \times 15)$	$diag([(2.2500e-0016)_{3\times3}\ (2.3504e-8)_{6\times6}\ (0.06e-16)])$
Measurement noise covariance $R(6 \times 6)$	$diag([(3e-4)_{3\times1}\ (2.3504e-7)]$

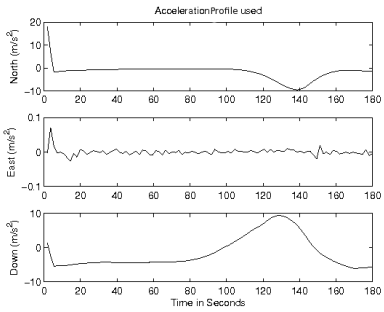

Fig. 1. Less than $1g$ manoeuvre used for simulation

B. Results

Figure 1 shows the acceleration profile used for the simulation purpose. Less than $1g$ manoeuvre is used to justify the fact that, RAP does not require high g manoeuvre to estimate the misalignment. Availability of mother measurement is taken in the interval of 1.8 seconds. Figures 2, 3 and 4 depicts the execution of both CPF and REPF based RAP algorithm, when the system is perfectly modelled. For the purpose of convenience in representation, CPF based RAP algorithm is designated as AMPF and REPF based RAP algorithm is designated by AMEPF in every plots of results. From these figures it can be seen that, less than 1 arc minute accuracy is achieved by both the filters over a time span of 10 seconds (from 3rd to 13th seconds) which is considered adequate for TA assuming 7°, 8° and 9° initial misalignment and both the filters converge in less than 5 seconds time which is typical for RAP.

To simulate the scenario of imperfect system model, parameters of the state transition matrix F as described in Equation 3 are perturbed by injecting about 10% errors in its constituent elements for the second run. For perturbation purpose, elements constituting ψ_a are chosen specifically, keeping others, like $\bigtriangledown_s^{sT}, \epsilon_s^{sT}$ (which are independent of and can not affect any parameters) in the system states, unperturbed. These parameters basically act as an additive noise to the system. Although similar results can be obtained by adding noise in the system, this approach is chosen to simulate imperfect system dynamics rather than noisy system. Performance of these two filters in this situation is recorded and shown in Figures 5, 6 and 7. It can be observed that, CPF is estimating with error in the range of 40 arc minutes, sometimes even showing nonconvergence. For the purpose of estimation of initial misalignment in the range of $[7^o - 9^o]$, this performance is considered poor. Contrary to the performance of CPF, REPF still manages to estimate the misalignment with the accuracy of < 5 arc minutes and converges in less than 6 seconds time which is at par with the standard of any RAP filter.

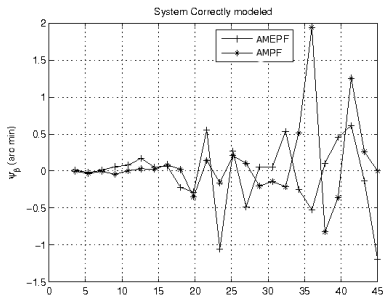

Fig. 3. Performance of two filters in the estimation of misalignment angle ψ_β when system is perfectly modeled

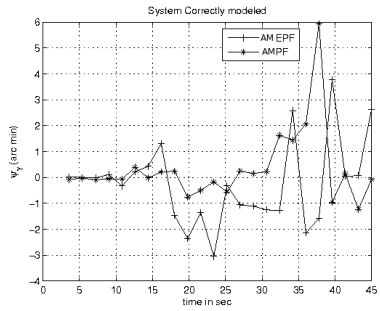

Fig. 4. Performance of two filters in the estimation of misalignment angle ψ_γ when system is perfectly modeled

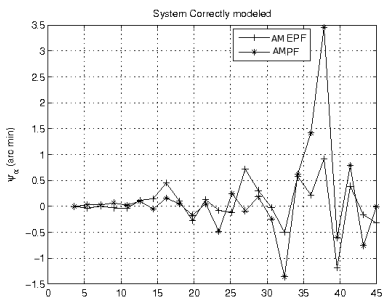

Fig. 2. Performance of two filters in the estimation of misalignment angle ψ_α when system is perfectly modeled

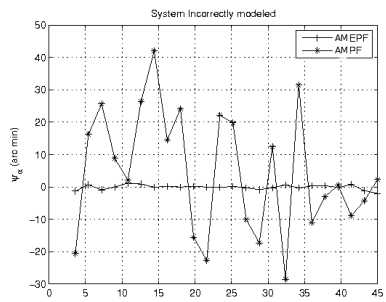

Fig. 5. Performance of two filters in the estimation of misalignment angle ψ_α when system is NOT perfectly modeled

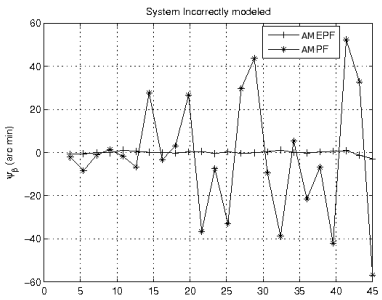

Fig. 6. Performance of two filters in the estimation of misalignment angle ψ_β when system is NOT perfectly modeled

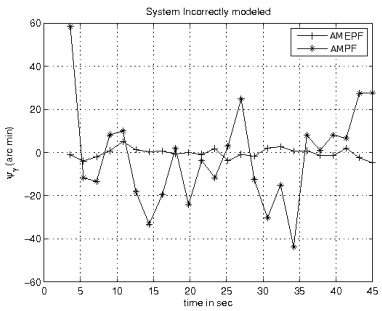

Fig. 7. Performance of two filters in the estimation of misalignment angle ψ_γ when system is NOT perfectly modeled

V. Discussion

To simulate imperfect system model, elements of state transition matrix was perturbed in the second run. This perturbation affected the initially generated particles by propagating through wrong system dynamics. Few of these corrupted particles, comparatively closer to measurement than others, were retained in the system by the method of resampling while others were dropped. CPF continues with these particles, which affects its performance altogether. On the other hand, the REPF based algorithm can use one of many choices of system dynamics in every iteration. By this way, it can get samples closer to measurement by covering more search space and thus, handling of poorly modelled systems becomes possible.

From the results presented in previous section and discussion presented above, it can be concluded that, REPF based RAP algorithm is best suited for situations when:

- knowledge of the system is not proper
- initial misalignment is large
- faster and accurate convergence is of interest
- large manoeuvre can not be performed as in tactical mission

Time complexity of both CPF and REPF algorithm are linear in terms of particle count. One factor affecting the time as well as space complexity of overall algorithm is the size of the state vector used and the size of the state transition matrix, which, in this case, is a 15×1 vector and 15×15 matrix. Reduction of the size of state vector can lead to better performance of the filter.

VI. Conclusion

An evolutionary strategy based in flight TA algorithm has been developed. Its performance has been compared with similar type of CPF algorithm. It is shown by computer simulation that, both the proposed REPF and CPF algorithms perform similar in normal situation, when knowledge of the system dynamics is good. In real time situation, factors such as interrupted supply of mother measurement, external aiding in the computation of state transition matrix makes the system behavior unpredictable and such systems are hard to model. It is shown by simulation that, a CPF fails to handle such nonlinear and time varying systems mostly due to the sample impoverishment problem. Proposed algorithm uses one among many system dynamics to select best particles and can perform satisfactorily even in such adverse situation.

Although comparable in terms of time as well as space complexity with a CPF, some implementation issues such as clever and efficient handling of state transition matrix, scheduling of some tasks of REPF in multiple processors, parallel execution of more than one algorithm in a single processor for more accurate and timely convergence of TA algorithm are some topics that need to be explored for further research.

Abstract— **Graphene is a 2-D atomic layer of carbon atoms with unique electronic properties like outstanding carrier mobility, high carrier saturation velocity, excellent thermal conductivity, high mechanical strength, transparency, thinness, and flexibility which make graphene an excellent choice of material for advanced applications in future solar cell design. We modeled a solar cell using graphene as the front electrode to study its performance and compare the performance with that of other possible contenders– indium tin oxide (ITO), widely used material at present and carbon nanotube (CNT), another promising material in this regard. Numerical solutions of the electrostatic and transport equations were obtained using the finite-element method. It was found that solar cell with graphene electrode can outperform the others. We also studied its performance as a function of various parameters. The developed model and obtained results are important for the design of solar cell with graphene as electrode.**

Index Terms— **CNT, Electrode, Graphene, ITO, Solar Cell.**

I. Introduction

The electrode of the solar cell module which is on the side of illumination has a significant impact on the energy conversion efficiency. Reflection, absorption and resistive losses of the electrode play an important role on the efficiency of the solar cell. So this front electrode must be highly transparent and conductive as well as must have very low resistance. Tin-doped indium oxide or ITO is the most widely used transparent-conducting material or Transparent Conductive Oxide (TCO). Such transparent conducting thin films are in widespread use as electrodes in a variety of optoelectronic devices. Currently it is used in most of the solar cells as its front electrode because of its optical transparency and electrical conductivity. But due to the supply constraint of ITO and increasing price, we must consider other materials which can replace ITO and give even better solar cell performance.

Graphene is a revolutionary material which can be considered as the primary replacement of ITO. It is a 2D carbon sheet with hexagonal crystal structure. It shows very high transparency of upto 97.7% whereas ITO has a transparency of 85% in the visible spectrum [1]–[4]. Graphene also has a superior electron mobility of 20,000 $cm^2/V.s$ as compared to 70 $cm^2/V.s$ for ITO [5]–[6].The high electron and hole transport mobility, large specific area and the inertness against oxygen and water vapour make graphene a promising candidate in photovoltaic application. Flexibility is one of the prime demand for upcoming electronic devices and solar cells. Graphene is simultaneously flexible and robust whereas ITO is rigid and fragile.

We also compare another possible candidate carbon nanotube (CNT), one dimensional carbon allotrope, which also has very favourable properties like high electron mobility conductivity and transparency to act as solar cell front electrode [7]–[9]. Unlike graphene, CNT presents higher contact resistance. Two dimensionality and structural flatness make it easier to combine graphene with other semiconductor material such as silicon.

In this paper, we observe the current density (J)-voltage (V) characteristics of our model with graphene as electrode and compare the performance with that obtained from solar cells with CNT and ITO electrodes. We also studied the effect of different parameters on the performance of our proposed model.

II. Solar Cell Model

With a view to study the performance of solar cell with graphene as front electrode, we solved electrostatic and transport equations in our proposed structure numerically. The base model, as shown in Fig. 1, consists of an intrinsic layer of silicon between n and p type silicon. At the top there is a thin layer of graphene which acts as the front electrode of the solar cell model.

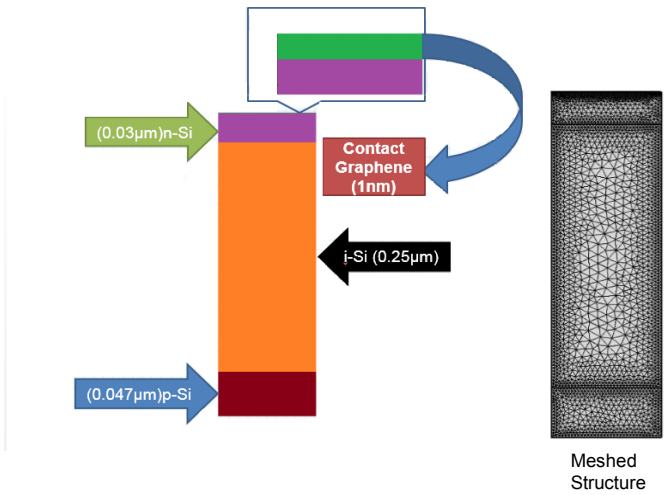

Fig. 1. Schematic cross section of p-i-n solar cell with graphene as electrode

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

The thicknesses of intrinsic, n and p type silicon and front electrode are assigned to be 0.25µm, 0.03µm, 0.047µm and 1nm respectively. The donor and acceptor concentration for silicon is considered to be 10^{17}cm^{-3}. The sheet density of graphene is 10^{-12} cm^{-2}[10]. Ali *et al.* shows that the concentration for ITO decreases with its thickness [11]. Here we use a thin electrode so the effect of thickness in the carrier concentration of ITO is considered.

We have solved Poisson's Equation and Drift-Diffusion Equation using finite element method with the help of COMSOL [12].

In electrostatics, Poisson's equation has the form of

$$\nabla.\mathbf{D} = \rho_v \tag{1}$$

Where $\mathbf{D}$ = electric displacement field = $\varepsilon\mathbf{E} = \varepsilon_o\varepsilon_r\mathbf{E}$ and ρ_v = free charge density.

The convection–diffusion equation is a combination of the diffusion and convection (advection) equations [13].

$$\frac{\partial c}{\partial t} = \nabla.(D\nabla c) - \nabla.(\mathbf{u}c) + \mathrm{R} \tag{2a}$$

Where c is the variable of interest (species i.e., electron or hole concentration for mass transfer), D is the diffusion coefficient $\mathbf{u}$ is the average velocity of the species. R describes sources or sinks of the quantity c. At steady state (i.e., $\partial c / \partial t = 0$) the equation takes the form as:

$$\nabla.(-\mathrm{D}\nabla \mathrm{c} + \mathbf{u}c) = \mathrm{R} \tag{2b}$$

This leads to drift-diffusion equation in semiconductor,

$$\frac{\mathbf{J_n}}{-q} = -D_n\nabla n - n\mu_n\mathbf{E} \tag{3a}$$

$$\frac{\mathbf{J_p}}{q} = -D_p\nabla p + p\mu_p\mathbf{E} \tag{3b}$$

Where n and p are the concentrations of electrons and holes, respectively, q is the charge of an electron, $\mathbf{J_n}$ and $\mathbf{J_p}$ are the electric current density due to electrons and holes respectively, $\mathbf{J_n}/-q$ and $\mathbf{J_p}/q$ are the corresponding particle currents of electrons and holes respectively.R in equation 2b represents carrier generation ($R>0$) and recombination ($R<0$), D_n and D_p are electron and hole diffusion coefficient, μ_n and μ_p are electron and hole mobility, respectively and $\mathbf{E}$ is the electric field vector.

According to the Beer-Lambert law we get generation, G which varies as light passes in the y direction as

$$G = G_o \exp(-\alpha\, \mathrm{y}) \tag{4}$$

The current density of the solar cell is obtained from

$$J = -J_{ph} + J_d \tag{5}$$

Where J_d is the diode current density where

$$J_d = J_n + J_p \tag{6}$$

Here J_n and J_p are the electron and hole current density respectively and J_{ph} is the photo-current density which is expressed as

$$J_{ph} = \frac{qG_o}{\alpha}\left\{1 - exp\left[-\alpha\left(\ell n + W + \ell p\right)\right]\right\} \tag{7}$$

Here α is the absorption coefficient of the medium through which light passes, G_o is the carrier generation rate at the top surface of solar cell, q is the charge of electron, W is depletion width and ℓn & ℓp are minority carrier diffusion length of electron and hole respectively.

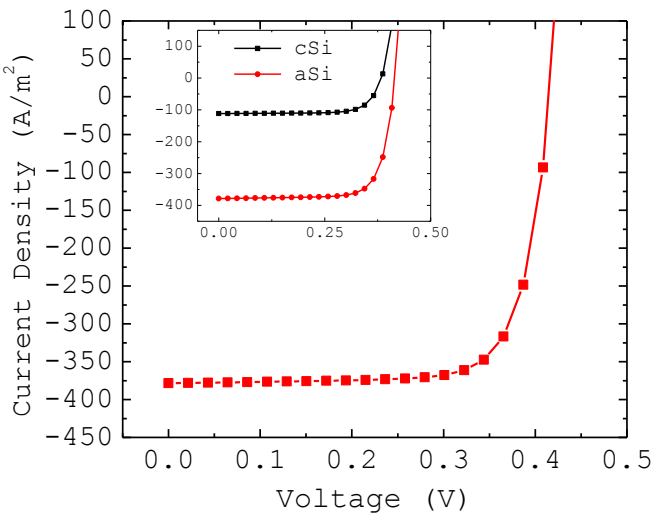

Fig. 2. J-V Characteristic for p-i-n graphene solar cell; Inset: Comparison between amorphous (Red) and crystalline (Black) silicon solar cell.

III. Results

We obtain different J-V characteristics as a result of our simulation. The input optical power is considered to be 1000W/m^2 of a wavelength of 530nm if not otherwise stated. Photocurrent density or short circuit current density (J_{ph}), open circuit voltage (V_{oc}), fill factor (FF) and efficiency (Eff) are the main indicator of the performance of a solar cell. We have used current density rather than only current. It is more convenient while comparing the characteristics of different modules or devices with different sizes.

Fig. 2 shows the J-V characteristics of p-i-n amorphous silicon solar cell with graphene as electrode. It shows that at 1000W/m^2 input optical power of wavelength 530nm, the photocurrent density, open circuit voltage and efficiency is 378.5 A/m^2, 0.4147 V and 12%, respectively.

According to theoretical calculation, photo-current densities for crystalline and amorphous silicon solar cell are 118A/m^2 and 415A/m^2, respectively.

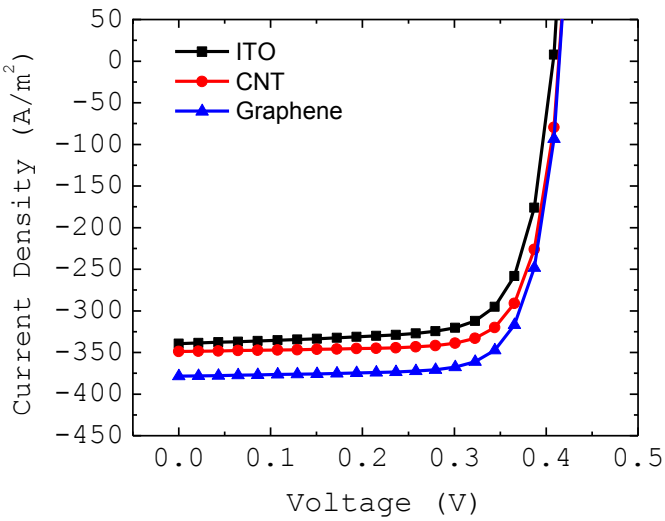

Fig. 3. Performance comparison among the solar cells with three different electrodes.

TABLE I
SOLAR CELL PERFORMANCE USING THREE DIFFERENT ELECTRODES

Performance indices	Graphene	CNT	ITO
J_{ph} (A/m^2)	378.5	349.5	339.3
V_{oc} (V)	0.4147	0.4135	0.4076
FF	76.45%	75.72%	68.23%
Eff	12%	10.9%	9.4%

The photo-currents from simulation are comparable with these theoretical values under same condition since in our simulation we obtain a photocurrent density of 111.25A/m^2 for crystalline silicon and 378.5A/m^2 for amorphous silicon at 1000W/m^2 input power. Amorphous silicon solar cell gives higher current due to higher absorption coefficient. The value of absorption coefficient is 1.0206x10^6 m^{-1} for crystalline and 1.58x10^7 m^{-1} for amorphous silicon [14].

In Fig. 3 we show the J-V characteristics obtained for the amorphous silicon solar cells with three different electrodes. The performances of solar cells with these electrodes are also presented in TABLE I for better comparison. The photocurrent density, open circuit voltage, fill factor and most importantly the efficiency is given for each solar cell with graphene, carbon nanotube and ITO electrode.

The best performance is obtained from graphene with a photocurrent of 378.5 A/m^2 and efficiency of 12% at 1000W/m^2 input power with a wavelength of 530nm. It also shows that carbon nanotube gives better characteristics than indium tin oxide.

Inclusion of intrinsic layer into the structure creates larger depletion region and thus the efficiency of solar cell is increased. This matches with the result obtained from our simulation as shown in Fig. 4 such that with the decrease of intrinsic layer length from 0.25µm to 0.09µm the photocurrent density as well as the efficiency decreases. It also shows that the photocurrent is significantly reduced when p-n junction is used instead of p-i-n.

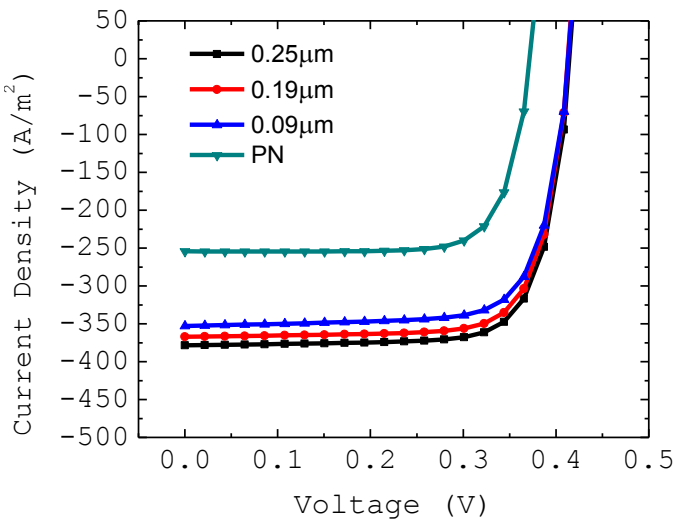

Fig. 4 J-V Characteristic for p-n solar cell and p-i-n solar cell with variation of intrinsic layer length (µm)

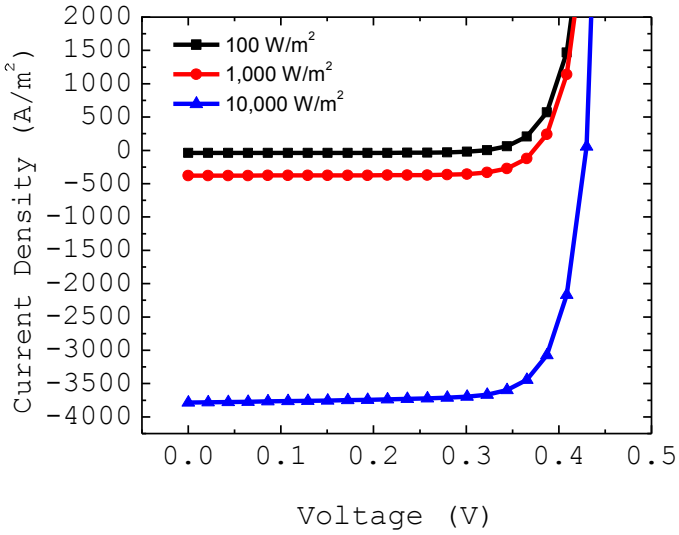

Fig. 5. J-V Characteristic for p-i-n graphene solar cell with varying input optical power intensity

At this stage, we vary the optical input power and obtain the result as shown in Fig 5. Since the current density is proportional to the input power intensity, if we make the input optical power ten times larger, the photocurrent also increases by ten times. For 100, 1000 and 10000 W/m^2 incident optical intensity the photocurrent density is 37.85, 378.5 and 3784.65 A/m^2, respectively. The open circuit voltage is a logarithmic function of input optical power. So it varies slightly with the variation of input power intensity.

As we increase the wavelength, keeping the input power intensity fixed, photon flux is increased due to decrease of photon energy and so does the generation up to a certain level. Hence the photo-current density increases for our proposed model as shown in Fig 6. Dimension of the model is a concerned issue in this regard.

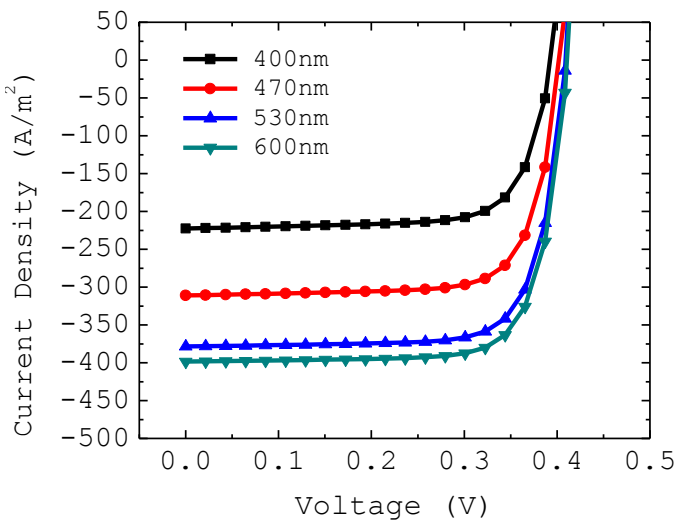

Fig. 6. Variation in current density with voltage for p-i-n graphene solar cell for different incident wavelength.

IV. Conclusion

In this work we developed a model of solar cell with graphene as electrode and studied the device performance. From the simulation we observed that the revolutionary material graphene gives better performance in comparison to CNT and ITO, two other solar cell front electrode candidates. Numerical results showed that the photocurrent is a strong function of input light intensity, wavelength of the incident light as well as the dimension of the structure. The properties of graphene make the material extremely suitable for using it as the electrode in solar cell and other electronic devices. Its flexibility and high mechanical strength can also pave the way to flexible and strong solar panels.

Effects of physical parameters on subthreshold characteristics of nitride and antimonide-based double material gate (DMG) HEMTs

Arman-Ur-Rashid*, Md. Aynal Hossain, Tanvir Rahman and Farseem M. Mohammedy
Department of Electrical and Electronic Engineering
Bangladesh University of Engineering and Technology (BUET)
Dhaka-1000, Bangladesh
*Email: arman0806161@yahoo.com

Abstract— **In this papar we have varied the physical parameters of double material gate (DMG) HEMT and noted the change in subthreshold characteristics. The physical parameters are: control-gate length, barrier layer thickness and the workfunction difference between two gate materials. A semi-classical analytical model has been used to determine the channel potential and electric field. One nitride-based and three antimonide-based formations have been used in this work and their results have been compared. We have found that nitride-based DMG HEMTs are less sensitive to process variation of gate fabrication compared to antimonide-based DMG HEMTs. It has been seen that variation in barrier layer thickness affects nitride-based HEMTs more strongly than antimonide-based DMG HEMTs, while the effect of change in workfunction difference is more prominent in antimonide-based HEMTs. Among the antimonide-based HEMTs, it have been seen that the formation with deep conduction band discontinuity is more susceptible to change in control-gate length than formations with shallow conduction band discontinuity. But effects of barrier layer thickness change and change in workfunction difference are more noticeable in shallow conduction band formations, making these formations more effective as double material gate (DMG) structures.**

Index Terms— **HEMT, antimonide-based, nitride-based, physical parameters.**

I. Introduction

With the continuous trend of scaling, the silicon-based MOSFET technology is rapidly approaching to its limit [1]. As a result new structures are continuously being investigated to produce faster, smaller and less power consuming device. HEMT (high electron mobility transistor) is one such device which is being extensively researched. HEMTs have inherent higher mobility and are easy to fabricate compared to same size MOSFETs [2]. In field of HEMT, nitride-based materials have already made their mark. Nitride-based HEMTs are well known for their ability to work in high voltage, high power environments [3]. They are also suitable to work in integrated circuits with ultraviolet photo detectors. On the other hand, researchers are interested in antimonide-based HEMTs for their low on-voltage, ultra high speed and very low power consumption characteristics [4]. Suitable for the integration of third generation infrared photo-detector with ultra-high speed transistor, antimonide-based materials are opening a promising window of research through HEMT structure [5].

To make faster devices, scaling is a must. Like other device-structures, HEMT is also going through scaling [6]. With the advancement of fabrication techniques and material science, even sub-micrometer range HEMTs with excellent speed performance are now reality [7]. But as the gate length decreases below 300nm, different short channel effects and carrier transport inefficiency become the prime concern. Much research is being done to solve these problems of HEMT. Various structures like double gate HEMT, split gate HEMT etc. were proposed , but none can solve the problems of short channel effect and carrier transport inefficiency simultaneously [8]. The ultimate solution was given by Long et al. [9] in his proposed Dual Material Gate (DMG) FET structure.

In DMG FET, two gates made of different materials of different workfunctions are joined laterally to create a single gate. The workfunction of one gate (M1) is chosen to be to be greater than the other (M2). Gate (M1) works as control-gate and gate M2 works as screening gate for drain voltage. It enhances the average electric field and inserts a step function in channel potential at the interface of two gates. The enhanced average electric field improves the carrier transport efficiency and the step function reduces the short channel effects. But as the scaling goes into deep sub-micron level, need for an analytical model of subthreshold behavior of DMG HEMT emerges. S.P.Kumar et al. [8] first proposed an analytical model for the subthreshold behavior of nitride-based DMG HEMT. In one of our previous paper [10] the model of [8] was modified and an analytical model for antimonide-based HEMTs was developed.

We have worked with three formations of antimonide-based HEMTs and a nitride-based HEMT. In [10] we used the barrier/channel formation of $Al_{0.7}Ga_{0.3}Sb/InAs$. Among the antimony-based material AlSb and GaSb are approximately lattice matched to InAs and these semiconductors are jointly known as 6.1A^o family. In this paper we also study the $Al_{0.7}Ga_{0.3}Sb/GaSb$ and $Al_{0.7}Ga_{0.3}Sb/In_{0.15}Ga_{0.85}Sb$ barrier/channel combinations and compare their results. We also derived the results of $Al_{0.2}Ga_{0.8}N/GaN$ DMG HEMT from the proposed model of [8] and compared those results with antimonide-based DMG HEMTs.

In this paper, we have varied three key physical parameters of different antimonide-based and nitride-based DMG HEMTs and compared the results. Our focus is on the change in minimum channel potential (φ_{limin}) due to change in physical parameters. This parameter is the key to understand the effect of DMG structure over the HEMT. So by varying the physical parameters we can not only understand the effects of possible

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

scaling of DMG HEMT but also the effectiveness of DMG structure over various formations.

II. MODEL FORMULATION.

Fig. 1 shows the cross-section of proposed DMG HEMT structure. Here, L1 and L2 are the lengths of gates with metal M1 and M2 respectively. L is the total length. The drain and source regions are doped uniformly with donor concentration N_d+=$10^{25}m^{-3}$. The workfunctions of metal M1 is chosen φ_1=5.3 V, which is greater than the workfunctions of metal M2 φ_2=4.1 V (if not stated otherwise). φ_1 is chosen greater than φ_2 to make the HEMT n-channel [12]. The gate voltage and drain voltage were chosen -0.2 V and 0.2 V respectively to make the barrier layers completely depleted and confined electrons in the heterointerface. The typical values of other parameters are listed in Table. I. If not stated otherwise these are values used in the model.

The details of the analytical model and simulation are given in [10] for antimonide-based DMG HEMTs and we followed the nitride-based DMG HEMT model from [8].

Table I. Lists of parameters

Parameter	Name of the parameter	Value
N_d	Doping in the barrier layer	10^{23} m^{-3}
L	Effective channel length	120nm
d_d	thickness of doped barrier layer	25nm
d_i	Thickness of spacer layer	5nm
ε_s	Dielectric constant of $Al_{0.7}Ga_{0.3}Sb$	13.1
T	Operating temperature	300K

In this paper we have chosen three different formations of antimonide-based DMG HEMTs to compare the effect of DMG structure within different antimonide-based HEMTs. The barrier layer is chosen to be $Al_{0.7}Ga_{0.3}Sb$ which gives us the freedom of bandgap engineering with ternary AlGaSb (Al=1~0.7) where minimum mole fraction of Al required to make type I-straddling heterojunction is 0.7. Moreover it gives better hole blocking performance in valence band [13]. The first channel layer is InAs which will provide large conduction band offset, high peak electron velocity and high electron concentration in InAs channel [4]. This will be the formation with the deepest conduction band discontinuity at the heterojunction used in our analysis. For our second HEMT's channel layer, we selected the $Ga_{0.85}In_{0.15}Sb$. It gives a shallower conduction band offset and its growth on GaSb substrate is well studied [10]. The third structure has GaSb as channel layer. It gives the shallowest band-offset in the heterointerface among the chosen formations. In case of nitride-based DMG HEMT we followed the structure used in [8].Table II. gives the lists of various formations of DMG HEMTs used in our paper.

Table II. Formations of HEMT

Barrier layer	Channel layer	Substrate
$Al_{0.7}Ga_{0.3}Sb$	InAs	GaSb
$Al_{0.7}Ga_{0.3}Sb$	$Ga_{0.85}In_{0.15}Sb$	GaSb
$Al_{0.7}Ga_{0.3}Sb$	GaSb	GaSb
$Al_{0.2}Ga_{0.8}N$	GaN	GaN

While forming HEMT structures, it is important to consider the strain in the heterojunctions [4]. Too much strain in forming the heterostructure degrades the mobility and thus hampers the main objective of using HEMT. Table III gives a percentage of strain for the various HEMTs in this paper.

Table III. Percentage strain in different heterojunctions

Heterostructure	Percentage of strain
InAs/ GaSb	0.6173
$Ga_{0.85}In_{0.15}Sb$/ GaSb	0.9426
$Al_{0.7}Ga_{0.3}Sb$/ GaSb	0.4544
$Al_{0.2}Ga_{0.8}N$ /GaN	0.4829

III. RESULTS AND DISCUSSION

We have used ATLAS device simulator to simulate channel potential and electric field distribution along the channel to verify the model of [10]. Fig.2 shows electric field variation vs normalized channel length and the channel potential vs. normalized channel length for DMG $Al_{0.7}Ga_{0.3}Sb$/GaSb HEMT. Close match between proposed model in [10] and ATLAS's simulation is evident from the figure.

In fig.3 we have shown the effects of varying the gate length

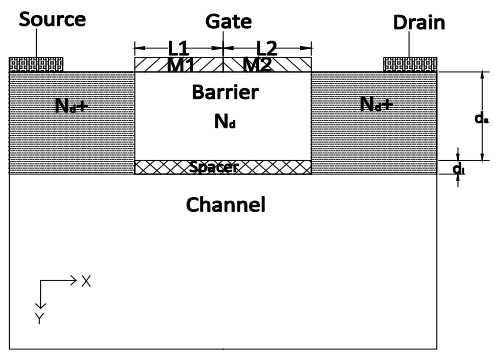

Fig.1: Cross sectional view of a DMG HEMT.

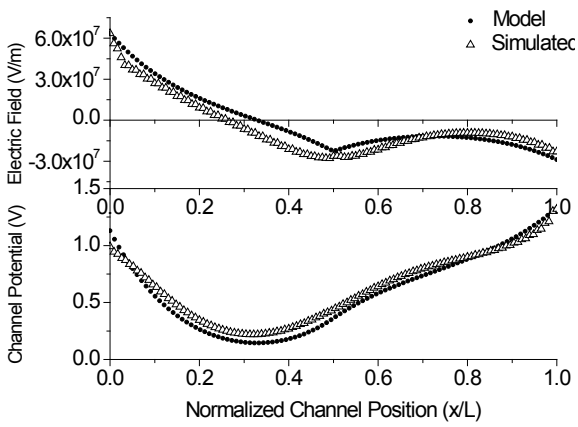

Fig.2: variation of channel potential and electric field vs the normalized channel length

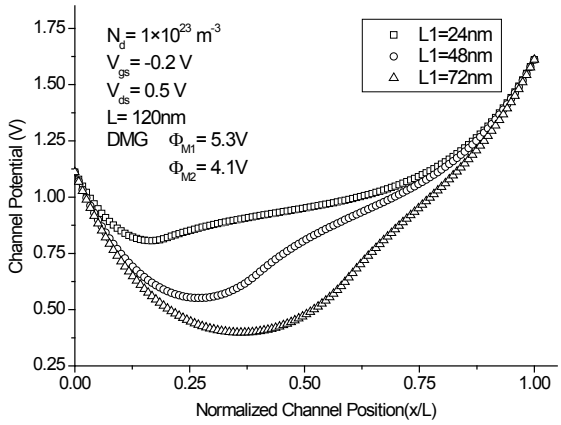

Fig.3: variation of channel potential with normalized channel position for different combinations of gate length L1 and L2, keeping the L constant for $Al_{0.2}Ga_{0.8}N$ /GaN DMG HEMT.

of first metal gate (L1) keeping the total gate length L constant. As we can see in the figure, the minimum potential (φ_{limin}) increases as the L1 decreases. It reduces the potential barrier and thus enhances the drive current (I_{on}). Moreover it increases the control of gate over the channel potential [14]. In table IV we have listed the change in φ_{limin} with change in L1 for various formations of HEMTs.

Table IV. Change in φ_{limin} for change in L1

HEMT composition	Change in φ_{limin}(volt) for change in L1 between 24-48 nm	Change in φ_{limin}(volt) for change in L1 between 48-72 nm
$Al_{0.2}Ga_{0.8}N$ /GaN	0.2548	0.1537
$Al_{0.7}Ga_{0.3}Sb$ /InAs	0.4279	0.2756
$Al_{0.7}Ga_{0.3}Sb$ /$Ga_{0.85}In_{0.15}Sb$	0.3668	0.2469
$Al_{0.7}Ga_{0.3}Sb$ /GaSb	0.3546	0.2197

From the table IV we see that the change of φ_{limin} in range (24-48) nm is always greater than the change in the range (48-72) nm. So while designing DMG HEMT L1 should be as small as possible with available fabrication process. From the data in the table IV it is evident that for nitride-based DMG HEMT the change of φ_{limin} is smaller compared to various antimonide-based DMG HEMT. It reveals that nitride-based DMG HEMTs are less dependent on process variation when comes to fabricate DMG structure. Among the antimonide-based DMG HEMTs, the $Al_{0.7}Ga_{0.3}Sb$ /InAs formation has the highest change in minimum-potential φ_{limin} for the change in control gate length, while the $Al_{0.7}Ga_{0.3}Sb$ /GaSb formation has the lowest. The deep conduction band discontinuity at the heterojunction produces more 2-D electron gas for $Al_{0.7}Ga_{0.3}Sb$/InAs enabling sharp change in potential barrier with the structural variation.

In fig. 4 we can see the effect of varying the barrier layer thickness (d) on DMG HEMT. We can see that as the barrier layer decreases the φ_{limin} increases. So reduction of barrier layer thickness reduces the channel potential barrier. It increases the drive current. It also ensures better gate control and improved carrier transport efficiency [15]. Table V lists the rate of change in φ_{limin} for change in barrier layer thickness (d). From the table we can see that rate of change in nitride-based DMG HEMT is higher compared to antimonide-based DMG HEMTs. It is because barrier layer $Al_{0.2}Ga_{0.8}N$ has lower dielectric constant compared to $Al_{0.7}Ga_{0.3}Sb$. As a result charge concentration is thinner and control of gate over the charge is larger. On the other hand the charge concentration in deep conduction band discontinuity at the heterojunction of $Al_{0.7}Ga_{0.3}Sb$/InAs is largest among the proposed concentration. As a result the control of gate is smaller. So change in thickness of barrier layer does not produce as strong effect as in the shallow heterojunction $Al_{0.7}Ga_{0.3}Sb$ /GaSb formations where concentration of carriers is comparatively thinner.

Table V. rate of change in φ_{limin} for change in barrier thickness (d)

HEMT composition	Rate of change in φ_{limin}(volt/nm)
$Al_{0.2}Ga_{0.8}N$ /GaN	0.04364
$Al_{0.7}Ga_{0.3}Sb$ /InAs	0.021920
$Al_{0.7}Ga_{0.3}Sb$ /$Ga_{0.85}In_{0.15}Sb$	0.02622
$Al_{0.7}Ga_{0.3}Sb$ /GaSb	0.034

In fig. 5 we see the effects of changing the workfunction

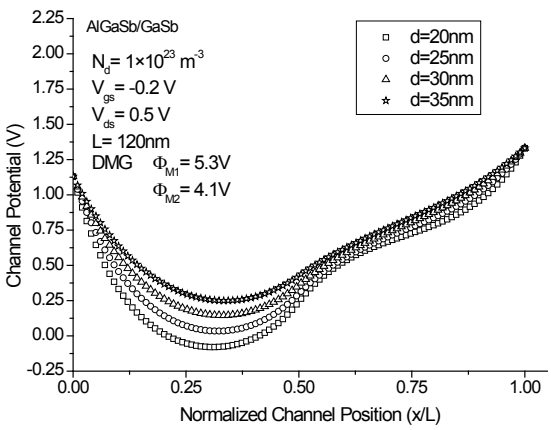

Fig.4: variation of the channel potential with the normalized channel position for different values of barrier layer thickness for $Al_{0.7}Ga_{0.3}Sb$/GaSb DMG HEMT.

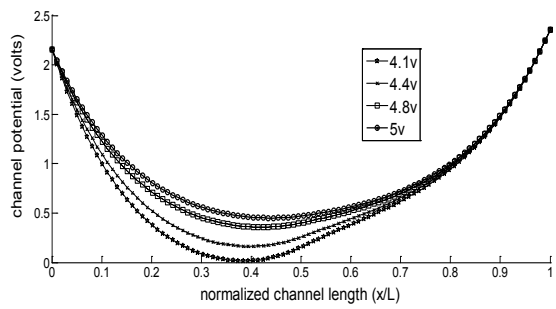

Fig.5: variation of channel potential with normalized channel position for DMG $Al_{0.7}Ga_{0.3}Sb$ /$Ga_{0.85}In_{0.15}Sb$ HEMT for different workfunction difference in between the gate metals.

difference between the two metal of the gate. The workfunction of the M1 (φ_1=5.3 V) is kept fixed, while M2 (φ_2=4.1, 4.4, 4.8, 5 V) is varied to vary the workfunction difference between two metal of the gate. As the workfunction difference increases, the φ_{limin} decreases. This means lower drive current. But it reduces the short channel effects and improves carrier transport efficiency [8, 10]. As a result, the overall (I_{on}/I_{off}) improves. In table VI the rate of change in φ_{limin} for change in workfunction difference of different formations of DMG HEMTs are listed.

Table VI. Rate of change in φ_{limin} for change in workfunction difference

HEMT composition	Rate of change in φ_{limin}(volt/volt)
$Al_{0.2}Ga_{0.8}N$ /GaN	0.0152
$Al_{0.7}Ga_{0.3}Sb$ /InAs	0.4803
$Al_{0.7}Ga_{0.3}Sb$ /$Ga_{0.85}In_{0.15}Sb$	0.554
$Al_{0.7}Ga_{0.3}Sb$ /GaSb	0.5754

From the table VI we can see that rate of change of φ_{limin} is lower in nitride-based HEMTs while higher in antimonide-based HEMTs. DMG structure is all about the difference in workfunctions between two metals of the gate. So DMG structure is more effective in antimonide-based HEMTs compared to their nitride-based counterpart. Among the antimonide-based DMG formations the swallow heterojunction $Al_{0.7}Ga_{0.3}Sb$ /GaSb gives the highest rate of change of φ_{limin} and thus more effective than deep heterojunction formations of $Al_{0.7}Ga_{0.3}Sb$ /InAs. This conclusion was also made in our previous paper [15] comparing other set of characteristics of DMG HEMT.

IV. Conclusions

To solve the problem of short channel effect and carrier transport inefficiency of the submicrometer range HEMTs, a new structure called double material gate (DMG) was proposed. But with the advent of fabrication technology, even the submicron range HEMT has become a field of active research. Thus it is extremely necessary to investigate the effect of variation of physical parameters on DMG HEMT. In this paper we varied three key physical parameters of DMG HEMT namely control gate length (L1), barrier layer thickness (d) and workfunction difference between two gate materials. We have used four different formations of DMG HEMT and compared the results to determine the effects. We have seen that nitride-based DMG HEMTs are less sensitive to the variation of control-gate length compared to antimonide-based DMG HEMTs. We have also seen that as the conduction band discontinuity at the heterojunction increases, the effect of control-gate length change also increases due to increase in 2-D electron gas. It was observed that the effect of changing barrier layer is more prominent in nitride-based DMG HEMT due to its low dielectric constant of the barrier layer. In case of varying the workfunction difference between two gate metals, we observed that increase in the workfunction difference has more prominent effect on antimonide-based HEMTs than nitride-based HEMT which proves that antimonide-based HEMTs will react more strongly to double material gate (DMG) structure. Also the effect of workfunction difference increases as conduction band discontinuity at the heterojunction between barrier and channel layer reduces. Thus DMG structure is more effective in the shallow heterojunction formations like $Al_{0.7}Ga_{0.3}Sb$/GaSb compared to deep heterojunction formations of $Al_{0.7}Ga_{0.3}Sb$ /InAs. We only considered semi-classical model in this work. An improved version of this work can be produced using Quantum Electrodynamics Model.

Acknowledgment

We would like to take this opportunity to thank Mr. Tonmoy Kumar Bhowmick for for his useful advices. This work was supported under BUET grant no. CASR#218, agenda 97, meeting held on 06/09/2009.

***Abstract*—For a Gaussian doped graded base *AlGaAs* Hetero -junction Bipolar Transistor (HBT), base transit time (BTT) has been determined using a suitable analytical model. Here the authors have investigated the dependency of base transit time on different physical and input parameters such as the collector current density, base emitter voltage etc. Electric field dependent carrier mobility also has been included into the analytic model and found that the base transit time worsens compared to the value found without taken the field dependent mobility into account.**

***Keywords*—Base transit time of AlGaAs HBT; Graded base; Gaussian doping; Field dependent mobility.**

I. Introduction

In this work, $AlGaAs$ has been chosen for its higher speed compared to SiGe HBT under normal operating condition. $SiGe$ HBTs had been introduced as the technology of choice for RF integrated circuits due to its high speed performance and mature silicon process [1]. This technology is also being used to develop electronics for space applications because of its excellent analog and radio frequency (RF) performance over an extremely wide range of temperatures [2]. On the other hand, $AlGaAs$ HBT process technology is reported to be used in the fabrication of large number of complex analog integrated circuits for commercial and military applications [3].

The transit time of a junction transistor has three components: emitter transit time, base transit time and collector transit time. Since the base transit time contributes to more than 70% of the junction transistor's total transit time [4], its speed is mainly determined by the factors which affects the base transit time of the device. The base transit time of a heterojunction bipolar transistor is influenced by many physical and electrical parameters and various other factors. These factors include base width, doping concentration profiles in the base region (uniform, exponential, Gaussian), various alloy material profiles in the base region (box, triangular, trapezoidal), velocity saturation effect, collector current density, electric field and doping dependent carrier mobility, bandgap narrowing and base resistance. In this paper the authors have investigated trend of some physical parameter, the effect of some of these parameters on the base transit time of an $AlGaAs$ HBT.

II. Basis of Analysis

For a trapezoidal Al profile inside the *npn* base of an $Al_yGa_{1-y}As$ HBT, the mole fraction y will be $m_{Al}x + y_E$ where, W_B is the base width, x is the distance of a point in the base from the base side of the *B-E* junction, $m_{Al} = (y_C - y_E)/W_B$; y_C and y_E are Al fraction at the collector and emitter end respectively. For y_E=0, and y_E=y_C, the profile becomes triangular and box shape respectively [5]. Total Al content within the base is called Al dose and can be calculated as $y_D = y_{av}W_B$ [6], where, $y_{av} = (y_C + y_E)/2$. The base transit time of an arbitrary HBT can be expressed as [7]

$$\tau_B = q\int_0^{W_B} \frac{n(x)}{J_n(x)}dx \tag{1}$$

where, $n(x)$ is the minority carrier concentration and $J_n(x)$ is the electron current density within the base, q is the charge of an electron. For the base region, $n(x)$ can be determined from the transport equations (for electron & hole) and electric field equation [8]. As the base width of today's high-speed HBT is even less than 30nm [6], so the carrier recombination in the base region can safely be neglected, resulting in J_p (hole current density) approximately zero and eventually J_n equals to J_c (collector current density). Using Einstein's relation $D_n(x) = V_T\mu_n(x)$, the current density becomes

$$-J_n = qD_n(x)\frac{n_{ie}^2(x)}{n(x)+N_B(x)}\frac{d}{dx}\left[\frac{n(x)\{n(x)+N_B(x)\}}{n_{ie}^2(x)}\right] \tag{2}$$

where, $D_n(x)$ and $\mu_n(x)$ are the electron diffusivity and mobility respectively, $n_{ie}(x)$ is the effective intrinsic carrier concentration. $N_B(x) = N_B(0)\exp(-mx^2)$ is the base doping concentration assumed to follow Gaussian distribution [9], $N_B(0)$ is the peak base doping concentration; $m = \frac{1}{2\sigma^2}$ and $\sigma = W_B/\sqrt{2\ln\frac{N_B(0)}{N_B(W_B)}}$. Under low electric field, the doping density dependent diffusivity in $GaAs$ can be written in the light of [10] as $D_{nGaAs}(x) = D_n\exp(m_1x^2)$, where, $D_{nl} = D_{n0}(N_B(0)/N_r)^{-\gamma_1}$; $D_{n0} = 207\ cm^2/s$[11]; $m_1 = m\gamma_1$; $\gamma_1 = 0.42$ and $N_r = 10^{17}cm^{-3}$. In presence of Al, the electron diffusivity is assumed to be changed following [12] as $D_{nAlGaAs}(x) = bD_{nGaAs}(x)$, where, $b = 1 + 3y_{av}$. The saturation velocity inside the $AlGaAs$ alloy also will differ from that in $GaAs$ and can be written in the light of [13] as $v_{sA} = cv_s$, where, $c = 0.342/[0.342 + y_{av}(1 + y_{av})]$; and $v_s = 7\times10^6\ cm/s$[14].

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

The effective intrinsic concentration in $AlGaAs$ in the light of [12] is $n_{ieAlGaAs}^2(x) = n_{ioGaAs}^2 \gamma_r e^{\frac{\Delta E_{geff}(x)}{kT}}$, where γ_r is the ratio of the effective DOS in $AlGaAs$ base to the effective DOS in $GaAs$ and can be written as $\gamma_r = \exp(-\sqrt{5y_{av}})$ [15], [16]. $n_{ioGaAs} = 2.1 \times 10^6 cm^{-3}$, is the intrinsic carrier concentration in undoped $GaAs$ [14]; k is the Boltzmann constant; T is the temperature in degrees Kelvin; $E_{geff}(x)$ is the effective bandgap reduction in the $GaAs$ base that can be expressed as $E_{geff}(x) = \Delta E_{gHD}(x) + \Delta E_{gAl}(x)$, where $\Delta E_{gAl}(x)$ is the BGN due to the presence of Al which is assumed to have a linear dependency on mole fraction; $\Delta E_{gHD}(x)$ is the BGN due to heavy doping effects and is identical to that of $GaAs$ [15]. An approximation of the Slotboom–de Graff BGN model [17] is used for this term [18] resulting $\Delta E_{gHD}(x) = qV_{gHD} \ln\left(\frac{N_B(x)}{N_r}\right)$, with, V_{gHD}= 0.0229V and the BGN due to the presence of Al can be written as [19] $\Delta E_{gAl}(x) = qV_{gAl}y(x)$, with, V_{gAl}= 10E-10V. Finally, the effective intrinsic concentration in $AlGaAs$ can be expressed as

$$n_{ieAlGaAs}^2(x) = n_{ieAlGaAs}^2(0)\exp\,(m_3x - m_2x^2) \quad (3)$$

where, $n_{ieAlGaAs}^2(0) = n_{ioSi}^2\, \gamma_r \exp\,(\gamma_3 y_E) \left(\frac{N_B(0)}{N_r}\right)^{\gamma_2}$;$\gamma_2 = V_{gHD}/V_T$; $\gamma_3 = V_{gAl}/V_T$; $V_T = kT/q$; $m_2 = m\gamma_2$; $m_3 = m_{Al}\gamma_3$. Under low level of injection, $n(x) \ll N_B(x)$ and the quasi-neutral condition in base becomes $p(x) = N_B(x)$ [20]. Putting this condition, the electric field equation for low injection becomes $E_{lAlGaAs}(x) = -V_T(m_3 + m_4x)$, where $m_4 = 2(m - m_2)$. Using the equations for $n_{ieAlGaAs}^2(x)$, $N_B(x)$ and $D_{nAlGaAs}(x)$, differential equation (2) for minority carrier concentration $n_l(x)$ can be solved for $n_l(x)$ as [21]

$$n_l(x) = exp\left(m_4\frac{x^2}{2} + m_3x\right)\left(n_l(0) - J_{nl}(B_1(x) + B_2(x) + B_3(x))\right) \quad (4)$$

At $x = 0$ (E-B boundary), electron concentration can be found by using [22] with necessary correction for $AlGaAs$ as-

$$n_l(0) = \frac{n_{ieAlGaAs}^2(0)}{N_B(0)} e^{\frac{V_{be}}{V_T}} \times f_w \quad (5)$$

$$\text{where, } f_w = \frac{1}{0.5 + \sqrt{0.25 + \frac{n_{ieAlGaAs}^2(0)}{N_B(0)} e^{\frac{V_{be}}{V_T}}}} \quad (5a)$$

Usage of this initial condition ensures the inclusion of Webster effect [23]. Putting $x = W_B$ in (4), the electron concentration at B-C boundary becomes

$$n_l(W_B) = \frac{n_l(0)exp\left(m_4\frac{W_B^2}{2} + m_3W_B\right)}{1 + qv_{sA}exp\left(m_4\frac{W_B^2}{2} + m_3W_B\right)(B_1(W_B) + B_2(W_B) + B_3(W_B))} \quad (6)$$

Assuming velocity saturation at the B-C depletion region, the low injection electron current density at $x = W_B$ will be $J_{nl} = qv_{sA}n_l(W_B)$, the base stored charge per unit area $Q_{Bnl} = q\int_0^{W_B} n_l\,(x)dx$, and the base transit time $\tau_{Bl} = \frac{Q_{Bnl}}{J_{nl}}$.

This value of low injection can be extended to incorporate moderate level of injection with slight modification using perturbation theory. The modified carrier concentration and current density for moderate injection are then, $n_m(x) = f_W n_l(x)$ and $J_{nm} = f_W J_{nl}$ respectively. Assuming that the injected electron concentration is perturbed by the modulated electric field from $n_m(x)$ only a little and also using quasi-neutrality of charge equation, minority electron concentration for moderate injection will be $n(x) = n_m(x) + \delta n(x)$ and hole concentration $p(x) = n(x) + N_B(x)$ becomes-

$$p(x) = p_m(x) + \delta n(x) \quad (7)$$

Now, (2) can be re-solved to find $n(x)$ for moderate injection, [9]

$$n(x) = \frac{\exp\,(m_3x - m_2x^2)}{p_m(x)}\left(n(0)p_m(0) + \frac{J_n}{qv_{sA}}N(x)\right) \quad (8)$$

where, $N(x) = \frac{a}{b}N_1(x) - \frac{v_{sA}}{bD_n}N_2(x)$; $N_1(x) = n_m(0)\{\exp(mx^2) - 1\} - J_{nm}\{B(x)\exp(mx^2) - B(0)\} + N_B(0)\left\{exp\left(-\frac{m_4}{2}x^2 - m_3x\right) - 1\right\}$; $N_2(x) = n_m(0)\{E_1(x) - E_1(0)\} - J_{nm}\{E_2(x) - E_2(0)\} + N_B(0)\{E_3(x) - E_3(0)\}$.

Boundary value of injected minority carrier at the collector edge, $n(W_B)$ can be found by putting $x = W_B$ in equation (8), and hence J_n for moderate injection can be calculated. To estimate base transit time, equation (1) has been utilized.

III. Result

To demonstrate the dependency of base transit time on various physical and input parameters, some typical relations are plotted in this section of the paper. Normalized injected electron concentration depends on the slope of base doping and is illustrated in Fig. 1. As the value of $N_B(W_B)$ increases, slope of base doping decreases. With the increase in slope of the base doping, $n(x)/n(0)$ decreases more sharply. The injected electron concentration profiles shown in Fig. 1 is not linear due to the built in electric field caused by the Gaussian base doping and the gradient in Al profile. It is also found that the minority carrier has maximum value at the base-emitter junction and minimum value at the collector-base junction. It decreases from its peak value as the distance from the emitter increases. At the collector-base junction the structure having the highest slope of base doping has the maximum normalized carrier concentration. In this work velocity saturation of electron at the collector-base junction is considered. So at collector-base junction, the minority carrier concentrations for low and high levels of injection are not zero.

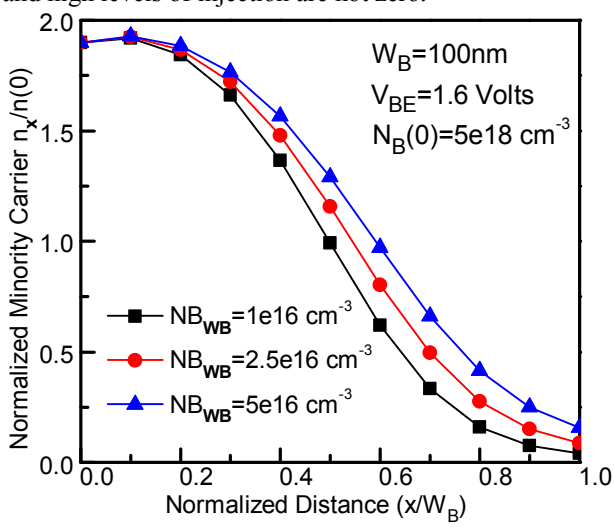

Fig. 1 Normalized minority carrier electron distribution within the base for different slopes of base doping with trapezoidal Al profile $y_C = 0.25$, $y_E = 0.1$.

The variation of collector current density J_C with base-emitter voltage V_{be} for three different shapes of Al profiles is

shown in Fig. 2 for low injection. Changing the value of y_E, triangular, trapezoidal or box Al profile effects are incorporated. J_C increases with V_{be} maintaining a constant logarithmic slope; with the increase in V_{be}, the slope of the curve decreases. Collector current density for J_C triangular shape Al profile is higher than that of box profile and for trapezoidal profile it remains in the middle. This is expected as the injected electron concentration at the collector base boundary ($n(W_B)$) is the highest for triangular Al profile and higher $n(W_B)$ contributes to higher J_C, which agrees with [24].

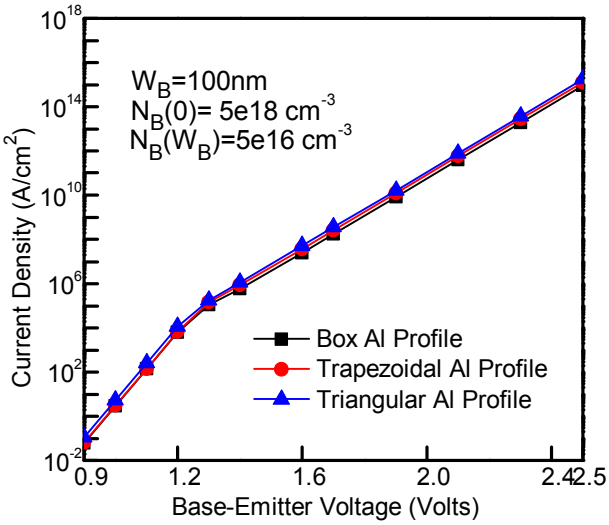

Fig. 2 Collector current densities for different shape of Al profiles (Box: $y_C = 0.25, y_E = 0.2499$, Trapezoidal: $y_C = 0.25, y_E = 0.1$, Triangular: $y_C = 0.25, y_E = 0.01$) as a function of base-emitter voltage.

The variation of base transit time with base-emitter voltage for various Al profiles is shown in Fig. 3. It is observed that for both low and moderate levels of injection the base transit time is independent of base-emitter voltage but the value of base transit time is larger for moderate injection region than that of low injection region. This is due to reduction of aiding field in the Gaussian doped base when the level of injection increases. For reduction in aiding field, electrons slow down and hence transit time increases. As V_{be} increases, base transit time increases in the intermediate level of injection.

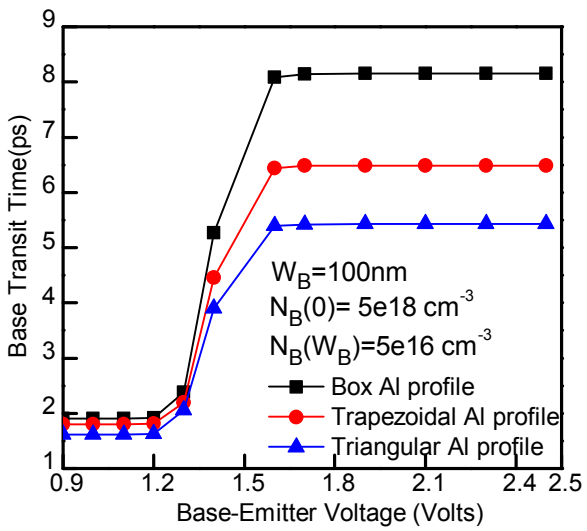

Fig. 3 Base transit time as a function of base-emitter voltage for different shape of Al profiles (Box: $y_C = 0.25, y_E = 0.2499$, Trapezoidal: $y_C = 0.25, y_E = 0.1$, Triangular: $y_C = 0.25,\ y_E = 0.01$).

From Fig. 3, it also can be observed that box shape Al profile takes the highest time to pass the electron to the collector, triangular Al profile takes the lowest time and the trapezoidal Al profile takes in-between time. This happens because the transport of electron through the base is assisted by the gradient in mole fraction profiles [25], which is highest for triangular profile, zero for box profile and in-between for trapezoidal profile. So for triangular Al profile, electron passes slower through the base to enter the collector.

One of the main objectives of this paper is to obtain base transit time of a Gaussian doped base $Al_yGa_{1-y}As$ HBT considering electric field dependence of carrier mobility in excess to doping dependent mobility. The effect of electric field dependence of mobility on base transit time was investigated and the result is shown in Fig. 4. The transit time is found to be higher if the field dependence of mobility is considered. This is because minority carrier mobility is inversely related to the absolute value of electric field [20]. With the increase in electric field, minority carrier mobility in the base region decreases. So, with the increases in electric field, it decreases the minority carrier transportation through the base region and hence contributes to the increase in base transit time.

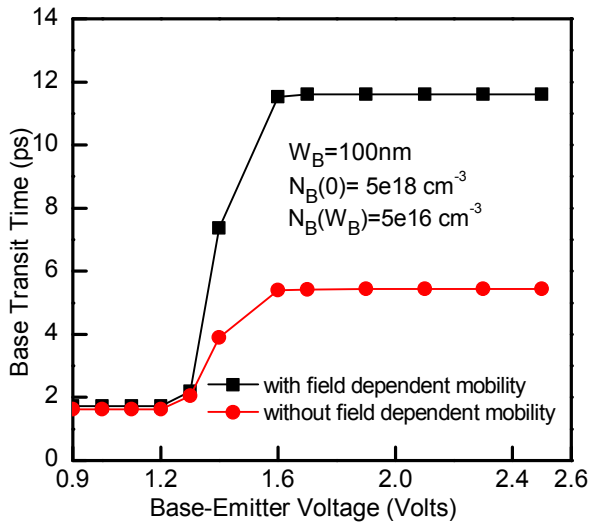

Fig. 4 Base transit time as a function of base-emitter voltage with and without field dependent electron mobility considering triangular Al profile ($y_C = 0.25, y_E = 0.01$).

The variation of base transit time (τ_B) with collector current density for different Al profiles is shown in Fig. 5. From this figure, it is understandable that base transit time is independent of collector current density for both low and moderately high level of injection but the value of base transit time is higher for high injection region than the base transit time for low injection region. This is due to the reduction of aiding electric field in the Gaussian doped base when the level of injection increases. Due to this effect, electron slow down and transit time increases. In the intermediate level of injection, base transit time increases as J_C increases. From the Fig.5, it is also perceptible that box shape Al profile takes higher transit time than triangular Al profile to pass the electron to the collector and the trapezoidal Al profile takes in-between time. This happens due to the difference in gradients of Al profiles. Fig. 5 follows Fig. 3 ($\tau_B\ vs. V_{be}$) as collector current is a logarithmic function of V_{be} (Fig. 2).

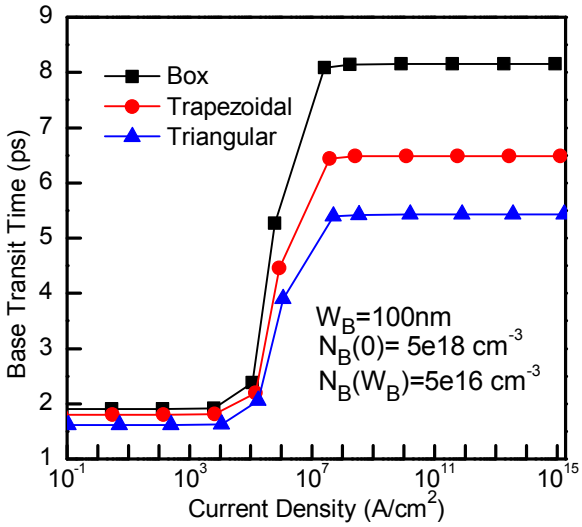

Fig. 5. Base transit time as a function of collector current density for different shape of Al profiles (Box: $y_C = 0.25, y_E = 0.2499$, Trapezoidal: $y_C = 0.25, y_E = 0.1$, Triangular: $y_C = 0.25, y_E = 0.01$).

IV. Conclusion

How the base-emitter voltage, collector current density, and electric field dependent mobility influence the base transit time of a $AlGaAs$ HBT with Gaussian doped base has been investigated for all types (box, trapezoidal and triangular) of Al profiles ranging from low level of injection to moderately high level of injection. It is found that the transit time decreases as the profiles change from box to triangular types. It is also observed that collector current density shows an increasing trend with raising base emitter voltage for similar trend of profile change as previous. If electric field dependent mobility is taken into account, the model gives higher transit time as predicted.

Abstract— **A compact analytical model of minority carrier concentration is presented for an exponentially-doped quasi-neutral region of Silicon solar cell. It is an iteration-free and integral-free mathematical expression that addresses the non-uniformity in doping and contribution from terrestrial solar spectrum. Due to the position dependency of transport parameters, the differential equation becomes intractable. The proposed model incorporates an elegant approximated carrier generation rate to overcome the problem and presents a new solution for minority carrier concentration by using the modified Bessel function and Hypergeometric function. The compact analytical solution is in good agreement with COMSOL drift-diffusion model and TCAD device simulator for a wide variation of doping and surface recombination velocity.**

Index Terms— **Analytical model, Exponentially doped emitter, Approximated generation rate, Compact solution.**

I. Introduction

An extensive study of minority carrier profile is essential for successful understanding of the performance and efficiency of a solar cell under illumination [1]. An obvious step in modelling solar cell is to analyse the transport phenomena of minority carrier as a function of doping profile and surface recombination velocity. The difficulty in developing analytical model for non-uniformly doped solar cell arises from the fact that the minority carrier transport parameters become dependent on position. Incorporation of these non-linear dependencies in the continuity equation and the minority carrier current equation makes the differential equation complicated. Hence, numerical analysis has become a common approach for describing the behaviour of minority carriers in solar cells. Although numerical model of solar cell, TCAD-based models [2, 3] and efficient computer codes like PC-1D, AMPS [4] can address the photovoltaic physics reliably, a complete analytical model helps to gain insight into the physics. Unlike numerical simulation, the mathematical analysis offers an excellent way to study the effects from specific contributions, which can be invaluable in computer aided design and device optimization. Besides, the analytical modelling has added advantages of faster calculation time and no convergence issues.

Under dark condition (no sunlight), several authors [5, 6] have analytically solved the minority carrier transport, taking into account the position dependencies. Verhoef *et al.* [5] has developed a closed-form expression for minority carrier transport by proposing new empirical expression of carrier mobility and lifetime; but the expression is developed excluding the carrier generation rate, rather focusing only on the dark saturation current. Analytical approach for illuminated solar cell also exists in literature [7-10], but these works contain multiple integral asymptotic series, which are not in closed-form and only accurate after certain number of iterations [11]. In this work, an analytical model is presented, which does not need any iteration or numerical integration. For developing this compact model, the carrier generation rate from solar excitation will be approximated by position-dependent exponential terms [12]. Along with that, the effects of doping-dependent lifetime and mobility are included in the transport equations by using the existing empirical equations [5]. To validate the developed analytical solution, a drift-diffusion based Finite Element Model (FEM) is implemented in COMSOL multi-physics. Besides, this work is compared with a 2-D numerical solar cell model created in Silvaco/Atlas device simulator, which incorporates Auger recombination, concentration-dependent Shockley-Read-Hall recombination and doping-dependent mobility.

II. General Solution for Minority Carrier Density

An exponentially doped n-type emitter region for an n(x)-p silicon solar cell, as shown in Fig. 1, is considered for analysis. This drift-field (DF) solar cell structure will be used to establish this model. Unlike previous works in [1, 7], this work will avoid any iterative or numerical scheme. The main focus of this work is to develop the analytical model for certain doping profile using advance mathematical functions, but the solution will be in a closed-form expression of position and spectrum. Contrary to existing literature, both lifetime and mobility variation with external excitation from solar illumination will be included, resulting in an all-in-one compact model. Since all transport parameters are functions of depth [9, 10], the analysis is considered for one dimension only. Besides, the minority carrier continuity and current equations are solved considering the quasi-neutrality and low-injection condition.

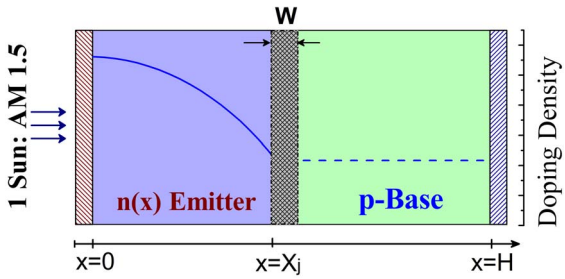

Fig. 1 A DF (Drift Field) solar cell structure

In steady state, the transport equations for excess minority carriers in the n-type emitter region are expressed by (1)-(2),

$$J_p(x) = J_{\text{Diffusion}}(x) + J_{\text{Drift}}(x) = -qD_p \frac{dp}{dx} + q\mu pE \quad (1)$$

$$\frac{dJ_p}{dx} = -q\frac{p}{\tau_p} + qG \quad (2)$$

Here, J_P denotes hole-current density, τ_P is the minority carrier recombination lifetime, μ is carrier mobility, D_P is hole diffusivity, p is the minority carrier (Hole) density and E is the electric field introduced due to non-uniform doping in emitter. Another important parameter is carrier generation rate (G), which is the result of exposed solar illumination. Generation rate is a function of depth into the material (x) and wavelength (λ) of incident solar spectrum. G(x) is generally considered as a sum of individual contributions over the whole solar spectrum, but it can be well approximated by a series of three to five exponential terms [13]. The approximated generation rate of minority carrier can be expressed by,

$$G(x) = \sum_{i=1}^{n} a_i e^{-b_i x} \tag{3}$$

The accuracy and validity of this approximation is already established in literature [12, 13] for different photovoltaic materials and different solar spectrums. For this model, standard terrestrial spectrum AM1.5G will be considered. The values of a_i and b_i recalculated for this work are mentioned in fig. 2. As seen in fig. 2, the approximated G(x) has good match with Silvaco/Atlas TCAD model.

Since the emitter is non-uniformly doped, lifetime (τ) and mobility (μ) is a function of doping (and hence, depth). The dependence of τ and μ on doping N is accounted by the following empirical relations [5] –

$$\mu(N) = MN^{-m} \tag{4}$$

$$\tau(N) = KN^{-k} \tag{5}$$

The above empirical equations predict the Experimental data [14] as a function of N quite well: k=1, K=1.3x10^{12} cm^{-3}/s for $10^{15}<N<10^{18}$ cm^{-3} and k=2, K=5.5x10^{30}cm^{-6}/s for $5\times10^{18} \le N<10^{20}$ cm^{-3}. This form of expression is common in literature. The model here uses these general parameters K, k, M and m to address the position dependency of mobility and lifetime in the final solution. Hence, the same model can be used to analyse a wide range of photovoltaic materials if the parameters are tailored appropriately for other doping profile and material properties.

The electric field associated with the exponential doping is taken into account by equation (6) for quasi-neutrality condition. The effect from doping gradient is included in the first term, but the band gap narrowing is ignored, i.e. $\Delta E_G \cong 0$.

$$E = -V_T \frac{d\ln N}{dx} + \frac{1}{q}\frac{d\Delta E_G}{dx} \tag{6}$$

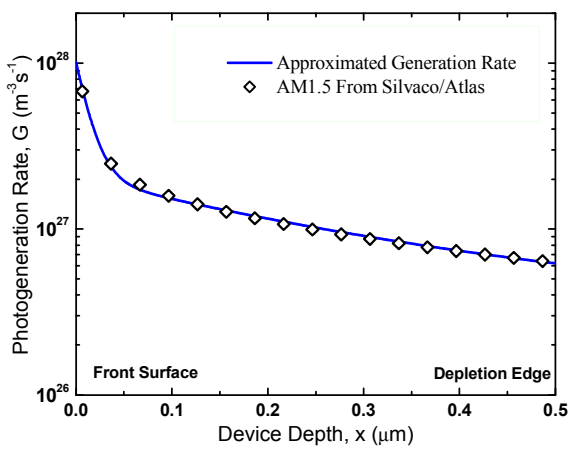

Fig. 2 Carrier generation rate (AM1.5G) along the depth. Solid line represents the approximated carrier generation in (3). Generation parameters – a_i ($\times10^{20}$ s^{-1}cm^{-3}): 78.1, 15, 4.8, 0.8, and 0.0011; b_i ($\times10^4$ cm^{-1}): 75.44, 4.19, 0.6, 0.052 and 0.0015; Symbol represents data from TCAD Device simulator.

When the emitter region is fabricated by implantation followed by a drive-in anneal, the doping profile follows an exponential dependence with depth. We are considering such an exponential doping in equation (7).

$$N(x) = N_{d0} e^{-\alpha x} \tag{7}$$

The peak doping concentration (N_{d0}) and exponential decay (α) are positive quantities. As mentioned, the lifetime and mobility will also vary according to equation (4)-(5). Both lifetime and mobility decrease along x and unlike previous analytical models, the variation of G(x) (fig. 2), N(x), μ(x), τ(x) will be considered together for developing a compact expression.

By placing equation (3)-(6) into equation (1)-(2) and after some mathematical manipulations, the minority carrier hole concentration p(x) can be expressed in terms of N.

$$\frac{d^2p}{dx^2} - (m-1)\frac{dp}{dx}\frac{d\ln N}{dx} - \left[m\left(\frac{d\ln N}{dx}\right)^2 - \frac{d^2\ln x}{dx^2} + \frac{N^{m+k}}{KMV_T}\right]p = -\left(\frac{N^m}{MV_T}\right)\sum_{i=1}^{5} a_i e^{-b_i x} \tag{8}$$

Equation (8) is a second-order non-homogeneous differential equation. By inserting N(x) from (7) into (8), the differential equation can be expressed as a function of device depth, x.

$$\frac{d^2p}{dx^2} + \alpha(m-1)\frac{dp}{dx} - \left[m\alpha^2 + \frac{N_{d0}{}^{m+k} e^{-\alpha(m+k)x}}{KMV_T}\right]p = -\left(\frac{N_{d0}{}^{m} e^{-\alpha m x}}{MV_T}\right)\sum_{i=1}^{5} a_i e^{-b_i x} \tag{9}$$

Substituting $z = \exp\left[-\alpha(m+k)x/2\right]$ will result in (10).

$$z^2\frac{d^2p}{dz^2} + (1-2A)z\frac{dp}{dz} - \left(\beta^2 z^2 + \kappa^2\right)p = -\sum_{i=1}^{5} C_i z^{D_i} \tag{10}$$

Here,

$$A = \left(\frac{m-1}{m+k}\right),\quad \beta = \frac{2}{\alpha(m+k)}\sqrt{\frac{N_{d0}{}^{m+k}}{KMV_T}},\quad \kappa = \left(\frac{2\sqrt{m}}{m+k}\right)$$

$$C_i = \frac{4N_{d0}{}^{m}}{MV_T\alpha^2(m+k)^2}a_i,\qquad D_i = \frac{2(b_i+\alpha m)}{\alpha(m+k)} \tag{11}$$

Finally introducing $p(z) = z^A u(z)$, equation (10) can be reduced to a non-homogeneous Bessel equation of order ν.

$$z^2\frac{d^2u}{dz^2} + z\frac{du}{dz} - \left(\beta^2 z^2 + \nu^2\right)u = -\sum_{i=1}^{5} C_i z^{\gamma} \tag{12}$$

Here, $\nu = \sqrt{A^2+\kappa^2} = (m+1)/(m+k)$, which is a non-integer number and $\gamma = (D_i - A)$. The homogeneous solution of (12) can be easily obtained in terms of modified Bessel function of first kind.

$$u(z) = C_1 I_\nu(\beta z) + C_2 I_{-\nu}(\beta z)$$

To obtain the particular solution of u(z) considering the non-homogeneous term in the right side of equation (12), the variation of parameter technique [15] is employed. Eventually substituting $p(z) = z^A u(z)$ gives the desired minority carrier profile as a function of z.

$$p(z) = P_1(z)\,C_1 + P_2(z)\,C_2 + P_3(z) \tag{13}$$

With,

$$P_1(z) = z^A I_\nu(\beta z),\ P_2(z) = z^A I_{-\nu}(\beta z)$$

$$P_3(z) = -\sum_{i=1}^{5} \frac{E_i \pi}{2\sin(\pi\nu)} \times z^A$$

$$\left[I_\nu(\beta z) \frac{2^\nu (\beta z)^{\gamma-\nu}}{(\gamma-\nu)\Gamma(-\nu+1)} {}_1F_2\left(\frac{\gamma-\nu}{2}; -\nu+1, \frac{\gamma-\nu+2}{2}; \frac{\beta^2 z^2}{4}\right) \right.$$

$$\left. - I_{-\nu}(\beta z) \frac{2^{-\nu} (\beta z)^{\gamma+\nu}}{(\gamma+\nu)\Gamma(\nu+1)} {}_1F_2\left(\frac{\gamma+\nu}{2}; \nu+1, \frac{\gamma+\nu+2}{2}; \frac{\beta^2 z^2}{4}\right) \right]$$

Here, I_ν and $I_{-\nu}$ are the modified Bessel functions of the first kind and ${}_1F_2$ is the generalized Hypergeometric function. $\Gamma\nu$ denotes the Gamma function of ν. C_1 and C_2 are constants which will be determined by using proper boundary conditions.

III. Results & Analysis

To analyse and understand the proposed mathematical model, an emitter with exponentially doping profile is considered under AM1.5 solar spectrum. The emitter doping at the front surface (x=0) is higher (10^{20} cm^{-3}) and then gradually falls to 5×10^{18} cm^{-3} at the depletion edge ($x=x_j$). Due to the range and non-uniformity in doping, lifetime and mobility inside the quasi-neutral emitter will vary intensely along depth. Besides, the quasi-neutral region has doping gradient; hence, carrier transport here will be also dominated by drift component from induced Electric field E(x). The boundary conditions in emitter for the DF cell [5] (fig. 1) is,

$$p(x_j) = \frac{n_i^2}{N(x_j)} \exp\left(\frac{V}{V_T}\right) \tag{14}$$

$$\left[\mu(x) E p(x) - D_p(x) \frac{dp(x)}{dx} \right]_{x=0} = S\, p(0) \tag{15}$$

The boundary conditions can easily be modified for z domain. The 1st boundary condition is evaluated at $z_j = \exp\left[-\alpha(m+k)x_j/2\right]$. The 2nd boundary condition describes front-surface characteristics through surface recombination velocity (S). Equation (15) involves the derivatives of p(z), which means the derivatives of Bessel function and Hypergeometric function are to be calculated first. Using the identities of differentiating Bessel and Hypergeometric function, $dp(z)/dz$ can be obtained as follows,

$$\frac{dp(z)}{dz} = X_1(z)\, C_1 + X_2(z)\, C_2 + X_3(z) \tag{16}$$

Here, $X_1(z) = Az^{A-1} I_\nu(\beta z) + z^A \frac{\beta}{2}\left[I_{\nu-1}(\beta z) + I_{\nu+1}(\beta z)\right]$

$$X_2(z) = Az^{A-1} I_{-\nu}(\beta z) + z^A \frac{\beta}{2}\left[I_{-\nu-1}(\beta z) + I_{-\nu+1}(\beta z)\right]$$

$$X_3(z) = -\sum_{i=1}^{5} \frac{E_i \pi}{2\sin(\pi\nu)} \times \left[F_{+\nu}(z) - F_{-\nu}(z)\right]$$

$F_{\pm\nu}(z)$ is defined in (17) which strongly depends on transport constants (K, k, M, m) and generation coefficients (a_i, b_i).

$$F_{+\nu}(z) = \frac{2^\nu \beta^{\gamma-\nu} z^{\gamma-\nu+A}}{(\gamma-\nu)\Gamma(-\nu+1)} \times$$

$$\left[{}_1F_2\left(\frac{\gamma-\nu}{2}; -\nu+1, \frac{\gamma-\nu+2}{2}; \frac{\beta^2 z^2}{4}\right) \left\{ \beta I_{\nu+1}(\beta z) + \frac{\gamma+A}{z} I_\nu(\beta z) \right\} \right. \tag{17}$$

$$\left. + {}_1F_2\left(\frac{\gamma-\nu+2}{2}; -\nu+2, \frac{\gamma-\nu+4}{2}; \frac{\beta^2 z^2}{4}\right) \frac{\beta^2 z}{2} \frac{(\gamma-\nu)(-\nu+1)}{(\gamma-\nu+2)} I_\nu(\beta z) \right]$$

Replacing the derivative in (15) and after some rigorous mathematical operations, the following equation is obtained:

$$C_1 T_{21} + C_2 T_{22} = T_{23} \tag{18}$$

Where,

$$T_{21}(z) = \left[MN_{d0}^{-m} V_T \alpha z^{\left(\frac{-2m}{m+k}\right)} \left\{ P_1(z) + \left(\frac{m+k}{2}\right) z X_1(z) \right\} - SP_1(z) \right]$$

$$T_{22}(z) = \left[MN_{d0}^{-m} V_T \alpha z^{\left(\frac{-2m}{m+k}\right)} \left\{ P_2(z) + \left(\frac{m+k}{2}\right) z X_2(z) \right\} - SP_2(z) \right]$$

$$T_{23}(z) = \left[SP_3(z) - MN_{d0}^{-m} V_T \alpha z^{\left(\frac{-2m}{m+k}\right)} \left\{ P_3(z) + \left(\frac{m+k}{2}\right) z X_3(z) \right\} \right]$$

These simplified equations obtained from the boundary conditions give the coefficient C_1 & C_2. Replacing C_1 & C_2 back in equation (13) results in a complete analytical expression of Hole profile p(z) for non-uniformly doped emitter of DF solar cell.

$$p(z) = \overbrace{\left[\underbrace{\frac{\frac{n_i^2}{N_d(z_j)} \exp(V/V_T)}{P_1(z_j) - \frac{T_{21}(z_0)}{T_{22}(z_0)} P_2(z_j)}}_{\text{Contribution from Biasing}} + \underbrace{\frac{T_{23}(z_0) + \frac{T_{22}(z_0)}{P_2(z_j)} P_3(z_j)}{T_{21}(z_0) - \frac{T_{22}(z_0)}{P_2(z_j)} P_1(z_j)}}_{\text{Contribution from Spectrum}} \right]}^{C_1} z^A I_\nu(\beta z)$$

$$+ \overbrace{\left[\underbrace{\frac{\frac{n_i^2}{N_d(z_j)} \exp(V/V_T)}{P_2(z_j) - \frac{T_{22}(z_0)}{T_{21}(z_0)} P_1(z_j)}}_{\text{Contribution from Biasing}} + \underbrace{\frac{P_1(z_j)\frac{T_{23}(z_0)}{T_{21}(z_0)} + P_3(z_j)}{\frac{T_{22}(z_0)}{T_{21}(z_0)} P_1(z_j) - P_2(z_j)}}_{\text{Contribution from Spectrum}} \right]}^{C_2} z^A I_{-\nu}(\beta z) \tag{19}$$

$$+ \underbrace{P_3(z)}_{\text{Illumination term}}$$

As seen from the compact expression above, the contribution from biasing, variable doping, surface states, dark component and spectrum response can be identified and separately analysed for optimizing cell design. The success of this work is that together all these contributions, as well as their inter-dependence can be explored effectively using one unified expression of minority carrier.

If the spectral contribution of solar illumination is completely removed, equation (19) simply represents the solution for dark condition, which is identical to equation (11) of Verhoef and Sinke [5]. Once the carrier profile is known, minority carrier dark and illumination current density (with corresponding drift and diffusion parts) is quite straightforward to obtain by simply placing (19) into (1).

The minority carrier profile for a thin (0.5μm) emitter, calculated using the developed model, is shown in fig. 3. As expected, the hole concentration strongly depends on the surface recombination velocity at the front interface. At the edge of emitter-base space-charge region, both the doping concentration and carrier injection for applied bias will determine the hole profile. The developed solution in equation (13) is compared with a Drift-Diffusion based COMSOL Multi-physics Model. The good match with COMSOL model guarantees the soundness of our mathematical solution. The proposed solution of (13) also shows good agreement with the TCAD model developed in Silvaco/Atlas, as depicted in fig 3. The reason behind the slight mismatch near the depletion edge

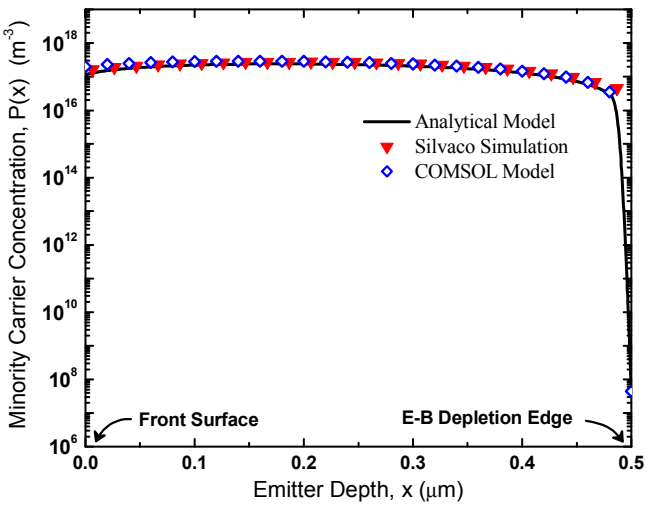

Fig. 3 Minority carrier Hole concentration for n-type Emitter (Depletion edge is at 0.5μm). The front surface recombination velocity (S) is 5×10^4 cm/s. The symbols represent the solution from numerical solar cell models (COMSOL drift-diffusion model and TCAD model) and line indicates analytical solution. Concentration dependent mobility and lifetime have been included in Silvaco/Atlas simulation.

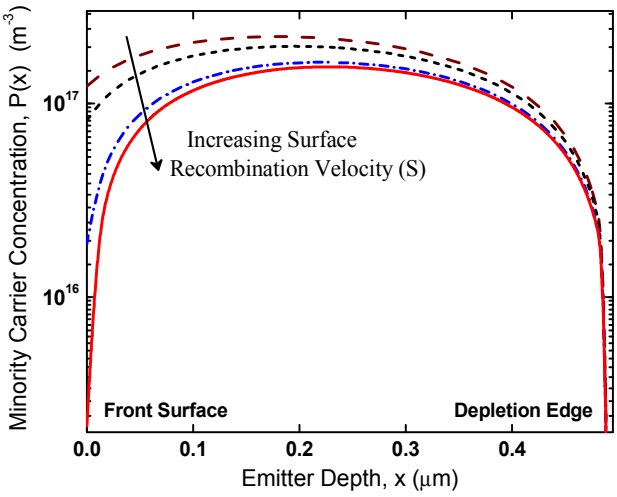

Fig. 4 Effect of surface recombination on Hole concentration. The front surface recombination velocity is varied from 5×10^3cm/s to 5×10^6cm/s.

is that, unlike Silvaco/Atlas, the carrier concentration at junction boundary is solely determined by $p_0 \approx n_i^2/N_D$ under short circuit condition (see equation (14) for applied bias V=0). The model also predicts the reduction of carrier near the top surface when the surface recombination velocity is increasing (fig. 4). In the figure, the minority carrier variation is presented for surface recombination velocities of 5×10^3, 5×10^4, 5×10^5 and 5×10^6 cm/s. While some of the previous analytical models only work well for either high S or low S [9], this analytical approach covers a wide variation of surface recombination velocity. As evident in the fig. 4, by varying S, the effect of using different front contact materials with different work-functions can be studied through this analytical model.

The complexity of the developed solution can be reduced by approximating the Hypergeometric function for thin-film emitters and by reducing Bessel function when its argument (βz) is in smaller range [15]. This model is easily expandable to other single & multi-layer bipolar photovoltaic devices, p-i-n solar cell and CIGS cell.

IV. Conclusions

This work proposes a new analytical model of minority carrier concentration for exponentially doped quasi-neutral emitter which incorporates the drift field, variable lifetime & mobility and solar illumination from standard spectrum. It has been found that this theoretical model predicts the carrier profile successfully over a wide range of doping and surface recombination velocity, at an added complexity of Bessel and Hypergeometric function. The solution is mathematically consistent with numerical physics-based model developed in COMSOL Multi-physics and shows good match with TCAD device simulator. This model can be a useful tool for analysing and optimizing simultaneous contributions from device dimensions, biasing, doping, surface condition and spectrum.

Abstract—**In this paper, the Capacitance-Voltage (C-V) and Ballistic Current characteristics of arsenide based surface channel Quantum Well (QW) MOSFET were investigated. Self-consistent simulation was performed by solving coupled Schrödinger-Poisson equation incorporating wave function penetration into oxide. Although Experimental C-V and I-V characteristics of the Surface Channel QW MOSFET are available in recent literature, a self-consistent simulation based C-V and I-V characterization is yet to be reported. We studied some important parameters variation like oxide material, doping concentration and their impacts on C-V characteristics. We have also simulated carrier transport in the Ballistic limit using top of the barrier approach.**

Index Terms **—Surface Channel, Quantum Well MOSFET, Self-Consistent Analysis, Gate Capacitance**

I. Introduction

Although successive device scaling needs to be continued for sustaining the evolutionary technological improvements, power consumption has been the bottleneck for future silicon CMOS technology scaling [1]. III-V semiconductors have emerged as potential candidates for future high frequency, low power logic applications [2]-[3]. With better carrier mobility, options for possible bandgap modulation, better carrier confinement in thin body structures; III-V materials could meet the demand of high performance solid state electronics in the future. III-V surface channel quantum well device structures incorporating high-k dielectric materials are considered to be promising device technologies. Surface channel device, though mobility is more affected by the interface, has stronger gate controllability over channel which is more desirable as devices are being scaled down aggressively [4]. Despite extensive experimental research, a thorough self-consistent simulation based study on C-V characteristics is yet to be done in literature. In this work, we have performed a simulation based study of C-V characteristics solving self-consistent Schrödinger-Poisson equation for $In_xGa_{1-x}As$ n type surface channel MOSFET. Also I-V characteristics of the n type surface channel device have been simulated semiclassically.This semi classical treatment of transport characteristics has successfully captured short channel effects like DIBL and it provides us with a fair upper level estimate of current in the surface channel MOSFET.

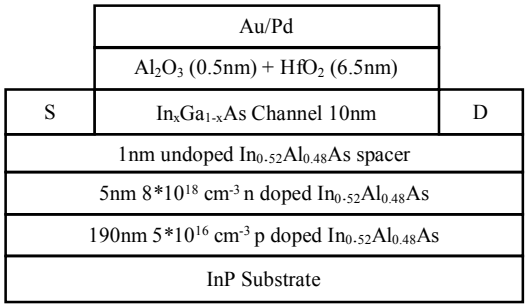

Fig. 1. Basic device structure of $In_xGa_{1-x}As$ surface channel QW MOSFET [5]

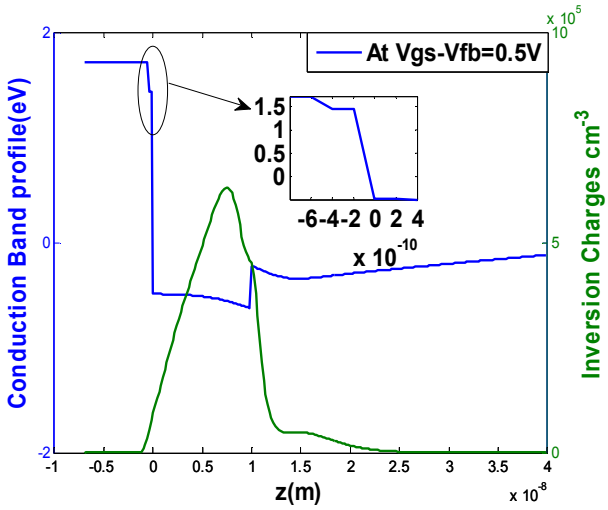

Fig. 2. Conduction band profile along with carrier profile (Inset, transition from 0.5nm Al_2O_3 to 6.5nm HfO_2 is shown (composite gate oxide))

II. Self-consistent C-V Modelling

We have developed a device simulator based on self-consistent solution of Schrödinger-Poisson equation [6]-[7] to characterize the device [5] in Fig. 1. The device has 5nm delta-doped n type $In_{0.52}Al_{0.48}As$ layer separated from channel by 1nm $In_{0.52}Al_{0.48}As$ spacer. In this work we have used Finite Element Method (**FEM**) for solving 1D Schrödinger-Poisson equation using MATLAB coupled with COMSOL. The conduction band profile and carrier profile for the device are illustrated in Fig. 2.

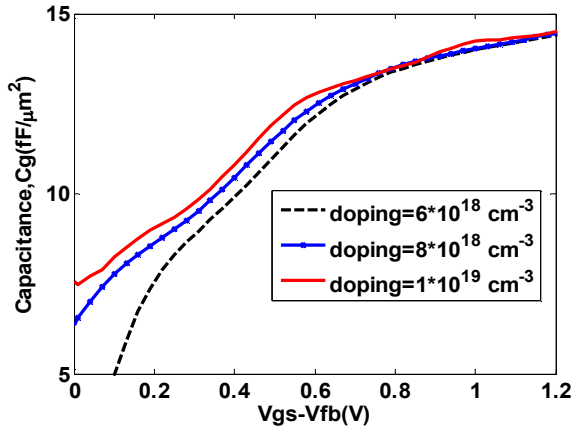

Fig. 5. Gate capacitance variation with various delta doping concentrations.

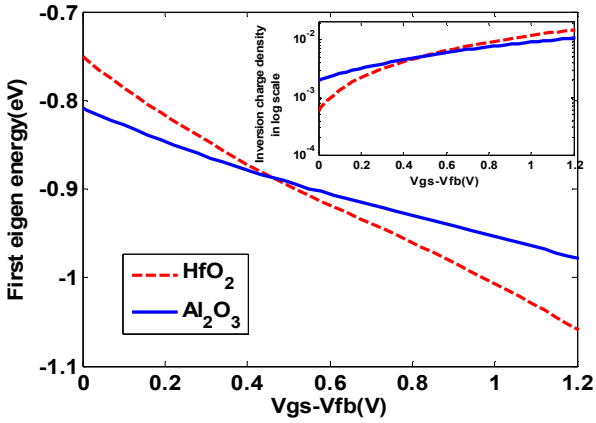

Fig. 4. First eigen energies and sheet carrier density with different dielectric materials for the same device.

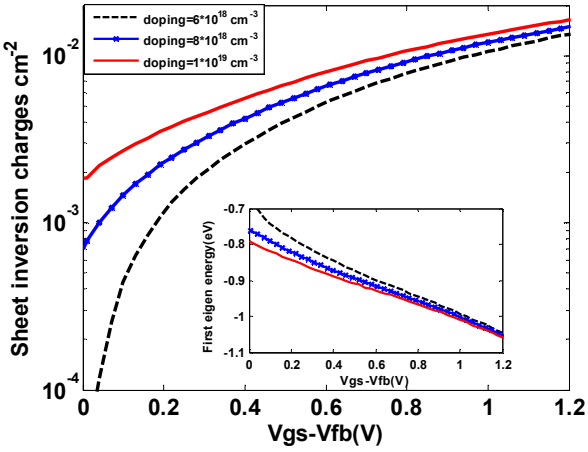

Fig. 6. Sheet carrier density and First eigen energies for different delta doping concentrations

From Fig. 2, we observe that the carriers are well confined within the quantum well channel. Delta doping concentration and dielectric materials are varied to find out its impact on C-V profile. All simulations are done at room temperature (T=300k.)

III. Results and Discussions

Due to higher gate control over channel sheet carrier, device with HfO_2 dielectric shows a higher inversion capacitance (Fig. 3). Fig. 4 shows change of eigen energy and sheet carrier density with gate bias for two different dielectric materials. Al_2O_3 provides slightly better confinement (not shown) at low gate bias. So we get lower eigen energy for it.But at higher bias the HfO_2 dielectric provides a better carrier confinement than Al_2O_3. So eigen energy is lower and confined charge is higher for HfO_2. Fig. 5 shows Gate capacitance variation with various doping concentrations. In Fig. 6, carrier concentration appears to be much higher at low gate bias in heavily doped device compared to lightly doped one. For low gate bias, the well (not shown) in the heavily doped device gets more skewed. Consequently carrier concentration at low gate bias is substantially higher for heavily doped device. At high gate bias however, the shape of the well remains almost same (not shown) for all doping concentrations. As a result, eigen energies become almost similar too (Fig. 6) and sheet carrier densities approach closer value.

However, the device with higher doping density still shows higher carrier concentration. Fig. 7 shows the simulated gate capacitance and experimental gate capacitance data [5] on the same plot. By taking the metal semiconductor work function difference into account, we find good agreement between the two C-V profiles. The simulation is performed without taking any non-ideal effects like fixed oxide charges, interface trapped charges or any other oxide defects which may explain the discrepancy between simulation and experimental observation.

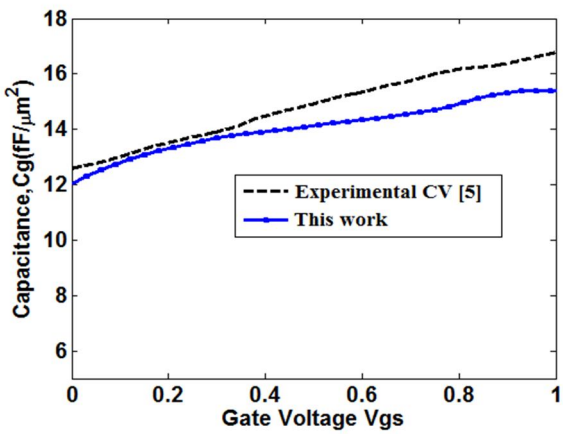

Fig. 7. Simulated and experimental gate capacitance profile.

IV. SEMI CLASSICAL BALLISTIC TRANSPORT MODEL

We have also developed a self-consistent simulator to characterize carrier transport through the device. In our treatment, the quantum effect in surface channel QW MOSFETs is accounted for by solving the Schrödinger equation in the gate confinement direction. From this solution we obtain discrete subbands within which carriers (electrons in our case) are constrained. To account for carrier transport a 1D solution to the Boltzmann Transport Equation (BTE) in the ballistic limit is calculated [8]. Assuming device widths are infinite and translational invariance holds, subband potential energies can only vary in one direction in response to different bias conditions. Therefore, a 1D solution will be sufficient to describe the electron transport within the MOSFETs.More specifically, this 1D solution provides a charge-sheet description.

The approach we have described above is called semi classical approach as the physics in the direction normal to the channel are treated quantum mechanically but carrier transport along the channel is treated classically.Semiclassical ballistic transport only considers the top of potential barrier in channel with everything above transmitted and below reflected. On the other hand, full quantum solution accounts for quantum effects in both the confinement and the transport directions. Semi classical approach can capture the thermionic emission current but it cannot account for any quantum related effects, such as electron tunnelling through the source-channel barrier and quantum interference within ballistic devices. Despite these limitations the semi classical approach gives a fair upper limit approximation of carrier transport across the channel.

V. TRANSPORT CHARACTERIZATION

The conduction band profile and normalized wavefunction obtained from quantum mechanical treatment along confinement direction are shown in Fig. 8. From the figure, we observe that the carriers are well confined within the quantum well channel even in transport condition.

Fig. 9 (both a & b) shows the computed self-consistent conduction subband profiles versus position under various Vgs & Vds bias points keeping one constant at a time.Here we plot the bottom of the first subband versus position, not the conduction band edge.Form Fig. 9 (a) we observe that for a fixed gate bias, increasing drain bias causes the energy of the sub-band portion at the drain end to decrease gradually.
Fig. 9 (b) shows the computed self-consistent potentials within the model nanoscale MOSFET under low and high drain bias with gate voltage as a parameter. At low gate voltages, the energy barrier between the source and drain is high. So the source and drain injected carriers are reflected off the channel potential barrier and the device is off. A high gate voltage lowers the potential energy barrier and electrons flow from source to drain. So the height of the energy barrier is controlled by the voltage on the gate.

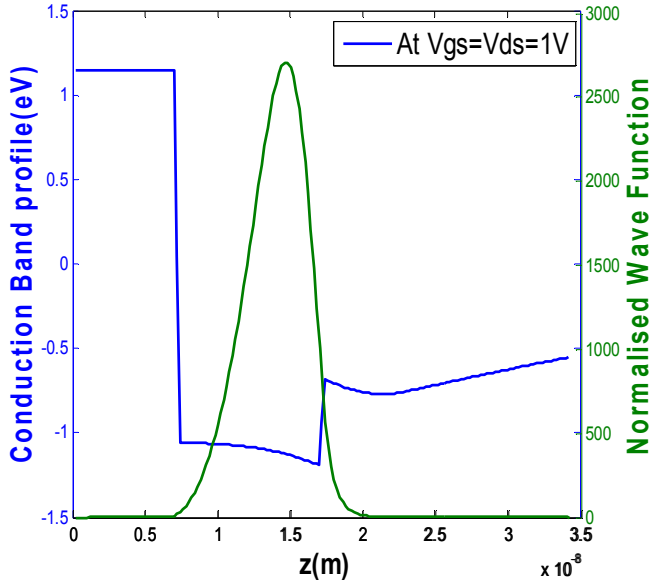

Fig. 8. Conduction band profile along with normalized wavefunction

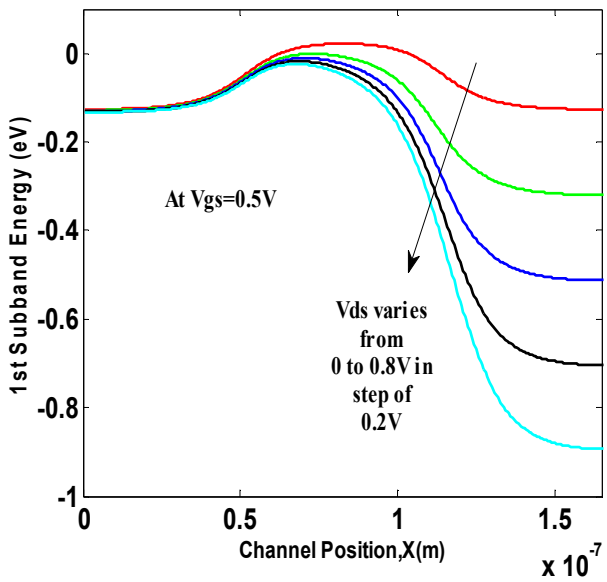
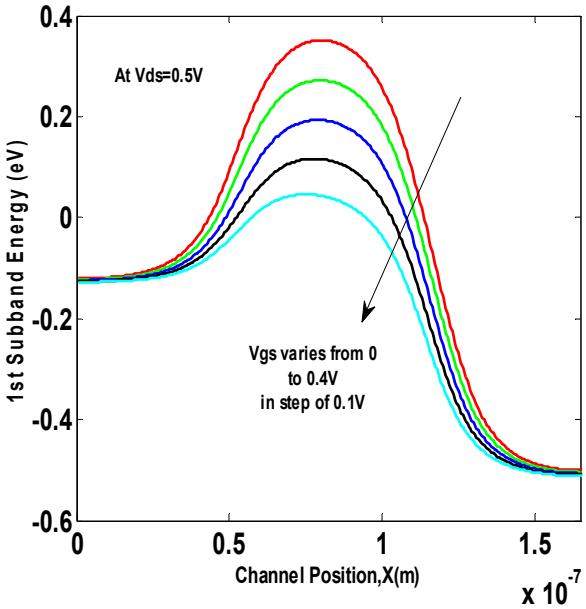
Drain Induced Barrier Lowering (DIBL) is an important short channel effect for nanoscale transistors. MOSFETs usually operate by modulating the potential barrier in the channel between source and drain. For long channel devices, this potential barrier is generally modulated by gate voltage.

However, as the channel length is being scaled down, voltage applied at the drain terminal starts to modulate this energy barrier in the channel near the source end. This phenomenon also leads to the lowering of threshold voltage for short channel devices. This effect has been captured by our simulator as observed from lowering of channel potential barrier for the 1st subband near the source end with increasing drain bias voltage (Fig. 9(a)).



(a)



(b)

Fig. 9. First subband profile versus channel position for (a) Vgs = 0.5 V and Vds varying from 0 V to 0.8 V (b) Vds = 0.5 V and Vgs varying from 0 V to 0.4 V.

Fig. 10 shows simulation results for intrinsic gate bias voltage ranging from 0.4V to 1V with 0.1V step and drain bias voltage ranging from 0V to 1.0 V. The ballistic current is higher than the reported experimental value for the same device. This mismatch between experimental and simulated data can be attributed to the absence of any inelastic scattering in our simulation. We have considered ideal contact without any contact resistance which also contributes to this discrepancy.

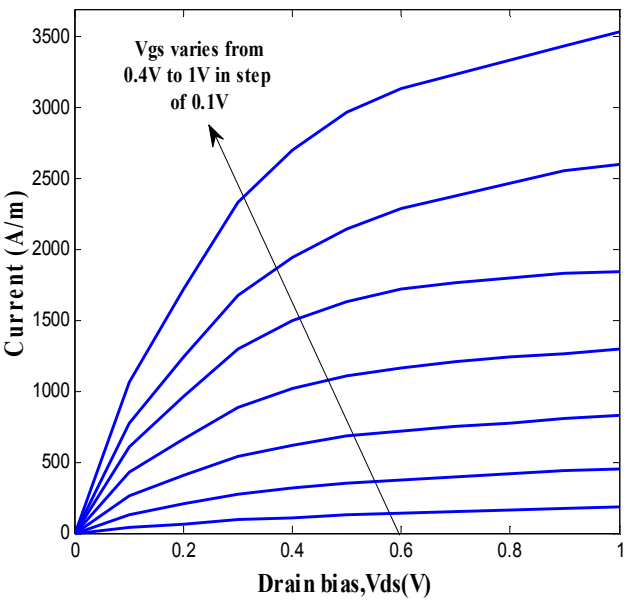


Fig. 10. The intrinsic I_d-V_{ds} characteristics for the simulated device structure.

VI. CONCLUSION

We have performed a self-consistent quantum mechanical C-V characterization of 55 nm Quantum Well device reported in [5].We observed that variations of doping concentration and oxide material have strong effects on C-V characteristics. HfO_2, as a high k insulator, provides much better control over channel than Al_2O_3.Delta doping variation causes large change in sheet charge density at low gate bias although the effect is less pronounced at higher bias. So higher delta doping can be a useful mean of increasing sheet charge density in the channel without altering the device structure. By keeping the length of side spacer region equal to gate length of the structure, the carrier transport through the channel has been analysed semi classically. We have determined subband profile in the $In_{0.53}Ga_{0.47}As$ channel quantum mechanically by solving coupled Schrödinger Poisson equation. Current in ballistic regime has been calculated using top of the barrier approach. The simulated ballistic current is higher than experimental measurements [5].This discrepancy can be attributed to the avoidance of scattering phenomenon in the QW channel. Also, in this approach, the effect of doped heterostructure stack along with contact resistance has been neglected. To get a more realistic picture of transport characteristics, quantum effect should be incorporated in transport direction using NEGF formalism [9]-[11].

Abstract— **In graphene dielectric multilayer structure, a very interesting phenomena such as epsilon near zero property rises naturally. However, this epsilon near zero property (along with the proper control of chemical potential and gate voltage) of graphene multi-layer stack has not been used so far to make novel photonic switches .In this article, we have shown theoretically that in graphene-dielectric stack, which acts as an anisotropic metamaterial, full control of reflection and so transmission of light at a specific wavelength or frequency can be controlled very simply by external gate voltage. This external voltage tunes the chemical potential and so the parallel permittivity of the anisotropic structure. Our theoretical prediction may pave the way to novel voltage control photonic logic switches, which may play as an intermediate solution before entering into all optical commercial switches (as current silicon and electron based CMOS technology is facing a dead end).**

***Index Terms*— Graphene, anisotropic metamaterial, reflection, chemical potential, tunability.**

I. Introduction

In condensed-matter physics, graphene can be considered as the latest and most valuable and promising material. One of very few two-dimensional materials, graphene has already shown its fascinating electrical properties due to its unconventional and amazing crystal and electronic properties [1]. Graphene transistors at first were thought to replace silicon logic transistors. However, due to the absence of band-gap they failed to do so though they have been successful in application of terahertz transistors [2]. Beside electronic applications, graphene has fascinating photonic applications such as transparent electrodes in displays and photovoltaic modules [3], photo-detectors [4] etc. Recently graphene based anisotropic metamaterials have gained enormous attention to researchers due to their exciting tunable electromagnetic properties [5], [6], [7], [8]. Graphene based multilayered metamaterials can show both elliptical and hyperbolic phenomena and they can be characterized as uniaxial anisotropic metamaterials. Hyperbolic metamaterials with hyperbolic dispersion have shown their extreme ability and applications exhibiting negative refraction [9], negative index [10], sub-wavelength imaging [11], light confinement [12], [13], nonlinearity enhancement [14], bio-sensing [15] etc. Graphene-dielectric multilayer structure can also behave as hyperbolic medium and has already been mentioned in literature [5], [6], [7], [8] for its applications in many occasions. But in this article, we are more interested in elliptical behaviour of graphene dielectric anisotropic metamaterials.

In this article, we have considered a graphene-dielectric multilayered anisotropic structure. The structure can both work as hyperbolic and elliptic metamaterial. We describe the permittivity behaviour of the structure at different frequency and also its dependence on chemical potential, which is the most exciting phenomena in graphene dielectric multilayered structure (as in case of metal-deielctric multilayered structure, it is not possible to change the electromagnetic characteristic of the structure after fabrication). This limitation can also be seen from our previous work [16] where Relation between Perfect tunneling and Band Gaps for SNG Metamaterials has been briefly discussed. But both perfect tunnelling phenomena and band-gaps are not actively tunable and they require both negative permeability and permittivity. As graphene is an actively tunable material, our multilayered structure is also tunable.By means of this tunability option, we theoretically show that reflection form the structure can be fully controlled very simply by external voltage using exciting behaviour of the graphene in THz range (where intra-band transitions dominate).

II. Theory

Uniaxial anisotropic metamaterial can be identified by the permittivity tensor.

$$\varepsilon = \begin{bmatrix} \varepsilon_{||} & 0 & 0 \\ 0 & \varepsilon_{||} & 0 \\ 0 & 0 & \varepsilon_{\perp} \end{bmatrix}$$

Where, $\varepsilon_{||}$ is the parallel permittivity and $\varepsilon_{\perp}$ is the longitudinal permittivity of the structure. There are two ways to engineer hyperbolic metamaterial structure:

a) Multilayer realization consisting of alternating sub-wavelength metal and dielectric layers.
b) Metal nanowires in a dielectric host.

These uniaxial materials can show both elliptic and hyperbolic dispersion if they satisfy the condition $(\varepsilon_{||}\varepsilon_{\perp}) > 0$ and $(\varepsilon_{||}\varepsilon_{\perp}) < 0$ respectively.

For metal dielectric hyperbolic metamaterial structure, as long as the length of one unit cell consisting one metal and one dielectric layer is less than the wavelength of light used, we can use effective medium theory.

By effective medium theory we get,

$$\varepsilon_{\parallel} = f\,\varepsilon_m + (1-f)\varepsilon_d$$
$$\varepsilon_{\perp} = \left(\frac{f}{\varepsilon_m} + \frac{(1-f)}{\varepsilon_d}\right)^{-1}$$
$$f = \frac{t_m}{t_d + t_m}$$

Where, t_m is the thickness of metal layer, t_d is the thickness of dielectric layer, ε_d is the permittivity of

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

dielectric layer, ε_m is the permittivity of metal layer and f is the filling ratio.

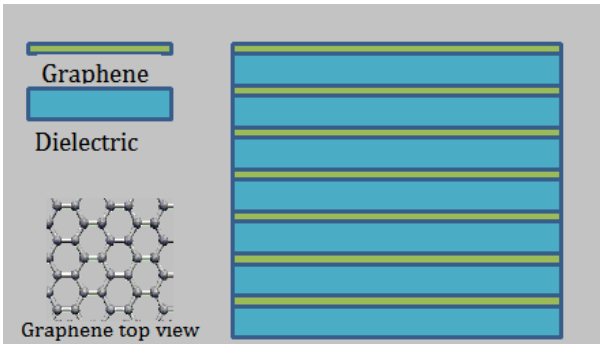

Fig. 1 Graphene-dielectric multilayer structure considered in this work.

Graphene is a single atom thick two dimensional plane of carbon atoms forming a hexagonal lattice layer of carbon atoms with a lattice constant of 0.264 nm. Transverse magnetic (TM) surface plasmons are supported by graphene. Recently it has been shown that graphene-dielectric alternating stack can work as a uniaxial anisotropic metamaterial similar to those of metal-dielectric anisotropic metamaterials in the mid infrared and THz frequencies. In case of graphene, in THz frequency range, intra-band transitions dominate. Frequency and chemical potential dependent conductivity of a monolayer graphene can be given by Kubo formula,

$$\sigma(\omega,\mu_c) = -\frac{j4\pi e^2 k_B T}{h^2(\omega - j2\mathcal{T})}\left(\frac{\mu_c}{k_B T} + 2\ln\left(e^{\frac{-\mu_c}{k_B T}} + 1\right)\right) - \frac{j4\pi e^2(\omega - j2\mathcal{T})}{h^2}\int_0^\infty \frac{f_D(-\xi) - f_D(\xi)}{(\omega - j2\mathcal{T})^2 - 16\left(\frac{\pi\xi}{h}\right)^2} d\xi \quad (1)$$

The effective permittivity can be derived in following form,

$$\varepsilon_g = 1 - j\frac{\sigma(\omega,\mu_c)}{\omega\varepsilon_o t_g} \quad (2)$$

$$\varepsilon_\parallel = \frac{t_g\varepsilon_g + t_d\varepsilon_d}{t_g + t_d} \quad (3)$$

$$\varepsilon_\perp = \frac{\varepsilon_g\varepsilon_d(t_g + t_d)}{t_g\varepsilon_d + t_d\varepsilon_g} \cong \varepsilon_d\ ;\ t_g \ll t_d \quad (4)$$

Where k_B is Boltzmann constant, T is temperature, h is plank's constant, μ_c is chemical potential of graphene, ω is angular frequency, $\mathcal{T}$ is phenomenological scattering rate (.1meV), t_g is the thickness of graphene layer, t_d is the thickness of dielectric layer and ε_d is the permittivity of dielectric layer and Fermi Dirac function $f_D(\xi) = \left(e^{\frac{\xi - \mu_c}{k_B T}} + 1\right)^{-1}$. In the THz range we can expect graphene-dielectric stack to act both as an elliptic media or hyperbolic media depending on the chemical potential.

Anisotropic epsilon near zero metamaterails have been demonstrated to show exciting full transmission even with impedance mismatch. Here at first, we demonstrate the physical conditions for full transmission and full reflection of an anisotropic metamaterial slab. We neglect absorption because in our selected frequency region loss is negligible and another mechanism for absorption in this kind of metamaterial, 'Slow light' [17], [18], [19] is absent as we are working on elliptical region. The slab will be fully transmitting if its permittivity along the transverse plane equals to 1 and its permittivity along propagation direction also equals to 1. This simply means that the slab has to be made of graphene and air stack though the dependence on longitudinal permittivity is much less than the parallel permittivity. If we can make a graphene structure spaced by air instead of dielectric then the longitudinal permittivity is always equal to 1 as long as the spacing of air $t_{air} \gg t_g$ (eqn. 4). Transverse permittivity of graphene–air/dielectric multilayered structure can be tuned at different frequency by tuning temperature and also chemical potential. Even with graphene-dielectric structure full transmission can be achieved because transmission through a uniaxial metamaterial slab is not critically dependent on longitudinal permittivity. And here instead of a garphene-air structure we consider a graphene-dielectric structure which will also show similar phenomena though the longitudinal permittivity is not equal to 1.

To obtain full reflection, the transverse permittivity has to be zero to achieve complete impedance mismatch. This is physically possible, as we can change the permittivity of graphene (varying graphene's chemical potential) by controlling external voltage or by changing the temperature.

The theoretical formula for reflection for a uniaxial anisotropic metamaterial can be given by following formula [20]:

$$R = |r|^2 = \left|\frac{\varepsilon_\parallel \tan\theta_t - \tan\theta}{\varepsilon_\parallel \tan\theta_t - \tan\theta}\right|^2 \quad (5)$$

$$\theta_t = \tan^{-1}\sqrt{\frac{\varepsilon_\perp \sin^2\theta}{\varepsilon_\parallel\varepsilon_\perp - \varepsilon_\parallel \sin^2\theta}}\ ;\text{TM polarisation}$$

Full impedance matching is achieved when $\varepsilon_\parallel = 1$ and when $\varepsilon_\parallel = 0$ full impedance mismatch is achieved for an anisotropic uniaxial metamaterial which can be seen from eqn. (5)

Graphene anisotropic metamaterial can be tuned by temperature or by chemical potential which can be achieved by applying gate voltage [5]. So for a specific dielectric thickness t_d, dielectric permittivity ε_d and specific chemical potential μ_c, we can obtain the frequency at which parallel permittivity of the structure is closely equal to 1 so higher transmission is achieved.

Relationship between gate voltage and chemical potential can be given by following formula [5], [21]

$$|\mu_c| = \hbar v_F\sqrt{\pi|a_o(V_g - V_{dirac})|} \quad (6)$$

Where, V_{dirac} is the voltage offset which is zero if there is no impurity or doping in graphene, v_F is the Fermi velocity (~1e6 ms^{-1}) [1] of Dirac fermions in graphene and $a_o = 9 \times 10^{16} m^{-1}V^{-1}$. Bias voltage can change the chemical potential though it is also possible to tune chemical potential by magnetic field and chemical doping.

Here we want to demonstrate an opto-electronic structure, which is basically a voltage controlled device. In this device, the carrier is photon and control mechanism is voltage. For 0 gate voltage, the anisotropic graphene-dielectric metamaterial is tuned so that it has transverse permittivity 1 at a specific frequency ~44.78 THz. And so we have almost full transmission or zero reflection. For high gate voltage (which

is calculated as 30.5 mV), transverse permittivity value decreases from 1 to 0. Thus we have almost full reflection.

III. Results and Discussion

In this section we discuss our theoretical results introduced in section II.

Fig.2 shows both the real permittivity (in parallel direction of the structure) and longitudinal permittivity of graphene-dielectric uniaxial anisotropic metamaterial. It can be seen that effective permittivity (in parallel direction) is a function of frequency. But the longitudinal permittivity is almost fixed at 2.2 as thickness of dielectric layer is much greater than the graphene layer thickness. This is also a basic difference in metal-dielectric multilayered structure as we can't make ultra-thin metal on dielectric so longitudinal permittivity of metal-dielectric metamaterial also changes with frequency. Again parallel permittivity can take both positive and negative values showing their capability of both elliptic and hyperbolic dispersion profile though in this paper we are only interested in elliptical region.

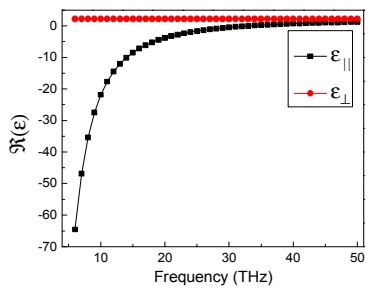

Fig. 2 Permittivity in parallel and longitudinal direction of graphene-dielectric metamaterial slab.

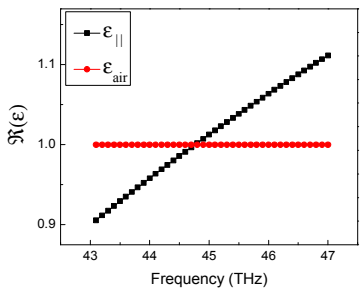

Fig. 3 Parallel permittivity of graphene-dielectric slab crossing air permittivity at a critical frequency

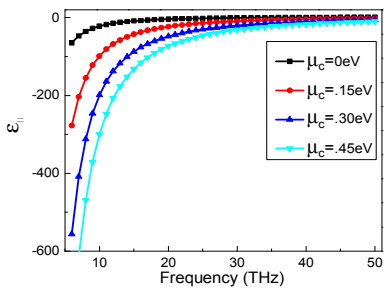

Fig. 4 Parallel Permittivity of graphene-dielectric metamaterial slab at different chemical potential.

Fig. 3 shows the parallel permittivity in the frequency range 43 THz to 47 THz. As in this range, graphene-dieletric multilayered metamaterial crosses the air permittivity. Permittivity of air is also shown in the graph to indicate the intersecting point of metamaterial permittivity and air permittivity. We name the intersecting frequency point as critical frequency as at this critical frequency the parallel permittivity of metamaterial is equal to one which is a necessary condition for almost zero refection. Also this critical frequency is obtained when the structure is unbiased that means at zero chemical potential or at zero gate voltage considering $\boldsymbol{V_{dirac} = 0V}$

Fig.4 shows both the real permittivity (in parallel direction of the structure) at different frequency with different chemical potential. For higher chemical potential or higher gate voltage, parallel permittivity obtains more negative value making the anisotropic structure to epsilon near zero to hyperbolic structure though in this paper we are not interested in the hyperbolic region as we want to vary the parallel permittivity between one to zero.

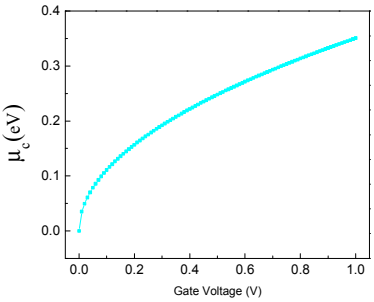

Fig.5 Chemical potential of graphene-dielectric metamaterial slab at different gate voltage.

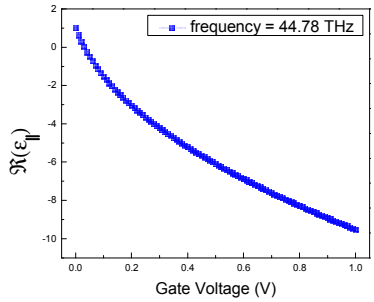

Fig. 6 Parallel Permittivity of graphene-dielctric metamaterial slab at different gate voltage at critical frequency 44.78 THz where the structure is tuned at parallel permittivity equaling one.

Fig.5 shows the relation between chemical potential and gate voltage. Chemical potential can be changed from 0eV to ~.35eV by applying gate voltage from 0 to 1V. Parallel permittivity is dependent on chemical potential and chemical potential is dependent on gate voltage. Parallel permittivity can be changed by applying gate voltage, which we can see from fig. 6. Here critical frequency is fixed at 44.78 THz. At this frequency, at zero biased condition, parallel permittivity of the structure is equal to ~1. This permittivity value (1) is the required condition for very low negligible reflection. Also from the figure it can be observed that gate voltage can tune the structure from elliptic to hyperbolic. Here we want to mention another point that the graphene can be chemically doped and by chemically doping, it is possible to obtain higher chemical potential value which will give the parallel permittivity condition of negligible reflection at a higher frequency. And also the thickness and permittivity of the dielectric layer can be changed (reduced) to obtain critical frequency at a high value than what we have used here.

Gate voltage induced (equivalently changing chemical potential (fig. 7)) zero to full reflection is clearly observed in

Fig.8. As our structure was tuned at critical frequency 44.78 THz, so that the real part of permittivity in parallel direction

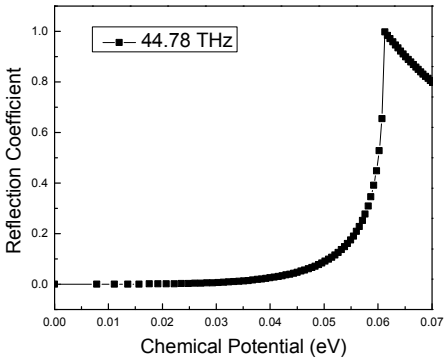

Fig. 7 Chemical Potential dependent reflection from the graphene dielectric metamaterial structure. As chemical potential is tuned by gate voltage, parallel permittivity of the structure changes and as a result reflection from the structure goes from zero to unity.

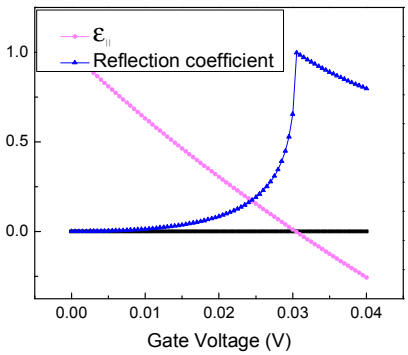

Fig. 8 Zero reflection from the structure at zero gate voltage, reflection increases as gate voltage is applied and reaches unity at 35mV, pink line shows the parallel permittivity of the structure as it changes from one to zero because of gate voltage, the structure changes its behavior from zero reflection to full reflection as it is expected.

meets the desired value one, we can observe negligible reflection at zero gate voltage or equivalently at zero chemical potential or for an unbiased structure. When the voltage is ramped, chemical potential of each graphene layer is changed and so as a result the parallel permittivity of the whole structure decreases and at a specific voltage parallel permittivity reaches zero which is the satisfactory condition for full reflection. And we obtain the voltage required for full reflection is 30.5mV. After this voltage permittivity crosses zero value to negative value letting the structure work as a hyperbolic metamaterial. So from above discussion if we apply a pulse from 0 to 35mV, we should observe zero to full reflection. In our work, we didn't mention the imaginary part of permittivity of graphene layer. This is because the imaginary part of the permittivity of graphene layer is relatively low compared to the real part at our critical frequency. Permittivities of the whole structure (parallel and perpendicular) are dependent on graphene's permittivity. So at our critical frequency, the imaginary part of the permittivity of the structure (parallel and perpendicular) is also relatively low compared to the real part. As a result, it should not hamper our theoretical predictions.

IV. Conclusion

In this article, we have at first briefly described the graphene-dielectric multilayered anisotropic metamterial, its permittivity properties in THz frequency range, dependence on chemical potential and equivalently on gate voltage. From simple theoretical calculation, it has been shown that the multilayer structure can be tuned to control the reflection properties of the device, which may act as a photonic switch. Our work may pave the way to novel manipulation of graphene based metamaterials in logic device applications for faster operation replacing current CMOS technology.

Abstract— **In this paper a design of a low cost data logger to log temperature and power consumption in a house is presented. The designed data logger is capable of logging four AC current and two temperature measurements. It is based on a low cost microcontroller PIC18F4550. Microcontroller is programmed using Mikrobasic. The circuit displays temperature measurements on an LCD display and all measurements are also stored in separate files on a sd card. Power consumption of two houses was logged for one year using a sampling time of 2 minutes. The data stored in a sd card is used for further analysis. This paper also presents design of data logger and a detailed analysis of energy consumption of two houses based on collected data. Data analysis indicates power consumption pattern and its variation over a year. Analysis indicates that the logged data and monthly data collected by the utility company give similar energy consumption.**

Index Terms— **House energy consumption, data logger design, microcontrollers, net-zero houses, energy analysis.**

I. Introduction

According to statistical agency of Canada [1] the total population of Newfoundland & Labrador is 526,896 till January 2014. Many houses are electrically heated. Energy consumption in each house is logged and recorded once a month by the utility company [2]. The total electricity consumption of each house varies with type and size of the house, no of occupants etc. A much frequent data logging is required to determine energy consumption pattern in a house. A data logger design is presented in this paper that is capable of logging house input currents and temperatures at a much higher rate. The designed data logger can also sense and record the inside and outside temperature of the house and total current coming into the house.

A number of data logger designs have been published in literature. For example in [3] multiple parameters (temperature, pH) of green house are logged using sensors which is transferred to a PC using NI-DAQ cards for analysis in LabVIEW. Rosiek [4] proposed a microcontroller based data acquisition system which collects data from different meteorological stations using eight sensors. To test the functionality of the designed system results are compared with two commercial data acquisition systems. Ameur designed [5] a data acquisition system to monitor growth of bananas in a greenhouse. They also used a temperature regulation card to keep the greenhouse temperature around 25 degree C for a better production of banana. Commercial data loggers do not reveal their design and provide a limited functionality. Data loggers have been used for energy analysis of houses. Shuqin [6] investigated residential house energy consumption patterns in summer in seven cities in China. It was observed that Hong Kong uses highest amount of household electricity compared to other cities. Lindberg [7] analysed 5 year long building energy consumption data, collected from a data acquisition system which used almost 520 sensors in each of 6 buildings. For different exterior wall material the data was collected for analysis. They showed for reducing building heating and cooling energy load, use of thermal mass of a house has significant effect. Authors [8, 9] presented an energy and economic analysis of a zero energy house with solar application and a conventional house. Among several conclusions it was observed that an air conditioner with a water-cooled air condenser saves noticeable electricity. Full design of a data logger and energy analysis of electrically heated houses is missing in the literature. A design of a low cost data logger and energy analysis of two houses is presented below.

II. Data logger Design

A data logger is an electronic instrument that records different physical or electrical parameters such as temperature, humidity, wind speed, current through an appliance over time. Data loggers are based on, a computer connected to a number of sensors and data storage. Power consumption in computers is high and data is lost in case of a power failure. Recent availability of low cost and low power microcontrollers allowed new design of data loggers. In this section a data logger design is introduced which records current consumption in a house and both inside and outside temperature of a house.

Four current sensors and two temperature sensors have been used in the design. Data logger circuit diagram is shown in figure 1. Figure 2 shows a photo of designed data logger. A 2x16 LCD is used to display required measurements. A microchip microcontroller PIC18F4550 is used for recording the data from the sensors. Data is stored in separate files on a sd card. Data taken from the temperature sensor is shown on a 2x16 LCD. And data taken from current sensors are directly saved in separate files on the sd card. For further analysis the data from sd card can easily be transferred to a computer.

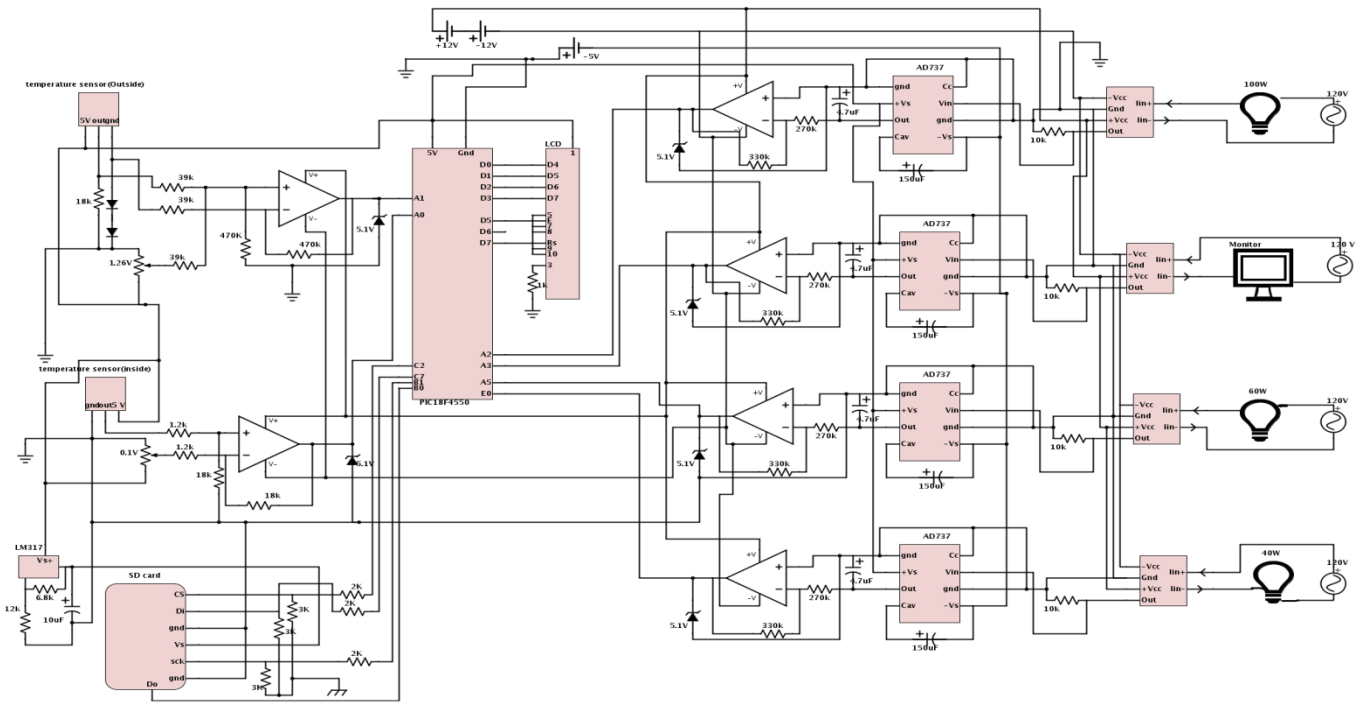

Fig.1 Data logger circuit diagram

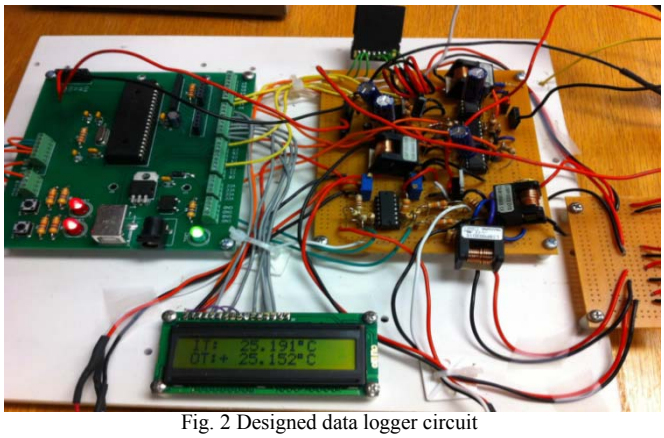

Fig. 2 Designed data logger circuit

A. Temperature sensor

LM35 series temperature sensor has been used whose output voltage is linearly proportional to the Centigrade temperature. Scaling factor of LM35 is +10mv/◦C, which means for every degree Celsius changes in temperature it gives 10mV analog output voltage. Two temperature sensors are used, one for the inside and another for the outside house temperature. Temperature range selected for the inside house temperature is (+10 to+40) C and for the outside temperature is (-30 to+40) C. Outputs of LM35 are amplified to 0-5V for input to microcontroller. Zener diodes (5.1V) are used for circuit protection.

B. Current sensors

Current sensors are connected in series with incoming current to a house in the main panel. Hall sensor based current sensors generate small ac voltage proportional to input current, Rated current for which is ±3A and maximum current is ±9A. Current sensor output voltage is converted to DC using arms to dc converters (AD737). Amplifiers are used to amplify the output of rms to dc converter to 0-5V for PIC microcontroller. Four identical circuits are used for four current sensors.

C. Microcontroller & Sd card

A PIC18F4550 microcontroller is used in the data logger design, which is the most important element in the whole circuit and needs a 5V to operate. This microcontroller uses a 10 bit resolution ADC converter. Both the current and temperature sensors give analog output which goes to the ADC(analog to digital conversion) port of the microcontroller. Thus analog value is converted to digital value to show on the LCD correctly. Conversion from analog to digital value is done using equation (1)

$$\text{Voltage}=(5 * \textit{value read by microcontroller})/1024 \quad (1)$$

A 2GB micro sd card of class 2 is used for the system design. The card is formatted with FAT16 file system. Operating voltage of Sd card is 2.7V-3.6V. A voltage regulator LM317 is used to supply 3.16 V to the sd card in the design. In basic connection 2K and 3K resistors are used on pin 1, 2 & 5. Resistors are used to lower the input voltage of the sd card.

D. Circuit diagram

Full data logger circuit is given in figure1. In the test circuit, different range of bulbs and a computer monitor was connected as the load to measure the currents using current sensors. The AC output voltage of the current sensor is converted to DC voltage using a rms to DC converter. The output of the converter is negative that is why inverting op-amp is used. For programming of PIC18F4550, mikrobasic compiler is used. Once a programme is written and compiled it generates a hex file which is loaded to the PIC using a device programmer. In figure2 the constructed data logger circuit is shown. When the picture was taken both the sensors were inside of the house. So in the LCD it is showing same temperature (25 degree C) for inside and outside of the house. And the current readings are saved in the sd card with both the temperatures. Some actual value readings from the sensors and saved on the sd card are shown in Table-1. Both

the inside and outside temperature are shown and both the sensors were inside of the house while the data was being logged. Outside temperature value is higher because that sensor was close to a light bulb. Value of only one current sensor is shown using a 100w bulb as the load.

TABLE I
ACTUAL SENSOR READINGS

Date	inside temperature C	outside temperature C	current(A)
13/6/14	25.64	26.99	0.834
13/6/14	25.77	27.07	0.834
13/6/14	25.81	27.38	0.834
13/6/14	25.84	29.53	0.834

III. HOUSE ENERGY ANALYSIS

Two typical electrically heated houses in St. John's are selected for the energy analysis. First one (house-1) is a two storey building with a semi-finished basement. Other house is a two storey house with a garage attached to it. From the utility company [2] and using a data logger the total energy consumption data of one year for both the houses was collected.

According to utility company total electricity consumption for house-2 was 27300 kwh in the year 2012(figure-3) and for house-1 total consumption was 15747 kwh in year 2010. Again using a data logger data of a whole year has been logged for both the houses. Sampling was done once every 2 minutes. Figure4 & 6 shows the monthly logged data value in the chart, from Jan (2012-2013) and from September 2003 to August 2004 for house-2 and house-1 respectively. For both the houses collected and logged power consumption data follows a similar pattern. Again in figure 3 and 4 we can see there is a mismatch between the measured and collected data by the utility company. It is because some data logger values were missing but the main reason of mismatch is that utility company do not measure energy consumption for 3 to 4 winter months in a year. Utility send an estimated bill and correct that later when all snow has melted away. Also the year long data is adjusted using year

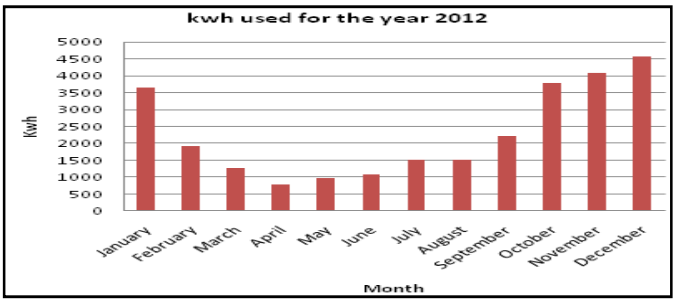

Fig. 3 Energy consumption by the utility in the year 2012 of house-2.

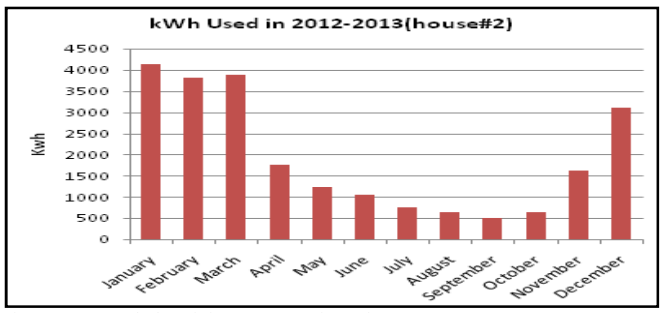

Fig. 4 Measured electricity consumption of year 2012-2013

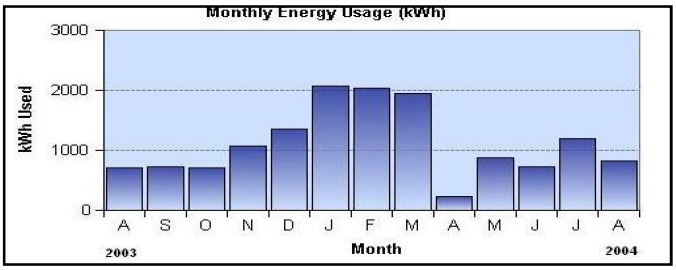

Fig. 5 Energy usage provided by the utility (2003-2004) for house-1.

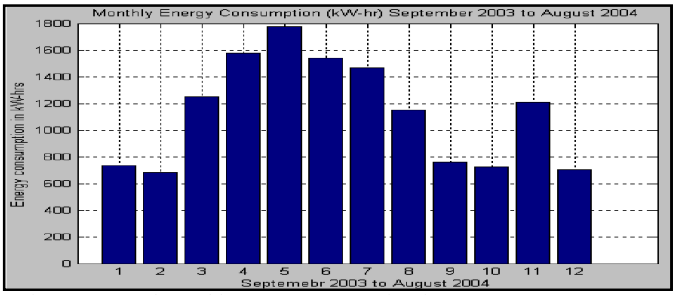

Fig. 6 Measured monthly energy consumption from Sept. 2003 to August 2004 for house-1

2012 and 2013 power consumption data. Figure 5 shows monthly energy consumption of house-1 from August 2003 to August 2004 as reported by the utility company. On the other hand figure 6 shows the measured energy consumption for year 2003-2004.Energy consumption in the year 2003-2004 was maximum in January 2004 (2084kWhr) while it was minimum in April 2004 (only 237 kWhr) [9]. It is clear from this data that measurements were not done at a regular interval and it also includes estimated values. In other words utility reported measurements are not a good indication of actual energy consumed in the house during winter months when their meter is not accessible. If we compare data in figure 5 and figure 6 we find similarity in pattern but energy consumption value reported by the Newfoundland power (fig. 5) and measured value (fig .6) for the month of April 2004 do not match. This mismatch is because of adjustment done by the Newfoundland power during that month. Figure 7 shows power consumption on a typical winter day in house 2. The start time of the data is

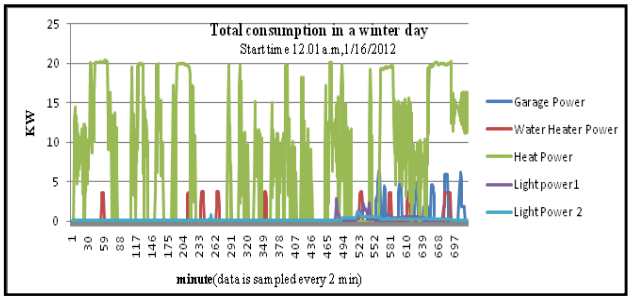

Fig. 7 Power consumption in typical winter day of year 2012

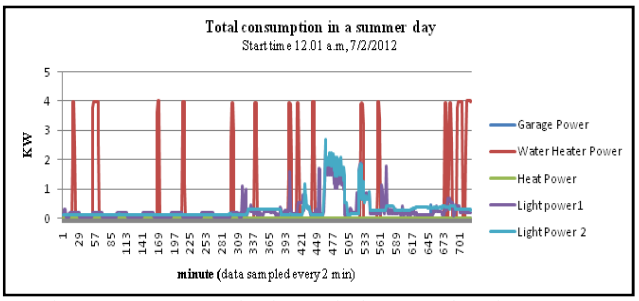

Fig. 8 Power consumption in a typical summer day of year 2012.

12.01 am at night. We can see that the main power consumption is due to heating. It indicated that most heating was done during night and late evening. Similarly Power consumption for the same house in a typical summer day is shown in figure 8. We can see there is no house heating power for the day. The major electrical load was electric water heater. In figure 9 hourly averages for a day in winter

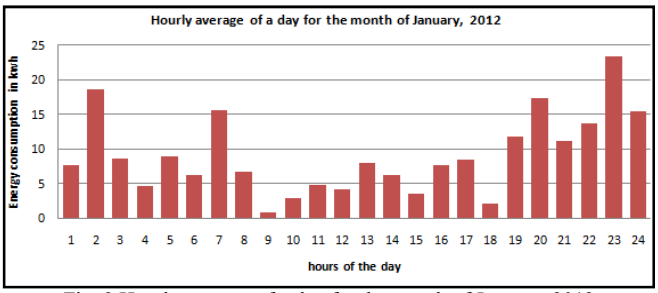

Fig. 9 Hourly average of a day for the month of January, 2012.

is shown using bar chart. We can conclude from this chart that consumption is high at night, late evening and in early morning. Similarly hourly average of a day in summer is

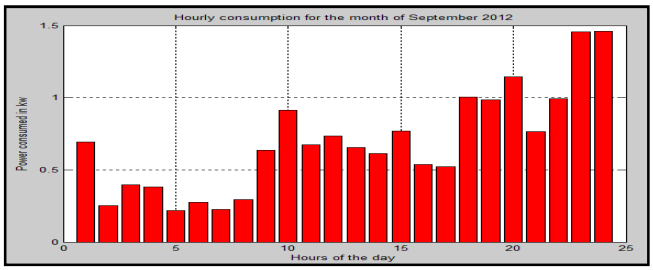

Fig. 10 Hourly average power consumption in September of house-2

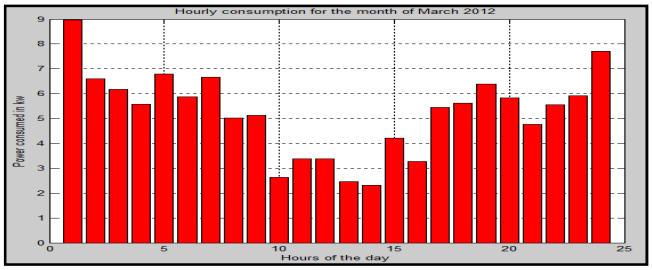

Fig. 11 Hourly average power consumption in March of house-2

observed where it can be noticed that the consumption is high in the afternoon. Again for house 2, from figure 10 & 11 we observe minimum hourly power consumption was below 1.5 kW in September whereas the maximum consumption was 9kW in the beginning of March in year 2012. For house-1, it is observed from figure12 that the maximum average hourly power consumption was in January 2004, which exceeded 5000W level. Similarly from figure13 the minimum hourly power consumption was 250W in early hours of the day in

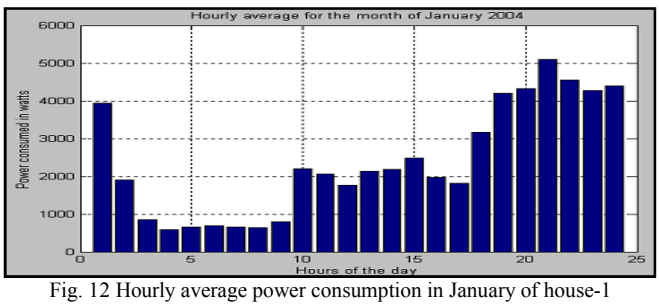

Fig. 12 Hourly average power consumption in January of house-1

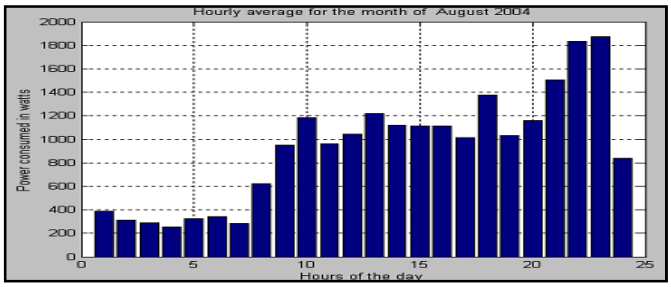

Fig. 13 Hourly average power consumption in August of house-1

August 2004. The hourly power consumption graphs are generated using matlab code using all the collected data, sampled every 2 min from the data loggers.

IV. Conclusions

Two houses in St. John's have been considered to analyse the power consumption for one year. Data of power consumption for both the houses is collected from utility company and then compared with the measured value from data logger. Data acquisition system was installed at home to give a true picture of energy consumption. A data logger that is used in the house is designed using two temperature sensors and four current sensors. This type of data logger can be used in almost every household to get different parameters of a house within a certain interval. Daily, monthly and yearly data can be analysed to understand the exact power consumption nature of the houses. Hourly average of each month and energy consumption in a winter day and in a summer day is shown by a time series plot for the house. Such plots are necessary to design a renewable energy system for a house and also to study human behaviour and energy usage.

***Abstract*— A switched capacitor based step up converter with high voltage gain is proposed in this paper. The proposed novel topology of the boost converter can provide almost threefold output voltage relative to its input at 50% duty cycle. In order to guarantee small switching losses and to eliminate the current spikes problem across the switches (which usually exists in classical converter), an inductor is used in the circuit which creates a resonant tank and assist in zero current switching (ZCS). In addition, the efficiency curve of the new converter circuit shows high value for a wide range of output power which is rare in literature. Besides, this proposed topology is free from the circuitry design complexity. In renewable energy systems like photovoltaic panels or fuel cells, where a high step up voltage is required, the proposed converter can bear its suitability.**

Keywords*— Switched capacitor, high voltage gain, zero current switching (ZCS), high efficiency, DC-DC boost converter.

I. Introduction

Boost converters have been widely used in many applications such as battery backup devices, uninterruptible power supply (UPS), wind turbine system, photovoltaic (PV) system etc. In order to satisfy the high DC voltage requirement as well as power quality, many researches have been conducted so far on how to design the DC-DC boost converter [1]-[2]. A conventional single phase single switch boost converter is shown in Fig. 1 where V_{gs} is the gate signal of the switch; V_s, I_s are the voltage and current through the switch and V_0, I_0 are the voltage and current at the output. The conventional boost converters are usually employed in high voltage and power factor correction (PFC) application due to its simple circuit structure. In theory, the voltage gain of the boost converter can be infinite when the duty cycle is close to one. However, the switch turn off period becomes short when the duty cycle increases towards one. As a consequence, the current ripples of the power devices are large with high step-up conversion which increases the power device conduction losses. Moreover, the voltage stress of the switch and the diode are proportional to the output voltage which is large in high output voltage applications [3].

To overcome the aforementioned problem and to increase the current rating, interleaved boost converters have been proposed in the literature. Interleaved boost converter in [3]-[8] can increase the power level and can minimize the current ripple but the efficiency of these converters are still limited by the output diode reverse recovery problem in high voltage applications. Besides, the use of bulky inductor as a boosting element increases the overall size, weight and losses of the interleaved boost converter. In order to remove the bulky inductor and to get high voltage conversion ratio, the switched capacitor concept based boost converters have been proposed in [9]-[11]. But the problem with these topologies is that, some switches remain floating in the structure and thereby it needs additional isolated gate driving circuits to operate which eventually makes the system more complex. Moreover, the converter still operates in hard switching mode resulting in large switching losses as well as high current spikes across MOSFETs. To minimize the switching losses and high current spikes problem across the switches, a new soft switching DC-DC boost converter circuit based on capacitor switching topology is proposed in this paper. The proposed converter can produce threefold voltage at its output compared to its input voltage at a fixed duty cycle (50%). A 1μH small inductor is placed in series with the input source to assist the zero current switching (ZCS) in the circuit. This ensures low switching losses and eliminates current spikes across the switch. Besides, the circuit shows fairly high efficiency over a broad range of output power. In order to prove the aforementioned features of the proposed circuit, simulations have been carried out which demonstrates the effectiveness of the circuit more clearly.

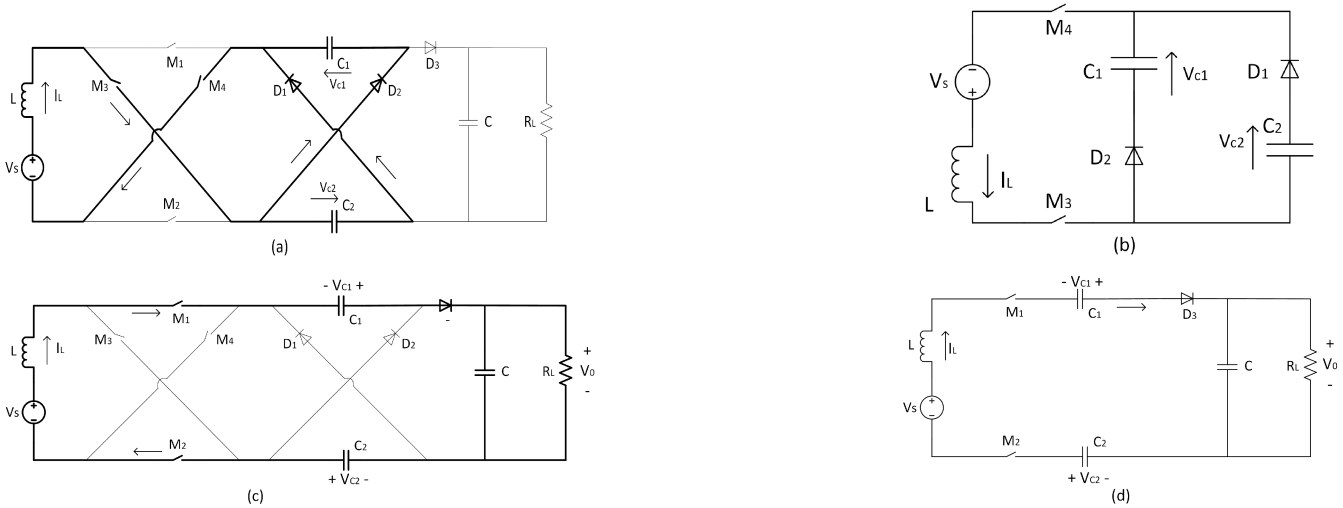

Fig. 3. (a) Current path of the proposed boost converter circuit for first state [t_0-t_1], (b) Equivalent circuit of the first state, (c) Current path for the third state [t_2-t_3], (d) Equivalent circuit of the third state.

II. Analysis of the Proposed Circuit Operation

The operating principle of the proposed boost converter with commutation is discussed step by step. But before analysing the operation of the circuit, several assumptions are made. It is considered that all the devices are ideal and the capacitance of the output capacitor is large enough so that the output voltage is fairly constant. All the simulated curves of current at different switching states are shown in Fig. 4. Here V_{g1} and V_{g2} are gate pulse of Switch M_1, M_2 & M_3, M_4 respectively.

1) First State [t_0-t_1]: At t_0, M_3 and M_4 switches are turned on. This creates a current path between the voltage source V_s and the capacitors C_1 & C_2. Fig. 3(a) shows the current path of the proposed converter and Fig. 3(b) is the simplified circuit at this state. Here the two diodes D_1 and D_2 are in a conducting state. Due to this close current path, capacitor C_1 and C_2 both get the opportunity to become charged to a voltage of V_s. Hence the inductor L and both capacitor C_1 and C_2 resonate together with voltage source V_s. They all start resonating at t_0 from the current equal to zero in sinusoidal manner. Since the current increases gradually at t_0, so both of the switches M_3 and M_4 are turned on under zero current switching (ZCS) condition. They stop resonating when the current reaches zero again at t_1 and both of the diodes (D_1 and D_2) will be reverse biased.

2) Second State [t_1-t_2]: At t_1, resonance stops and the inductor current becomes zero. The currents through the switches are also zero. The switches M_3 and M_4 are turned off at this state under zero current switching (ZCS). The voltage of both the capacitors (C_1 and C_2) remains unchanged.

3) Third State [t_2-t_3]: At t_2, switch M_1 and M_2 are turned on and diode D_3 is in a conducting mode. Both of the switches are turned on under ZCS condition. Total circuit configuration is illustrated at Fig. 3(c) and its equivalent circuit is displayed at Fig. 3(d). Now it is evident from Fig. 3(d) that we can get the output voltage from the capacitor C which discharges to the load R_L. To perform the ZCS in the circuit, a small valued inductor (1μH) is added in series with the voltage source. The voltage induced across the inductor is too small due to its small value and we can neglect it. Now neglecting the inductor voltage we can write-

$$V_0 \cong V_s + V_{C1} + V_{C2} \tag{1}$$

Where V_{c1} and V_{c2} are the voltage of capacitors C_1 and C_2 respectively which have same value and it is almost equal to the input voltage V_s (50V). From the above expression it is vivid that the proposed converter circuit provides almost three times larger voltage at the output relative to its input. In addition, the current across the inductor changes in a sinusoidal manner at this state. Mathematically, we can express-

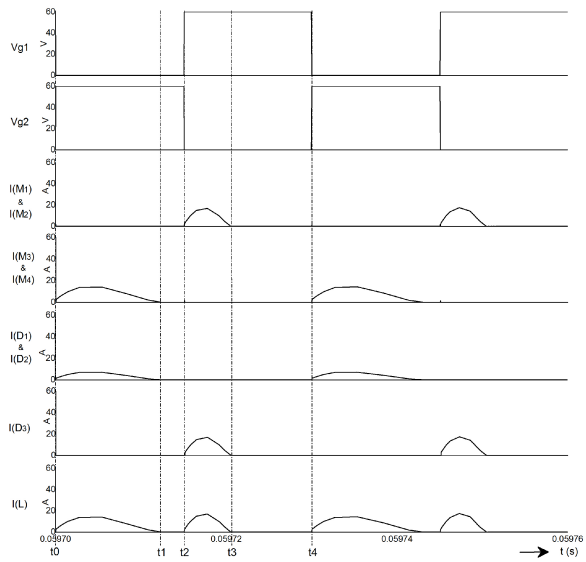

Fig. 4. Analysis waveforms of the proposed converter.

$$I_L = I_M \sin \omega_0 (t - t_2) \quad (2)$$

Here, I_M=Maximum amplitude of the inductor current.

$$\omega_0 = \frac{1}{\sqrt{2LC_{eq}}}$$

C_{eq} is the equivalent capacitance of the circuit.

4) Fourth State [t_3-t_4]: At t_3, the current through the inductor (L) as well as the switches M_1 and M_2 becomes zero. So, at this state, both switches M_1 and M_2 are turned off under ZCS condition.

III. Performance Appraisal

The proposed converter can manipulate the high efficiency power conversion and provide a wide range constant efficiency curve. We have compared the conversion performance result for hard switching and soft switching for our proposed converter circuit. The simulations are carried out in PSPICE software and the parameters are given in TABLE I.

TABLE I. KEY PARAMETER CONSIDERATIONS

PARAMETERS	VALUE
V_{in}	50V
V_{out}	More than 140V
Switching frequency f_{sw}	33.3KHz
Duty Cycle	50%
Charge pump capacitor C_1,C_2	6 µF
Output Capacitor, C	1500 µF
Inductor, L	1 µH
MOSFETs	IRF530
Diode	MBR10100

In Fig. 5, the output voltage curves of the capacitors are depicted when hard switching is occurred. Fig. 5(a) and Fig. 5(b) exhibit the output voltage of C_1 and C_2 capacitors while Fig. 5(c) displays the total output voltage across the capacitor C. The voltage profile of the capacitors (C_1 & C_2) is totally undesirable as the charging and discharging state across them is erratic in nature. So the performance of the converter deteriorates during hard switching as the switching loss goes high and we get lower output voltage (almost 130V) across the capacitor C.

On the other hand, Fig. 6 provides the simulated curves during the soft switching (under ZCS condition). It is evident from the Fig. 6(a) and Fig. 6(b) that the voltage profile of the capacitors C_1 and C_2 has improved. These two curves are smooth and unruffled compared to the previous case. Due to soft switching, low switching loss occurs and the converter provides high output voltage (more than 140V which is almost three times relative to the input).

The switching loss, which reduces the output voltage of the converter, occurs due to high current across the MOSFET. Fig. 7 depicts the phenomenon more lucidly. Fig. 7(a) and Fig. 7(b) are the current curves of M_1 and M_3 during the hard switching where it can be observed that a large current spike (more than 200A) generates across the M_1 and M_3. But Fig. 7(c) and Fig. 7(d) represent the current curves during soft switching which indicate the lower magnitude of MOSFET current (around 10A). Due to larger current across the switch, larger switching loss occurs which reduces the output voltage as well as the overall efficiency of the converter.

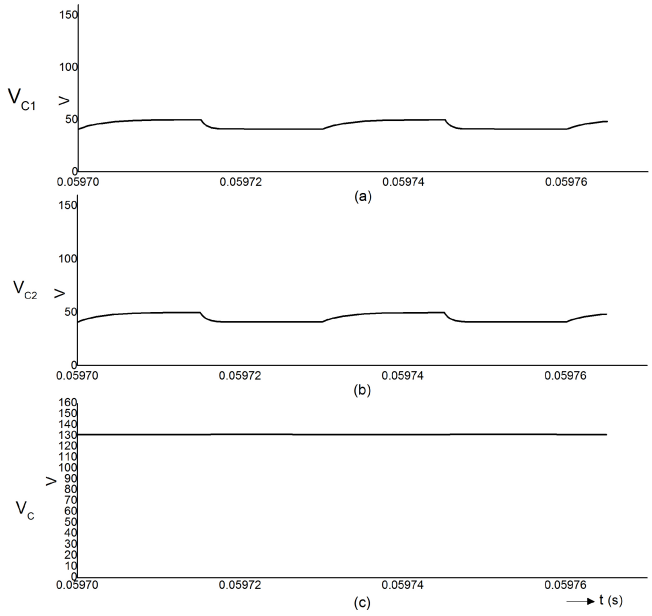

Fig. 5. Voltage without ZCS (a) across capacitor C_1 (b) across capacitor C_2 and (c) across capacitor C

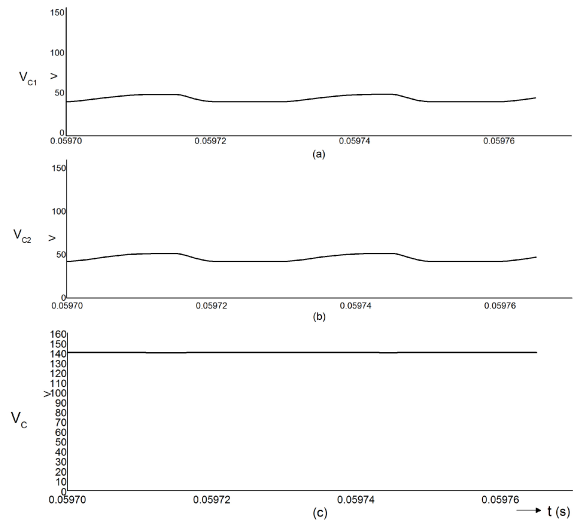

Fig. 6. Voltage with ZCS (a) across capacitor C_1 (b) across capacitor C_2 and (c) across capacitor C

IV. Efficiency Curves

It has previously been mentioned that the converter circuit with hard switching (without ZCS) provides lower efficiency than with soft switching (with ZCS). In order to verify the statement, we have simulated the efficiency curve. Fig. 8 shows the efficiency curve without ZCS where it indicates that highest 82% to 85% efficiency at a certain range of output power. But the Fig. 9 shows both with and without ZCS efficiency curves where it is clearly observed that the efficiency of the converter becomes 92% to 97% at a certain range of output power with ZCS. All of these statements have

been summed up in TABLE II. In addition, the efficiency curve with ZCS also remains at a high value for a wide range of output power which is one of the major features of the proposed converter.

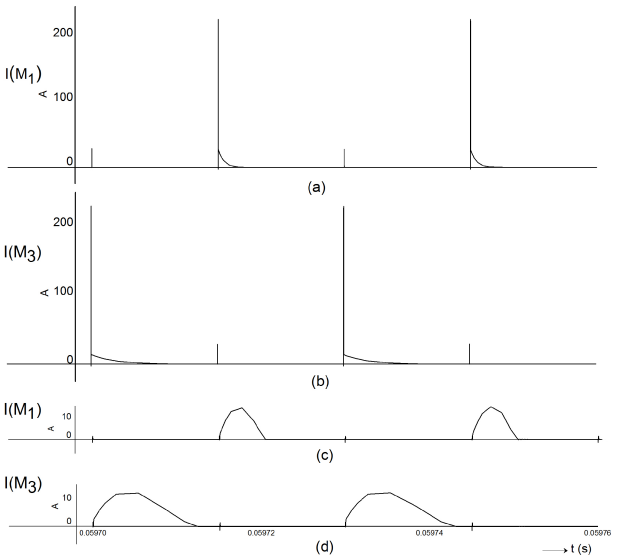

Fig. 7. Output current without ZCS (a) across MOSFET M_1 (b) across MOSFET M_3 and with ZCS (c) across MOSFET M_1 (d) across MOSFET M_3

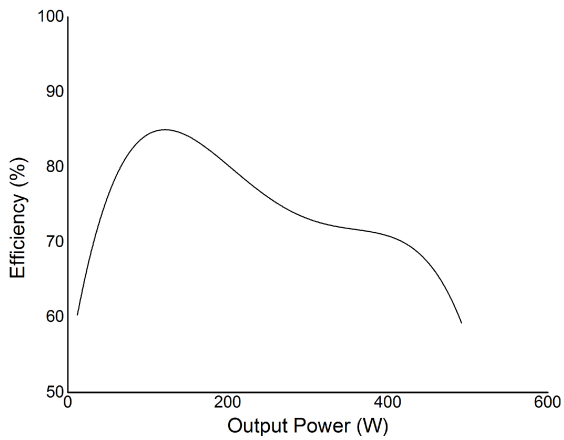

Fig. 8. Efficiency curve for the proposed Boost Converter with Hard switching (without ZCS)

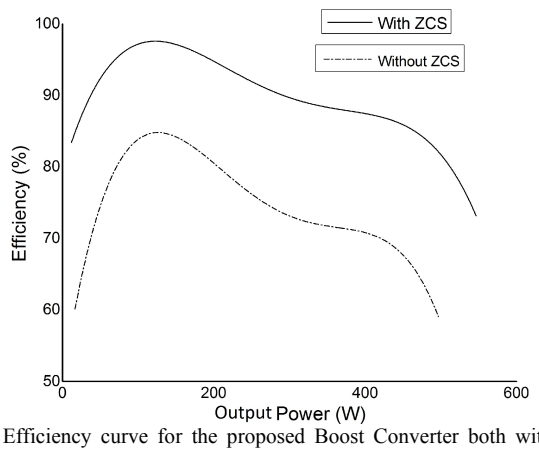

Fig. 9. Efficiency curve for the proposed Boost Converter both with Hard switching and Soft switching (without and with ZCS)

TABLE II. COMPARISON BETWEEN HARD & SOFT SWITCHING

Input Power for Hard Switching (W)	Input Power for Soft Switching (W)	Same Output power for both switching (W)	Efficiency at Hard Switching (%)	Efficiency at Soft Switching (%)
66.85	54.019	50	74.79	92.56
119.24	102.88	100	83.86	97.20
178.31	154.44	150	84.12	97.12
248.57	210.83	200	80.46	94.86
328.68	271.97	250	76.06	91.92
410.73	334.70	300	73.04	89.63
488.28	396.24	350	71.68	88.33
565.61	457.19	400	70.72	87.49
665.77	524.04	450	67.59	85.87

V. CONCLUSION

In this paper, a novel topology of boost converter is proposed and analyzed which can provide a high voltage gain at its output. Moreover, a method of soft switching with ZCS is presented that ensures a minimum switching loss and eliminates the current spikes which usually exists in classical converter. The proposed circuit is simulated and the results are presented in this paper. The efficiency curve exhibits that, for a wide range of output power, the efficiency of the circuit remains at a high value. So, for a system where large voltage step-up is necessary, this proposed boost converter suits properly.

Abstract—**Design and simulation of a fast, efficient and cost effective charge controller for Photovoltaic (PV) System is presented. To harness maximum power from the PV panel, the charge controller is equipped with Maximum Power Point Tracking (MPPT) feature. An efficient algorithm for MPPT is developed combining the Constant Voltage (CV) MPPT and the Incremental Conductance (IncCond) MPPT method. The new method, unlike CV, can obtain the actual power from PV and work faster than IncCond. The open circuit voltage, V_{oc}, needs to be taken only once in order to minimize the power loss. The performance of this charge controller is demonstrated via the simulation in Powersim (PSIM) using the parameters of a practical solar panel (Solarex MSX-60). Furthermore, this paper delineates elementary concepts of PV system so as to help beginners get a strong basic idea about PV systems and MPPT.**

Index Terms—**charge controller; dc-dc converter; MPPT; Constant Voltage MPPT; Incremental Conductance MPPT; SEPIC converter; Buck Converter.**

I. Introduction

Even today when global warming is an important issue of discussion not only among environmentalists, but also among commoners and industrialists alike, we still rely on fossil fuels for much of our energy needs. Only 10% of global energy supplied comes from the renewable energy sources [1-13]. Although Sun is the primary source of all energy, solar energy plays such a miniscule role that it is listed behind the other sources of energy in terms of the contribution for meeting the world's energy demand. Photovoltaic (PV) energy is one of the leading sources of renewable energy, which gets more preference in comparison to other forms of alternate energy due to its availability, simplicity, lower maintenance, environmental friendliness, reliability and many other benefits.

A PV array (which is comprised of several solar cells) uses photons of light to generate electricity through photovoltaic effect – the creation of voltage or electric current in a material upon exposure to light. The amount of solar energy that strikes a given area over a specific time is called insolation. Insolation per unit time is defined as irradiance. As the irradiance increases, more power is generated.

The temperature also has an effect on the solar cells in that the higher the temperature, the lower the power generated. Even at fixed irradiance and temperature, a solar cell does not produce steady voltage or current. I-V characteristic of the solar cell changes as the load is varied across it. The I-V and subsequent P-V characteristics of a typical solar cell are provided in Fig. 1 and Fig. 2 [13].

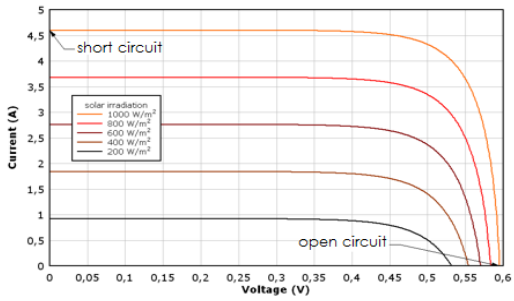

Fig. 1 I-V characteristic of solar cell for different irradiance levels

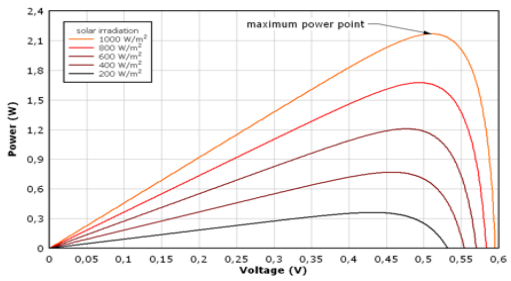

Fig. 2 P-V characteristic of solar panel for different irradiance level

A PV cell has non-linear current-voltage qualities. The power delivered by the PV array increase, up to a certain point, as more and more current is drawn from it. In order to ensure that a PV array is producing the maximum output power, a technique called Maximum Power Point Tracking (MPPT) is used. The voltage of the PV array, at which the maximum power is delivered, can be defined as V_{mpp}.

There are many MPPT algorithms [11-20]. Some of the more commonly used and effective MPPT techniques are the Constant Voltage (CV) method [3,4], β method [5], System Oscillation method [6,7], Ripple Correlation method [8], Incremental Conductance method (IncCond) [9] and the Perturb and Observe method [10-12]. Among the MPPTs CV has the easiest algorithm, hence easiest to implement. The power delivered to the load is momentarily interrupted and the open-circuit voltage (V_{oc}) is measured. The controller then resumes operation with the voltage controlled at a fixed ratio, such as 0.76, of V_{oc}. A particular constant, k, is defined as:

$$k = V_{mpp}/V_{oc} \quad (1)$$

The value of the duty cycle (D) is then calculated from the equation:

$$D = (k \times V_{mpp})/V_{oc} \quad (2)$$

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

This method however, yields an approximate result and the variation in V_{mpp} due to climate change is not taken into account.

The theory of the incremental conductance method is to determine the variation in direction of the terminal voltage for PV modules by measuring and comparing the incremental conductance (I/V) and the instantaneous conductance (ΔI/ΔV) of PV modules. If the value of the incremental conductance is equal to that of the instantaneous conductance, then the MPP is obtained; the MPPT algorithm calculates the optimal duty cycle D in order to maximize the power flow. IncCond needs less iteration than the Perturb and Observe (P&O) method and consequently needs a lower time to reach the MPP. Moreover, unlike the P&O, the IncCond technique allows the MPP to be reached without any fluctuation around the MPP.

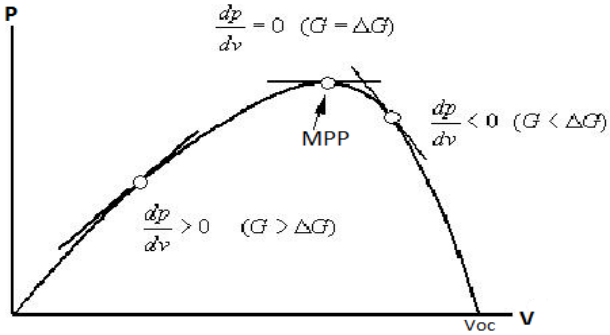

Fig. 3 Incremental conductance at different position of P-V curve

II. Proposed MPPT Technique

A MPPT method combining CV and the IncCond methods has been proposed. The new MPPT takes open circuit voltage by momentarily disconnecting load. During that time a capacitor is used to supply power to load. By switching gate of the SEPIC converter, which is used for performing the MPPT operation, at a fixed rate, a fraction of V_{oc} is supplied to the load. Next by varying duty cycle according to IncCond algorithm, MPP is reached. The algorithm is depicted in Fig. 4.

III. Proposed Design

The design and simulation of the proposed charge controller was performed using the PSIM simulation software. The block diagram of the proposed charge controller is shown in Fig. 4. The input was taken from the built-in PV model of the software. Irradiance and temperature were required as input for the PV model. It was then connected to a SEPIC converter in which PWM switching signals where provided by the MPPT algorithm. The output of the sepic converter was then connected to a buck converter in order to ensure that the voltage output of the buck converter is kept at 14 V which is required in order to effectively charge a 12 V battery.

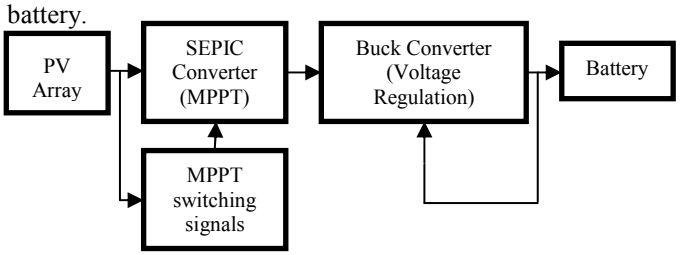

Fig. 5 Block Diagram of the Charge Controller System

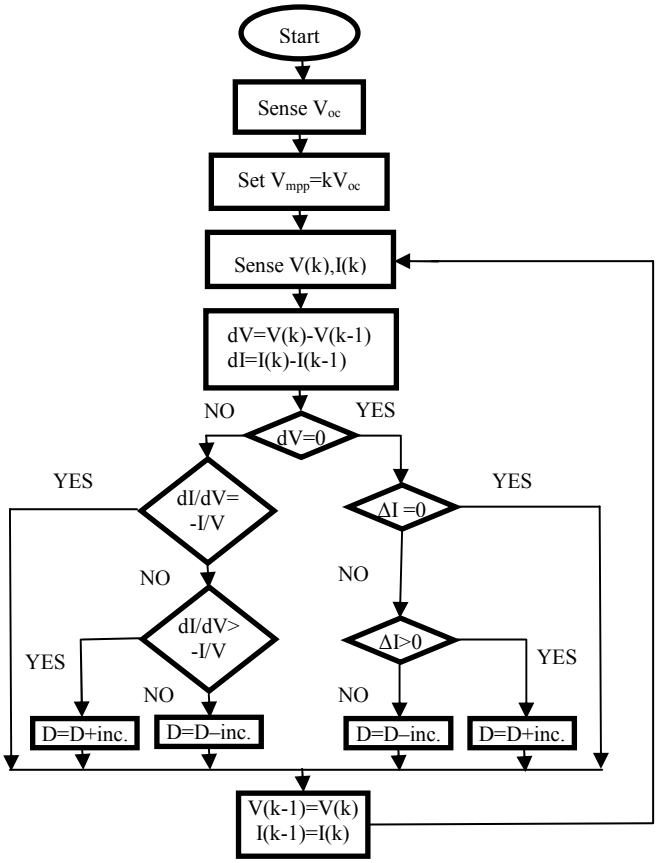

Fig. 4 Algorithm of the proposed MPPT technique

A. SEPIC Converter

The PV array is connected to the SEPIC Converter in which the gating signals are provided via the MPPT Algorithm discussed earlier. A SEPIC is a DC-DC converter similar to a buck-boost converter [14] which is helpful in applications where the input voltage is above and/or below the intended output. In comparison to the buck-boost converter, it has an output with the same polarity as the input voltage and via the use of the series and additional capacitors can respond more quickly to the changes in input and output. The voltage and current values of the PV array are measured by a voltage and a current sensor respectively and the gates of the SEPIC converter are thus switched accordingly in order to ensure that the PV array is in the ideal operating condition. The parameters of the SEPIC converter are defined by the equations given below

$$D = \frac{V_o + V_f}{V_i + V_o + V_f} \tag{3}$$

$$\Delta I_L = 30\% \times \frac{I_i}{n} \tag{4}$$

$$L1a(\min) = L1b(\min) = \frac{1}{2} \times \frac{V_{i(\min)} \times D_{\max}}{\Delta I_L \times f_{sw(\min)}} \tag{5}$$

$$C_o \geq \frac{I_o \times D_{\max}}{\Delta V_{rpl} \times f_{sw(\min)}} \tag{6}$$

Where D = duty of the converter, V_f = forward voltage drop of the diode, V_i = input voltage, V_o = output voltage, ΔI_L = inductor ripple current, η = worst-case efficiency, L1a = L1b = inductor values, f_{sw} = switching frequency, C_o = Capacitor value, I_o = output current

B. Buck Converter

The output of the SEPIC converter is connected to a buck converter which is in turn used for voltage regulation. In a buck converter, the output voltage is less than the input voltage [15, 16]. The output of the buck converter was compared with a reference voltage and the error signal was sent to the PI controller, the output of the PI controller was then compared with a triangular wave and the resultant pulses were then used for switching of the MOSFET buck converter. The parameters of the buck converter are defined by the equations given

$$V_o = D \times V_i \tag{7}$$

$$\Delta I_L = \frac{V_o(V_i - V_o)}{f_{sw} \times L \times V_i} \tag{8}$$

$$\Delta V_{rpl} = \frac{\Delta I_L}{8 \times f_{sw} \times C} \tag{9}$$

Where D = duty of the converter, V_i = input voltage, V_o = output voltage, ΔI_L = inductor ripple current, L = inductor value, f_{sw} = switching frequency, C = Capacitor value, I_o = output current, ΔV_{rpl} = output ripple voltage

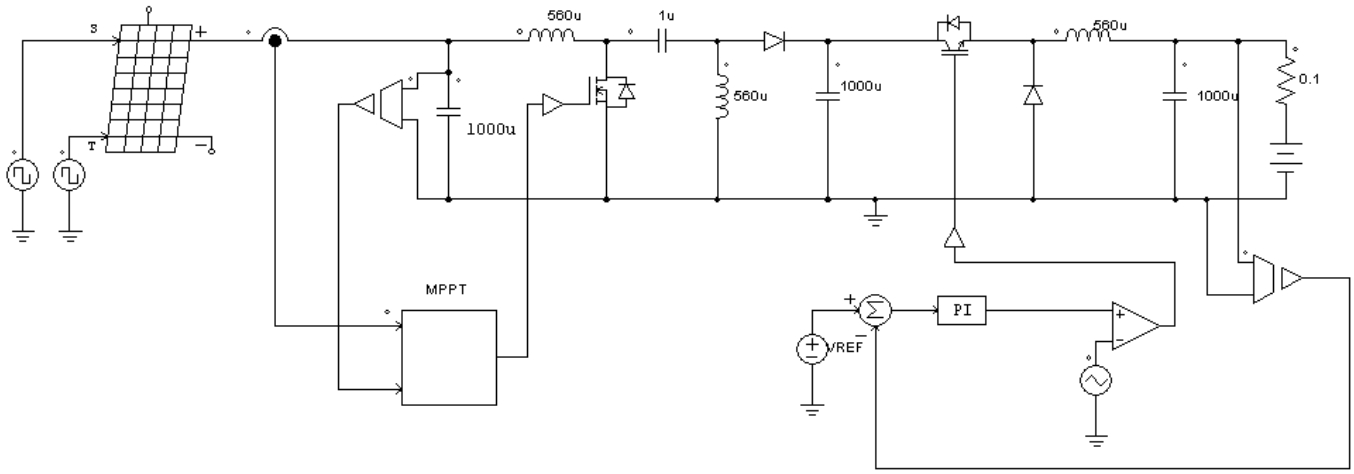

Fig. 5 Full Circuit Diagram

IV. Simulation Results

The PSIM simulation results are provided in this section. The irradiance was varied from 600 to 1000 W/m^2.

V. Conclusions

Design of a charge controller using SEPIC and buck converters along with modified Incremental Conductance has been presented. The simulation results depicting the behaviour of the charge controller have been presented in the previous section. In the future, the simulation results would be expanded and the hardware of the charge controller would also be constructed.

Abstract—**This paper proposes a reliable fault diagnosis approach of induction motors using two dimensional (2D) signal processing techniques with acoustic emission (AE) signal. The proposed approach first converts time domain AE signals into 2D gray-level images to exploit texture information from the converted images. Then, a 2D Gabor filter with various scales and orientation angles is applied to each gray-level image to reduce abnormalities and enhance texture information, and the singular valued decomposition (SVD) algorithm is utilized to extract a feature vector, where the diagonal singular values of SVD are used as the feature vector of each fault. Finally, the texture feature vector is used as an input of multi-class support vector machines (MCSVMs) to classify each fault, where the Gaussian radial basis function kernel is utilized with SVMs to deal with non-linear fault features of the AE signal. To evaluate the performance of the proposed fault diagnosis approach, this paper uses multiple bearing defects under different noisy conditions. The experimental results indicate that the proposed approach achieves an average classification accuracy of 99.9% and outperforms conventional fault diagnosis algorithms in classification accuracy.**

Index Terms—**Texture Features, Fault Diagnosis, Gabor Filter, Singular Valued Decomposition, Induction Motors.**

I. Introduction

Texture feature extraction has been playing a significant role in fault diagnosis. Therefore, a number of researchers have worked on extracting different texture features for fault diagnosis [1]-[8]. Do *et al.* [1] proposed a texture feature extraction based fault diagnosis model, where a scale invariant feature transform (SIFT) algorithm was used to extract texture information. As the SIFT is invariant to image rotation, translation and scale variation and partially invariant to illumination changes, coefficient diagnosis of motor faults was expected even in the presence of background noise. However, the major drawbacks of the SIFT include: (i) uncertainty in the number of keypoints for different images, and (ii) high computational cost for the processing of 128-dimensional feature descriptors. Shahriar *et al.* [4] proposed local binary patterns (LBP) based texture fault diagnosis model, where LBP provides a binary code for each pixel of an image that is calculated by thresolding the local neighbours at the gray level of the pixel of interest. However, due to the non-adaptive selection of the number of neighbour pixels and radius of the LBP operator, it is not robust to extract features from the images. Dinh *et al.* [5] proposed a 2D fault diagnosis model, where the authors used dominant pixels using the Gaussian distribution function to extract the texture features. Although this algorithm is very simple and has low computational complexity, the non-adaptive selection of derivatives order and threshold value in the Gaussian radial function effects on the fault classification degradation. Jia *et al.* [7] proposed a fault classification model using a global neighbourhood structure (GNS) map, where GNS maps were calculated by averaging the local neighbourhood structure (LNS) map of central pixels. The non-adaptive selection gap between central pixels, size of searching window, and neighbour window are the major drawbacks in this model, which may decrease the classification accuracy.

To overcome of these limitations inherent in the conventional algorithms, this paper proposes a reliable texture feature based fault diagnosis model, where a 2D Gabor filter is utilized to remove abnormalities in the converted gray-level images and SVD is used to extract the significant information of the Gabor filtered image. Finally, an MCSVM is used to classify each AE fault of an induction motor.

The rest of this paper is organized as follows. Section II describes more details about the proposed fault diagnosis approach, and Section III presents experimental results and analysis. Finally, Section IV concludes this paper.

II. Proposed Fault Diagnosis Approach

The proposed fault diagnosis approach for multiple faults of bearing defects is composed of an optimal band selection, a gray-level image conversion, texture feature extraction, and classification. Fig. 1 shows a block diagram of the proposed approach. In this study, we use three different AE fault signals: inner, outer and roller. These AE signals were directly collected from the three different axial AE sensors attached to the surface of an induction motor. In addition, a normal bearing is used as a baseline in this study.

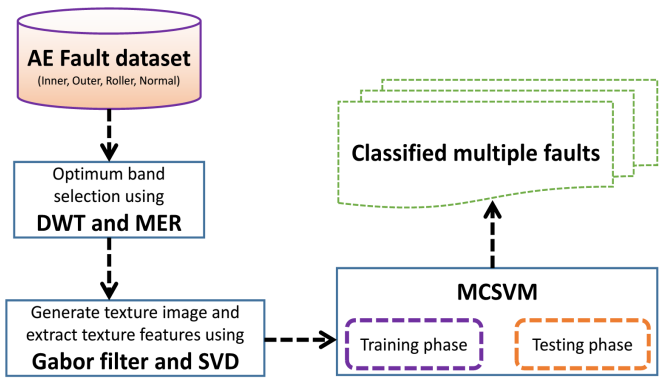

Fig. 1 Propose fault diagnosis approach based on 2D texture feature extraction.

In general, most of the AE information lies in the high frequency components, where maximum energy is located. Therefore, we apply the discrete wavelet transform (DWT) and maximum energy ratio (MER) to select the significant frequency bands. There are four different combinations of coefficients in the DWT: approximation-approximation (A-A), approximation-detail (A-D), detail-approximation (D-A), and detail-detail (D-D) coefficients [3]. In this study, we use A-D combination to select the significant frequency components because most of the AE fault information is located at the high frequency and it has the symmetric property of energy distribution. In addition, we set to 8 for the maximum level of DWT because most of the energy is located at up to 8th level. Finally, a time domain AE signal is reconstructed by selecting the optimal energy band using the MER algorithm which is expressed as:

$$Ratio_E = \frac{E_i}{\sum_{i=1}^{l} E_i} * 100 \tag{1}$$

where E_i is the energy of each level of wavelet decomposition and l is the maximum number of decomposition level.

In contrast to the conversional 1D fault diagnosis algorithms [9]-[18], the proposed 2D fault diagnosis approach can reduce noise effects and allow to use small size of input signal by converting time domain 1D AE signals to 2D gray-level images, where texture information of each fault is visible. Fig. 2 presents an example of the conversion process, where amplitude of each sample is normalized as an intensity value of pixel.

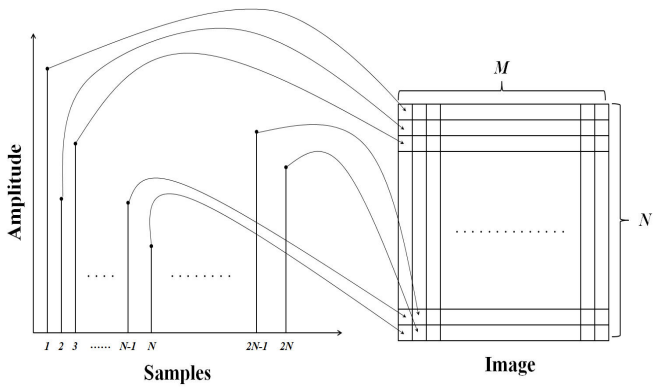

Fig. 2 An example of 1D time domain to 2D gray-level image.

Then, we apply a 2D Gabor filter with various scales and orientation angles to each gray-level image to extract the global information for each fault image. The Gabor filter has the following mathematical properties: (i) it has a smooth and differentiable shape, (ii) it does not have side lobes neither in space nor frequency domain, and (iii) it generates high-dimensional representation. Fig. 3 shows resultant texture images of different faults with and without using the Gabor filter, where the texture information is more visible by using the Gabor filter.

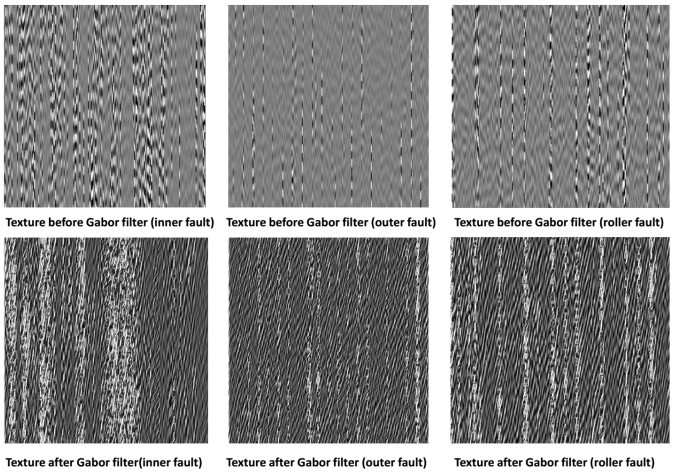

Fig. 3 Resultant texture images with and without using the Gabor filter.

We then utilize singular valued decomposition (SVD) [9] to replace a large dimensional data points with a small dimensional space and expose substructure of the original data more clearly ordering it from most variation to the least. A rectangular matrix of size mxn can be decomposed with the SVD using the following equation [9]:

$$A_{mn} = U_{mm} S_{mm} V_{nn}^T \tag{2}$$

where $U^T U = I$, $V^T V = I$; the columns of U are orthonormal eigenvectors of AA^T, the columns of V are orthogonal eigenvectors of $A^T A$, and S is a diagonal matrix containing the square roots of eigenvalues, $\sigma_1, \sigma_2, \sigma_3, ...\sigma_m$ from U or V in descending order. The matrix S is represented as follows:

$$S = \begin{bmatrix} \sigma_1 & 0 & 0 & 0 & 0 \\ 0 & \sigma_2 & 0 & 0 & 0 \\ 0 & 0 & . & 0 & 0 \\ 0 & 0 & 0 & . & 0 \\ 0 & 0 & 0 & 0 & \sigma_m \end{bmatrix}.$$

Since singular values of SVD contains meaningful information of the 2D space, we decompose SVD with each Gabor filtered image and collect a feature vector considering the singular values only. In this study, the size of each feature vector is 512, where the converted image size is 512x512.

III. Experimental Results

The use of a real dataset is important in the performance evaluation of the fault diagnosis approach. In the experiment, we set a test rig, as depicted in Fig. 4. We made physical cracks in different locations of the induction motor bearing and recorded AE signals using AE sensors. To make cracks on the surface of the bearing, a diamond cutter bit and air speed grinding tool were used. In our experimental dataset, each fault has 90 different signals. The length of each signal is 0.5 second and sampling frequency of each signal is 1MHz. Each SVM was trained with 50% of total dataset and the rest of the dataset were utilized for testing. Table I presents detailed statistical information of the AE fault signals.

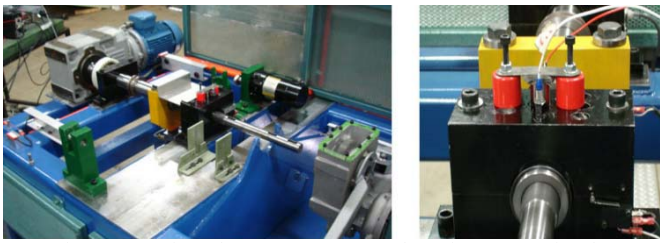

Fig. 4 A test rig and AE sensors to record continuous AE signals.

TABLE I
STATISTICAL INFORMATION OF AE FAULT SIGNALS USED IN THIS STUDY

Parameters	Values
Operating frequency	15
Slim ratio	1
Rotation per minute	900
Maximum display frequency	900
Outer defect frequency	78.6285
Inner defect frequency	116.3715
Roller defect frequency	74.5980

In this study, we evaluate the performance of the proposed fault diagnosis approach in terms of classification accuracy, where classification accuracy is measured with respect to true positive (TP). TP is the number of faults in class i that are correctly classified into the class i. In addition, we utilize a multi-class support vector machine (MCSVM) as a classifier, which consists of four distinct SVMs, as presented in Fig. 5.

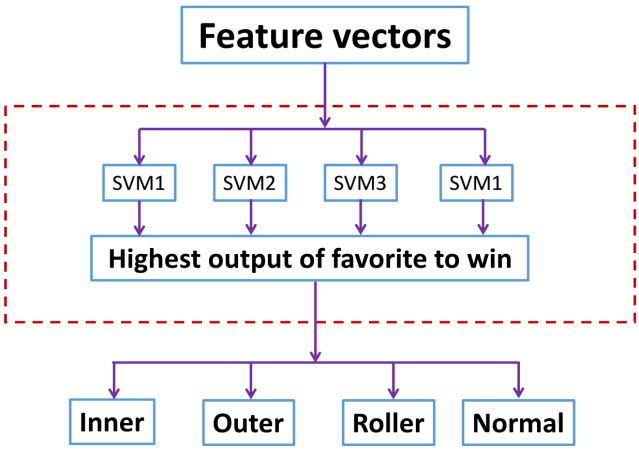

Fig. 5 One-against-all MCSVM for classifying multi-faults into the appropriate fault category.

SVM can work as a non-linear classifier with numerous kernel functions, such as polynomial, Gaussian radial basis function, fisher, graph and string kernels. In this study, we uses the Gaussian radial basis function kernel in each SVM due to its simplicity and dynamic non-linear classification capacity since numerous statistical information of AE signals overlaps with each other and we need to use a non-linear classifier to separate the numerous faults based on the statistical parameters, as shown in Fig. 6.

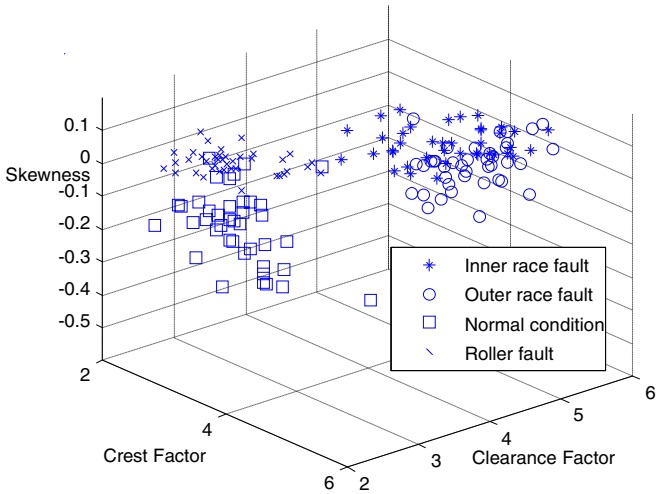

Fig. 6 Nonlinear properties of different AE fault signals.

Table II shows the results of the proposed fault diagnosis approach. The proposed approach achieves 100% classification accuracy with the experimental AE fault dataset except for the inner case in which 99.3% classification accuracy is achieved with the proposed approach.

TABLE II
CLASSIFICATION ACCURACY OF PROPOSED MODEL WITH DIFFERENT SNRS

SNR	Inner	Outer	Roller	Normal
No noise	100	100	100	100
20dB	99.3333	100	100	100
15dB	99.3333	100	100	100
10dB	99.2444	100	100	100

In addition, we compare the performance of the proposed model and other conventional fault diagnosis algorithms with respect to classification accuracy. Table III presents classification accuracy of the proposed model and two other conventional models.

TABLE III
CLASSIFICATION ACCURACY OF THE PROPOSED APPROACH AND OTHER STATE-OF-ARTS ALGORITHMS

Models	Inner	Outer	Normal	Roller	Average
Nguyen et al. [5]	84.72	93.06	100	100	94.445
Kang et al. [6]	99.41	100	100	93.89	98.325
Proposed approach	99.56	100	100	100	99.89

Nguyen *et al.* [5] proposed a fault diagnosis algorithm using a texture feature extraction technique, where texture feature information was extracted by selecting dominant pixels only. The authors used *n*th-order partial derivatives of the Gaussian function and the number of significant pixels depends on the order of partial derivative and threshold value. In that model, optimal selection of the parameters is significantly important to control the classification accuracy. Kang et al. [6] proposed a fault diagnosis algorithm using short-term energy (STE) with SVD to classify the fault signals of an induction motor. The authors divided each time domain signal into a number of subparts and measured STE of each subpart STEs. Then, feature vectors were extracted from the decomposed image with the SVD. Although the method exhibited improved performance compared to other conventional methods, it still misclassified for a few fault signals that the energy distributions of these fault signals are

quite similar. Overall, the proposed approach outperforms other fault diagnosis algorithms for all the cases in classification accuracy.

IV. CONCLUSION

This paper presented a reliable fault diagnosis approach based on the 2D signal processing techniques. In this study, time-domain AE signals were first converted into 2D gray images to exploit texture features from the converted images of each faulty AE signal. Feature vectors were then extracted by decomposing SVD with a 2D Gabor filer. As singular values of SVD contain significant information, we calculated feature vectors of numerous faults by considering the diagonal single values of SVD. Finally, using the distinctive features as inputs, an MCSVM identified each fault of the induction motor. The experimental results indicated that the proposed approach exhibited average 99.89% classification accuracy for our AE dataset and outperforms other conventional algorithms.

Laboratory-Based Project-Oriented Introductory Course for Electrical Engineering

Wayne Blanding[1,*] and Kala Meah[1,*]

[1]Electrical and Computer Engineering, York College of Pennsylvania
York, PA, USA
[*]wblandin@ycp.edu; [*]kmeah@ycp.edu

Abstract—**Based on evidence from assessment data and in discussions with engineering employers, the Electrical and Computer Engineering program at York College of Pennsylvania saw the need to revise its freshman engineering experience. This paper describes the need for this new course and discusses the architecture and pedagogy of the course. Of particular interest were the goals of ensuring all students developed proficiency in operating basic electric/electronic test equipment, skills in basic DC circuit analysis techniques, exposure to a broad range of electric/electronic devices, and introduction to fundamentals of engineering design. Consequently the course was primarily laboratory based and project oriented.**

Index Terms—**engineering education, freshman engineering experience, electrical engineering, engineering design.**

I. Introduction

York College of Pennsylvania is a small, private college in south-central Pennsylvania, USA. It is primarily an undergraduate school with a wide variety of majors. Its engineering programs include Mechanical, Electrical, and Computer Engineering all of which are ABET [1] accredited.

Prior to the course revision described in this paper, all engineering programs had identical course requirements in the freshman year, which included a two-course sequence introducing students to engineering as a discipline and exposing students to all three engineering disciplines offered at the college. These courses were primarily project-based and hands-on.

As part of this curriculum revision, the essential elements of the original two-course sequence were repackaged into a single course offered in the fall of the freshman year and incorporated the essential learning objectives of these courses (computer-aided drawing, introduction to each engineering discipline, introduction to the machine shop). The Mechanical Engineering students then split from the Electrical and Computer Engineering students in the second semester of the freshman year to their own introductory courses, Introduction to Mechanical Engineering and Introduction to Electrical Engineering.

This paper describes the driving factors that led the Electrical and Computer Engineering (ECE) majors to make this curriculum change, the organization and structure of the new Introduction to Electrical Engineering course as a laboratory-based and project oriented class, and provides initial information regarding the instructor assessment and student feedback from the first offering of the class to students.

II. Course Requirements and Structure

This section describes the needs which motivated the development of this new course, the course outcomes that were defined as the curriculum was developed, and the vision for the organization of the course.

A. The Need for a New Course

The Electrical and Computer Engineering program had maintained the original two-semester common curriculum with the Mechanical Engineering program since its inception in 2006. By 2011 sufficient assessment data was obtained to reveal areas where the curriculum could be strengthened. Specifically:

1) *Test Equipment Proficiency*: The introductory electrical engineering course which teaches DC and AC circuit analysis techniques occurs in the spring sophomore year in the curriculum. Course instructors in their assessment reports noted that lack of student proficiency with basic test equipment (multimeter, power supply, function generator, oscilloscope, breadboarding) hindered the laboratory component of the course and resulted in less productive activity being accomplished during laboratory periods. If students had this proficiency entering into this class, student learning of the essential concepts of DC and AC circuit analysis could be enhanced.

2) *Engineering Design Experience*: As originally structured, the Electrical and Computer Engineering programs contained an introduction to engineering design in the freshman year but had limited opportunity for any significant engineering design projects until the major Capstone design experience in the senior year. The Capstone design experience is the culminating design experience for students in which they spend a year working as part of an interdisciplinary project team of 12-20 working on an engineering design and construction project. Course instructors noted in their assessment reports that students entered into the first Capstone design course underprepared and needed several weeks to gain an understanding and appreciation of the engineering design process. Loss of this time at the start of the course limited the team's progress in that first semester, which pushed activities into the second semester leading to a crisis management mentality by the end of the second semester. If students had opportunity to engage in a shorter design project early in the junior year to learn about the design process, then the Capstone design course could more effectively achieve its instructional goals.

3) *Engineering Can Be Fun*: A key factor in retaining engineering students after the first year is a sense of connection with the discipline, a sense of enthusiasm about a career in engineering, and a sense that engineering can be fun. Fundamentally students need to have some external motivation to be able to push through the challenges and difficulties they will face in pursuing an engineering degree. This requirement was developed in an effort to improve first-year retention within the major, defined as the ratio of the

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

number of students who returned for the start of their sophomore year compared to the number who initially enrolled as freshman. For the four years prior to this new course coming on-line, the first-year retention averaged 65%.

B. Course Outcomes

In order to address the issues discussed in section *A* above, the new Introduction to Electrical Engineering course needed to have a heavy hands-on focus, where each student in the class got nearly daily hands-on practice in building and testing circuits using test equipment. Consequently the new course was structured as a two-credit hour laboratory course meeting for six hours each week.

The new course also brought forward some of the basic DC circuit analysis techniques previously taught in the sophomore-level circuits class. The effect of bringing forward this material opened up room in a junior-level circuits class to engage in a 4-week design project to introduce students to engineering design in a more formal and rigorous manner than that introduced in the freshman year.

The new course, being about 70% hands-on with laboratory activities and projects, was also intended to positively motivate students to remain in the major and to give students the sense that engineering work can be fun.

With these overarching goals laid out for the new course, a set of course outcomes were established. These course outcomes support the student outcomes established for the Electrical and Computer Engineering majors which are the (a) through (k) student outcomes from Criterion 3 of the Criteria for Accrediting Engineering Programs, published by the Engineering Accreditation Commission of ABET.

Following completion of the Introduction to Electrical Engineering course, students should (letters in parenthesis indicate student outcomes (a) – (k)):

- Be proficient in the use of electronic test equipment (multimeter, power supply, function generator, oscilloscope) (k)
- Conduct, analyse, and interpret results from an experiment (b)
- Be proficient at drawing, reading, and interpreting a circuit schematic (g)
- Be familiar with the content and use of component data sheets and is able to extract needed information from data sheets (g)
- Be proficient in applying circuit analysis techniques to solve circuit models containing voltage sources, current sources, and resistors (a)
- Be familiar with the functions, use, and typical applications of other circuit elements (a)
- Be familiar with the engineering design process and is able to perform an engineering analysis and design of a simple engineering design problem (c)

C. Course Organization

The course was organized to meet three times a week, for two hours at each class session in one of the electrical engineering laboratories. During each class session a variety of methods were used to deliver educational content to the students and involved some combination of instructor delivery of information to the students, student individual or group problem-solving work, individual hands-on laboratory work, and group (two-person teams) project-based work. Typically from two to four activities were planned for each class session.

For the initial offering of the course in Spring 2014, out of the 41 class days scheduled, the class engaged in laboratory work for 18 of the first 22 class sessions. During this time students also developed skills in DC circuit analysis techniques. The final 15 class sessions (5 weeks) of the course were broken up into a two-week project illustrating the engineering design process and a second three-week project where students in teams of two designed and built a device to customer specifications.

Evaluation of student knowledge consisted of a combination of in-class and out-of-class worksheets, laboratory reports, four hour-long exams, the two projects, and a hands-on practical exercise as the “final exam” for the course. The hands-on practical exercise consisted of a timed laboratory experiment requiring students to breadboard a simple circuit and demonstrate proficiency in the use of each piece of test equipment used by students in the course.

III. Laboratory Exercises

The laboratory work was a key focus of the course in terms of ensuring that students developed proficiency in use of test equipment. For this reason, the course was designed such that students worked individually in the laboratory exercises.

Laboratory exercises were written for a variety of intents and purposes including:

- Learning the use and operation of a particular piece of test equipment
- Exploratory labs investigating a theoretical topic before the theory is presented (e.g., series and parallel equivalent resistance rules)
- Confirmation labs designed to illustrate a theoretical topic after the theory is presented (e.g., Kirchoff’s Voltage and Current laws)

This mixture of laboratory types was intended to provide variation in how topics were developed in the class and to retain student interest/motivation.

The time at which a lab activity was performed was also varied—sometimes the lab exercise occurred at the beginning of class, at other times the laboratory exercise occurred mid-class or near the end of class.

As this course is the student’s first exposure to engineering laboratory activities, the laboratory handouts were highly structured. The philosophy of the Electrical and Computer Engineering program is to develop student laboratory writing skills over a number of courses, with each course providing a scaffold for subsequent courses in terms of expectations.

For this course, the laboratory handouts included a set of analysis questions leading students through the thought process of analysing the data that they have recorded and noting potential sources of experimental or measurement errors. The intent of these structured questions was to expose the student to the thought process needed to independently and without prompting analyse the results of an experiment in a subsequent course.

The final question for each laboratory exercise included a reflection prompt forcing students to engage in critically thinking about what they learned from the experiment and how the experiment relates to real-life phenomena.

IV. Projects

This course includes two projects to facilitate students’ experience on brainstorming, component selection, subsystem

development, system integration, packaging, and documentation while solving real world engineering problems. Project I and II durations were two weeks and three weeks, respectively.

A. *Project I—Assistive Technology for Disabled Individual*

This project idea was adopted from IEEE real world engineering project (IRWEP) library [2] and modified to provide a real world experience in the classroom. Students were asked to fabricate a device for a person with severe apraxia. This person is unable to interact independently with outside world. Occupational therapist examination reveals that only reliable movement of the patient is the hip which lifts the left knee. The objective of this device is to provide the patient an ability to turn on/off a portable fan. The original IRWEP design was on breadboard and uses a relay with 3 V signal power supply. This project packaged the product as a standalone battery operated device with an on board voltage regulator to satisfy the need of various voltage requirements. The relay was replaced with a semiconductor switch. This was a group project and each group consists of two students. A functional block diagram of this project is shown in Fig. 1. ADXL335 accelerometer was used to sense the movement of the knee. Expected inputs and outputs of each block were discussed in the class and students were provided with circuit diagrams. The objective was to teach students how electronic component processes input information to provide the required output. System integration and user interface were discussed to emphasize user friendliness of the device. Students' responsibility was to build and test each subsystem on a breadboard separately to ensure the expected input and output relationships. Once all subsystems were tested appropriately, students were asked to integrate all subsystems and to test for overall system performance.

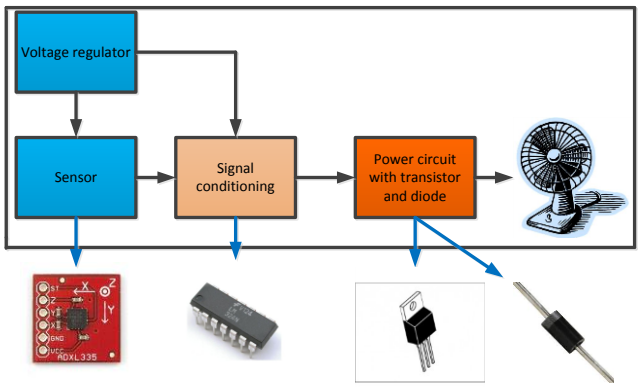

Fig. 1 Functional block diagram of project I.

After the successful testing on the breadboard, packaging was the final step for project I. Students were provided with packaging materials. The machine shop was also available for use. The device was required to have an on/off switch, an adjustment knob, and connecting terminals for the fan and power supply. A finished product of project I is shown in Fig. 2. Ten of the 15 devices produced by students worked perfectly. The remaining devices worked on the breadboard, but failed to work correctly when packaged.

B. *Project II—Let There Be Light*

Project II was an open ended problem with specific customer requirements. Students were asked to develop an inexpensive, reliable, clean, safe, and efficient source of light for people in under-developed countries who currently do not possess it. This project was adopted from IEEE real world engineering project (IRWEP) library [3] and modified to provide a project design experience with real world constraints to freshman engineering students. The original IRWEP design narrowed the component selection by asking students to use LED, photoresistor, and battery. This design project asked students to select components based on the problem statement, constraints, and their analysis. This project packaged the product with a simple on/off switch to make it a turn-key device.

1) *Problem Statement*: A remote village of 500 people has limited access to electrical power and, as a result, the village homes are lit with candles and kerosene lamps after dark. The villagers share a common solar collector in the village square. This centralized power source can be used to charge portable electronic devices during daylight hours. The objective of this project is to develop a prototype portable lighting system that is cleaner and safer than kerosene lamps. The device will be charged during the day in the village square and is to provide enough light for a villager to read for a minimum of two hours at night. Each team represents a company who will bid on this project. As part of the bidding process, each team must design and build a prototype according to the project specifications below. Each team is in a competition with other teams, and so should consider design ideas to be proprietary. The device should be: low cost, reliable, energy efficient, easy to recharge, easy to operate, safe to use, environment friendly, and durable. Each team had a budget of $50.00 and in house resources such as a stockroom containing standard parts, the machine shop, and a 3D printer.

Fig. 2 A finished product of project I.

2) *Project Planning and Execution*: This was a three-week long project and students were provided with a day-by-day schedule starting with brainstorming, design concept, and finishing with final project presentation, report, and device. Fig. 3 shows some of the devices that students developed as a part of project II. There were 14 devices and all of them were functional and met the requirement of two hours reading time.

V. Outcome Assessments

Proficiency in electronic test equipment use, conducting experiment and gathering data, and engineering design were the driving factors leading to development of this course. Throughout the semester instructors observed students and helped them to achieve the above skills. The end of semester practicum test was used to gauge students' ability to use

equipment/component to build a circuit on breadboard and to collect appropriate data. More than 80% students satisfied this requirement.

Fig. 3 Efficient light sources developed by students.

ABET requires continuous assessment and improvement of engineering courses for a successful accreditation. Electrical and Computer Engineering program at York College of Pennsylvania developed a strategy to complete an outcome assessment rotation in every three years. As a part of this process student outcome (c)—an ability to design a system, component, or process to meet desired needs within realistic constraints such as economic, environmental, social, political, ethical, health and safety, manufacturability, and sustainability use assessed on project II using performance indicator c.1—Designs a system, component, or process to meet desired needs within quantitative constraints. Table I shows the assessment rubric with student achievement.

TABLE I: Student Outcome Assessment

Assessment Rubric			
Attribute	**Exceeds Expectations**	**Meets Expectations**	**Below Expectations**
Project design quantitative specifications: Design a lighting source to operate for at least 2 hours and provides sufficient light for a person to read at night	• Final design met the 2-hour lifetime specification • Final design met the illumination specification • Engineering analysis was correct and supported actual performance	• Final design met the 2-hour lifetime specification • Final design met the illumination specification • Engineering analysis had flaws resulting in an incorrect expected source lifetime	• Final design did not meet one or both specificati ons.
Student Achievement			
Number (%) of teams:	6/14 (43%)	8/14 (57%)	0/14 (0%)

VI. Student Feedback

Student feedback is an important part of the process to develop and improve an engineering course. During this first time offering instructors regularly sought student feedback to adjust and improve the course material to benefit students' learning. Students were surveyed anonymously twice to gauge their interest in course materials and learning abilities. The final survey included three parts: overall course, project I and project II. 23 students out of 28 returned the final survey. Fig. 4 shows survey questions with student's feedbacks for the overall course. Survey results show that majority of students enjoyed and learned the materials while having fun doing so.

Students were also asked to list 3 things they like about the class/course and to list 3 things they do not like about the class/course. Here are some highlighted responses from students:

A) 3 Things Students Like About the Class/Course

- Projects were very fun and rewarding,
- Frequent labs and homework helped me remember the materials,
- Real-world applications through projects,
- Many hands on opportunities.

B) 3 Things Students Do Like About the Class/Course

- Homework problems were hard,
- Could not pick partner for the second project,
- Sometime lab felt rushed. Should be a 3-credit course,
- Too early in the morning.

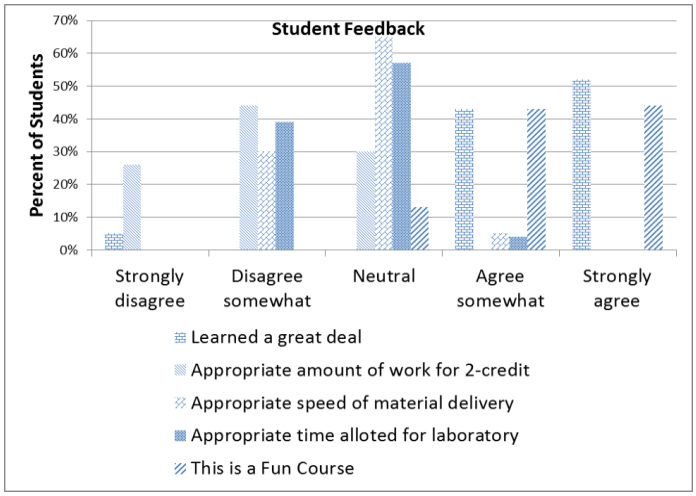

Fig. 4 Students' feedback on the course.

VII. Conclusion

This introductory course for electrical engineering was successfully developed and taught for the first time. The objective of the course was achieved through hands on laboratory work and solving real-world problems with projects. Survey results showed that students were engaged and learned the course materials while having fun. The greatest challenge of this course was to show the freshman electrical and computer engineering students the link between theory and application. Students' outcome assessment and feedback show that this course successfully created that link and kept the students' interest high in engineering education.

Abstract—**In traditional classroom setting, lecturing is the prominent method of transferring knowledge to students. However this passive mode of instruction does not keep student engaged and interested longer in the class. Although mobile devices are used extensively in everyday life and have a bad reputation of creating distraction during class, it can be used to make student's class participation more interactive and engaging. This paper presents one such approach, which is fundamentally different than existing ones by allowing students to participate in active learning during class session by using their mobile devices. This research envision interactive problem applications which will run in student mobile devices, which faculty can initiate remotely and where student can actively participate to solve problem in a hands-on manner. This paper presents the development of a Karnaugh map interactive mobile application and its incorporation into Mobile Response System.**

Index Terms—**Active learning, Interactive problems, Hands-on activities.**

I. Introduction

In a traditional face-to-face classroom setting, if faculty is only using lecturing to deliver course material, they will loose attention of many students, minutes after the class has begun. In recent years, classes in Science, Technology, Engineering and Mathematics (STEM) courses faced a significant learning barrier, which is the problem of students' inability to keep engaged and interested in classroom. Particularly the proliferation of mobile devices in daily life and its use during the class makes this problem exacerbated. In this research, we explore the applicability of using mobile devices in the classroom and incorporation of interactive problem solving using those devices to increase class engagement and active learning for students. By allowing the students to solve hands-on problems in their preferred devices will create a friendly learning environment where students want to remain, be active and be skill full. This paper presents one such interactive problem (IP) application (app) designed to be deployed using the Mobile Response System (MRS) [1]. This app facilitates Karnaugh map (k-map) simplification for students by allowing them to interact with the problem at hand. Faculty can define the k-map problem using a server side tool and use the MRS backbone to initiate a hands-on session during class time in student's mobile devices. This paper presents ways to develop IP app and ways to incorporate that IP in the MRS software.

II. Background

There has been a plethora of research work performed to address the lack of student engagement and motivation during class time. However, the research presented in this paper is different because along with providing a mobile interactive problem-solving platform it also provides a teaching methodology that goes hand-in-hand with this software tool.

A. Teaching Methodology

To improve student learning in the STEM disciplines, we need evidence based teaching and learning methods [2]-[4], which is based on constant monitoring of outcomes from assessment and resulting continuous improvement of the applied method. Study shows that in order to improve student learning in the STEM disciplines, traditional pedagogical approaches are not enough to transfer critical knowledge to students. A feedback driven, evidence based teaching and learning technique has to be devised and implemented in our classes to transfer knowledge to students. One of the key factors of such evidence based teaching methodology is for students to actively participate in class and receive instant feedback about their performance in such hands on activities. In that regard, evidence based teaching methodology was incorporated and assessed for couple of semesters. The findings [5] from that study and student's use of mobile devices during class time has encouraged us to developed this interactive problem solving teaching methodology. As several other [6]-[7] research works have shown that using technology during class can improve student's learning abilities, we are confident that the presented teaching tool will also have positive impact on student in-class engagement and problem solving skills.

B. Mobile Response System

To facilitate interactive problem solving in real-time manner, a comprehensive backend system is necessary. To satisfy requirements for interactive problem solving, a Mobile Response System is developed, which is independent of any interactive problem or its domain and transparent to the end user. MRS is a client-server software that allows the faculty to dynamically prompt the students with interactive problems synchronized with the lecture material in their mobile computing devices (Clients). Students are then able to actively interact with the problem through multiple steps and send their work back to the faculty computer (Server). MRS then performs grading of the exercises, by using the provided rubric. The other important features supported by MRS are immediate and context-sensitive feedback, anonymous question, polling, summarized grading etc. More information about MRS can be found in [1] and [8].

C. Interactive Problem (IP)

An IP is one, where students have to devise the answer following a set of steps and by following a particular algorithm/process. In each step, students have to make key choices that will have impact on the next step of the interaction. During these interaction steps, students can go back and forth and change their answer. This will allow them to see what is the affect of different selection on the result and

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

how every piece fits together. Problems can be started bottom up or at the middle to give students different perspective on the problem and assess their problem solving skills. Only after the student traverse each of the steps or the allotted time to answer a problem runs out, the result of their interaction is sent back to the server as the answer of that student. Each problem has a rubric that not only grade correct answers but also partial answers to gauge student's problem solving skills and thinking models. Each IP has two different components. One at the server side to define the problem and other at the client-side to allow students to interact with the problem. In the server side, the intended problem and the rubric have to be defined by using the MRS standard protocol. On the client side, an app needs to be developed to allow corresponding interactive-ness. MRS provides corresponding Application Programmer Interface methods to convert user provided definition into the corresponding MRS format. Different parts of the format are as follows:

- *Question type*: It must match the Android package name of the client side interactive app and the package name of the server side program for that IP.
- *Question number*: Any number or word, as long as there is no other definition with the same question number.
- *Time to Answer*: Have to be expressed in seconds (which in turn is converted to milli-seconds for better time keeping) with the lower limit of 0 and with the upper limit of the maximum value allowed in a long variable.
- *Instruction/Description*: Any instruction or description associated with this IP. This is optional.
- *Problem Components*: Any number of components needed to render the corresponding IP app on the client.
- *Rubric Components*: Any number of components needed to process the answer of the student and what background information from the IP app should be monitored. The number of problem component and the number of rubric component can be different and has no upper value.

D. Related Work

Different studies [9]-[10] have found the benefits of using mobile devices in classrooms and in recent years, there has been a plethora of work [11]-[12] performed to incorporate mobile devices in classrooms. However, these works are traditional in nature and lack the interactive-ness needed in todays engineering classrooms. In Science and Engineering courses, students need to actively solve problems by interacting with the problem in a hands-on approach. Students cannot develop skills such as synthesizing a problem and developing critical thinking only by using multiple-choice or true-false questions. It is our belief that by presenting the problems as interactive entities, where students can actively play with the problem to solve it; we will be able to improve student's critical thinking and problem solving skills. Although there has been a lot of work on algorithm animation and visualization, there are hardly any [13] interactive tools for supporting k-map simplification as presented in this paper.

III. Interactive Problem App

To utilize MRS for facilitating interactive problem solving, one needs to follow several sequences of steps and some simple rules as shown in Figure 1 and described in the following sub-sections. Although the K-Map problem is used as an example to describe the process, the MRS software is developed independent of any problem domain. This allows it to be used by any one as long as they follow the described process and develop their own interactive problem and its rubric.

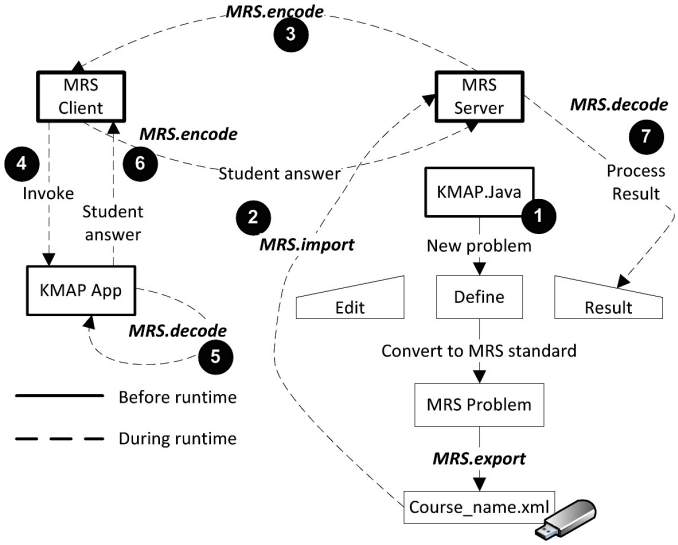

Figure 1. Component organization and workflow.

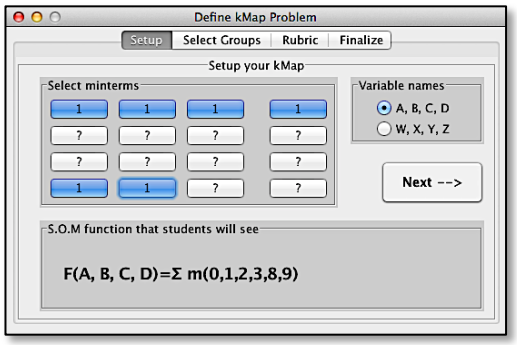
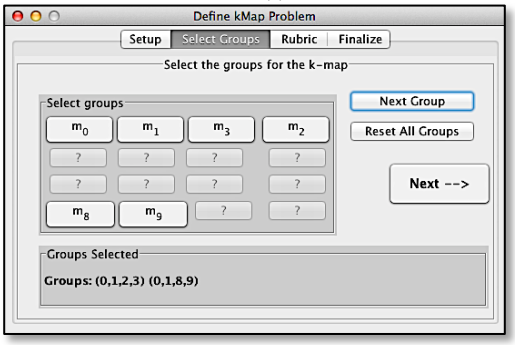
- *Step 1*: In this step, the IP has to be defined following the MRS protocol as described in Section II.C. If a server side program is written by the user to define the IP instead of defining it by hand, following rules needs to be followed:
  - The program should be in a package with the same name as the package of the IP app and the corresponding question type.
  - The program should have three methods, *define*, *edit* and *result* so that MRS can dynamically call them for corresponding functionality; i.e. *define* to define a new problem, *edit* to edit an existing definition and *result* to process student answers and produce corresponding graphical representation.
- *Step 2*: Once the IP is defined and saved in the storage as a XML representation, it can be imported to MRS by using the MRS GUI, which uses ***MRS.import*** to read the IP definition on the file. One file can have multiple types of IPs in it with unique question numbers.
- *Step 3*: Faculty uses the broadcast button in MRS to broadcast the IP definition to clients and MRS uses the ***MRS.encode*** to broadcast it to all available clients. In encoding and broadcasting, MRS does not include the rubric components of the definition.
- *Step 4*: Once the MRS client receives the encoded definition, it finds the corresponding IP app (by matching the question type with the app package name) and invokes it with the encoded definition as an Android Intent [14] with the key "QUESTION".
- *Step 5*: Once the IP app is invoked, it needs to get the encoded question with the key "QUESTION" and then use the ***MRS.decode*** method to convert it to the workable definition format.
- *Step 6*: Once student submit an answer or the time to answer the problem runs out, the IP app will quit and return the student response/result as Android Intent to MRS with the key "ANSWER". Once MRS client receives that Intent, it forwards that contained message back to the server using ***MRS.encode.***
- *Step 7*: MRS server locates the server side program to process the result and invokes the *result* method.

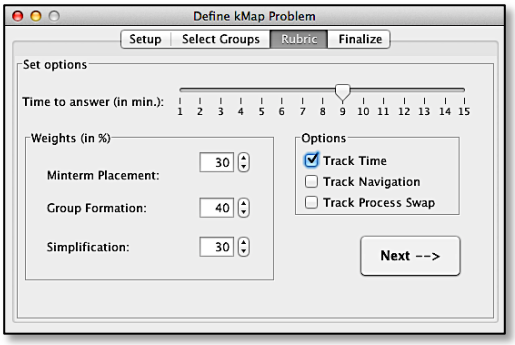
A. Server Side



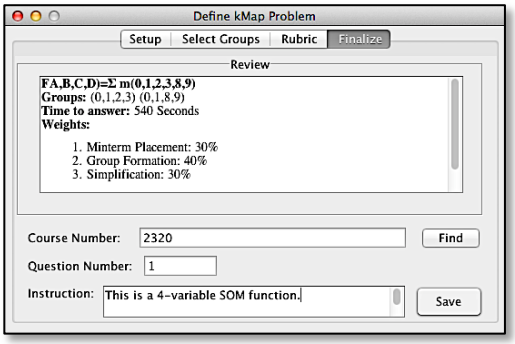
(a)



(b)



(c)



(d)

Figure 2. Defining the k-map IP.

For the k-map IP, at the server side a GUI-based program is designed for easy design of a problem. It follows a sequence of intuitive steps for the user to define a K-map IP. As shown in Figure 2 (a), faculty can choose their min-terms for the expression to be simplified and then choose the valid groups (Figure 2 (b)), set different parameters for problem solving and how it will be graded (Figure 2 (c)) and finally can review (Figure 2 (d)) the problem before saving it to the file. In each step, corresponding validity checks are made to make sure faculty is producing a correct k-map problem. For instance, when selecting groups, faculty will be prompted if the grouping does not follow any allowed rules of the algorithm.

Once the faculty saves the IP definition, it looks something like Figure 3. MRS uses a simple XML schema, which is space saving and faster to decode and manipulate. If faculty do not want to design a GUI, they can use any text editor to define their IP following the definition scheme and the XML schema.

```
<q_type>edu.wssu.kmap</q_type>
<q_num>2</q_num>
<q_time>540000</q_time>
<q_inst>Sample kmap problem</q_inst>
<comp_num>2</comp_num>
    <comp>SOM 0, 1, 2, 3, 8, 9</comp>
    <comp>Variable Names: A,B,C,D</comp>
<comp_num>7</comp_num>
    <comp>Groups |(0,1,2,3) (0,1,8,9)</comp>
    <comp>Placement weight: 30%</comp>
    <comp>Grouping weight: 40%</comp>
    <comp>Simplification weight: 30%</comp>
    <comp>Track student time: true</comp>
    <comp>Track student navigation: false</comp>
    <comp>Track process swap: false</comp>
```

Figure 3. IP definition as saved in the file.

Now, faculty can use the MRS server side GUI to import that problem definition and broadcast it to the available clients as shown in Figure 4. Once all student responses is received back from the clients, either a set of standard statistical tools (average, standard deviation, frequency etc.) within MRS will be used to produce the graphical representation of the student responses or the *result* method of the user definition program will be called to produce corresponding representation.

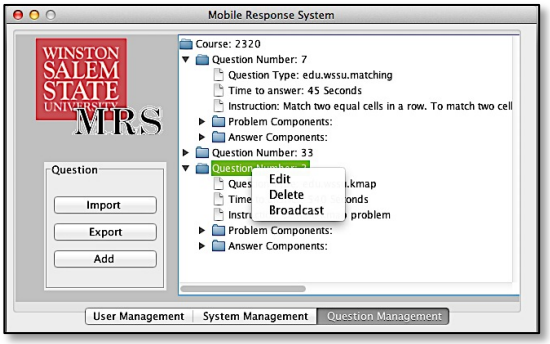


Figure 4. MRS GUI to manipulate IP definition.

B. Client Side

On the client side, students run the MRS client and use their credentials to log into the system. Once they do that, they are presented with the screen as shown in Figure 5. Students can also send anonymous questions or feedback using the client. Once a problem definition is received by the client, it finds the corresponding IP app and pass the definition to it. As shown in Figure 6, student is prompted with the given problem and the app allows the student to traverse back and forth to interact with the problem and solve it within the given time. At first, students can select cells corresponding to the equation (Figure 6(a)). This tests, whether students learned how the map is laid out and what every cell points to. Once this step is finished, students make groups with the cells following the minimization algorithm (Figure 6(b)). Students can select any cell and each group made will take a different colour (with the group number as superscript) to distinguish it from other groups. This will test whether student understands different characteristics of making groups. Next, students interact with

each group and select variables from each group (Figure 6(c)) following the minimization algorithm. This tests whether students fully comprehend the algorithm. The app checks for algorithm validity (such as grouping) with student responses but since the rubric is not sent to the clients, can never tell the student whether his/her answer is correct or not. That way, students cannot figure out the correct answer by iterations. Only after all students submitted their answer, the faculty will be able to show them the correct answer. It is completely up to the developer of such IP app on how much interaction and how many screens they want the student's to encounter during the allotted time.

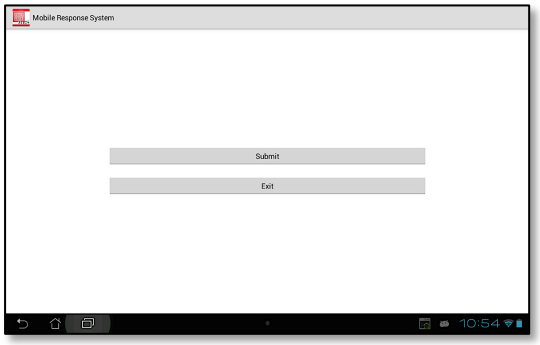

Figure 5. MRS Client.

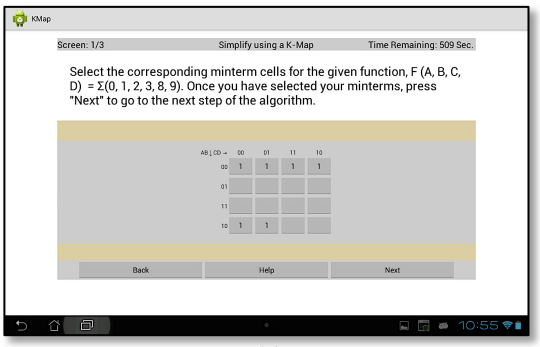
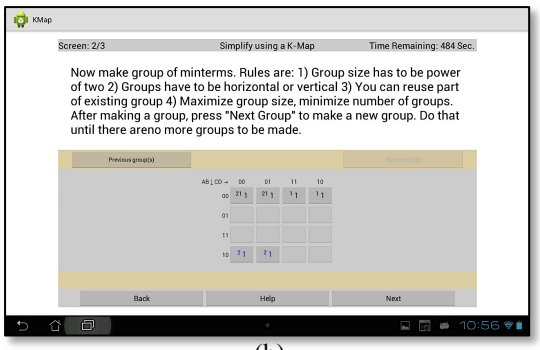
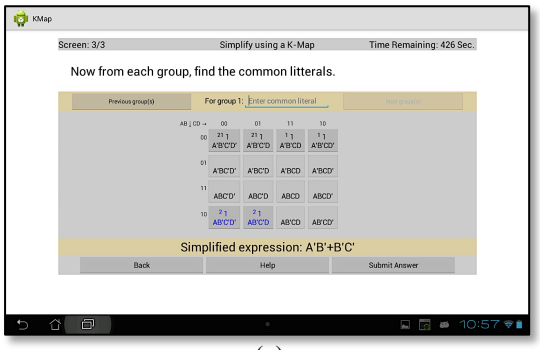


(a)



(b)



(c)

Figure 6. IP interactions.

C. *Evaluation Plan*

One sophomore level hardware organization course (offered in both semesters) is selected to assess the system in Fall of 2014. This course is a good candidate for evaluation of this approach because it assess mathematics and problem solving skills and we can incorporate several kinds of interactions during the class to enhance these skills. Also, student performance and course evaluation data for last couple of years are available to compare with the new data after deploying the new methodology. Both formative and summative evaluation is planned with the help of data collection, pre and post tests, student surveys, performance data comparisons and focus groups.

IV. Conclusions

Interactive problem solving during class time will allow students to engage and participate more on the class activities and retain more of the lecture content. This paper presents an interactive problem app and its associated components and its incorporation into the Mobile Response System software. Although not presented, software quality matrices for the developed interactive problem app are measured and they fall within acceptable range. Evaluation plan is presented which will be implemented in the future.

University-Industry Research Collaboration

Nemai Chandra Karmakar
Electrical and Computer Systems Engineering, Monash University
Clayton, VIC 3150, Australia
Email:nemai.karmakar@monash.edu

***Abstract*—University and industry research collaboration hugely impacts an academic's research career and curriculum development. The collaboration brings new prospects of research funds, real world problems and research challenges, and new ingredients in curriculum development. The collaboration also creates innovation and provides national economic benefits. The paper presents the mechanism to university-industry research collaboration.**

***Index Terms*—University-industry relationship (UIR), engagement model, intellectual property, research excellence, research impact, research collaboration, absorptive capacity**

I. Introduction

Universities make significant contributions to the economic development of a nation. A direct benefit comes from their pedagogical operations to educate and train young-adult student cohorts. In publicly-funded tertiary institutions like research universities, a major activity beyond the conventional pedagogy is research. In both developed and developing countries, governments fund research activities and support infrastructure, staff and research projects. This funding amounts to about ten billion dollars per year in the Australian context [1, 2]. OECD countries such USA, the European Union and Canada are bigger contributors of research funding as the population and the mass of economic activities are larger compared to those for Australia. In those countries, vibrant university-industry collaborations and research cultures exist [3]. In Asian developed and developing countries such as China, India, Japan, Korea, Singapore and Thailand, significant strides in research funding are observed [4]. Universities generate, share and disseminate new knowledge, train students for the betterment of national economic benefits and growth, and finally, obtain recognition. The commercial aspects of pedagogical practices such as higher degree research student (HDR) supervision and income generation from the outcomes of HDR research projects are not usually perceived as the main activity of universities. In most universities, the main income comes from students' tuition fees for teaching courses. A very small fraction of total university income comes from funded research and revenue from licensing fees for innovations. In Australian universities, most research funding comes from the federal government's nationally competitive research grant schemes. The success rates of these grant applications are as low as less as 20% [5]. Academics and researchers under the schemes focus on high quality publications to fulfil the benchmarks for excellence of research of Australia (ERA). Thus, the research outcomes of these funded projects generate publications, citations and prestige in the form of university world rankings. However, ERA also acts to deter university-industry interaction and innovation. Industry wants to protect intellectual property (IP) and products instead of producing high quality publications. IP protection works against publication and academics suffer from publication barriers when they are heavily engaged in industry-based research and innovation. The philosophies of university and industry are disparate. While the university focuses on pedagogy, the gathering and sharing of new knowledge and its recognition, industry focuses on return on investment. This gap can be reduced with innovation through collaborative research projects. However, to bring these two entities closer for the greater benefit of the national economy requires long term strategic planning.

This paper addresses these barriers in university-industry collaboration and considers how university and industry can overcome these barriers with mutual trust, by sharing cultural values and the successful execution of collaborative research projects.

II. University-Industry Collaboration

Integration between industry's needs and university research is needed for the smooth translation of research outcomes to the economic benefit of a country [6]. For research negotiation and collaboration between educational institutions and industry, the guidelines are as follows:

(i) There must be industry participation in the development of the research project to ensure its relevance. It must be updated regularly to keep abreast of the needs of the industry, particularly in areas experiencing rapid change.

(ii) The research project should provide HDR students/researchers the opportunity to acquire industrial experience via internships and design projects conducted by professional engineers and faculty members with industrial experience. There should be an industrial attachment unit to facilitate this aspect of the program [7, 8, 9].

(iii) There must be a communication channel between the educational institution and the industry, especially so that the industry can give feedback to the faculty concerned on: a) the quality of the research outcome, b) the absorptive capacity of the research outcome by the industry, and c) the relevance of the research outcomes to the global market place.

Universities suffer from insufficient links with real-world problems and narrowly focused learning objectives. Therefore, industry links are significant in the following ways:

(i) university-industry links create a real-world research atmosphere. HDR students and researchers acquire a sense of belonging to real-world problems. They see applications of their research outcomes in commercial settings, and a result, develop confidence in addressing the challenges which arise.

978-1-4799-4166-7/14/$31.00 ©2014 IEEE

(ii) The link generates IP for all parties concerned. IP generation is imperative for the sustainable development of the national economy and provides extra income for the university. The revenue from university inventions is used in activities such as scholarships for HDR students to conduct further research, upgrading equipment and facilities, and expanding university infrastructure.

(iii) Industry collaboration also brings brand names and prestige to institutions.

(iv) Industry obtains employment-ready graduates from collaborative links with universities.

Fig. 1 University offerings to businesses in collaboration

Therefore, the facilitation of linkages between industry and university with government support is crucial. An effective and sound framework similar to SBIR can enhance this drive significantly [6]. Substantial streams of external funding, enhanced opportunities for professors and graduates to work on groundbreaking research projects, vital inputs to keep teaching and learning on the cutting edge of a discipline, and the impact of delivering solutions for pressing global challenges are the key benefits of university-industry collaboration [3, 10].

Universities are huge places where teaching and research run concurrently. Universities are huge depositories of knowledge, have skilled workforces, and aim for excellence in research and state-of-the-art laboratory facilities. Therefore, universities can offer a wide range of skilled workers, resources and ideas to conduct industry-sponsored research projects. As shown in Fig. 1, universities can offer a range of facilities in university-industry interaction: (i) create talent pipeline; (ii) provide ready access to affordable and rapid resources for SMEs such as skilled workforce, equipment, lab facilities and new and fresh ideas. This leads to improved productivity of SMEs. (iii) Strong brands and international networks, (iv) problem-solving services to businesses such as desk-top reviews and initiation of collaboration, (v) increased funding support for research collaboration through government funding and internal research grants such as faculty strategic research funds, (vi) improved pitching processes to attract venture capitalists and innovators, (vii) excellence of research that creates impacts in productivity in businesses, and finally (viii) recruitment services in particular disciplines for SMEs. Therefore, SMEs greatly benefit from the collaboration. University-industry collaboration brings the following benefits to SMEs: (i) Easy access to best science at cheapest price. (ii) Easy gateway to network. (iii) Development of research culture and innovation. (iv) Joint supervision and mentoring of research students and making them employment-ready for industry. (v) Leverage of research funding and resources via university research.

From the above analysis, it is obvious that university-industry collaboration brings many significant benefits to both entities. However, there are certain barriers that hinder access to university expertise and resources by SMEs. The main barrier is the difference of perceptions of SMEs and universities. The philosophies of these two entities are very different. Industry's main priority is doing business and therefore, they focus on "*return on investment*". SMEs invite universities to collaborate in research for the following two reasons: (i) to facilitate their new product/service development; and (ii) improved productivity for cost-effectiveness and increased profit margins. Time is money for industry. The timeliness of delivery of productivity and services is imperative in the interaction. This rigidity of timeliness requires sound planning of collaboration. Usually university-industry interaction goes through a range of activities before any concrete collaboration can be initiated.

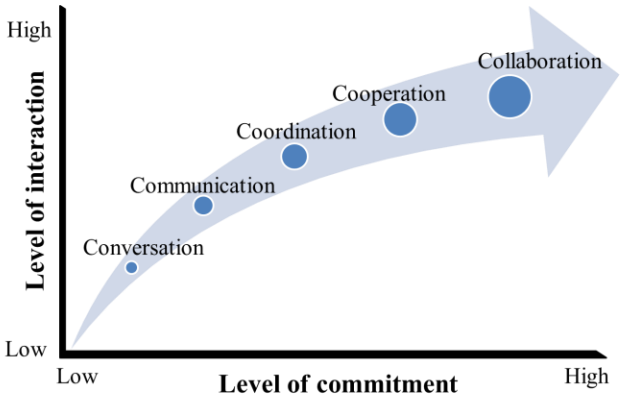

Fig. 2 Interaction and commitment levels for successful university-industry interaction

Fig. 2 shows these interactions and their levels of commitment [11]. As Fig. 2 shows, interaction between university and industry starts with very low level of negotiation in the form of conversations between key personnel. This facilitation may happen through the commercialization arm of the university or individual researchers and the marketing/engineering managers of SMEs. In this initial phase of negotiation, they come to know each other and try to find common ground and interests that may further establish communication between higher-level management and streamline discussion. After successful communication, coordination of specific thematic topics that have potential for investigation is initiated by coordinators on both sides. Usually business development managers (BDMs) and specific team members of SMEs engage in further discussions to set the topic and its specifics. A framework is established in the coordination process. The engagement model is established through this coordination process. Cooperation between the two entities facilitates the development of an engagement model with two vital ingredients of collaboration: financial commitment and research agreements. Once this phase is finalized and

successful outcomes are achieved through secured funding, the actual collaboration happens. The whole process may take a few months to a few years for university and industry to reach high-level commitment to focused and effective collaboration. The ingredients for successful collaboration are: (i) **P**atience, (ii) **P**erseverance; (iii) **P**erformance; (iv) **P**ro-activeness, (v) **P**re-condition; (vi) **P**erception; (vii) **P**articipation; (viii) **P**romotion; and (ix) **P**oliteness. These attributes are necessary for both parties concerned to initiate and execute successful collaboration.

III. REMOVING HURDLES IN COLLABORATION

Although all parties concerned—university, industry and government—understand the significance of university-industry collaboration for sustainable economic growth and improved productivity of the country, many systemic barriers hinder successful collaboration [6]. Two important reports present the impacts of university-industry collaboration in both the developed and developing worlds [3, 12]. The impacts are: financial insolvency; cultural gaps; lack of absorptive capacity of research outcomes by SMES, lack of links/knowledge/network, and finally, different time scale.

SMEs may lack understanding of the university research culture and operation, and may not know the appropriate university research group for collaboration on certain projects. New SMEs perceive universities as sub-contractors of projects, and set stringent guidelines and time-scales to deliver the outcomes of the project. These cultural mismatches in needs, goals and priorities hinder research collaboration.

The most effective approach to bridge the gap is to facilitate relationship-building through many negotiations, demonstrations of research outcomes, and inviting SME personnel to research seminars and university open days on a regular basis. Executives may offer to teach courses and develop interaction. Work placements of university graduates to SMEs and the development of research programs aligned with the needs of industry help bridge the cultural gap [7, 8]. Work placements and industrial research projects without any financial commitment encourage SMEs to bridge the cultural gap and create win-win situations for both parties. Both government and universities can offer HDR scholarships for industry-sponsored projects.

From the above discussion on overcoming cultural barriers to improve university-industry collaboration, it is apparent that both universities and industry need to work closely to understand each other's cultures and strive to remove the barriers. The driving forces for collaboration are: (i) willingness to collaborate; (ii) improved standards in SMEs and development of a sense of belonging to a larger community to build the nation; (iii) good quality assurance and benchmarking in project deliverables; and finally, (iv) preparedness for international competitiveness, which is important for the current open market economy. In the following sections, effective engagement models are described.

IV. GOVERNMENT SUPPORTED ENGAGEMENT MODEL

Fig. 3 shows the various steps of negotiations and collaboration between university and industry. Once negotiations at various levels succeed though observation, reflection, planning and action (action research), which could be motivated by *market push* or *market pull*, an engagement model as shown in Fig. 3 can be implemented [13]. After comprehensive negotiations with industry and understanding their needs and market opportunities, an academic researcher can identify a research domain.

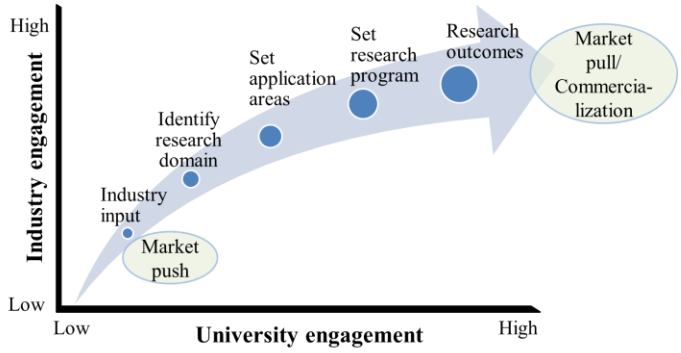

Fig. 3 University-industry engagement model

Fig. 4 shows the government-supported industry-university engagement model. Government-supported research programs often demand that university researchers secure cash and in-kind commitments from industry before lodgment of applications to funding bodies. Once these industry supports are obtained after comprehensive negotiations following the stringent engagement model depicted in Figure 4, university researchers apply for grants from the government. These grant schemes are highly competitive and internationally recognised experts review the applications. If successful, government departments such as the ARC invite researchers to execute research agreements with industry before starting the project. Industry has the right to withdraw support at any time and/or prolong negotiations to come to an agreement. This depends on the market opportunities, cash flow, changes in priorities and restructuring of innovation drives. If the research agreement is not finalised by the deadline set by the funding body, the government funding is returned to the funding body. Once the project commences, the university researchers report progress according to the milestones set by the industry partners. The researchers are required to submit annual progress reports to the funding body. If progress is not satisfactory, both industry and the funding body may withdraw support. A final report is prepared and submitted to the department and industry partner once all PhD students graduate and the funding is exhausted.

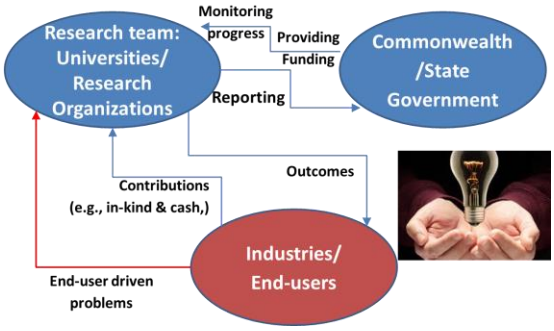

Fig. 4 Government supported university-industry engagement model

V. Conclusion and Recomendations

Improved productivity and sustainable economic growth are two key priority areas for a country to maintain her citizens' living standard and competitive advantages in the global economy. The Australian economy depends mainly on primary industries such as mining and agriculture. High technology manufacturing is leaving Australia due to the cheaper production costs in the developing world. Job losses, training people with new skills and the creation of new jobs to maintain living standards of families are the biggest challenges for Australia. Sustainable growth can only be maintained with innovation and knowledge-based economic activities. Innovations through university-industry collaboration can greatly enhance Australia's competitive advantages. SMEs make a major contribution to Australia's GDP and private sector employment. However, Australian SMEs work mainly in service sectors [14]. Developing synergies in the services and manufacturing sectors with high technology components underpins improved productivity and sustainable growth. The university-industry collaboration culture is developing in Australia but needs significant encouragement to translate inventions to innovations for business success. Some nationally-competitive grant schemes such as ARC Linkage Projects, Commercialization Australia and Cooperative Research Centres are the major contributors to research collaboration. However, the requirement of matching funds from industry, financial limitations of SMEs for R&D, cultural gaps, lack of absorptive capacity and networks, and different time-scales are key barriers to collaboration. Understanding various engagement models, ownership of IP and removing barriers in IP protection and publication through negotiation can assist the development of a conducive culture of university-industry collaboration. Irrespective of the scale of success of such research collaboration, university-industry interaction brings many tangible benefits to pedagogical practice, awareness of real-world issues, and strategic partnerships for the economic benefit of Australia. A large-scale centre for research excellence with long-term vision in a collaborative atmosphere can bring more benefits for Australian innovations. The government should develop a more comprehensive and easy-to-access research collaboration culture and support for SMEs and universities. Large profitable organizations can also play a bigger role in developing university-industry synergies. They should work collaboratively with SMEs, universities and government to facilitate university-industry engagement for the greater economic benefit of Australia.

University-industry collaboration is vital for the economic growth and competitive advantage of any country. This collaboration can be fostered and enhanced with cooperation, sound vision, planning, and execution with support from government and large profitable industries.
