**FEBRUARY 2024**

## **APPROVAL**

This Thesis titled “**A Machine Learning Approach for Early Detection and Improved Decision-Making for Lung Cancer Diagnosis**”, submitted by **KM. ZAYEDUL HASAN** to the Department of Computing and Information System, Under CSE, Daffodil International University, has been accepted as satisfactory for the partial fulfillment of the requirements for the degree of MS in Management Information System and approved as to its style and contents. The presentation was held on 03 February, Saturday, 2024.

## **BOARD OF EXAMINERS**

  
**Professor Dr. Sheak Rashed Haider Noori**  
**Professor and Head**  
Department of CSE  
Faculty of Science & Information Technology  
Daffodil International University

**Chairman**

  
**Dr. Md Zahid Hasan**  
**Associate Professor**  
Department of CSE  
Faculty of Science & Information Technology  
Daffodil International University

**Internal Examiner**

  
**Sazzadur Ahamed**  
**Assistant Professor**  
Department of CSE  
Faculty of Science & Information Technology  
Daffodil International University

**Internal Examiner**

  
**Dr. Firoz Ahmed**  
**Professor**  
Department of ICE  
University of Rajshahi

**External Examiner**

## DECLARATION

I hereby declare that, this thesis has been done by us under the supervision of **Dr. Md Zahid Hasan**, Associate Professor, Department of CSE, Daffodil International University. I also declare that neither this thesis nor any part of this thesis has been submitted elsewhere for award of any degree or diploma.

Supervised by:

**Dr. Md Zahid Hasan**  
Associate Professor  
Department of CSE  
Daffodil International University

Submitted by:

**KM. ZAYEDUL HASAN**  
ID: 222-17-528  
MS in MIS program  
Department of CSE  
Daffodil International University

## ACKNOWLEDGEMENT

First I express our heartiest thanks and gratefulness to almighty God for His divine blessing makes us possible to complete the final thesis successfully.

I really grateful and wish our profound our indebtedness to **Dr. Md Zahid Hasan** Associate Professor, Department of CSE, Daffodil International University. Deep Knowledge & keen interest of my supervisor in the field of “**Health Informatics**” to carry out this thesis. His endless patience, scholarly guidance, continual encouragement, constant and energetic supervision, constructive criticism , valuable advice, reading many inferior draft and correcting them at all stage have made it possible to complete this thesis.

I would like to express our heartiest gratitude to **Dr. Sheak Rashed Haider Noori, Professor and Head, Department of CSE**, for his kind help to finish our thesis and also to other faculty members and the staff of CSE department of Daffodil International University.

I would like to thank our entire course mate in Daffodil International University, who took part in this discuss while completing the course work.

Finally, I must acknowledge with due respect the constant support and passion of my parents.

## **ABSTRACT**

Lung cancer is presently the leading cause of cancer-related mortalities worldwide. Environmental conditions, lifestyle habits, and genetics are the main causes of lung cancer. Early detection of lung cancer is pivotal in preventing its severe consequences. The integration of machine learning algorithms in the healthcare industry has led to significant advancements in disease diagnosis. These algorithms help medical professionals diagnose lung cancer accurately in the early stages. In this study, we propose using Quadratic Discriminant Analysis to improve the accuracy of lung cancer diagnosis by analyzing the symptoms of lung cancer patients. Our proposed technique is more suitable for diagnosing lung cancer with higher accuracy and precision compared to previous techniques. The methodology has demonstrated an impressive overall accuracy of 98% based on empirical results.

# CHAPTER 1

## INTRODUCTION

### 1.1 Introduction

Lung cancer is a major public health concern and one of the leading causes of death across the globe. According to the World Health Organization (WHO), lung cancer is responsible for 18% of global mortality, resulting in approximately 1.8 million deaths per year [1]. Consequently, early diagnosis strategies are necessary to detect and treat lung cancer globally.

The lung is a vital organ that collaborates with other organs and tissues to enable inhalation and exhalation within the respiratory system. The primary function of the lungs is to transfer oxygen from the air to the bloodstream while releasing carbon dioxide into the atmosphere through gas exchange. Lung cancer is a disease that occurs when cellular abnormalities in the lungs multiply uncontrollably, which can lead to severe and potentially life-threatening complications [2]. Early detection and prompt treatment of lung cancer markedly ameliorate the chances of a successful recovery.

Machine learning techniques have the potential to unveil hidden patterns from the clinical data that can significantly enhance decision-making in healthcare [3]. Early and accurate detection of illnesses is a crucial aspect of disease management, and machine learning can facilitate this process by enabling healthcare professionals to identify diseases during their early stages [4].

Initially, we utilized statistical analysis to determine the correlation between the risk factors of lung cancer, and then we examined the relationship between lung cancer and its features. Furthermore, we also explored the significance of the features of lung cancer using Chi-square test. Finally, we have evaluated four distinct machine learning classifiers, namely Linear Discriminant Analysis, Bootstrap Aggregating, Gradient Boosting, and Quadratic Discriminant Analysis. The Accuracy, Sensitivity, Precision, and F1-Score are employed to assess the performance of machine learning classifiers. These evaluation measures are crucial in determining the effectiveness and reliability of machine learning classifiers. Our research aims to assess the accuracy of various machine-learning approaches in correctly predicting lung cancer patients from clinical datasets.

## 1.2 Motivation

The primary aim of utilizing machine learning in lung cancer diagnosis is to revolutionize healthcare by saving lives. There are several key motivations:

- Early detection
- Personalized medicine
- Cost-effective treatment plans
- Data-driven improved decision-making.

## 1.3 Research Objectives

The research objective of machine learning in lung cancer is to implement algorithms and models that can effectively analyze medical data to anticipate the risk of lung cancer. The primary objectives are enlisted following:

- To compare the diagnostic performance of several machine learning algorithms for lung cancer.
- To compute the correlation among the risk factors of lung cancer.
- To calculate and evaluate the importance of the factors contributing to the onset of lung cancer.

## 1.4 Report Structure

There are five chapters in the report, each of which will be presented with guidelines. We covered the introduction of this research in Chapter 1. The importance of early detection of lung cancer using machine learning is emphasized in Chapter 1. Additionally, the motivation and objectives of this research are also discussed. In Chapter 2, we reviewed the existing literature on the diagnosis of lung cancer. Furthermore, the scope of the problem and challenges of the research are also covered. The research methodology is highlighted in Chapter 3. This chapter covers data collection procedures, data statistics, and algorithm of machine learning classifiers. The results and performance of all the machine learning classifiers of our research are explored in Chapter 4. The results of the research, the conclusion, and future work are presented in Chapter 5.

## **CHAPTER 2**

### **BACKGROUND**

#### **2.1 Introduction**

The analysis of previous research presents findings on diverse clinical datasets of lung cancer. Various methods and techniques such as data mining, machine learning, and deep learning were used to analyze and predict these datasets.

#### **2.2 Related Works**

Firstly, R. Patra [5] implemented different machine learning algorithms to predict lung cancer, including Neural Network, Radial Basis Function Network, Support Vector machine, Logistic Regression, Random Forest, J48, Naive Bayes, and K-nearest neighbors. The Radial Basis Function Network was found to have the highest accuracy of 81.25% on lung cancer data.

K. Danjuma [6] evaluated machine learning classification schemes for post-operative life expectancy in lung cancer patients. He applied three machine learning algorithms namely J48, Naive Bayes, and Multilayer Perceptron. The Multilayer Perceptron achieved 82.3% accuracy for clinical prognosis as the best classifier.

ACC Omar et al. [7] applied various machine learning techniques to predict lung cancer such as K-Nearest Neighbors, Support Vector Machine, Multilayer Perceptron, and RBF Classifier. The best classifier was the Multilayer Perceptron, which achieved an accuracy of 90%.

MI Faisal et al. [8] employed eight machine learning algorithms with Support Vector Machine, C4.5 Decision tree, Multi-Layer Perceptron, Neural Network, Naïve Bayes, Random Forest, Majority Voting, and Gradient-boosted Tree for the prediction of lung cancer and the suggested Gradient-boosted Tree outclassed the other ML algorithms with the accuracy of 90%.

M. Mamun et al. [9] executed four ensemble techniques namely XGBoost, LightGBM, Bagging, and AdaBoost for detecting lung cancer and the XGBoost attained the highest accuracy of 94.42%.

Finally, E. Dritsas [10] implemented 14 machine learning algorithms including Naïve Bayes, Bayesian Network, Logistic Regression, Logistic Model Tree, Support Vector Machine, Stochastic Gradient Descent , J48, Random Tree, Rotation Forest , Reduced Error Pruning Tree, Random Forest , AdaBoostM1, Artificial Neural Network, and Multi-layer Perceptron to predict lung cancer. The recommended Rotation Forest reached the most accuracy of 97.1%.

## **2.1 Scope of The Problem**

The diagnosis of lung cancer using a machine learning approach is a complex and challenging task. We required a systematic technique to succeed, but there are flaws in that strategy. In this study, we utilized a public dataset of lung cancer that had limited data. Machine learning models may face difficulties when dealing with small sample sizes in datasets [11]. Insufficient sample size can lead to overfitting and poor model generalization in machine learning. Our training model, although effective, has been developed with limited data and underlying patterns. Therefore, there is a possibility of confusion with new sample data for diagnosing lung cancer.

## **2.2 Challenges**

Our main goal is to increase the accuracy of our developed model to the highest possible level. However, to achieve this, we require a larger clinical dataset of lung cancer patients from local hospitals in our country. The primary dataset will replace the current secondary dataset that we have, which has a limited number of samples.

## CHAPTER 3

### RESEARCH METHODOLOGY

#### 3.1 Introduction

An overview of the research and the methodologies used for study is discussed in this section. It includes the dataset, research strategy, and the structure of the study. It facilitates a reliable framework to diagnose lung cancer patients in the earlier stage. To efficaciously diagnose lung cancer, several steps must be taken. The flowchart of the proposed framework is shown in Fig. 3.1.1.

Fig. 3.1.1. The flowchart of the proposed framework.

### 3.2 Dataset

We utilized the overt lung cancer dataset for our research [12]. The dataset has 309 samples with 15 independent variables and one dependent variable. The feature information of the dataset is exhibited in Table 1.

Table 1: The feature information of the lung cancer dataset.

| Feature               | Data Type    |
|-----------------------|--------------|
| Gender                | Qualitative  |
| Age                   | Quantitative |
| Smoking               | Qualitative  |
| Yellow Finger         | Qualitative  |
| Anxiety               | Qualitative  |
| Peer Pressure         | Qualitative  |
| Chronic Disease       | Qualitative  |
| Fatigue               | Qualitative  |
| Allergy               | Qualitative  |
| Wheezing              | Qualitative  |
| Alcohol Consuming     | Qualitative  |
| Coughing              | Qualitative  |
| Shortness of Breath   | Qualitative  |
| Swallowing Difficulty | Qualitative  |
| Chest Pain            | Qualitative  |
| Lung Cancer           | Qualitative  |

### 3.3 Statistical Analysis

The dataset contains 270 lung cancer patients and 39 healthy controls of the samples. Figure 3.3.1 depicts the information of the class variable Lung Cancer. According to the dataset, 87% of the samples have lung cancer, whereas 13% do not.

Fig. 3.3.1. The comparison between lung cancer patients and healthy controls.

The Pearson correlation analysis is utilized to identify significant attributes in this dataset that impact the classification of a lung cancer patient [13]. The Pearson's correlation among the independent variables is delineated in a pyramidal heat-map in the Fig. 3.3.2. The independent features of pairs (Yellow Finger, Anxiety), (Swallowing Difficulty, Anxiety), (Shortness of Breathness, Fatigue) have a stronger positive correlation and their values are .60, .48, and .42 correspondingly. The independent variables of pairs (Gender, Alcohol Consuming) and (Yellow Finger, Alcohol Consuming) have a stronger negative correlation and their values are -.45, and .40 respectively.

Fig. 3.3.2. The Pearson's correlation among the independent features.

The correlation of independent features to dependent feature is showed in Table 2. Independent features Allergy, Alcohol Consuming, Swallowing Difficulty, Coughing, and Wheezing are positively correlated with the dependent feature Lung Cancer and values are .33, 0.29, 0.26, .25 and .25 respectively.

Table 2: The correlation of independent features to dependent feature.

| Feature               | Correlation with Lung Cancer |
|-----------------------|------------------------------|
| Gender                | -.067                        |
| Age                   | .089                         |
| Smoking               | .058                         |
| Yellow Finger         | .18                          |
| Anxiety               | .14                          |
| Peer Pressure         | .19                          |
| Chronic Disease       | .11                          |
| Fatigue               | .15                          |
| Allergy               | .33                          |
| Wheezing              | .25                          |
| Alcohol Consuming     | .29                          |
| Coughing              | .25                          |
| Shortness of Breath   | .061                         |
| Swallowing Difficulty | .26                          |
| Chest Pain            | .19                          |

We utilized the chi-square test to determine the feature score according to the importance based on the relationship between a categorical variable and a class variable [14]. The feature score of association with lung cancer using the Chi-square test according to their Feature Score is presented in Table 3. The most significant features namely Allergy, Alcohol Consuming, Swallowing Difficulty, Wheezing, Coughing, Peer Pressure and Chest Pain, and their feature score 14.71, 11.40, 11.06, 8.51, 8.03, 5.35, and 4.96 respectively.

Table 3: The feature score of association with lung cancer using Chi-square test.

| <b>Feature</b>        | <b>Feature Score of Association with Lung Cancer</b> |
|-----------------------|------------------------------------------------------|
| Allergy               | 14.71                                                |
| Alcohol Consuming     | 11.40                                                |
| Swallowing Difficulty | 11.06                                                |
| Wheezing              | 8.51                                                 |
| Coughing              | 8.03                                                 |
| Peer Pressure         | 5.35                                                 |
| Chest Pain            | 4.96                                                 |
| Yellow Fingers        | 4.37                                                 |
| Anxiety               | 3.25                                                 |
| Fatigue               | 2.29                                                 |

### 3.4 Data Preprocessing

As part of our data preprocessing, we removed 33 duplicate samples from the lung cancer dataset to enhance its practicality [15]. After deleting 33 samples out of 303 samples, we scaled the remaining 276 samples for the improvement of the machine learning performance [16].

### 3.5 Linear Discriminant Analysis

Linear Discriminant Analysis (LDA) is used for classification and recognition in machine learning, and it was introduced by Fisher [17] in 1936. To classify lung cancer patients, the primary goal of LDA is to augment the distance between the means of separated classes while reducing the variance within each class [18].

---

Algorithm: Linear Discriminant Analysis

---

Step 1: Input:

X: Lung cancer dataset, which contains of n samples and m classes

y: class label for each sample

Step 2: Calculate the mean of each class  $\mu_k$

Step 3: Calculate the scatter matrices:

Intra-class scatter matrix:  $S_{wc}$

Inter-class scatter matrix:  $S_{bc}$

Step 4: Calculate Eigenvalues and Eigenvector:

$S_{bc}^{-1} * S_{wc} * v = \lambda * v$  ;  $v$  and  $\lambda$  are the eigenvector and the eigenvalue

Step 5: Select Discriminative Feature :

$X_{new} = X * T$ ; T is the matrix with selected top eigenvector

Step 6: Classification:

After transforming the features, LDA utilizes them for classification employing other classifiers.

---

### 3.6 Bootstrap Aggregating

An ensemble-based Bootstrap Aggregating merges predictions from several models and learns from unlike subsets of data using bootstrapping to improve accuracy by reducing variance and over-fitting [19].

---

Algorithm: Bootstrap Aggregating

---

Step 1: Input: X: Lung cancer dataset

Step 2: Set initial weight to lung cancer dataset

Step 3: Normalize the weights

Step 4: To train the classification model

Step 5: To choose the based on lowest error

Step 6: To update the weight of training data of classification model

Step 7: To do classification

---

### 3.7 Gradient Boosting

Another ensemble-based Gradient Boosting was used in our study. It uses sequential training to combine weak learners with strong learners [20]. It takes input as a pair of data points  $(x_a, y_b)$  for the training and gives an output of classification tree  $T_G$  for the diagnosis of lung cancer.

### 3.8 Quadratic Discriminant Analysis

Quadratic Discriminant Analysis (QDA) is a more generalized version of Linear Discriminant Analysis (LDA). In contrast to LDA, QDA computes separate convergence matrices for each class. [21]. The Quadratic Discriminant Function is represented in the following Equation 1.

$$\delta_i = \frac{1}{2} \log |\Sigma_i| - \frac{1}{2} (x - \Sigma_i)^T \Sigma_i^{-1} (x - \Sigma_i) + \log \pi_i \quad (1)$$

---

Algorithm: Quadratic Discriminant Analysis

---

Step 1: Input:

X: Data Matrix of lung cancer, which contains of N samples  $[x_i]_{i=1}^N$

z: class label for each sample

Step 2: Compute the mean of each class  $\mu_i$

Step 3: Compute the scatter matrices

Step 4: Compute the covariance matrix for each class  $\Sigma_i$

Step 5: Computer the inverse covariance for each class  $\Sigma_i^{-1}$

Step 6: For all (class  $w_i$ ,  $i = 1, 2, \dots, c$ ) do

    Calculate the quadratic discriminant function ( $\delta_i$ ) as in equation (1)

End for

Step 7: Do the classification

---

## CHAPTER 4

### EXPERIMENTAL RESULTS AND DISCUSSION

#### 4.1 Classification Performance Assessment

The evaluation measures are used to assess the classification model. The utilization of the evaluation measures is performed to determine the efficacy of the classification model [22]. The instances of Lung Cancer patients are labeled as the detected class as well as the healthy controls are designated as the non-detected class. Here,

- Positive (P): Lung Cancer patient
- Negative (N): Healthy Control
- True Positive ( $TP$ ): Lung Cancer patient is classified as a detected class.
- False Positive ( $FP$ ): Healthy control is categorized as a detected class.
- True Negative ( $TN$ ): Healthy control is recognized as a non-detected class.
- False Negative ( $FN$ ): Lung Cancer patient is classified as a non-detected class.

The evaluation measures are defined as below:

- Accuracy =  $\frac{TP + TN}{TP + FN + TN + FP}$
- Sensitivity =  $\frac{TP}{TP + FN}$
- Precision =  $\frac{TP}{TP + FP}$
- F1-score =  $\frac{2TP}{2TP + FP + FN}$

## 4.2 Experimental Results

The four machine learning classifiers, Linear Discriminant Analysis (LDA), Bootstrap Aggregating (Bagging), Gradient Boosting (GBoost), and Quadratic Discriminant Analysis (QDA), are trained using all features for distinguishing the Lung Cancer patients and the healthy controls. The Python library known as scikit-learn is used to perform the machine learning classification tasks [23]. These machine learning classifiers were trained and tested on 180 and 56 instances of the Lung Cancer dataset. Confusion matrices [24] are used to evaluate four classification models. The results of the classification models are shown in Table 4 - Table 7.

Table 4 shows that Linear Discriminant Analysis identifies 42 of 47 Lung Cancer patients are diagnosed as Detected, while 5 of 9 healthy controls are Non-Detected, hence the TP, FN, TN, and FP of LDA are 42, 5, 5, and 4.

Table 4: The Confusion Matrix of Linear Discriminant Analysis.

| Linear Discriminant Analysis |                     |                     |                     |
|------------------------------|---------------------|---------------------|---------------------|
| Lung Cancer                  |                     | Class of Prediction |                     |
|                              |                     | <i>Detected</i>     | <i>Non-Detected</i> |
| Actual Class                 | <i>Detected</i>     | <b>42</b>           | 5                   |
|                              | <i>Non-Detected</i> | 4                   | <b>5</b>            |

The TP, FN, TN, and FP of Bootstrap Aggregating are 43, 4, 6, and 3, as Table 5 specifies that Bagging distinguishes 44 out of 47 Lung Cancer patients as Detected and 6 out of 9 healthy controls as Non-Detected.

Table 5: The Confusion Matrix of Bootstrap Aggregating.

| Bootstrap Aggregating |                     |                     |                     |
|-----------------------|---------------------|---------------------|---------------------|
| Lung Cancer           |                     | Class of Prediction |                     |
|                       |                     | <i>Detected</i>     | <i>Non-Detected</i> |
| Actual Class          | <i>Detected</i>     | <b>43</b>           | 4                   |
|                       | <i>Non-Detected</i> | 3                   | <b>6</b>            |

Table 6 exhibits that Gradient Boosting recognizes that 7 of 9 healthy controls are Non-Detected and 44 of 47 Lung Cancer patients are Diagnosed as Detected; for these reasons, the TP, FN, TN, and FP of Random Forest are 44, 3, 7, and 2.

Table 6: The Confusion Matrix of Gradient Boosting.

| Gradient Boosting |                     |                     |                     |
|-------------------|---------------------|---------------------|---------------------|
| Lung Cancer       |                     | Class of Prediction |                     |
|                   |                     | <i>Detected</i>     | <i>Non-Detected</i> |
| Actual Class      | <i>Detected</i>     | <b>44</b>           | 3                   |
|                   | <i>Non-Detected</i> | 2                   | <b>7</b>            |

Table 7 shows that Quadratic Discriminant Analysis classifies 47 of 47 Lung Cancer patients are diagnosed as Detected, while 8 of 9 healthy controls are Non-Detected, as a result the TP, FN, TN, and FP of Quadratic Discriminant Analysis are 47, 0, 8, and 1.

Table 7: The Confusion Matrix of Quadratic Discriminant Analysis.

| Quadratic Discriminant Analysis |                     |                     |                     |
|---------------------------------|---------------------|---------------------|---------------------|
| Lung Cancer                     |                     | Class of Prediction |                     |
|                                 |                     | <i>Detected</i>     | <i>Non-Detected</i> |
| Actual Class                    | <i>Detected</i>     | <b>47</b>           | 0                   |
|                                 | <i>Non-Detected</i> | 1                   | <b>8</b>            |

Figure 4.2.1 shows the performance of all classification models, with Quadratic Discriminant Analysis outperforming the others. Quadratic Discriminant Analysis predicts the maximum number of True Positives and True Negatives as well as the minimum number of False Positives and False Negatives.

Fig. 4.2.1. The classification results using machine learning classifiers.

### 4.3 Discussion

The performance of the machine learning classifiers using the evaluation measures is itemized in Table 8. Quadratic Discriminant Analysis achieved the maximum accuracy of 98% whereas Linear Discriminant Analysis, Bootstrap Aggregating, Gradient Boosting achieved 84%, 88%, and 91% respectively.

While the sensitivity of LDA, Bagging, and GBoost was 89%, 91%, and 94% correspondingly, QDA accomplished the highest sensitivity of 100%.

QDA achieved the highest precision at 98%, while LDA, Bagging, and GBoost achieved 91%, 93%, and 95% respectively.

Finally, QDA reached the maximum F1-Score of 99%, whereas Linear Discriminant Analysis, Bootstrap Aggregating, and Gradient Boosting achieved 90%, 92%, and 95%, respectively.

Table 8: The classification performances using machine learning classifiers.

|                                        | Accuracy | Sensitivity | Precision | F1-Score |
|----------------------------------------|----------|-------------|-----------|----------|
| <b>Linear Discriminant Analysis</b>    | .84      | .89         | .91       | .90      |
| <b>Bootstrap Aggregating</b>           | .88      | .91         | .93       | .92      |
| <b>Gradient Boosting</b>               | .91      | .94         | .95       | .95      |
| <b>Quadratic Discriminant Analysis</b> | .98      | 1           | .98       | .99      |

The comparisons of related works are presented in Table 9. These comparisons clearly show that the best classifier for predicting lung cancer is Quadratic Discriminant Analysis (QDA).

Table 9: The comparisons of related works for the diagnosis of lung cancer.

| Study                | Best Classifier Based on Machine Learning Technique | Accuracy |
|----------------------|-----------------------------------------------------|----------|
| R. Patra [4]         | Radial Basis Function Network                       | 81.25%   |

| E. Dritsas [9]       | Rotation Forest                                     | 97.1%    |
| Our Study            | Quadratic Discriminant Analysis                     | 98%      |

## **CHAPTER 5**

### **CONCLUSION AND FUTURE WORK**

#### **5.1 Conclusion**

The early and precise detection of lung cancer is crucial for effective treatment. In this regard, machine learning algorithms based on a patient's symptoms have emerged as a promising tool for early diagnosis. In this study, various machine learning algorithms were analyzed to determine the most effective model for detection. The Quadratic Discriminant Analysis algorithm was found to have the highest accuracy rate of 98% and a precision rate of 100%. Early detection of lung cancer can significantly reduce associated costs and mitigate risks. Thus, the proposed system holds promise in providing a viable solution that can help improve the health outcomes of patients with lung cancer.

#### **5.2 Future Work**

We will collect a comprehensive clinical dataset of lung cancer patients from regional hospitals in our country. After this procedure is finished, we aim to implement a cloud-based approach to support clinicians in diagnosing lung cancer with higher accuracy.
