The received signal consists of total B sub bands with the boundaries located at $F_1 < F_2 < .... < F_B$. Therefore, total N_T CU nodes, each having M antennas is assigned to perform spectrum sensing on some sub bands. Moreover, we have considered a fusion center (FC) that has a single antenna. Signals received from the multiple antennas go through the energy detectors and the local decision is made at every CU. The received samples are represented by Y with a sample index n where and $n = 1, 2, ...N$. The local spectrum sensing problem can be formulated as binary hypothesis problem [18]:

$$Y_{i,j}(n) = \begin{cases} \eta_{i,j}(n) : H_0 \\ h_{i,j}s(n) + \eta_{i,j} : H_1 \end{cases} \tag{2}$$

where H_0 and H_1 represent signal absence and signal presence, respectively. $Y_{i,j}(n)$ is the signal from i^{th} CU with j antenna that has N samples where $i = 1, 2, ...N_T$ and $j = 1, 2, ...M$. h_{ij} is fading channel coefficient of the $i'th$ CU at antenna j. If the CU knows nothing about the waveform transmitted by the PUs in a frequency band of interest, energy detection is more suitable for detection[10] since it is only based on the measured energy of the received signal in that band.The principle of energy detection [18] is based on the difference between the energy of PU transmission signal and the noise. In the energy detection process, the energy of the received signal measured in a fixed bandwidth S over an observation time period T. The observed energy of a CU by a single antenna for a single sub-band is denoted by E and defined as: In conventional system, coarse sensing is performed with single antenna but in our proposed system it is performed by multiple antennas. Fine detector is performed with large number of samples to detect the band. In this paper, energy detection is used for fine sensing. In conventional case, fine sensing is performed by single antenna and to obtain one vacant band only. However, in proposed system, fine sensing is performed by multiple antennas and total numbers of vacant bands are dependent on number of CRU to utilize vacant band. If total vacant bands are smaller than number of required bands, the fine detector needs to seek up to last band.

$$E = \sum_{n=1}^{N} |Y(n)|^2 \tag{3}$$

The noise in each sample is a Gaussian random variable with mean zero and variance σ_η^2 and the signal variance σ_y^2. As a result, if PU is absent, $\frac{Y}{\sigma_\eta{}^2}$ follows a central chi-square distribution with N degree of freedom. Otherwise, $\frac{Y}{\sigma_\eta{}^2}$ follows a non-central chi-square distribution with N degree of freedom and a non-centrally parameter N_γ

$$\frac{Y}{\sigma_\eta{}^2} \sim \begin{cases} X_N{}^2, H_0 \\ X_N{}^2(N_\gamma), H_1 \end{cases} \tag{4}$$

where γ is the Signal to Noise Ratio (SNR). By the central limit theorem, the test statistic can be approximated as a Gaussian distribution.

$$\begin{aligned} H_0 :& E \sim Normal(N\sigma_\eta{}^2, 2N\sigma_\eta{}^4) \\ H_1 :& E \sim Normal(N(\sigma_\eta{}^2 + \sigma_y{}^2), 2N(\sigma_\eta{}^4 + \sigma_y{}^4)^2) \end{aligned} \tag{5}$$

The performance of detection is measured by two parameters P_d and P_f . The Rayleigh fading occurs when a signal experiences a Non-Line-of-Sight multipath. Due to Rayleigh fading, the signal amplitude follows a Rayleigh distribution, and the SNR of the PU signal at each CU follows an exponential distribution whose Probability Density Function is given by:

$$f_\gamma(\gamma) = \frac{1}{\gamma} e^{\frac{\gamma}{\hat{\gamma}}}, \gamma > 0 \tag{6}$$

where $\hat{\gamma}$ is the mean SNR value.

B. Frame structure for cooperative spectrum sensing

The cooperative spectrum sensing and detection is the combination of sensing and reporting period. Fig. 1 shows the time frame structure for cooperative spectrum sensing where total Q frames exist. The total frame time T of a frame is divided mainly into two parts: detection time T_d and transmission time $T - T_d$. Further, T_d is consisted of sensing time T_S and reporting time T_R.

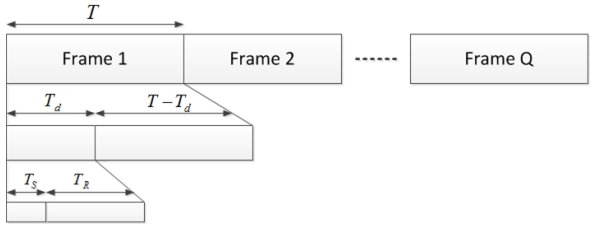

Fig. 1. The Frame structure for Cooperative Cognitive Radio

III. The Proposed Multiple Antenna and DS-Theory Based Cooperative Sensing

The overall process of the proposed scheme is shown in Fig. 2. The total spectrum sensing and decision process consists of three main parts: local sensing in CUs, data fusion to fusion center and final processing for global decision in fusion Center. In local sensing stage the sensing operation is performed by multiple antennas; and multiple sub-bands are sensed together instead of single band. The data of multiple bands are sent to FC in ordered sequential manner for making final decision. Upon obtaining the target detection and false alarm the FC manages to stop reporting for all the CUs.

The details of these operations are provided below:

A. Multiple-antenna based sensing and detection

In this paper, it is assumed that multiple antennas are uncorrelated. Energy of received signal at each antenna is calculated independently and the energy is added to perform detection. Fig. 3 shows multiple antenna signal detection and combining process for a single sub-band. For multiple bands, it is required to minimize processing complexity to reduce time and energy cost. Since the equal gain combining (EGC) method has relative lower complexity order for processing as compared to other methods complexity, in this paper EGC is utilized for signal detection. Pre-detection diversity signal output Y of a CR can be written as:

$$Y_j(n) = g_j[S_j(n) + \eta_j(n)] \tag{7}$$

Where, g_j is the weight factor from antenna $j = 1, 2, ..., M$ and $S_j = h_j s(n)$. For EGC, the branch weights are all set to unity.

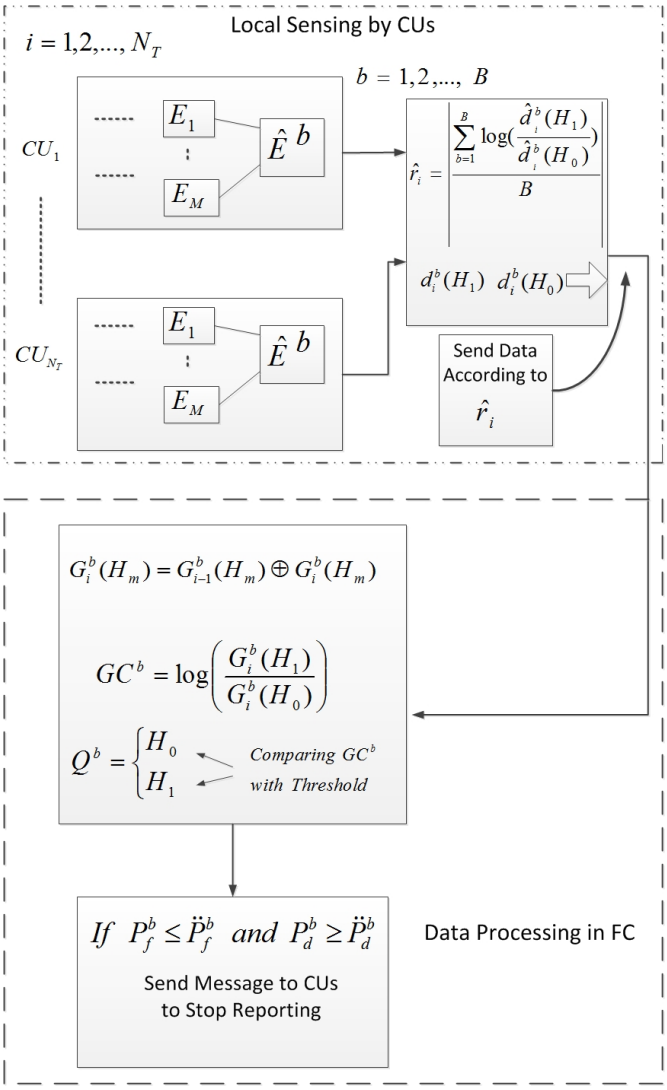

Fig. 2. Overall Structure of Multi-antenna and DS-theory Based Spectrum Sensing

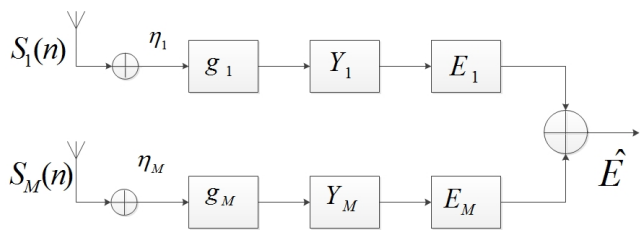

Fig. 3. Block diagram of pre-detection energy combining scheme for multiple antennas

The calculated energy for antenna j becomes:

$$E_j = \sum_{n=1}^{N} |Y_j(n)|^2 \tag{8}$$

However, the total observed energy of the CU by multiple antennas is denoted by $\hat{E}$ and defined as:

$$\hat{E} = \sum_{n=1}^{N} E_j \tag{9}$$

Therefore, for uncorrelated multiple antenna case, H_0 and H_1 hypothesis can be expressed as:

$$\begin{aligned} H_0 &: \hat{E} \sim Normal(MN{\sigma_\eta}^2, 2MN{\sigma_\eta}^4) \\ H_1 &: \hat{E} \sim Normal(MN({\sigma_\eta}^2 + {\sigma_y}^2), 2MN({\sigma_\eta}^4 + {\sigma_y}^4)^2) \end{aligned} \tag{10}$$

B. DS-theory based sequential data fusion for multiple bands

1) Local data and reliability calculation: : The D-S theory of evidence is applied to make final decision of CU's detection, the frame of discernment is defined as: $\{H_0, H_1, \zeta\}$, where ζ is ignorance hypothesis which denotes either hypothesis is true. After sensing time, each CU will estimate its self-assessed decision credibility which is equivalent to Basic Probability Assignment (BPA) for two hypotheses. The BPA function for local hypothesis measurement for every band $b(b = 1, 2, ..., B)$ can be written as a form of the cumulative density function which is found in [12] as follows:

$$\hat{d}_i^b(H_0) = \int_{\hat{E}_i}^{+\infty} exp(\frac{-(Y - \sigma_{ni})^2}{2{\sigma_{ni}}^2})dx \tag{11}$$

$$\hat{d}_i^b(H_1) = \int_{-\infty}^{\hat{E}_i} exp(\frac{-(Y - \sigma_{si})^2}{2{\sigma_{si}}^2})dx \tag{12}$$

$$\hat{d}_i^b(\zeta) = 1 - m_i(H_0) - m_i(H_1) \tag{13}$$

The sensing data reliability r_i of i'th CU for single band $(b = 1)$ can be defined as follows:

$$r_i = \frac{\hat{d}_i^b(H_1)}{\hat{d}_i^b(H_0)} \tag{14}$$

However, the reliability for multiple bands is denoted by $\hat{r_i}$ and calculated as:

$$\hat{r_i} = \frac{\sum_{b=1}^{B} log(\frac{\hat{d}_i^b(H_1)}{\hat{d}_i^b(H_0)})}{B} \tag{15}$$

Each CU transmits the data of all bands in the order of reliability $(\hat{r_i})$ of sensing result to FC where the final decision of every band is made individually based on a sequential test.

2) Reporting and global decision: : In this paper, we have considered reservation reporting method for ordered sequential reporting mechanism and followed the similar parameters of IEEE 802.11. The total reporting time consists of two main parts: reservation period and reporting period which is shown in Fig.4.

Reservation period:
In reservation period, each CU performs a reservation by utilizing a short burst signal according to a selected reservation timeslot in the common control channel. The node that has higher sensing results reliability $(\hat{r_i})$ has higher order in the reservation time and will be allowed to report in a priority

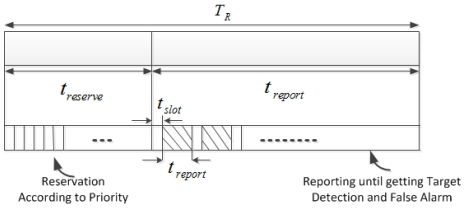

Fig. 4. Reservation reporting method

basis to FC.

Reporting period:

In reporting period, before transmitting the sensing report, the nodes have to listen to a short time for the burst signal from fusion center, which is equivalent to slot time. And a polling period is required to transmit data. Upon making final decision, the FC will perform burst to cancel reporting and decision message is sent to all CUs to stop their reporting. At FC, the BPA is sequentially combined in the order of data arrival for b^{th} band as follows:

$$G_i^b(H_m) = G_{i-1}^b(H_m) \oplus G_i^b(H_m) \tag{16}$$

$m = 0, 1$ and $G_{i-1}^b(H_m)$ and $G_i^b(H_m)$ are $(i-1)^{th}$ and i^{th} global BPA of hypothesis H_m respectively and is defined by DS theory. The global decision credibility ratio of bth band at the ith report is denoted by GC^b and is given as:

$$GC^b = log\frac{G_i^b(H_1)}{G_i^b(H_0)} \tag{17}$$

where GC^b is compared with threshold for final decision. The decision credibility ratio is justified with threshold for making final decision (Q) forbi^{th} band as follows:

$$Q^b = \begin{cases} H_0;\ if\ GC^b(H_m) < -\lambda \\ no\ decision;\ otherwise \\ H_1;\ if\ GC^b(H_m) > \lambda \end{cases} \tag{18}$$

Therefore global probability of false alarm P_f^b and detection P_d^b for the bth band is calculated as follows:

$$P_f^b = Prob(\frac{\hat{H}_1}{H_0}) \tag{19}$$

$$P_d^b = Prob(\frac{\hat{H}_1}{H_1}) \tag{20}$$

Where $\hat{H}_1$ and $\hat{H}_0$ are occupied and null hypothesis respectively detected in the fusion center.

C. Detection time and throughput

The total detection time is divided into two parts: sensing time and reporting time.

1) Sensing time: The total sensing time varies for single (multiple) antenna and bands. Sensing time for single band requires sensing only certain number of sample of a band. And single antenna does not need additional time for combining the signal. Therefore, sensing time for single band by single antenna is as follows:

$$T_S = N_S t_e \tag{21}$$

where N_S is the number of sample and t_e is the time for sensing single bit. Sensing by multiple antennas is performed in parallel way. Thus, it does not need any additional time for sensing by multiple antennas. However, after calculating energy in each antenna, all energies are combined to justify total energy. Thus for multiple antennas, it is needed a very small time for combining energies. Sensing time for single band by multiple antennas:

$$T_S = N_S t_e + t_{comb} \tag{22}$$

where t_{comb} is the time to add energy from multiple antennas. For multiple bands, each band is sensed individually to calculate energy. Therefore, it is required B times of single antenna for B bands. Sensing time for multiple bands by single antenna is:

$$T_S = \sum_{b=1}^{B} N_S t_e \tag{23}$$

Sensing time for multiple bands with multiple antennas becomes:

$$T_S = \sum_{b=1}^{B} N_S t_e + t_{comb} \tag{24}$$

2) Reporting time: All the bands of every CU are reported in a single time slot. In the first phase all the CUs perform reservation for ordered sequential reporting and the reservation time is denoted by $t_{reserve}$. And in the second phase the CU reports to the FC. For single band, every CU sends data of H_0 and H_1 hypothesis in a time slot. Total reporting time for single band with single antenna case is as follows:

$$T_R = N_{T1}(t_r + t_{slot}) + t_{reserve} \tag{25}$$

where N_{T1} is the required number of CU to obtain global target probability of detection and false alarm, t_r and t_{slot} are the reporting time and slot time respectively. For single and multiple bands, reservation time is equal. However, slot time depends on the number of CUs reporting. And since every CU sends multiple bands data of H_0 and H_1 hypothesis in a time slot, the reporting time increases. Total reporting time for multiple band with single antenna case is given by:

$$T_R = N_{T1}(\hat{t_r} + t_{slot}) + t_{reserve} \tag{26}$$

where $\hat{t_r}$ is the reporting time for multiple bands and $\hat{t_r} > t_r$. Reporting time for single band with multiple antennas is:

$$T_R = N_{T2}(t_r + t_{slot}) + t_{reserve} \tag{27}$$

where N_{T2} is the required number of CU to obtain global target probability of detection and false alarm for multiple antennas. Reporting time for multiple band with multiple antennas is given by:

$$T_R = N_{T2}(\hat{t_r} + t_{slot}) + t_{reserve} \tag{28}$$

Therefore, total detection time consists of sensing time and reporting time and can be written as:

$$T_d = T_S + T_R \tag{29}$$

IV. Simulation Result

In order to evaluate the proposed scheme for global detection, the numerical simulation results have been experienced under different conditions, which are shown in Figs.5-9. The general parameters are as following: all the simulations are conducted with the assumption that the presence and absence are equal (0.5). The Bandwidth of each sub-band is $6MHz$. Fig. 5 shows the global false alarm and miss detection for different SNRs $(-14\ to - 10dB)$. Firstly, we have considered a cognitive radio network environment with 100 nodes each of which independently senses the primary user presence and absence by energy detection. The performance shown in Fig.5 is for 10% reporting of total nodes. The comparative performance is shown by single and 4 antennas where every CU performs sensing on single and multiple bands. From the figure it is evident that the global false alarm probability is lower and detection probability is higher in the case of multiple antennas and vice versa for single antenna. Moreover, for multiple bands the probability of false alarm increases and detection decreases due to the decrement of reliability for multiple bands.

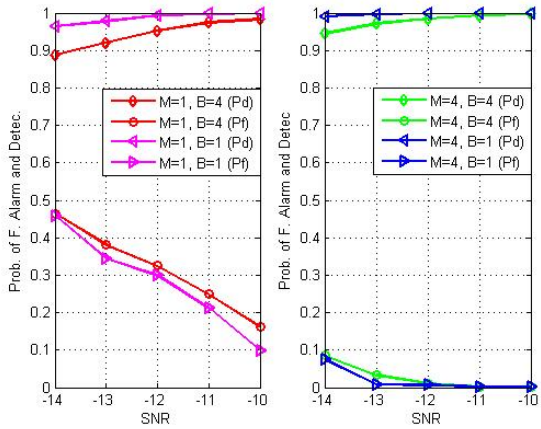

Fig. 5. ROC curve for Prob. of false alarm and detection for different SNRs

The total error probability for different percentage of reporting is plotted in Fig.6. It is assumed that every CU endures $-14\ dB\ SNR$. The total error probability is defined as a combination of the probability of miss detection and false alarm and for B bands it can be written as follows: $\epsilon_{total} = \frac{\sum_{b=1}^{B} P_f^b P(H_0) + (1-P_d^b)P(H_1)}{B}$. From Fig.6, it is observed that total error probability decreases as the number of reporting increases. In addition to that, multiple bands have higher probability of error as compared with single band. Moreover, utilizing 4 antennas has lower error probability as compared with utilizing single antenna. The Fig.7 shows total error probability for different number of samples when total 10% reporting are considered with $SNR\ -14\ dB$. Note that these samples are taken for only single band and for multiple bands the sample is multiple of the number of band. As the number of samples increases, the sensing time will increase and total error probability will be improved due to the cost of longer sensing time.

The required numbers of CUs reporting to obtain target probability of detection and false alarm for different number

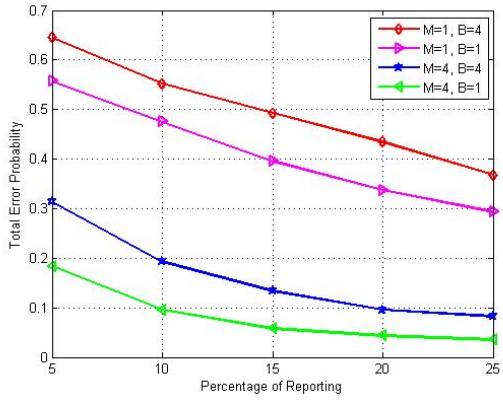

Fig. 6. Total error probability according to the percentage of reporting

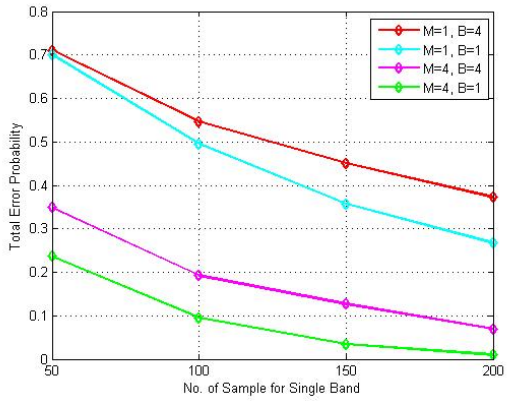

Fig. 7. Total error probability according to the number of samples for single band

of SNRs are observed in the Fig.8. The target probability of detection and false alarm are set as $P_d^b \geq 0.9$ and $P_f^b \leq 0.1$ respectively. From Fig.8, the following observations are obtained: For low SNR, the gap between single and multiple bands for single or multiple antennas are higher. As the SNR decreases, average reliability decreases and the gap becomes larger. For multiple bands $(m = 4)$, single antenna based cognitive radio needs a large number of nodes reporting, compared with CU with multiple antennas. For instance, single antenna-based sensing requires $72,\ 50\ and\ 34$ nodes reporting respectively when SNR is $-14,\ -13\ and\ -12$ respectively. On the other hand, multiple antennas-based sensing requires $12,\ 8\ and\ 4$ nodes reporting to obtain the target probability. The same phenomenon is observed in the case of single and multiple antennas for single band. Additionally, the single band case requires less number of CUs reporting than multiple bands case. Fig. 9 shows the required reporting time to obtain target probability of false alarm and detection for different values of SNRs. The simulation parameters for calculating reporting time are provided in table 1. As depicted in Fig.9, the multiple band and single antenna $(M = 1, B = 4)$ case has the highest reporting time. For single band with single antenna has second higher reporting time but CU with multiple antenna has significantly lower reporting time as compared with CU

TABLE I. THE PARAMETERS FOR CALCULATING REPORTING TIME

Parameters	Values
Slot time: t_{slot}	20 μ sec
Poll time: $t_p = 10 * (t_{slot})$	200 μ sec
Reporting slot interval for single band: $t_r = 3 * t_p$	20 mili sec
Reporting slot interval for multiple band: $t_r = 5 * t_p$	1 mili sec
Reservation time:$t_{reserve} = 5 * N_T * t_{slot}$	6 mili sec

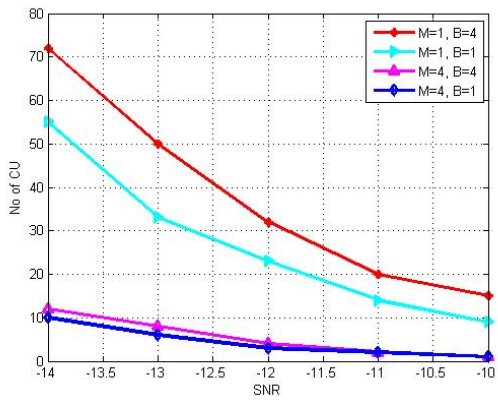

Fig. 8. The required number of CUs to obtain target probability of false alarm and detection according to SNR when 100 samples are taken for each band

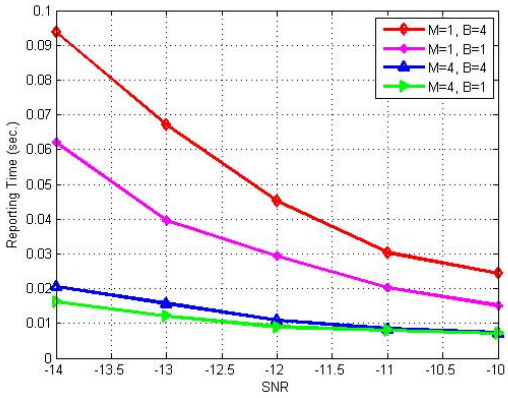

Fig. 9. The required reporting time to obtain target probability of false alarm and detection according to SNR

with single antenna. For instance, the required reporting time is 60 $milli-seconds$ when $SNR = -14dB,\ M = 1\ and\ B = 4$, and the required reporting time is 60 $milli-seconds$ when $SNR = -14dB,\ M = 1\ and\ B = 1$. These reporting times are approximately more than 100 $milli-seconds$ when 3 to 4 times higher than multiple antenna case.

V. CONCLUSION

In this paper, we have proposed a multiple antennas based multi-band cooperative spectrum sensing for cognitive radio network. The ordered sequential reporting is justified with the DS-theory based reliability. The efficiency of relative performance for global sensing is justified in terms of throughput. It has observed that the proposed multiple antennas based multi-band sensing with DS-theory based ordered sequential reporting have higher efficiency over single antenna, single band and traditional reporting method for augmenting the throughput significantly.

***Abstract*— In this paper, a metamaterial based triangular shaped electromagnetic cloak is presented. The pi-shaped metamaterial shows wideband NZRI (near-zero refractive-index) characteristics in the C-band of microwave spectra. The metamaterial was then utilized in designing a triangular shaped cloak. The cloak hides a metal cylinder electromagnetically where the metamaterial shows NZRI property. At the cloaked frequency, the normalized scattering width (NSW) of the object was reduced to zero. This is a promising design for wideband NZRI characteristics and C-band electromagnetic cloaking operation.**

Keywords—Cloak; C-band; Metamaterials

I. INTRODUCTION

Advances in metamaterial have opened many opportunities to tailor the electromagnetic property of a device. Metamaterial is a naturally unavailable artificially constructed composite material that may have some extraordinary electromagnetic properties, like, negative permittivity, negative permeability, etc. Due to these existing properties, it has applications in many fields like, design of filter, antenna, cloak and so on [1-4].

In the field of invisibility cloak design, metamaterials can play an interesting role. To cloak (hide) an object, electromagnetic waves is manipulated in such a way around an object to be cloaked, that the wave will bend around the object and makes the object hidden to the outside world. For cloaking operation, near zero refractive index (NZRI) metamaterial has good prospect [5]. There are some metamaterials are found in the literature, but very few of them have NZRI property [6-9]. Among the other cloaking methods, 'scattering cancellation' is a one kind of method that had been studied in some of the literature for cloaking operation [10-13]. In this method, an object can be cloaked by reducing the scattering cross section (SCS) of the object, which can be done by metamaterial shell. To cloak an object the SCS should be kept below one [14]. However, most of the cloaking structures were cylindrical or square shape. Moreover, these cloaks were not designed for C-band.

This paper reveals a new metamaterial-based 'triangular-shape' cloak. It operates in the C-band. For numerical analysis, the finite integration technique was adopted. The metamaterial was designed first and then it was applied for building the cloak device. The measured result was presented for metamaterial that agrees well with the numerical result as well.

II. STRUCTURE OF THE UNIT CELL

The Fig.1a shows the proposed metamaterial unit cell structure. The structure has been designed with two complementary copper arms with a little split between them and all of them having a thickness of 0.035mm. The design parameters are, *d=6, g=0.33, h=6, l=8, m=1, n=1.5, p=6.27, q=1, s=0.5* all in mm unit. The design was done on the FR-4 substrate material with dielectric constant 4.2 and loss tangent 0.002 and thickness 1.6mm.

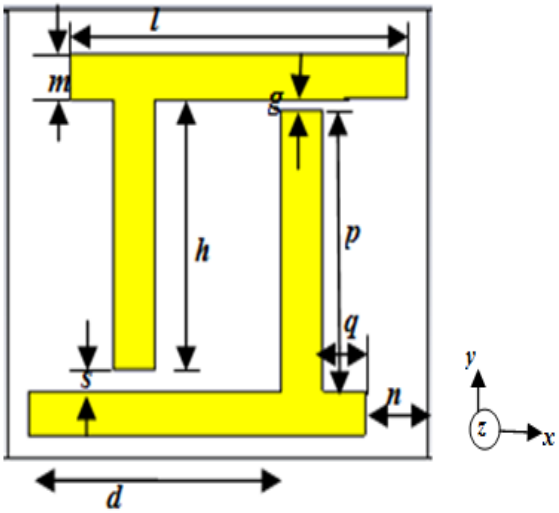

Fig. 1. The proposed unit cell structure

III. METHODOLOGY

For numerical analysis finite integration technique based, software, 'CST Microwave Studio' was adopted. Using two waveguide ports, the electromagnetic wave was propagated in the z-axis of the unit cell and the S-parameters' were calculated. The simulation was done in the frequency range of 5 GHz -9 GHz.

The NRW-method mentioned in [15] was utilized for the calculation of effective medium parameters. The simplified formulae have been given below,

$$V_1 = S_{21} + S_{11} \quad (1)$$

$$V_2 = S_{21} - S_{11} \quad (2)$$

$$\mu_r \approx \frac{2}{jk_0 d} \frac{1 - V_2}{1 + V_2} \quad (3)$$

$$\varepsilon_r \approx \frac{2}{jk_0 d} \frac{1 - V_1}{1 + V_1} \quad (4)$$

$$\eta = \sqrt{\varepsilon_r \mu_r} \quad (5)$$

Where, ε_r is the effective permittivity, μ_r is the effective permeability, 'd' is the thickness of the substrate, k_0 is the wave number and η is the refractive index.

The metamaterial was then used to design a triangular shaped cloak. A cylinder made of aluminium was chosen as object to be cloaked. The transverse electric wave was propagated parallel to the axis of the cylinder through the z-axis of the cloak structure from left to right side to observe the cloaking effect.

IV. Cloak Design

As a part of further work, the metamaterial was applied in designing a triangle-shaped cloak design. For designing the cloak, the wall composed of 2×2 unit cells of the proposed metamaterial was prepared. Three metamaterial walls were prepared and a triangular-shaped cloak was formed. The cloak structure is seen in Fig. 2.

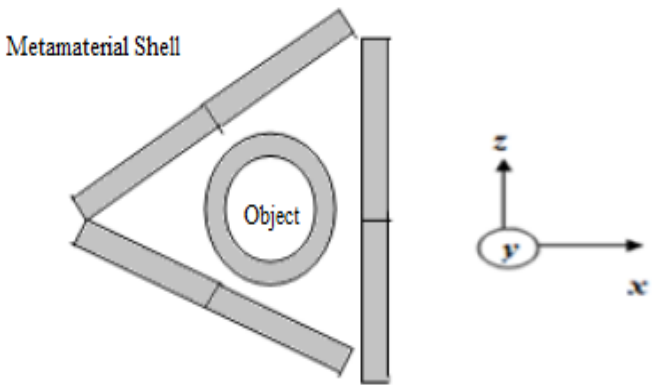

Fig. 2. The proposed cloak structure (top view)

The inner and outer radius of the object is 4mm and 5 mm respectively and the height of the object was kept 20mm.

V. Results and Discussion

The numerical results of S-parameters are presented in Fig.3 for the unit cell. The S-parameters results show one sharp resonance at 8.29 GHz.

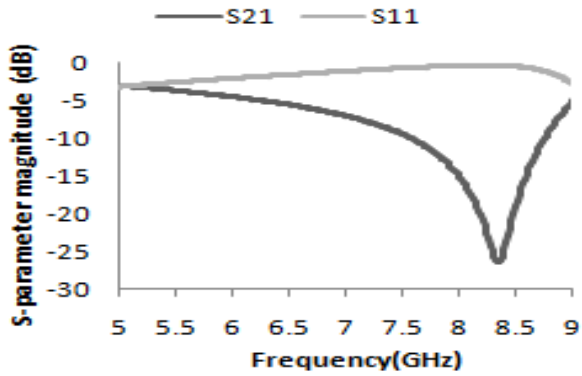

Fig. 3. S-parameter magnitude

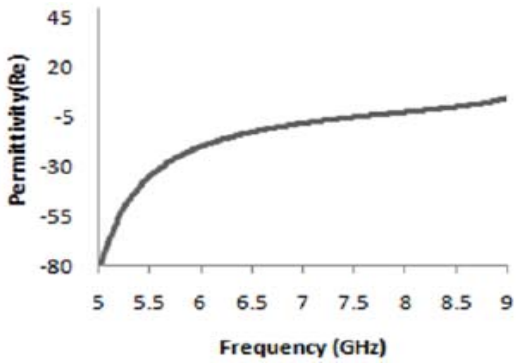

Fig. 4. Numerical real peak of permittivity (ε)

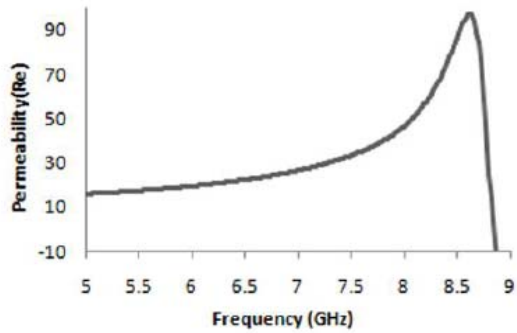

Fig. 5. Numerical real peak of permeability (μ)

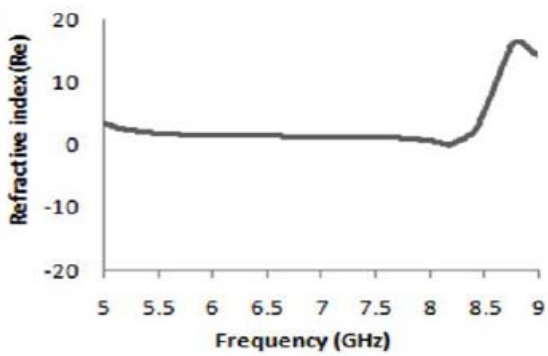

Fig. 6. Real magnitude of refractive index (η) for the unit cell

In Fig. 4 and Fig. 5 the effective permittivity and effective permeability is shown against frequency consecutively. In the Fig. 4 the permittivity curve shows negative magnitude from the 5 GHz to 8.45 GHz. However, in the Fig.5, the permeability curve displays positive peak in the same region. Moreover, at the frequency of 8.29 GHz, the permittivity curve shows negative magnitude and the permeability curve displays positive peak.

In the Fig. 6, the real magnitude of the refractive index curve is shown. It is evident that the refractive index curve displays near-zero refractive index (NZRI) region that is within the frequency range of 5 GHz to 8.40 GHz. The NZRI property has good prospects of designing an invisibility cloak.

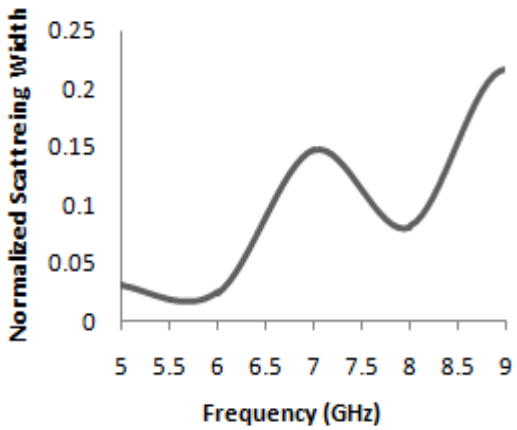

Fig. 7. Numerical value of NSW of the cloaked object

The Fig. 7 reveals the simulated outcome of the NSW of the cloaked object. Normalization of the cloaked object was done with the bare object. It is apparent from the Fig.7 that the scattering width shows the lowest value at 5.67 GHz that is very close to zero. The metamaterial also shows near zero refractive index property there. It depicts that the metallic cylinder is being cloaked at this frequency (5.67 GHz).

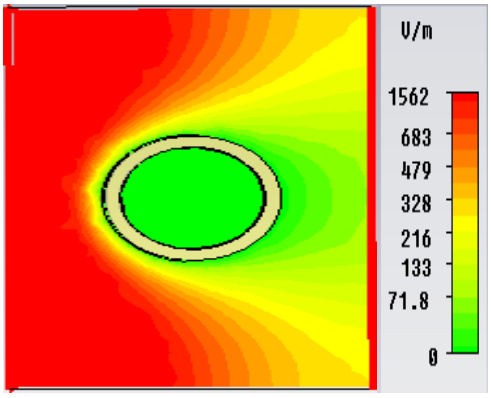

Fig. 8. E-field distribution of bare object for *x-y*-plane (mm) at 5.67 GHz

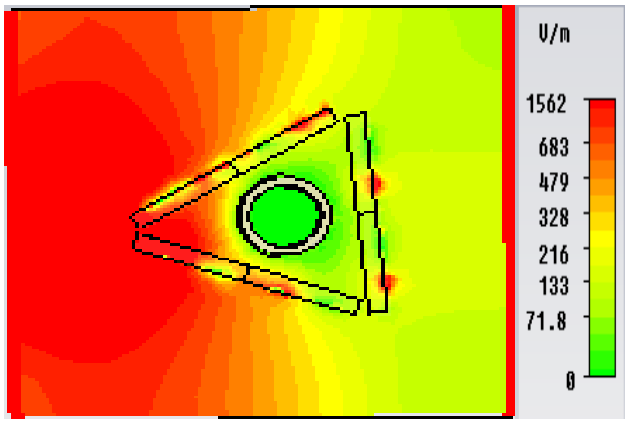

Fig. 9. E-field map in the *x-y*-plane (mm) when the object is covered with the metamaterial at the uncloaked frequency

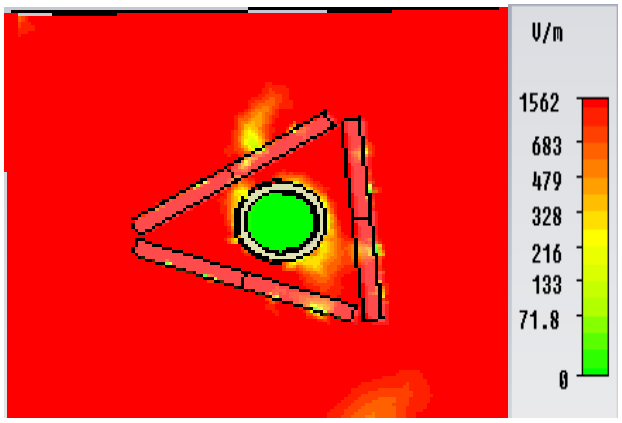

Fig. 10. E-field map in the *x-y*-plane (mm) when the object is covered with the metamaterial at the cloaked frequency (5.67 GHz).

The Fig. 8 shows the field distribution for uncloaked or bare object where some shadow in the forward direction is seen at 5.67 GHz. This shadow refers to the forward scattering of waves from the object. Fig. 9 shows the field distribution of the object at the frequency of uncloaked state. It is clear that the scattering in the forward direction is still present at the right side of the object. However, in the Fig. 10, the object inside the cloak, but at cloaked frequency is presented where the is clear that the forward scattering is completely alleviated and the scattered wave has returned to its original path. Therefore, the existence of the metal cylinder will remain completely undetected at that certain cloaked frequency.

VI. Conclusion

This paper presents a new metamaterial-based electromagnetic cloak that hides a metallic cylinder in a certain frequency of the C - band region. The metamaterial also shows more than 2 GHz NZRI property in the cloak region. Cloaking has good applications in the defense sector,

especially for stealth coating of aircraft or missile. Therefore, the this cloak can be applied in the C-band applications besides other cloaking device.

***Abstract*—In optical communication signal router is a novel photonic component used to ensure communication between optical networks. Signal routing has a significant commercial demand in dense wavelength division multiplexing. This paper presents the description of designing a 1x16 signal router using Mach-Zehnder electro-optic Switch operating at 1.55 µm. To design the router we used 2x2 Mach-Zehnder electro-optic switch made by titanium diffused lithium niobate (Ti:$LiNbO_3$) which is used as waveguide medium in designing the desired signal router. Enhanced performance of the switch with reduced insertion loss, excess loss and high extinction ratio was evaluated first and then the router was implemented using that optimized switch. 16 switches were required to implement the router. Optical power can be switched to each of the 16 output ports with the application of applied voltage at each central electrode of the 16 MZI switches. The results are observed using finite difference beam propagation method of OptiBPM12.2 simulation software.**

Keywords—Mach-Zehnder interferometer, Electro-optics switch, Insertion loss (IL), Extinction ratio (ER), Signal router.

I. INTRODUCTION

Mach-Zehnder interferometer is a basic component in photonic lightwave circuit (PLC). It is a classical mirror interferometer which was the most common dual-beam-interferometer for a long time and used in measuring refractive index distributions of transparent objects. It was developed by Mach and Zehnder in 1892 [1]-[2]. Now-a-days it has been used for many applications such as electro-optic switch, modulator, optical sensor, wavelength filters, multiplexers etc [3]-[7]. Directional coupler, Y-shaped splitter, multimode interference coupler etc are used as power splitter and combiner in Mach-Zehnder interferometer [8]-[10]. Electro-optic based 2x2 MZI optical switch using directional coupler requires materials with high nonlinear characteristics such as LiNbO3, KNbO3 etc [11]-[14]. LiNbO3 shows some advantages of having zero residual birefringence, less complexity, high electro-optic coefficient, high speed of operation but it is subjected to polarization sensitivity [8]. Such switches are suitable for time division signal processing and signal routing. Andy W. Brown and Min Xiao demonstrated an all-optical two-port signal router [15]. Ruiqiang Ji experimentally investigated a spatially non-blocking five-port optical router based on micro-ring resonators, which was tuned through the thermo-optics effect and 12.5 Gbps high-speed signal transmission rate was obtained [16]. S. K. Raghuwanshi analytically demonstrated a 1x4 signal router based on 2x2 electro-optic MZI switch and showed the variation in output power due to change in control signal [17]. Santosh Kumar constructed a 1x8 signal router with the application of control signal [18]. As demand for systems with higher capacity is increasing rapidly, so to adapt and to build a large optical cross-connect (OXC) for wide-area communication network and also to provide high-speed interconnections between a no of processors in a parallel, distributed computing system [19], signal router with high configuration is required. In this paper we will demonstrate a 1x16 signal router based on electro-optic effect. Section II represents basics of electro-optic switch, section III shows the construction of 1x16 signal router and section IV shows the simulation results and section V gives a conclusive study.

II. BASICS OF ELECTRO-OPTIC SWITCH

Electro-optic effect is referred to the change in the optical properties of a material with varying electric field. The term includes a number of distinct phenomena, which are, i) the change of the absorption coefficient and ii) the change of the refractive index and permittivity. Second term is referred to Pockels effect i.e. the change in the refractive index which is linearly proportional to the change in electric field. Only certain crystalline solids show the Pockels effect like $LiNbO_3$, $KNbO_3$, $NH_4H_2PO_4$, (ADP), KH_2PO_4 (KDP), $LiTaO_3$ and CdTe etc. The relation of refractive index n with applied electric field E is given below [20].

$$n(E) = n + a_1 E + \frac{1}{2} a_2 E^2 + \cdots \tag{1}$$

The change in refractive index and the resulting change is phase can be calculated by equation 2 and equation 3 [17].

$$\Delta n = (\frac{n^3}{2}) rE \tag{2}$$

$$\Delta\varphi = \frac{2\pi}{\lambda}[(\frac{n^3}{2}) rE] L. \tag{3}$$

L describes substantial length required to obtain certain phase change for directing light into desired path, which is for a 2x2 MZI electro-optic switch 10000 µm and r represents the

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

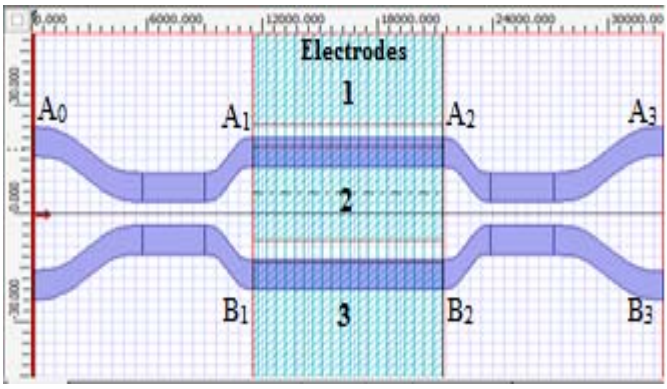

Fig. 1. 2x2 Mach-Zehnder electro-optic switch.

electro-optic coefficient and for $LiNbO_3$, it is 3.66×10^{-10} m/V. Now, if we consider that the voltage difference between two electrodes shown in Fig. 1 is V and d is the distance between the electrodes, then electric field is V/d. So, we can write

$$\Delta\varphi = \frac{2\pi}{\lambda}[(\frac{n^3}{2})\frac{V}{d}r]L. \tag{4}$$

When applied voltage is 0 V, phase change i.e Δφ become zero and with voltage V the phase change Δφ is π. This particular voltage is called V_π and is given by,

$$V_\pi = \frac{\lambda}{n^3}\frac{1}{r}\frac{d}{L}. \tag{5}$$

Now let us find power at output ports of the switch. From Fig. 1 we can see that inputs at first directional coupler i.e to the power splitter denoted as A(Z) and B(Z), which are described by the following equations [21].

$$A(\mathrm{Z}) = \{[\cos(qz) + j\frac{\delta}{q}\sin(qz)]A(0) - j\frac{k}{q}k\sin(qz)B(0)\}\exp(-j\delta_z) \tag{6}$$

$$B(\mathrm{Z}) = \{-j\frac{k}{q}\sin(qz)]A(0) + [\cos(qz) - j\frac{\delta}{q}\sin(qz)]B(0)\}\exp(j\delta_z) \tag{7}$$

Here q represents the number of local peaks of electric field propagating along the x and y-axis directions and given by

$$q = \sqrt{(k^2 + \delta^2)} \tag{8}$$

And also,

$$\delta = 2\pi\left(\frac{l_1 - l_2}{\lambda}\right) \tag{9}$$

In equation 9, l_1 represents the coupling length of the upper waveguide, where l_2 is the coupling length of the lower waveguide and k is the wave number. Let us consider that the case light is launched into the upper waveguide of a MZI. Since both arms have the same waveguide structures; so, δ=0 which results in, $A(0)=A_0$ and B(0)=0. Here the first coupler which functions as power splitter is a 3-dB coupler with kl=π/4, so the light splitting ratios can be written as,

$$A_1 = A_0\cos(kl) = \frac{A_0}{2} \tag{10}$$

$$B_1 = -jA_0\sin(kl) = -j\frac{A_0}{\sqrt{2}} \tag{11}$$

l is the coupling length. After light being traveled through the interferometer arms, the output from these arms A_2 and B_2 will be,

$$A_2 = A_1\exp(-j\beta L) = \frac{A_0}{\sqrt{2}}\exp(-j\beta L) \tag{12}$$

$$B_2 = B_1\exp(-j\beta L + J\varphi) = -j\frac{A_0}{\sqrt{2}}\exp(-j\beta L + j\varphi) \tag{13}$$

L is the length of switching region and φ represents an excess phase shift at the second arm of the interferometer. The second coupler is also a 3-dB coupler where kl=π/4. So, the outputs are given by [20],

$$|A_3|^2 = |A_0|^2.\sin^2(\frac{\varphi}{2}) \tag{14}$$

$$|B_3|^2 = |A_0|^2.\cos^2(\frac{\varphi}{2}) \tag{15}$$

If the voltage applied is 0 V, then φ = 0, the output will be switched to the lower port as $|B_3|^2 \approx |A_0|^2$. With the certain applied voltage for which φ =π, the output will be switched to the upper port as $|A_3|^2 \approx |A_0|^2$. For a 1x16 signal router the same theory is applied, only difference is that 16 control signal is to be varied to launch light to the desired port.

III. Construction of 1x16 Signal Router

To design a 1x16 signal router, 16 individual 2x2 MZI switches are required. No of switches could not be minimized, because it will either increase the width of the device or electrodes will overlap each other. The device then will not function accurately. Titanium diffused lithium niobate waveguide is used to design MZI switch. The switch is made on Z-cut wafer of lithium niobate with air surrounding. It is not more than 33000 μm long and 100 μm wide. The waveguide has a width of 8.0 μm along X-axis. In 3D wafer properties air is defined as coating material with thickness of 2.0 μm and substrate is defined as lithium niobate with a thickness of 10 μm. Three electrodes created on buffer layer with 0.3 μm thickness and refractive index of 1.47. The buffer layer has horizontal and vertical permittivity of the order of 4.

TABLE I. SIMULATION PARAMETERS.

Reference index	Modal
Wavelength	1.55 µm
Polarization	Transverse magnetic (TM)
Mesh-number of points	2000
BPM solver	Paraxial
Engine	Finite Difference
Scheme parameter	0.5
Propagation step	1.3
Boundary condition	Transparent Boundary Condition (TBC)

Thickness of each electrode is 4.0 µm. Both first and third electrodes have a width of 50 µm with zero voltage applied. The second electrode is defined with a width of 26 µm and voltage of 0 V. The separation of 1-2 and 2-3 is 6 µm. Table I shows the list of simulation parameters.

Before constructing 1x16 signal router we optimized the device parameters. Best performance was found for 0.0775 µm titanium strip thickness, 8 µm waveguide width, 9900 µm arm length, 34 µm arm gap, 14.5 µm 3dB coupler gap with outputs at 0 V, 0.000437526 mW and 0.997974 mW and at 8.8 V, 0.997974 mW and 0.000437526 mW for port 1 and 2 respectively. As a result we obtain 33.581 dB extinction ratio and 0.00881 dB insertion loss, 0.0069 dB excess loss for both cross state and bar state [22], where in reference [8] lowest insertion losses were 0.0138 dB and 0.0129 dB & maximum extinction ratios were 30 dB and 29.9 dB for cross sate and bar state respectively obtained with titanium strip thickness of 0.0825 µm. In figure 2,3,4,5,6 simulation results for optimized electro-optic 2x2 MZI switch are shown. Fig. 2 shows refractive index propagation of the optimized device.

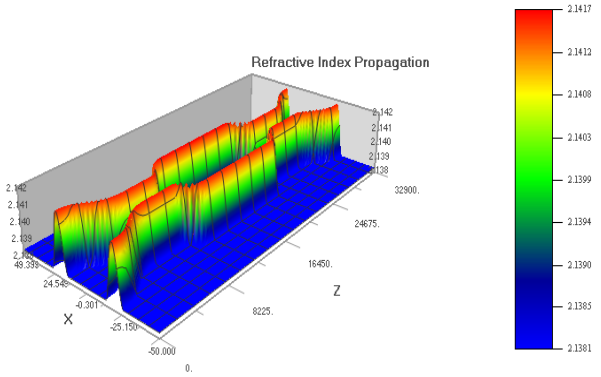

Fig. 2. Refractive index propagation of MZI switch (3D view) .

Optical field propagation for both 0V and 8.8 V are shown in Fig. 3. Fig. 4 ensures that light is switched completely from port 1 to port 2 with the application of applied voltage. It takes 11 iterations to switch light from port 1 to port 2. Fig. 5 represents power in output waveguides for a voltage range of

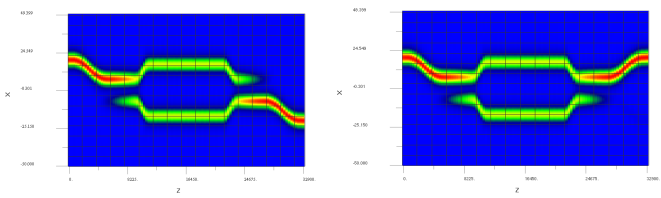

Fig. 3. Optical field propagation at 0 V and 8.8 V respectively.

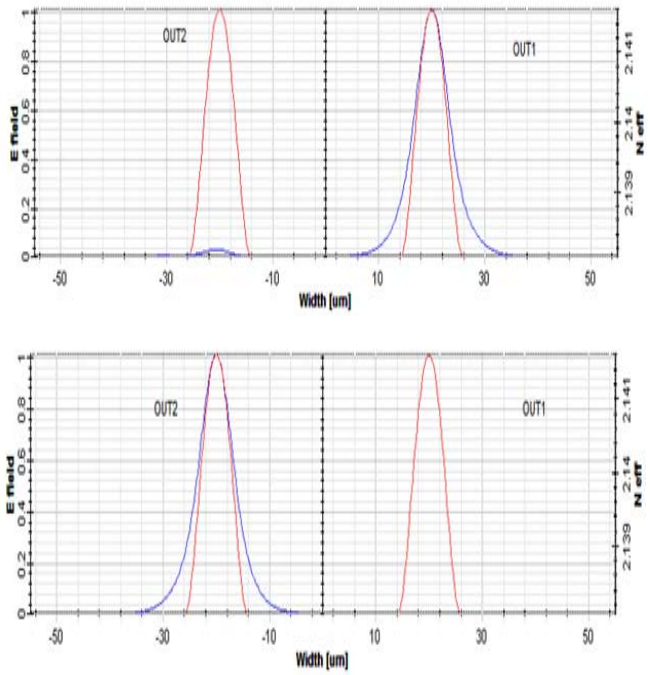

Fig. 4. Electric field at 0V and 8.8 V respectively.

0 V to 8.8 V and from Fig. 6 we can observe power overlap integral characteristics versus distance of propagation of waveguide for both low and high voltage. These results are obtained by running the following visual script,

Const NumIterations = 11

Fig. 7 and Fig. 8 show the layout and refractive index propagation of 1x16 signal router respectively. Central electrode of each switch was positioned 5.5 µm above from the original axis.

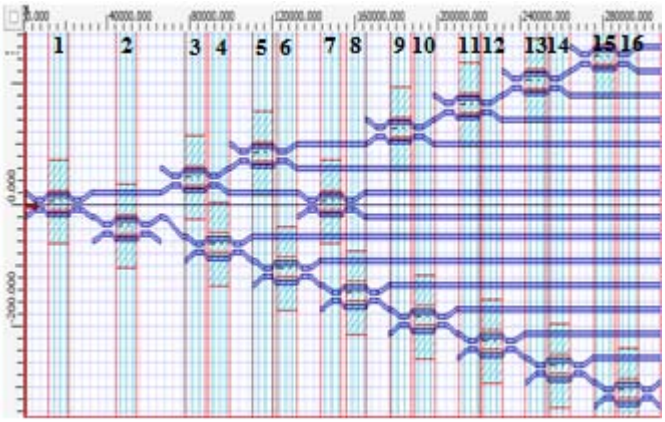

Fig. 7. Layout of 1x16 signal router.

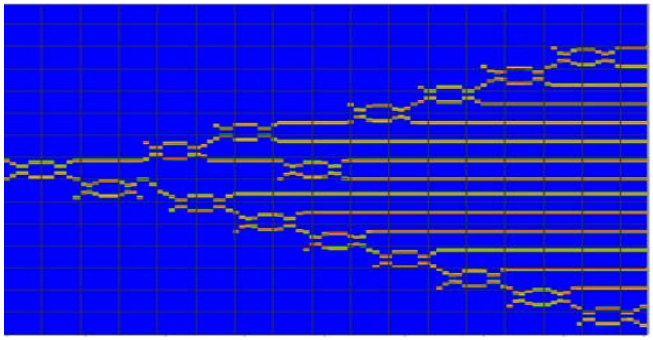

Fig. 8. Refractive index propagation of 1x16 signal router.

MZI switches are numbered as 1, 2, 3 and so on. we assumed the second electrode of each switch as control electrode and they are also numbered similarly as S_1, S_2, S_3 etc.

IV. Simulation Results

Results are observed by OptiBPM software. From Fig. 7 we can see that there are 16 output ports. To switch power into one of these ports particular combination of voltages across the central electrodes of these 16 MZI switch is required. The width of this structure is not more than 700 µm and length is not more than 307600 µm. Table II shows output power at 16 different ports on the basis of control signal S_1, S_2, S_3, S_4, S_5, S_6, S_7, S_8, S_9, S_{10}, S_{11}, S_{12}, S_{13}, S_{14}, S_{15}, S_{16} representing voltages across central electrodes of 16 switch respectively. In table II logic 0 represents 0 V and logic 1 represents 8.8 V and X represents don't care condition. S_1 is kept high to switch upper 8 output ports and with S_1 low lower 8 output ports are to be switched. When S_1 is high output goes to MZI 3, with S_3 kept at 0 V output goes to MZI 5, again with S_5 low output goes to MZI 9, with S_9 low output goes to MZI 11, consequently with S_{11}, S_{13}, S_{15} low output goes to the output port 1. Similarly for each of the combinations shown in table II we can find high output at desired output port. Fig. 9 shows the optical field propagation at different output ports.

TABLE II. Different combinations of control signal of 1x16 signal router.

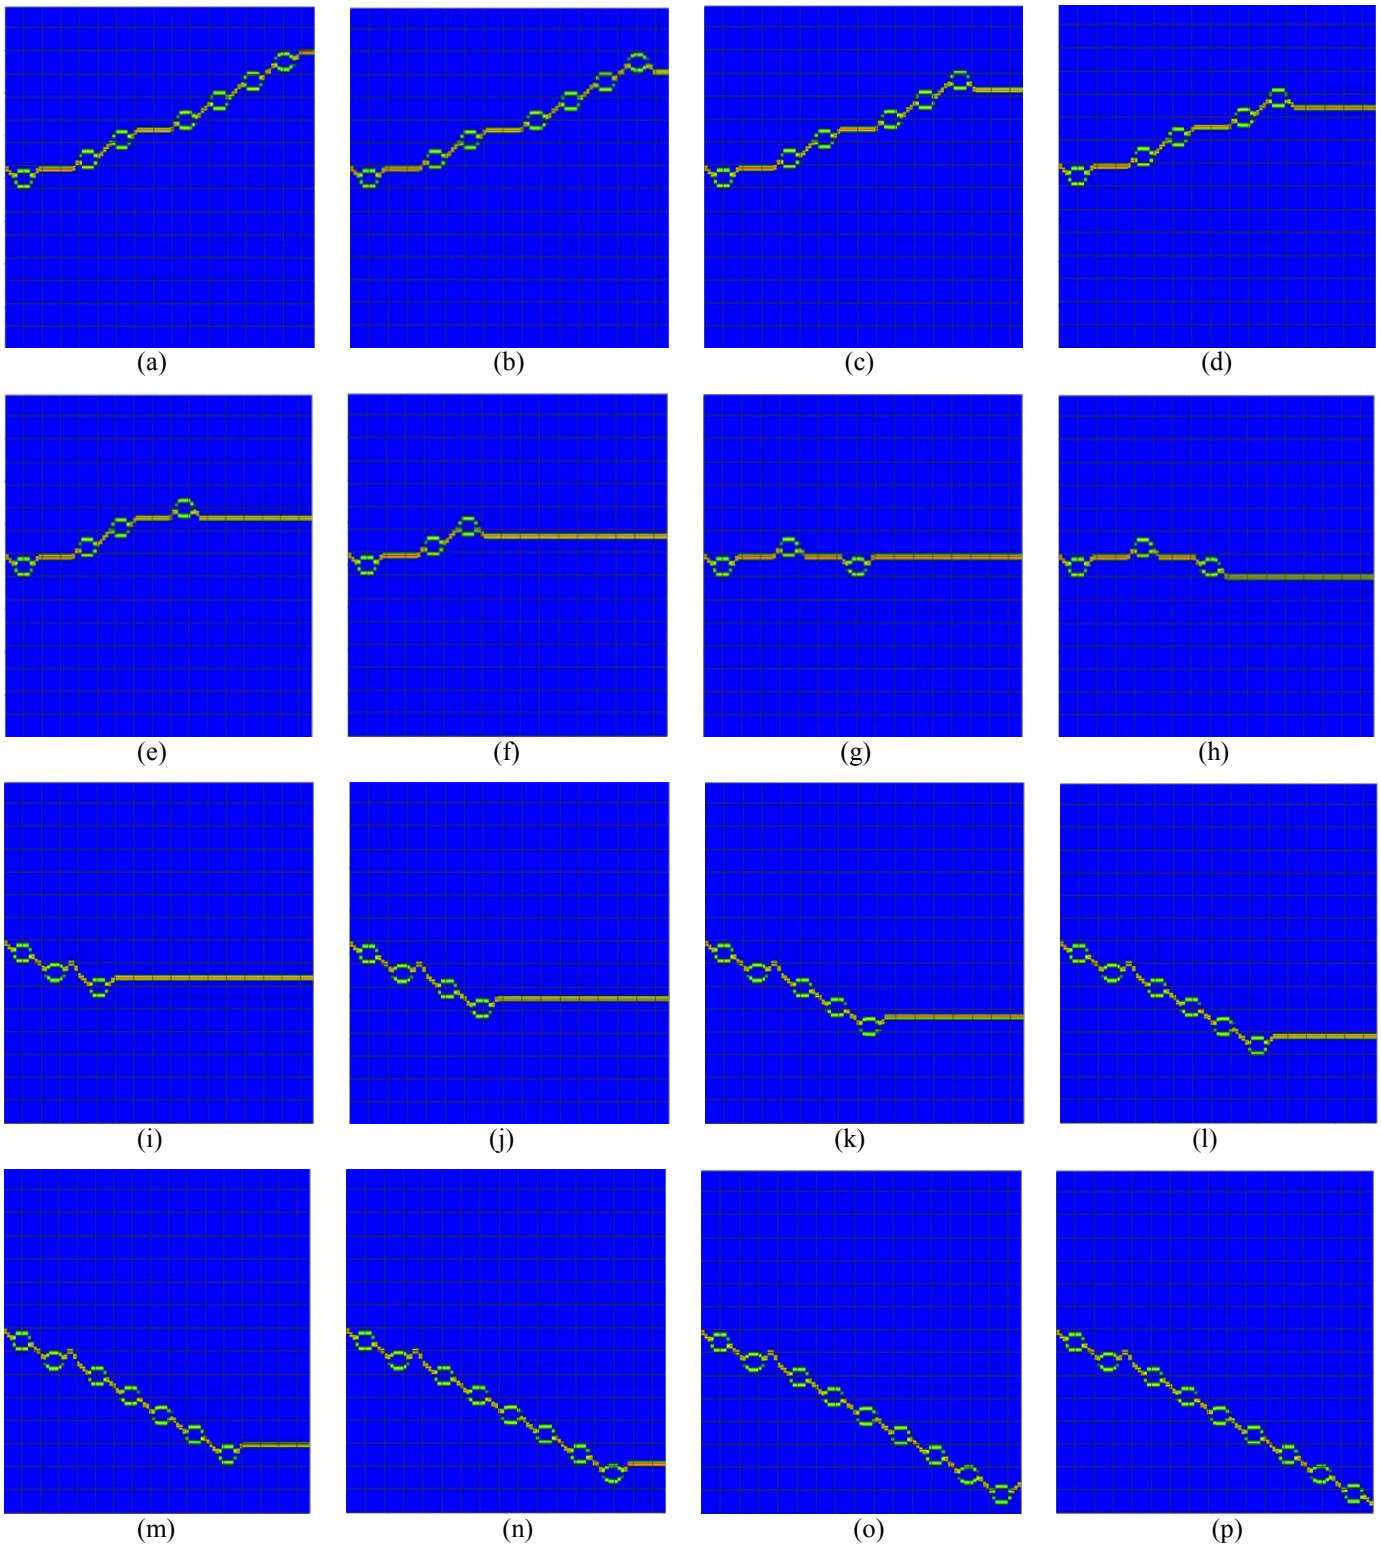

Fig. 9. Optical field propagation at (a) port 1, (b) port 2, (c) port 3, (d) port 4, (e) port 5, (f) port 6, (g) port 7, (h) port 8, (i) port 9, (j) port 10, (k) port 11, (l) port 12, (m) port 13, (n) port 14, (o) port 15, (p) port 16.

V. Conclusion

This paper gives elaborate discussion on a 1x16 signal router. 16, 2x2 electro-optic switches are used in construction, which gives the device a length of 307600 µm and width of 700 µm. At first the fundamental device i.e. MZI switch is optimized and we obtained lowest insertion loss of 0.00881 dB, excess loss of 0.0069 dB and highest extinction ratio of

33.581 dB. Then outputs for different combinations of control signals are observed and we find power being switched to each one of 16 output ports for each combination.

Enhanced Wi-Fi Direct Power Saving with Power Control for the Mobile Phone

Nam Gon Kim[1,*], Hyun Hak Cho[1], Chang Min Eun[1], and Ok Hyun Jeong
[1]Department of Electronic Engineering, Sogang University, Seoul, Republic of Korea
[*] E-mail: kimngon88@sogang.ac.kr

Abstract— **Wi-Fi Direct, that is a peer-to-peer specification based on IEEE 802.11 standard by Wi-Fi Alliance, defines the role of power saving mechanism. However, it indicates only basic rule and does not specify effective environment and the way of configuration for each parameter. In this paper, we studied the way of the optimizing Power Save Mode (PS Mode) for Wi-Fi Direct in the mobile. To maximize efficient of the PS Mode, we dynamically controlled sleep period each fixed a beacon signal period, called Target Beacon Transmit Time (TBTT) and we adapted power control scheme based on IEEE 802.11. As a result, to schedule sleep period of NoA on the power control has a benefit for the total transmission time and power consumption.**

Keywords—Wireless LAN, Wi-Fi Direct, Power Save Mode (PS Mode), Notice of Absence(NoA) protocol.

I. INTRODUCTION

In the last decade, as a variety of mobile devices including tablet PC and mobile phone have been spread and communication technology has advanced rapidly, the data traffic has increased exponentially. Device-to-device communication, such as Wi-Fi Direct using a wireless LAN has emerged to distribute traffic based on the communication technology of at least 150Mbps speed of 4G. It was not a big issue in the past, because AP is connected to an external power source without mobility. However, recent mobile devices have a high degree of mobility and use simultaneously other wireless communication such as LTE and GPS so it increases load on the mobile phone. In other words, the continuity of battery without any external power source is arising as main issue.

For this purpose, Wi-Fi Alliance has published a new standard called Wi-Fi Direct (Wi-Fi P2P) by making up for a low-speed communication in ad-hoc network and a problem based on infrastructure in conventional wireless LAN based on IEEE 802.11 [2]-[3]. Specially, it describes efficient communication methods by concurrent operation, service discovery and power saving. We studied with a focus on PS Mode because the transfer of data payload occupies a large portion on data transmission.

Wi-Fi Direct defines two way of power saving: the Opportunistic Power Save (OppPS) and the Notice of Absence (NoA) in technical specification. OppPS Protocol is a method of determining the sleep state of Group Owner (GO) whether the clients send the data using the beacon signal. On the contrary, NoA Protocol is a method for determining a transmission timing of the client in accordance with the state of GO through the beacon signal. However, the standard defines only basic transmission Protocol. It is difficult to use the protocols of PS Mode to specify parameter configuration without describing the criteria.

Therefore, we studied how to set up efficiently the parameter of PS Mode utilizing the IEEE 802.11 network and how to optimize PS mode to avoid the ambiguity of configuration without additional overhead. Thereby, we intended to reduce the power consumption of peer-to-peer communication in the mobile environment. In this paper, we have experimented that controlling the sleep period and transmission power level of the Wi-Fi Direct using the channel information for efficient parameter setting.

We tested using the Network Simulator-3 that operates based on the C ++ in Linux OS. We tried the simplest structure with two mobile devices, each GO and Client is connected 1:1 peer-to-peer network. The simulations have been performed by modifying the number of the power level of transmission for power control and the count for NoA parameter. Namely, the simulation has been conducted by changing the sleep period and transmission level each channel state during a fixed TBTT to compare the basic operation of NoA protocol.

The paper is organized as follows. Chapter 2 reviews the background and proposal. It shows that simulation is conducted how to setup the experimental environment in chapter 3. It indicates results of implementation and analysis of performance in chapter 4. Lastly, chapter 5 sets out the conclusions of this paper.

II. BACKGROUND AND PROPOSAL

First, we discuss power save mechanism of IEEE 802.11 and Wi-Fi Direct. Then, we consider the propriety of using the power control for the power saving. Finally, we propose optimizing the Wi-Fi Direct power saving with power control scheme.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

A. Related work

As specified in the standard [3], a WLAN based on IEEE 802.11 is available a power save mechanism for the power management. It determines the AP with other station to stay in one of the states; idle, awake, or sleep. In IEEE 802.11, the AP on PSM periodically announces state to mobile stations through the Traffic Indication Map (TIM) contained in the beacon frames. The stations wake up periodically to listen to the beacon from the sleep state. Similarly, Wi-Fi Direct also defines two power management protocols [2]. The OppPS protocol is advantageous for burst data transmission when it comes to the power consumption. In contrast, the NoA protocol has profit to transmit dynamic data traffic with the Delivery Traffic Indication Map (DTIM) for power consumption [7].

Another approach about the power management is the power control. Several power/rate adaptation mechanisms have been proposed for multiple rates supported by 802.11 [13]-[14]. For example, Multi-rate adaptation algorithms were proposed to improve throughput performance in ad hoc networks. Another rate control algorithms are developed specifically to extend past algorithms with power control. However, power or rate adaptation algorithms use to minimize interference among neighboring Stations.

In Wi-Fi Direct, only channel 1, 6 and 11 are employed because they have low degree of interference. We need to shift the usage of power adaptation algorithm for its usage to only adjust the power level of RF channel.

B. Proposed method

To increase the efficiency of the NoA protocol, we applied the power control scheme to power saving mechanism. The power control scheme is an efficient scheme to reduce the channel interference caused to use adjacent channels. However, because of using less interference channel in Wi-Fi Direct, we exert the power control scheme to adjust the transmission power level for reducing power consumption. Also, we have to limit the maximum transmission level to mobile environment. The experiments have been performed with Power-controlled Auto Rate Fallback (PARF) algorithm [5] for power control as changing the two factors and optimizing the parameter.

III. Experimental Environment

A. The setup of simulator

We modified the C++ code of Wi-Fi module which had been implemented in ns-3 and we implemented a NoA protocol of Wi-Fi direct communication. Ns-3 contains various models of high-quality validated and is spread over a large community of users and developers [4]. The simulation models a wireless network interface controller based on the IEEE 802.11 standard [3]. The IEEE 802.11 MAC protocol is implemented with several C++ classes on ns-3. We have simulated based on Broadcom's BCM4335 chipset for power model of realistic environments. The results of simulation were verified transmitted packets with Wireshark [6]. Only to analysis the NoA protocol through the data transfer, we simulated without device discovery, service discovery and group formation on Wi-Fi Direct. Also, to analysis the transfer a single MPDU, we simulated an 802.11g. Table 1 indicates the configuration of the power module for Wi-Fi Direct.

For wireless systems, the radio channel is the propagation loss and propagation delay model and ignore real-world effects such as multipath fading and channel capture. First, we have to examine the effects of the number of power level of transmission and the count of NoA parameter. Then, we implemented and experimented dynamic scheduling the sleep period according to the channel state on power control scheme. The available transmission is a minimum 0 dBm and maximum 16 dBm.

TABLE I. The Configuration of Power Module in NS-3

Parameter	Value
Target Chipset	BCM4335, Broadcom
Standard	802.11g / 54Mbps (OFDM)
Input Voltage	3.6V
Sleep Current	0.1mA
Tx Current	76mA

B. The network architecture of experiment

The network structure for the experiment can be seen in Fig 1. Only for two mobile devices, GO and Client is connected 1:1 peer-to-peer network. We confirmed by transmitting a packet for 60 seconds on condition that the respective parameters of NoA were changed. During 60 seconds, the Client is moved 30 meters at the GO where is 5 meters away. It stays during every 15 seconds. After that time, it is placed a new position where is 10 meters away from previous position. In other words, the distance increases 10 meters per 15 seconds. Consequentially, the position of the Client has a different channel conditions respectively. The TBTT for NoA parameter is 10.24ms; the sleep period was a 50% duty cycle. Outputs for power consumption in the simulation showed to watt.

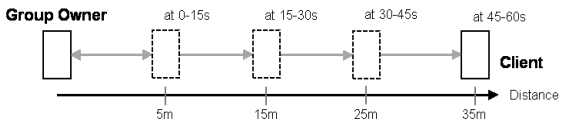

Figure 1. The network structure for the simulation

IV. Analysis of Simulation Result

A. The configuration of NoA parameter

The NoA protocol of PS Mode timing is scheduled by the values of Start time, Interval, Duration and Count. The Start time is the start time of NoA schedule. The Interval indicates the absence time. The Duration is the period of each absence. The Count is the number of absences. GO announces every beacon message to client with these four parameters. GO

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

changes the state at determined time, Client keeps NoA schedule most recently received. The example of operation for P2P GO NoA protocol with power control is shown as Fig 2.

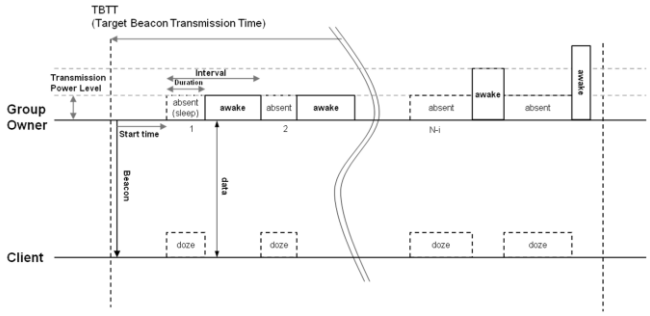

Figure 2. The example of operation for P2P GO NoA protocol with power control

1) *The number of transmission power levels*

First, we have carried out the simulation to verify the effect of power control. When the data is transmitted from WLAN devices, the maximum transmission power is typically 16~20 dBm. To use the adaptation of power control, we configured 16 dBm for maximum powers. The number of transmission power levels available between 0 dBm and 16 dBm and we turned from 4 to 16 sequencely raising 2 degrees. The Count is configured 4. At the rate of awake and sleep, that is duty cycle, is 50%.

2) *The number of count*

Next, it was set equal to a total time of transmitting the data for performance comparison of each experiment. In other words, the total processing time multiplied by the time of interval and count was configured the same one scheduling period of NoA. And by increasing the count from 4 to 12, simulation was performed with maintaining a TBTT. The setup of dividing maximum transmission level is 4. And duty cycle is fixed to 50%.

3) *The optimization of the NoA parameter*

Last, we simulated the proposed optimizing Wi-Fi Direct PS mode with power control. The simulation is conducted by scheduling sleep period and changing transmission power level according to the channel conditions. In the channel condition which is deteriorated in step 4 shown as Fig 1.; Case 1 is that sleep period is fixed the ratio of the awake and sleep time by one-to-one, the 50 percent of duty cycle. Case 2 has the time of scheduling sleep period from 87.5 to 12.5 percent per 15 seconds when the packets are transmitted. In contrast, in Case 3, the packets are transmitted with increasing the duty cycle from 12.5 to 87.5 percent. All of these cases are configured 4 as the number of transmission power level and count.

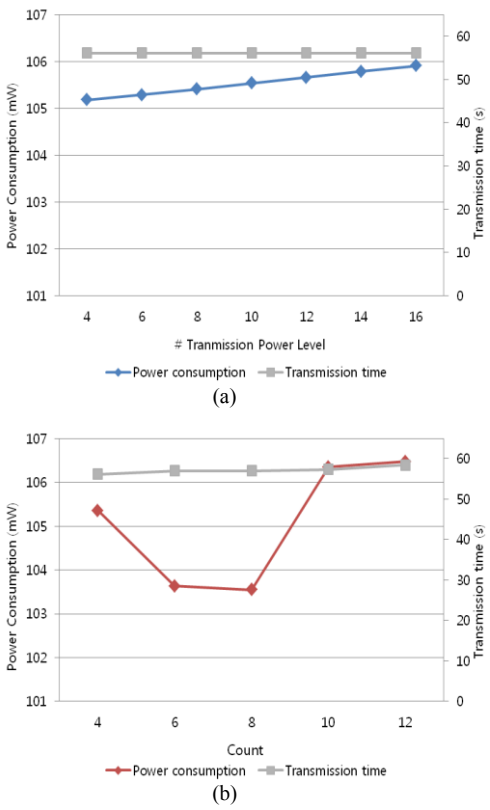

Figure 3. (a) The power consumption with the number of transmission power levels (b) The power consumption with the number of count

B. *The result of simulation*

1) *The number of transmission power levels*

We were tested by varying the number of transmission power level. In 4 to 16 levels, the power consumption was observed that the more the number of transmission power level, the more power consumption is represented. This could be the result of increasing the frequency of performing power adaptation according to the channel state for the more number of power level. The power consumption with changing the number of transmission power levels is shown in Fig 3-(a).

2) *The number of counts*

Fig 3-(b). shows power consumption with the count of NoA. The following are the results of experiments by changing the count of the NoA protocol. As the count is smaller as shown in the graph, power saving effect is larger until 8. For the total transmission time, it also completed a transmission in the first but it was little difference. While the effect of power saving is improved in infrequent scheduling and flat channel cases, it has the disadvantage that it is impossible to change flexibly the parameters due to less frequency of the scheduling in the channel which has large fluctuation. Eventually, the efficiency of NoA power saving as to the count is expected to be influence by the variation rate of channel state.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

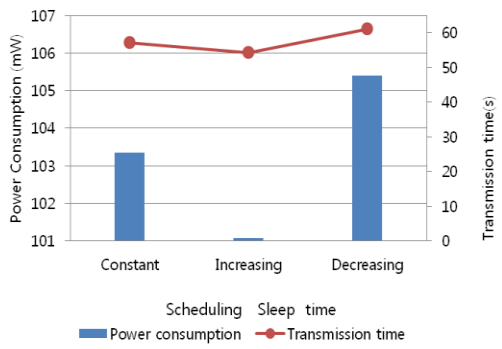

Figure 4. The power consumption in accordance with the way of dynamic scheduling.

3) *The optimization of the NoA parameter*

Finally, It is confirmed that the case 2 (Increasing sleep time) is presented the best performance in terms of the total transmission time and power consumption. Conversely, the result of case3 has the most power consumption and long transmission time. This is because the case 2 was scheduled a way to increase the capability of the transmission with NoA protocol as the transfer consumes less power when a good channel at power adaptation algorithm. As a result, it can be seen that the case 2 of performance is the best way better than 3.34% in the constant case. The power consumption in accordance with the way of dynamic scheduling is shown as Fig 4.

V. CONCLUSION

This paper has mentioned about how to use the Wi-Fi direct based on IEEE 802.11 as it is widely popular in recent years, and prepared to seek how to use a little more effective PS Mode for an increasingly important power issue. In the environment for performing power adaptation scheme according to the channel condition of the Wireless LAN, to use the NoA scheduling protocols in an efficient manner, it is good to scheduling by dividing appropriately according to the number of transmission power level in the environment and reducing the value of count in the maximum flexibility. Above all things, it is that the way to improve the power efficiency using the NoA protocol scheduling is to secure the awake time in good channel and to increase the frequency of the scheduling with the maximum flexibility in poor channel.

***Abstract*—High Peak-to-Average Power Ratio (PAPR) is one of the main drawbacks that may limit practical applications of Orthogonal Frequency Division Multiplexing (OFDM) System. Based on the well known Selective Mapping (SLM) method of PAPR reduction, in this paper, we propose a new phase sequence generation technique from Condex matrix that can achieve better PAPR reduction compared to the generally used Bauml sequence. From the simulation results, we show that our proposed phase sequence achieves 4.0 dB higher PAPR reduction compared to original SLM method and also reduces the computational overhead about 59 percent.**

***Keywords*—OFDM; PAPR; SLM; condex matrix**

I. Introduction

The concept of Orthogonal Frequency Division Multiplexing (OFDM) in terms of parallel data transmission and frequency division multiplexing was first developed in the 50s [1]. It offers a considerable high spectral efficiency, multipath delay spread tolerance, immunity to frequency selective fading and so forth [2]. At present, OFDM is considered as a strong candidate for the next generations of mobile communication systems. However, one significant problem with OFDM systems is that it can give rise to very high values of Peak-to-Average Power Ratio (PAPR). Over the last decade, various techniques to reduce PAPR have been proposed. For example, clipping and filtering, companding and coding, multiple signal representation and so forth [3–5]. The last kind includes Selected Mapping (SLM) and Partial Transmit Sequence methods (PTS) [6, 7]. Clipping and filtering is the simplest technique but it may cause in-band distortion and out-of-band radiation. In-band distortion can not be reduced by filtering and results in performance degradation, while out-of-band radiation reduces the spectral efficiency. The coding technique does not cause distortion or out-of-band radiation, but it lacks spectral efficiency. In SLM scheme, PAPR reduction is achieved by multiplying the independent phase sequences to the original input data and determining the PAPR of each phase sequence and input data combination. The combination with the lowest PAPR is transmitted. Generally Bauml sequence, based on the value set of (± 1,$\pm j$), is used in SLM. In this paper, Condex phase sequence based SLM is proposed to reduce PAPR of OFDM signal. Here, we show that Condex matrix based sequence can be used for improved PAPR reduction capability with less computational overhead.

II. Background

A. OFDM System Model

Let us consider an OFDM system consisting of N sub-carriers in the frequency domain, where vector $X = [X_0, X_1, ..., X_{N-1}]$ denotes the input data blocks. Each symbol in X is used to modulate a sub-carrier, and the input symbol vector is called the input symbol sequence. For N-th sub-carrier, let $f_k, k = 0, 1, ...N-1$. In the OFDM system as the adjacent sub-carriers are orthogonal to each other, let, $f_k = k.\Delta f$, where $\Delta f = 1/(NT)$ and T is the symbol duration. Therefore, the complex baseband representation of the transmitted OFDM signal is given by:

$$x(t) = \frac{1}{\sqrt{N}} \sum_{k=0}^{N-1} X_k e^{j2\pi k t \Delta f}, 0 \leq t \leq NT \tag{1}$$

where $j = \sqrt{-1}$, Δf is the sub-carrier spacing, and NT denotes the useful data block period. If $x = [x_0, x_1, ..., x_{N-1}]$ denotes a discrete time OFDM signal vector, then x corresponds to the Inverse Fast Fourier Transform (IFFT) of X. that is, $x = QX$, where Q is the IFFT matrix.

B. PAPR

In general, PAPR is defined as the ratio between the maximum power and the average power for the envelope of a baseband complex signal during an OFDM symbol period. The PAPR of the OFDM signal $x(t)$ can be written as follows:

$$\text{PAPR} = \frac{\max\limits_{0 \leq t \leq T} |x(t)|^2}{E(|x(t)|^2)} \tag{2}$$

where $E[.]$ is the expectation operator which denotes the average value over the time duration of OFDM symbol. The PAPR reduction techniques are concerned with reducing max $|x(t)|$. In practical situation, the discrete-time signals are mostly used.

In OFDM system, some input sequences would result in higher PAPR than others. For example, an input sequence that requires all such carriers to transmit their maximum amplitudes would certainly result in a high output PAPR. Thus, by limiting the possible input sequences to a smallest sub set, it is possible to obtain output signals with a guaranteed low output PAPR.

Some of the important performance factors that should be considered while judging the performance of a PAPR reduction technique are PAPR reduction capability, spectral spreading, bit error rate, computational complexity, loss of data rate etc. In this paper, we focus on reduction of PAPR as well as computational complexity.

III. SLM TECHNIQUE

In the SLM technique, the transmitter generates a set of sufficiently different candidate data blocks, all representing the same information as the original data block, and selects the most favorable for transmission [6, 8]. A block diagram of the SLM technique is shown in Figure 1. Each data block is multiplied by U different phase sequences, each of length N, $B^{(u)} = [b_{u,0}, b_{u,1}, ...b_{u,N-1}], u = 1, 2, ..., U$, resulting in U modified data blocks. To include the unmodified data block in the set of modified data blocks, we set $B^{(1)}$ as the all-one vector of length N.
Let us denote the modified data block for the u_{th} phase sequence $D^{(u)} = [D_0 b_{u,0}, D_1 b_{u,1}, ...D_{N-1} b_{u,N-1}], u = 1, 2, ..., U$, after applying SLM to X, the multi-carrier signal becomes

$$d_k^{(u)} = \sum_{n=0}^{N-1} D_n.b_{u,n}.exp(\frac{j2\pi kn}{N}) \;\; 0 \leq k \leq N-1. \qquad (3)$$

Among the modified data blocks $D^{(u)}$, the one with the lowest PAPR is selected for transmission. Information about the selected phase sequence need to be transmitted to the receiver as side information. At the receiver, the reverse operation is performed to recover the original data block. For implementation,the SLM technique needs U times IDFT operations, and the number of required side information bits is $log_2 U$ for each data block. This approach is applicable with all types of modulation and any number of subcarriers.

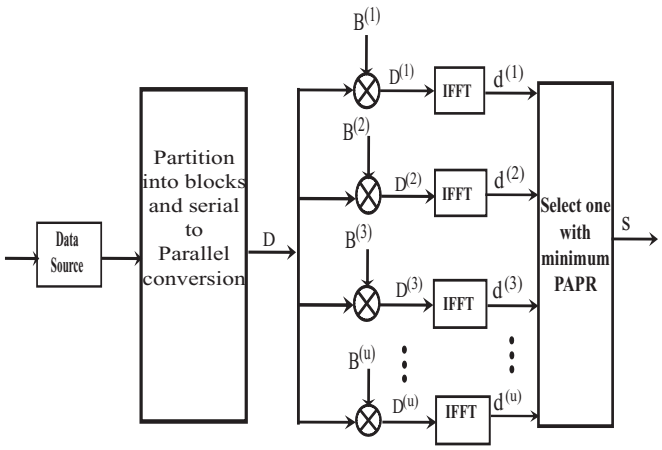

Fig. 1. Block diagram of the SLM technique with U different signal representation and phase weights to produce a minimized PAPR signal

The amount of PAPR reduction for SLM depends on the number of phase sequences U and the design of the phase sequences. There are extensions of SLM technique which does not need explicit information to be sent to the receiver. For further information see the reference [9].

IV. PHASE SEQUENCE GENERATION USING CONDEX MATRIX

PAPR of the OFDM system can be reduced by selecting appropriate phase sequences in the SLM method. In order to do so, in this paper, we have investigated a set of counter-example matrices to condition number estimators [10, 11], and practically have selected the SONEST [11] to generate proper phase sequences for the OFDM system. We term this matrix here as Condex matrix. Using the algorithm as in [11], a Condix matrix (C) of order 4 can be writhen as:

$$C = \begin{bmatrix} 1.0000 & 0.0000 & 0 & 0.0000 \\ 0.0000 & 59.7379 & -10.6796 & -48.0583 \\ 0 & -10.6796 & 2.9417 & 8.7379 \\ 0.0000 & -48.0583 & 8.7379 & 40.3204 \end{bmatrix} \qquad (4)$$

From the above equation $C^{(u)} = [C_0^{(u)}, C_1^{(u)}, .., C_{N-1}^{(u)}]$ can be defined with each row of the normalized Condex matrix C. Each input data block $D = [D_0, D_1, ...D_{N-1}]$ is multiplied with U different phase vectors $C^{(u)}, u = 1, 2, ..., U$ Then, all U subcarrier vectors are transformed into time domain to get the following:

$$d^{(u)} = IDFT\{D^{(u)}\} = IDFT\{D_{(n)}.C_n^{(u)}\} \qquad (5)$$

Finally, the one with the minimum PAPR is selected for transmission.

V. SIMULATION RESULTS

In this section, we show simulation results depicting the comparative performance of SLM technique using Condex and Bauml phase sequence. The simulation parameters are introduce in Table I. Fig. 2 shows the number of symbols that achive minimum PAPR versus Condex phase sequence

TABLE I
SIMULATION PARAMETERS

Number of Sub-carriers (N)	64
Modulation Technique	$BPSK$
Phase Sequences	$Bauml\ and\ Condex\ Matrix$
Length of Phase Sequences	64
Number of OFDM Symbols	$10,000$
Simulation Tool and Version	MATLAB [7.8.0.347 (R2009a)]

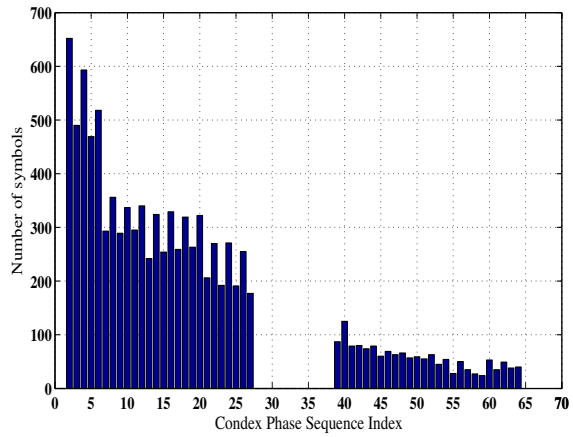

Fig. 2. Complexity diagram for SLM scheme (Condex Phase Sequence) with minimum PAPR

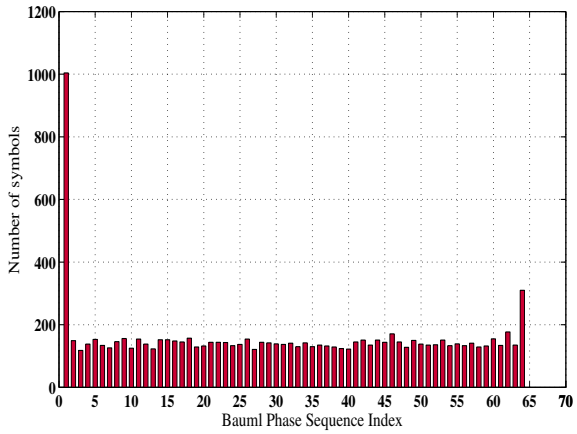

Fig. 3. Complexity diagram for SLM scheme (Bauml Phase Sequence) with minimum PAPR

index, we call this plot as the complexity diagram since it depicts the number of search operations required to achieve a certain level of PAPR. It can be observed from the figure that the highest number of symbols with minimum PAPR can be seen at the phase sequence number 2. With the increasing number of Phase sequence index from 2 to 27, it is also observed that the number of symbols is continuously decreasing. Similar decreasing phenomenon for number of symbols is also seen as we go along from phase sequence number 39 to 64. Moreover, it is observed from the figure that regarding number of symbols, even phase index showed better performance than odd one.

In Fig. 3, we show the number of OFDM symbols with minimum PAPR versus the Bauml phase sequence index. It is observed that about $1,000$ out of total $10,000$ OFDM symbols meet the minimum PAPR requirements at phase sequence index 1 while less than 200 symbols did the same

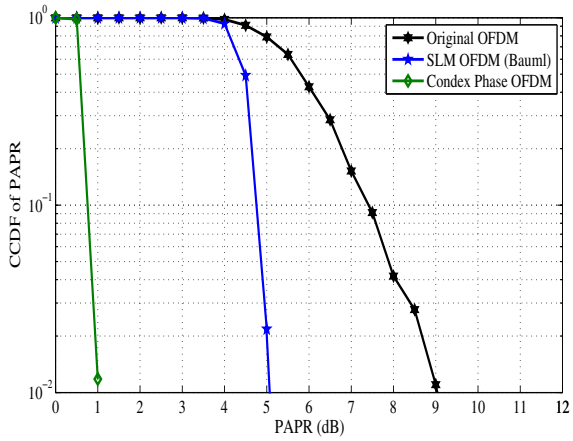

Fig. 4. CCDF vs. PAPR of OFDM Blocks

for index 2 to 63 with the exception of index 64 which has slightly higher number of such symbols.

Now the CCDFs of PAPR for Condex matrix, Bauml phase sequence and original OFDM are plotted against PAPR (dB) in Fig. 4. It shows that for a probability of 10^{-2}, the corresponding PAPRs of Condex matrix, Bauml phase sequence and original OFDM are 1dB, 5.1dB and 9.0dB, respectively.

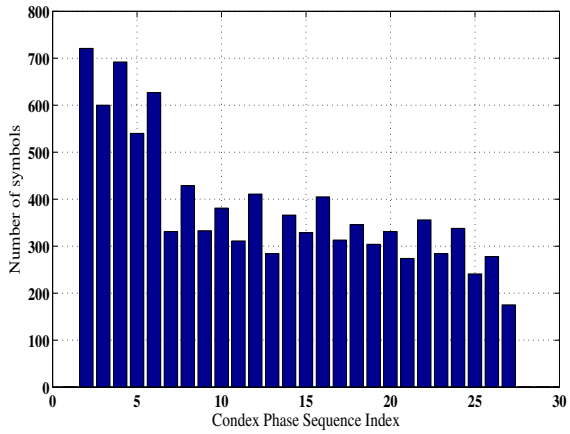

Fig. 5. Complexity diagram for SLM scheme (Condex Sequence from 2 to 27 index) with minimum PAPR

Since Fig. 2 shows that large number of OFDM symbols satisfy minimum PAPR requirement when sequence no. is between 2 to 27, we focused in this region and show the corresponding complexity diagram in Fig. 5. Since total no. of sequence are reduce from 64 to 26, it implies that only 26 numbers of iteration is required to attain almost the same level of PAPR that previously required 64 iterations. It means, a complexity reduction has been reduce by 59%.

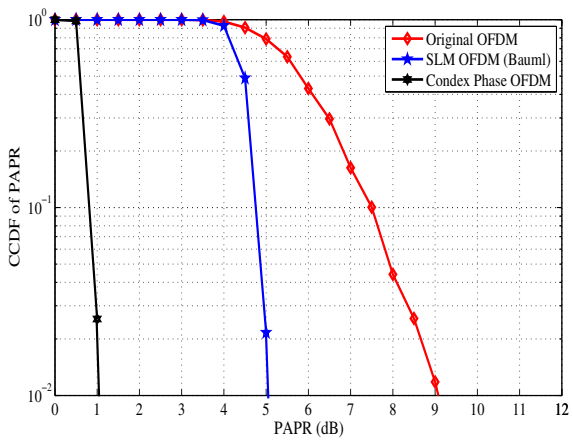

Fig. 6. CCDF vs. PAPR of OFDM Blocks Corresponding to Fig. 5

.

Figure 6 shows the comparative CCDF of PAPR for Condex and Bauml phase sequence based SLM techniques with that of original OFDM. We see for Condex sequence no. 2 to 27 that for a probability of 10^{-2}, the corresponding PAPR of Condex, Bauml and original OFDM are 1.1dB, 5.1dB and 9.0dB, respectively, which means had to sacrifice 0.1dB PAPR compared to Fig. 4.

VI. Conclusion

Large PAPR of transmitted signals may be a main cause of performance degradation of OFDM system. Several techniques have been proposed for PAPR reduction. But most of them cannot achieve simultaneously a large reduction in PAPR with high frequency efficiency, low complexity and good error correction. No specific PAPR reduction technique is the best solution for all multicarrier transmission. It is an important issue to choose the right phase sequence for original SLM method according to the above mentioned requirements. Using this techniques, we showed that it is possible to simultaneously achieve significant reduction in PAPR along with low computational overhead. The PAPR reduction capability was evaluated using MATLAB simulation tool, the results show that the proposed scheme offers better PAPR reduction than other schemes consider here. The simulation results (Figs. 5 and 6) show that the computational complexity can be reduced up to 59% if we sacrifice little 0.1 dB PAPR. In our future work, we have plans of investigating the effects of higher order modulation scheme such as 4-QAM,8-QAM using ours proposed method. This will help to make a comparative study of different modulation scheme from the perspective of PAPR performance.

***Abstract*—The energy efficiency aspect of cellular networks is a vital topic of research over the recent days. As energy consumption is on the rise and the price of electricity is increasing very rapidly, necessity to reduce electricity usage in every aspect is becoming much more significant. The power grid infrastructure, from which the cellular networks attain the required electricity for operation is considering a significant change from the traditional electricity grid to the smart grid. The base stations, which are the main candidates for energy consumption in cellular networks, remain in operation even when there are a very few users or no user at all. In this paper, we propose an effective application scenario of the femtocell technology for power saving purpose of cellular networks. Effective deployment of femto-access-points in the required places can reduce the power usage of cellular networks by turning off the redundant base stations. Moreover, the signal to noise plus interference ratio is also enhanced in comparison to the traditional scheme. The base station turn off probability and the energy consumption in the overall network are analyzed. The comparison results show that the proposed energy efficient model can significantly reduce energy consumption and increase the service quality of the cellular users.**

Keywords*— *Smart grid, cellular network, energy consumption, QoS, and femtocell

I. Introduction

The smart grid *(SG)*, also called smart power grid, intelligent grid, intelligrid, future grid or intragrid, is an enhancement of the 20th century power grid. The traditional power grids are normally used to carry power in one way direction only. These power grids generally carry power from a few central generators to a large number of users or consumers. On the other hand, SG creates an automated and distributed advanced energy delivery network by using the two-way flow of electricity. The SG uses modern information technologies and is capable of distributing power in a more efficient way. It also emphasizes on energy saving of the different smart appliances and commodities [1].

Recently, rapidly rising energy price has led to a trend of studying the energy efficiency aspect of communication networks. The cellular operators pay a handsome amount of electricity bill which has become a significant portion of their total expenditure. The CO_2 emissions produced by wireless cellular networks all over the world are equivalent to those from more than 8 million cars. In a typical wireless cellular network, base stations (BSs) consumes 60 − 80% energy of the overall cellular network's energy consumption. Almost 120,000 new base stations are deployed throughout the world every year to provide necessary support to the cellular users [2]. Our survey works suggest that a base station consumes more than 85% of its peak energy even when there is little or no traffic. Therefore, a dynamic operation of the cellular base stations based on the traffic is very much essential for the energy efficient approach of cellular networks. The proposed model in this paper is expected to reduce the energy consumption of cellular networks to a significant level. However, this model is much more applicable for some remote areas where there are a very few cellular users and a base station remains in operation continuously to serve those few users. Using the simulation results, we show that the proposed scheme can save energy of cellular networks and improve the quality of service (QoS) to a certain level.

The rest of this paper is organized as follows. Section II shows the proposed energy efficient model. Section III shows the performance analysis of the proposed scheme. Finally, conclusions are drawn in the last section.

II. Proposed Energy Efficient Model

Suppose a cellular network is powered by smart grid where there is a flow of electricity and communication simultaneously as shown in Fig. 1.

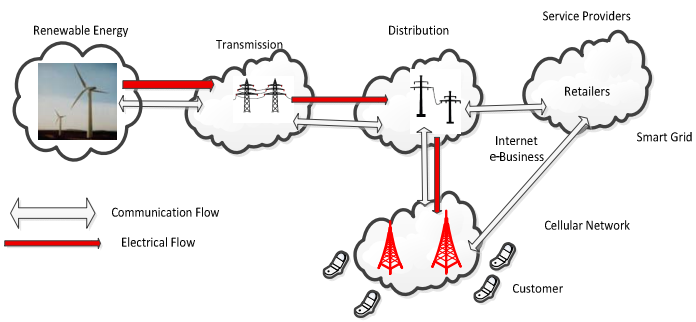

Figure 1. A cellular network powered by the smart grid [2].

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

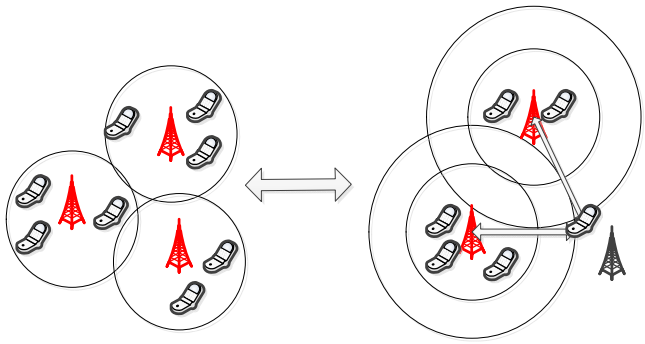

Figure 2. Coverage extension and energy saving with coordinated multipoint (CoMP) [2].

In [2], the authors proposed a model in which the redundant base station is turned off and the users of that network are served by coverage extension of the neighboring base stations using the coordinated multipoint method for energy saving purpose. This model is showed in Fig. 2.

If the redundant base station is turned off as shown in Fig. 2, a decent amount of energy can be saved if the existing user is served by the neighboring base stations. But we propose another model for saving energy of cellular networks using femtocell network which may turn out to be a very promising solution for saving more energy of cellular networks especially in remote areas.

In our proposed model, femto-access-points are installed in some places which have the most probability of carrying a mobile user in the entire cellular network served by a base station. The femto-access-points (FAPs) are low-power, small-size home-placed base stations that enhance the service quality for the indoor mobile users [3]. Fig. 3 shows an example of the proposed energy efficient model. When all the users remain inside the femtocellular coverage region, the macrocellular BS is allowed to turn off. But if any user stays outside the femtocellular coverage, the macrocellular BS must remain in operation to serve that particular user. Periodic checking of user's location and the QoS is tested by the dynamic checking application of the SG. Our purpose is not only saving energy of cellular networks but also to increase the service quality of the existing users. Femto-access-points are ideal for this case as these devices run with very low operating power and at the same time can enhance the QoS to a significant level.

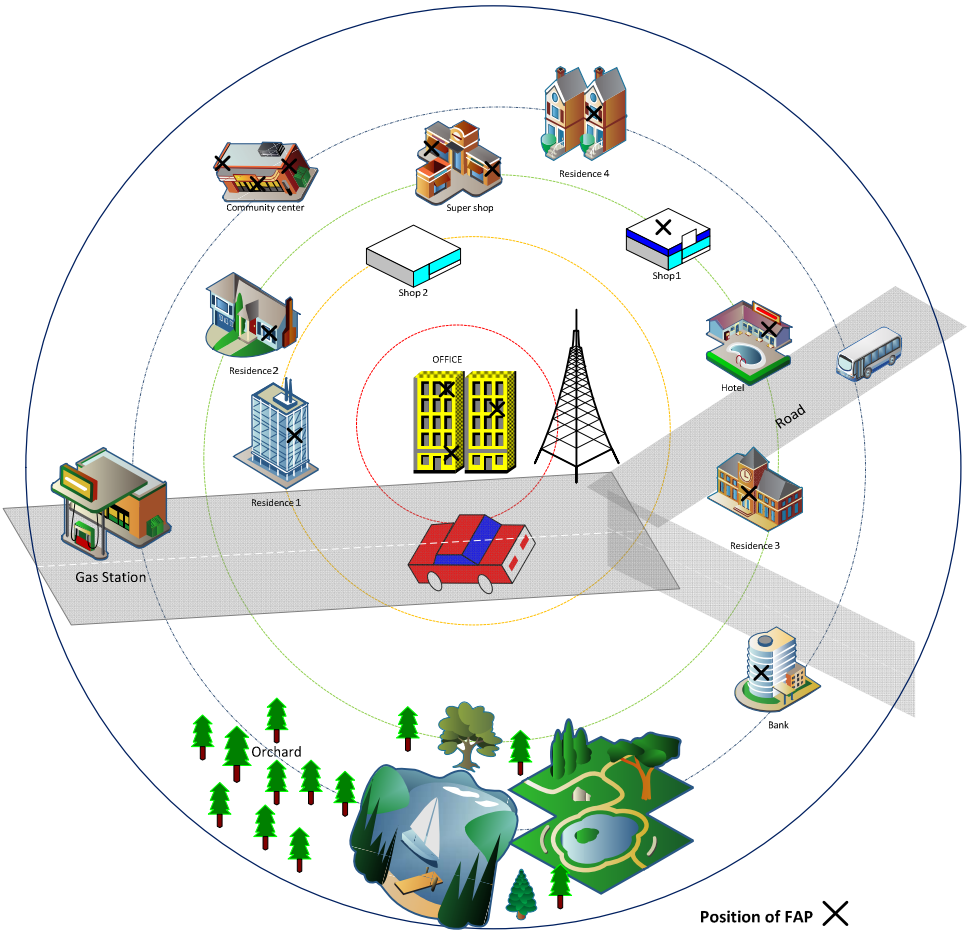

Figure 3. Proposed energy efficient model with femtocell/Macrocell integrated network.

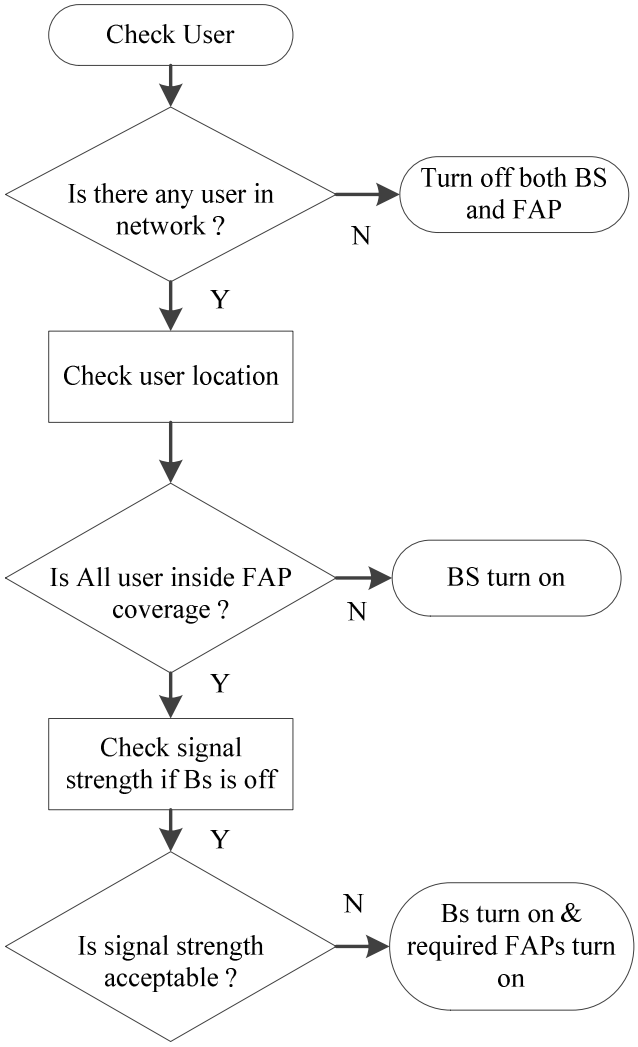

Figure 4. Flow chart showing the condition for the BS to be turned off in the proposed scheme.

Femtocells are small base stations with low transmission power, and with almost all cellular functionalities, but a limited coverage to end users in indoor environments. A femtocell allows service coverage extended to indoor environments, especially where wireless access is limited or unavailable, without expensive deployment cost.

A flow chart is shown in fig. 4 which shows the algorithms of the proposed scheme. The network will first check the existence of a user. If no user exists in the network, both the macrocellular BS and the FAPs will remain off. If any users exist, then the network will search for user's location. When any of the users remain outside the FAP coverage area, the BS will not be allowed to turn off. But, if all users exist inside the femtocellular network, then the network will check the signal strength available for the users if the BS is shut down. The BS will shut down if the signal strength is found within acceptable limit, otherwise; it will remain on in order to provide network support to the existing users. This model requires a periodic checking of the position of each user inside the network. By adopting this process, the macrocellular BS will sometimes remain turned on and sometimes remain turned off.

III. PERFORMANCE ANALYSIS

This section provides the probability analysis performance and the signal quality performance of our proposed model.

A. Probability Analysis

When a redundant BS is shut down and the users of that area are to be served using FAPs, then it is required to analyze the probability of the existence of a user under the femtocell coverage area. If all users are within the femtocell coverage area then the BS may remain shut down and service is provided to the user by the femtocell network, but if any user remains outside the femtocell coverage area, then the BS must be turned on in order to provide service to that user.

For simplicity in calculation, we have divided the total considered area into 4 sub-circles each with a fixed distance from the center point of the main circle. The coverage area of a macrocellular BS is assumed to be 500m. We performed our analysis assuming 15 FAPs in the total coverage area. All the stations considered in the coverage area have a specific factor according to the importance of that station for carrying users. The factors assumed for each station is given in Table I. The coverage area of a FAP is determined by

$$a=4\square r^2$$

where r is the radius of each FAP coverage.

If there exist stations with n number of factors then Let, A_1 is the area under user existence probability factor f_1, A_2 is the area under user existence probability factor f_2, A_3 is the area under user existence probability factor f_3, and A_n is the area under user existence probability factor f_n.

Let the remaining area where no FAPs are installed is A_M with a user existence probability factor of f_M

The probability of a user to exist in the FAP coverage area is given by

$$P=\frac{f_1\sum_{i=1}^{N_1}A_{1i}+f_2\sum_{i=1}^{N_2}A_{2i}+f_3\sum_{i=1}^{N_3}A_{3i}+.....+f_n\sum_{i=1}^{N_n}A_{ni}}{\left(f_1\sum_{i=1}^{N_1}A_{1i}+f_2\sum_{i=1}^{N_2}A_{2i}+f_3\sum_{i=1}^{N_3}A_{3i}+.....+f_n\sum_{i=1}^{N_n}A_{ni}\right)+f_mA_m} \quad (1)$$

where N_1 is the number of places under user existence probability factor f_1, N_2 is the number of places under user existence probability factor f_2, N_3 is the number of places under user existence probability factor f_3, N_n is the number of places under user existence probability factor f_n.

The probability of the BS to be turned off with the number of user can be expressed as

$$p=\left(f_p\right)^n \quad (2)$$

where f_p is the average importance factor considered for the entire region and n is the number of user.

The analysis is performed assuming only 15 FAPs in the considered total area. The performance would be better if more number of FAPs are used. However, FAPs should be installed in the places where there is a big possibility of users to exist. Unplanned deployment of FAPs in the network may result in no significant advantage for saving energy. Table II summarizes the values of the parameters that we used in our analysis.

TABLE I: SUMMARY OF NUMBER OF FAP AND DIFFERENT FACTORS USED IN ANALYSIS

Station Name	No. of FAP	Factor *(f)*
Office	3	1 (=f_1)
Super shop	2	0.8 (=f_2)
Community center	3	0.8 (=f_2)
Residence 1	1	0.7 (=f_3)
Residence 2	1	0.7 (=f_3)
Residence 3	1	0.7 (=f_3)
Residence 4	1	0.7 (=f_3)
Bank	1	1 (=f_1)
Hotel	1	0.7 (=f_3)
Shop 1	1	0.7 (=f_3)
Shop 2	0	0.3 (=f_3)
Remaining free space	0	0.01 (=f_3)

TABLE II: SUMMARY OF THE PARAMETER VALUES USED IN ANALYSIS

Parameter	Value
Carrier frequency	1800 [MHz]
Transmit signal power by the macrocellular BS	1.5 [kW]
Transmitted signal power by a FAP	15 [mW]
Power required for operation of a macrocellular BS	2 [kW]
Power required for operation of a macrocellular BS	8 [W]
Height of a macrocellular BS	100 [m]
Height of a FAP	2 [m]
Distance of the MS from reference FAP	7 [m]
Lpen	20 [dB]
Lsh	8 [dB]
Range of a macrocellular BS	500 [m]
Range of a FAP	15 [m]
Average importance factor, f_p	0.7
Total received noise	$7 * 10^{-7}$ [mW]

The probability of a macrocellular BS to be turned off increases rapidly with the increase of FAPs installed in the considered network. As FAPs are very low power consuming devices, installment of a large number of FAP in the network will still result in less energy consumption compared to that by the BS alone. Fig. 5 shows the comparison of the probability for 3 different number of users existing in the network. As the number of user increases, the probability of the BS to be turned off decreases. So, the BS needs to be turned on when the number of user is more in the network as there will be a probability of at least one user to stay outside the femtocell network region.

Fig. 6 shows the comparison between 3 different cases for BS turn off probability. The energy saving possibility is enhanced if more FAPs are used. If only 5 FAPs are used in the network, the probability of the BS to be turned off is nearly 5% when 5 users exist in the network. But if 25 FAPs are used for the same network, the probability of the BS to be turned off is more than 50% for the same number of user.

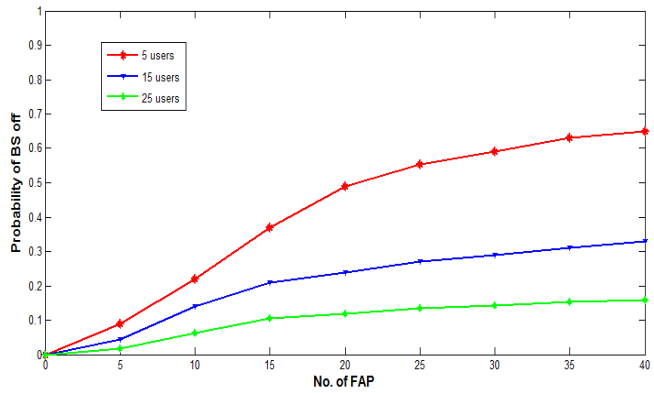

Figure 5. Probability of macrocellular BS to be turned off with increasing FAP for different number of users.

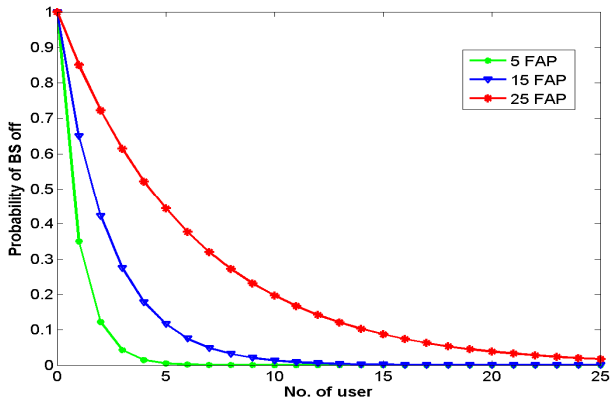

Figure 6. Comparison of macrocellular BS turn off probability with number of user for different cases.

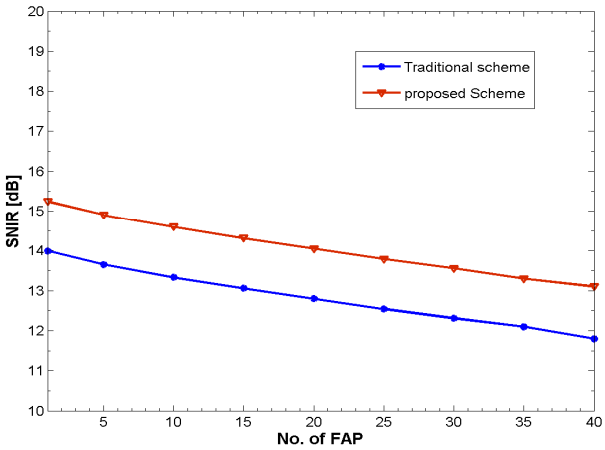

Figure 7. Comparison of *SNIR* levels between the proposed model and the traditional model

B. SNIR Analysis

The propagation model for a macrocell case can be expressed as:

$$L = 36.55 + 26.16\log_{10} f_c - 3.82\log_{10} h_b - a(h_m) + [44.9 - 6.55\log_{10} h_m] \log_{10} d + L_{sh} \quad [dB]$$

$$a(h_m) = 1.1[\log_{10} f_c - 0.7]h_m - (1.56\log_{10} f_c - 0.8) \tag{3}$$

where fc is the center frequency in MHZ, h_b is the height if the macrocellular BS in meter, h_m is the height of the MS in meter, d is the distance between the macrocellular BS and the MS in kilometer, Lsh is the shadowing standard deviation.

The propagation model for a femtocell case can be expressed as [3]:

$$L_f = 20\log_{10} f_c + N\log_{10} d_1 + 4n^2 - 28 \quad [dB] \tag{4}$$

where fc is the center frequency in MHZ of the femtocell, n is the number of walls between the MS and the FAP, and d_1 is the distance between the FAP and the MS in meter.

The received *SNIR* level of a femtocell user in a macrocell/femtocell integrated network can be expressed as:

$$SNIR = \frac{S_0}{I_m + I_f + N} \tag{5}$$

Simulation results show that the proposed model provides better signal-to-noise plus interference level. Fig. 7 demonstrates the comparison of SNIR level between traditional scheme and proposed scheme. The effect of the macrocellular BS and the number of FAPs has been considered here. As the BS will not remain turned on for all the time in the proposed model, there will be a decrease in the average noise level. Thus, the SNIR level is increased in the proposed model according to equation (5).

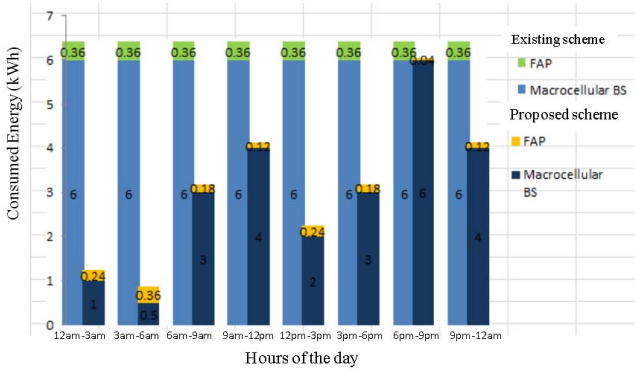

Figure 8. Comparison of energy consumption between the proposed model and traditional model

C. Comparison of Energy Consumption

In our proposed model, the macrocellular BS will only remain shut down if the existing FAP can provide proper service to all the active users. In general, the number of active user becomes low in the middle of the night. So the BS may remain shut down for most of the time during late night. Thus, a large amount of energy can be saved in that period of night. However, the BS may remain turned off even in different times of the day if the FAPs can provide proper service to the existing users in that period of time. The FAPs consume very low energy compared to the macrocellular BS. So using many FAPs can still result in significant energy saving.

If we compare the energy consumption of the cellular network for the traditional model and the proposed model, there is a large amount of energy saved in the proposed model as the main energy consuming element for cellular network i.e., the macrocellular BS remains off for a certain period of time in this model. Fig. 8 shows the comparison of energy consumed between the traditional model and the proposed model. The saving of energy can be increased further by installation of FAPs in required places where there is a great possibility of carrying mobile users. For vehicular environment, the proposed model in [4] is good enough to serve the mobile users.

IV. CONCLUSIONS

Saving of energy in cellular network communication is an important issue as energy prices are increasing day by day. Energy efficiency of the cellular network can be enhanced by the use of femto-access-points. Proper utilization of FAPs can result in improved service quality and reduction in the consumed energy of macrocellular base station. If the base station is allowed to turn off even for a small amount of time, a significant amount of energy can be saved as most of the energy required in the cellular communication is consumed by the base station. Our proposed model can be used extensively for energy saving purpose in cellular communications. Femtocells are a novel wireless networking technology that has several advantages including lower cost, better signal quality, and reduced infrastructure cost. In this paper, we

discussed the advantages of femtocellular network for saving energy of cellular communication networks. The various performance analysis and the comparison results are presented. The simulation results demonstrate that the deployment of femtocells will significantly reduce the consumption of energy of cellular networks.

Abstract— **In this paper, the crystallographic orientation-dependent performances of 635nm red quantum well (QW) laser are numerically studied. The electronic and optical characteristics of the laser are investigated by solving time independent Schrodinger equation using finite difference method. The results are obtained in (001), (101), ((111), (113), and (211) orientations and found that there is a substantial correlation of the peak gain and peak emission wavelength with crystal orientations. The maximum and minimum gains are estimated in (113) and (211) orientations and the peak emission wavelengths are found 640nm and 648nm for the crystal orientations (113) and (211). The orientation dependent energy band dispersion profiles are used to explain the results presented here.**

Keywords— VCSEL, Red laser, QW, Crystal orientation

I. INTRODUCTION

Vertical cavity surface emitting laser (VCSEL) can be used as a high power laser source in medical science, communication and industrial sectors. Red VCSEL was first demonstrated in 1992 (optical pumping) and 1993 (electrical pumping) at Sandia National Laboratories [1], [2] and Chiao Tung University in Taiwan [3]. Recent research demonstrates that lasers at 635nm wavelength are the exact vibration of a healthy living cell and is optimal for healing and most beneficial for stimulating acupuncture points [4]. Red lasers are also used in photodynamic therapy, solid state laser pumping, semiconductor surface inspection, sensor and other applications which led us to concentrate our interest in 635nm red laser [5]-[7].

Generally gallium indium phosphide ($Ga_xIn_{1-x}P$) is used in the active region of the quantum well (QW) material for red laser [8], [9]. In a QW structure energy levels are discretized due to the quantum confinement effect. Lasing occurs due to transition of electrons from the conduction band minima to different valance sub-bands. This transition plays an important role in determining the optical gain and emission wavelength of a laser. To understand the orientation dependent gain and peak emission wavelength characteristics the proposed VCSEL is modeled using time independent Schrodinger equation.

The band structures of QW strongly depend on crystal orientation [10]. Recently, some works [11]-[13] reported on orientation dependent growth techniques and laser performance. The growth of high quality epitaxial layer on (201) GaAs substrate was reported by Woolf et al. [11]. Orientation dependent growth of InGaAs/InP was noticed by Zwinge et al. [12]. Nootzel and Plog grown AlAs/GaAs multi-layered structure on (210) oriented substrate [13]. Metal Organic Chemical Vapor Deposition and Molecular Beam Epitaxy techniques are suitable for the growth of thin, uniform non-(001) crystal orientated QW structure. Although, it is possible to fabricate thin active region on non-(001) oriented substrate, it becomes very difficult to grow thick laser due to structural degradation. Wafer bonding technique is used to avoid this type of structural degradation [14], [15].

In infrared range, orientation dependent performance of InGaSb laser was reported in the past [16]. But in the visible range, orientation dependent characteristics of lasers have not been reported yet. Here, we have studied the performance of a 635nm $Ga_{0.5}In_{0.5}P/(Ga_{0.5}Al_{0.5})_{0.5}In_{0.5}P$ red laser in different crystal orientations. The orientation dependent optical gain and peak emission wavelength are investigated and their characteristics are explained by the energy separation between the conduction and valence band as well as magnitude of momentum matrix elements.

II. BAND GAP ENERGY CALCULATION

The peak emission wavelength of laser mainly depends on the band gap energy of the material used in active region. So, the selection of composition of the semiconductor material used in the active region and barrier layer is very important. In this structure GaInP is used in the active region and AlGaInP is used in the barrier of QW.

The band gap energy of $Ga_xIn_{1-x}P$ is given [17] by-

$$E_{gw}(Ga_xIn_{1-x}P) = E_g(GaP)x + E_g(InP)(1-x) - bx(1-x)$$

where, E_{gw} is the band gap energy of the material used in the QW, x is the mole fraction of Ga and b is the bowing parameter.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

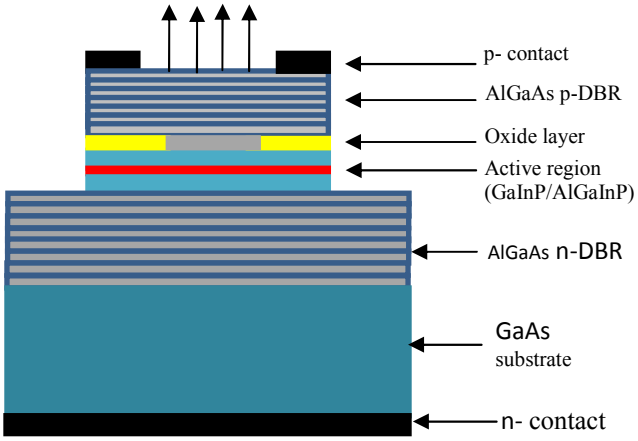

Figure 1. Structure of $Ga_{0.5}In_{0.5}P/(Ga_{0.5}Al_{0.5})_{0.5}In_{0.5}P$ red laser.

Here $(Ga_{0.5}Al_{0.5})_{0.5}In_{0.5}P$ is used in the barrier layer. The bandgap energy of the barrier material is determined using the following relationship [18]

$$E_{gb} = E_{gw}(Ga_x In_{1-x} P) + 0.36$$

III. DEVICE STRUCTURE

"Fig. 1" shows the proposed VCSEL where $Ga_{0.5}In_{0.5}P$ ternary alloy is used in the active layer and $(Ga_{0.5}Al_{0.5})_{0.5}In_{0.5}P$ quaternary alloy in the barrier layer. The QW structure is grown on n+ GaAs substrate. Above the substrate, an n-AlGaAs high reflectivity distributed bragg reflector is grown. Then the active region having a thickness of 8nm is sandwiched between two barrier layers each with a thickness of 10nm. Above the upper AlGaInP barrier layer an oxide aperture is used for current and index confinement. Highly doped contact layers are grown at the top and the bottom of the surface for the formation of ohmic contact.

III. ORIENTATION DEPENDENT GAIN

The optical gain of QW structure by considering the valence band intermixing effect can be expressed [19] by

$$g(E) = \frac{2q^2\hbar}{n\varepsilon_0 c m_0^2 LE} \sum_{n,m} \int_0^\infty \frac{k_t M_{nm}(k_t)(\Gamma/2\pi)}{(E_{cn}(k_t) - E_{kpm}(k_t) - E)^2 + (\Gamma(2\pi)^2} (f_c^n - f_v^m) dk_t \quad (1)$$

where q is the free electron charge, $\hbar$ is the reduced Planck constant, n is the refractive index, ε_0 is the free space dielectric constant, c is the speed of the light, E is the photon energy, M_{nm} is the momentum matrix, $\Gamma = 2\pi\frac{\hbar}{\tau}$ where τ is the relaxation time, f_c^n ***and*** f_v^m are the fermi functions for the conduction and valance bands, E_{cn} *is* n-th conduction subband, E_{vm} is mth valence subband, n and m denote the electron states in the conduction band and heavy/light hole states in the valence band, respectively. The momentum matrix M_{nm} is given by

$$M_{nm}(k_t) = \frac{3}{4}[<\Psi_n | g_m^{(1)}>^2 + \frac{1}{3}<\Psi_n | g_m^{(2)}>^2]M_b^2$$
$$= \frac{3}{4}[\frac{1}{3}<\Psi_n | g_m^{(3)}>^2 + <\Psi_n | g_m^{(4)}>^2]M_b^2 \quad (2)$$

where $M_b^2 = (\frac{m_0}{m_e} - 1)\frac{m_0 E_g(E_g + \Delta)}{6(E_g + (2/3)\Delta)}$ (3)

Here Ψ_n ***and*** $g_m^{(j)}$ are the conduction and valence bands wave function, M_b is the bulk average crystal momentum matrix, m_0 is the free space mass, m_e is the effective mass of electron, Eg is the band gap energy and Δ is the split off valence band energy seperation. In our calculation orientation dependent hole effective mass has not been considered.

The expression of the rotation matrix is as follows

$$O_R = \begin{pmatrix} \cos\theta\cos\phi & -\sin\phi & \sin\theta\cos\phi \\ \cos\theta\sin\phi & \cos\phi & \sin\theta\sin\phi \\ -\sin\theta & 0 & \cos\theta \end{pmatrix} \quad (4)$$

where, $\theta = \tan^{-1}(\frac{\sqrt{h^2+k^2}}{l})$ and $\phi = \tan^{-1}(k/h)$

The Hamiltonian matrix in (hkl) orientation can be calculated by the following equation [20]

$$H^{hkl} = UH^{(001)}U^* \quad (5)$$

where $U = R(\theta)R(\phi)$ (6)

Here, $R(\theta)$ and $R(\phi)$ represent the spinor rotations which transform the (001) orientated valence band Hamiltonian to arbitrary crystal orientated Hamiltonian matrix. The expressions of $R(\theta)$ and $R(\phi)$ can be given by [20]

$$R(\theta) = \begin{pmatrix} \alpha^2 & -\sqrt{3}\alpha^2\zeta & \sqrt{3}\alpha\zeta^2 & \zeta^3 \\ \sqrt{3}\alpha^2\zeta & \alpha^3 - 2\alpha\zeta^2 & -2\alpha^2\zeta + \zeta^3 & \sqrt{3}\alpha\zeta^2 \\ \sqrt{3}\alpha\zeta^2 & 2\alpha^2\zeta - \zeta^3 & \alpha^3 - 2\alpha^2\zeta & -\sqrt{3}\alpha^2\zeta \\ \zeta^3 & \sqrt{3}\alpha\zeta^2 & \sqrt{3}\alpha^2\zeta & \alpha^3 \end{pmatrix} \quad (7)$$

Here $\alpha = \cos\frac{\theta}{2}$ and $\zeta = -\sin\frac{\theta}{2}$

$$R(\phi) = \begin{pmatrix} e^{i(3/2)\phi} & 0 & 0 & 0 \\ 0 & e^{i(1/2)\phi} & 0 & 0 \\ 0 & 0 & e^{-i(1/2)\phi} & 0 \\ 0 & 0 & 0 & e^{-i(3/2)\phi} \end{pmatrix} \quad (8)$$

IV. RESULT AND DISCUSSION

Using "(1)" the gain of the laser is determined at 300k for different crystal orientations. "Fig. 2" shows the orientation dependent optical gain of the laser. It is seen that the peak gain and peak emission wavelength have crystal orientation dependence. The value of the peak gain with its emission wavelength is enlisted in Table I.

TABLE I

Orientation	Peak optical gain (cm^{-1})	Peak emission wavelength (nm)
(001)	1063	640
(101)	1017	644
(111)	1003	646
(113)	1178	642
(211)	847	648

The orientation dependent lasing characteristics of the QW VCSEL can be are described by energy dispersion profiles. To compare the energy separation characteristics, in different sub- bands the dispersion profiles are plotted in "Fig. 3" in the same scale where the valence band dispersion profiles of $Ga_{0.5}In_{0.5}P$/ $(Ga_{0.5}Al_{0.5})_{0.5}In_{0.5}P$ are presented in (001), (101), (111), (113) and (211) orientations. In this figure HH1, HH2 and HH3 indicates first, second and third heavy holes and LH1 is the first light hole bands. Lasing action occurs due to the allowed transition from conduction sub-band C1 to valence sub- bands HH1.

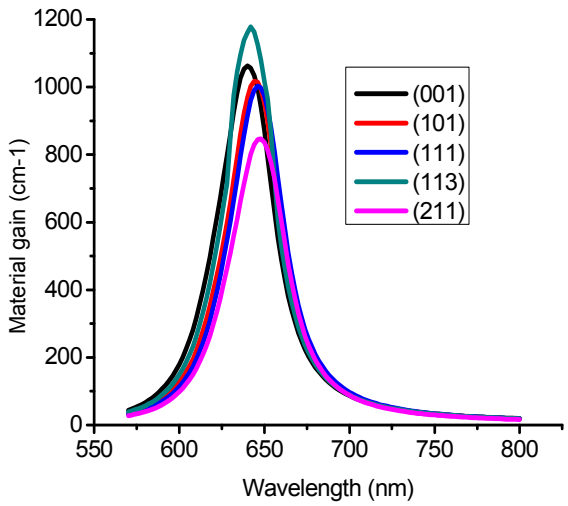

Figure 2. Optical gain spectrum of $Ga_{0.5}In_{0.5}P/(Ga_{0.5}Al_{0.5})_{0.5}In_{0.5}P$ red laser as a function of crystal orientations

Other transitions such as intra-subbands transitions are forbidden because it reduces the gain of the laser. Among the intra-subbands, transition probability is maximum between HH1 and LH1, which is reduced when the energy separation between HH1 and LH1is higher. For higher gain intra-subband transition should be reduced. For a particular orientation, the higher gain can be obtained when the energy separation between HH1 and LH1 becomes higher in the dispersion profiles. Since the energy separation between HH1 and LH1 is maximum and minimum in (113) and (211) orientation, the optical gain of the laser is found to be maximum and minimum in (113) and (211) orientations.

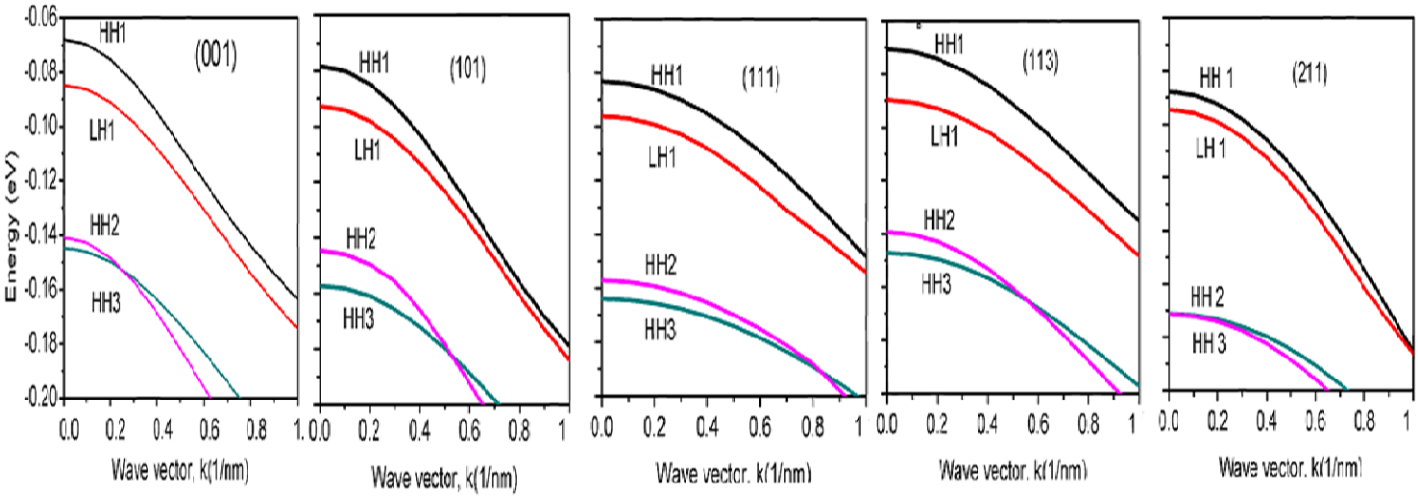

Figure 3. Valence band dispersion profile of $Ga_{0.5}In_{0.5}P$/ $(Ga_{0.5}Al_{0.5})_{0.5}In_{0.5}P$ red laser in different crystal orientation

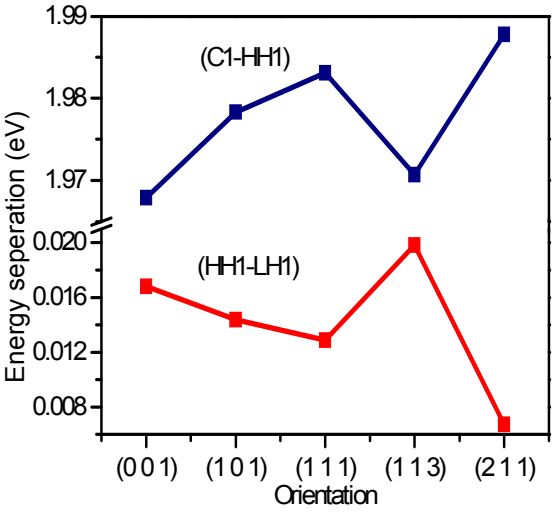

Figure 4. Orientation dependent energy separation between (C1-HH1) and (HH1-LH1)

In order to explain the wavelength dependence of peak emission wavelength the energy separation between the conduction (C1) and heavy hole (HH1) bands is estimated from the energy band dispersion profiles and plotted in "Fig. 3". It is found in Fig. 3 that the energy separation between conduction band minima and valence band maxima changes with crystal orientations. The energy separation between C1-HH1 is found to be 0.0168, 0.01438, 0.01287, 0.01983 and 0.00673 eV corresponds to the orientations (001), (101), (111), (113), and (211), respectively. This clearly explains why the peak emission wavelengths are shifted with crystal orientation. As seen in Fig. 2 the peak emission wavelength changes from 640nm to 648nm for the change in crystal orientation from (001) to (211). That is, laser with tunable characteristic can be obtained by changing the crystal orientation in the material used in active region.

To understand the orientation dependent peak gain of the laser, the energy separation between (HH1-LH1) and momentum matrix elements are further determined. The results are shown in Fig.4 and Fig. 5, respectively. The lower intra band mixing effect is observed in (131) orientation and higher in (211) orientation. Further, the orientation dependent peak gain can be explained by the momentum matrix elements, which depends on the overlapping wave functions of electrons and holes. "Fig. 5" shows that the transition probability is maximum in (113) orientation and minimum in (211) orientations. As a result, higher optical gain is estimated in (113) and lower in (211) orientation.

V. CONCLUSION

The optical gain characteristics of $Ga_{0.5}In_{0.5}P/(Ga_{0.5}Al_{0.5})_{0.5}In_{0.5}P$ 635nm red laser is investigated here in different crystal orientations. The peak gain is found to be

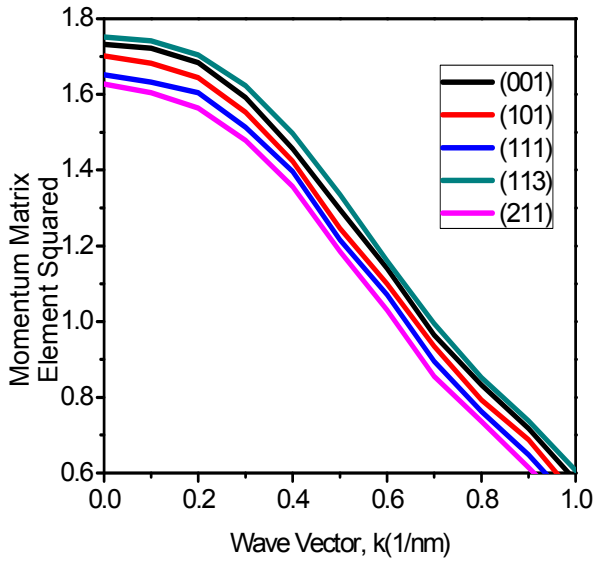

Figure 5. Crystal orientation dependent momentum matrix element squared for C1-HH1 transition

maximum in (113) orientation as the band mixing effect is minimum here. Also, the value of the momentum matrix element for the transition from C1 to HH1 and energy seperation between HH1 and LH1 is found to be higher in (113) orientation in comparison to other orientations. The peak gain is minimum in (211) orientation as the band mixing effect is maximum here. It is also seen that the peak emission wavelength varies from 640nm to 648nm when the orientation changes from (001) to (211). This demonstrates that tunable laser with various optical gains can be realized by changing crystal orientation in the active layer material.

Abstract—**A simple planar antenna of high gain for long term evolution (LTE), global system for mobile communications (GSM), Bluetooth, worldwide interoperability for microwave access (WiMAX), digital cellular services (DCS), personal communication services (PCS), wireless local area network (WLAN), and global positioning system (GPS) mobile terminals is presented. The antenna has wide -6 dB reflection coefficient bandwidth of 2.17 GHz (1.33 – 3.5 GHz). The antenna has a compact size of 44.9 mm ×35.5 mm × 0.87 mm placed one side of the substrate of dimension 35.5 mm × 75.5 mm. The antenna has high gain of 3.85 dBi at 2.7 GHz, maximum directivity is 5.04 dBi at 2.7 GHz and total efficiency of the antenna varies between 61% and 95% within the wide impedance bandwidth. In addition, the antenna gain and efficiency is almost constant in individual operating band of operation. Dimensions of the antenna are optimized for wide impedance band. Antenna radiation patterns are presented at 1.5, 2, 2.5, and 3 GHz.**

Keywords—Planar monopole antenna, LTE, TDD, FDD, GSM, Bluetooth, WiMAX, DCS, PCS, WLAN, and GPS.

I. INTRODUCTION

Growing demand of data rates accelerate towards next generation wireless mobile communication having wideband antenna installed within hand-held mobile devices [1] – [5] and also required added services support e.g. global positioning system (GPS), worldwide interoperability for microwave access (WiMAX), wireless local area network (WLAN), Bluetooth etc. [6] – [12]. Broadband/wideband antenna not only support these bands but also increases the channel capacity [5] – [8].

Long term evolution (LTE) bands (LTE-1 to LTE-40) can be divided into two major categories based on their dependency like time division duplex (TDD) band and frequency division duplex (FDD) band [13] – [14]. These bands cover three wide bands, lower one from 0.698 GHz to 0.966 GHz, middle band from 1.427 GHz to 2.69 GHz and the higher band from 3.4 GHz to 3.8 GHz [15] – [20]. In parallel of LTE support mobile terminals need to cover GSM bands for voice only [21] – [24].

Smartphones are attractive because of their additive services like GPS (1.559 – 1.61 GHz), Bluetooth (2.4 GHz ISM band), WiMAX in 2.3, 2.5, 3.5 GHz band, WLAN in 2.4 GHz band, digital cellular services (DCS) in the band 1.71 – 1.88 GHz, and personal communication services (PCS) in the band 1.85 – 1.99 GHz together with LTE and global system for mobile communications (GSM) support [1], [5], [34] - [36].

Several antennas has been proposed in the previous years for the use in hand held mobile devices including planar monopole [1], [6], [8], [9], planar inverted-F [5], [7], array antenna, reconfigurable antenna [2] , [3], slot antenna [10]. Also, different feeding technique e.g. multi resonance feed structure [11], hybrid feed [14], different isolation technique [24], dielectric resonator feed [19], and modified ground plane e.g. protruded [17] has been used to achieve multiband operation having limited form factor. Moreover, several antennas have been proposed for WiFi and WiMAX applications where inverted-L load [25] – [29], F-L load [30] – [32] and planar wire antenna [33], leaky wave antennas [37] [38] have been considered for gain enhancement but the size of those antennas are not feasible for hand-held mobile terminal. Most of the proposed antenna for smartphone applications comes with wideband that covers 1.6 GHz to 2.7 GHz and recently one paper has been published that support additional 3.4 – 3.8 GHz band [3].

In this paper, a technique is presented to remove notch exist in current design and using the proposed technique a simple planar wideband antenna is presented for LTE, GSM, Bluetooth, WiMAX, DCS, PCS, and GPS applications. The antenna design strategy are briefly described in Section II. Section III presents the simulation results and the paper ended with a conclusion in Section IV.

II. WIDEBAND ANTENNA DESIGN STRATEGY

The antenna is designed using low cost FR-4 substrate with dielectric constant 4.3 and loss tangent 0.025 in CST Microwave Studio. Thickness of the substrate is 0.8 mm and thickness of copper cladding is 0.035 mm. Fig. 1 shows the design steps in achieving continuous band antenna as a replacement for having a notch. Firstly, the antenna radiating legs are connected to form a loop antenna. Then, two parasitic is placed on the either side of the feeding line to form capacitive effect and finally a capacitor is placed in the right arm of the antenna, shown in Fig. 1(a), 1(b), 1(c), and 1(d), respectively.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

Fig. 2 present the top view and bottom view of the antenna. For feeding arrangement, coaxial connector is used and the antenna feeding is comes from the bottom of the antenna, shown in Fig. (2). Overall dimension of the substrate is 35.5 mm × 60.5 mm and the antenna radiator dimension is 44.9 mm × 35.5 mm. Dimension of the feeding arrangement is 10.5 mm × 31.4 mm, shown in Fig. 3, also the detailed structure of the antenna presented. Here all values are in mm. The values of the capacitor C is 2 nF and is placed by creating a gap of 1 mm. In our design we have used antenna in [1] as a reference, shown in Fig. 1(a), and we modify the structure to achieve continuous band by following aforementioned procedure/steps.

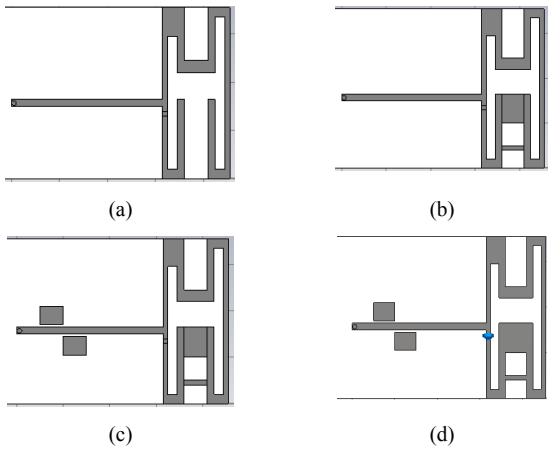

Fig. 1. Antenna design strategy for wideband operation (a) base antenna structure [1], (b) right legs are connected with two radiating elements of size 5 mm × 6.5 mm and 5 mm × 1 mm, (c) two parasitic radiator placed with a gap of 0.5 mm with the 50 Ω feeding line, and (d) final structure with addition of 2 nF capacitor on the right arm of the loop in a 1 mm space.

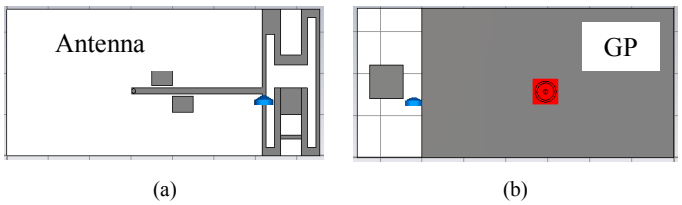

Fig. 2. Structure of the proposed monopole antenna (a) top view and (b) bottom view.

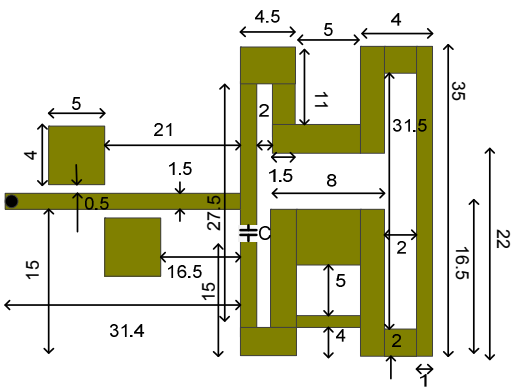

Fig. 3. Detailed geometry of the proposed antenna. Here all values/dimensions are in mm.

III. Resuls and Discussion

The antenna proposed in [1] covers 1.5 to 4.12 GHz with notches around 2.5 GHz and 3.84 GHz, shown in Fig. 4 (line AA). These two notches block the LTE 7 and radio frequency identification bands. Firstly we increase the band of the antenna by connecting two right radiator of U shape using two parallel radiator of dimension 5 mm × 6.5 mm and 5 mm × 1 mm, respectively, shown in Fig. 1(b). These two connected radiator improves the bandwidth but not reduced the notch completely, shown in Fig. 4 (line BB). After that, two parasitic patch of size 4 mm × 5mm is placed with a gap of 0.5 mm from the feeding strip shown in Fig. 1(c). This parasitic patch removes the notch slightly but has no effect on the bandwidth of the antenna, shown in Fig. 4 (line CC). To further reduce the notch at 3.84 GHz, manual impedance matching can be employed. A capacitor of size 2 nF, decided by parametric simulation studied in software, is placed on the right arm of the antenna because this arm giving resonance at that frequency, reduces the notch completely, shown in Fig. 4 (line DD). Here the positioning of the capacitor, 1 mm away from the 50 Ω feeding line.

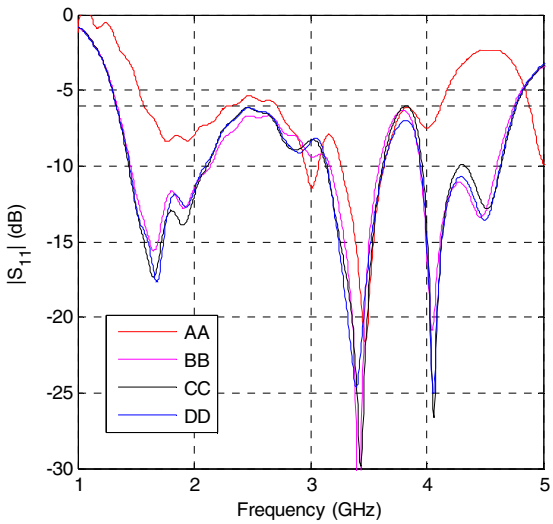

Fig. 4. Reflection coefficient of the proposed antenna for the geometry presented in Fig. (1). Here, return loss corresponds to AA, BB, CC, and DD are for the structure shown in Fig. 1(a), 1(b), 1(c) and 1(d), respectively.

After finalizing the structure, the detailed geometry are presented in Fig. 3 and the simulated reflection coefficient are shown in Fig. 5. The proposed/modified antenna has a wide impedance bandwidth of 3.43 GHz, from 1.33 GHz to 4.76 GHz, with a voltage standing wave ratio (VSWR) 3:1 (-6 dB reflection coefficient or 6 dB return loss). From the figure it can easily be observed that the proposed antenna can provide multi band operation to support GPS, DCS, PCS, WLAN, Bluetooth, WiMAX, and LTE.

Total efficiency of the antenna is varied between 61% and 95%, shown in Fig. 6. Total efficiency is minimum at 3.8 GHz and maximum at 1.6 GHz. Because of the non-symmetric structure the efficiency has significantly changes within the

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

operating bandwidth which leads to the change in gain/realized gain and directivity of the antenna, shown in Fig. 7.

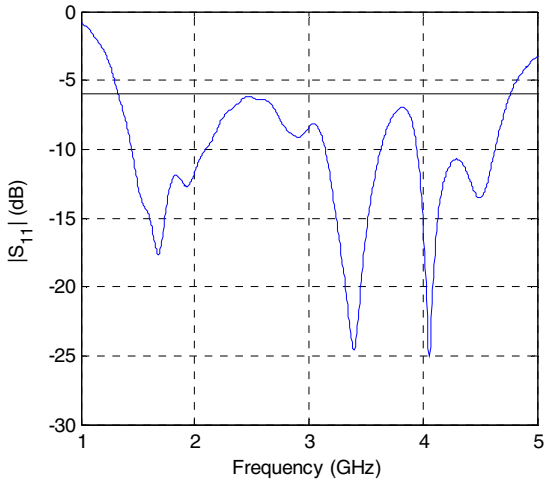

Fig. 5. Reflection coefficient vs frequency of the proposed antenna.

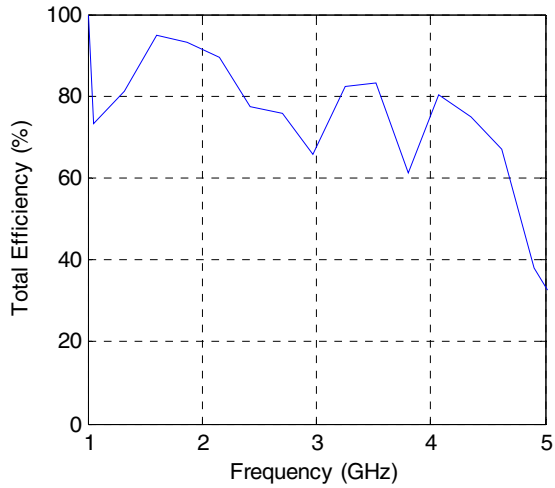

Fig. 6. Total efficiency of the proposed antenna vs frequency.

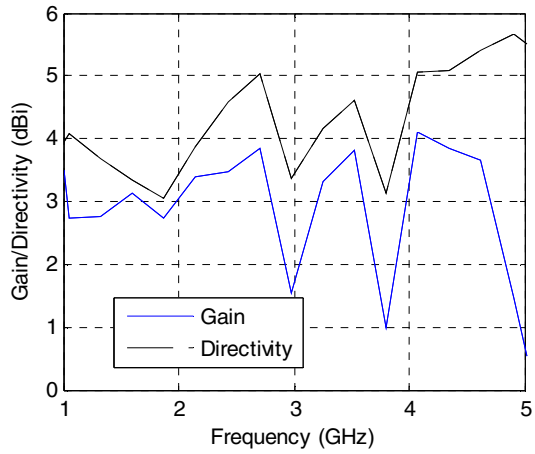

Fig. 7. Gain and directivity of the proposed antenna as a function of frequency.

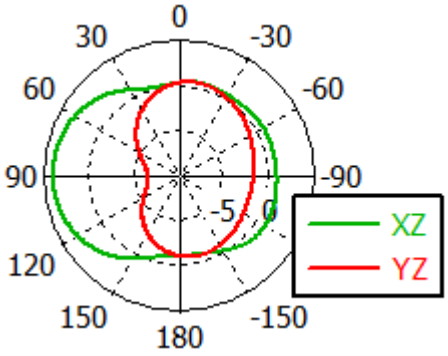
(d)



(e)

Fig. 8. Radiation patterns of the proposed antenna at (a) 1.5 GHz, (b) 2 GHz, (c) 2.5 GHz, (d) 3 GHz, and (e) 3.5 GHz.

Realized gain of the antenna is changes from 1.55 dBi (at 2.975 GHz) to 3.85 dBi (at 2.7 GHz) while the directivity of the antenna changes from 3.06 dBi (at 1.875 GHz) to 5.04 dBi (at 2.7 GHz), shown in Fig. 7. However, the gain variation within an individual band is less than 0.5 dB, e.g. < 0.5 dB at GSM 1800, <0.5 dB at ISM band. Directivity is always higher than realized gain which is expected. Realized gain is about 2.3dBi for GPS, DCS, PCS, and WiMAX band, and above 2.5dBi for WLAN, and Bluetooth. The proposed antenna has a directivity of 2.6 – 2.5 dBi for GPS, DCS, PCS band. 2.7 – 4.5 dBi directivity is achieved for WiMAX, WLAN band. The overall directivity of the antenna is above 3.06 dBi for all through the operating frequency

Radiation patterns of the antenna at 1.5, 2, 2.5, 3, and 3.5 GHz are shown in Fig. 8. At frequencies, below 3.5 GHz, this antenna radiation pattern is like planar monopole antenna having radiation almost omnidirectional shown in Fig. 8(a), 8(b), 8(c), 8(d), and 8(e). Though the antenna bandwidth covers till 4.7 6GHz but there are improvement in radiation patterns required to make this antenna useful beyond 3GHz. In obtained results, nulls have been observed on the radiation patterns and these nulls are generated because current are highly condensed along the right and left edges of the antenna loop.

IV. Conclusion

A wideband planar monopole antenna for LTE, GSM, Bluetooth, WiMAX, DCS, PCS, and GPS mobile devices/smartphones was designed. The bandwidth improvement of this antenna has been achieved through adding two parasitic element near the feeding line for capacitive effect and then adding a series capacitor in the loop monopole to maintain the impedance matching at the notch frequency. The simulated return loss, antenna efficiency, directivity and the radiation pattern suggest the potential use of this antenna for wide band operation in mobile devices.

***Abstract*- For underwater surveillance and observations, the widely used medium is the acoustic wave based underwater wireless sensor networks (UWSNs). But acoustics in underwater environment face high challenges to meet the necessity for fast transmission rates in different newly emerging underwater operations. Then again, underwater network systems based on radio frequency (RF) have incredible potential for supporting fast information transmission. In light of this, we propose and examine two three dimensional (3D) cluster-based UWSN architectures for identifying intruders in an underwater surveillance area. The proposed architectures comprised of cluster heads (CHs) and sensor nodes (SNs) senses the presence of an intruder inside the surveillance area and then pass the real-time location of the intruder to a coastal base station (BS) via a sink situated at water surface. All the data transfers from SNs to BSs are RF based. The data of the received RF signal strength and the positions of the SNs and CHs are the information used for calculating the intruder's position. For assessing the proposed system architectures' localization capacities in a seawater circumstance, substantial simulations are carried through. Localization precision of the architectures is altogether examined in terms of inaccuracy in distance and direction estimations. Effect of different framework parameters on the performance is likewise interpretatively scrutinized exhibiting noteworthy performance discord between the architectures.**

Keywords–intruder detection; target localization; RF based UWSN; 3D sensor networks; underwater communications

I. Introduction

For enquiring into the resourceful underwater worlds, research on underwater operations conveys great significance as almost seventy five percent of the surface of the planet Earth is covered by water, most part by ocean and seas [1]. While investigating this prodigious area of underwater, UWSN systems have been approved by the analysts as an attainable, minimal effort arrangement [2] as the advances in sensor technologies have made sensor networks utilizable for any kind of circumstances. Objectives of deploying UWSNs include navigations, observation on sea boundaries, mine surveillance, trace and rescue operations, preventing cataclysms, seaward investigations, oceanography and numerous sea-going applications [1]-[2]. In most cases UWSNs use acoustics as transmission media. Notwithstanding, with the increment in the quantity of fast moving submerged vehicles and independent weapons in current times, there is a concern for speedier transmission media like optical or radio frequency (RF), particularly for detection and tracing purposes, as the transmission speed by acoustics is slower than the needed [3]. But then, optical wave is not feasible for major submerged applications as it requires line of sight (LOS) with tight arrangement and clear water in its transmission way [4]. In this way, how to utilize the RF's quick transmission capacity in underwater environment to make real-time high-throughput applications achievable is catching the attention of the related academic group. Numerous long sought aims, for example, real-time localization and transmission, resistance to acoustic clamor, turbidity and pressure slopes; diminished effect on marine life and ability of non-LOS communications can be attained utilizing RF based UWSNs which acoustic based systems cannot [5], [6].

Given this situation, this paper is meant to investigate the designs of submerged surveillance system for localizing unwelcomed objects utilizing RF as transmission coverage. Our broad survey shows that there is progressing investigation on RF communication based underwater intruder localizing systems and this field needs more efforts. Beforehand, a two dimensional (2D) submarine locating procedure utilizing a dispersed sensor system of binary-detection capacity was proposed in [7]. Furthermore, the writers in [8] introduced 2D two disseminated particle filter based object locating and tracing strategies utilizing clustered UWSNs. Then again, submerged 3D target identification and tracking strategies utilizing UWSNs were presented in [9]-[11]. The entry time of the reverberation messages originating from the object is utilized for deciding the distance from the sensor to the object in [9]. At that point trilateration is used to compute target's location. Node's position and the above speed will then be utilized for tracking the submerged target. Nonetheless, all the previously stated works are carried out in light of acoustic network systems. Provided the feasibility of diversified applications of UWSNs proven by the time, further sea trials have been carried out in [12] to introduce EM into the UWSNs with a view to undersea target detection & tracking using EM-acoustic combination.

Therefore, this paper proposes and explores two 3D UWSN architectures for identifying and locating intruders underwater. Each architecture comprises of a cluster-based UWSN formed utilizing sensor nodes (SNs) and cluster heads (CHs), a sink situated at the water surface and an inland base station (BS) with the essential mathematical models for localization. The inspiration of utilizing cluster based UWSNs originates from their powerful topology and the certainty of their inclination in extended system life through effectual energy sparing techniques [13], [14]. Every step in the communications from the SNs to the BS via CHs are proposed to be by means of RF. Intruder locations are computed utilizing the data of received RF signal strength and the positions of SNs and CHs. Performances of the presented architectures are assessed using substantial simulations.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

Localization precision is analyzed and compared in terms of inaccuracies in both distance and direction approximations. Effect of system size and signal identification threshold on the system perfection is likewise examined.

The remaining of the paper is organized as follows: Section II introduces the general outline of the proposed localization strategies. Then in Section III, Proposed architectures are illustrated in detail. Section IV characterizes new performance metrics and then the simulation results with insightful investigation in Section V. The paper concludes in Section VI by abridging the key findings.

II. Proposed Overall Localization Scheme

The general operation guideline of the proposed submerged intruder identifying and locating strategy is talked about in this segment. The network comprises of two fundamental components, SNs and CHs. Again, every SN involves low power sensor bundle and an omnidirectional RF transmitter. The sensor bundle of every SN uses distinctive standards for detecting an intruder, for example, movement sensor, pressure sensor (as a fast moving intruder will acquaint pressure amid drawing nearer to the system), metal identifier (to guarantee whether the intruder is of metal body) and passive sonar (to be sure whether the approaching intruder has a motor, particularly when submarines are to be recognized). To mention, the proposed architectures are outlined independent of the kind of detecting methods of the SNs. A CH alongside a team of SNs constructs a cluster. Every CH comprises of RF transmitter and recipient. Collecting the neighborhood data from SNs and/or different CHs and sending those to the sink are the duties of a CH.

These SNs and CHs, being organized in a specific position, construct the clusters in 3D underwater space and subsequently develop to the architectures discussed in the segment III. The working rule of the general localization strategy as appeared in Fig. 1 is as follows: Both SNs and CHs typically stay in dormant or rest mode for energy saving. Receiving RF signal strength above than a specific threshold P_{th} either from another CH or from the close-by SNs can just alter the CH's to active mode, while an SN just after sensing an intruder. When an intruder enters the reconnaissance zone, the nearby SNs sense the vicinity of the intruder and alter to active mode. Detecting the vicinity of an intruder, SN transmits its location information utilizing RF signal of power P_{SN} and frequency f_{SN}. After receiving RF signal from SNs, CHs are switched to active mode. These active CHs gather the location data of the SNs and the strength of the received RF signal from the SNs. At that point the necessary pieces of information are sent to the particular CHs of the direct upper layer using RF signal of power P_{CH} and frequency f_{CH} and so on. The data, in this manner, gets to the surface sink from the CHs of the topmost layer. The accumulated data is then transmitted to the inland BS for handling and approximating the location of the object. All the transmissions including SN-CH, CH-CH, CH-surface sink and surface sink-BS are based on RF signal.

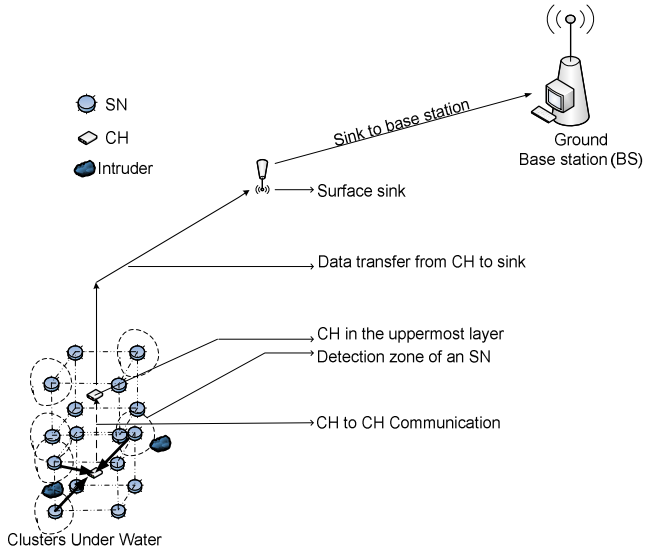

Fig. 1: Overall model of the proposed localization schemes.

III. Proposed UWSN Architectures

Proposed UWSN architectures for recognizing intruders are presented here below. We assume a plane seabed and overlook the versatility of system components. SNs and CHs are organized in 3D space constructing the basic building block as shown in Fig. 2(a). The XY plane of the arrangement is viewed as parallel to the seabed and the Z-axis is considered along the sea depth. The fundamental building block is repeated to build the UWSN covering a reconnaissance region of a cubic area $D_x \times D_y \times D_z$, where D_x, D_y, and D_z are the length of the observation region along the X-, Y-and Z-axes respectively. The evolved UWSN is shown in Fig. 2(b). Based on the localization rule, we now propose two distinct intruder detecting architectures symbolized as A_1 and A_2, which are discussed in detail in following sections.

A. Architecture A_1

In topology A_1, SNs are allocated at each of the eight vertices of a rectangular cuboid of cubic dimension $\Delta_x \times \Delta_y \times \Delta_z$ as illustrated in Fig. 2(a). In this manner, the whole UWSN is constructed by allocating SNs at each Δ_x, Δ_y and Δ_z distance along X-, Y- and Z-axis respectively. Then again, one CH is set at the focal point of every cuboid. Along these lines the distance of a CH from the SNs of its cuboid is equal to $D_{CE} = \frac{1}{2}\sqrt{\Delta_x^2 + \Delta_y^2 + \Delta_z^2}$. The UWSN, in this manner, has eight SNs encompassing every CH and vice versa.

Under A_1, we assume that each CH holds the information about its own position coordinate. As soon as an SN senses an unwelcomed approaching object, it alerts the nearby CHs around by transmitting RF signal. If a CH receives RF signal of power above P_{th} transmitted by the SN, the CH switches to active mode and sends its coordinate to the exact upper layer's

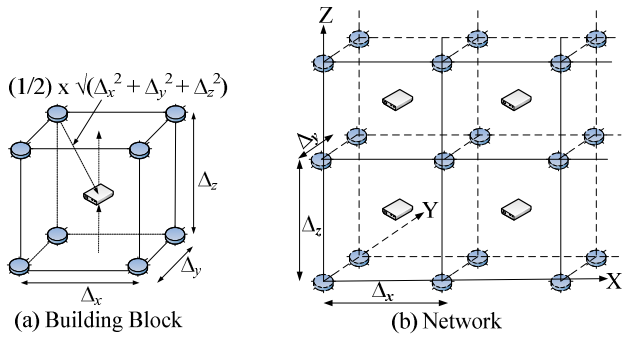

Fig. 2: Topology for architecture A_1 and A_2.

CHs through RF signal. By means of this flow of location data from CHs of one layer to those of the upper layers, the coordinates of the CHs initiating RF signal transmission is consequently known to the BS, which are also the CHs nearer to the target. If the BS receives the location data from N CHs, then the approximated coordinate (x_{est}, y_{est}, z_{est}) of the target is given by

$$x_{est} = \frac{1}{N}\sum_{i=1}^{N} x_i \tag{1}$$

$$y_{est} = \frac{1}{N}\sum_{i=1}^{N} y_i \tag{2}$$

$$z_{est} = \frac{1}{N}\sum_{i=1}^{N} z_i \tag{3}$$

where (x_i, y_i, z_i) is the coordinate of the ith active CH in 3D.

B. Architecture A_2

Architecture A_2 utilizes the same topology of A_2. However, the location approximation principle in A_2 is significantly different than that of in A_1. Architecture A_2 utilizes both the location information of the active CHs (from the CHs nearest to the target) and additionally the power of RF signal a CH received from the SNs. First, similar to A_1, an approximate location (x_{int}, y_{int}, z_{int}) of the target is calculated using (1)-(3). After that, the primarily approximated position of intruder is fine tuned to acquire a new coordinate (x_{est}, y_{est}, z_{est}) by utilizing the information of the received RF power at CHs from the SNs. The equations for this fine tuning are as below

$$x_{est} = \frac{1}{N}\sum_{i=1}^{N} \frac{(P_{max} - P_i)x_{int} - (P_{int} - P_i)x_i}{P_{max} - P_{int}} \tag{4}$$

$$y_{est} = \frac{1}{N}\sum_{i=1}^{N} \frac{(P_{max} - P_i)y_{int} - (P_{int} - P_i)y_i}{P_{max} - P_{int}} \tag{5}$$

$$z_{est} = \frac{1}{N}\sum_{i=1}^{N} \frac{(P_{max} - P_i)z_{int} - (P_{int} - P_i)z_i}{P_{max} - P_{int}} \tag{6}$$

where P_i is the true value of the strength of the RF signal that was received by the ith CH. P_{max} and P_{int} are the strength of the received RF signal at i^{th} CH if the SN were situated at the location of the CH and (x_{int}, y_{int}, z_{int}) respectively. Each of the power values utilized in (4)-(6) are expressed in dBm. Eq. (4)-(6) basically make use of the fact that the received signal strength expressed in dBm diminishes linearly with travelled distance from the transmitter, i.e., the closer the receiver's position to the transmitter, the bigger will be the value of the received power (ignoring all kind of fading).

IV. Performance Metric

For assessing the performance of the proposed intruder localization architectures, performance metrics are defined below, which calcuate the error in location approximation in terms of distance and direction. For doing this, at first the reference point is shifted to the approximated location (x_{est}, y_{est}, z_{est}) of the intruding object as demonstrated in Fig. 3. After this, the original position of an intruding object is re-calculated in spherical coordinate denoted as (r, θ, φ) with respect to the new reference.

A. Error in Distance Estimation

If (x, y, z) is the true position of the intruding object which is our target of localization, then the absolute distance r between the original and the approximated location is hereby assumed as a measure of error. The localization inaccuracy can be given by

$$r = \sqrt{(x_{est} - x)^2 + (y_{est} - y)^2 + (z_{est} - z)^2} \tag{7}$$

Then the normalized mean square error (NMSE) in location approximation defined as the mean of r^2 normalized by the square of the minimum separation between two SNs can be written as

$$NMSE_r = \frac{\sum_{i=1}^{M} r_i^2}{M\left[\min\left(\Delta_x, \Delta_y, \Delta_z\right)\right]^2} \tag{8}$$

where M is the number of Monte-Carlo simulations.

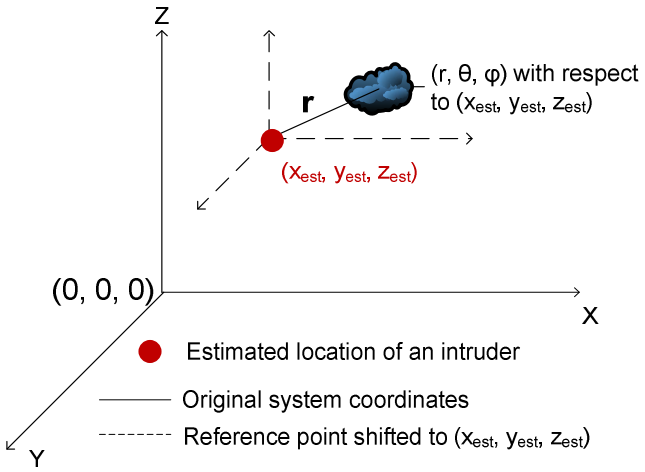

Fig. 3: Shifting of reference point for calculating the errors in localizations.

B. Error in Direction Estimation

The polar angle θ and the azimuthal angle φ of the actual location of an intruder with respect to the approximated location is considered as the measures of error in direction approximation. This can be given by

$$\theta = cos^{-1}\left(\frac{z - z_{est}}{r}\right), -90° \leq \theta \leq 90° \quad (9)$$

$$\varphi = tan^{-1}\left(\frac{y_{est} - y}{x_{est} - x}\right), -180° \leq \varphi \leq 180° \quad (10)$$

V. Simulations, Results and Discussions

A. Simulation Setup

Substantial simulations using MATLAB are implemented for assessing the performance of the proposed target localization topologies. The average results illustrated below are obtained by averaging the results over 1000 individualistic simulations. Without losing the generalized state, a 3D UWSN with measurement $D_x = D_y = D_z$ is assumed. An underwater RF propagation model with a given path-loss $20\times(\log_{10}e)\times 2\pi\times\sqrt{(\sigma \times f \times 10^{-7})}$ dB/m is used, where f is the transmission frequency in Hz and σ is the conductivity of water in S/m [5]. For fresh water, usual value is $\sigma = 0.01$ S/m, but this value is much bigger for seawater due to the increased salinity level dependent on the depth of water and temperature also [5]. Localization performance of the topologies is assessed considering salty water environment using $\sigma = 4$ S/m. Two different frequencies, $f_{SN} = 6$ kHz and $f_{CH} = 3$ kHz, and transmission power $P_{SN} = 100$ mW and $P_{CH} = 1$ W are used. If not otherwise specified, network size $D_x\times D_y\times D_z = 400\times400\times400$ m^3, $\Delta_x = \Delta_y = \Delta_z = 20$ m and the detection threshold $P_{th} = -60$ dBm are used for simulations.

B. Result Analysis

Cumulative distribution functions (CDFs) of the errors in distance and direction approximation are illustrated in Figs. 4(a)-4(c) from which, it is obvious that in spite of the use of same architecture, the better accuracy of A_2 compared to that of A_1 is directly attributed to the further fine-tuning of the initially approximated location using the information of received RF power. This additional feature however may increase the cost, computational complexity and energy consumption in CHs. On the other hand, both the polar and the azimuthal angle errors nearly follow uniform distributions over the same ranges respectively for both the architectures as seen in Figs. 4(b)-(c). The conclusion drawn from Fig. 4(a) is also corroborated by the NMSE plots in Fig. 5.

Performance of the architectures in terms of NMSE in the approximated distance normalized by 20×20 m^2 for three different detection thresholds is illustrated in Figs. 5(a)-(c). Insights identified by observing the figures: *At first*, we observe increasing trends of NMSE of both the architectures with the increase of the length of the sides of the 3D UWSNs. This increase in the length of the sides of the networks implies that keeping the relative positions as well as the number of SNs and CHs unchanged, D_x, D_y and D_z are increased in equal steps leading to increased distances among the nodes in the networks. Consequently, SNs are more distant from the target to be identified, higher distance between the SNs and the corresponding CHs which the SNs have to communicate with and CHs at a higher distance from the upper layer CH can communicate with those in the upper layer leading to decreased accuracy and increased NMSE. Besides, with the

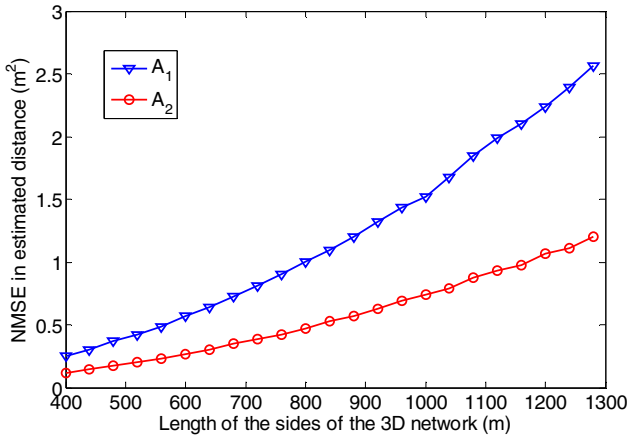
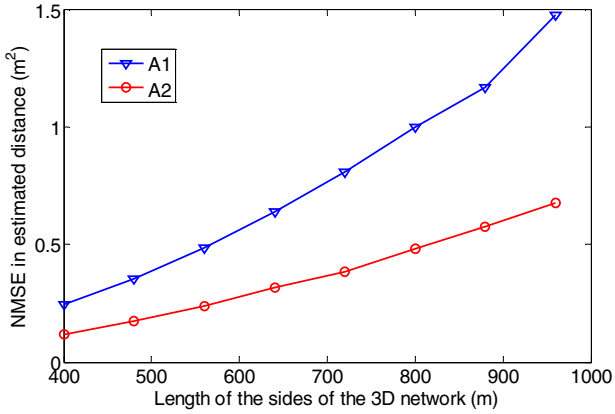
(c) Azimuthal angle φ

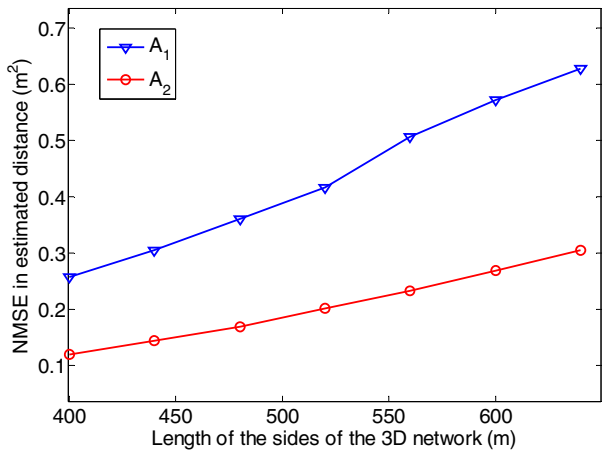
Fig. 4: CDF of estimation errors in distance and direction.



(a) P_{th} = -90 dBm



(b) P_{th} = -60 dBm



(c) P_{th} = -30 dBm

Fig. 5: NMSE in distance estimation with network length.

increase of detection threshold from -90 dBm to -30 dBm, the maximum network dimension is correspondingly reduced from 1280 m to 640 m. *Secondly*, from the better performance of A_2 compared to that of A_1, we can infer that the utilization of received power information for calculating the intruder location significantly improves the network's localization accuracy.

VI. Conclusion

The propositions of this paper include two different RF based 3D UWSNs architectures for the identification and localization of submerged intruders. The proposed architectures are both same in the topology but different in the method of estimating the location of intruding objects. Localization performance has been assessed in terms of NMSE of estimated distance as well as the polar and the azimuthal angles. Simulation results have illustrated a great effect of network's working rule on the localization performance. It has been recognized that the using of information of received RF signal strength in location approximation can essentially ameliorate the localization correctness. Furthermore, it has been identified that with the increase of the network dimension as well as the RF signal identification threshold, precision of the topologies in identifying intruding objects reduces significantly. Our future work will comprise more complicated network scenario including mobility, shadowing and multi-path fading. The localization capacity will be further upgraded by integrating further supplementary features, such as denoising filters, channel approximation mechanisms and angle-of-arrival (AoA) information.

[1,2]Department of Electrical and Electronic Engineering, Khulna University of Engineering & Technology, Khulna-9203
[*]E-mail: ash.kuet@gmail.com

Abstract— **This paper represents a highly birefringence circular-lattice Photonic Crystal Fiber (PCF) which compensates polarization and chromatic dispersion covering the E to U communication bands (1310–1640 nm). The finite element method (FEM) with perfectly matched layers is applied to investigate the guiding properties of the proposed PCF. From simulation, it is observed that the proposed PCF has dispersion coefficient about -220.9032 to -792.7265 (ps/nm-km) for E to U band. Particularly at the wavelength of 1550 nm the value of dispersion coefficient is found to be -678.1918 (ps/nm-km) and nonlinear coefficient is 56.41 ($W^{-1}Km^{-1}$). Besides that at that particular wavelength (1550 nm), the proposed PCF offers high birefringence which is about 0.0108 with the confinement loss of 0.0582 dB/km.**

Keywords— Chromatic dispersion, Photonic crystal fiber, Finite element method, Fiber birefringence, Confinement loss.

I. INTRODUCTION

In optical fiber communication systems, dispersion limits the maximum transmission distance and the bit rate [1]. Because the optical pulse get broadened due to dispersion while transmitting through the fiber. Thus, the dispersion must be compensated during the long distance optical data transmission system. Generally, a standard single-mode optical fiber have positive dispersion from 10 to 20 ps/(nm.km). To successfully compensate the positive dispersion of SMF over a long distance, short piece of a dispersion compensating fibers (DCFs) having large negative dispersion are widely used and commercially available [2]. Generally, conventional DCF fibers give a high negative dispersion only at a particular wavelength but not over wide band [3]. Photonic crystal fiber (PCF), known as 'holey' fiber, is a micro-structured fiber consisting of air hole arrays that run along the waveguide length of the fiber, which have unique properties that are not realized in standard optical fiber [4, 5].

The PCF is a single material optical fiber which contains microscopic air-holes in a silica background running down the length of the fiber. As a result the entire structure forms silica-air microstructure that causes lower refractive index in the cladding region and higher refractive index in the core [3]. In addition, the index-contrast between the core and cladding increases due to the silica-air microstructure in the cladding which helps to tailor the optical properties of the PCF. Modulating some parameters of the silica-air micro structure, it is possible to tune the dispersion properties of the PCF which helps to specially design the broadband dispersion compensating fiber (DCF).

Several designs of dispersion compensating PCFs (DCPCFs) have been proposed to achieve high negative dispersion as well as a suitable bandwidth for dispersion compensation in [6-16]. Silva et al. proposed a Ge-doped-core PCF using a genetic algorithm shows an average negative dispersion of −212 (ps/nm-km) [6]. But the main drawback of this structure is fabrication difficulties due to the doped core. To obtain a wide compensation bandwidth and a zero ultra-flattened dispersion coefficient, a honeycomb structure PCF has been proposed by Nghiem et al. [7]. A dual core PCF with a highly doped internal core reported by Huttunen et al. [8] which have dispersion coefficient was about −59,000 ps/(nm-km). But, these fibers exhibit more confinement loss and fabrication process more difficult. The PCFs mentioned above have not taken into account about the polarization effect and hence these are less attractive for polarization maintaining applications. To eliminate the effect of polarization mode dispersion, High birefringence property can be easily created by altering the air hole sizes near the core area [9,10] or by distorting the shape of the air holes [11,12]. Highly birefringent photonic crystal fibers are also suitable for various applications including optical device and sensing applications. Recently, Habib et al. proposed a hybrid octagonal structure with dispersion coefficient of −465.5 ps/(nm-km) and birefringence of the order 2.68 × 10−2 [13].But, Due to smaller air holes in the inner PCF, the design is more complex than the previously reported. More recently, Haque et al. proposed a hybrid circular structure with dispersion coefficient of −650 ps/(nm-km) and birefringence of the order 2.1 × 10−2[14]. In spite of attractive birefringence, this hybrid PCF is also difficult to fabricate due to its design complexity and higher no. of rings.

In this paper, we proposed a unique circular photonic crystal fiber with four air-hole rings over a widely used wavelength bands considering the polarization issue. The main advantages of the proposed structure are the design simplicity along with high negative dispersion, high birefringence and attractive nonlinear coefficient which are very crucial for high-bit rate transmission network, nonlinear optics and sensing applications. Simulation results show that it is possible to achieve large negative dispersion of about -220.90 to -792.72 ps/(nm-km) over E to U telecommunication band. At λ=1.55 μm, values of dispersion coefficient, nonlinear coefficient and birefringence are found to be -678.1918 ps/(nm-km), 56.41 (W-1km-1) and 0.0108 respectively.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

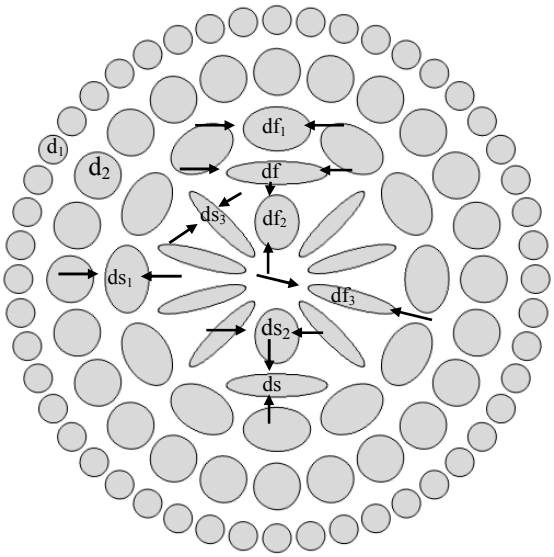

Figure 1. Air hole arrangement of the proposed DC-PCF

II. DESIGN MODEL

Fig.1 represents the air hole arrangement of proposed C-PCF. However, the construction of the CPCF for broadband dispersion compensation is mostly identical with C-PCF with these elliptical air holes which have been used to enhance the dispersion compensating capability. The proposed C-PCF contains only four air-hole rings and the material is taken to be silica which is simplest design respect to other design [6-18].

The 1st and 2nd elliptical air holes of the first ring with diameter in x direction is df and in y direction is ds which are rotated at angles 150and 450 respectively. To break symmetry of 1st ring 3rd elliptical air hole with diameter in x direction is df2 and in y direction is ds2 which is rotated 900 and just above it 4th elliptical air hole is taken which diameter in x direction is ds3 and in y direction is df3.Similarly, 5th, 6th, 7th, 8th, 11th and12th air holes of the 1st ring have diameter in x direction is df and in y direction is ds and these are rotated at angles 1350, 1650, 1950, 2250, 3150 and 3450 respectively where 9th elliptical air hole with diameter in x direction is df2 and in y direction is ds2 which is rotated 2700 and just above it 10th elliptical air hole is taken which diameter in x direction is ds3 and in y direction is df3.Diameter of second ring air holes are in x direction is ds1 and in y direction is df1 and rotated at an angle 300.The diameters of third and fourth air holes are d1 and d2 with rotation angles 150 and 7.50 respectively.

III. ANALYSIS OF MODEL AND OPTICAL CHARACTERISTICS OF PCF

The finite element method (FEM) is very suitable for handling complicated geometry structures of hollow core as well as solid Photonic Crystal Fiber. It is used to calculate chromatic dispersion, birefringence, confinement loss and effective area. The COMSOL 4.2 software is used as simulation tools.

A. Chromatic Dispersion

The performance of PCF directly effects by chromatic dispersion. Because, it affects pulse broadening, phase-matching conditions etc. It also affects to determine bandwidth and power requirements of device in which the fiber will be used. Nowadays, minimization of chromatic dispersion is one of the most challenging issues of optical fiber communication. The chromatic dispersion in ps/(nm-km) is easily calculated from the following equation[14]

$$D(\lambda) = -\frac{\lambda}{c}\frac{d^2\,\mathrm{Re}[n_{eff}]}{d\lambda^2}. \tag{1}$$

Where, $\mathrm{Re}[n_{eff}]$ is the real part of effective refractive index, λ is the wavelength, c is the velocity of light in vacuum.

B. Birefringence

In PCF, the birefringence properties are imperative for eliminating the effect of polarization mode dispersion (PMD) and in stabilizing the operation of optical devices, and can also be used in sensing applications. It can be achieved by creating asymmetric core. The birefringence is defined as a difference between effective refractive indices of two fundamental polarization modes and can be written as [14]

$$B = \left| n_x - n_y \right|. \tag{2}$$

Where, n_x and n_y are the mode indices of the two orthogonal polarization fundamental modes.

C. Confinement loss

Confinement loss is the light confinement ability within the core region. The confinement loss L_c in dB/km is then obtained from the imaginary part of $\lfloor n_{eff} \rfloor$as follows [15]:

$$L_c = \frac{\left(20\times10^6\right)}{\ln(10)} k_0\,\mathrm{Im}[n_{eff}]. \tag{3}$$

Where, $\mathrm{Im}[n_{eff}]$ represents the imaginary part of the wavelength dependent refractive index and $k_0 = 2\pi/\lambda$ is the wave number in the free space.

D. Effective Area

The effective area in μm^2 of the proposed PCF is obtained from [17] and is given by A_{eff} [14] ,

$$A_{eff} = \frac{(\iint |E|^2 dxdy)^2}{\iint |E|^4 dxdy}. \tag{4}$$

Where, E is electric field vector in the medium.

E. Nonlinear Coefficient

The nonlinear coefficient in $W^{-1}Km^{-1}$ can be obtained from the effective area [17] and is given by γ [14],

$$\gamma = \left(\frac{2\pi}{\lambda}\right)\left(\frac{n_2}{A_{eff}}\right) \quad (5)$$

IV. Simulation Result and Discussion

At operating wavelength of 1550 nm, Fig.2 represents the fundamental mode Optical Field distribution of designed C-PCF for both X and Y polarization. According to simulation, it is clearly seen that the optical field for X and Y polarization light is firmly confined into the center core region due to the relatively higher refractive index of the core as compared with the lower refractive index of the cladding region.

Fig.3. shows Chromatic dispersion at X-polarization and Y-polarization. As wavelength is increased, Chromatic dispersion coefficient increases monotonically and at 1550 nm wavelength for X and Y polarization the chromatic dispersion coefficient are found to be -678.1918 ps/(nm-km) and -607.7927 ps/(nm-km) respectively. The X-polarized mode is slightly higher in magnitude than the Y-polarized mode which represents fast axial mode. However, for optimum design parameters the designed fiber shows a very high negative dispersion coefficient of about -220.9032 to -792.7265 ps/(nm-km) over 1310 to 1640 nm bands which reduces the length of DCFs and higher cost.

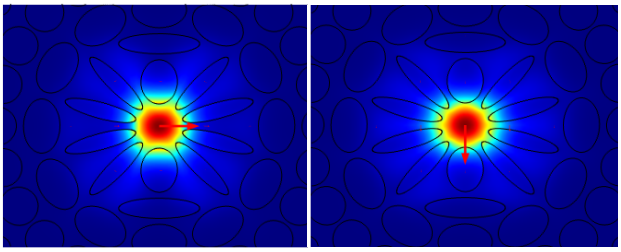

Figure 2. Optical Field distribution of fundamental mode for X and Y polarization at operating wavelength of 1550 nm.

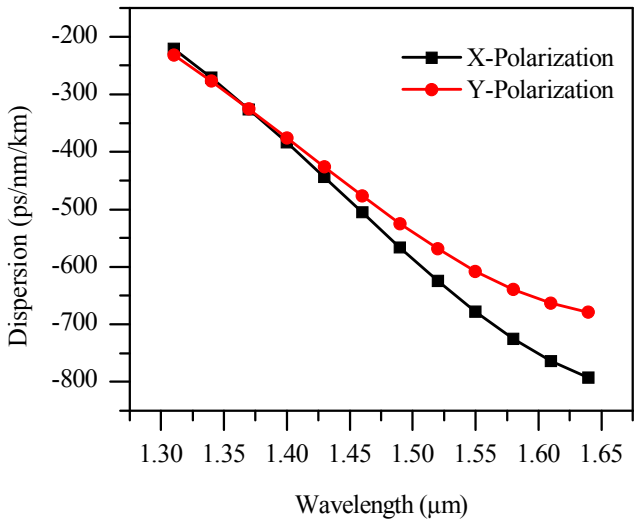

Figure 3. Chromatic dispersion properties of proposed PCF for optimum design parameters.

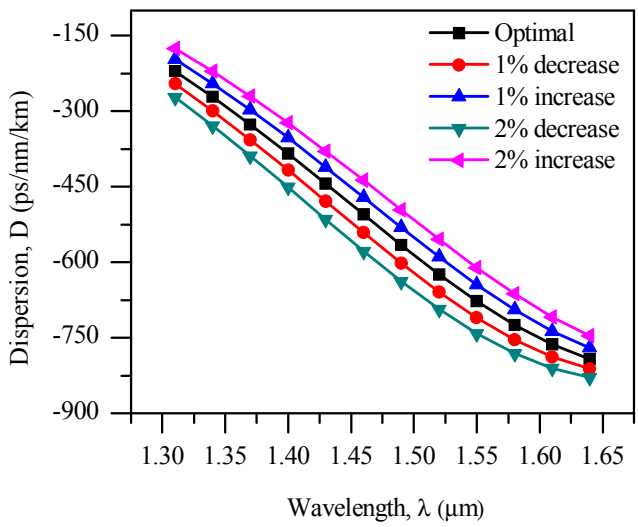

Figure 4. Chromatic dispersion properties of proposed PCF: optimum dispersion and effect of changing pitch.

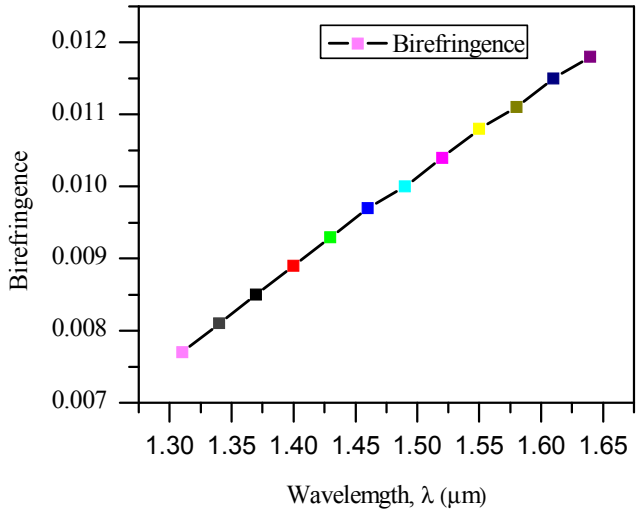

Figure 5. Birefringence properties of proposed PCF for optimum design parameters.

Fig.4 shows the effect of changing pitch on dispersion behavior whereas other parameters remain constant. For wavelength bands 1310-1640 nm, it is seen that the peak value of negative dispersion increases with the decrease of pitch due to greater index difference while the peak value decreases with the increase of pitch. From curve, it is observed that, there is an insignificant effect on dispersion behavior when pitch is varied as ±1% to ±2%.

Fig.5. shows wavelength dependent birefringence of the proposed PCF for optimum parameters. It shows a high birefringence with increase in operating wavelength and at 1550 nm wavelength, the birefringence is about 1.08×10^{-2}. Where the current conventional polarization mode fiber shows

a modal birefringence of about 5×10^{-4} which is 21.6 lower than the proposed PCF.

The effects of changing the pitch on birefringence are shown in Fig.6. Here, it is seen that the birefringence of the proposed PCF increases rapidly with decrease in pitch due to the high index difference between two orthogonal polarization axes while decreases with increase in pitch due to low index difference between the two modes. Simulation result shows that as the pitch varies from +1% to +2% birefringence decreases whereas the pitch varies from -1% to -2% birefringence increases.

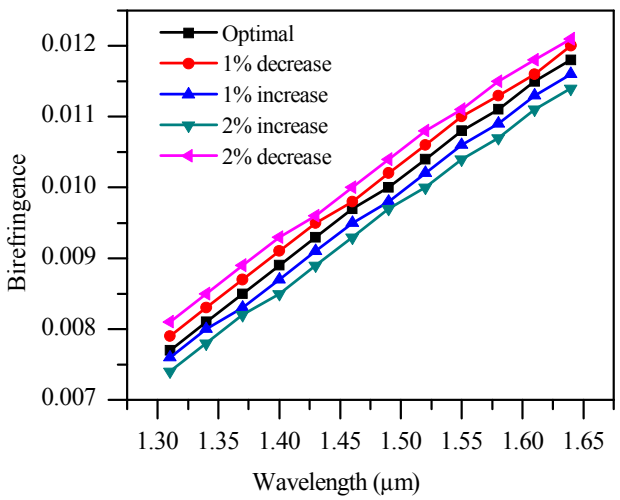

Figure 6. Birefringence of proposed PCF: optimum birefringence and effect of changing pitch

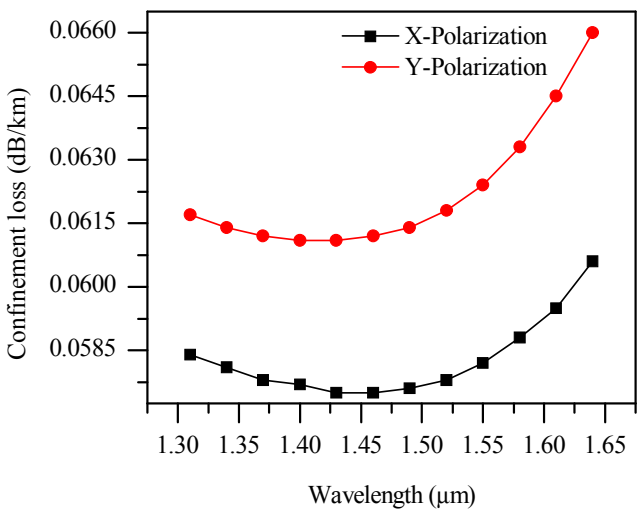

Figure 7. Confinement loss properties of proposed PCF for optimum design parameters.

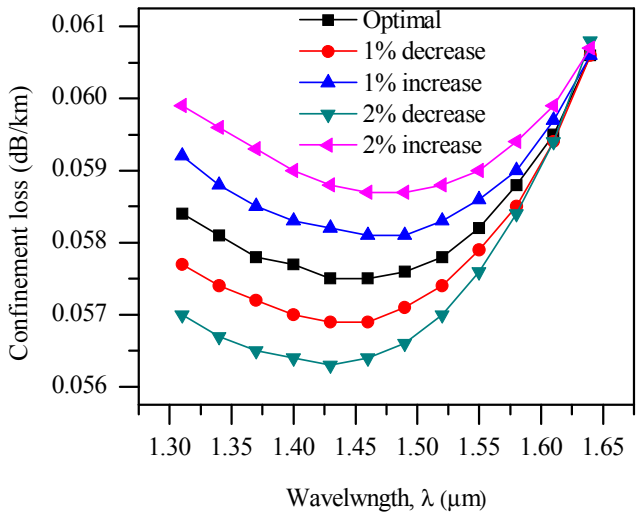

Figure 8. Confinement loss of proposed PCF: optimum confinement loss and effect of changing pitch .

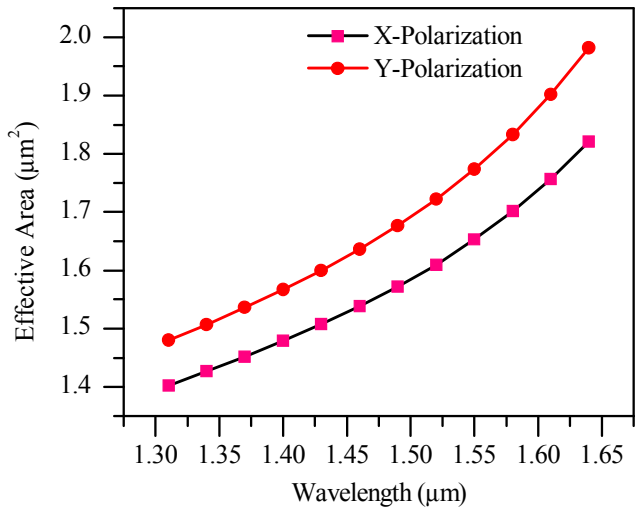

Figure 9. Effective Area of proposed PCF for optimum design parameters.

Fig.7. shows the confinement loss against wavelength for optimum design parameters. From this figure, it is observed that the confinement loss is about 0.0582 and 0.0624 for X-polarization and Y-polarization respectively. It is seen that confinement loss of Y-polarization is greater than X-polarization and increases with increase in wavelength but the value of confinement loss is in limit without causing any leakage.

The effects of changing the pitch on confinement loss are shown in Fig.8. Here, it is seen that the confinement loss of the proposed PCF increases rapidly with increase in pitch while decreases with increase in pitch.

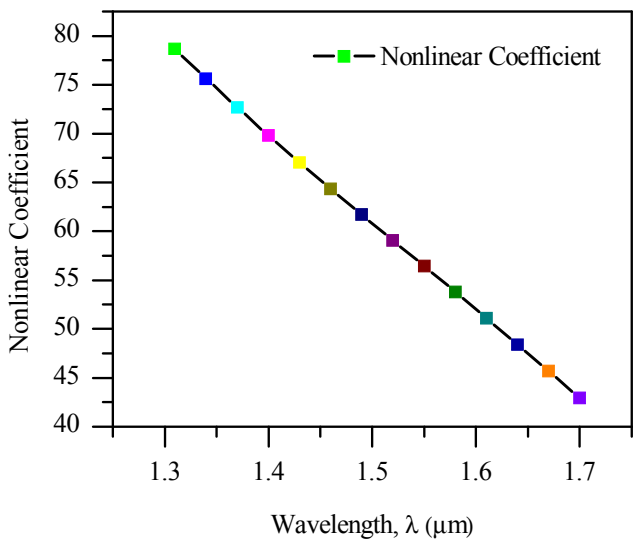

Figure 10. Nonlinear Coefficient of proposed PCF for optimum design parameters.

Simulation result shows that as the pitch varies from +1% to +2% confinement loss increases whereas the pitch varies from -1% to -2% confinement loss decreases.

Simulation result also shows that the effective area of the fiber increases with increase in wavelength as in Fig.9. At 1550 nm wavelength, the value is 1.7735 μm^2 . Due to small effective area, it is expected that the proposed PCF will be insensitive to bending and have low bending loss [15].

Fig. 10 shows nonlinear coefficient for optimum parameters. At 1550 nm, the nonlinear coefficient is found to be 56.41$W^{-1}km^{-1}$.This characteristic is suitable for dispersion compensation and effective in self-phase modulation for switching, pulse-forming, wavelength conversion applications and supercontinuum generation for frequency metrology [16].

"Table 1" shows comparison of the proposed PCF with the other existing design [14, 15]. It shows that proposed PCF is simple in design than others, because it contains only 4 air hole rings. Though, birefringence of proposed PCF is less, negative dispersion and nonlinear coefficient is higher than the other existing design [14,15].

CONCLUSION

A 4 rings Circular lattice PCF with elliptical and circular air holes has been investigated for its large negative dispersion properties as well as high birefringence and low confinement loss. It ensures large negative dispersion and high birefringence which are in the range of -220.9032 to -792.7265 (ps/nm-km) and 0.0077 to 0.0118 respectively at operating wavelengths 1310 nm to 1640 nm. It is expected that the proposed C-PCF will be applicable for broadband dispersion compensation in future optical fiber technology.

TABLE I. COMPARISON BETWEEN PROPOSED PCFS AND OTHER PCF AT 1.55 μm

PCFs	$D(\lambda)$ *ps/(nm.km)*	*Birefringence*	γ *($W^{-1}km^{-1}$)*	*No. of rings*
Ref.[13]	-491.5	3× 10-2	39.53	5
Ref.[14]	-650	2.10× 10-2	45.5	5

***Abstract*—This paper presents a novel Ultra Wide Band (UWB) wearable textile antenna for body area networks. The proposed antenna consists of a hexagonal radiating patch and a partial ground plane. The substrate of the proposed antenna is made of Dacron fabric with permittivity 3. Ultra wide bandwidth is achieved by optimizing the geometry, introducing a square notch in the partial ground plane and introducing novel slot pattern on the radiating patch of the antenna. This novel slot represents the "wireless antenna" icon. The dimension of the proposed antenna substrate is 40×34×1.7 mm^3 and the bandwidth 16.56 GHz starting from 2.6 GHz to 19.16 GHz for return loss less than -10 dB. The gain variation is from 2 dB to 6.35 dB and average total efficiency more than 83%. Maximum power of 17.39 mW may be set as input to the proposed antenna in order to guarantee compliance with the IEEE C95.1-1999 safety standard. The proposed antenna design details and simulated results are presented by Commercial electromagnetic simulation package CST Microwave Studio.**

Keywords—UWB; body area network; wearable textile antenna; patch antenna

I. INTRODUCTION

Wearable textile systems are very promising technology since their demands for navigation, tracking, portable communication, and public safety requirements are increasing rapidly. In recent years, the presence of wearable textile systems expressed the necessity for Wireless Body Area Network (WBAN) system to provide standalone outfit [1]. Antenna is the fundamental part of wearable textile system in WBAN. At present, textile antenna is one of the most impressive and cutting edge research areas of modern era. The textile antenna for wearable applications is actually the bond that integrates cloth into the communication system. These are made from textile materials and placed on body, into clothing or may be worn as a button antenna. Wearable textile antenna is mostly used microstrip patch antenna if textile fabric is used as substrate. However, the main limitation of the traditional microstrip patch antenna is limited bandwidth that restricts its applications. Due to this reason, Ultra Wide Band (UWB) technology is considered to be a favorable choice which provides wider bandwidth.

UWB is a radio technology, used for short-range communication. It occupies a bandwidth of at least 25% of the centre frequency or more than 1.5 GHz unlike the narrower frequency band of the conventional systems. UWB signal uses Orthogonal Frequency Division Multiplexing (OFDM) as the modulation technique to occupy the wide frequency band. The commercial use of frequency bands from 3.1 to 10.6 GHz for UWB systems was approved by the Federal Communications Commission (FCC) in 2002 [2]. UWB offers extremely low radiated power in low/medium data-rate applications based on narrow pulses, thus being very attractive for body worn battery operated devices in wearable computing.

Numerous papers have been published about the design, fabrication and applications of wearable antennas and systems. Previously reported works are based on single frequency band wearable antennas [3] and later dual frequency band wearable antennas [4]. In the recent researches, Wideband and UWB technology is one of the most fascinating choices for WBAN applications. Many of UWB antennas using rigid substrate material [5-6], large in size and small bandwidth [7-10][12-13] have been reported. However, it is quite difficult to obtain large bandwidth with compact size and a very low thickness in case of wearable antennas. In this paper, a novel and compact design of wearable textile antenna is proposed for WBAN applications by merging the UWB technology with wearable textile technology.

This paper is motivated from the above reported papers and presents a novel design of a wearable hexagonal UWB textile antenna. Novelty of this work is – the slotted area of hexagonal patch that represents the "wireless antenna" icon which is unique and also compact in size. The bandwidth of the proposed antenna operates in the wide range, achieving the UWB system requirements.

The outline of this paper is organized as follows. Section II represents a brief description of the wearable antennas. Design of the proposed wearable textile antenna and simulated results are illustrated in Section III & IV respectively. Finally, the conclusions of this research work are presented at the end of this paper in Section V.

II. WEARABLE ANTENNAS

Wearable textile antenna is usually consisted of three different layers which made of two types of material. A metallic conducting patch is on the top of a non-conducting dielectric substrate and a conducting ground plane is beneath the dielectric substrate.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

A. Non-conducting Material

The most important properties of textile antennas in wearable applications are flexibility to conform to the body, comfort to touch, and softness. Permittivity or Dielectric constant of the antenna substrates has a significant role in antenna designing. Different substrates having different dielectric constants affect the antenna performance in various ways. Textile substrate materials generally have a very low dielectric constant which reduces surface wave losses and improves antenna's bandwidth. Here, hypalon coated Dacron fabric textile material is used as the antenna substrate for dielectric constant is $\varepsilon_r = 3$ while the loss tangent is $\tan\delta = 0.025$. The properties of Dacron fabric include high tensile strength, high resistance to stretching, outstanding electrical property and durability.

B. Conducting Material

In order to build the communication system, an electrically conducting material is required for the radiating patches as well as for the ground plane. However, for the purposes of textile antenna designs, a conducting material needs to satisfy several requirements such as having a low and stable electrical resistance (1 ohm/square) in order to minimize losses, material must be homogeneous over the antenna area, and the variance of the resistance through the material should be small. Therefore, the conducting properties of various materials used in antenna fabrication and packaging play an important role in achieving the desired performance of antenna designs. Based on the above-mentioned facts, Perfect Electric Conductor (PEC) is used in this paper as the conducting materials for the radiating patch (front side) as well as for the ground plane (back side). A 50Ω transmission line is also made with this conducting material.

III. Antenna Design

The proposed antenna consists of a hexagonal patch with slotted area and fed by a microstrip line, and a partial ground plane. The structure of proposed antenna is shown in Fig. 1 (Front view), Fig. 2 (Cross-sectional view), Fig. 3 (Back view) and Fig. 4 (Phantom). Instead of resonance frequency or operating frequency, lower band edge frequency and entire bandwidth become the design considerations for UWB antenna. The lower band edge frequency (f_l) in GHz, has been calculated for UWB antenna according to (1) given below [11]:

$$\text{Lower band edge frequency, } f_l = \frac{c}{\lambda} = \frac{72}{(H + r + T)} \quad (1)$$

where, H is the height of the hexagonal patch in mm, r is the radius of the equivalent cylindrical monopole antenna in mm and T is the gap between ground plane and hexagonal patch in mm.

With reference to configurations in Fig. 1 with side length (L_p), the dimensions of H, r and D_p of the equivalent cylindrical monopole antenna are obtained (by equating their areas) as follows:

$$\text{Radius, } r = \frac{3L_p}{4\pi} \quad (2)$$

$$\text{Height, } H = \sqrt{3}L_p \quad (3)$$

$$\text{Diameter, } Dp = 2L_p \quad (4)$$

By selecting the value of L_p, the following parameters: r, H, D_p and f_l can be computed using (1-4). The dimensions of proposed antenna parameters are provided in Table I and computed parameters value of the proposed antenna are provided in Table II.

TABLE I. Dimensions of The Proposed Antenna Parameters

Parameters		Size (mm)
Substrate	Length	40
	Width	34
	Thickness	1.7
Ground	Length	16
	Width	34
	Thickness	0.5
Patch	Height (H)	20.551
	Side Length (L_p)	11.865
	Thickness	0.5
Feed Line	Length	18
	Width	4.6
	Thickness	0.5

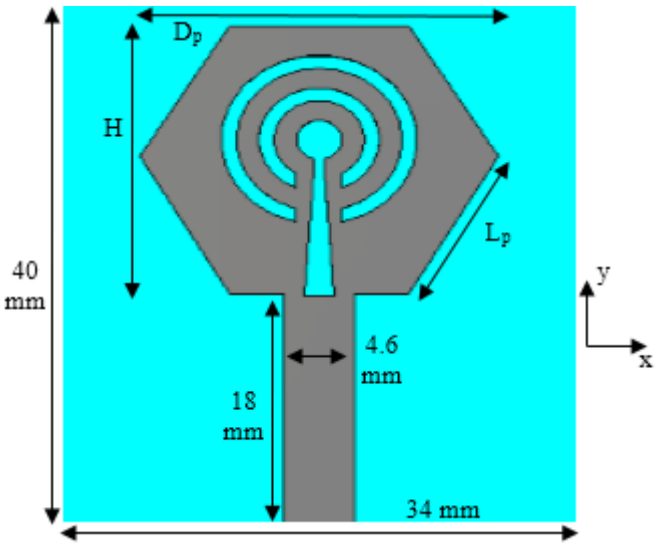

Fig. 1. Geometry of the Proposed Antenna (Front view)

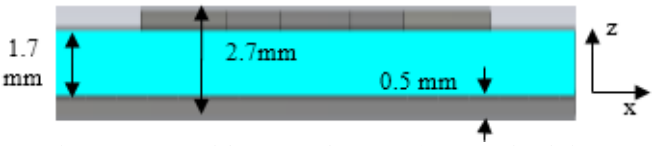

Fig. 2. Geometry of the Proposed Antenna (Cross-sectional view)

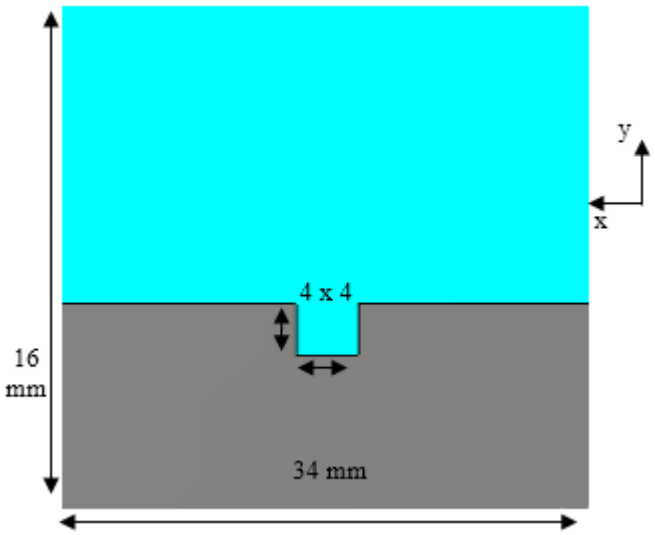

Fig. 3. Geometry of the Proposed Antenna (Back view)

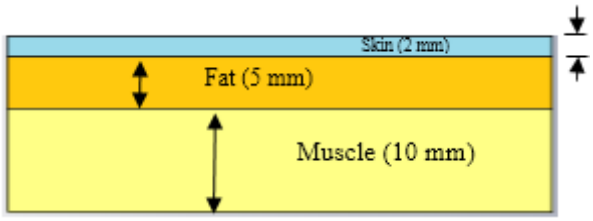

Fig. 4. Human Body Model (Phantom)

TABLE II. COMPUTED PARAMETERS VALUE FOR THE PROPOSED ANTENNA

L_p (mm)	r (mm)	H (mm)	T (mm)	D_p (mm)	f_l (GHz)
11.865	2.833	20.551	1.36	23.73	2.91

In order to enhance the bandwidth, one slotted circle along with a slotted triangle is introduced at the centre and two partial slotted rings are introduced at the top of the slotted triangle of hexagonal radiating patch.

TABLE III. OPTIMIZED VALUES FOR SLOTTED AREA OF PATCH

Parameters		Size (mm)
Radius of slotted circle at center, R_1		1.5
Triangle	Length	11
	Width (W_1, W_2)	0.5, 2
Slotted ring (Middle)	Inner radius, R_2	3
	Outer radius, R_3	4
Slotted ring (Outside)	Inner radius, R_4	5.5
	Outer radius, R_5	6.5
Distance between ring and circle, d		1.5

The overall slotted area of hexagonal patch represents the icon of "wireless antenna" shown in Fig. 1. Optimized values for slotted area of the patch are provided in Table III. Fig. 2 illustrates the cross-sectional view of the proposed antenna which indicates the thickness of different layers. A rectangular notch with size 4×4 mm^2 is also introduced on the top of partial ground plane (Fig. 3) to improve bandwidth of the presented antenna. The proposed antenna is mounted on the body phantom which model is shown in Fig. 4. The distance between antenna and phantom is 1 mm. Hence, it is explicit that the overall dimension of the antenna is quite small as compared to others. Commercial electromagnetic simulation package CST Microwave Studio is used to design the antenna.

IV. RESULTS AND DISCUSSION

This section analyzes the performances of the proposed UWB wearable textile antenna in terms of return loss (S_{11}), radiation patterns, antenna gain and efficiency over frequency, radiation effect on the body.

A. S_{11} Analysis of the Proposed Antenna

The simulated S_{11} plot over frequency of the proposed UWB wearable textile antenna is shown in Fig. 5.

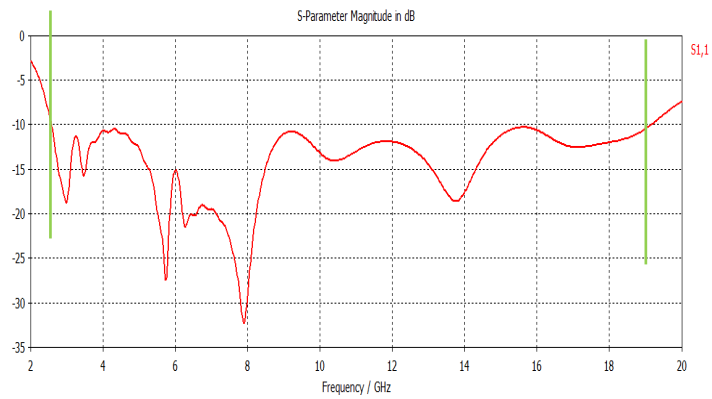

Fig. 5. Simulated S_{11} result

Fig. 5 indicates that the proposed antenna occupies a bandwidth of 16.56 GHz starting from 2.6 GHz to 19.16 GHz for S_{11} less than -10 dB. Lower edge frequency of simulated result is almost equal to the computed value. Hence, a very less number of incident waves reflect back to the source.

B. Radiation Patterns of the Proposed Antenna

The simulated azimuth and elevation radiation patterns at different frequencies of the proposed UWB wearable textile antenna are shown in Fig. 6 and Fig. 7 respectively.

The azimuth radiation patterns of the UWB wearable textile antenna at 3, 5.75, 7.9 and 13.75 GHz have been shown in Fig. 6. Theta (θ) has been set to both 0 and 90 degree for all values of phi (φ) to obtain azimuth radiation pattern. At 3 and 7.9 GHz, it exhibits almost omni-directional radiation pattern. Little deformation of radiation pattern is observed at 5.75 GHz. At 13.75 GHz, it has quite significant distortion from omni-directional pattern.

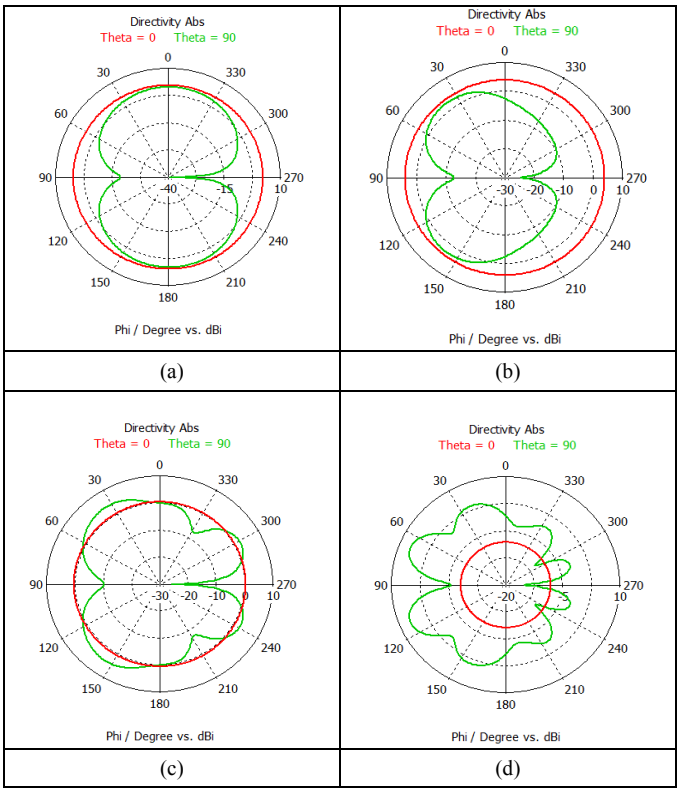

Fig. 6. Azimuth radiation patterns at (a) 3GHz, (b) 5.75 GHz, (c) 7.9 GHz and (d) 13.75 GHz

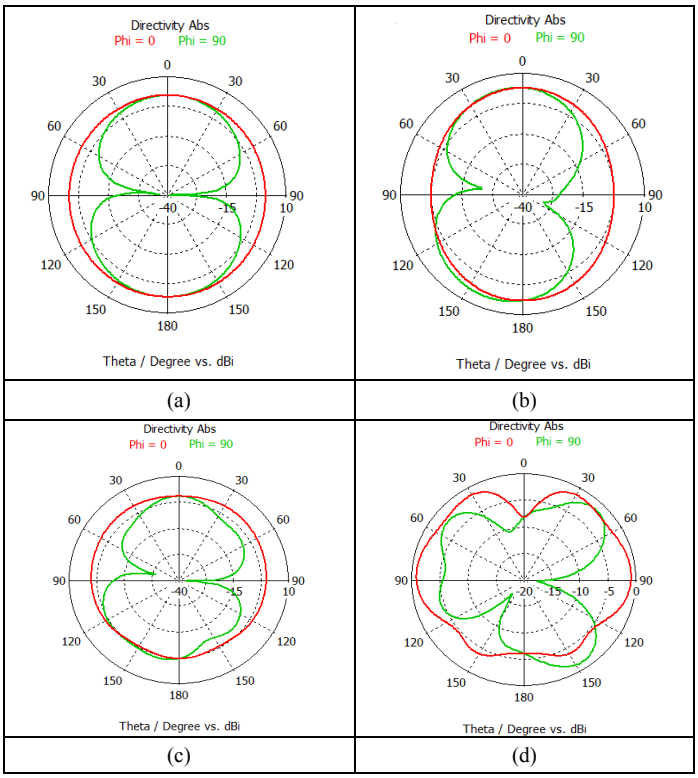

Fig. 7. Elevation radiation patterns at (a) 3GHz, (b) 5.75 GHz, (c) 7.9 GHz and (d) 13.75 GHz

Similarly for elevation pattern, phi (φ) has been set to both 0 and 90 degree for all values of theta (θ). The elevation radiation patterns of the UWB wearable textile antenna at 3, 5.75, 7.9 and 13.75 GHz have been shown in Fig. 7. At 3 and 7.9 GHz, it also exhibits almost omni-directional radiation pattern whereas little deformation of radiation pattern is observed at 5.75 GHz and quite significant distortion from omni-directional pattern observed at 13.75 GHz.

The analysis of Fig. 6 and Fig. 7 shows that the significant deviation of radiation patterns is found at higher frequencies. Furthermore, the data of radiation patterns (i.e.- main lobe magnitude, main lobe direction) of the UWB wearable textile antenna at 3, 5.75, 7.9 and 13.75 GHz have been provided in Table IV.

TABLE IV. DATA OF RADIATION PATTERNS AT DIFFERENT FREQUENCIES

Freq. [GHz]	**Main Lobe Magnitude [dBi] Direction [degree]**	**Theta (θ) [Degree]**		**Phi (φ) [Degree]**	
		0	**90**	**0**	**90**
3	Magnitude	2	1.2	2.8	2.8
	Direction	27	358	180	179
5.75	Magnitude	3.8	2.6	3.8	4.8
	Direction	86	142	180	163
7.9	Magnitude	0.2	4.1	1.2	0.2
	Direction	88	35	38	0
13.75	Magnitude	-8.2	7	-0.9	-1.5
	Direction	44	67	86	146

C. *Antenna Gain and Efficiency Results of the Proposed Antenna*

The variations of gain versus frequency and total efficiency versus frequency of the wearable textile UWB antenna designs are demonstrated in Fig. 8.

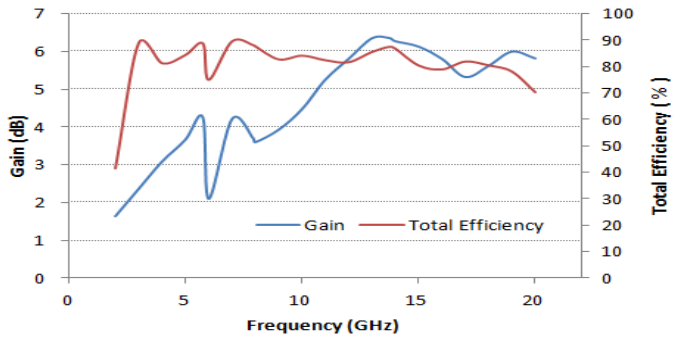

Fig. 8. Simulated Gain and Total Efficiency vs. Frequency

The highest gain and maximum total efficiency is achieved about 6.35 dB at 13.75 GHz and 90% at 7 GHz respectively

whereas the lowest gain and minimum total efficiency achieved almost 2 dB at 6 GHz and 75% at 6 GHz in the entire frequency range 2.6 ~ 19.16 GHz. From Fig. 8, the gain of the antenna varies significantly with changing frequencies while the efficiency varies slightly though it doesn't affect the overall performance. However, the gain variation is from 2 dB to 6.35 dB and average total efficiency more than 83%.

D. Specific Absorption Rate (SAR)

The SAR is a parameter to measure the power deposition in a human body when it is exposed to an electromagnetic field. For a net input power of 0.2 W at frequency 7.9 GHz incident to the antenna, the maximum 1 g averaged (1 g avg.) SAR value is found to be equal to 18.4 W/Kg. Therefore, in order to guarantee conformance with the IEEE C95.1-1999 (1 g avg. SAR ≤ 1.6 W/kg [14]) safety standard, the maximum allowed net input power has to be limited to 17.39 mW.

E. Comparison of the Proposed Antenna with Reported UWB Antennas

Table V shows the comparison of the proposed wearable UWB textile antenna with reported UWB antennas in terms of dimensions and occupied bandwidth.

TABLE V. COMPARISON WITH REPORTED UWB ANTENNAS

Ref. no.	Dimensions	Bandwidth
Proposed Antenna	34 x 40 mm^2	16.56 GHz (2.6–19.16GHz)
Ref. [7]	120 x 130 mm^2	3 GHz (1-4 GHz)
Ref. [8]	30 x 30 mm^2	10.4 GHz (3.6–14 GHz)
Ref. [10]	25 x 10 mm^2	8.2 GHz (3–11.2 GHz)
Ref. [12]	32 x 52 mm^2	10.04 GHz (3.11–13.15 GHz)
Ref. [13]	35 x 35 mm^2	9 GHz (2.8–11.8 GHz)

Comparison shown in Table V reveals the suitability for UWB applications as comparing with reference antennas. The overall performance of the proposed "wireless antenna" icon slotted hexagonal antenna on Dacron fabric material indicates that the drawbacks of reported UWB antennas have improved. Thus, the proposed antenna suits well to demonstrate the UWB characteristics.

V. CONCLUSION

In this paper, a novel UWB wearable textile antenna for body area network is presented. A novel slot pattern on hexagonal radiating patch is introduced that represents "wireless antenna" icon. A square notch in the partial ground plane is also introduced in this design. The proper selection of dimensions, square notch on the partial ground plane and positions of novel slot on the radiating patch strongly affects the antenna to achieve ultra-wide bandwidth. The proposed antenna design provides 16.56 GHz bandwidth ranges from 2.6 to 19.16 GHz with compact size on flexible substrate material. S_{11} characteristics illustrates that it has good impedance matching between antenna and transmission line with all over its occupied bandwidth. The antenna exhibits almost omni-directional radiation pattern but it has quite significant distortion from omni-directional pattern at higher frequencies. The gain of the antenna varies significantly with changing frequencies while the total efficiency varies slightly though it doesn't affect the performance. However, the gain variation of the antenna is from 2 to 6.35 dB and average total efficiency more than 83%. The IEEE C95.1-1999 standard is found to limit the aximum allowable net input power to 17.39 mW. Thereby, conclusion can be drawn that overall performance of the proposed antenna indicates that it is suitable candidate for UWB wearable textile applications. Reducing the size as well as increasing the bandwidth could be focus towards the further improvement of this design.

***Abstract*—In this paper we have presented a rectangular microstrip patch antenna with circular Electromagnetic Band Gap (EBG) structure. The operating frequency of the patch antenna along with EBG structure is 7.3 GHz. All the simulation is done by using Computer Simulation Technology Microwave Studio (CST-MWS). In comparsion with the rectangular EBG structure, improvement has been achieved in the overall antenna return loss by 10.22% bandwidth by 8.89% and gain by 16.84%.**

Keywords— bandwidth; EBG; gain; patch antenna; return loss

I. Introduction

In recent years the microstrip patch antennas have made great progress as they offer more advantages and better prospects compared to other antennas. For example they are lighter in weight, lower in volume, lower in profile and easier to fabricate [1]. However, the main drawbacks of microstrip patch antennas are low bandwidth, low efficiency and relatively large size [2]. In case of the design of a microstrip patch antenna the most important prospect is to increase the inherent narrow bandwidth of antenna and to miniaturize the patch antenna size. The bandwidth of the antenna can be improved by increasing the substrate thickness [3]. Again, in order to minimize the other drawbacks, the substrate, ground plane and the patch of the microstrip patch antennas can be incorporated with different materials and structures. For example DGS [4], two layer Substrate [5] and metamaterials among which using metamaterials is found to be the most suitable approach [6].

Metamaterials are basically artificially engineered materials which exhibit electromagnetic properties that are not found in nature (e.g. negative refractive index and both negative permittivity and negative permeability). In 1967 Veselago discovered the concept of metamaterials [7]. He hypothesized an unknown material that possesses a negative permeability and permittivity in the same frequency range and it shows the abnormal electromagnetic properties when the uniform plane-wave propagation was studied [7]-[9]. As a result, the left-handed material (LHM) has a reverse basic feature of light, such as negative refractive index (NRI) [8]-[9]. Surprisingly, the idea got only little attention until the year 2000 when smith further studied the LHM and realized this material was a periodically-arranged conducting concrete and it shows extraordinary properties [9].

The EBG structures can be categorized as a special type of metamaterial due to their unique band gap features. This unique property has been applied to design antenna systems with better gain and efficiency, lower side-lobes and back-lobe levels by suppressing surface wave modes [2], [10]. The effect of using EBG structure is found to be the reduction of the patch resonant length and the bandwidth as a result of stronger capacitive coupling [2].

Paper [11] proposes a rectangular microstrip patch antenna along with metamaterial structure at a height of 3.2mm from the ground plane, which consists of a Split Ring Resonator (SRR). The paper focuses on increasing the bandwidth of low profile microstrip patch antenna by Double-Negative properties. The aforementioned design has increased the bandwidth by 300MHz.

Similarly paper [12] introduce a bandwidth enhancement of a narrow band rectangular microstrip antenna on square shape (EBG) patch structure. The measured results show better return loss and good impedance matching which resulted in an increase of bandwidth to more than 39.63% after the EBG structure was introduced. Both of these papers, [11] and [12], show improvement in antenna bandwidth. Considering all these articles, the novelty of our work is that we have proposed a more effective EBG structure for the patch antenna which is capable of increasing the antenna bandwidth, return loss as well as the gain of the patch antenna.

II. Design Specification

A. Patch Antenna Design

The Patch Dimension has been calculated using the following equation.

Step-1: Patch width

$$w = \frac{v_0}{2f_r}\sqrt{\frac{2}{\varepsilon_r+1}} \quad (1)$$

Where

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

v_0 = The velocity of light.

ε_r = Dielectric constant of substrate.

Step-2: Effective Dielectric constant of the rectangular microstrip patch antenna.

$$\varepsilon_{eff} = \frac{\varepsilon_r+1}{2} + \frac{\varepsilon_r-1}{2}\left(\frac{1}{\sqrt{1+\frac{12h}{w}}}\right) \quad (2)$$

Step-3: Patch Length

$$L = L_{eff} - 2\Delta L \quad (3)$$

$$L_{eff} = \frac{c}{2f_r\sqrt{\varepsilon_{eff}}} \quad (4)$$

Calculation of Length Extension

$$\Delta L = 0.412h\frac{(\varepsilon_{eff}+0.3)(\frac{w}{h}+0.264)}{(\varepsilon_{eff}-0.258)(\frac{w}{h}+0.8)} \quad (5)$$

Step-4: Inset Feed

$$50 = R_{in}\,(\cos(\frac{\pi}{L}y_0))^2 \quad (6)$$

R_{in}=The input impendence at the leading radiating edge of the patch. While 50 (Ω) is the desired impendence.

Table I

Rectangular Microstrip Patch Antenna Specifications

Parameters Name		Dimensions without EBG (mm)	Optimized Dimension With Circular EBG Shape (mm)
Patch Width	W	14.53	14.53
Patch Length	L	11.53	8.95
Inset Feed	y_0	3.125	3.41
Inset Gap	g	1.901	0.38
Feed Length	L_f	13.202	11.895
Feed Width	W_f	1.901	1.9010
Substrate Width	W_S	31.02	31.0170

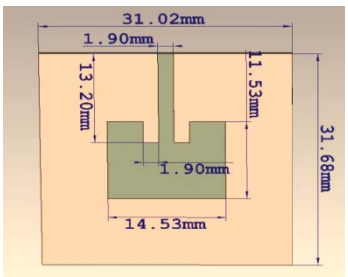

Fig. 1: Patch antenna without EBG.

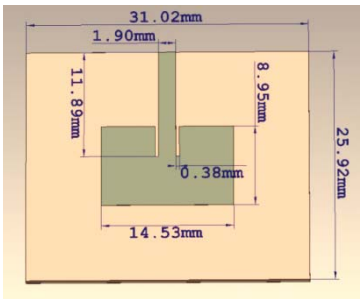

Fig. 2: Patch antenna with EBG

B. EBG Structure Design

Some equations have been adopted with a view to designing the EBG structure. The following equations are as follows for the square EBG structure,

$$L = 0.10\lambda \quad (7)$$

$$D = 0.02\lambda \quad (8)$$

and for the circular shape the radius of the circle is given by,

$$r = 0.10\lambda \quad (9)$$

Table II

DIMENSION OF EBG STRUCTURE

Parameters	Values (mm)
L	4.88
D	2.80
Radius r	2.44

The geometry of EBG structures (both rectangular and circular shapes with proper dimension) is shown in the following figure 3. Rogers R03003 has been chosen as antenna substrate due to flexibility for high frequency application compared to FR4 substrate.

Table III

Nicholson-Ross-Weir (NRW) technique is used as a conversion approach. Both permeability and permittivity is obtained from S-parameter using this approach [13].

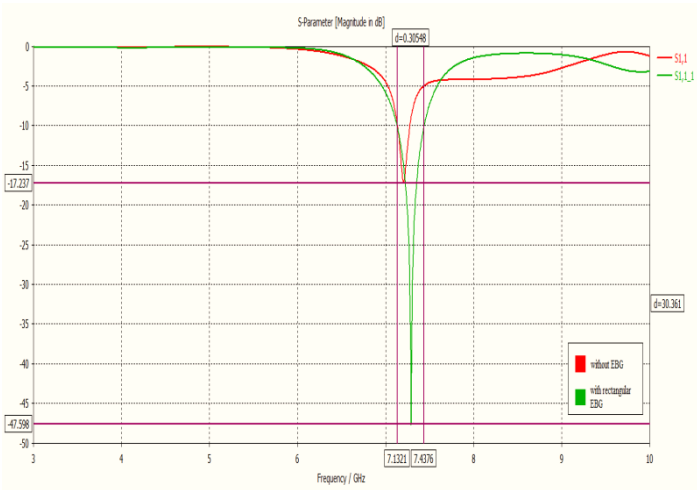
III. Simulation Results

Antenna design and simulation are based on CST-MWS 2015 using frequency domain solver. From the simulation the results associated with Bandwidth, Return loss and Gain are discussed in details.

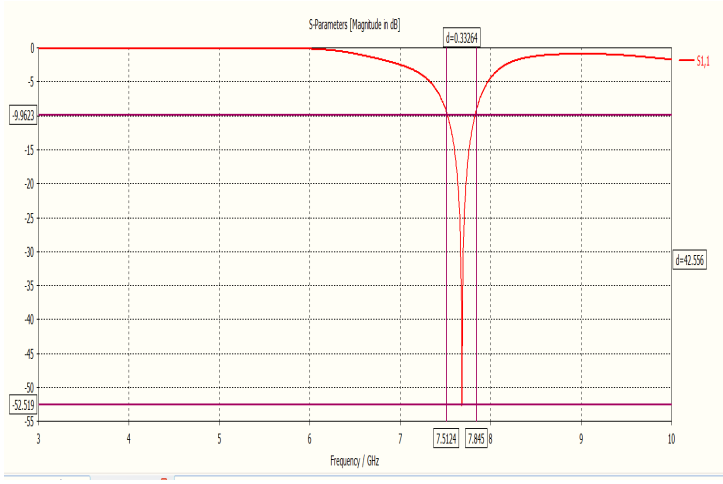
A. Return Loss and Bandwidth

Fig-4(a) shows the return loss plot of patch antenna without EBG and with rectangular EBG. From the following figure we can see that the return loss S_{11} of antenna without EBG is -17.24 dB and the return loss S_{11} of the rectangular EBG patch antenna is -47.598dB. According to fig-4(b) when we have introduced the circular shape of EBG on the ground plane of the antenna the return loss S_{11} has improved from -47.598 dB to -52.519dB.

In case of bandwidth, patch antenna without the EBG structure provides 154.27MHz, with rectangular EBG structure provides 305.48MHz, and with circular EBG structure provides 332.64 MHz.



(a)

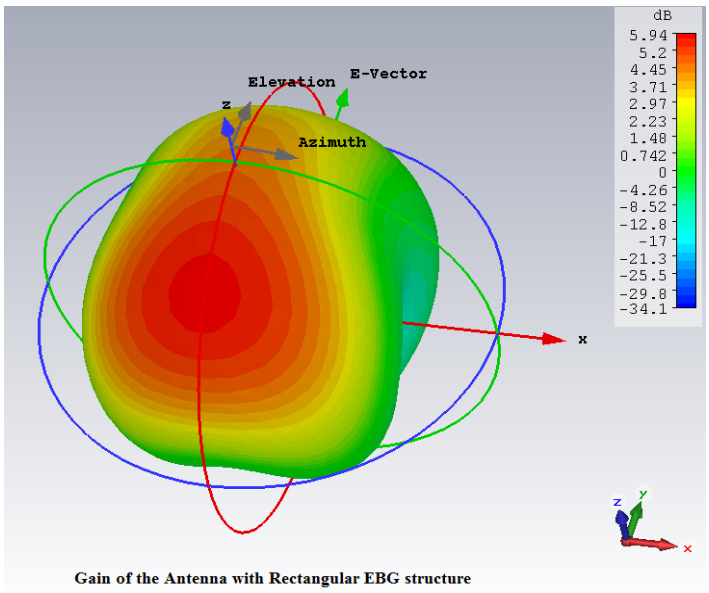


(b)

Fig. 4: (a) Return loss plot of the antenna without EBG and with rectangular EBG. (b) Return loss plot of microstrip patch antenna with Circular EBG structure.

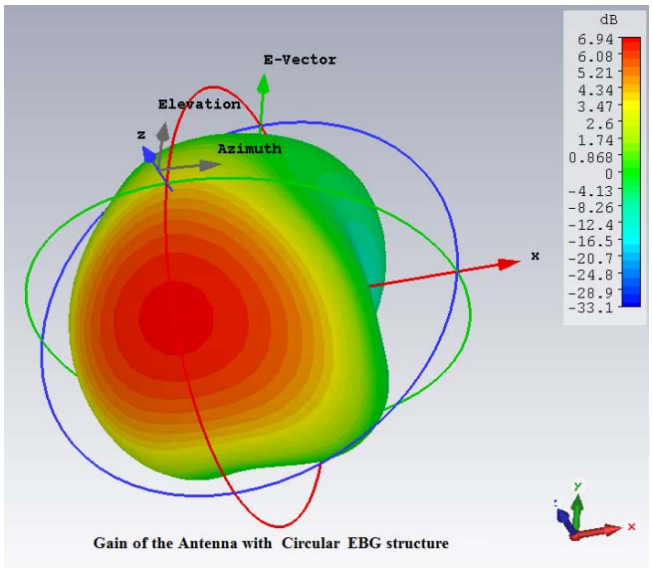
B. Gain

Figure-5 provides 3-D plot of antenna gain for both rectangular and circular EBG structures. Normally the gain of the patch antenna without EBG structure is $7.92dB$. Patch antenna with rectangular EBG provides gain 5.94 dB . For circular EBG the gain improves from 5.94 dB to 6.94 dB.



(a)

978-1-4673-9257-0/15/$31.00 ©2015 IEEE



(b)

Fig. 5 (a) 3-D plot of antenna gain in dB for rectangular EBG structure (b) 3-D plot of antenna gain in dB for circular EBG structure.

Table IV
Comparison table between the simulation results

	Patch antenna without EBG	Patch antenna with Rectangular EBG	Patch antenna with Circular EBG	Improvement with respect to rectangular EBG (%)
Return loss	-17.24	-47.647	-52.519	10.22
Bandw -idth	154.27	305.49	332.64	8.89
Gain	7.92	5.94	6.94	16.84

This table represents the comparison between the simulation results in terms of Return loss, Bandwidth and Gain. It is seen that patch antenna with Circular EBG structure produced improved results.

IV. Conclusion

We have simulated the patch antenna with rectangular and circular EBG structures and after the comparison of the simulated results we have found that the EBG structure on the antenna ground plane with the circular shape provides improved results than rectangular EBG structure.

V. Future Work

Though from the simulation it is seen that the antenna bandwidth, return loss and gain have improved significantly with respect to rectangular shape of EBG but in comparison to patch antenna without EBG the gain is comparatively small. Different types of shape can be tried to improve the antenna performance

***Abstract*—A novel modified dumbbell shape electromagnetic bandgap structure (EBGSs), trapezoidal slotted dumbbell shape EBGS, has been introduced. Very wide stopband and improved low-pass performances have been reported for particular designs using them. These designs are compared with conventional dumbbell shape EBGS. Trapezoidal slotted dumbbell pattern has shown very attractive performance with very sharp attenuation and significantly reduced ripple heights in insertion loss curve.**

Keywords—Dumbbel shape EBGS, Electromagnetic bandgap structure, Low-pass filter, Trapezoidal slotted EBGS.

I. INTRODUCTION

It is well known that periodic structures at the beneath of microstrip transmission line (T-line) shows very attractive band rejection property for microwave and millimeter wave frequencies [1]-[3]. Such periodic structures are called as Electromagnetic bandgap (EBG) structures or photonic bandgap (PBG) structures [4]; they are very popular in different types of microwave filter designing due to their unique behavior of rejecting certain frequencies [5]. EBG structures have found potential application in planner microwave devices such as patch antenna, phased array antenna, microwave filters, resonators [6]-[8]. Different kinds of electromagnetic bandgap structures (EBGSs) are proposed by the researchers around the world such as circular and square shapes [9], rectangular shape [10]; dumbbell shape [5], tuning fork shape [11], E-shape [8]. Periodic dumbbell shape EBGS (DS-EBGS) in the ground plane of a microstrip T-line introduces high line inductance and capacitance in microstrip line; therefore, it results wider and compact [11] stopband and low-pass [12], [13] performances. Various patterns of DS-EBGS are being studied e.g. square slotted, rectangular slotted, tapered, hybrid etc. and very promising performances are being explored by researchers [14], [15].

In this paper, we have proposed a modified dumbbell shape pattern where instead of square slots as bigger slots, trapezoids are used to give dumbbell look which is referred as trapezoidal slotted DS-EBG. Performance of this particular pattern has been compared with the same sized DS-EBGS. Another design is observed where we have noticed a wider stopband; but that performance later turned to low-pass when an increased number of EBG element are used.

This work is sponsored by Eastern University, Dhaka, Bangladesh. We are grateful to the organization for providing the financial support.

II. DUMBBELL SHAPE EBG PATTERNS

DS-EBG pattern, basically, consists of two bigger slots and a smaller slot where the smaller slot adjoins the bigger slots. Bigger slots generally are square in shape; but recently rectangular shape is taking over due to significant improvement and variation in the performance. The narrow slot is usually a rectangle. Such dumbbell like shape with square slots are, in fact, conventional DS-EBGS – formerly termed as defected ground structure (DGS) [12].

A. Rectangular Slotted DS-EBGS

In Fig. 1(a), a rectangular slotted DS-EBGS is shown. Various types of performances (i.e. wider stopband, dual-band, multi-band and LPF) of rectangular slotted DS-EBGS have been reported in [14]. In the figure, *b* and *c* are two arms of bigger slot and *g* and *h* are width and length of narrow slot respectively. It is reported that the bigger slots of dumbbell shape EBGS introduce inductance whereas the narrow slot introduces capacitance to the microstrip transmission line shown in Fig. 1(b) [12]-[13].

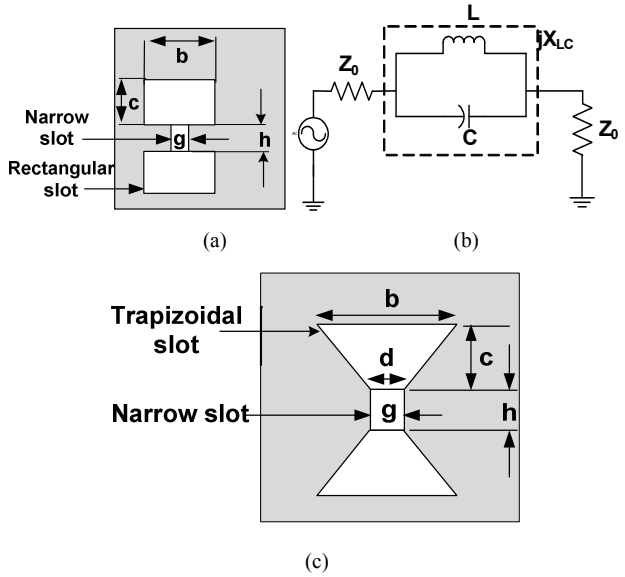

Fig. 1. (a) Conventional dumbbell shape EBGS with rectangular bigger slots, (b) equivalent circuit of conventional dumbbell shape EBGS, (c) trapizoidal slotted DS-EBGS.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

B. Trapizoidal Slotted DS-EBGS

Figure 1(c) displays a typical trapezoidal slotted DS-EBGS, where *b*, *d* and *c* are the bigger arm, smaller arm and height of the trapezoid respectively. From the figure, it can be seen that instead of square or rectangular slots two trapezoidal slots have been used at both end of the narrow slot. Height and width of the narrow slot is *h* and *g* respectively.

III. EBGS ASSISTED T-LINES

In this paper, we have designed four different designs, where in all the cases the width of the microstrip transmission line is 2.2642mm for maintaining the characteristic impedance (Z_0) 50Ω. Dielectric constant (ε_0) and thickness of the substrate are 2.45 and 31mil (0.7874mm) respectively.

A. Designs 1 : Rectangular Slotted Dumbbell Shape (b=8mm)

In this design, the width (*g*) and length (*h*) of the narrow slot are 2 mm and 1.27mm respectively; therefore, the area of the narrow slot is 2.54mm^2. The dimension of the bigger rectangular slot is b = 8mm and c = 3.987mm respectively; thus, the area of a bigger slot is 31.896 mm^2. Thus the total area (A_{EBG}) of the rectangular slotted DS-EBGS is 66.332mm^2. Inner element spacing (*a*), formally defined as center to center distance between two EBG elements, is 10.4308mm and number of EBGS elements is nine shown in Fig. 2(a).

B. Designs 2 : Trapizoidal Slotted Dumbbell Shape (b=8mm)

This pattern contain trapezoidal slot in place of rectangular slot shown in Fig. 1(c) and the size of the trapezoid is *b* = 8 mm, *d* = 2mm and *c* = 3.987mm; therefore, the area of the trapezoid is 19.94mm^2. The size of the narrow slot is *g* = 2mm and h = 1.27mm, same as the rectangular slotted dumbbell shape design. Thus the total area of an EBG element becomes 42.42mm^2, which is much less than that of design 1. Here, *a* = 10.4308mm too.

C. Designs 3&4: Trapizoidal Slotted DS-EBGS (b=4.622mm)

In this design *b* = 4.622 mm, *d* = 2 mm and *c* = 3.987 mm; the narrow slot: *g* = 2 mm and *h* = 1.27 mm. Thus the total area of an EBG element becomes 28.942 mm2, which is much less than that of design 1 and 2. We have observed the performances of this trapezoidal slotted DS-EBGS for different number of EBG elements at the beneath of T-line where a = *10.4308 mm.*

1) Designs 3 using 5 EBGSs: In this design we get five EBG elements at the beneath of T-line.

2) Designs 4 using 9 EBGSs: In this case the same size of trapezoidal slotted DS-EBGS is used; but the number of EBG element is nine.

IV. S-PARAMETER PERFORMANCES

All the simulations have been performed by using a method of moment (MOM) based software named Zeland IE3D. Simulation results obtained from this EM software have been found in good agreement with the experimented results [8], [11]. We have actually verified the simulated results with experimented results in [5]; however, in this paper we have also confirmed that the simulated result follows theoretical consideration.

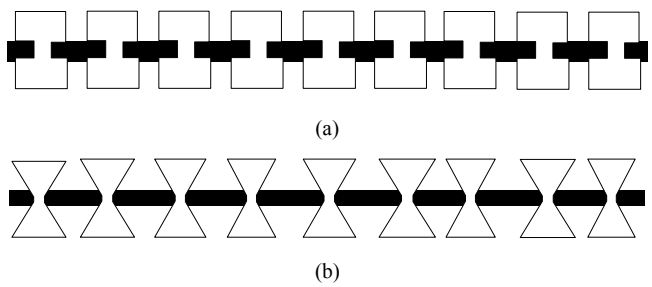

Fig. 2. EBGS assisted microstip T-line having (a) design 1: DS-EBGS with rectangular bigger slots, (b) design 2: trapizoidal slotted DS-EBGS.

In this paper, we performed all the simulations for more than 20 GHz frequency. Results have been discussed in terms of insertion loss (IL), return loss (RL), bandwidth (BW) and maximum ripple heights (RH) at passband from the Scattering parameter (S-parameter) performance of the designs. IL and RL curves are described as S_{21} and S_{11} respectively in the s-parameter performance.

A. S-parameter of rectangular DS-EBGS: Design 1

From the Fig. 3, a bigger stopband is found in Design 1. The stopband started at 4.59 GHz and ended at 17.89 GHz; therefore, the stop bandwidth is 13.3 GHz, which is quite wider than usual. However, passband width is 4.1 GHz and -3dB cut off frequency is observed at 4.13 GHz. Maximum ripple height of IL curve at the passband is -3.32dB.

B. S-parameter of trapezoidal slotted DS-EBGS: Design 2

Though the bigger arm of the trapezoid is identical to the bigger arm of the rectangular slot and height of the trapezoid is

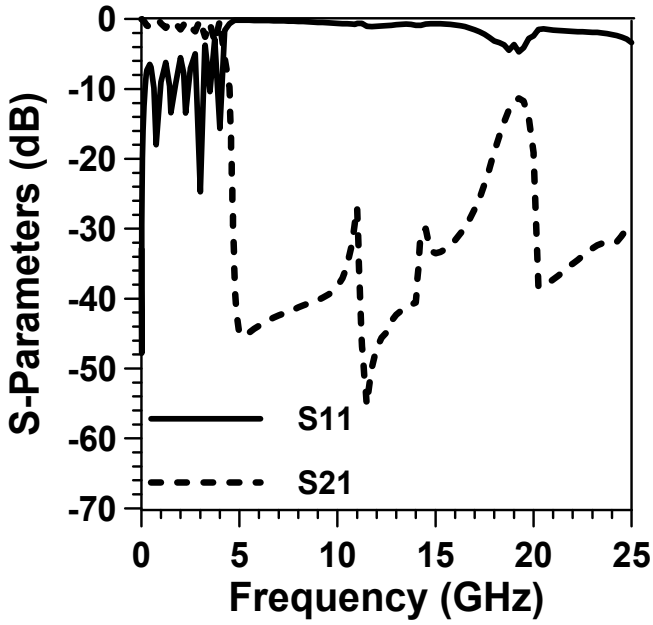

Fig. 3. S-parameter performance of rectangular slotted dumbbell shape EBGS assisted microstrip transmission line (Design 1).

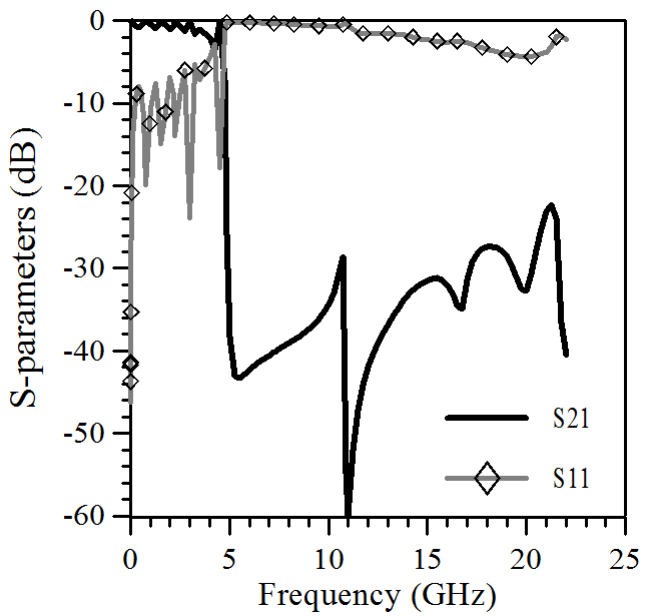

Fig. 4. S-parameter performance of trapizoidal slotted dumbbell shape EBGS assisted design of Design 2.

equal to the other arm of the rectangle, the trapezoidal slot DS-EBGS exhibits a distinguished low-pass performance up to 22 GHz simulation as showed in the Fig. 4. The stopband started from nearly 4.81 GHz. However, passband width is 4.62 GHz and -3dB cut off frequency is observed at 4.60 GHz. Maximum ripple height of IL curve at the passband is -3.33dB. Comparison with the performance of rectangular slotted DS-EBGS is shown in the Table I.

C. Performance of Design 3 & 4

T-line consisting of five trapezoidal slotted DS-EBGSs and nine EBGSs have resulted in a wider stopband and a low-pass performance respectively (shown in Fig. 5). We have observed following performances from this pattern by changing the number of EBGS only.

1) Wider Stopband performance using 5 EBGSs: Band rejection property is started at 5.68 GHz for five EBGS

TABLE I. S-PARAMETER PERFORMANCES OF ALL DESIGNS

Design Title	Different Values of S-parameter				
	Passband at -10dB (GHz)	*-3 dB cutoff frequency (GHz)*	*Stopband at -20dB*	*Max. RH (dB)*	*Total etching area (mm^2)*
Design 1	4.10	4.13	13.3	-3.32	66.332
Design 2	4.62	4.60	LPF started 4.813	-3.33	42.42
Design 3 (5 EBGs)	4.47	5.258	12.984	-1.31	28.942
Design 4 (9 EBGs)	4.20	5.058	LPF started 5.513	-1.94	28.942

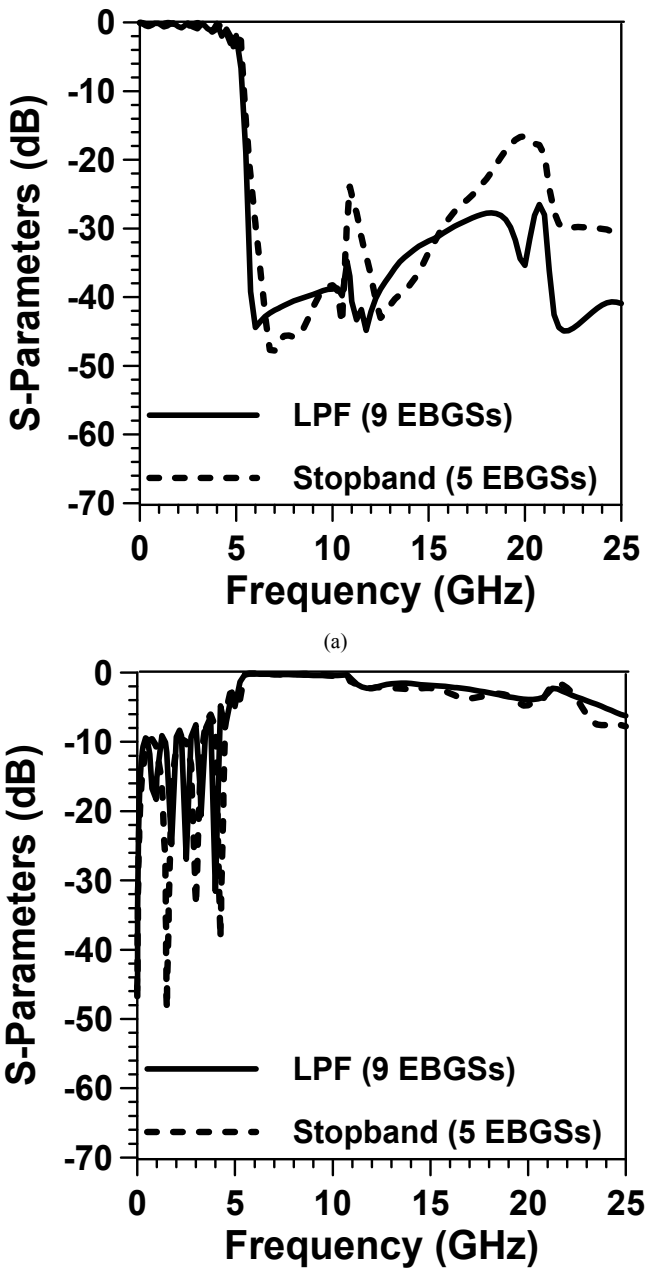

Fig. 5. (a) Insertion loss (S_{21}) curve (b) return loss (S_{11}) curve of trapizoidal slotted DS-EBGS assisted design having five and nine EBGS elements.

assisted design, the stopband width is 12.984 GHz which is larger too. Passband, -3dB cut off frequency and maximum RH at passband for this designs are 4.47 GHz, 5.258 GHz.

2) Low-pass performance utilizing 9 EBGSs: Passband, -3dB cut off frequency and maximum RH at passband for nine EBGSs assisted designs are 4.2 GHz, 5.058 GHz and -1.94 dB respectively. A prominent low-pass performance is observed from this design. Performances are compared in the Table I.

Number of EBGS, basically, has a bearing on the IL curve – the more EBGSs are used the more IL occurs [2]. However,

from the Fig. 5(a), S_{21} curve did not follow the conviction of the other frequencies except near 20 GHz. In essence, the proposed trapezoidal slotted DS-EBG structure performs better band-rejection compared to rectangular slotted DS-EBGS, although etching area is smaller. In contradiction, we know that if the etching area of EBGS (i.e. area of EBGS) is larger, more insertion loss meant to happen. From the earlier discussion, it is obvious that trapezoidal slotted DS-EBGS exhibits quite improved rejection performance.

V. Result Validation

Simulation results are obtained from Zeland IE3D usually are in good congruency with the experimented results [2], [5], [9]. However, to validate the results obtained from this simulation tool a standard 50 Ω T-line without having any EBG element etched at the ground plane has been simulated. Figure 7 shows the performance of this simulation where, it is seen that IL curve (S21) stand along the 0dB line i.e. no insertion loss is observed and return loss remained bellow -20dB; which is theoretically expected performance. Sine, the simulated result followed the theoretical realization; hence it can be considered that all the simulation results we get from the Zeland ie3d simulator will find very well agreement with experimented results.

VI. Conclusion

The design, consisting five trapezoidal slotted DS-EBGS, elements shows well formed wide stopband; in addition to that same trapezoidal slotted DS-EBGS with nine EBGS elements shows distinguished low-pass performance. While compared with rectangular slotted DS-EBGS of same bigger arm and height, it is observed that a trapezoidal slotted DS-EBG pattern has resulted very improved low-pass performance too, whereas the rectangular slotted dumbbell shape EBGS has shown a wider stopband. Therefore, band-rejection property of the proposed design is quite better than that of conventional DS-EBGS. We believe, the proposed pattern will find potential application for such low-pass filter designing soon.

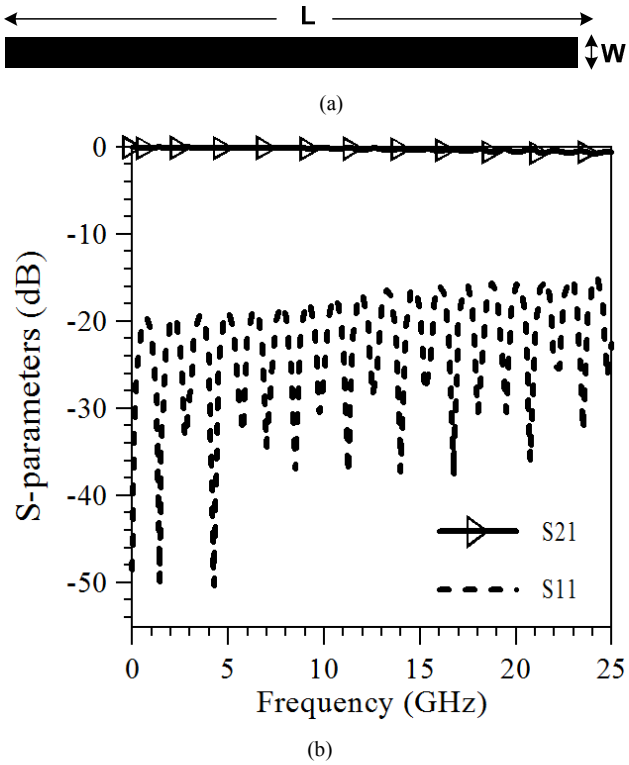

Fig. 6. (a) Standard 50Ω microstrip T-line without any EBGS (b) performance of the standard microstrip T-line.

Abstract— **At present Cognitive Radio Network (CRN) is one of the contemporary research area in order to improve efficiency as well as improve spectrum utilization factor of wireless communication. The impression of profitable CRN (i.e., simultaneous presence of primary and secondary users in licensed bands) is increasing popularity in wireless communication research. In fact fixed unlicensed band is used by wireless users in different networks to complete data communication. However, in practical number of wireless users are increasing day by day and guides this limited bandwidth to a saturation state. In CRN as at the absence of primary user, the secondary users access the channels of licensed bands; thereby the Medium Access Control (MAC) protocol for CRN faces many challenges. The challenges include throughput maximization, channel rendezvous amongst the secondary users, minimize delay, and to keep continuing data transmission without interfering the primary users. A large number of sender initiated MAC protocols have been proposed for CRN to solve these challenging issues. However we argue that efficient channel rendezvous in many scenarios still a major concern in accordance with the rest of the mentioned challenges. In this paper, we have come up with a Receiver Initiated Multi-channel (RIM) Medium Access Control (MAC) protocol named as RIM-MAC exploiting the pseudorandom number channel sequence and hopping method for multi-channel rendezvous amongst the secondary users of CRN. This protocol is efficient scheme for channel rendezvous success rate. We have analyzed and implemented our proposed RIM-MAC protocol, and found that it provides better performance in terms of throughput, rendezvous rate and delay.**

Keywords—Cognitive radio, psedurandom number channel sequence, channel rendezvous, primary user, secondary user.

I. INTRODUCTION

Cognitive Radio Network (CRN) gains popularity in the research area because it enables the current fixed spectrum channel assigned by FCC to be utilized by the new users [1]. It is noteworthy that most of the spectrums assigned to television channels, radio channels dividends a huge amount of bandwidth and are kept idle most of the time; whereas wireless network users (i.e., WLAN and Wi-fi users) share a small range of spectrum. In practical, when there are many wireless users at a time, the network gets congested because of the limited number of channels with less bandwidth. Hence, it is predictable that bandwidth would not be sufficient to provide better support for the wireless users in terms of quality of service (QoS), throughput and delay. So, the ultimate solution is to find out some alternative. CRN is one of the possible solutions to overcome this problem. Cognitive radio (CR) is an intelligent transceiver, adaptive and network technology, which can be configured with dynamism property. It has ability to automatically detect free or available channels from wireless spectrum and change its transmission parameters enabling more communications to run concurrently. In point of fact, CRN is structured with both the secondary user (SU) and primary user (PU) in which, SUs consist CR-enabled radios and the PUs whose radios need not be CR-enabled [2]. Cognitive capability means to the ability to sense opportunities in spectrum where and when channels are not employed by PUs [3].

In view of the fact that, the SUs operate separately on dissimilar channels based on availability (i.e., during the absence of primary users), channel rendezvous seems to be the most challenging issue in CRN. Fig. 1, illustrates that nodes *A* and *Y*, *W, C* and *X*, *B* and *Z*; the pairs of SUs opportunistically make channel rendezvous on channel 1, channel 3, and channel 5 respectively, where no PU exists. Note that channel 2 and 4 are occupied by the PUs. Hence, SU do not have any activity on these channels. It is observed that, there are different approaches exist for channel rendezvous between two SUs in CRN. *Firstly,* the *common control channel* (CCC) approach for channel rendezvous [4] creates bottleneck situation on the common control channel.

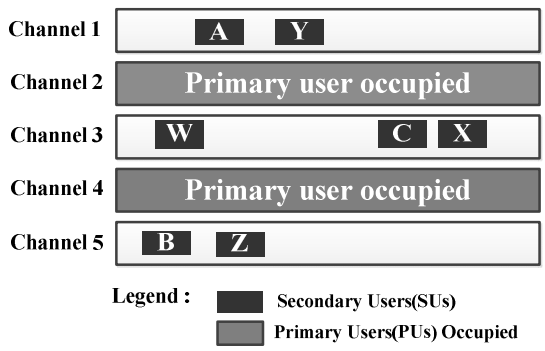

Figure 1: Basic communication manner in CRN

Furthermore, rendezvous scheduling complexity may arise. *Secondly,* the *channel hopping* approach [5-6] can be used by the SUs to discover each other on a channel while hopping different channels. This approach uses *pseudorandom sequence* according to available channel list. When PU is occupied channel(s) gradually, then decrease channel rendezvous rate as well as increase channel rendezvous delay. Conversely, if two SUs follow reciprocally exclusive sequence, still after lots of iterations, those may not succeed in

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

discovering each other [7]. *Finally*, in *synchronization approach* [8], nodes are needed to be synchronized; hence synchronous overhead becomes the main concern for a large network.

Considering the above mentioned limitations on different channel rendezvous approaches, we have motivated to design an efficient channel rendezvous technique using *pseudorandom number channel sequence* for making channel rendezvous between SUs considering all channels.

The rest of the paper is organized as follows: in Section II the background study and problems domains are presented. Section III describes the proposed RIM-MAC protocol design. Analysis and performance evaluation are described in Section IV and V respectively, and Section VI concludes the paper.

II. Related Work and Problem Statement

Till date, a number of MAC protocols have been proposed for CRN to solve the channel rendezvous problem, where the protocols either use any one approach of the followings or make the combinations amongst those; such as- *common control channel approach* [9-12], *channel hopping approach* [6], and *synchronization approach* [8].

A. Common Control Channel Approach

In this approach selects one channel that serves as a rendezvous channel and all the essential control information is exchanged among the SUs on this channel [9-12]. When a SU wishes to communicate with its potential receiver (i.e., another SU), at first it switches to the CCC during *control interval* and attempts to negotiate with its potential receiver using a control packet. When negotiation is complete on CCC, the SU switches to negotiation channel [5] which is available or common to both and then data communication can be accomplished during the *data exchange interval* through available channel. In addition, bottleneck situation may occur in the CCC when multiple nodes negotiate for rendezvous in a single channel.

B. Channel Hopping Approach

In the channel hopping approach [6], each SU generates a pseudorandom sequence using its own available channels. According to predefined hopping sequence SU switches/hops from one channel to another until finds its neighbor. When two SUs meet on a channel which is common between them, they need to exchange the necessary control information as well as complete their data communication. Hence, we conclude that a large number of iterations are required for channel rendezvous using pseudorandom channel hopping sequence as well as, even after lots of iterations; neighbor discovery of SUs may not be successful if SUs follow mutually exclusive pseudorandom sequence [7].

C. Synchronization Approach

In this approach [8] time is divided into N number of equal time slots of fixed duration. Each time slot is dedicated to one channel for control signal exchange. At the end of the network initialization state, all nodes are synchronized and every node has the information about its neighbors and their respective channel sets. To exchange the control signals it chooses one of the channels common between itself and its neighbor during at the beginning of specified time slot. Therefore, nodes are needed to be synchronized; hence, synchronization overhead occurs in this approach and increase the rendezvous delay.

Considering the above mentioned limitations of different channel rendezvous approaches, in this paper we have proposed a RIM-MAC protocol for SUs. The proposed method makes a pseudorandom number channel sequence according to total number of channels for rendezvous among the SUs.

III. Proposed RIM-MAC Protocol Design

A. Protocol Overview

RIM-MAC is a multichannel asynchronous duty-cycling MAC protocol. It does not require nodes to synchronize. It also does not use common control channel behavior. In this protocol design a ***beacon packet*** (i.e., Hello Packet) is considered to exchange all the control information of a SU node. Each SU has a ***prediction state*** (i.e., *initial state*) to learn about receiver's available channel set, *beacon sending time* and *pseudorandom number channel sequence*.

In RIM-MAC protocol, a node avoids choosing channels that are occupied by PU. When a node wakes up on a channel according to pseudorandom number channel sequence to send a beacon, it uses a CCA (Clear Channel Assessment) technique to check and make sure the channel is idle/free before beginning its transmission. If the channel is idle/free, the node sends the beacon and complete data transmission with their potential sender node. If the channel is occupied by PU, the receiver node skips the channel and goes to sleep; and wait on that channel till a cycle time, denoted by T_C (i.e., mentioned later). Additionally, after waiting the nodes switch to next pseudo randomly chosen channel and repeat the CCA technique and beacon sending method.

B. Network Model

Fig. 2 is shown as simple cognitive radio network model. In this model SUs are mentioned as S (i.e., Sender Node) and R (i.e., Receiver Node). We know that in IEEE 802.11b standard protocol uses only 16 channels. SU can occupy any channel among the standard channel list of ISM band. Here, for simple explanation we have assumed only 5 channels. The PUs is mentioned as P_S in sender side and P_R in receiver side respectively.

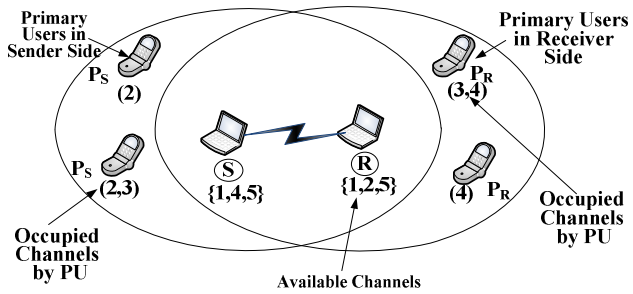

Figure 2: Simple CRN model

In sender range PUs occupied channel(s) are (2, 3) and in receiver range PUs occupied channel(s) are (3, 4). So the available channel(s) set of *S* is {1, 4, 5} and available channel(s) set of *R* is {1, 2, 5}. In the next sections we have used these available channel(s) list for explanation.

C. Protocol Operation

RIM-MAC is a multichannel asynchronous duty-cycling MAC protocol. The design of RIM-MAC is mainly encouraged by the multi-channel EM-MAC [13] protocol for WSN. RIM-MAC protocol operation is categorized into three phases such as-*Network Initialization State, Stable Phase and Adaptive Phase* which are described in the following sections.

1) Network Initialization State

Each SU node equipped with a single radio multi-channel transceiver and can act as a sender or a receiver and maintains a common communication characteristic. Initially it is considered that a node has a packet to send to a receiver but does not have the receiver's ***prediction state*** (i.e., receiver's available channel list, beacon time and pseudorandom number channel sequence). Hence, at the initialization the node having data (i.e., the sender *S*) starts sensing the first available channel of its own pseudorandom number channel sequence. *Firstly*, the sender checks that if the channel is occupied by any PU, it switches to the next channel of pseudorandom number channel sequence; otherwise, it enlists the channel in its available channel list and waits for receiver's beacon on that channel. If the sender does not receive beacon from the receiver during its waiting time interval on that channel, then the sender switch to another channel and so on. After receiving the beacon from the receiver, the sender sets a flag in the header of the data packet sent to the receiver, requesting the receiver to embed its prediction state in the following beacon. Thus, the node gets aware of the receiver's beacon time offset on respective available channels and maintains the same for future data communication. So the receiver beacon should be sufficient to ensure that the receiver will visit the channel at least once during this time. Let T_C be the cycle time interval of a node and the node wakes-up on different channels using the pseudorandom number channel sequence using the T_C cycle time interval. However, if the next channel(s) of the pseudorandom number channel sequence is occupied by the PU the node stays on its current channel and after elapsing appropriate T_C cycle time interval(s) it switches to the next available channel. It should be sufficient to ensure that receiver will visit the available channel at least once during this time. So the maximum waiting time of a sender on a channel would be

$$T_{Wait} = N_{ch} \times T_C \qquad (1)$$

Where, T_C is the cycle time, and N_{ch} is the total number of channels. Fig. 3 illustrates the initialization state of protocol. Based on the *overlapping principle* [14] it is expected that *S* would receive the beacon from *R* and subsequently sends the data packets and complete communication. If the sender does not receive a beacon from the receiver after waiting T_{Wait}, the sender switches to the next channel and repeats the waiting procedure. If the sender is unable to rendezvous with the receiver after waiting on all channels, the sender assume that

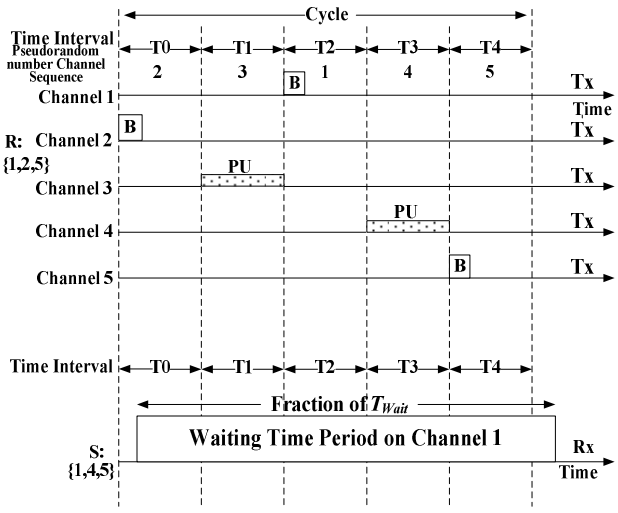

Figure 3: Network initialization state

the receiver is unreachable. In contrast, the same node, when acts as a receiver, then it sends the beacon to its potential sender(s) posterior to the waiting time *(T_{Wait})* for its own receiver's beacon.

2) Stable Phase

Every SU node independently decides and maintains its own pseudorandom number channel sequence switching behavior, wake-up offsets and available channel list. A sender rendezvous with a receiver on a particular channel by predicting the receiver's wake-up channel, wake-up offset and available channels. We denote that a SU *Sender* as node *S* and a SU *Receiver* as node *R*. Fig. 4 illustrates an example of the operation of proposed RIM-MAC, with time progressing from left to right. As RIM-MAC is a receiver initiated multichannel MAC protocol, a receiver node *R* first sends a beacon on an available channel (i.e., no primary user is on that channel) according to its generated pseudorandom number channel sequence. On the contrary, it is assumed that the sender *S* is well aware of receiver's channel sequence, available channel list and beacon time offset on different channels. Hence, the sender *S* proactively remains on the receiver's available channel to receive the beacon from node *R* and consequently sends data to *R*. As shown in Fig. 4, sender *S* has channel {1, 4, 5} as its available channel list. Now receiver *R* first scans the channels according to its pseudorandom number channel sequence. Thus, on a particular time offset/interval receiver *R* sends a beacon *B* to sender *S* and initiates a communication on available channel 2 during cycle time T_C, but on that time sender *S* is not stayed on that channel because channel 2 is occupied by PU for *S*. So *R* does not get any data from sender *S*. Now *R* switches to next channel(s) and so on. Here, channels 3 and 4 are occupied by PU so receiver skips these channels and switches to next channel. The channel 1 is available to *R,* so *R* sends a beacon to sender *S* on this channel. After receiving the beacon *B* from *R*, node *S* sends the data packet *D* to *R*. In reply, *R* sends an acknowledgement beacon *B* to *S* to acknowledge the data packet receipt. Moreover, the acknowledgement beacon *B* works as a request for another data packet to be sent to *R* by *S* or another sender. In the providing example no other data packet is available so *S* and *R*

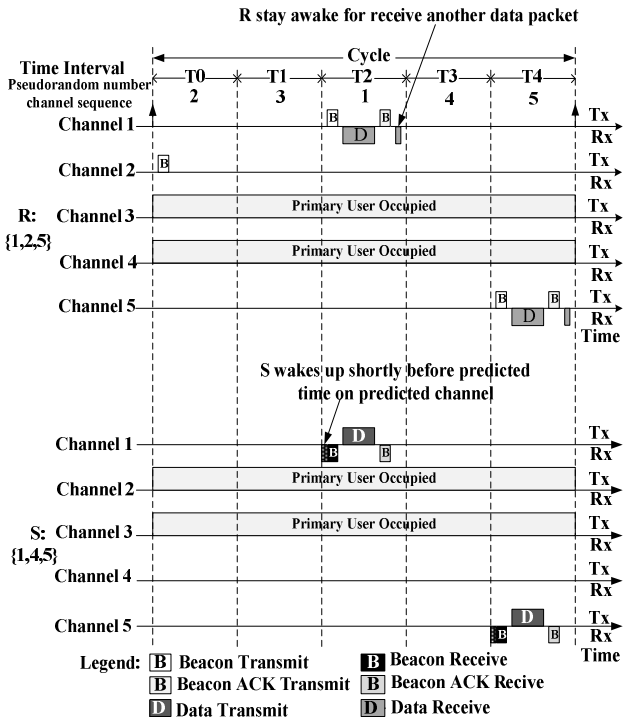

Figure 4: RIM-MAC protocol operation scenario.

quickly go back to sleep. After Cycle time T_C, R wakes up for the second time on another available channel such as 5 and complete data packet transmission with S and so on. Hence, sender S has prediction state of R, so S wakes up shortly before predicted time on predicted channel(s) before data transmission.

3) Adaptive phase

In adaptive phase, we have assumed that after sometimes or next cycle, when available channel list of R is updated with few additional channels due to non-occupation of PUs. In such case, receiver R follows its own pseudorandom number channel sequence for sending beacon in the newly added channel(s). In contrast, it is expected that S will be updated about the changes in available channel list in R through the earlier/later beacons. Thus it can perform data transmission with R in the newly added channel(s). When, available channel list of R is updated with fewer channel(s) due to channel occupation of PUs.

In such case, receiver R follows its own pseudorandom number channel sequence for sending beacon in the available channel(s) only. Here as well S will be updated or presume about the changes in available channel list in R. Thus it can perform data transmission with R in the newly added channel(s). Let, after few seconds previous sender S now acts as a new receiver R, and its available channel(s) list is {1, 4, 5} and its pseudorandom number channel sequence is 31542. Therefore, new receiver R follows its own pseudorandom number channel sequence and completes the data transmission with another sender S according to stable phase. Fig. 5 illustrates new adaptive operation in this case.

IV. Rendezvous Delay Analysis

For channel rendezvous delay analysis, we have considered three cases as follows: worst case rendezvous delay analysis, best case rendezvous delay analysis and average case rendezvous delay analysis.

Case 1: Worst case rendezvous delay analysis

If a sender S has no prediction state of R, then S first waits on an available channel until getting the receiver beacon. Let T_C be the cycle time interval of a node and the node wakes-up on different channels using the pseudorandom number channel sequence using the T_C cycle time interval. However, if the next channel(s) of the pseudorandom number sequence is occupied by the PU the S stays on its current channel and after elapsing appropriate T_C cycle time interval(s) it switches to the next available channel. It should be sufficient to ensure that receiver will visit the available channel at least once during this time. So worst case rendezvous delay would be calculated as follows:

$$T_{Wait}^{Worst} = N_{ch} \times T_C \tag{2}$$

Here, T_C = Cycle time, N_{ch} is the total number of channels.

Case 2: Best case rendezvous delay analysis

In the best case sender S would get the beacon exactly on its first available channel without wait. So the best case rendezvous delay would be calculated as follows:

$$T_{Wait}^{Best} = \delta;\ Where\ \delta \rightarrow 0 \tag{3}$$

Case 3: Average case rendezvous delay analysis

Average case rendezvous delay would be calculated as:

$$T_{Wait}^{Average} = \delta;\ where\ \delta \rightarrow \frac{N_{ch} \times T_C}{2} \tag{4}$$

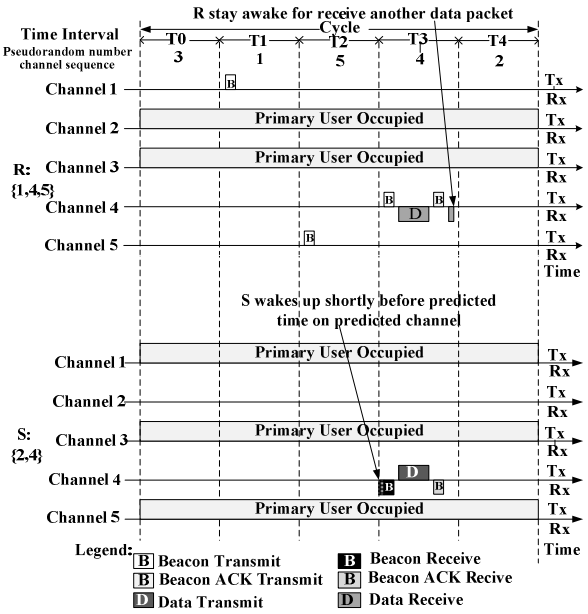

Figure 5: RIM-MAC protocol operation in adaptive phase

V. PERFORMANCE EVALUATION

We have demonstrated the performance evaluation of our proposed RIM-MAC protocol and compare the results with that of a CCC-MAC protocol and SYN-MAC protocol. We have used our own simulation model developed in Java Platform (NetBeans IDE 7.0) and we have implemented our proposed RIM-MAC, CCC-MAC and SYN-MAC protocols and compare the results with among them. In this simulation environment, 10 channels are used for modeling licensed channels for PUs and randomly some of the channels made free/unlicensed and set available to the SUs. Maximum 20 nodes are deployed in 500 x 500 m^2 area to make variation in number of PU and SU. 10 nodes are chosen randomly as the sources and the other 10 nodes as destinations. The transmission range of each node is set to 250*m*. In this simulation, 10 simulation cycles are considered, each having a cycle period of 10 seconds. Hence, total simulation time is 100 seconds. Each data packet is considered to cost 1 Joule for single transmission, which is used to calculate energy consumption of each node. In case of data packet transmission failure, 1 Unit (i.e., Second) is assumed, which is used to calculate delay of each node. In our simulation, for evaluation the performance of Proposed RIM-MAC, SYN-MAC and CCC-MAC, we have considered five performance metrics such as- *Throughput, Rendezvous Success Rate, Rendezvous Delay, Packet Transmission Success Rate,* and *Energy Consumption.*

A. *Throughput Performance*

Fig. 6 shows the aggregated throughput of proposed RIM-MAC with the SYN-MAC and CCC-MAC protocols as the network traffic is increased. The throughput of RIM-MAC is significantly higher than SYN-MAC and CCC-MAC. The main cause for this behavior is that a CCC among all the nodes is not always available and so many times a connection is not established. Hence, due to these failures the throughput is significantly lower in CCC-MAC. In SYN-MAC when nodes are increased, then synchronization overhead is increased so connection problem and problem of message collaboration among the nodes are increased. So throughput is comparatively lower than the RIM-MAC. In RIM-MAC, there is no control signal shared with among all nodes and hence, nodes are communicated any time any available channel(s). Therefore, RIM-MAC has the better throughput from the SYN-MAC and CCC-MAC protocols.

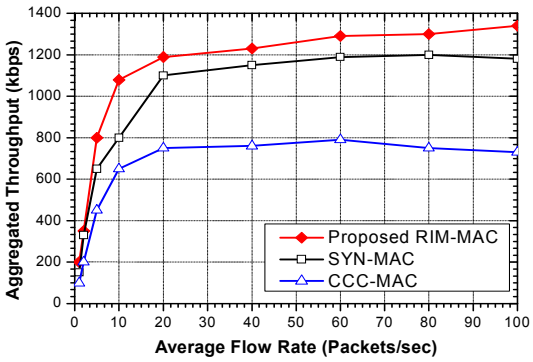

Figure 6: Average throughput Vs flow rate

B. *Rendezvous Success Rate*

Fig. 7 demonstrates the results of rendezvous success rate in percent with respect to simulation time for channel rendezvous. As shown in figure, in 1st cycle, rendezvous success rate among the SUs in RIM-MAC is 100%, in SYN-MAC is 100% and in CCC-MAC is 70%, and so on. After 10th cycle of simulation, it is observed that the rendezvous success rate in RIM-MAC is 60% and steady, and SYN-MAC and CCC-MAC are abrupt. So, it can be concluded that proposed RIM-MAC protocol provides higher rendezvous success rate than the SYN-MAC and CCC-MAC approaches.

C. *Rendezvous Delay Rate*

Fig. 8 demonstrates the outcome of rendezvous delay in second with respect to simulation time for channel rendezvous. As shown in figure, in 1st cycle, rendezvous delay among the SUs in RIM-MAC is 0 (i.e., no delay), in SYN-MAC is 1 and in CCC-MAC is 3, in 2nd cycle; rendezvous delay among the SUs in RIM-MAC is 0 in SYN-MAC is 1 and in CCC-MAC is 4 and so on. Finally at 10th cycle of simulation, it is observed that the rendezvous delay in RIM-MAC is 4 and steady, and SYN-MAC and CCC-MAC are increased. So, it can be concluded that proposed RIM-MAC protocol provides lower rendezvous delay than the SYN-MAC and CCC-MAC approaches.

D. *Packet Transmission Rate*

Fig. 9 exhibits the results of packet transmission success rate in percentage with respect to simulation time. In figure, in 1st cycle, packet transmission rate among the SUs in RIM-MAC is 100%, in SYN-MAC is 90% and in CCC-MAC is 70% and so on. It is also observed that in 10th cycle, the packet

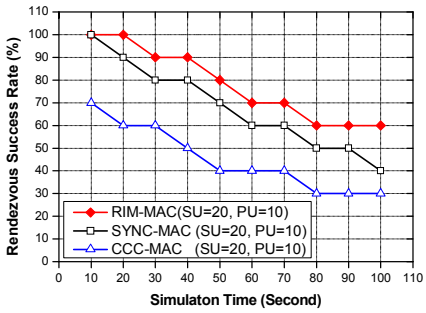

Figure 7: Rendezvous success rate with respect to simulation time

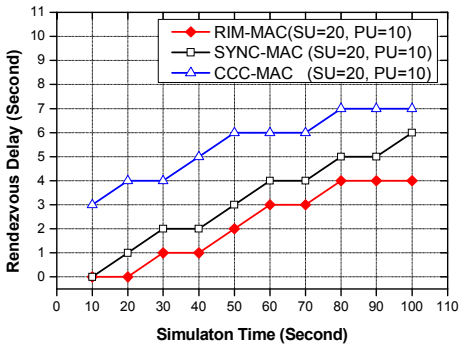

Figure 8: Rendezvous delay with respect to simulation time

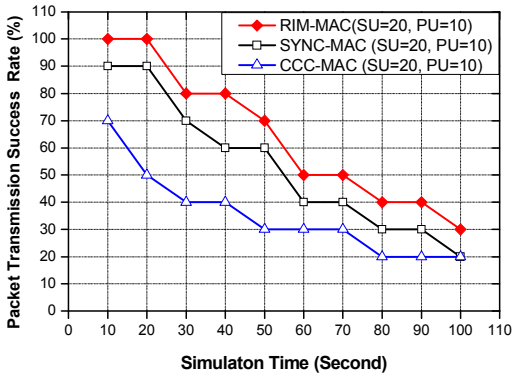

Figure 9: Packet transmission success rate with respect to simulation time

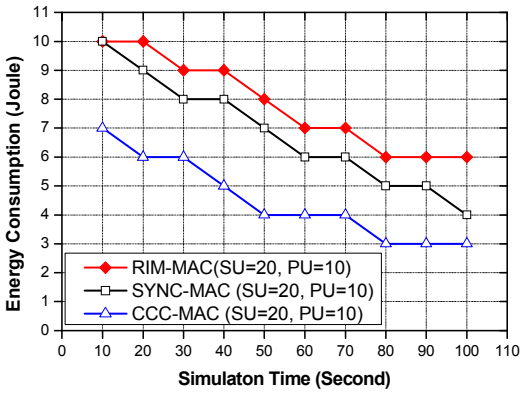

Figure 10: Energy consumption with respect to simulation time

transmission success rate in RIM-MAC is 30%, and 20% in SYN-MAC and CCC-MAC respectively. So we can say that RIM-MAC protocol provides higher packet transmission success rate than the SYN-MAC and CCC-MAC protocols

E. Energy Consumption

Fig. 10 illustrates the outcome of energy consumption in second with respect to simulation time. It is observed in RIM-MAC rendezvous success rate and packet transmission success rate is higher than the SYN-MAC and CCC-MAC which are shown in Fig. 7 and 9 respectively. So it is concluded that the energy consumption in proposed RIM-MAC is higher than the SYN-MAC and CCC-MAC.

VI. CONCLUSION

In this paper we have presented a new CRN MAC protocol and channel rendezvous scheme using pseudorandom number channel sequence based mechanism for SUs considering all the channels of the list. Proposed RIM-MAC protocol algorithm ensures that maximum number of SUs can make channel rendezvous and successfully complete their data transmission with each other. This protocol automatically eliminates the control channel saturation problem and synchronization overhead. In addition, this protocol increases throughput, maximize channel rendezvous success rate, maximize packet transmission rate and reduces delay.

Abstract—**Today's technology in communicating among wireless systems are more complicated and sophisticated with more opportunities, services and facilities to its users. As wireless network technology advances so as the challenges associated with it increases to solve some basic problems such as congestion, interference, call admission and service quality control etc. In the macro integrated femtocellular or heterogeneous wireless network the system capacity enhancement in a low congestion environment is a key issue to focus on and to do so a novel approach is proposed in this paper. We propose an opportunistic system approach where intelligent resource reallocation (IRR) scheme is used to create opportunity to its user to be connected in the high capacity advanced wireless network system with reduced congestion. Performance of our proposed scheme is given in this paper where we can see that how capacity and congestion of wireless network are correlated to provide a reliable wireless system.**

Keywords— Opportunistic system, congestion, system capacity, interference, intelligent resource reallocation.

I. INTRODUCTION

Complex wireless technology is today's demand for high traffic in communication channel [1], [2]. There are different ways of resource allocation to provide better reliable network coverage to serve user's demand. In existing technology capacity of a particular communication channel is predefined that is fixed. For this predefined channel capacity user per channel is also fixed. This channel condition makes the system performance poor. System performance poor means low signal strength, high signal-to- noise plus interference ratio (SNIR), high congestion, low throughput, low quality of service for user [3]. These problems origins from different part of the system design considerations such as power control scheme, frequency allocation scheme, and interference mitigation technique etc [4]. All these problems can be reduced in a considerable limit by applying proper intelligent techniques. Cognitive or opportunistic radio system is a way where cognitive user can use dedicated channel in different way but not in the presence of dedicated user in that channel [5].

When interference is low, SNIR is high and hence increased system capacity [6]. Again when number of user is high in a system then interference may increase which in turn create possibility of reducing system capacity. Also when power control and frequency planning are not adequate in the system then it causes high interference effect [7]. Improper frequency allocations also make wastage of valuable resource. So, user suffers from congestion problem in busy areas. This congestion problem causes higher rate of call drops. To reduce call drop problem call admission control is required.

In this paper we focus on reducing congestion problem and also making system capacity dynamic of wireless network by applying intelligent resource reallocation (IRR) scheme where system capacity can be increased in some extent to support extra users according to existing user's resource utilization natures. New frequency allocation is proposed to make dynamic system capacity for both macrocell and femtocell wireless networks which is shown in Fig. 1. They are: (a) available frequency; dedicated frequency use and opportunistic frequency use (left portion of Fig. 1), and (b) reserved frequency; macrocell frequency share and femtocell frequency share (right portion of Fig. 1). To make user equipment (UE) compatible with proposed opportunistic system as shown in Fig. 2(a), existing UE should have extra mode sensing and switching mechanisms installed inside it. So, user equipments (UEs) for both macrocell and femtocell are proposed to be reconfigurable capability such as to use the above mentioned proposed frequency allocation schemes as: full mode resource utilization and reserve mode resource utilization states, respectively as shown in Fig. 2(b) [8]. Some other measurable parameters such as user's mobility/speed threshold, signal strength threshold, and decision threshold are also considered for our analysis. Here, the author's contribution is in the proposed IRR scheme, where system supports extra opportunistic user in a dedicated channel which is not fully occupied by its dedicated users at the same time seamlessly. Rest of this paper is organized as follows: section II provides our proposed opportunistic system approach; system modeling is given in section III, section IV presents the numerical results, and finally conclusions are drawn in the last section.

II. PROPOSED OPPORTUNISTIC SYSTEM APPROACH

A. Opportunity Creation in Proposed IRR Scheme

Proper resource utilization should be guaranteed in order to confirm reliable wireless communication with low cost by providing different intelligent ways which is termed as opportunity creation. Here, we provide intelligent resource reallocation (IRR) scheme which is an opportunity creative

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

scheme by which overall system capacity of advanced heterogeneous wireless network can be increased along with reduced congestion problem. Congestion problem occurs when available system resource is smaller than demanded by users. For instance, let us consider a wireless system where macrocell and femtocell coexists to form advanced wireless network as shown in Fig. 3. From Fig. 3 we can see that, a channel k is allocated to j dedicated user group (UG_{dj}) where $j = 1, 2, \ldots, J$ and $l < J$ in different time slot number, N_{ts} uniformly without prior knowledge about user's actual resource demand as shown in Fig. 2(a) or actual required resource utilization as shown in Fig. 2(b). Now resource utilization occurs by different users according to their type of activities and in this case activities are not same for all users which mean different activities for each user. For this reason with existing fixed resource allocation scheme capacity of wireless network is fixed as shown in Fig. 3. With this fixed capacity of existing system users experiences more congestion problem as shown in Fig. 4, along with high rate of call drop, increased intra- and/or inter-system handover problem. To avoid these problems we proposed IRR scheme among heterogeneous system for users by considering different preliminaries and measurement of different system parameters as shown in Fig. 5.

B. *Capacity Enhancement and Congestion Reduction*

The capacity of a wireless system should be adequate to support extra users without overloading channel, increasing interference level, and higher call drop problems. Call drop rate increases with high rate of user's resource utilization in a fixed or limited capacity wireless system and also which causes high congestion problem. Fig. 6 depicts an intelligent way of resource reallocation technique to make a system with limited capacity into a dynamic capacity. Figure 6 shows that how the capacity of a particular channel in advanced macro integrated femtocellular or heterogeneous wireless network changes from fixed capacity to variable capacity according to user's activity such as actual resource demand and utilization. The natures of activities of different users are different located at the same geographic region that is under the same (only femtocell or macrocell nework) or different network (heterogeneous network) which is serving them. We can also see that each channel is reallocated at different time slots and different hypothesis are allocated for each utilization time slot for UG_{dj} such as hypotheses $H_{01,k}$ is given to first time slot (UG_{d1}), fourth time slot (UG_{d4}) and last time slot (UG_{dJ}) user group over channel k and $k = 1, 2, \ldots, K$. The hypothesis $H_{01,k}$ is indicating that among these three dedicated users group each user's resource utilization state is up to lower threshold limit ($\gamma_{low,k}$). These lower limits is less than 50% of maximum capacity of serving channel k where we can easily create opportunity for new cognitive or opportunistic user groups (UG_{cj}) where $j = 1, 2, \ldots, J$ and $l < J$ at different time slots number, N_{ts} such as UG_{c1}, UG_{c4} and UG_{cJ}. Then UG_{d1}, UG_{d4}, and UG_{dJ} and UG_{c1}, UG_{c4}, and UG_{cJ} user groups get new hypothesis notation from system as hypothesis $H_{11,kNd}$ (fully utilized channel by UG_{dj}) and hypothesis $H_{00,kNc}$ (empty channel available for UG_{cj}),

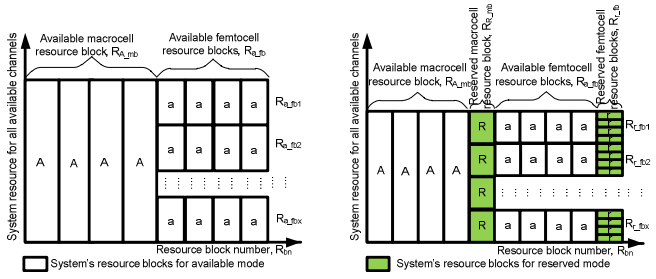

Figure 1. Allocated resource status in a channel for poposed IRR scheme in existing advanced heterogeneous wireless network.

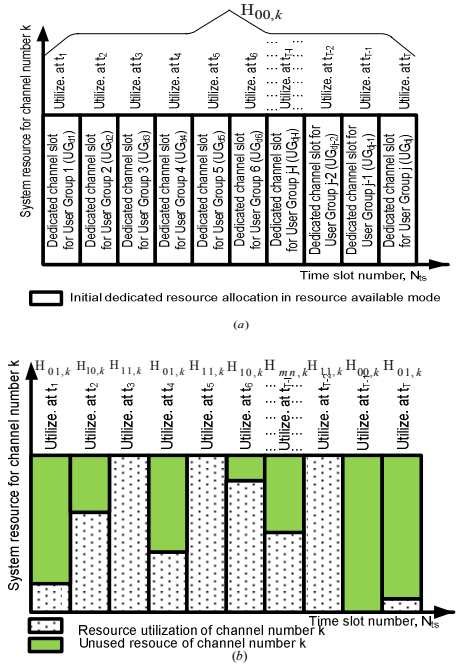

Figure 2. Allocated (a) resource status and (b) resource actual utilization status in a channel for existing advanced heterogeneous wireless network.

respectively. From hypothesis $H_{00,kNc}$, system can allow new opportunistic user to be served and hence capacity is increased. This process is done for each hypothesis except $H_{11,kN}$. Therefore, by comparing between two types of capacity such as without IRR that is fixed system capacity and with IRR that is dynamic system capacity, it is obvious that with proposed IRR scheme the dynamic system capacity serves more users than existing system having fixed capacity. The white area with dashed circle of different femto access points (FAPs) of later scenario indicates resource scarcity. With resource scarcity the new users can not be connected to the system and hence causes call drops, low signal quality and congestion problem for the existing system. With proposed IRR scheme the former scenario shows less congestion for the same number of users causing high user satisfaction in existing system. Resource is reallocated by the system in such a way that each connected users (FAPs with dotted white colored coverage area as shown in Fig. 7) can be served properly and unutilized resources are harvested to reallocate

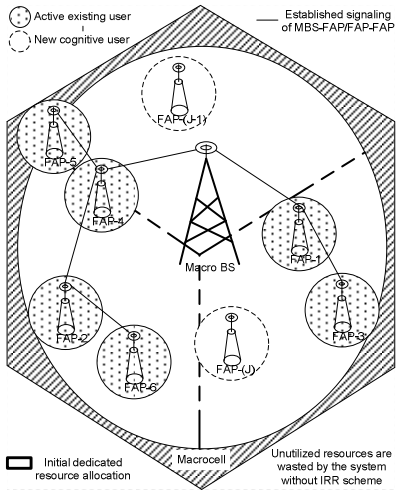

Figure 3. Scenario of capacity problem in existing advanced heterogeneous wireless network.

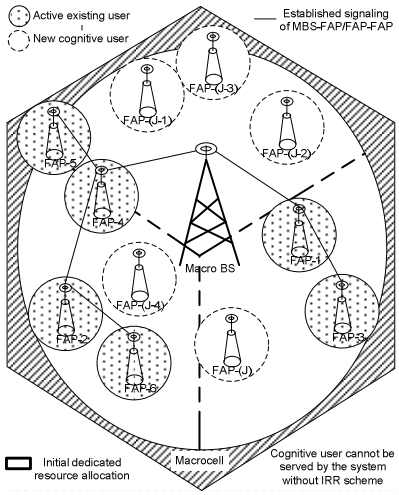

Figure 4. Scenario of congestion in existing advanced heterogeneous wireless network.

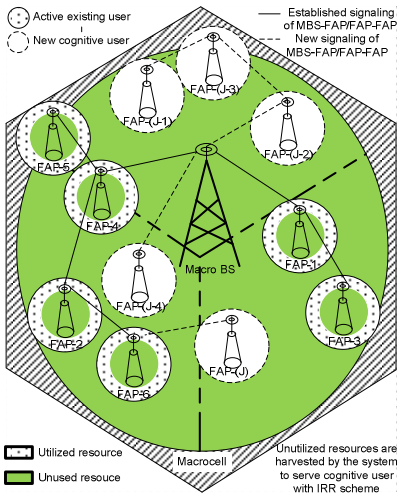

Figure 5. Scenario of resource utilization with IRR scheme in existing advanced heterogeneous wireless network.

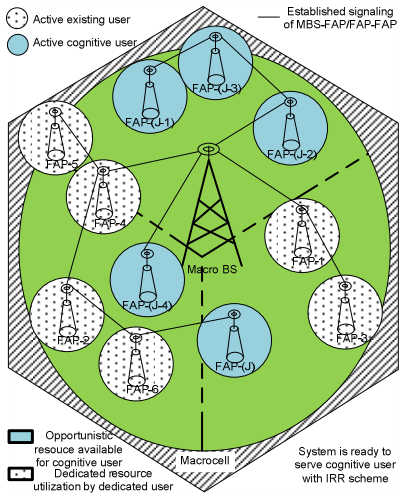

Figure 7. Scenario of IRR scheme with dynamic capacity and reduced congestion in existing advanced heterogeneous wireless network.

them to new users (FAPs with light blue colored coverage area as shown in Fig. 7). As in the network, rate of association of new users increases in a particular area causes congestion problem so, as reverse process (rate of existing user leaving the network) reduces this problem. But there is a predefined minimum resource allotment is required to allow a new user in a network which put limits to minimization of congestion. Therefore, proposed IRR scheme outperforms over existing scheme in minimizing congestion in the advanced heterogeneous wireless network. In proposed IRR scheme, when capacity increases for a certain user groups (causing congestion for existing system), causes less congestion as shown in Fig. 7 problem by opportunity creation by the system itself in an intelligent way.

III. System Modeling

In this section we provide a model of our system with k number of channels. Advanced wireless network system having macro integrated femtocellular that is heterogeneous network is modeled here and details are given in the following:

A. Hypothesis for Opportunistic System Approach

We consider four binary hypotheses to provide coordination among different allocated channels and its user's. These hypotheses are:

$$\mathrm{H}_{00,k} = (\text{"}Full\ Empty\text{"}) = Full\ Opportunity\ (FO)$$

$$\mathrm{H}_{01,k} = (\text{"}Partial\ Occupied\text{"}) = High\ Partial\ Opportunity\ (HPO)$$

$$\mathrm{H}_{10,k} = (\text{"}Partial\ Empty\text{"}) = Less\ \ Partial\ Opportunity\ (LPO)$$

$$\mathrm{H}_{11,k} = (\text{"}Full\ Occupied\text{"}) = No\ Opportunity\ (NO)$$

where 0 (channel utilization absent) and 1 (channel utilization present), respectively gives user channel utilization states over channel k and $k = 1, 2, \ldots, K$.

B. Some Decision Preliminaries

- System monitors environment continuously to identify load flow.
- If system finds any user doing real time activity then system gives this user highest priority of reliability that is not to interrupt.
- If system finds any user doing non real time activity then system gives this user lowest priority of reliability that is tries to interrupt.
- If system manages to create opportunity for new users then reallocation of resources occurs.
- System gives access to new user to avoid congestion by taking proper measurements of user's mobility, required resource demand, resource utilization type, and duration of activity etc.

C. Necessary Mathematical Relations

Decision probability of providing proper hypothesis to a channel during channel resource reallocation is

$$\Pr(\mathrm{H}_{mn,k}) = \frac{1}{4k}\Delta_k \tag{1}$$

where $\Pr(\mathrm{H}_{mn,k})$ is probability of providing proper hypothesis to a channel with subscript notation m (where $m = 0\ or\ 1$) and n (where $n = 0\ or\ 1$), and Δ_k is decision threshold over channel k and $k = 1, 2, \ldots, K$.

Channel resource utilization threshold is

$$Z_{u_j,k} = \begin{cases} \gamma_{0,k}(H_{00,k}) \\ \gamma_{low,k}(H_{01,k}) \\ \gamma_{up,k}(H_{10,k}) \\ \gamma_{max,k}(H_{11,k}) \end{cases} \quad \text{for user u_j, whwre j=1,2,} \ldots \text{,J} \tag{2}$$

where $Z_{u_j,k}$ is channel utilization threshold for user u_j, $j = 1, 2, \ldots, \mathrm{J}$ of channel k and $k = 1, 2, \ldots, K$.

Actual utilized channel capacity is

$$C_{Z,k} = \sum_{k=1}^{K} C_k Z_{u_j,k} \tag{3}$$

where $C_k = W_k \log_2(1 + SNIR_k)$ is actual capacity with channel bandwidth W_k and signal-to-noise plus interference ratio $SNIR_k$ of channel k and $k = 1, 2, \ldots, K$.

Opportunistic utilizable channel capacity is

$$C_{O_Z,k} = \sum_{k=1}^{K} C_k \Pr(\mathrm{H}_{mn,k})(1 - Z_{u_j,k}) = \frac{1}{4k}\sum_{k=1}^{K} C_k \Delta_k (1 - Z_{u_j,k}) \tag{4}$$

where $1 - Z_{u_j,k}$ is channel opportunistic utilizable spaces for user u_j, $j = 1, 2, \ldots, \mathrm{J}$ of channel k and $k = 1, 2, \ldots, K$.

User's satisfaction in resource utilization is

$$S_{u_j,k} = \begin{cases} \sum_{k=1}^{K} s_k Z_{u_j,k}, & \text{for static capacity system} \\ \sum_{k=1}^{K} s_k Z_{u_j,k} + \frac{1}{4k}\sum_{k=1}^{K} s_k \Delta_k (1 - Z_{u_j,k}), & \text{for dynamic capacity system} \end{cases} \quad \text{where } s_k = \begin{cases} 0 \\ 1 \end{cases} \tag{5}$$

where $S_{u_j,k}$ is total user's satisfaction of satisfied user, and s_k is user's level of satisfaction (0 for no satisfaction and 1 for satisfied) per channel for total user u_j, $j = 1, 2, \ldots, \mathrm{J}$ of channel k and $k = 1, 2, \ldots, K$.

Total revenue gain of operator is

$$R_k = \sum_{r=1}^{k} r_{v,k}\left(\sum_{k=1}^{K} C_k (Z_{u_j,k}) + \frac{1}{4k}\sum_{k=1}^{K} C_k \Delta_k (1 - Z_{u_j,k})\right) + r_{f,k} \tag{6}$$

where R_k is revenue earning of operator, r_{vk} rate of variable cost, and r_{fk} rate of fixed cost for contribution of user u_j, $j = 1, 2, \ldots, \mathrm{J}$ of channel k and $k = 1, 2, \ldots, K$.

D. Some Basic Observations of System

- Is it healthy (without any abnormality) system or not?
- Is it fully occupied or not?
- Is there any unused resource exists or not?
- Is there any user that demanding more or less overhead than system can provide or not (near/far-location effect)?

- Is there any user that is only connected without doing any significant activity for a long/predefined/any specified time or not?
- Is there any user that needs to use the system urgently with low/high mobility or not?
- Is there any user that is leaving the system urgently with low/high mobility or not?
- Is congestion exists or not?
- Is congestion exists due to non availability of resources or not?
- Is congestion exists due to uncontrolled traffic flow in a busy area/hot spot or not?
- Is the quality of signal adequate or not?
- Is the rate of user movement inwards or outwards of the system high/low creates congestion or not?
- Is call drop rate is high/low due to congestion or not?
- Is there any unused resource which is already allocated or not?

Finally, system search for unused resources and reallocate it again to enhance overall wireless system capacity as shown in Fig. 7.

IV. NUMERICAL RESULT

Let us, consider a system as shown in Fig. 3 where number of serving channel is k with $k = 1, 2, \ldots, K$.

A. Table and Algorithm

1) Data table for analysis: The conditional values used in the analyses are given in the following table. Different threshold values are also given in the table.

TABLE I. CONDITIONAL VALUES USED IN ANALYSES

Sl. No.	Criteria Details		
	Description	***Lower limit***	***Upper limit***
1	Full opportunity[a], $H_{00,k}$	0.76	1.00
2	High partial opportunity[a], $H_{01,k}$	0.51	0.75
3	Less partial opportunity[a], $H_{10,k}$	0.26	0.50
4	No opportunity[a], $H_{11,k}$	0.00	0.25
5	Number of femto user per FAP, u_j_f	0	5
6	Number of existing FAP, n_{fap}	1	100
7	Number of extra FAP, n_{fape}	1	20
8	Number of existing macro user, u_j_m	0	1000
9	Number of extra macro user, u_j_{me}	0	400
10	Number of channel, k	1	10
11	Decision threshold, Δ_k	0	1
12	Channel utilization threshold, $Z_{u_j,k}$	0.00	0.95

a. Hypothesis selection criteria. (For IRR scheme)

2) Algorithm for hypothesis selection: To select and reshedule the resources, proper hypotheses selection for each channel is required and is given as follows.

a) Step 1: After system power is on, system initialization and basic system parameters reading process is done.

b) Step 2: Check network environment to get information about user, network, and available resouce allocation, utilization, and management.

c) Step 3: Acoording to step 2 select proper frequency selection schem and power control scheme.

d) Step 4: System continuously monitors the network and user's activity to control traffic.

e) Step 5: At initial stage that is when full opportunity is avalable $(\gamma_{0,k})$ for all users then system selects hypothesis $H_{00,k}$ as shown in Fig. 2(a) for channel k and $k = 1, 2, \ldots, K$.

f) Step 6: When user's activity increses in each channel and in a particular channel resource allocation is utilized upto lower threshold limit $(\gamma_{low,k})$ of that channel by the user's of that particular channel then system selects hypothesis $H_{01,k}$ as shown in Fig. 2(b) for channel k and $k = 1, 2, \ldots, K$.

g) Step 7: Again user's activity increses in each channel and in a particular channel resource allocation is utilized upto upper threshold limit $(\gamma_{up,k})$ of that channel by the user's of that particular channel then system selects hypothesis $H_{10,k}$ as shown in Fig. 2(b) for channel k and $k = 1, 2, \ldots, K$.

h) Step 8: Now user's activity increses in each channel and in a particular channel resource allocation is fully utilized up to maximum limit $(\gamma_{\max,k})$ of that channel by the user's of that particular channel then system selects hypothesis $H_{11,k}$ as shown in Fig. 2(b) for channel k and $k = 1, 2, \ldots, K$.

i) Step 9: While system doing this each time, system conditions changes and step 5 to step 8 is repeated according to users activity as shown in Fig. 6. Thus, the capacity of the system changes from static to dynamic to a certain extent according to different criteria.

B. User satisfaction performance comparison

Figure 8 shows that, the capacity of a particular channel in advanced macro integrated femtocellular or heterogeneous wireless network provides better user's satisfaction. For existing system the capacity is static so number of user for a specific channel number k is fixed though that channel is not fully utilized by all the users all the time. For this reason at busy time extra user causes congestion problem. Mean while if that extra user can be served with reserved resource as shown in Fig. 1 (right portion) which is proposed in IRR scheme for the system, then user would suffer less congestion problem which ensures higher user's satisfaction.

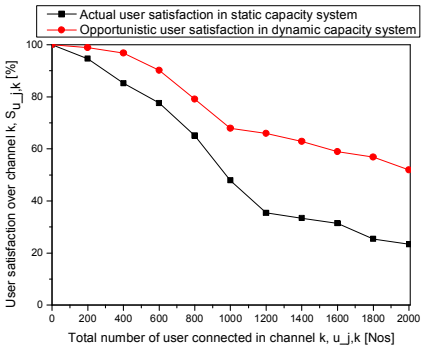

Figure 8. Performance evaluation for user satisfaction versus total number of user connected in both static and dynamic capacity system.

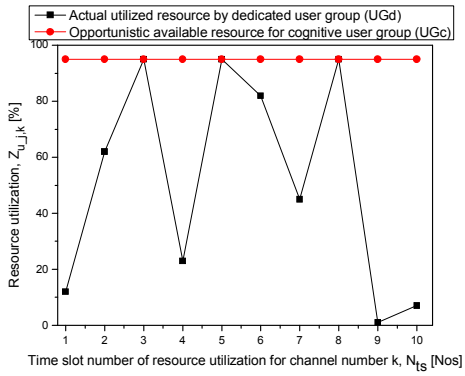

Figure 9. Performance evaluation for resource utilization versus time slot number of resource utilization for channel number k for both static and dynamic capacity system.

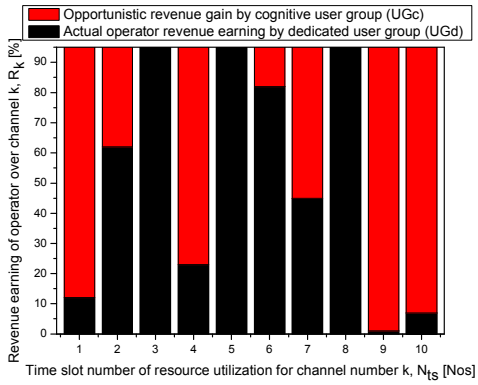

Figure 10. Performance evaluation for revenue earning of operator versus time slot number of resource utilization for channel number k for both static and dynamic capacity system.

C. *Resource utilization and revenue earning of operator performance comparison*

Figure 9 depicts efficient resource utilization for the system with less congestion with proposed IRR scheme than typical fixed resource allocation scheme. When there is less actual resource utilization in existing system then higher the opportunistic resource utilization exists in IRR scheme. We can see from Fig. 9 that for a specific channel number k when user's resource utilization is high, then low possibility of opportunity to reallocate the resource to extra users of that particular channel.

Figure 10 shows a revenue gain of operator when efficient resource utilization occurs for the system with less congestion with proposed IRR scheme than typical fixed resource allocation scheme. When there is less actual resource utilization in existing system then higher the opportunistic resource utilization exists in IRR scheme which in turn provides revenue gain opportunity to system operator. Here, when resource utilization for a specific channel number k is higher then number of user for that channel k is high and hence higher the revenue gain for system operator.

V. CONCLUSIONS

Advanced wireless network is a demanding issue for reliable and high speed communication with low power consumption, and user friendly service. For this reason user satisfaction level need to be consider as an evaluation parameter in both systems that is with existing fixed capacity and with proposed IRR scheme dynamic capacity. The user satisfaction level outperformed in proposed IRR scheme utilized system than existing typical system with increased number of users as shown in performance curve. In near future traffic will increase exponentially more than today so, channel capacity requirement would be higher than today's system. To do so with limited resources best utilization of resource is required. Along with capacity problem, dense traffic in communication channel causes significant congestion. To reduce these capacity and congestion problems together, proposed IRR scheme is a strong candidate to face the challenges associated. Performance of existing fixed capacity system in resource utilization and revenue earning of operator is poor than proposed IRR scheme performance as shown in evaluation line and bar graphs, respectively. Thus, proposed IRR scheme is promising one.

Abstract— **An important parameter in integrated optical device is the propagation loss of the waveguide. Its characterization gives the information of the fabrication quality as well as the information of other passive devices on the chip as it is the basic building block of the passive devices. Although, over the last three decades many methods have been developed, there is not a single standard present yet. This paper presents a comparative analysis of the methods existing from the past as well as methods developed very recently in order to provide a complete picture of the pros and cons of different types of methods and from this comparison the best method is suggested according to the authors opinion. To support the claim, apart from the analytical comparison, this paper also presents a comparison performed with the experimental results between the suggested best method which is recently proposed by Massachusetts Institute of Technology (MIT) researchers based on undercoupled all-pass microring structure and the popular cut-back method.**

Keywords— Integrated optics, Si photonics, waveguide propagation loss, microring reseonator.

I. INTRODUCTION

The most important feature that has made 'Silicon' the ideal and best candidate for next generation of interconnection network on chip requiring large bandwidth is the fact that it is compatible with complementary metal-oxide-semiconductor (CMOS) technology. This property has made it possible to fabricate optoelectronic chip monolithically in a cost-effective way using Silicon-on-insulator (SOI) platform [1].

A natural planar optical waveguide with a refractive index of about 3.5 for Si core and 1.46 for SiO_2 cladding at 1550 nm is provided by SOI structure. Very strong optical confinement in waveguide is possible using this high refractive index difference. This structure also allows to make waveguides with small bend radii and makes silicon the best choice for making the important photonic devices like microring having very low bend radius. Moreover this fact enables to reduce the footprint of the devices and increase the density of the integration [2].An important parameter in integrated silicon photonic devices is the propagation loss of waveguide. So to ascertain the suitability of the silicon waveguides for specific application, it is very essential to characterize the loss properly. Most of the propagation losses in Si nanowire arise mainly due to the sidewall roughness and this roughness is a result of the fabrication process, more specifically lithography and etch process [3]. Typical Roughness value is of the order of 2 nm (having a correlation length of ~40nm), which is a large value for a Si waveguide width of submicron order. So, this high roughness results to a high propagation loss of the order of 2 dB/cm [4].

Also, we know that the quality of all the passive element can be specified by knowing the quality of the silicon waveguide as it is the fundamental building block of a silicon photonic circuit. So, characterizing the waveguide loss not only help us to know the quality of the waveguide in terms of fabrication accuracy but also gives us a hint about the quality of the other passive device on the silicon chip.

There is not a single standard yet for measurement of the waveguide loss [4]. Many methods have been developed over the last three decades for measuring the loss accurately. In this paper the common loss characterization methods which are generally used will be described and their pros and cons will be presented. Also the methods, which researchers have proposed recently will be compared with the existing commonly used methods. From this comparison a conclusion will be drawn to suggest the best method according to the authors opinion. To support the claim, the suggested best method which has been reported in 2013 by the Massachusetts Institute of Technology (MIT) researchers [4] will be explained in a greater detail with some simulation results and its superiority will be assessed experimentally by comparing with an existing popular method.

II. DESCRIPTION OF DIFFERENT TYPES OF LOSS CHARACTERIZATION METHODS

A. Commonly used methods

The methods which are commonly used to measure the waveguide loss can be categorized into four types.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

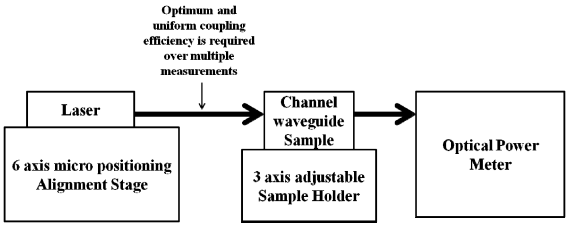

Figure 1. The measurement setup for cut-back method

These are: (i) the cut-back or paper-clip method; (ii) the Fabry-Perot resonance method; (iii) scattered light measurement method and (iv) Sliding prism method [5]. These methods are described briefly in the following subsections.

(i) Cut-back or paper-clip method

This method is based on a very simple concept. A channel waveguide sample of length l_1 is excited by a laser and then output power from the waveguide P_1 is measured. The same procedure is followed for another length l_2 and output power P_2 is measured. Therefore, we can write

$$\frac{P_1}{P_2} = exp^{-\alpha(l_1 - l_2)} \quad (1)$$

Here waveguide propagation loss (α) is in cm^{-1}. Hence, α in dB/cm

$$\alpha = 10\, log_{10}\left(\frac{1}{l_1 - l_2} ln(\frac{P_1}{P_2})\right) \quad (2)$$

However, it is not easy to make waveguides of different lengths maintaining the same quality. So, in order to change the length of the waveguide it is cut after each measurement. After cleaving the waveguide sample the edge of the waveguide facet is polished. A series of measurements are done following this procedure with different sample lengths. The output power is measured by using a optical power meter [5], [6]. The measurement setup is schematically shown in the fig. 1.

In spite of the fact that this method is very fast and simple, the accuracy of this method is poor. Because it is difficult to maintain uniform facet quality and coupling efficiency during every measurement after cutting the waveguide.

(ii) Fabry-Perot (FP) resonance method

This method is based on the concept that a waveguide can be thought of a Fabry-Perot cavity where the two facets can act as mirrors. So, the Fabry-Perot resonances can be used to measure the propagation loss [5].

The waveguide propagation loss α can be written as,

$$\alpha = -\frac{1}{L} ln\left(\frac{1}{R}\frac{\sqrt{I_{max}/I_{min}} - 1}{\sqrt{I_{max}/I_{min}} + 1}\right) \quad (3)$$

where R is the reflectivity of the facet and L is the sample length, I_{max} and I_{min} denotes the maximum and minimum transmission intensity respectively [7].

This method is more accurate than cutback method as it is more repeatable [5] and is independent of the requirement of the input coupling knowledge. But here another problem arises which is the requirement of facet reflectivity estimation and the accuracy of this method mostly depends on the knowledge of facet reflectivity [7]. Moreover, it is necessary to use a stabilized light source to maintain constant input power over Fabry-Perot fringes measurement and a source having narrow line-width.

It has been shown in [8] that, the requirement of the knowledge of facet reflectivity can be eliminated by measuring the transmission and reflection both from FP cavity. But in that case the power from the input facet need to be measured very precisely and carefully. Moreover, both from the input and output sides, similar coupling efficiencies are needed. These requirements are very complex to accomplish in the experimental setup.

So, the problem with the FP resonance method is that the experimental procedure is quite complex here.

(iii) Scattered light measurement method

This method is based on the concept that the scattered light can be measured from the top of the surface along the waveguide length in order to measure the loss [9]. It is assumed in this method that the amount of scattered light will increase with the increase of the propagated light inside the waveguide. An optical fiber can be scanned along the waveguide length in order to collect the light [5]. Though this method is independent of input coupling losses, it can be easily understood that the accuracy of this method is limited by the wafer surface quality [7].

(iv) Sliding prism method

The propagation loss can be measured by using the sliding prism method. This is also a widely used method. This method is based on the concept of measuring the guided power at varying distance from the input coupling region through the use of sliding prism placed at right-angle and thus measuring the propagation loss [10].

An experimental setup for this method is shown in fig. 2 [5]. The slab waveguide sample must be clamped very tightly under the prism. In order to couple the prism with the modes of the waveguide, either the guided mode or the substrate mode, the contact between the prism and the waveguide must be very good. Also dirt free prism must be needed [5].

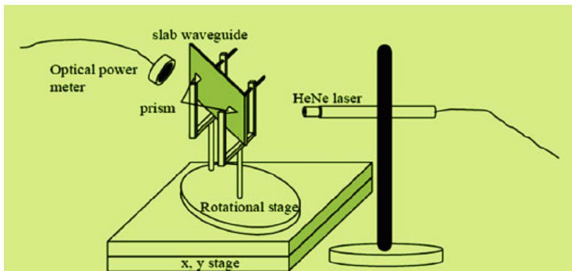

Figure 2. The measurement setup for sliding prism method [5]

The problem with this method is that the requirement of complex mechanical arrangement makes the experimental procedure difficult.

B. *Recently developed methods*

(i) Modified FP method

In conventional FP method, in order to fulfill the necessity of narrow linewidth source, external cavity tunable lasers are used. But it is not easy to stabilize it when wide wavelength region is needed. Moreover this kind of light source is also expensive. So broadband low-coherence source, which has low cost, is desirable.

It has also several other advantages over high coherence tunable lasers such as more stability in comparison to the tunable lasers and it is less prone to reflections. Also it is possible to measure over multiple wavelengths in one single measurement in contrast to the tunable laser [7].

But the issue with the broadband source such as superluminescent diode is, with the change in wavelength the input power also changes which made it difficult for the broadband source to be used in FP method. In [7], Sareh tabi *et al*. proposed a modification in conventional FP method, where they suggest a way of curve fitting in order to solve the issue of power change in broadband light source. So, in this modified method the experimental procedure has been simplified due to the use of broadband superluminescent diode.

This method also suggests a way in order to solve the reflectivity measurement issue, since for accurate measurement, the knowledge of the reflectivity is needed. They have rewritten the equation (3) as

$$-\alpha L = ln\left(\frac{1}{R}\right) + ln\left(\frac{\sqrt{I_{max}/I_{min}} - 1}{\sqrt{I_{max}/I_{min}} + 1}\right) \quad (4)$$

After that, measurement for different length waveguides are done and the value of $ln\left(\frac{\sqrt{I_{max}/I_{min}}-1}{\sqrt{I_{max}/I_{min}}+1}\right)$ is plotted with respect to length L. From this plot, the loss and the reflectivity both can be measured without assuming either of the two. Loss (α) can be found from the slope of the curve and reflectivity (R) can be measured from the intercept.

This method was proposed in 2008. Although this method is not very recent, in comparison to the other methods, proposed long ago, it can be considered as a recent method.

To summarize, this method uses curve fitting approach to solve the power consumption issue in broadband low-coherence source and eliminates the requirement of the narrow linewidth source which is very difficult to stabilize. Also, the reflectivity measurement issue is solved by taking measurement from different length waveguides. So, by solving the problems of conventional FP method, this modified FP method provides very accurate results.

(ii) Method based on undercoupled All-Pass microring structure

This is a very simple method proposed by the Massachusetts Institute of Technology (MIT) researchers in 2013 [4], which can measure the loss very accurately using simple undercoupled microring structure. The loss is measured here by way of fitting the experimental spectrum with the simulated curve generated from the developed all-pass model. The concept of this method is based on the interplay between standing wave modes and traveling ring modes which arise due to back-reflection from edge roughness.

In this method a number of microrings are coupled with a common bus waveguide with different bus to ring gap. All of the rings have radius around 10 micrometer and the radius is varied very slightly in order to have different free spectral ranges. Fig. 3 shows the schematic diagram of the structure.

In fig. 4 the five resonances corresponding to the five rings are shown. It can be seen that the first three rings which do not show any splitting in the resonances represent the overcoupled condition whereas the last two rings showing clear splitting represent undercoupled condition. The microring quality factor degrades very largely in undercoupled condition which results in a splitting in the resonance. This is because the waveguide loss effect is dominant here over the low bus to ring coupling amount. Thus, the effect of loss is very clear and explicit here. So, the ideal condition for precisely measure the waveguide loss is undercoupled condition.

In the fig. 5 the effect of loss change on the overcoupled and undercoupled resonances have been shown and it can be seen that, in the undercoupled spectrum responses are highly sensitive to α as the depth of the split resonances changes very fast with the increase of the loss.

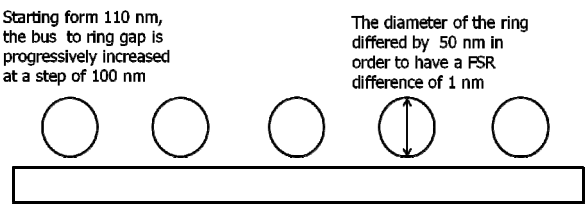

Figure 3. The schematic diagram of the all-pass architecture used in this method

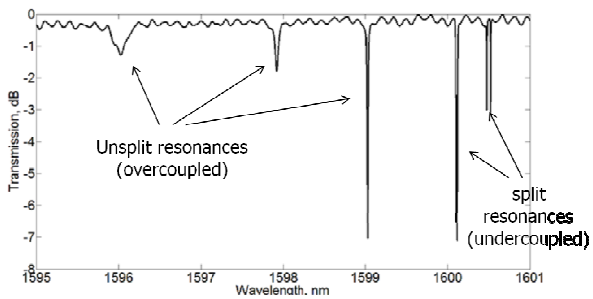

Figure 4. The spectral scan showing the five resonances for the rings having different bus to ring gap.

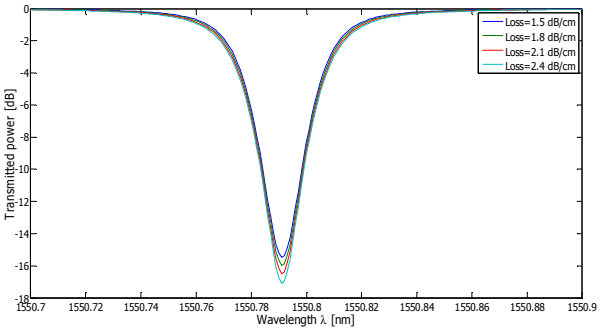
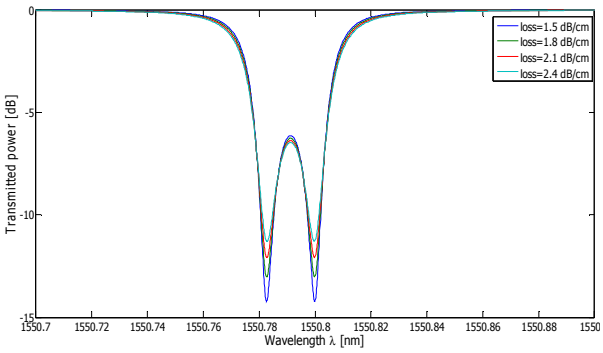
But, the change of loss does not have a significant effect on the response in overcoupled condition. It has been seen from the simulation results that the more we moves toward the under (over) coupled regime the more (less) sensitive the response becomes with respect to loss.

So, by way of curve fitting, this model propose to measure the waveguide propagation loss in undercoupled condition in order to see the effect of loss more clearly, thus measuring the propagation loss more accurately. Also this model is better from those models which measures the loss by assuming that critical coupling condition is met [11], because spotting the critical coupling condition is extremely difficult and it is highly intolerant [4].

Also, from the model developed it is found that in the undercoupled condition, if the reflection coefficient i.e. the amount of reflected light due to the backscattering increases the separation between the spitted peaks increases as shown in fig.6. This is because, this model considers that each scattering point leads to a backward reflection which is again reflected by the same scattering point after a round trip and thus forms a standing wave. This standing wave interacts with the radiation unaffected by scattering. In summary, the standing wave formation which is due to the intercavity scattering of light is a scenario similar to Fabry Perot (FP) cavity and the propagation of the light radiation which is unaffected by scattering is a scenario similar to travelling wave cavity. The competition between these two cavities determines the presence of the usual transmission dip [4].



(a)



(b)

Figure 5. Effect of loss change in (a) overcoupled and (b) undercoupled condition

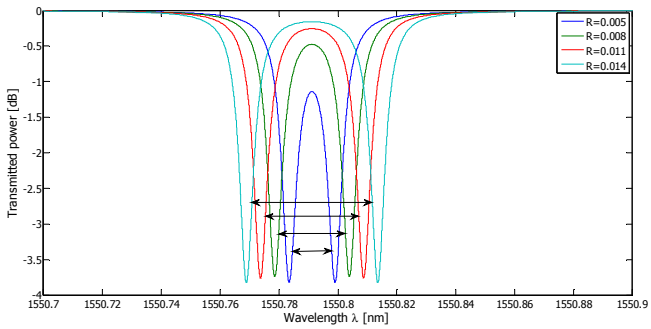


Figure 6. Effect of Reflection coefficient (R) change in undercoupled condition

So, considering all these effects, the simulated spectrum is fitted with the experimental spectrum by changing the value of loss, reflection coefficient and coupling coefficient and finally it gives the value of loss.

The fitting method based on this model is very accurate as seen from a comparison with another model reported in [12] which also assumed the backscattering as the reason for splitting in the resonances. But that model which is based on the concept of double ring filter does not lead to very good fitting in comparison to this model which is based on the competition between FP and travelling wave cavity. Indeed it has been shown in [4], the average loss measured for a number of samples using fitting of this model is 1.7 dB/cm and using the fitting of that double ring based model is 1.1 dB/cm. So, the loss is underestimated.

In summary, the advantage of this method lies on the fact that it is independent of input coupling loss and reflection which leads to very accurate measurement of propagation loss.

III. COMPARATIVE ANALYSIS OF THE METHODS

The popular cut back method, although provides very simple and direct measurement of the loss, has very poor accuracy because of various reasons. Firstly, the quality of the facet changes each time after the cutting. Secondly, The measurements must be performed under optimum input coupling efficiency. Moreover, the coupling efficiency cannot be maintained exactly same for every measurement [13].

In the conventional FP method the requirement of the exact knowledge of facet reflectivity limits the accuracy. Also the need for using stabilized narrow line width sources makes the experimental procedure very difficult.

The sliding prism technique requires extracting light with 100% efficiency. Also, the mechanical arrangement is quite complicated here. A new method, which is a modification of conventional sliding prism technique based on sliding right angle-prism (RP), is proposed in [10] in order to make the operation convenient. This method uses a RP and non sliding isosceles prism (IP) together to get accurate result. But still the method is a bit complex in comparison to other characterization methods.

TABLE I. A COMPARISON OF THE LOSS CHARACTERIZATION METHODS

Comparison parameters	Cut back	Sliding prism	Scattered light measurement	FP resonance	Modified FP	All-pass undercoupled
Input coupling loss dependency	Yes	No	No	No	No	No
Experimental Procedure / Mechanical Arrangement	Simple	Complex	Simple	Complex	Simple	Very simple
Requirement of the estimation of facet reflectivity	No	No	No	Yes	Yes (solved through curve fitting)	No
Curve fitting	No	No	No	No	Yes	Yes
Curve fitting quality	N/A	N/A	N/A	N/A	Very good	Very good
Accuracy	Poor	Poor	Poor	Poor	Good	Good
Reason for the limited accuracy	Requirement of the same facet quality and coupling efficiency over multiple measurements	Requirement of 100% light extraction efficiency	Dependency on the wafer surface quality	Requirement of facet reflectivity knowledge and narrow linewidth stable source	N/A	N/A

The accuracy of the method based on the scattered light measurement depends very strongly on the wafer surface quality.

The modified FP method seems to be very accurate as this method provides the solution of the problems of conventional FP method and may be adopted very widely for loss characterization in future. The experimental procedure has been simplified through the use of curve fitting by using the low coherence broadband source instead of high coherence tunable lasers. This method also provides a way to measure both the reflectivity and loss together without the assumption of the either.

The method based on the undercoupled all-pass microring structure seems to be the best in terms of accuracy and experimental simplicity. This method is totally independent of the input coupling loss and has tolerance to the ring to bus gap choice. This method measures the loss in undercoupled condition where the effect of loss have dominant effect over the bus to ring coupling. So, the loss effect is very explicit here which makes it possible to accurately measure the loss. Moreover, The fitting method, which is based on the concept of the competition between FP cavity and travelling wave cavity, provides very good fitting in contrast to the other fitting model based on double ring cavity.

In table 1 a comparison of different types of methods is presented and it can be said that the best method in terms of simplicity and accuracy is the method based on undercoupled all-pass microring structure.

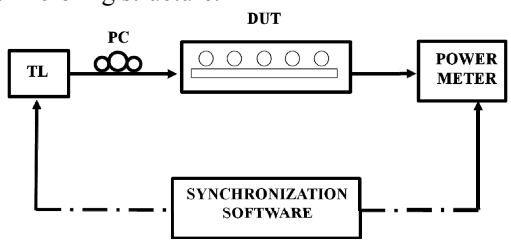

Figure 7. Experimental setup to measure the loss using the method based on all-pass structure

IV. EXPERIMENTAL COMPARISON OF COMMONLY USED 'CUT BACK METHOD' AND METHOD BASED ON 'ALL-PASS UNDERCOUPLED STRUCTURE'

The method based on all-pass undercoupled structure is used to experimentally measure the losses of ten samples. The experimental setup for spectrum measurement is shown in fig. 7. The light from a tunable laser (TL) is coupled into the device under test (DUT) through a polarization controller (PC) that maximizes the coupling efficiency between the fiber and the input grating coupler of the device under test. Then with a synchronized power meter the output spectrum is collected from the 'through' port grating coupler.

By way of fitting the undercoupled resonances taken from all the spectra with the simulated curve, the average loss has been measured as 2.14 dB/cm. The measured loss from the cutback PCM structure is 1.98 dB/cm. So, the loss in the cutback method is underestimated because of its limited accuracy.

V. CONCLUSION

As characterization of loss is an important step to know the quality of the fabrication process many loss measurements methods have been proposed over the last three decades. But still there is not a single standard for this loss characterization. This paper presents a comparative analysis of all types of loss characterization methods in order to provide a complete picture of the advantages and disadvantages of the methods. Widely used loss characterization methods from past are compared with two recently developed methods. From the comparison, the recent method based on undercoupled all-pass microring structure is suggested to be best in terms of simplicity and accuracy. To support this claim an experimental comparison between this method with the popular cut-back method is shown and it is found that the loss is underestimated in cut-back method due to its limited accuracy.

ACKNOWLEDGMENT

The authors would like to thank Scuola Superiore Sant'Anna, Pisa (SSSUP), Italy for providing the laboratory

facility for this work. The authors would also like to acknowledge the support of Institute of Microelectronics (IME), Singapore for the fabrication of PICs that have been used for the loss measurements.

Abstract—**In this paper, a new complementary triangular split ring resonator (CTSRR) is proposed and the impact of CTSRR on conventional patch antenna is investigated at 2.44 GHz for WLAN applications. The electromagnetic behavior of CTSRR, as well as their equivalent circuit is developed and explained. The demonstrated theoretical approaches result in a meaningful improvement than in comparison to conventional patch antenna. The parametric studies are completed in this work with the different orientation pattern of CTSRR structure. This is exposed that with the increment of CTSRR on patch, antenna performances improve, but resonance frequency shifts toward lower frequency region.**

Keywords—Complementary triangular split ring resonator (CTSRR), gain, directivity, microstrip patch antenna (MPA), wireless local area network (WLAN).

I. INTRODUCTION

During modern centuries, there is immense evolution in wireless local area network (WLAN) applications. Providing of a quality service for the recently increased demand in WLAN is a core level concern as usually for antenna and communication devices. The WLAN is used in our everyday life applications such as notebooks, mobile phones, routers etc. To meet the daily increasing needs, antennas used in WLAN applications are noteworthy factor. With respect to performance, a low cost feed network with miniaturization in size is also very important to carry out in terms of antenna design. Therefore, microstrip patch antenna (MPA) with compactness, low cost and ease of fabrication is effective for WLAN applications and these are widely presented in books and papers in the last decade [1-3].

The standard microstrip patch antenna has a very low gain, low efficiency, low power handling capacity, narrow bandwidth, simple, and inexpensive to manufacture using modern printed–circuit technology [1]. Many researchers have amended the parameters and modified geometry to produce better performance of the patch antenna considering required applications. These improvements cover several shapes of antennas, addition of special structures, and attachment of RF components or integrated circuits into the patch antenna [2].

Now a day's split ring resonator (SRR) is used to produce the desired magnetic response which influences the applied EM field. Several theoretical and experimental works have been studied by researchers on SRR and their potential applications [4-5].There are many types of split ring resonator design such as edge coupled SRR (EC-SRR) [6],broadside-couple SRR (BC-SRR) [7], nonbianisotropic SRR (NB-SRR) [8] and etc. However, there is a very few work on resonator based patch antenna with conventional substrates. Therefore, proper background understanding of resonator and possible impacts on conventional MPA are indispensable. In this work, a complementary triangular split ring resonator (CTSRR) has been proposed on conventional inset feed patch antenna and effect of the CTSRR on regular MPA has been analyzed from various viewing platform.

II. GEOMETRIC VIEW OF CTSRR

The geometric view of the single unit of complementary triangular split ring resonator is shown in Fig. 1.The outer and inner length of the CTSRR structure is L_{out}= 4.25mm and L_{in}= 3.25mm respectively. The dimension of the resonator gap W_s =0.98mm and the thickness of the triangle T_r =1mm. The distance between two TSRR is 0.66 mm and each dimension is similar to the single unit of CTSRR structure.

For a given resonance frequency (f_r), dielectric constant (ε_r), the design equations for calculating patch width (W) and length (L) of our conventional inset feed rectangular microstrip patch antenna (RMPA) are [9]

$$W=\frac{1}{2f_r\sqrt{\mu_0\varepsilon_0}}\sqrt{\frac{2}{\varepsilon_r+1}}=\frac{c}{2f_r}\sqrt{\frac{2}{\varepsilon_r+1}} \qquad (1)$$

Where, C = free space velocity of light, ε_r =Dielectric constant of substrate, f_r = Resonance Frequency. This width, W makes equal to about half a wavelength. It leads to good radiation efficiencies and acceptable dimensions.

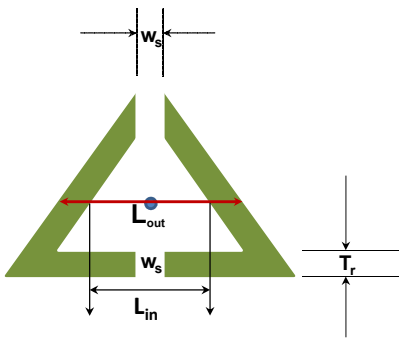

Figure 1. Top view of CTSRR Structure

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

In order to account for the fringing and the wave propagation in the line [10] an effective dielectric constant (ε_{reff}) must be obtained.

$$L_{eff} = \frac{c}{2f_r\sqrt{\varepsilon_{reff}}} \qquad (2)$$

$L_{eff} > L$ .Thus, the resonance condition is

$\beta^{(n)}L_{eff} = n.\frac{\pi}{2}, n = 1, 2, ...$ which depends on L_{eff} , not L.

The effective patch length

$$\frac{\Delta L}{h} = 0.412\frac{(\varepsilon_{erff} + 0.3)(\frac{W}{h} + 0.264)}{(\varepsilon_{erff} - 0.258)(\frac{W}{h} + 0.8)} \qquad (3)$$

Equation (3) shows that the extension of the length ΔL is a function of the ratio $\frac{W}{h}$ and ε_{erff} .

To calculate the effective length, it has been added the length *L* to the extension of the length ΔL.

$$L_{eff} = L + 2\Delta L \qquad (4)$$

The length and width of ground plane L_g and W_g are given as

$$L_g = 6h + L \qquad (5)$$

$$W_g = 6h + L \qquad (6)$$

Where h = substrate height

Substrate height *h* is chosen considering surface wave & spurious radiation minimization for a given dielectric constant such that

$$h \le \frac{c}{4f_r\sqrt{\varepsilon_r - 1}} \qquad (7)$$

After calculating all the data, optimized values (ε_r=2.2, substrate height *h*= 1.5 mm) for patch width and length are *W*= 49.4 mm and *L*= 40 mm. For impedance matching, edge impedance of 50 ohm has been used for all cases and simulation has been done by CST microwave studio.

III. Equivalent Circuit Model: CTSRR Geometry

In Fig. 2(a), the geometrical view of a CTSRR and other dimensions are indicated. The modified structure of CTSRR is newly designed with strip width *c* and spacing g_1 and g_2 between the divided parts of triangle. The equivalent circuit model of the TSRR is presented in Fig. 2(b), which behaves as a resonant cavity modeled by an *LC* circuit. The inductance is due to the gap between the two halves of CTSRR and the capacitance is due to the gaps in the rings itself. The divided pure copper part of triangle contributes a total inductance *L* and C_{g1}, C_{g2} are the gap capacitances due to the triangular splits within the upper and the bottom part respectively. Here, magnetic field H, perpendicular to the plane, allows the creation of gaps capacitance at the opening of the ring.

The electromagnetic properties of CTSRRs have been already analyzed in [11] and [12]. This analysis shows that CTSRRs behave as an *LC* resonator that can be excited by an external magnetic flux and exhibits a strong diamagnetism above their first resonance. CTSRRs also exhibit cross-polarization effects (magneto electric coupling) [12] so that excitation by a properly polarized time-varying external electric field is also possible. This resonant behavior is due to capacitive elements such as gaps and splits, and in turn results in very high positive and negative values of permeability close to f_0 .Therefore, the orientation of the TSRR structure with respect to an electric field may affect the strength of the resonance.

CTSRR can be mainly considered as a resonant magnetic dipole that can be excited by an axial magnetic field [11]. In a more rigorous analysis, the cross-polarization effects in the SRR [11], thus, this element will also exhibit a resonant magnetic polarizability along its y-axis (see Fig. 2 (a)) and, therefore, its main resonance can also be excited by an external magnetic field applied along this direction [13].These features do not affect the intrinsic circuit model of the elements, although they may affect its excitation model.

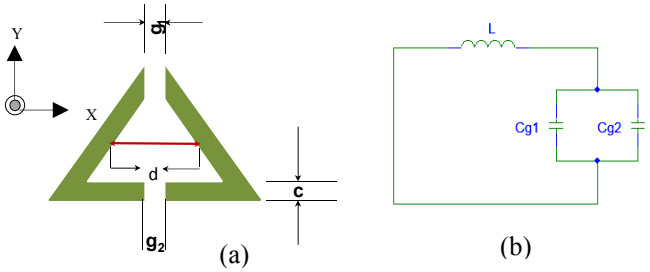

Figure 2. (a) Geometric view of CTSRR, (b) Equivalent circuit of CTSRR

IV. Antenna Design with Complementary Triangular SRR Design

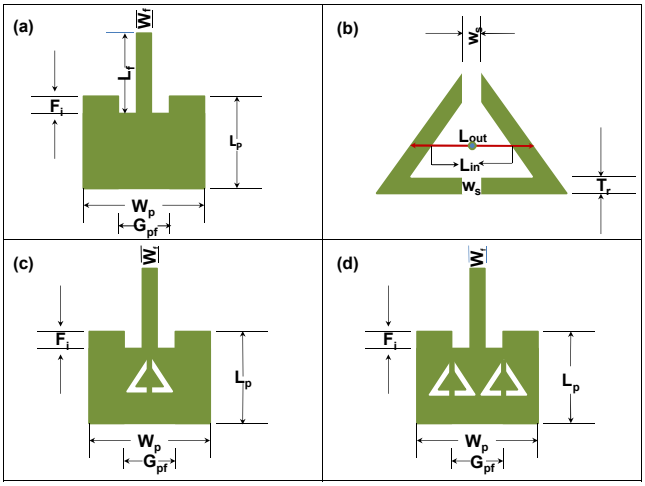

Figure 3. Schematic diagram of (a) Conventional patch antenna, (b) Top view of CTSRR, (c) Antenna with CTSRR, and (d) Antenna with dual CTSRR.

This design is simulated in CST Microwave Studio using a commercially available Roger RT/Duroid 5880 material as substrate with dielectric constant ε_r =2.2 and dielectric loss tangent δ=0.0002. The dimension of the substrate is 50 mm width x 51 mm length. The ground plane is printed in the back side of the substrate with same dimension. A 50Ω port is used to feed power into the radiator. The length of the inset feed (L_f) and the width of the feed line (W_f) for all antennas have been adjusted considering impedance matching. Fig.4 shows the geometrical top view of inset feed patch with different structures. The dimension parameters are shown in following TABLE I.

TABLE I. DIMENSION OF ANTENNA & PROPOSED CTSRR

Geometric Name	Symbol	Dimension (mm)
Resonator outer width	L_{out}	4.25
Resonator inner width	L_{in}	3.25
Thickness of TCR	T_r	1.00
Resonator gap	W_s	0.98
Patch length	L_p	40
Patch wide	W_p	49.4
Substrate length	L_s	52.7
Substrate wide	W_{sb}	50
Feed length	L_f	25.5
Feed wide	W_f	4.85
Slot or Gap of Feed line	G_{pf}	3.5
Substrate height	H	1.5

V. RESULT AND DISCUSSION

In this comparative study it has been studied on the analysis of CTSRR structure on patch antenna design, increment of the number of CTSRR on patch and various orientations of CTSRR structures. The key performance analysis results have been investigated.

The return loss (RL) is a ratio between reflected and transmitted waves at the input of an antenna. In the impedance matching network, better RL is desirable for lower insertion loss, surface wave loss, and spurious radiation loss. From TABLE II, we find that at resonance frequency (f_r), 2.400 GHz, RL of -30.835 dB is obtained for conventional patch antenna and -28.64 dB and -33.39 dB is achieved at f_r of 2.422 GHz and 2.440 GHz for CTSRR and DCTSRR respectively. The RL of patch antennas with various structures are described in Fig. 5. The f_r has been shifted because of fringing effect on MPA due to inclusion of CTSRR. Intersecting point of return loss at - 10 dB line of this design has been evaluated for bandwidth (BW) calculation and for all three antennas obtained BW is almost equal.

For WLAN antenna design the gain and directivity are some other important features need to consider achieving good signal strength for end point user. For conventional antenna gain and directivity of 7.72 dB and 8.09 dBi has been obtained, respectively. Here, proposed resonator structure contains split gaps in opposite ends which store charges and influences radiation pattern on *Z* direction. For 1 CTSRR, gain, and directivity of 7.85 dB, and 8.15 dBi and for 2 TSRR, 7.75 dB and 8.11 dBi has been obtained, individually.

TABLE II. SIMULATED PERFORMANCE OF THE CONVENTIONAL PATCH AND THE OPTIMIZATION DIMENSION OF PATCH ANTENNA

Antenna	Resonance Frequency (f_r) (GHz)	Return Loss(dB)	Gain (dB)	Directivity (dBi)
Normal	2.400	- 30.835	7.72	8.09
1 TSRR	2.422	- 28.864	7.85	8.15
2 TSRR	2.440	- 33.392	7.75	8.11

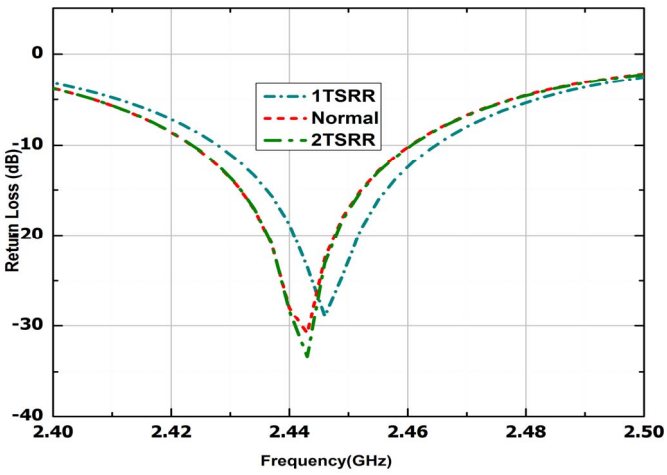

Figure 4. Return loss of normal patch antenna, TSRR & proposed DTSRR.

The radiation pattern is a graphical representation of the relative field strength transmitted from or received by the Antenna, Simply it can be said that the power radiated or received by the Antenna is the function of angular position and radial distribution from the Antenna. In Fig. 6 radiation pattern of the proposed Antenna is revealed. The directivity has been improved by 0.02dBi and radiation efficiency of antenna increase from 91.76% to 94.49%.

From above analysis, we found better RL, optimized gain and directivity for dual CTSRR. So orientation of CTSRR and increment of CTSRR unit cell on conventional patch antenna may have some influence. In this phase of optimization process, antenna performance has been measured with respect to unit cell orientation keeping internal distance equal for all case studies. Fig.7 shows the various orientation of resonant cut triangle of proposed antenna which has been denoted from A to J. All oriented dual CTSRR pattern perform on nearly same resonant frequency. The comparison of return loss among various orientationsis represented in TABLE III and IV. After extensive analysis of data and simulated results among ten oriented patterns from A to J, optimum performance has been obtained by pattern A with 7.75 dB gain and -33.391 dB of return loss while others are inferior than A. These intensive analyses prove that antenna performance also varies with orientation of recommended CTSRR.

TABLE III. THE RETURN LOSS OF PATCH ANTENNA FOR DIFFERENT DETSRR PATTERN A TO PATTERN E

TSRR Orientation	Resonant frequency, f_r (GHz)	Return loss (dB)	Gain (dB)	Directivity(dBi)
A	2.443	- 33.391	7.75	8.11
B	2.443	- 28.245	7.73	8.10
C	2.443	- 28.175	7.73	8.21
D	2.428	- 23.968	7.39	8.29
E	2.428	-24.727	7.40	8.16

TABLE IV. THE RETURN LOSS OF PATCH ANTENNA FOR DIFFERENT DETSRR PATTERN F TO PATTERN J

TSRR Orientation	Resonant frequency, f_r (GHz)	Return loss (dB)	Gain (dB)	Directivity(dBi)
F	2.428	- 25.449	7.39	8.16
G	2.428	- 24.790	7.41	8.25
H	2.434	- 32.747	7.56	8.27
I	2.437	- 31.636	7.57	8.29
J	2.434	-34.127	7.56	8.28

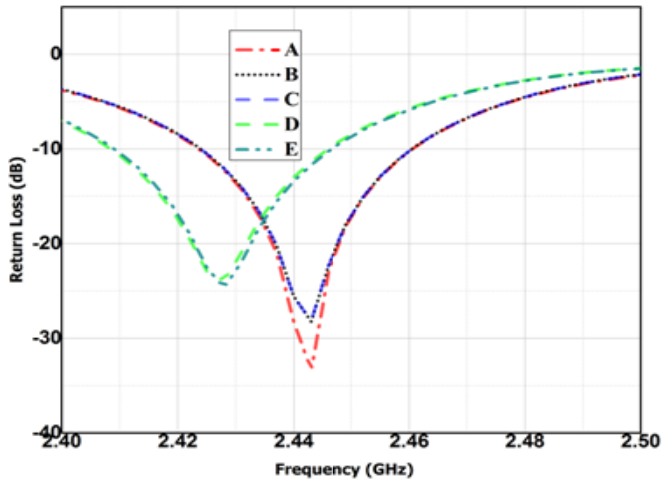

Figure 7. The return loss of patch antenna A to pattern E and pattern F to pattern J.

The directivity is alternative noticeable feature need to consider on WLAN antenna design. The directivity is the capability of an antenna to concentrate energy in a particular direction when transmitting or receiving energy in a specific course. The gain can be linked with directivity using a factor named antenna efficiency. Therefore, the design of MPA with high-directivity is not only essential but also a puzzling assignment. In Fig.10, (a) and (b) represent the Far field gain in polar form and (c) and (d) denotes the Far field directivity pattern from A to J.

In this phase of research our goal is to analysis the performance measurement of WLAN antenna with respect to the increment of CTSRR unit cell. The number of CTSRR addition has been aligned various ways on the patch antenna. TABLE V describes the various antenna parameters with respect to the number of triangular resonators. The variation of return loss in patch antenna with respect to increment of TSRR is expressed in Fig.11.This may be due to addition of capacitive charge concentration across width of MPA. So, incorporation of CTSRR on MPA can be utilized as frequency shifter.

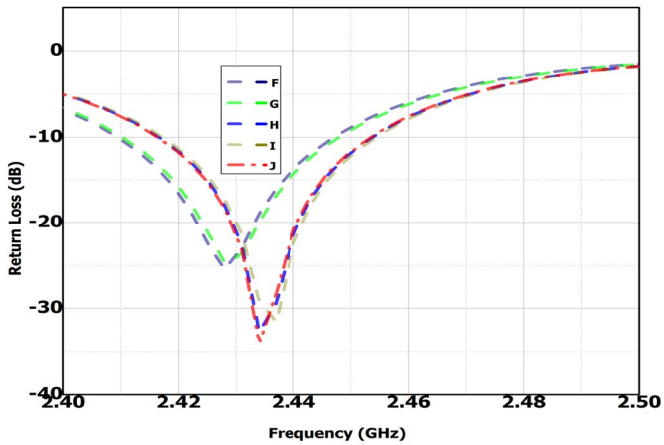

Figure 8. The return loss of patch antenna pattern F to pattern J.

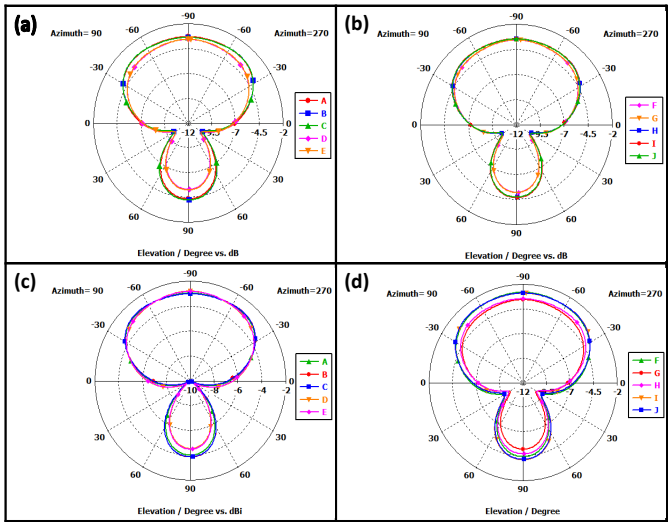

Figure 9. (a) Far field gain from orientation A to pattern E(b) Far field gain from orientation F to pattern J (c) Far field directivity from orientation A to pattern E (d) Far field directivity from orientation F to pattern J.

TABLE V. RETURN LOSS OF PATCH ANTENNA WITH INCREMENT NUMBER OF TSRR ROW WISE ALIGNMENT

Antenna	Resonant frequency, f_r (GHz)	Return loss (dB)	Gain (dB)	Directivity(dBi)
One CTSRR	2.446	- 28.864	7.85	8.29
Two CTSRR	2.443	- 33.391	7.75	8.25
Three CTSRR	2.437	- 36.114	7.31	8.21
Four CTSRR	2.434	- 41.765	7.34	8.30
Five CTSRR	2.434	-35.824	7.33	8.31
Six CTSRR	2.434	-45.386	7.29	8.24

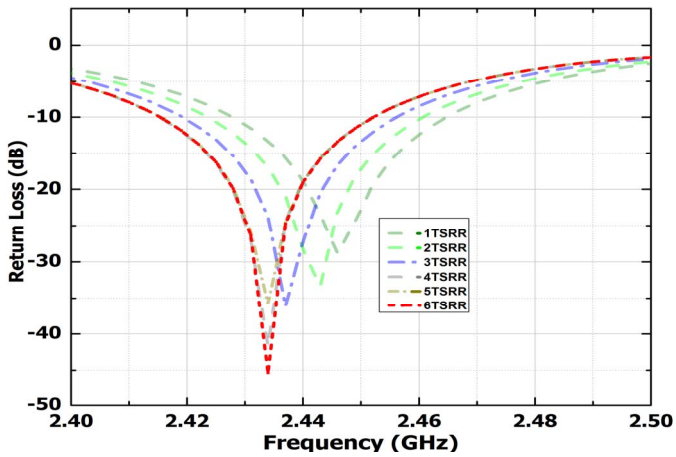

Figure 10. Return loss of patch antenna with respect to increment of TSRR.

From TABLE V, and figure 10, we observe that highest gain is achieved on antenna with one CTSRR and most directivity is achieved on antenna with five CTSRR. But on the other hand, return loss improves with respect to increment of CTSRR on patch and interestingly this shifts to lower frequency region. This may be due to concentration of electron and its impact on electromagnetic field distribution. Therefore, this finding can be indispensable for frequency tunable solution.

VI. CONCLUSION

The impact of CTSRR on the performance of microstrip patch antenna is theoretically investigated. For various orientation of CTSRR and increment of CTSRR unit cell, the antenna resonates between 2.43 to 2.45 GHz bands. The antenna shows a directional radiation pattern and capacitive charge develops in gap-cut position improves gain and directivity. Numerical study of the effect and physical parameters of CTSRR on antenna has been carried out. Resonance frequency shifts toward the lower frequency region with the increment of CTSRR unit cell. So, proposed design may be helpful for frequency tunable solution. Expected improvement in bandwidth, and impact of gain and directivity with respect to addition of CTSRR on Patch has not been observed flawlessly due to patch antenna feeding technique or perfect impedance matching. Future modified feeding network or designs can be effective to overcome this problem.

***Abstract*—A new type of antenna is presented in this paper. The main structure is a slot-loaded microstrip patch antenna fed by a half-width microstrip line. Two different types of antenna structure are combined together to make a single element antenna, and the radiation properties of both antennas are utilized in the proposed highly efficient antenna. Radiation from the antenna structure is achieved primarily from the first higher-order microstrip mode. The 10 dB return loss bandwidth of the antenna is 640 MHz (5.41 GHz to 6.05 GHz). The antenna produces a directive beam with a peak gain of 9.1 dBi, and the variation of the gain within the 640 MHz impedance bandwidth is only 1.35 dB.**

***Index Terms*—Microstrip patch antenna, leaky-wave antennas (LWAs), half-width (HW), WiMAX, Wi-Fi.**

I. Introduction

Microstrip-based antennas are attractive due to their planar low-profile configuration, fabrication simplicity, and ease of integration with microwave and millimeter-wave circuits. Low profile antennas for different wireless local area network (WLAN) systems such as wireless fidelity (Wi-Fi) and worldwide interoperability for microwave access (WiMAX) are highly desirable [1]–[3]. Wi-Fi (IEEE 802.11 standard) operates in the 2.4 GHz band (frequency range 2.4–2.5 GHz), and 5 GHz band (frequency ranges are: 5.15–5.35 GHz, 5.47–5.725 GHz, and 5.725–5.875 GHz) [1], [2]. Different standards for WiMAX have been developed by the IEEE 802.16 working group, such as 5.725–5.86 GHz [4].

Different types of antennas have been developed to meet the above mentioned requirements, most of which are patch antennas [1], [4]–[9]. Another attractive research area is microstrip leaky-wave antennas (LWAs) which usually use a microstrip line to achieve radiation. Microstrip LWAs are also planar low profile, and they have inherent beam scanning capabilities [10], [11]. The fundamental mode of a microstrip line does not radiate at lower frequencies because the electric field is strongly bound between the microstrip and the ground plane. The first higher-order mode of a microstrip line produces radiating leaky waves. Microstrip LWAs were proposed in the late 1970s with methods to excite the first higher-order microstrip mode [12]. A half-width microstrip LWA has been developed in [13] which operates in the first higher-order mode. In order to excite a microstrip line in its first higher-order mode a shorting wall was introduced along the center of the microstrip line and hence the width of the line is reduced to half of the original width. The shorting wall allows a microstrip line to excite the first higher-order mode. This antenna is called a half-width microstrip LWA (HW-MLWA). Research has been conducted on HW-MLWAs to steer the antenna beam by sweeping the frequency, or at a fixed frequency [14]–[21].

In this paper a microstrip patch antenna fed by a HW microstrip LWA is presented for 5.5 and 5.8 GHz Wi-Fi and WiMAX applications. Two different antennas, a HW-MLWA and a slot-loaded patch antenna, are cascaded to make a single directive antenna with relatively higher gain.

II. Antenna Configuration

The configuration of the antenna investigated in this paper is shown in Fig. 1. It was designed and analysed using CST Microwave Studio. The antenna is designed to be fabricated on a Rogers RT5880 substrate with a thickness (t) of 1.575 mm, dielectric constant (ε_r) of 2.2, and loss tangent (tan δ) of 0.0009. All the parameters of the antenna were optimized using parameter analysis conducted in CST. The length (L) and width (W) of the substrate and ground plane are 76.5 mm and 40 mm, respectively, i.e. the dimensions of the whole antenna are 76.5 mm $\times$ 40 mm. The complete structure can be divided into three different sections: (i) patch section, (ii) HW-MLWA section, and (iii) feed section.

A. Patch Section

The right section (Fig. 1(a)) of the antenna is the patch section which consists of a rectangular patch. The length (l_p) of the patch is 15 mm whereas the width (W) of the patch is the same as the width of the substrate i.e. 40 mm. A slot with dimensions of 5 mm $\times$ 30 mm ($w_s \times h_s$) is located at the middle of the patch.

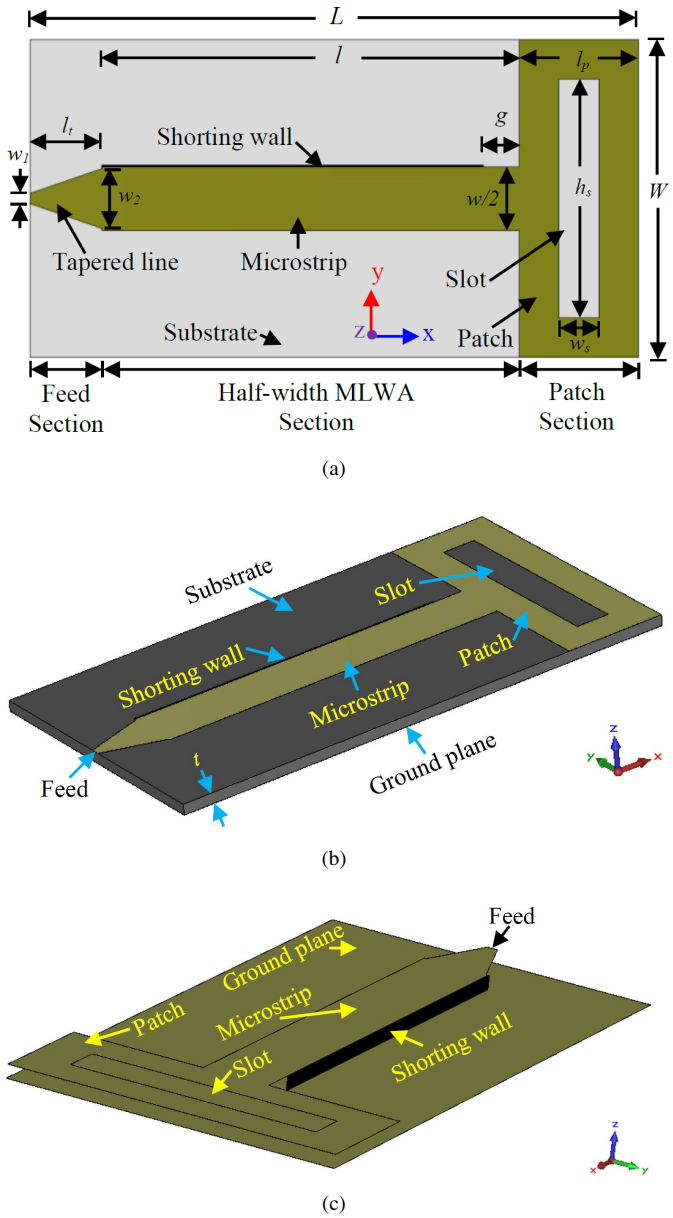

Fig. 1. Proposed microstrip antenna: (a) top view, (b) perspective view, and (c) perspective view (substrate omitted).

B. HW-MLWA Section

The middle section of the structure is the half-width microstrip LWA section, which consists of a HW-MLWA. The length (l) (along x-axis) and width ($w/2$) (along y-axis) of the microstrip line are 52.5 mm and 8 mm, respectively. As discussed earlier, in an implementation of a HW-MLWA, one edge of the microstrip is shorted to the ground plane by a shorting wall [Fig. 1(c)]. A gap (g) is introduced between the patch and the shorting wall [Fig. 1(a)]. The gap improves the impedance matching and allows the wave to propagate towards the patch. The optimum value of the gap (g) was found to be 4.5 mm, from full-wave parametric analysis conducted in CST.

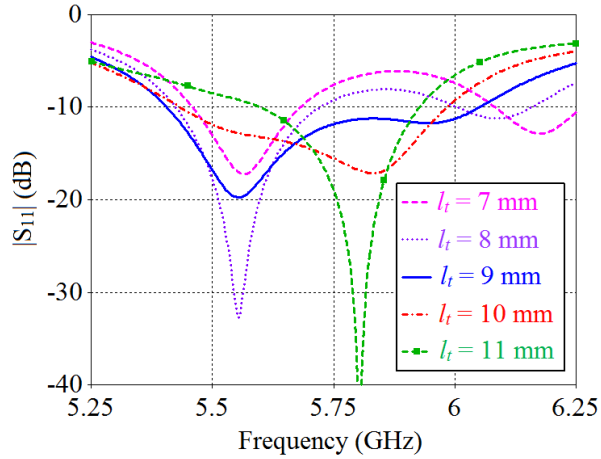

Fig. 2. Variation of reflection coefficient of the antenna in Fig. 1 with the length (l_t) of the tapered line.

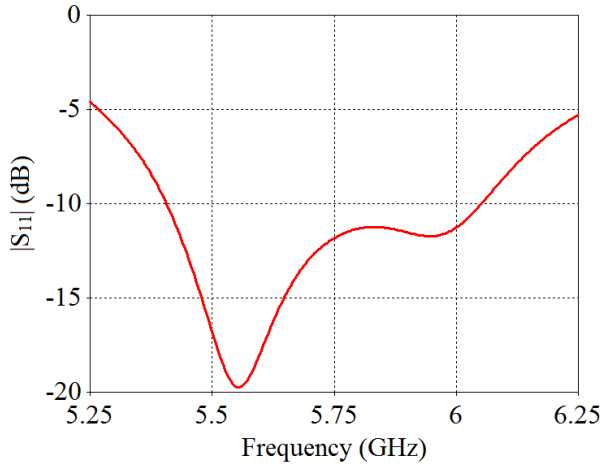

Fig. 3. Predicted $|S_{11}|$ of the antenna in Fig. 1.

C. Feed Section

The third and last section is the feed section, which is at the left side of Fig. 1(a). The antenna is fed from one end through a tapered line. To achieve good impedance matching, the dimensions of the tapered line have been optimized through some parametric studies. The effect of the tapered line length (l_t) on the return loss is depicted in Fig. 2, which shows that the best matching is achieved with l_t = 9 mm. The optimum values of the width (w_1) at the feed end and the width (w_2) at the microstrip end of the tapered line were also determined using similar parametric analysis and found to be 1.3 mm and 7.5 mm, respectively.

III. Results and Discussion

A. Reflection Coefficient

The antenna is excited from the left side by a discrete port in CST as shown in Fig. 1. Fig. 3 represents the input

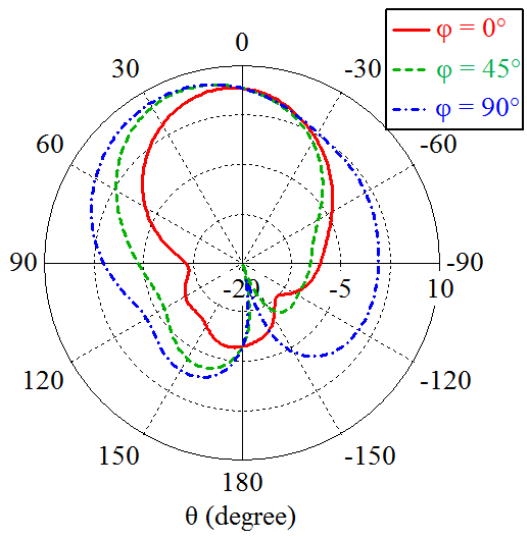

Fig. 4. Predicted radiation pattern cuts on constant-ϕ plane at 5.47 GHz.

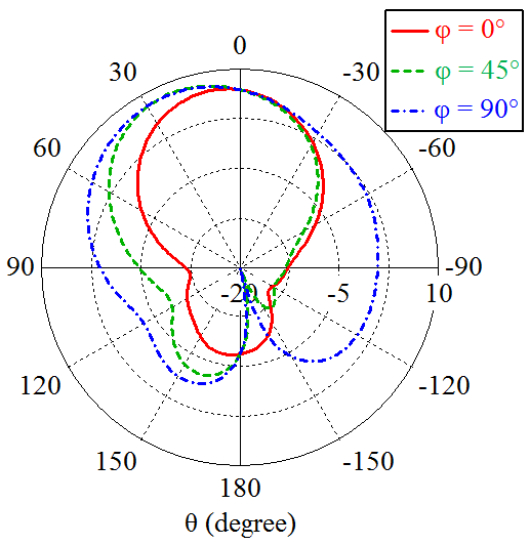

Fig. 5. Predicted radiation pattern cuts on constant-ϕ plane at 5.5 GHz.

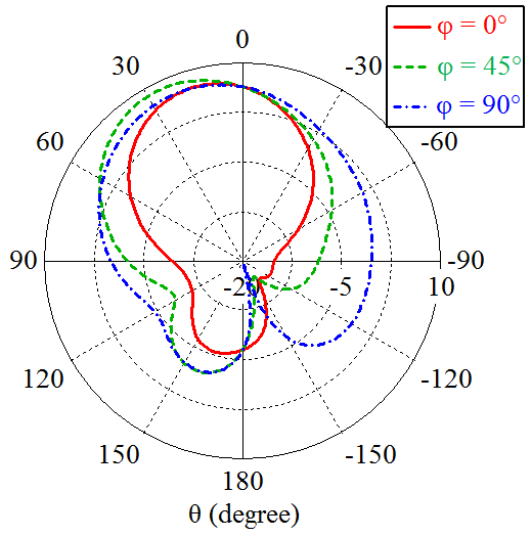

Fig. 6. Predicted radiation pattern cuts on constant-ϕ plane at 5.8 GHz.

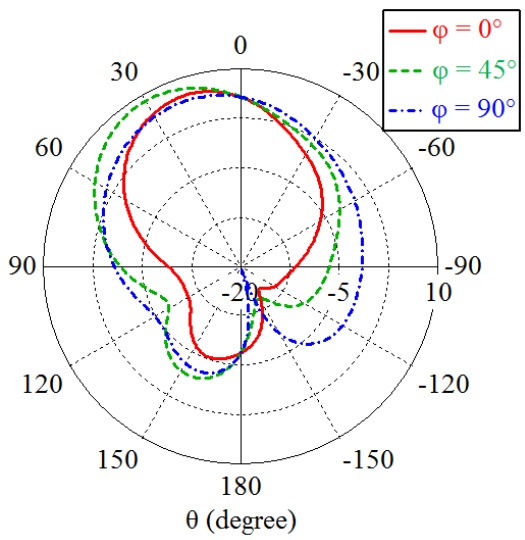

Fig. 7. Predicted radiation pattern cuts on constant-ϕ plane at 5.875 GHz.

reflection coefficient of the antenna in Fig. 1. It can be seen that the antenna has a -10 dB reflection bandwidth from 5.41 to 6.05 GHz.

B. Radiation Pattern

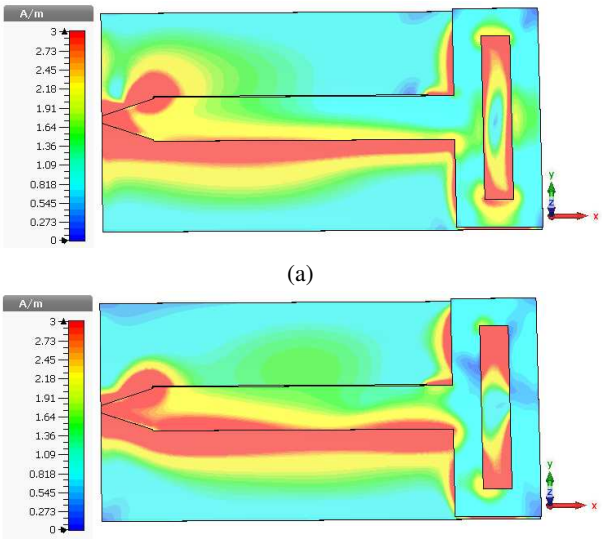
Figs. 4 – 7 show the radiation patterns of the antenna at four different frequencies. In order to represent the antenna beam properly the radiation pattern cuts are taken at three different constant-ϕ planes. The antenna beamwidth is narrow in the ϕ = 0° plane. However, the beamwidth is much wider in the ϕ = 90° plane. At lower frequencies the beam points closer to the boresight (Figs. 4 and 5), where, in this case, the boresight is the z-direction, perpendicular to the plane of the antenna structure. With an increase of frequency the beam in the ϕ = 0° plane shifts slightly towards the x-axis (Figs. 6 and 7). Though the beam in the ϕ = 0° plane changes slightly with frequency, the beam in the ϕ = 90° plane remains almost the same.

C. Surface Current Distribution

Fig. 8 displays the surface current distributions of the antenna at 5.5 and 5.8 GHz. It can be observed that at lower frequencies [Fig. 8(a)] most of the power radiates from a section closer to the feed and less power radiates from the patch. As the frequency increases the power travels further and more power radiates from the patch end as shown in Fig. 8(b).

D. Gain and Directivity

The variation of the directivity and gain of the antenna with frequency are shown in Fig. 9. The peak directivity of



(a)

(b)

Fig. 8. Surface current distribution (amplitude) at: (a) 5.5 GHz and (b) 5.8 GHz.

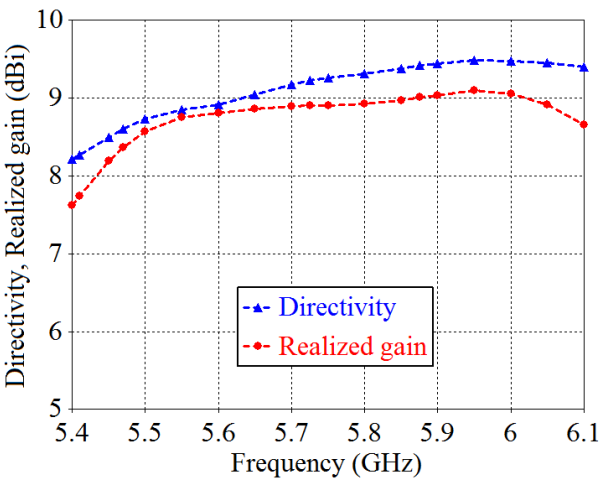


Fig. 9. Predicted directivity and gain of the antenna with frequency.

the antenna within the impedance bandwidth is 9.5 dBi at 5.95 GHz. The directivity is greater than 8.26 dBi within the impedance bandwidth. The peak gain of the antenna is 9.1 dBi at 5.95 GHz, and its variation within the impedance bandwidth is only 1.35 dB. It can be seen that the gain and directivity are low at lower frequencies and increase with frequency. This is due to the short effective aperture at lower frequencies and the long effective aperture at higher frequencies, as described in Section III-C.

E. Antenna Efficiency

Fig. 10 represents the radiation and total efficiencies of the antenna within its operating band. The radiation efficiency of the antenna is more than 98% throughout the operating band. The total efficiency of the antenna is over 84% within the impedance bandwidth and over 90% between 5.42 GHz

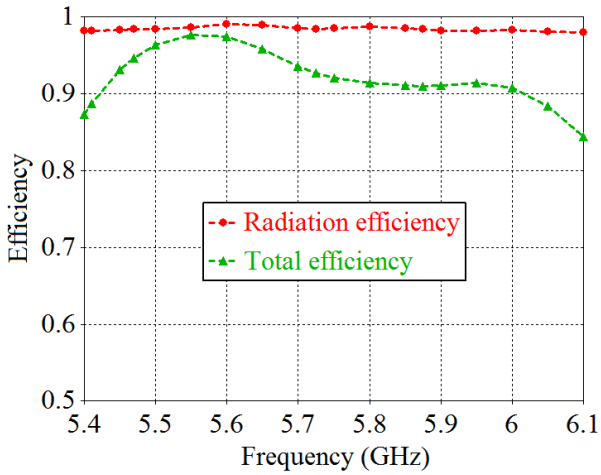

Fig. 10. Predicted radiation and total efficiencies of the antenna with frequency.

TABLE I
GAIN COMPARISON OF DIFFERENT ANTENNAS

Antenna Structure	Antenna Peak Gain
PIFA in [4]	4.4 dBi at 5.75 GHz
Self-complementary antenna in [7]	3.8 dBi in 5.8 GHz band
T-shaped monopole antenna in [8]	≈ 4 dBi in 5.8 GHz band
Printed monopole antenna in [9]	3 dBi between 5 and 6 GHz
Proposed antenna	9.1 dBi between 5.41 and 6.05 GHz

and 6.01 GHz. The total efficiency is very high from 5.47 to 5.66 GHz, almost equal to the radiation efficiencies. Since the total efficiency considers the mismatch losses, so where the return loss is high the deviation between the total and radiation efficiencies is low. For example, at 5.55 GHz the return loss is 19.7 dB ($|S_{11}|$ = -19.7 dB), the radiation efficiency is 98.6% and the total efficiency is 97.7%.

F. Comparison between the Proposed and Reference Antennas

In this subsection a comparison between the proposed and reference antennas is given in terms of antenna gain. The gains of different antennas are listed in Table I together with that of the proposed antenna. It can be seen that the proposed antenna has significantly higher gain than these reference antennas. Some of the antennas have been reported have high gain, e.g. antennas in [2], [3]. However, these antennas use a separate matching network for impedance matching.

IV. CONCLUSION

A slot-loaded patch antenna that is fed by a half-width microstrip LWA is presented in this paper. The proposed antenna is a combination of two different antennas, a LWA and a patch antenna. This antenna is able to produce a directive beam with very high gain. The Impedance bandwidth of the proposed antenna is 640 MHz and its gain is consistent within

its operating band. The predicted peak gain of the antenna is more than 9.1 dBi and its gain is above 7.75 dBi between 5.41 and 6.05 GHz. Moreover, the radiation efficiency of the antenna is above 98% and its total efficiency is over 84% throughout the operating band.

***Abstract*— A new approach with aluminum nitride (AlN) based parasitic strip wideband patch antenna has been introduced for 2.5 and 5.8 GHz wireless applications. The novelty of the proposed design is inherited in reduction of edges of patch which influences antenna performance. The impedance bandwidth of the antenna is 0.28 GHz for the first resonance, whereas 2.04 GHz for the second resonance with an antenna radiation efficiency of 89.6% and 95.32%, respectively.**

***Keywords*— Patch antenna, parasitic strip, multi-resonant, Aluminum Nitride**

I. INTRODUCTION

In this era of modern communication, prompt expansions in wireless communications have been established in order to meet the growing demand of the end terminal user. The 2.5 GHz and 5.8 GHz ISM bands are very popular for both wireless metropolitan area networks (WMAN) and wireless local area network (WLAN), respectively. Thus a multi-resonant antenna is more desirable for operations of WMAN and WLAN together. To meet the daily snowballing thirst in these operating bands, numerous antenna models with different feeding techniques have been recently anticipated for compact, efficient, and low cost design [1-4]. For an example, planar inverted-F antennas (PIFA) [5-7] are used in multiband operating at 2.5 GHz and 5.8 GHz for wireless applications. The PIFA are normally made of a large ground plane which makes the antenna bulkier. To reduce the dimension of PIFA, the feed probe point has been externally shorted. As a result, this technique leads to a decrease in the bandwidth. Besides numerous designs of fractal antennas using capacitive coupling [8], planar monopoles [4], and planar slot antenna with embedded metal strip [9] have been also suggested. In terms of design methodology, the fractal antennas are more complex, whereas the planar monopole antenna has also a large ground plane. The feeding technique of planar slot antenna is intricate to design. To overcome this problem another multi-resonant antenna, consists of bent strips printed on substrate, has been proposed [10]. However, these types of antennas are complicated in geometry and require long transmission lines [11]. Additionally, a modified feeding network is required to mitigate the difficulties like spurious feed radiation, surface wave loss, and long feed length. Therefore, it is immense important to take in account the issues such as wideband, compactness in size, and multiband for designing an antenna.

Parasitic strips for achieving resonance are well known for designing an antenna. Shorted parasitic element with monopole antenna has been employed for operation in both wideband and dual band [12-13]. Parasitic elements assure the wide banding of an antenna with many resonance frequencies which appear neighboring to the main frequency band. However, to control the resonance frequencies, details understanding of parasitic strip patch antenna are required. In this paper, a modified edge cut parasitic strip antenna for dual band operation with AlN substrate has been introduced. The antenna design; optimization and simulation have been done with Finite Element Method (FEM) based 3D full-wave electromagnetic solver HFSS v15. The antenna is comprised of modified feeding network with 50 Ω port impedance and small ground plane. The resonant frequency of the proposed antenna can be varied by tuning the length of the patch. The reflection coefficient and bandwidth are improved due to changing the width of the patch with edge cuts.

The layout of this proposal is outlined as follows: the details on Antenna evolution, design and geometry are illustrated in section 2. Results and discussions on the return loss, gain and efficiency are presented in section 3. Finally, a conclusion is depicted in section 4.

II. ANTENNA DESIGN

A. Substrate Selection

Growths in the area of III-nitride (GaN, InN, and AlN) semiconductors have been remarkable due to their inherent properties such as wide bandgap, high critical electric field, low intrinsic carrier concentration, high-electron mobility, and high-drift velocity [14]. Those parameters are very promising for high frequency, high power, and high temperature device applications. Among III-nitrides, AlN has a huge prospective to use as a substrate for a patch antenna because of wide bandgap (6.1 eV), low dielectric constant (4.84), and high critical electric field for breakdown (450 kV/cm). These suggest that AlN substrate is advantageous for wideband patch antenna.

B. Antenna Evolution

The antenna is derived and progressed from a conventional T shape parasitic strip antenna depicted in Fig. 1. The reflection coefficient has been presented for all three models.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

The antenna resonates near 2.5 GHz and 5.8 GHz for all three cases. From the Fig. 1 this is indicated that after the inclusion of edge cut on patch, antenna reflection coefficient and BW has been improved (model 3). Also the patch of proposed antenna has a 4~8% reduction in area in comparison with the patch area illustrated for model 1 and 2 in the Fig. 1. The smaller size of the proposed antenna improves dual band wireless performance. A comparative analysis is shown at table 1.

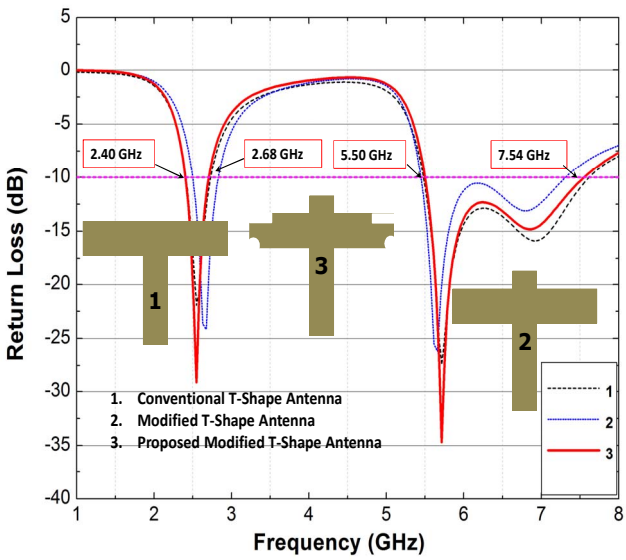

Fig 1: Antenna evolution

Table 1: Comparative analysis of conventional antenna and proposed antenna

Parameter	Conventional Patch	Proposed Antenna
Frequency(f_r)	2.5 GHz	2.5 GHz
Patch Width (W)	Patch Width $W=\frac{1}{2f_r\sqrt{\mu_0\varepsilon_0}}\sqrt{\frac{2}{\varepsilon_r+1}}=\frac{c}{2f_r}\sqrt{\frac{2}{\varepsilon_r+1}}$	
Patch Length (L)	Effective Length, $L_{eff}=\frac{c}{2f_r\sqrt{\varepsilon_{reff}}}$	
Substrate Dimension	L_s= 6h+L W_g = 6h +W	
Dimension	W = 37 mm; L = 29 mm; Height, H= 1.6 mm; L_s= 37 mm; W_s = 46 mm	W = 26.5 mm; L = 4.5 mm; H= 1.6 mm; L_s= 40 mm; W_s = 40 mm
Patch Area	1073 mm^2	156 mm^2
Substrate Area	1702 mm^2	1600 mm^2

C. Design and Geometry

Fig. 2 shows the geometry of our projected antenna. The modified patch shape with finite ground plane is printed on the same side over the AlN substrate of dielectric constant (ϵ_r) 4.84 and height of 1.6 mm. The transmission feed line of 50 Ω is printed on the back side of the substrate. The patch size occupies an overall volume of 6.28 mm^3 printed on a substrate of 40 mm * 40 mm. The physical dimension of the antenna is given in table 2.The width of the feed line W_2 and overlapping extended patch on feed line, D_2-D_1 has been kept fixed considering impedance matching. The edge cut has some advantages as these can control the surface wave loss, spurious radiation loss and reduce the patch size.

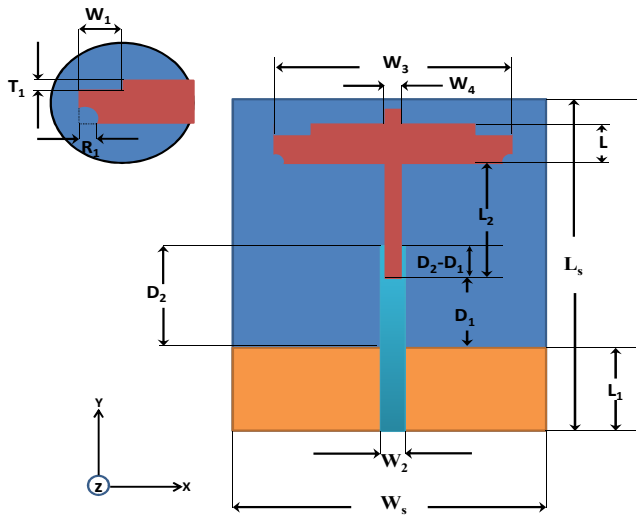

Fig 2: Geometry of the proposed antenna

Table 2: Physical Dimension of Antenna

Geometric Name	Parameter	Dimension (mm)
Substrate Length	L_s	40
Substrate Width	W_s	40
Finite Ground	L_1	12
Feed Width	W_2	3
Feed length	$D_2 + L_1$	21
Patch Length	L	4.5
Extended Patch Width	W_3	26.5
Patch Cut Width	T_1	0.6
Patch Cut Length	W_1	3
Circular Cut Radius	R_1	1.5
Patch Length	W_4	1.95

III. RESULTS AND DISCUSSIONS

A. Return Loss

The return loss (RL) is a factor that is identified as a ratio between reflected and transmitted waves at the input of an antenna. In the impedance equivalent network, improved RL is required for perfect matching. For the proposed antenna,

couple of design parameters that influences the antenna performances is the width W_3, length L, rectangular edge cut W_1, and circular edge cut R_1. The effect of these design parameters on antenna performance can be described from surface current distribution on dual resonant frequencies. In Fig. 3 and 4 the simulated RL with respect to antenna patch width (W_3) and length (L) has been represented.

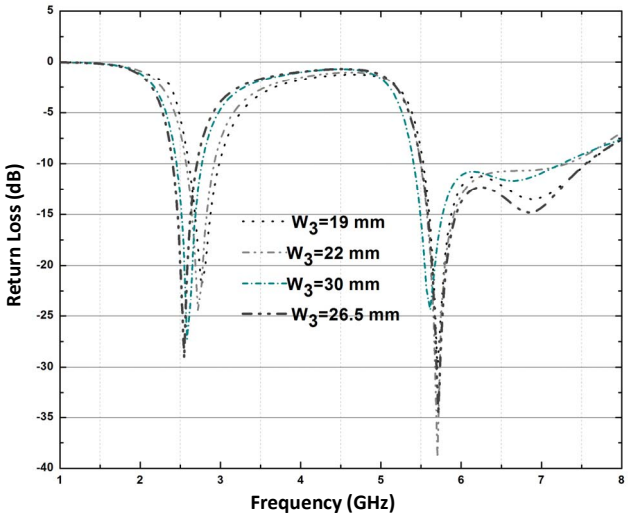

Fig 3: Return loss of antenna with variation of w_3

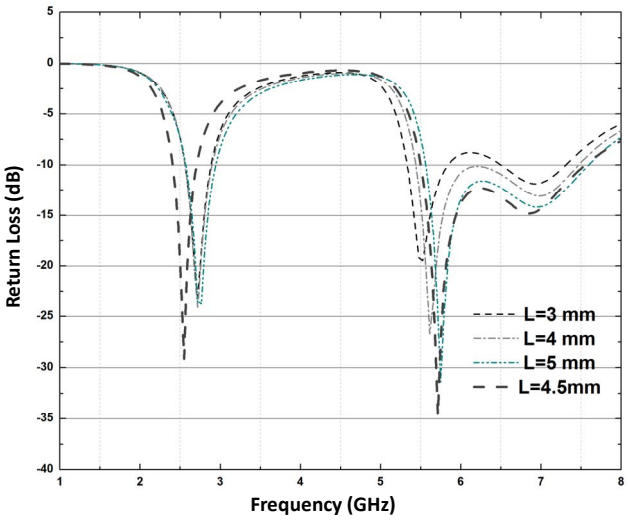

Fig 4: Return loss of antenna with variation of L (w_3=26.5mm)

B. *Electric Field, Surface Current and Polarization:*

A detailed dissemination of the excitation of the patch and the polarization of the antenna can be obtained by investigating field distribution and surface current analysis at resonance frequencies. Fig. 5(a) and 5(b) depicts the E field distribution of dual resonant frequencies near 2.5 GHz and 5.8 GHz. At the fundamental resonant frequency of 2.5 GHz and 5.8 GHz, E-field at the end of the patch is maximum and minimum at center. From Fig. 5, it is observed that E-field changes side according to instantaneous phase of the applied signal and can be denoted for multi-resonant behavior using TM_{nm} mode.

The surface current distributions of the proposed antenna in both of the bands are shown in Fig. 6(a) and 6(b). At lower resonance frequency, 2.5 GHz, the surface current along the patch are parallel with the horizontal component of the antenna whereas at lower portion on finite ground plane, surface current are vertical to horizontal component. On the other hand surface current at 5.8 GHz are parallel to horizontal component on both patch and finite ground plane. Therefore, with the increment of W_3, two resonance frequencies can shift in the lower region and by increasing L, the current path for lower region is lengthen and effects lower resonant frequency whereas higher resonant frequency remain steady. Rectangular and circular edge cut on patch may influence to minimize spurious radiation, surface wave loss, effective dielectric constant (ε_{reff}), influences radiation pattern, and enhances impedance bandwidth.

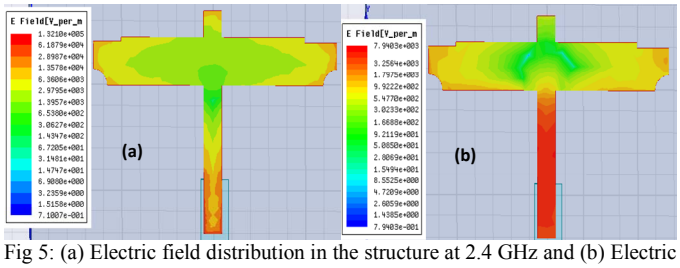

Fig 5: (a) Electric field distribution in the structure at 2.4 GHz and (b) Electric field distribution in the structure at 5.8 GHz

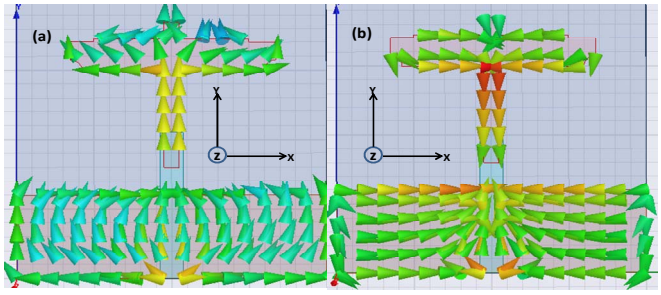

Fig 6:(a) Surface current distribution in the structure at 2.5 GHz and (b) Surface current distributions in the structure at 5.8 GHz

C. *Gain and Efficiency*

Fig. 7 depicts the 3D total gain at two resonant frequencies. The pattern is almost omnidirectional for both the bands. The last adaptive gain is 2.58 dB with peak efficiency of 89.6% at 2.5GHz and 3.69 dB with peak efficiency of 95.32% at 5.8 GHz. Fig. 8 (a) and 8 (b) depict radiation efficiency and peak gain with respect to operating bands. The return loss can be expressed in terms of voltage standing wave ratio (VSWR) which is 1.07 and 1.05 respectively for lower and higher bands. The transmitted and reflected powers are 99.90% and 99.97% for resonance frequency (f_r) of 2.52 GHz and 5.78

GHz with a mismatch loss of 0.003 dB and 0.001 dB [15].

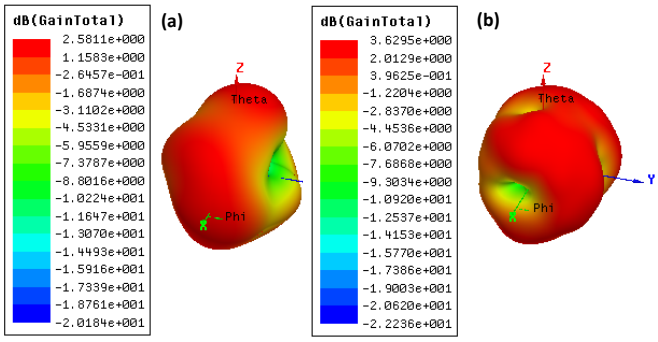

Fig 7: (a) 3D polar plot at 2.5 GHz and (b) 3D polar plot at 5.8 GHz

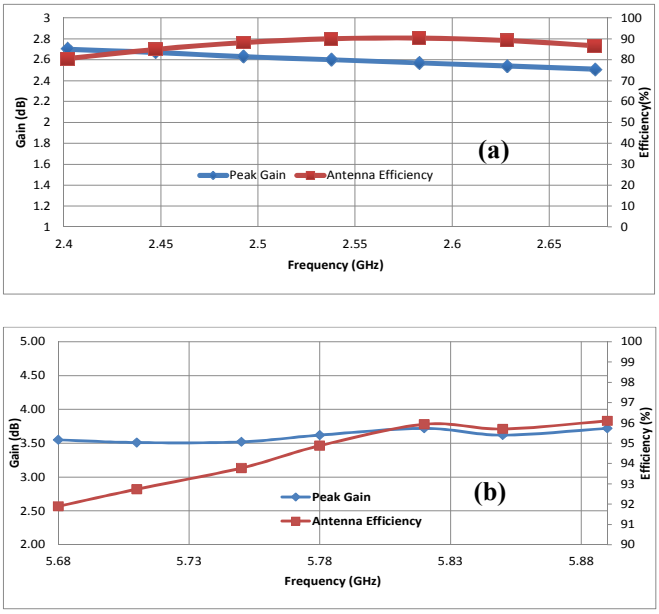

Fig 8: Simulated peak gain and efficiency of the antenna, (a) 2.5 GHz and (b) 5.8 GHz

IV. CONCLUSION

To recapitulate, the impact of modified patch shape on gain and radiation characteristics of multi-resonant wideband patch antenna with a parasitic strip are theoretically investigated to be used in wireless applications using AlN substrate. The proposed antenna model on AlN, featuring high band gap and high electron mobility may influence a significant role on fabrication of practical antenna. The exclusive reduction of ground plane and patch area in comparison with other multi-resonant antennas have been established also. From the simulation results, it has been observed that the antenna resonates at 2.52 GHz and 5.78 GHz with a bandwidth of 0.28 GHz and 2.04 GHz, separately, an impedance BW of 11.67% and 35.17%, respectively. The gain pattern of antenna is almost omnidirectional with radiation efficiency of 89.6% and 95.32% at lower and higher resonant, individually. These results regard that proposed modified patch on AlN with a parasitic strip is a highly potential structure for the wideband antenna for multi-band wireless applications.

***Abstract*— Electromagnetic Band Gap (EBG) structures which is an exclusive innovation in modern microwave design arena by reason of their high potential and less intricacy of designing in the microwave and millimeter-wave integrated circuits. This paper examines the relationship between the filling factor (FF) of the annular ring structure on couple-line and capacitive coupling for improving the performance. A number of methods, method of moments (MOM) for numerical analysis and uniform distribution with constant aspect ratio (AR) for designing the circuit are used. In like manner, the parametric comparison has been demonstrated considering selectivity, 3-dB bandwidth (3-dB BW), insertion loss and return loss in the passband. Consequently, not only a very wide passband upto 49% increment but also a return loss upto 65 dB which illustrates great matching are achieved. Although, the insertion loss is less than 0.2 dB in the passband, but the selectivity shrinks with expanding bandwidth. In short, remodelling of the selectivity can be done by appropriately choosing the filling factor for annular ring pattern on the couple-line as well as on the transmission line.**

Keywords—3-dB Bandwidth; Aspect Ratio; Insertion Loss; Selectivity; Return Loss.

I. INTRODUCTION

Recently, Electromagnetic Band Gap structures (EBGs) which is a subset of metamaterials have grown in reputation as a result of less complexity in fabrication, superior efficiency, compact architecture and cooperative integration with microwave and millimeter-wave circuits. In brief, this metamaterials have such exclusive properties which is noteworthy for a single natural crystal [1]. However, the stopband and bandgap property of the structures can be influenced by some sophisticated design parameters. Like element spacing, number of the element on transmission line, aspect ratio and volumetric ratio of the elements, dielectric and radiation losses are the predicament for designing the EBG structures [2]. Furthermore, the efficacy of the wideband system is disturbed by the harmonics transmission which may cause increasing radiation loss. To enhance the performance of the propagation characteristics, a particular factor (namely, slow wave mode propagation) is analysed for achieving the low insertion loss [3]. On the other hand, bandpass filters having wideband, low insertion loss in the passband and wide attenuation in the stopband are the passband and wide attenuation in the stopband are appropriate for microwave system. However, by modifying the coupling coefficient of the couple-line and impedence of the transmission line, not only the pass bandwidths and transmission zeros of the filter can be regulated but also wider stopband and sharp selectivity can be achieved [4]. In addition, to increase the coupling coefficient pair of slots parallel to the microstrip line engraved on the ground plane for attaining wide bandwidth in the passband was reported in [5]. Also, the dielectric and radiation losses can be minimized without the coupling gaps. As a result, low insertion loss in the passband can be obtained with good matching. Moreover, adding two tuning stubs and dual mode characteristics, the performance of the bandpass filter in both passband and stopband can be significantly enhanced [6].

In this exposition, a lower insertion loss, better impedence matching, enhanced bandwidth and wider stopband asymmetric couple-line filter with annular ring EBG structure is proposed. In fact, annular ring structures are used in the four stage couple-line section for better optimization in the coupling coefficient. Besides, in both of the 50Ω transmission line to enhance the pass bandwidth and reduce the radiation losses in the coupled line section higher volumetric ratio element are used. In short, to enhance the 3-dB bandwidth with low insertion loss and large stopband is the individuality of this exposition.

The asymmetric couple-line bandpass filter with annular ring structures has a number of exclusive features, which includes the following:

a. The structure is compact and simple.
b. The optimization in the coupling coefficient has been made in this filter which proves the good matching.
c. The passband provides wide 3-dB bandwidth.
d. The filter has sharp rates of roll-off transfer function.
e. The insertion loss is very low with wider stopband performance.

The whole structure is simulated by method of moments (MOM) based EM software *Zeland IE3D.*

II. DESIGN THEORY

The annular ring pattern is etched on the ground plane of standard 50Ω transmission line with a period "*a*" which is a

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

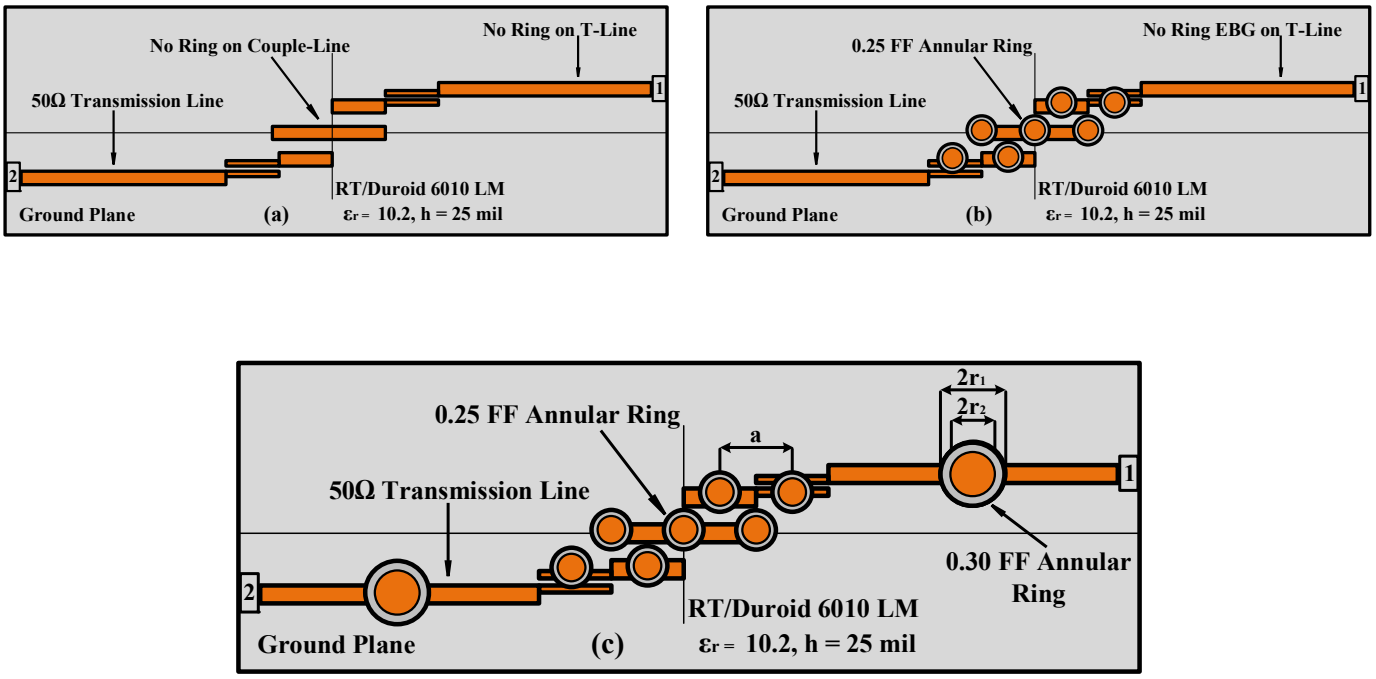

Fig. 1: Schematics of the (a) Published reference model by T. Itoh et al. [3]; (b) Proposed designed couple-line filter with 0.25 FF annular ring on four stage couple line and no EBG ring on transmission line; (c) Proposed designed couple-line filter with 0.25 FF annular ring on four stage couple line and 0.30 FF annular ring on both of the transmission line; where the AR=0.535, period, a=150 mil in 50Ω transmission line etched on the ground plane of the RT/Duroid 6010LM, h=25 mil.

crucial parameter to attain stopband characteristics. Moreover, filling factor of the annular ring patterned EBGs are drafted from the equation:

$$FF = \frac{r_1}{a} \tag{1}$$

Where, Filling Factor (*FF*), outer ring radius (r_1), spacing between two elements (*a*).

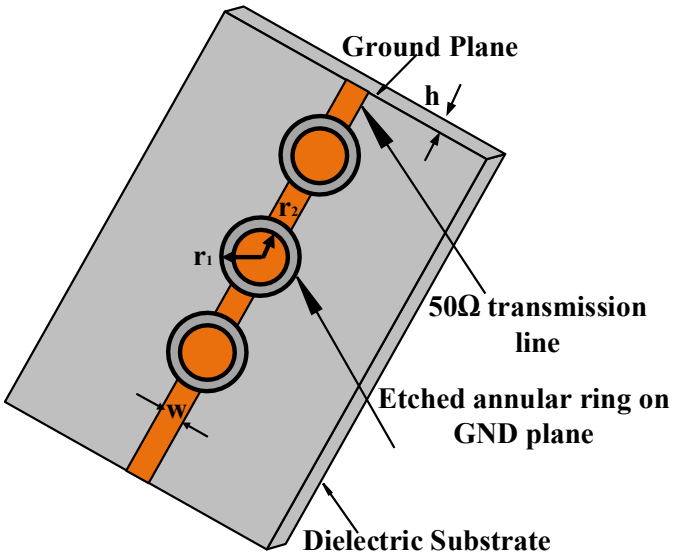

Fig. 2: Three-dimensional (3-D) view of the conventional annular ring architecture on a 50Ω transmission line.

Aspect ratio (AR) of the annular ring may be defined as the ratio of the inner ring radius (r_2) to outer ring radius (r_1) which is an exclusive feature.

$$AR = \frac{r_2}{r_1} \tag{2}$$

The center frequency of the stopband [7] can be calculated using:

$$\beta a = \pi \tag{3}$$

Where, β is the wave number of dielectric slab, *a* is the period of the annular ring pattern.

III. Proposed Structures

The proposed asymmetric couple-line filters were composed on RT/Duroid 6010 LM substrate with dielectric constant of 10.2 and thickness of 25 mil. For good tuning and simulation scope, the annular ring assisted couple-line bandpass filter is simulated by MOM based EM software Zeland IE3D. Outer ring radius r_1 can be developed from the filling factor. Likewise, inner ring radius r_2 would always be determined by aspect ratio. Nevertheless, the aspect ratio kept consistent at 0.535 while the volumetric ratio of ring structure is varied.

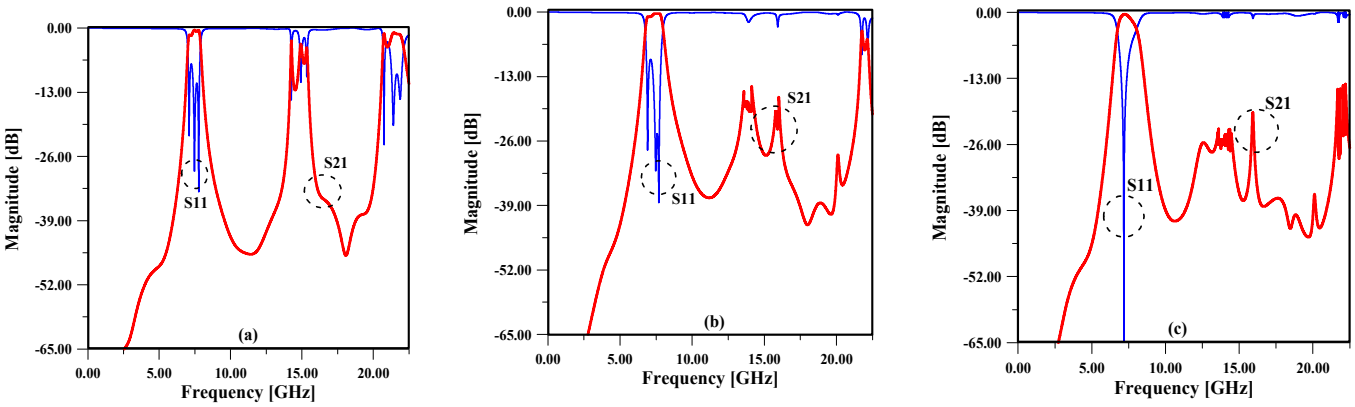

Fig. 3: Simulated frequency response of the (a) Published reference model by T. Itoh et al. [3]; (b) Proposed designed couple-line filter with 0.25 FF annular ring on four stage couple line and no EBG ring on both of the transmission line; (c) Proposed designed couple-line filter with 0.25 FF annular ring on four stage couple line and 0.30 FF annular ring on both of the transmission line; where the AR=0.535, a=150 mil in 50Ω transmission line etched on the ground plane of the RT/Duroid 6010LM, h=25 mil.

A. Design 1 :

As can be seen in Fig. 1(a), the reference asymmetric couple-line bandpass filter have four couple-line segments, lower and upper transmission line. Again, no EBG element on couple-line as well as on both of the 50Ω transmission line. This four stage coupled line filter with 0.5 dB equal ripple response where center frequency is at 7.5 GHz. In Fig. 3(a), at initial passband insertion loss starts from 120 dB. The filter has sharp selectivity of 45.95 dB/GHz and 3-dB cut-off frequency at 7.03 GHz. As the filter is tightly coupled, it results of a very narrow bandwidth. The return loss in the passband is 33.10 dB. But from Fig. 3(a), the filter is influenced by the spurious transmission in the conclusive stopband.

B. Design 2 :

Observing from Fig. 1(b), the proposed asymmetric couple-line bandpass filter have seven annular ring EBG elements with 0.25 FF on four section couple-line. But, like the Fig. 1(a), no annular ring EBG element are etched on both of the 50Ω transmission line. Consequently, for utilizing the ring element on couple line the balance between the capacitive coupling and coupling coefficient is established. In Fig. 3(b), insertion loss starts from 125 dB. As a result of balanced coupling, the 3-dB pass bandwidth has increased which is 1.17 GHz. But the matching in the Fig. 3(b) not increased significantly compare to Fig. 3(a). Likewise, no significant coupling has done as no ring EBG is etched on both of the transmission line which results no significant improve in matching in the passband. Although, the bandwidth is increased, but the selectivity is 34 dB/GHz. As seen from Fig. 3(b), not only the ripple is diminished in the passband but also the spurious transmission in conclusive stopband is also reduced. For further improvement of the overall performance (namely, coupling coefficient) of the asymmetric couple-line bandpass filter, annular ring EBG with certain FF need to be used in the both 50Ω transmission line for better coupling.

C. Design 3 :

As illustrated in Fig. 1(c), the proposed asymmetric couple-line bandpass filter have seven volumetric ratio of 0.25 annular ring EBG element on four segment couple-line like the Fig. 1(b). But, this proposed design has 0.30 FF annular ring EBG element has placed at center on both of the 50Ω transmission line. At first the coupling settled on the four stage couple-line, it also yields the mutual coupling between both of the 50Ω transmission line. Still, the signal gets weaker at the end of the port due to the dielectric and radiation losses as a result of tight coupling. Finally, with a proper volumetric ratio of 0.30 ring structure has placed on the middle for further improvement in the coupling. As seen from Fig. 3(c), insertion loss starts from 134 dB. Furthermore, not only the 3-dB pass bandwidth increased to 1.25 GHz but also the matching in the passband has significantly improved to 65 dB. But, the value of selectivity reduced to 30.81 dB/GHz which is normal compared to the bandwidth. Alternatively, the spurious transmission due to the skin effect in the conclusive stopband is also reduced significantly which results a very large stopband compared to Fig. 3(a) and Fig. 3(b).

IV. RESULTS

As illustrated in Fig. 4, Fig. 5 and Table I, a comparative study has done by virtue of their rigorous parametric analysis (namely, selectivity, return loss S_{11} in the passband, 3-dB bandwidth and percentage enhancement in the bandwidth) with respect to the volumetric ratio. In this section, overall improvement in the efficacy of the couple-line filer will be presented meticulously.

TABLE I

COMPARATIVE STUDY BETWEEN THE PERFORMANCE OF ASYMMETRIC COUPLE-LINE BANDPASS FILTER; *AR=0.535* REMAIN CONSTANT.

EBG on T-Line	Selectivity [dB/GHz]	S_{11}(Passband) [dB]	3-dB BW [GHz]	BW Enhancement [%]
Ref. [3]	45.95	33.10	0.84	N/A
No EBG	34.00	38.50	1.17	39.39
0.30 FF	30.81	65.00	1.25	48.81

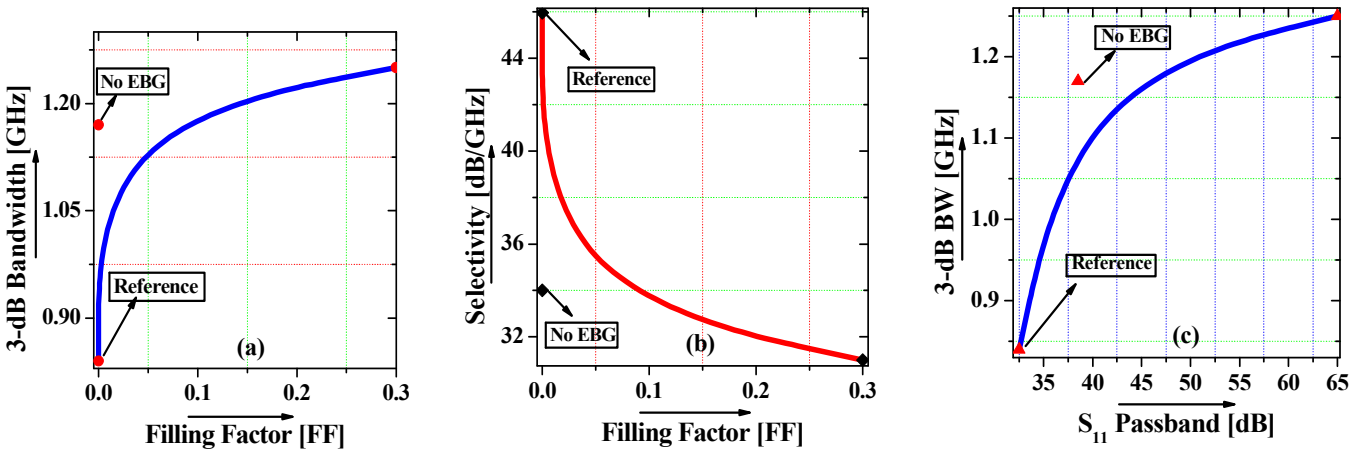

Fig. 4: Comparative study between the Published reference model by T. Itoh et al. [3], Proposed designed couple-line filter with 0.25 FF annular ring on four stage couple line and no EBG and 0.30 FF annular ring on both of the transmission line representing (a) FF vs. 3-dB BW; (b) FF vs. Selectivity; (c) return loss in the passband vs. 3-dB BW; where the AR=0.535, a=150 mil in 50Ω transmission line etched on the ground plane of the RT/Duroid 6010LM, h=25 mil.

A. Bandwidth Enhancement :

In this article, one of the most significant findings is 3-dB bandwidth enhancement with respect to the filling factor. As can be seen in Fig. 4(a) and Table I, reference filter is about less than 0.90 GHz while the proposed structure with no EBG in transmission line has 1.17 GHz and 0.30 FF EBG on transmission line has 1.25 GHz respectively. As the filter is tightly coupled, so the radiation loss due to skin effect will be more. Likewise, adding EBG on transmission line has equally distributed the capacitive coupling throughout the total transmission line. The consequence of that is, enhancement in the 3-dB bandwidth with a uniform and healthy coupling. The value of the curve increases gradually with a proper pattern. In Fig. 4(a), the curve is parabolic which shows a saturation in the coupling.

B. Shrinkage in Selectivity :

As can be seen in Fig. 4(b), the curve is decreasing exponentially which is noteworthy. The reference has the selectivity of 45.95 dB/GHz with a narrow bandwidth and no proper EBG pattern either on the couple-line or on the 50Ω transmission line. Nevertheless, involvement of the annular ring pattern on the couple-line in Fig. 1(b) and on both of the couple-line and on the T-line in Fig. 1(c), selectivity immediately falls off from 45.95 to 34 and 30.81 dB/GHz respectively. In conclusion, as the width of the passband rises, low selectivity occurs.

C. Improvement of Matching :

As illustrated in Fig. 4(c) and Table I, in the passband of the reference filter return loss is about 33.10 dB as a result of the non-uniform tight coupling between the couple-lines. At first, inclusion of the 0.25 FF ring pattern on couple-line improve the coupling balance at small-scale. Furthermore, inclusion of 0.30 FF ring with already placed 0.25 FF ring pattern on couple-line

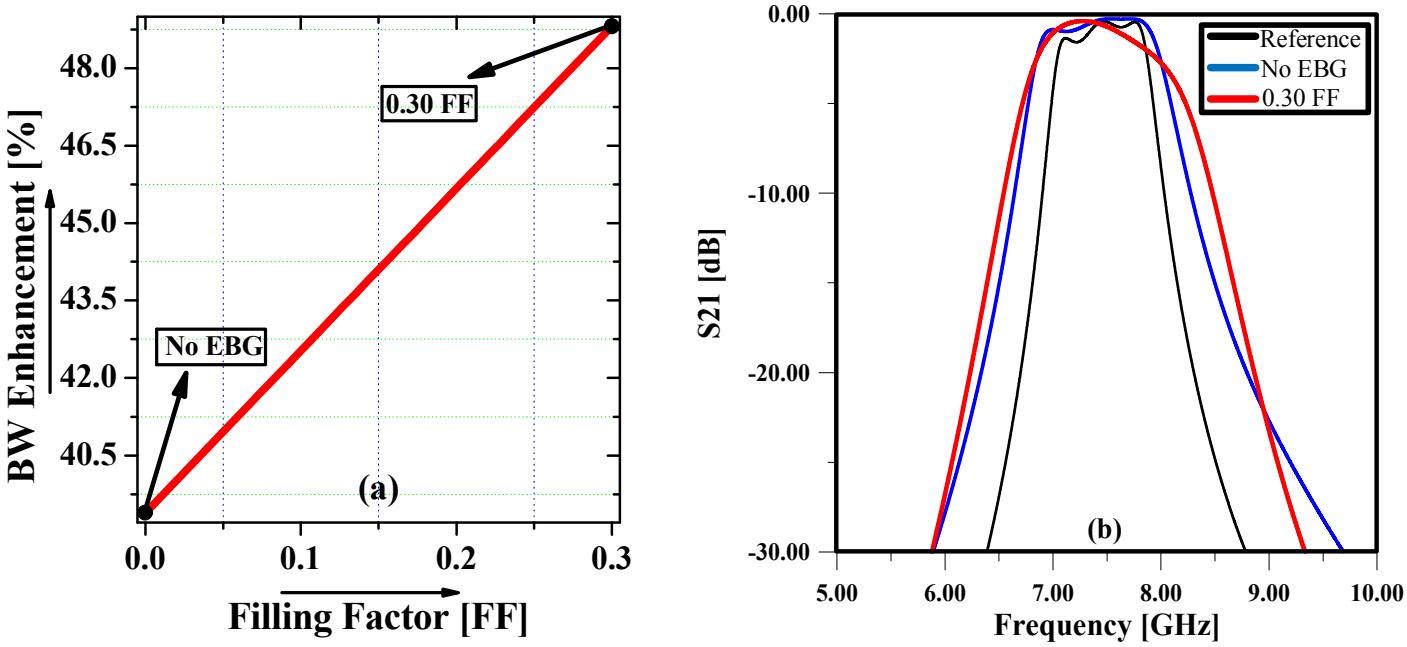

Fig. 5: Graphical representation of the (a) FF vs. percentage (%) of bandwidth enhancement; (b) frequency vs. insertion loss in the passband, black line-reference, blue line-no EBG on T-line, red line- 0.30 FF on T-Line; where the AR=0.535, a=150 mil remain constant.

a drastically improved matching in the passband of 65 dB can be observed in Fig. 4(c). From the Fig. 4(c), it can be observed that coupling is distributed consistently along the lower and upper transmission line.

D. Percentage of Bandwidth Enhancement :

As observed from Fig. 5(a) and Table I, the straight line which has very sharp tangent exhibits the percentage advancement of the bandwidth. From Fig. 5(a), the design with no EBG pattern on transmission line has increment of 39.39% and the pattern with 0.30 FF ring EBG on transmission line has 48.81%.

E. Low Insertion Loss :

Observing the Fig. 5(b), both insertion losses of the proposed circuits are improved significantly over the reference one. Furthermore, reference one bandwidth is bit narrower than both of the proposed designs. Likewise, at the tip of the passband in the reference model, ripple is present. With the increment of the filling factor, the ripple was no more with very smooth frequency response in the passband.

V. Conclusions

In this paper, the equal length asymmetric couple-line with annular ring patterns that can be utilized to effectively comprehend the bandpass filter is demonstrated. Furthermore, to certify the design method two examples of microstrip annular ring patterns on transmission line is established. In the illustrated cases, the 3-dB bandwidth increases by 39.39% and 48.81% respectively. Likewise, by properly placing the annular ring patterns on the couple-line section, sharp selectivity and more efficient passband can be obtained. On the other hand, appropriately selecting the volumetric ratio on both lower and upper transmission line, the matching and spurious transmission can be further improved. Alternatively, polynomial distribution with ring architecture can play a vital role for further improvement of overall efficacy of the couple-line filter.

***Abstract*— Electromagnetic Band Gap Structures (EBGs) have been developed to improve the efficiency of microwave and millimeter-wave devices, grown into most prominent framework by virtue of their unique electromagnetic and electrical properties. This article inspects the relationship between the operating performances of the low pass filter with the different EBG pattern. In this article, two high selectivity, wide stopband low pass filters (LPF) etched on ground plane with Tschebycheff polynomial distribution are proposed. A number of methods, method of moments (MOM) for numerical analysis and Tschebycheff polynomial distribution for designing the circuit are used. Moreover, to increase the stopband bandwidth of the new filters, a hybrid structure is used. The filter using ten dumbbell annular ring (DAR) patterns has improved selectivity of 47.19%, great matching upto 80 dB, negligible insertion loss less than 0.2 dB and two rejections in the stopband within 6.25 GHz, 12.97 GHz. In brief, this high selectivity, compact, wide stopband low pass filters were designed to alleviate the problem of low selectivity and small stopband bandwidth in microwave communication.**

Keywords—Low Pass Filters; Tschebycheff Polynomial Distribution; Selectivity; Dumbbell Annular Ring, Insertion Loss.

I. INTRODUCTION

In recent times, Electromagnetic Band Gap structures (EBGs) which is a subset of metamaterials have grown in reputation considering some periodic patterned, quite extraordinary and sophisticated properties. However, such high level properties is infrequent for a single natural material [1]. In microwave sector, EBGs display wider bandpass, steeper and deeper band rejection properties. In this present day, EBG assisted microstrip filters are frequently playing a role in modern microwave and RF engineering. To minimize the spurious transmission and register the compactness of circuits, numerous active and passive microwave and millimeter wave devices have been fabricated. However, due to the predicament of the modeling, utilizing an EBG structure for the fabrication of these components. Such as the element spacing, operating frequency, width, height of the substrate, thickness, irregularity of the surface, volumetric ratio of the EBG element, pattern of the elements which have influence on bandpass and band rejection properties. In addition, other complication in EBG circuit due to the radiation from aperiodic etching with no proper formulation as a result of the inappropriate selection of dielectric substrate [2].

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

In this paper, applying Tschebycheff polynomial distribution with dumbbell annular ring (DAR) patterned EBG structures inscribe on the ground plane of a microwave transmission line is proposed. On the whole, microwave assisted low pass filter return loss, insertion loss and selectivity enhanced performance where Tschebycheff polynomial distribution are employed to fabricate the filter. Moreover, two new sharp selectivity, wide stopband low pass filter based on hybrid pattern (namely, only DAR and DAR with interleaved circular) concepts, is the novelty of the paper. Developing wider, deeper stopband and suppressing ripples in the passband are great features of the Tschebycheff polynomial. A unique measure of the Tschebycheff polynomial the side lobe level (SLL) is exploited to manage the width of stopband insertion loss, the depth of passband return loss, ripples in both passband and stopband, selectivity. Consequently, with the Tschebycheff distribution ripple, width and depth of the stop bandwidth can be mitigated with the improvement of selectivity of the transfer function at cut-off frequency [3].

The proposed low pass filter utilizing the Tschebycheff polynomial distribution with the novel Hybrid structure not only has some specific ground of originality but also has some unique features, which includes the following:

a. The stopband is greater than 12 GHz which is very wide than that of a traditional low pass filter.
b. Two architectures will be fabricated according to the Tschebycheff polynomial distribution.
c. The ripple is less than 0.2 dB and significant improvement in matching in the passband.
d. The rates of roll-off transfer function is very sharp.
e. The return loss in the stopband is negligible.

All the structures are simulated by method of moments (MOM) based EM software *Zeland IE3D*.

II. DESIGN THEORY OF STRUCTURES AND POLYNOMIAL DISTRIBUTION

Tschebycheff polynomial has a convenient characteristic of equal ripple characteristic which is observed for a selective side lobe level (SLL). The Tschebycheff excitation coefficient are determined by the SLL. The recurrence formula [4] for Tschebycheff polynomial:

$$T_m(z)=2zT_{m-1}(z)-T_{m-2}(z) \quad (1)$$

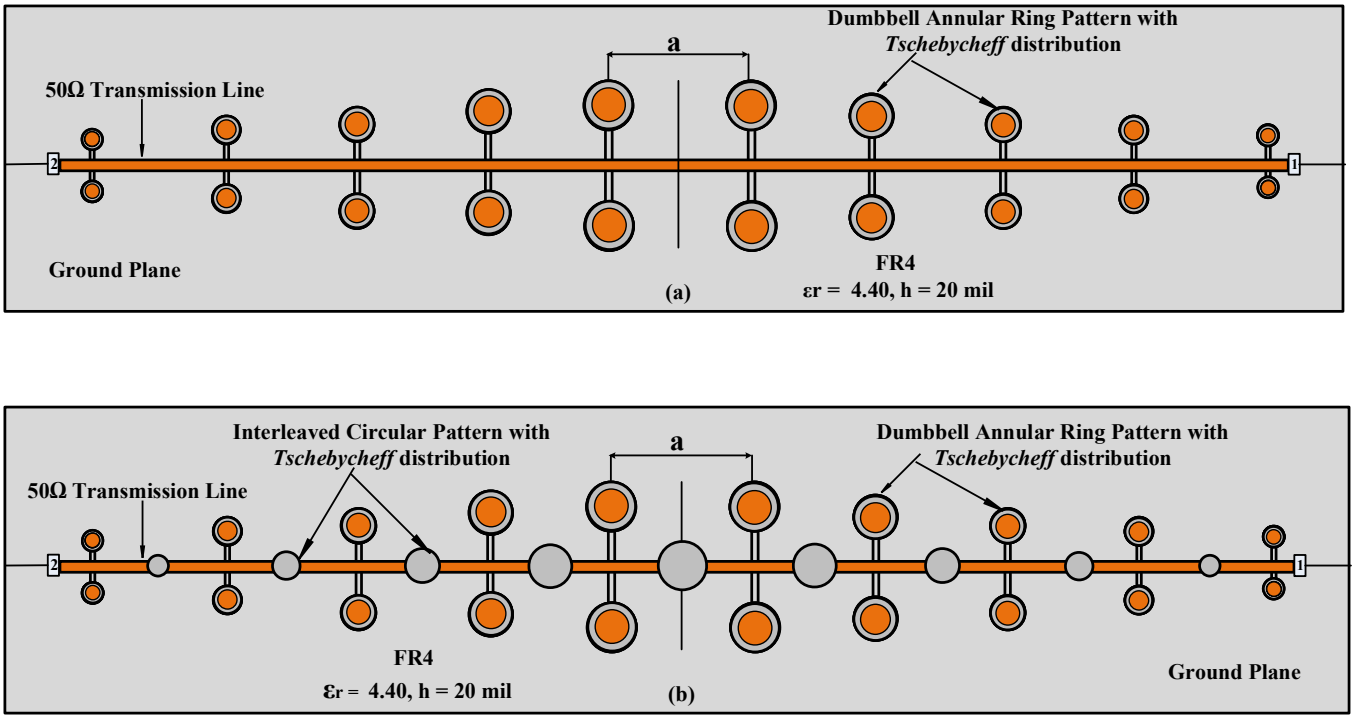

Fig. 1: Schematics of the (a) Proposed designed dumbbell annular ring assisted low pass filter on transmission line; (b) Proposed designed low pass filter with dumbbell annular ring with interleaved circular (Hybrid) pattern on the transmission line; where the AR=0.535, FF=0.25, period, a=320 mil in 50Ω transmission line etched on the ground plane of the FR4 substrate, h=20 mil.

Every polynomial can be evaluated using:

$$T_m(z)=\cos[m\cos^{-1}(z)];\ -1 \le z \le +1 \qquad (2)$$

$$T_m(z)=\cosh[m\cosh^{-1}(z)];\ z\langle -1,\ z\rangle +1 \qquad (3)$$

As major to minor lobe ratio for 25 dB, the amplitude of coefficient will be:

$$0.40\ 0.51\ 0.72\ 0.90\ 1\ 1\ 0.90\ 0.72\ 0.51\ 0.40$$

The volumetric ratio of each circular element will be:

$$FF=\frac{r}{a} \qquad (4)$$

Where, Filling Factor (*FF*), radius of each element (*r*), spacing between two elements (*a*).

On the ground plane, the ring pattern is placed into the standard 50Ω transmission line with period "*a*" which is a influential parameter for achieving sharp selectivity and wider stopband. However, the filling factor for annular ring will be:

$$FF=\frac{r_1}{a} \qquad (5)$$

Where, outer ring radius (r_1). The ratio of the inner ring radius (r_2) to outer ring radius (r_1) is called Aspect ratio (AR).

$$AR=\frac{r_2}{r_1} \qquad (6)$$

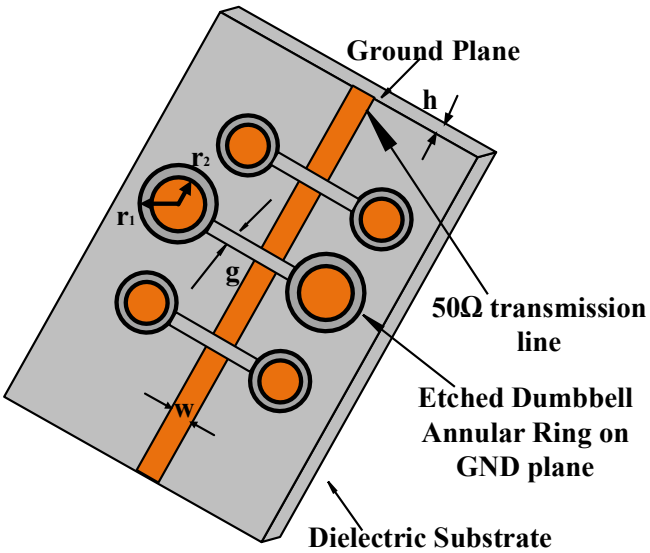

Fig. 2: Three-dimensional (3-D) view of the conventional dumbbell annular ring structure with Tschebycheff distribution etched on a ground plane on a 50Ω transmission line, grey- etched portion, colour-copper portion; where, w and g are the width of the transmission line and arm of the dumbbell annular ring respectively.

The center frequency of the stopband can be calculated using:

$$\beta a=\pi \qquad (7)$$

Where, β is the wave number of dielectric slab, a is the period of the annular ring pattern.

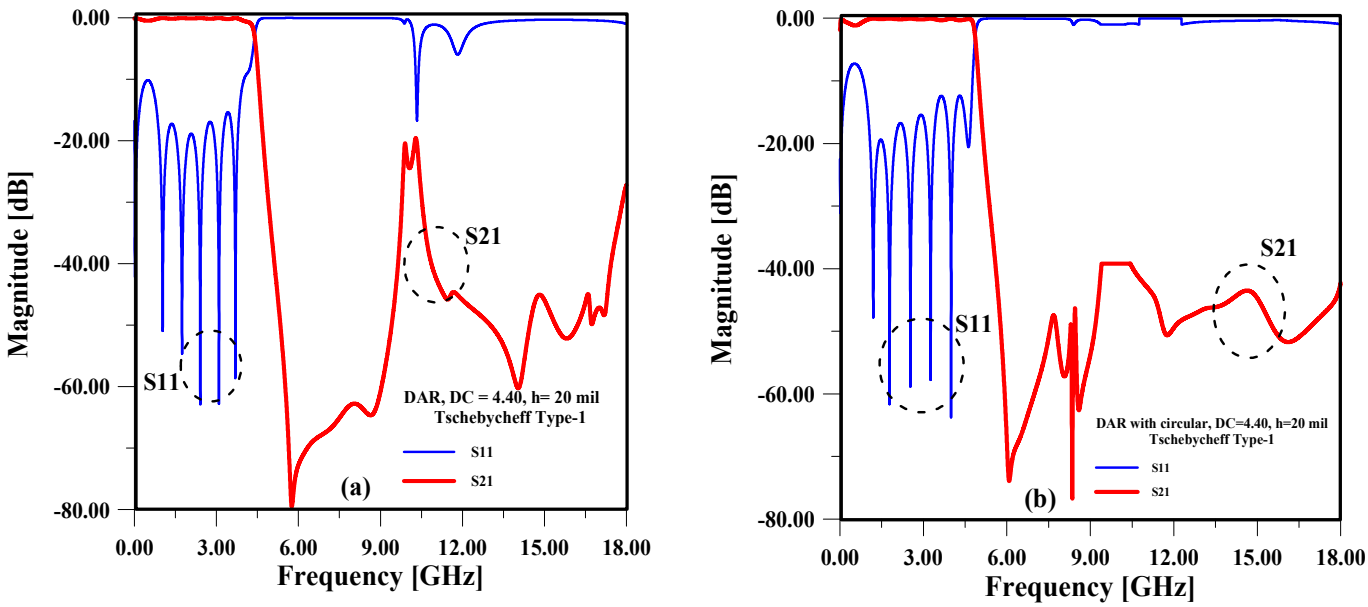

Fig. 3: Simulated frequency response of the (a) Proposed designed dumbbell annular ring assisted low pass filter on transmission line; (b) Proposed designed low pass filter with dumbbell annular ring with interleaved circular (Hybrid) pattern on the transmission line; where the AR=0.535, FF=0.25, period, a=320 mil in 50Ω transmission line etched on the ground plane of the FR4= 4.40 substrate, h=20 mil; AR = 0.535 remain constant throughout the analysis.

III. PROPOSED DESIGN STRUCTURES

The dumbbell annular ring (DAR) structured low-pass filters were constructed on FR4 substrate with dielectric constant of 4.40 and thickness of 20 mil. For simulation purpose and great tuning, the couple-line filter is simulated by EM software Zeland IE3D. Outer ring radius r_1 which derives from filling factor and inner ring radius r_2 which can be obtained from aspect ratio, this both factor are kept consistent at 0.25 and 0.535 respectively throughout the analysis. Likewise, 25-dB Side lobe level with ten amplitude coefficient will determine the dimension for each of the dumbbell annular ring (DAR) as well as the capacitive coupling between them. Besides, Tschebycheff polynomial distribution are applied with center frequency at 10GHz. Selectivity, 20-dB IL BW and 10-dB RL BW, this three significant parameters will be taken account to find out the structure for the low pass filter with the best, reliable and remarkable efficacy.

A. Only Dumbbell Annular Ring (DAR) structure on T-Line:

As can be seen from Fig. 1(a), the proposed filter have ten dumbbell annular ring (DAR) EBG elements with 0.25 FF, arm width and height of the structure are 113 and 10 mil respectively. But, like the Fig. 1(b), no other (namely, circular) pattern EBG element are etched on the 50Ω transmission line. However, by the Tschebycheff polynomial for 25-dB SLL not only the dimension of the DAR will vary but also spacing between each DAR will also fluctuate accordingly. As a result, spacing between two DAR will increase with Tschebycheff distribution However, the coupling between each element is strong which results in sharp selectivity. Although the structure is symmetric, but the capacitive coupling between each of the dumbbell annular ring are unbalanced and weak in compare with Fig. 1(b). To improve the overall coupling and bandgap properties, circular patterned EBG structures is utilized in between the DAR in Fig. 1(b).

TABLE II
PERFORMANCE COMPARISON BETWEEN DIFFERENT LPF

Filter Structures	Selectivity [dB/GHz]	Stopband isolation S_{21max} [dB]	Ripple Height [dB]
Ref. [3]	20.92	61.50	< 0.5
Ref. [5]	6.29	68.00	< 5
Ref. [6]	24.28	65.30	2
Only DAR	89.47	80.00	< 0.2
DAR with Circular	130.77	78.60	< 0.2

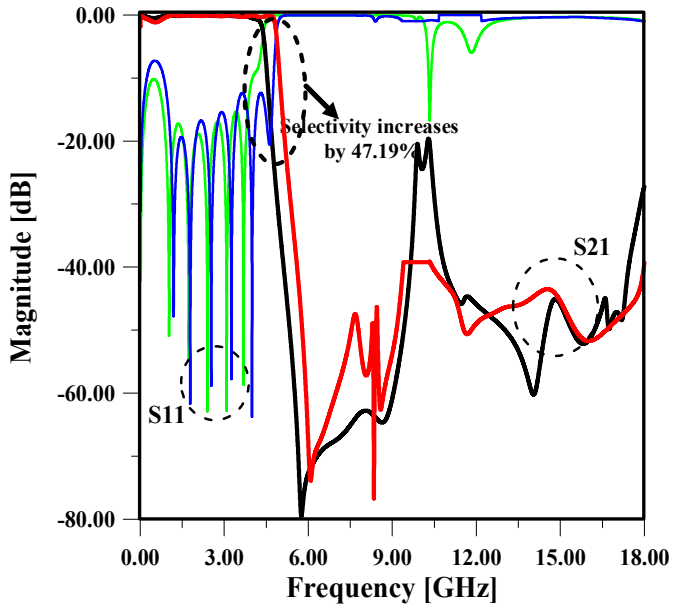

Fig. 4: Comparative study between two proposed low pass filters with Tschebycheff polynomial distribution; where, green-only DAR (S_{11}), black-only DAR(S_{21}); blue-DAR with circular (S_{11}), red- DAR with circular (S_{21}).

B. Dumbbell Annular Ring (DAR) with circular structure on T-Line:

As illustrated in Fig. 1(b), the proposed DAR assisted low pass filter have ten dumbbell annular ring EBG elements with 0.25 FF, arm width and height of the structure are 113 and 10 mil respectively. Likewise, nine circular patterns with the same volumetric ratio as annular ring, this EBG element with Tschebycheff distribution and same spacing between them like DAR are etched on the 50Ω transmission line. Moreover, in this design the dimension of DAR will also fluctuate in agreement with 25-dB SLL Tschebycheff polynomial. Consequently, the coupling between the patterns become stronger and balanced than design 1. Besides, the ripple in the stopband also diminishes with high rates of roll-off transfer function. Likewise, this hybrid design also prevails with very wide stopband with increased selectivity. In brief, DAR with circular pattern yields a unique combination, which constitutes more attractive bandgap properties in EBG structure.

IV. RESULTS

Modeling the low pass filters (LPF) by Tschebycheff polynomial distribution with hybrid patterns to realize the performance of the LPF is examined. As can be seen from Fig. 3(a), Fig. 3(b) and Table-I, it is found that, in Tschebycheff distribution with FR4 substrate for structure with only DAR and DAR with circular exhibit selectivity, 20-dB IL and 10-dB RL bandwidth of 89.47 dB/GHz, 6.25 GHz, 4.55 GHz and 130.77 dB/GHz, 12.97 GHz, 4.98 GHz respectively. However, FR4 is a lossy substrate at high frequency [7]. Nevertheless, the structure-1 displays negligible insertion loss in the passband with ripple less than 0.2 dB, great selectivity, well impedence matching upto 60 dB and very wide stop bandwidth upto 6.5 GHz. Besides, the structure-2 reveals very wide return loss bandwidth upto 5 GHz with ripple not greater than 0.2 dB, excellent matching, sharper roll-off and wider stop bandwidth upto 13 GHz. Although, in design-2, modeling is robust because of circular pattern are etched between the DAR on 50Ω transmission line. Also, the arm length of the annular ring fluctuates according to the Tschebycheff polynomial. Similarly, annular ring has a unique feature namely, aspect ratio which is equivalent of variable capacitance, so in design-2 exhibits profound performance than design-1. Observing the Table-I, design-2 has more stable passband performance with increase in 10-dB RL bandwidth as well as 3-dB cut-off frequency. At 11 GHz, design-1 exhibits poor performance in the stopband. With stronger coupling in design-2, this disturbance due to spurious transmission is alleviated. Consequently, the width and depth of the stopband increases. Besides, the maximum isolation of the stopband in design-1 is greater than design-2 with 1.75% increment. The width of the stopband has been expanded 107.52% in design-2 than design-1. As illustrated in Fig. 4, the selectivity in design-2 is sharper than design-1 with amount of 47.19%. Furthermore, from the observation of comparative study in Table II, performance of different low pass filters, it is appreciated that roll-off rates has been improved significantly with a minimum amount of 2.67 times by the proposed two structures. Moreover, the depth of the stopband is upto 80 dB and passband ripples is quite negligible. In conclusion, only DAR and DAR with circular patterns reveal more superior passband and stopband performance with Tschebycheff distribution respectively.

V. CONCLUSIONS

A new hybrid, wide stopband, low insertion loss and high selectivity microstrip low pass filter has been demonstrated. A low pass filter with hybrid structure namely, dumbbell annular ring (DAR) and circular is introduced. A new design was developed to increase not only the rate of roll-off transfer function but also the width of the stopband. However, with the hybrid design forming more stable capacitive coupling, the dielectric and radiation losses are reduced significantly. The consequence of that is, negligible

ripple in the passband with superior matching. The new low pass filters were designed to alleviate the low selectivity and small stop bandwidth in microwave communication.

***Abstract*— This paper presents dispersion flattened (DF) large mode area (LMA) fiber design based on single cladding structure using finite element method (FEM) with perfectly matched layer (PML) boundary. The modal properties of the PCFs are investigated due to change in cladding parameters. To improve these properties of PCF our proposed design has obtained satisfactory results especially for flattened dispersion, effective area and splice loss. It has been shown that proposed PCFs can obtain very low dispersion variation 0.3537 ps/(nm.km) along 1300nm to 1700nm wavelength, with both a large effective area more than 82 μm^2 and splice loss of 0.0040 dB in 1550nm wavelength. As the properties obtained from simulation are suitable for the C+L+U communication bands, our proposed design can be used within these bands with better performance.**

Keywords*— Photonic crystal fibers; ultra-flattened dispersion; large effective mode area; nonlinear coefficient; splice loss;

I. Introduction

Photonic crystal fiber (PCF) [1] has received increasing attention because of its novel optical characteristics [2]. Fiber-optic communication system has brought revolution in the telecommunication industry. It is advantageous in comparison with other communication system [3]. PCFs are characterized by numerous cladding air holes arranged in an orderly manner over the whole fiber length [4]. As there are several parameters to tailor in a PCF, it can be utilized to obtain very useful properties like flat negative dispersion [5], large mode effective area [6], very high or very low nonlinearity [7], splice loss [5] and low bending loss [5]. By modulating the parameters of holey cladding, the above properties can be controlled [7]. Because of high attenuation of these types of fibers, PCFs are still under investigation as high-speed optical transmission media but recently, the attenuation level has been lowered to the order 0.28 dB/km at the 1550 nm wavelength [8]. This has encouraged the researchers to rethink the applicability of PCFs in signal transmission and modern fabrication technology is giving momentum to such thinking.

Optical transmission systems require PCFs with large effective mode area is required not only to support broadband optical transmission but also to minimize the coupling losses to standard single mode fibers (SMFs) [7]. To design large mode-area (LMA) fibers, it is desired that fibers should remain single-mode (SM) to ensure the high beam quality, which is measured through beam quality factor $M2$ (<1.2) for diffraction limited operation [9]. Again, in communications systems dispersion-flattened fiber (DFF) is very effective for optical data transmission over the broadband wavelength range [10]. For example, in wavelength division multiplexing communication systems it is essential to maintain a uniform response in different wavelength channels. This is strictly achieved by ensuring ultra-flattened dispersion characteristics of fibers [7]. Splice loss and nonlinearity are other important key factors for designing PCF. When connecting two fibers using splicing technique, geometrical misalignments occurs that leads to losses known as splice loss. Controlling the splice loss of the fiber, it will be of great use in fiber to the home (FTTH) application [11]. The nonlinearity of a fiber depends on effective area and it is inversely proportional to the effective area of the fiber. There are so many literatures dealing with large mode effective area with flattened dispersion [2,7], [12-14]. Some of which even warrant low splice loss [7], [11] as well. There are only a few papers dealing with PCFs having LMA, dispersion-flattened characteristics, low splice loss and nonlinearity at the same time.

Pourmahayabadi *et al*. [13] have proposed such an LMA PCF in 2009. They have theoretically achieved dispersion variation 1.75 ps/(nm.km) in 1.53μm to 1.57 μm wavelength but their effective area is only 20.0535 μm^2. Razzak *et al*. [7] have proposed another MOF LMA PCF design in 2010. They have theoretically achieved effective area of more than 150 μm^2 with dispersion variation 0.6 ps/(nm.km) in 1.4μm to 1.7μm wavelength and a splice loss of 0.19 dB. The PCF proposed in [7] and [13] have not mentioned about nonlinearity of their designs.

In this paper, we propose a two layer cladding PCF characterized by a common pitch and three different air-hole dimensions. The whole work aims at designing and numerical simulating the large mode effective area, flattened dispersion, low splice loss and low nonlinearity photonic crystal fiber. PCFs with such novel properties are suitable for telecom applications.

II. Numerical Analysis

The key propagation properties of the PCF are evaluated using Finite Element Method (FEM). The FEM directly solves the Maxwell equations to best approximate the value of the effective refractive index [15-16]. A commercial full-vector

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

finite-element software (COMSOL) has used for both the modal and loss analyses. To allow accurate evaluation of the insertion losses, anisotropic perfectly matched layer has included in the finite-element model. We have also used Sellmeier equation to evaluate the refractive index of silica. Following equations are used to evaluate dispersion D, effective area A_{eff}, nonlinear coefficient γ and splice loss L_s. The main concern of this paper is to obtain ultra flattened and low dispersion variation, large effective area, low nonlinearity and low splice loss. The dispersion D with respect to λ is given by

$$\text{Dispersion, } D(\lambda) = -\frac{\lambda}{c}\frac{d^2}{d\lambda^2} R_e[n_{eff}] \quad (1)$$

Here, $D(\lambda)$ is in ps/(nm km) and $Re[n_{eff}]$ is the real part of the effective refractive index n_{eff}. The material dispersion is directly included in the FEM calculation. The effective area A_{eff} is given by

$$\text{Effective area, } A_{eff} = \frac{\left(\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}|E|^2\,dxdy\right)^2}{\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}|E|^4\,dxdy} \quad (2)$$

Where, E is the electric field distribution and A_{eff} is in μm^2. The study of A_{eff} is, thus, an important starting point in understanding of the nonlinear phenomena in PCFs.

$$\text{Nonlinear coefficient, } \gamma = \left(\frac{2\pi n_2}{A_{eff}\lambda}\right)\times 10^3 \quad (3)$$

Where, n_2 is the nonlinear refractive index for silica. The nonlinear coefficient is inversely proportional to the effective mode area. The splice loss can be obtain from the following:

$$\text{Splice loss, } L_s = -20\log_{10}\frac{2w_{SMF}w_{PCF}}{w_{SMF}^2 + w_{PCF}^2} \quad (4)$$

Where, w_{SMF} and w_{PCF} are the (Mode Field Diameter) MFDs of the (Single Mode Fiber) SMFs and the PCFs, respectively.

III. Geometry of The MAC-PCF Design

We have proposed two hexagonal geometrical designed PCFs and both are arranged 8 air hole rings in the cladding region with silica background.

A. MAC-PCF-1

Fig. 1 shows our proposed MAC (Multiple Air holes Core) -PCF-1 design. The design has two layer cladding is composed of a common air-hole pitch, Λ_1. It has three different air-hole diameters d_c, d_1 and d_2, where d_c is less than d_1 and d_2 is greater than d_1. Dimension of the first ring is lowered down to flatter the dispersion characteristics and air-holes of inner rings are chosen smaller to achieve larger mode area. Moreover, five air holes having diameter d_c are placed in the core to obtain large effective area using smaller pitch. The pitch among five air holes is in the core by the relation (Λ_1*0.5). The air hole diameter of 1st four rings is d_1 and 2nd four rings are d_2.

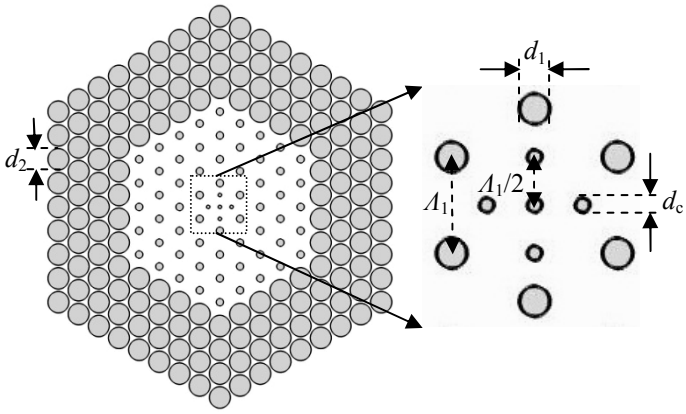

Fig. 1. Design of MAC-PCF-1.

B. MAC-PCF-2

Fig. 2 shows our another proposed MAC (Multiple Air holes core)- PCF-2 design. The design has also two layer cladding is composed of a common air-hole pitch, Λ_2. It has three different air-hole diameters d_c, d_1 and d_2, where d_c is less than d_1 and d_2 is greater than d_1. Like previous design, five air holes having diameter d_c are placed in the core to obtain large effective area using smaller pitch. The pitch among five air holes is in the core by the relation (Λ_2*0.5). In MAC-PCF-2 design diameter of all the air holes is kept d_1 except 5th ring having air hole diameter d_2 in fig. 2. As a result we have obtained almost same effective area and more flattened dispersion curve but using lower pitch in Fig. 1 than Fig. 2.

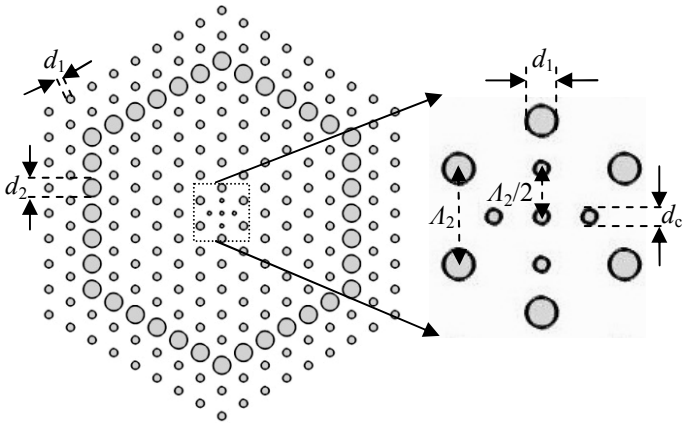

Fig. 2. Design of MAC-PCF-2.

IV. Simulation Results

Fig. 3 shows the optical field distribution for both x and y polarization at 1550 nm wavelength of MAC-PCF-1 and MAC-PCF-2. It is seen that the optical field is well confined to the outer side of the core due to the presence of air holes in the core region which increases the effective area.

Fig.4 shows the wavelength dependence of dispersion variation of the proposed two designs for y-polarized mode respectively with optimum design parameters. In MAC-PCF-1, we set pitch, Λ as 3μm, d_c=0.225 μm and d_1=0.5025 μm, d_2 = 1.35 μm. But in MAC-PCF-2, we set pitch, Λ as 2.5μm, d_c=0.1875 μm and d_1=0.39375 μm, d_2 = 0.875 μm. In Fig. 3,

MAC-PCF-1 shows almost flattened dispersion for y-polarization from 1500 nm to 1700 nm wavelength but MAC-PCF-2 shows more flattened dispersion than MAC-PCF-1 for y-polarization from 1300 nm to 1650 nm wavelength.

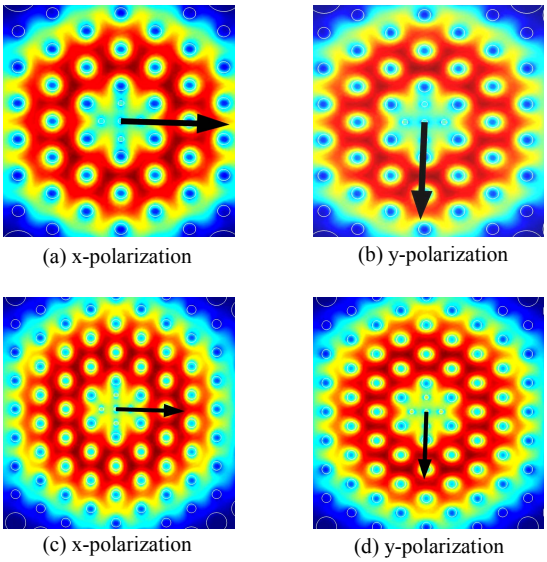

Fig. 3. Optical field distribution at 1550 nm wavelength of MAC-PCF-1 (a) &(b) and MAC-PCF-2 (c) & (d)

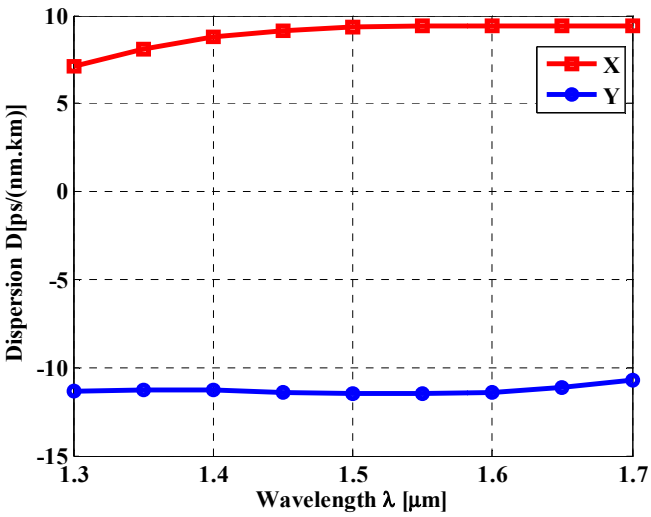

Fig. 4. Dispersion for optimum parameters of MAC-PCF-1 and MAC-PCF-2.

Fig 5(a) and 5(b) show the Effect on dispersion of pitch *Λ* variation in MAC-PCF-1 and MAC-PCF-2. The MAC-PCF-1 and MAC-PCF-2 show dispersion variation of 2.32 and 0.3537 ps/(nm.km) respectively from 1300 nm to 1650 nm wavelength.

The effective area or simply the effective area is the area where the beam intensity drops to 13.5% of the maximum value and the diameter of which is called the mode field diameter (MFD). Fig. 6 shows wavelength dependence of effective area of MAC-PCF-1 and MAC-PCF-2. We have obtained 82.88 μm^2 in MAC-PCF-1 and 83.45 μm^2 in MAC-PCF-2 at 1550 nm wavelength which is very high compared to that of conventional fiber. The PCFs with flattened dispersion and relatively high effective area would be useful to support broadband optical transmission and also in wavelength division multiplexing systems. Fig 7(a) and 7(b) also show the effect on effective area of pitch *Λ* variation in MAC-PCF-1 and MAC-PCF-2.

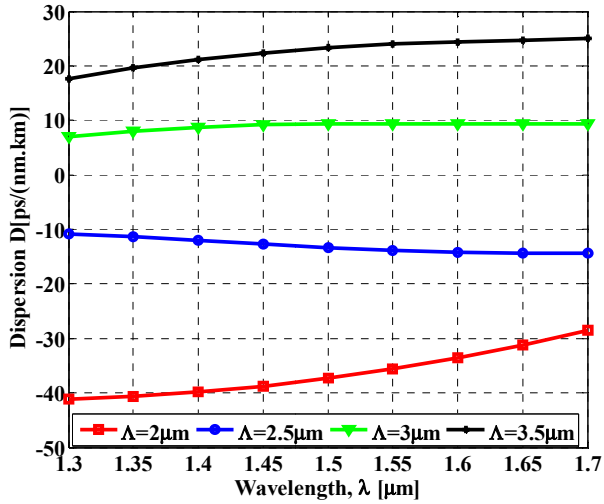

Fig. 5(a). Effect of dispersion of pitch *Λ* variation in MAC-PCF-1.

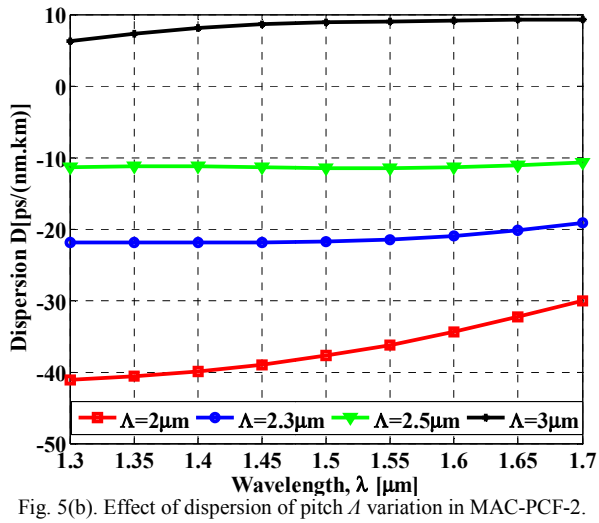

Fig. 5(b). Effect of dispersion of pitch *Λ* variation in MAC-PCF-2.

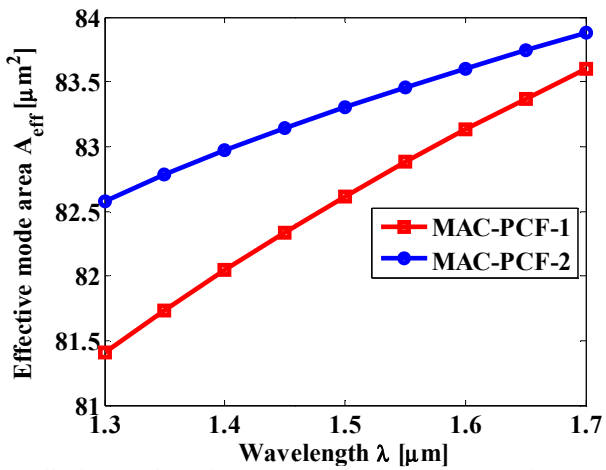

Fig. 6. Effective area for optimum parameters of MAC-PCF-1 and MAC-PCF-2.

One can observe from Fig. 5(a) & 5(b) and Fig. 7(a) & 7(b) that the flattened dispersion curve cannot be obtained for large effective area.

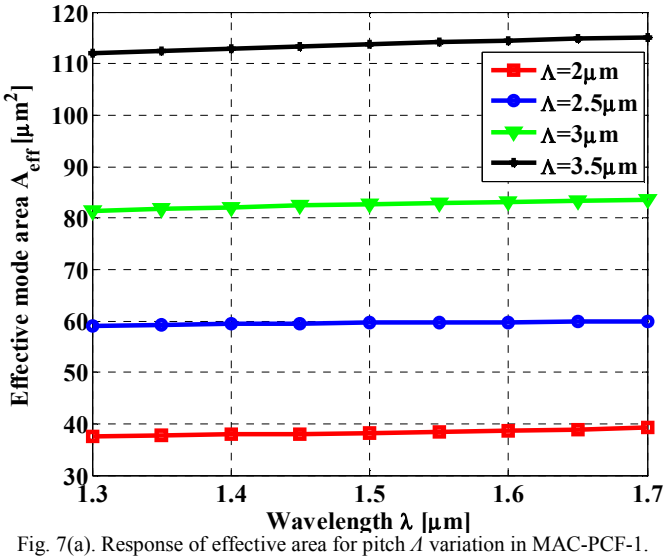

Fig. 7(a). Response of effective area for pitch *Λ* variation in MAC-PCF-1.

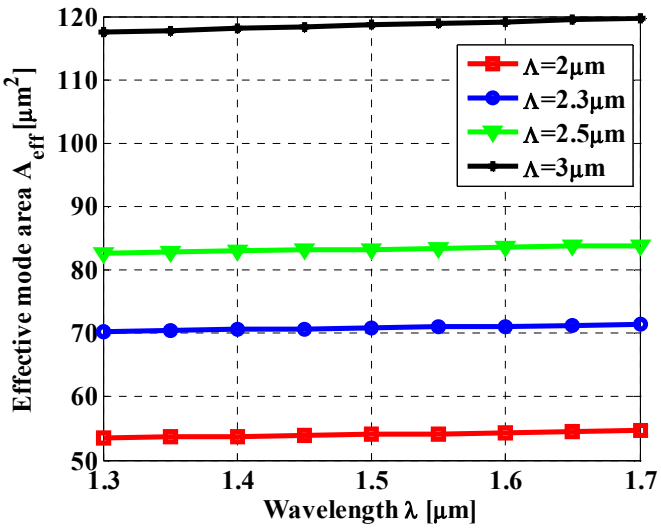

Fig. 7(b). Response of effective area for pitch *Λ* variation in MAC-PCF-2.

The nonlinear coefficient of PCFs depends on the value of the nonlinear refractive index and the effective area of the PCF. A lower value of the effective area gives a higher nonlinear coefficient and vice-versa as the value of n_2 is constant for silica PCFs. One can see from Fig.8 the MAC-PCF-2 has very low nonlinear coefficient than MAC-PCF-1. The MAC-PCF-2 design shows maximum effective area at wavelength 1550 nm than MAC-PCF-1.

The splice loss is a very important design consideration for single mode fibers. When coupling two similar fibers or a PCF with a single mode fiber (SMF) using the splicing techniques, a mismatch occurs due to the dissimilar MFD or geometrical misalignments during the fusion process that leads losses known as the splice loss. We have obtained 0.0031 dB in MAC-PCF-1 and 0.0040 dB in MAC-PCF-2 at 1550 nm wavelength in Fig. 9. By controlling the splice loss of the fiber, it will be of great use in these telecommunication applications.

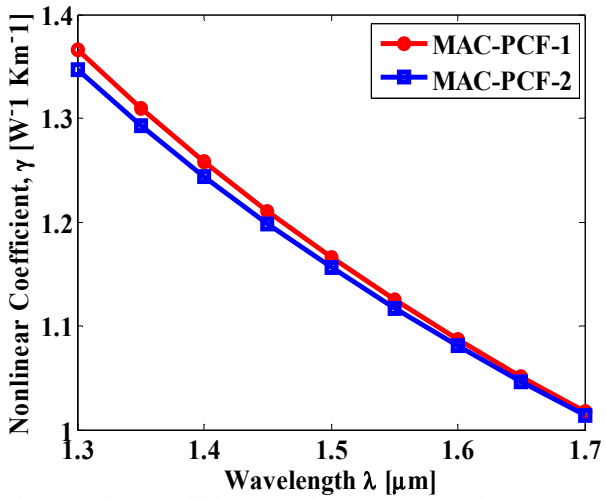

Fig. 8. Nonlinear coefficient for optimum parameters of MAC-PCF-1 and MAC-PCF-2.

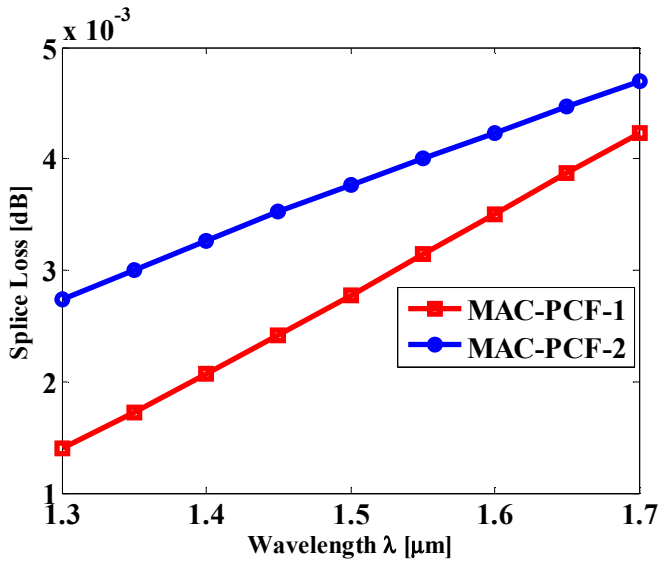

Fig.9. Splice loss for optimum parameters of MAC-PCF-1 and MAC-PCF-2.

V. COMPARATIVE STUDY

Finally a comparison is given in table I between properties of the designed PCFs and existing PCFs. It is clear from table that the four-ring photonic crystal fiber (PCF) structure addressed in [12] has low variation in dispersion curve over the telecommunication band but area is too low. Our proposed designs are better than four-ring (PCF) structure [12]. Our effective area is not so high than DF-PCF [2] but they mention about their dispersion variation only for 1.53μm to 1.57 μm and high splice loss. The large effective mode area microstructure optical fiber [7] has better effective area than ours but the splice losses of our designs are better than the microstructure optical fiber [7]. At the last though the large mode area (PCF) [13] has low dispersion variation but their area is poor and there is nothing about splice loss.

TABLE I. COMPARISON OF PROPOSED PCF DESIGN WITH THE EXISTING PCF.

PCFs	effective area in μm^2	D(Λ) ps/(nm.km)	Dispersion variation ps/(nm.km)	Splice loss dB
Ref [2]	80	4.7	<0.8 in 1.53μm to 1.57 μm	1.6
Ref [7]	122	-27.2	0.6 in 1.4μm to 1.7μm	0.19
Ref [12]	13.2	-	±0.25 in 1.295μm to 1.725 μm	-
Ref [13]	20.05	38.4	1.75 in 1.53μm to 1.57 μm	-
MAC-PCF-1	**82.88**	**9.18**	**2.32 in 1.3μm to 1.7 μm**	**0.0031**
MAC-PCF-2	**83.45**	**-11.50**	**0.3537 in 1.3μm to 1.7 μm**	**0.0040**

VI. CONCLUSION

In this paper, light guiding properties of PCF have been investigated based on FEM method with PML boundary for telecommunication and wavelength-division multiplexed (WDM) communication systems. The design of air hole(s) in the core of PCF which carrying flattened dispersion in the telecommunication band is investigated. This design offers large mode area with low splice loss. This fiber is easy to fabricate due to its hexagonal design. The proposed MAC-PCF-2 offers very low dispersion variation 0.3537 ps/(nm.km) for 1300nm to 1700nm wavelength and MAC-PCF-1 offers very low splice loss of 0.0031dB in 1550nm wavelength. So both PCFs can be used for specific applications.

***Abstract*—The emergence of nano-electromagnetic communication becomes appealing for potential applications in nano-scale Body Area Network (BAN). In this work a new energy aware communication model for nano-electromagnetic communication in Terahertz (THz) Band is developed based on clustering scheme for the performance improvement of BAN. The proposed conceptual network model is used to determine channel capacity. A closed-form expression for outage probability is also derived. The approach is extended to determine outage capacity for maintaining a constant rate with a specified outage probability. Simulation shows that in term of outage capacity, proposed scheme outperforms the random forwarding scheme.**

***Index Terms*—Nanotechnology, Body Area Network, Cluster, Terahertz, Outage Capacity.**

I. Introduction

Nanotechnology emerges as a promising paradigm to manupulate matter at a subatomic or nanometer level. At this level, the most basic functional unit is nano-machine which is capable of performing tasks like computing, storing, sensing or actuation. Typically such nano-machines are integrated devices around 10-100 μm^2 in size. Based on applications, multitudes of different nano-devices are used [1]. Interconnected nano-machines form nano network and execute collaborative tasks in a distributed manner. Existing electronic devices are scaled down from micro to nano domain in top-down approach. In bottom-up approach, molecular components are used to realize nano-machines. The bio-hybrid approach develops nano-machine by using biological elements as patterns to be replicated with systhesized component.

In recent years, the breadth of potential applications have been expanded tremendously with the advancement of nanotechnology. First, in the biomedical domain, nanomaterials are currently used in human body to monitor glucose, sodium and cholesterol, i.e. , in health monitoring, to support immune system, drug delivery system, to detect presence of infectious agents or to identify specific types of cancer [2]. Another domain is responsible for revealing the complexity of the induced defense signaling networks of plants by deploying molecular and genomic tools, controlling biodiversity, assisting biodegradation [3]. Again, in military and defense applications, nanotechnology can be deployed in advanced nuclear, biological and chemical (NBC) defenses and sophisticated damage detection systems for surveillance etc. Finally, in industrial domain, nanomaterials can be used for self-cleaning anti-microbial textiles, manufacturing processes and quality control procedures [1][4].

To be used in multiple nano-scenarios, classical communication paradigms need to undergo a profound revision. Based on the used transmission medium, different communication techniques - acoustic, nanomechanical, molecular and electromagnetic (EM) communication paradigms are proposed in literature [5]. At nano level, acoustic communication implies the integration of ultra-sonic transducers in nanomachines and transmission of information through acoustic energy such as pressure variations [1]. Nanomechanical communication is modeled by transmitting information through hard junctions between transmitter and receiver. In molecular communication, molecules with encoded information move as carriers from transmitter nanomachine to receiver nanomachine in a bio-inspired fashion. In EM communication, novel nanomaterial based components are used to modulate and demodulate electromagnetic waves. In acoustic communication, radio frequency transceivers and acoustic transducers represent a major barrier in integration at nanoscale because of their size. The nanomechanical communication holds the drawback by requiring physical direct contact between transmitter and receiver nanomachines. Most promising approaches for nanotechnology are therefore molecular and EM communication.

Recent advancements in Terahertz (0.06 - 10 THz) Band communication has opened the door to a new generation of nano-electromagnetic communication. Network, operating in THz Band promises new solutions for vast areas of applications such as health monitoring, military biochemical weapons monitoring, agricultural plant monitoring etc. As many molecules have resonance frequencies within the THz band, THz radiation may exploit the advantage of penetration of many opaque materials and the high selectivity, enabling their detection when they are present [6].

Health care is one of the fundamental right and thus it gets more attention for the researchers to developed energy efficient, low cost, simple, scalable e-Health solution. Espe-

978-1-4673-9257-0/15/$31.00©2015 IEEE

cially due to population aging, health care has to be made affordable in the future.With the increasing demands in body-area applications, current candidate systems have difficulties in performing consumer electronic device functions and health care application at the same time. Personal health monitoring is increasingly important to detail changes of our health status. A new emerging paradigm is the use of body area network of nano sensors based on THz Band in health care application. It is important to understand the limits of EM power exposure that human body can sustain without any crucial biological damages.

An energy efficient forwarding scheme at nano level is proposed in this paper to improve the performance of body area network so that it can facilitate e-Health application. The remainder of the paper is organized as follows. Related works on existing scheme is presented in section II. System model is presented in section III. Section IV and V includes channel behaviour model and simulation results respectively. And finally the work is concluded in section VI.

II. Literature Review

It is imperative to develop new and efficient communication and networking techniques to overcome unique challenges and requirements of nanonetworks.

Interconnecting nanoscale communication networks to the wider internet extends the Internet of Things to the Internet of Nano Things (IoNT). A reference architecture of IoNT was introduced in [7]. THz Band was considered for nano electromagnetic communication. Again, major research challenges in terms of channel modeling, information modulation and protocols for nanonetworks were highlighted from the communication and information theoretic perspective. For intrabody disease detection, a wireless nanosensor network at nanoscale was proposed in [8] as an application of IoNT. From the energy efficient point of view, proposed hexagonal cell based nanosensor network was analyzed for data transmission efficiency exploiting the hybrid, direct and multi-hop methods. A new energy efficient clustering of sensor nodes in ad hoc sensor networks was presented in [9] which guaranteed the fairly uniform cluster head distribution across the network.

Electromagnetic (EM) communications among nano-devices over the THz Band was focused in [10] with a view to developing a physical channel model. Developed propagation model was used to investigate signal path loss, molecular absorption noise and channel capacity of EM network.

In [11], Wireless Nano Sensor Network (WNSN) based on electromagnetic communication in THz Band was used to develop a new routing algorithm along with an efficient MAC protocol for communication. Focusing the attention on a WNSN operating in a health monitoring scenario, network behaviour was investigated. [12] is another approach where a new communication scheme for electromagnetic WNSNs was presented to evaluate the performance in terms of information capacity for single user case as well as aggregated network capacity for multi user case. In [13], performance of multi-hop links were analyzed and SER and outage probability were approximated based on end-to-end signal-to-noise ratio (SNR).

To better characterize the performance of channel, [14] is another approach where outage capacity was maximized over cut-off fading states for wireless channels. Authors assumed that both transmitter and receiver had full channel state information (CSI).

III. System Model

A. Assumptions and network Modeling

We assume that a network of nano sensor nodes are implanted on human body to construct a body area network. We assume that all nodes are constrained in energy. The proposed system architecture is shown in fig. 1.

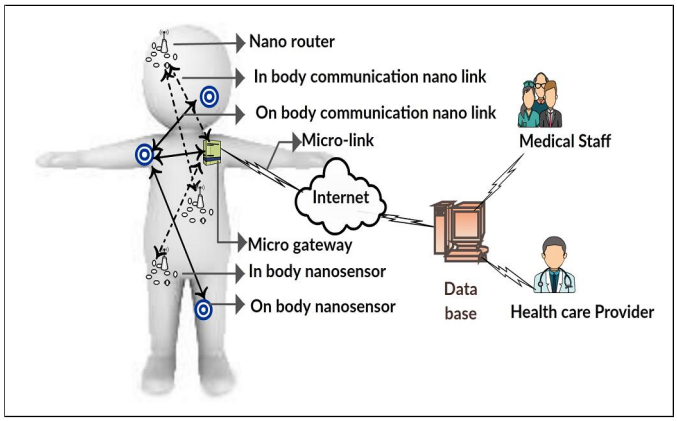

Fig. 1. A possible Scenario

The communication is considered to take place from inside of the body to the outside of the body through nano sensor nodes. Nano routers deployed in in-body communication to aggregate information coming from in-body nano sensors. Micro-gateway a wireless interface connection nano sensors to internet is used to collect data and forward them to the health care provider and medical staff.

B. Cluster Composition:

Clusters are formed to maintain efficient connectivity among deployed nano sensors. The proposed technique uses residual energy, denoted by $E_{residual}$, and packet forward ratio, denoted by PFR, to choose the cluster coordinator, CC. At first $E_{residual}$ of n nano sensors will be checked and among them m nodes having greater $E_{residual}$ from a certain threshold value will be selected as participants in cluster constellation. From m nano sensors the node with X_{max} will be selected as CC, where

$$X_i = \frac{1}{2}\left\{\frac{PFR_i}{PFR_{max}} + \frac{E_{residual_i}}{E_{max}}\right\} \qquad i = 1, 2, \cdots m. \quad (1)$$

Elected CC will broadcast short range advertisement message to remaining $(m-1)$ nano nodes. Active nano sensors having higher $RSSI$ will send join request to elected CC and register them as cluster member, CM. Similar process will be continued among rest of the nodes to form clusters. Re-clustering will be done periodically for distributing load

uniformly among all nodes. Fig. 2 is the cluster-based scenario of our proposed scheme.

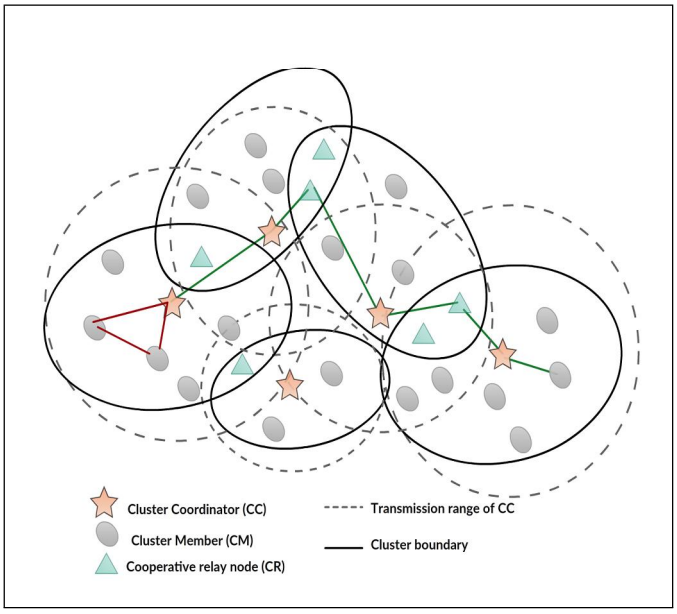

Fig. 2. A possible cluster-based Scenario

C. Communication Framework:

Communication framework is consisting of intra-cluster and inter cluster communication. Intra-cluster communication involves CC and CMs in communication. Energy efficiency is taken as a measure of extent to conduct communication. We assume that $E(d_{ik})$, $E(d_{ij})$ and $E(d_{jk})$ denote energy bit consumption through direct link ik, via link ij and jk respectively(figure 2). If equation (2) is satisfied, then data will transmitted directly to CC. Otherwise CM will use single-hop to reach CC.

$$\exists(d_{ij}, d_{jk})\{E(d_{ij}) + E(d_{jk})\} > E(d_{ik}), \tag{2}$$

where d_{ij} is distance between node i and j.

Cluster coordinators of different clusters conduct inter cluster communication. Cooperative relay nodes (CR) act as cluster gateways to conduct communication when CCs are out of transmission range of one another and operate under decode-and-forward (DF) cooperative strategy [15]. Flow chart of communication framework is depicted in fig. 3.

IV. Channel behavior Model

Nano-electromagnetic communication through human tissue suffers from frequency selective path loss and several attenuation due to shadowing and molecular absorption.

The absorption loss, A_m, is attenuation due to the molecular absorption. The type of molecular composition of the medium and concentration make it vary from medium to medium. A_m can be derived from Beer-Lambert law as [10]:

$$A_m(f, d_{i,j}) = \frac{1}{\tau} = e^{K(f)d_{i,j}}. \tag{3}$$

Here $K(f)$ stands for molecular absorption coefficient, f is frequency, τ is the transmittance of medium and $d_{i,j}$ is the distance between nanosensor i and j.

As our considered medium human body, the value of $K(f)$ for human body,$K(f)_{HB}$ is calculated as weighted average of different absorption coefficients of water molecules spreading over it in [16].

While propagating through human tissues, the expanded wave experiences attenuation named spreading loss, denoted by A_s [17].

$$A_s(f, d_{i,j}) = \left(\frac{4\pi f d_{i,j}}{c}\right)^2. \tag{4}$$

Here, c stands for speed of light in vacuum.

In THz band, transmission range of nano devices is limited due to large spreading loss. Shadowing occurs during transmission of signal between transmitter and receiver. Considering transmitted power, P_t from source, the received power, P_r at destination due to shadowing can be written as,

$$P_r(i,j) = P_t(i) G d_{i,j}^{-\eta} X_{i,j}, \tag{5}$$

where,

$X_{i,j}$	=	$10^{\frac{\xi_{i,j}}{10}}$ which represents log-normal random process representing the effect of shadowing,
$\xi_{i,j}$	=	Normal distributed random variable with zero mean and standard deviation σ
G	=	Constant representing the mean value of received power at distance $d_{i,j}$ from transmitter
η	=	Path loss exponent

Total received power in dB at destination due to molecular absorption, spreading and shadowing can be written as,

$$P_{total}(i,j) = P_r(i,j) - A_m(f, d_{i,j}) - A_s(f, d_{i,j}) \tag{6}$$

The interference power, P_I, can be expressed as,

$$P_I(k,j) = \sum_{k\epsilon(n:n\backslash i)} P_r(k,j) - A_m(f, d_{k,j}) - A_s(f, d_{k,j}) \tag{7}$$

If Signal to interference plus noise ration (SINR) of j hops are denoted by $\gamma_1, \gamma_2, \cdots, \gamma_j$ respectively, then γ_j can be computed from (8).

$$\gamma_j = \frac{P_{total}(i,j)}{P_I(k,j) + N(f, d_{k,j})}. \tag{8}$$

Here $N(f, d_{k,j})$ is Additive White Gaussian Noise.

Path loss due to shadowing in molecular level follows log-normal distribution. So, γ_j follows log-normal distribution under log normal shadowing .The probability density function (PDF) of γ_j is then given by

$$f_{\gamma_j}(\gamma) = \frac{1}{\gamma_j}\frac{\varepsilon}{\sigma\sqrt{2\pi}} exp - \left[\frac{(10\log_{10} - \mu)^2}{2\sigma^2}\right]. \tag{9}$$

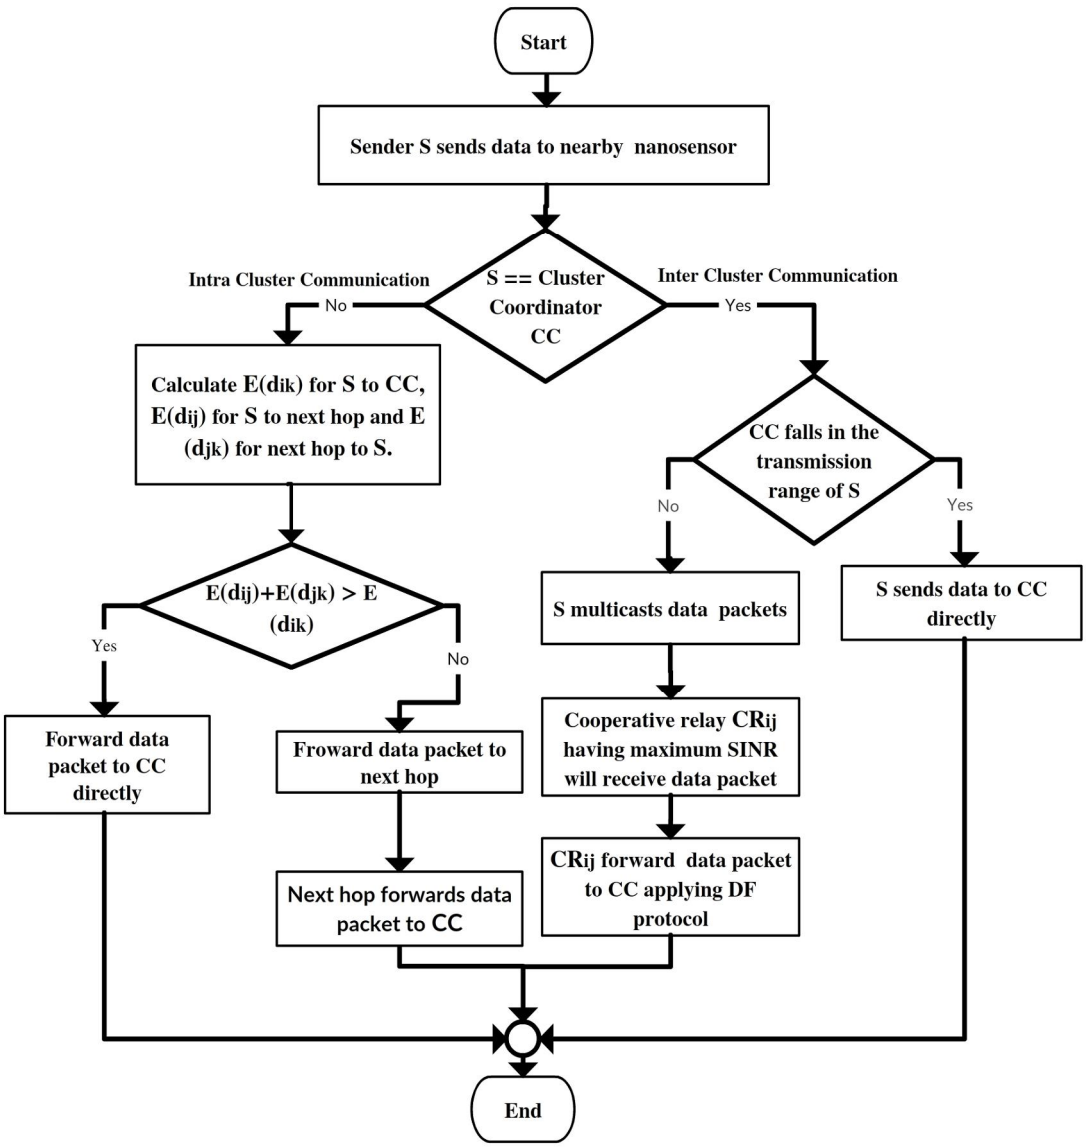

Fig. 3. A flow chart of Communication Framework

The probability that system can be in outage, denoted by P_{out}, is designed based on a certain specified threshold γ_{th} and can be expressed as [18]:

$$\begin{aligned} P_{out} &= Pr(\gamma_j < \gamma_{th}) \\ &= \int_0^{\gamma_{th}} f_{\gamma_j}(\gamma) d\gamma_j \\ &= \int_0^{\gamma_{th}} \left[\frac{1}{\gamma_j} \frac{\varepsilon}{\sigma\sqrt{2\pi}} exp - \frac{(10\log_{10}\gamma_j - \mu)^2}{2\sigma^2} \right] d\gamma_j \\ &= \int_0^{\gamma_{th}} \left[\frac{1}{\gamma_j} \frac{\varepsilon}{\sigma\sqrt{2\pi}} exp - \frac{1}{2}\Big(\frac{10\log_{10}\gamma_j - \mu}{\sigma}\Big)^2 \right] d\gamma_j \\ &= \frac{a\varepsilon}{\sigma} \times \left[1 - \frac{1}{2} erfc\Big(\frac{a\ln\gamma_{th} - b}{\sqrt{2}}\Big) \right] \end{aligned}$$

$$\text{where, } a = \frac{10\log_{10} e}{\sigma} \quad \text{and} \quad b = \frac{\mu}{\sigma}.$$

Here, (10) characterises cumulative density function (CDF) of γ_j.

It is shown in [10] that, a summation of capacity of each narrow sub-channel states THz channel capacity. Given PDF, $f_{\gamma_j}(\gamma)$, of γ_j, the capacity of channel, denoted by C, can be obtained from

$$C = \int_0^{\infty} B\log_2(1+\gamma_j) f_{\gamma_j}(\gamma) d\gamma_j \quad b/s. \tag{10}$$

Where, B is the bandwidth of each sub-channel.

Outage capacity determines the constant data rate in non-outage fading states subject to a given P_{out} and it can be

defined as:

$$C(P_{out}) = B\log_2(1+\gamma_j)(1-P_{out}). \quad (11)$$

V. Simulation Results

The performance evaluation of proposed cluster based forwarding scheme for Body Area Network using nano-electromagnetic communication is investigated in this section. The joint effects of path loss and shadowing have been considered for the simulation. In this paper, the Monte Carlo simulations have been performed for outage capacity analysis. Fig. 4 shows the BPSK and QPSK constrained outage capacity

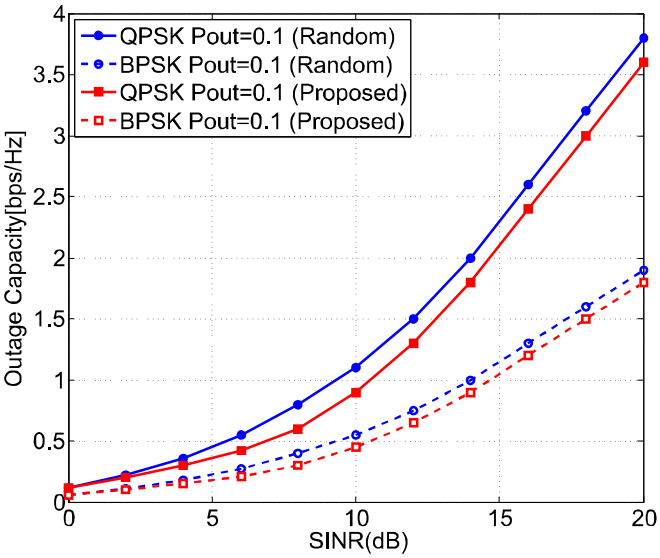

Fig. 4. Outage capacities for BPSK and QPSK

as a function of SINR in dB with 10% outage probability. For the given P_{out}, fig. 4 shows that, with BPSK values $C_{(p_{out})}$ is approximately $1.9bps/Hz$ and for QPSK it increases to $4bps/Hz$. In both cases, the proposed scheme outperforms random scheme.

Fig. 5 shows the performance comparison of outage capacity values obtained from the proposed expression and from Monte Carlo simulation. For simulating, outage capacity is considered as a function SINR for different values of outage probability. The results show that the proposed energy efficient cluster based forwarding scheme outperforms the random forwarding scheme.

VI. Conclusion

This work has proposed an energy efficient routing scheme for THz based nano-scale communication with a view to improving the performance of BAN. Link SINR has been calculated based on joint impact of shadowing, molecular absorption attenuation and spreading loss. Outage probability and outage capacity have been considered as performance metric for proposed scheme. Simulation results show that proposed scheme outperforms random forwarding scheme.

Graphene nanoribbon based Antenna For Terahertz Band Communication

Sakib Adnan[1],Md.Osman Goni[2]
Department Of Electronics & communication Engineering
Khulna University of Engineering & Technology, Khulna 9203, Bangladesh
{sakibadnan7[1], osmanhku[1]}@gmail.com

***Abstract*—Nanotechnology has enabled the use of nano-sized devices for various purposes i.e. biological, industrial, and military and especially in communication field. By using graphene the antennas can be implemented in nano scale. And the miniature antennas would work more efficiently then the conventional antennas. The miniature device can transmit data in terabyte scale. Conventional antennas would require very high frequency which is quite unfeasible. But the slower movement of electrons in graphene would enable the grapheme nano antennas to operate at a feasible frequency.[1][2].In this paper we designed, Graphene nano ribbon based antenna that would operate in terahertz band and investigatedits radiation characteristics in the 2.45-2.98 THz band. The proposed antennas are also compared with the conventional antennas operating in terahertz band. The antenna is simulated by using the finite element method based simulator -CST (computer simulation technology).**

Keywords—Nanoantennas,Graphene,nanoribbon,Terahertz band ,Patch antenna.

I. INTRODUCTION

Communication among the nano scale devices is an unsolved challenge.The main obstacle to solve this problem is that when we do the miniaturization of conventional antennas that would require very high radiating frequency. This is unfeasible because the power of the nano scale devices are very low[1].Again miniaturization process of transceiver at these very high frequencies is still an unsolved problem. Moreover, intrinsic material properties of common metals remain unknown at the nano scale [7][9]. The use of nanomaterial to fabricate miniature antennas can help to overcome these limitations[2][8]. Due to micro cracks, the metallic antennas can't transmit properly in the terhertz band. And for that reason graphenenano ribbon based antennas are more efficient than the metallic antennas in nano scale. In graphene, the carrier mobility is mainly limited by the acoustic phonon scattering of the graphene lattice and it is referred to as the intrinsic carrier mobility. Graphene offers a new approach to THz communications because of its ability to support the propagation of Surface- Plasmon Polariton (SPP) waves in the terahertz frequency band[17][18] .In this paper we discuss about the designing process of the GNR based antennas and the radiation characteristics of these antennas in terahertz band.

II. NANO ANTENNAS

Nano systems cannot be accomplished by simply decreasing the length of these metal antennas mainly because that could enforce the use of extremely high resonant frequencies within the optical array. The possibility regarding nano networks could be affected in the event that this approach ended up used because of:

• The very low limited power used in this Nano systems.

• The low electron mobility in metals where Nano scale structure are considered.

These problems occur at nano transceivers to operate at such a high frequency [4].

III. GRAPHENE BASED NANO-ANTENNA THEORY

Graphene is the building material of carbon nano tubes (1991) and grapheme nano ribbons (2004)[3].

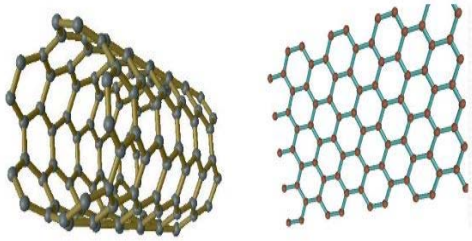

Figure 1. Carbon Nano tube (left), graphene Nano ribbon (right)

The two main important theories that are important for graphene based Nano antenna. First one is that nano patch antennas can be manufactured by graphene. And the second one is that there are several quantum effects that alter the propagation of electromagnetic waves in grapheme[3].

Initial resonant frequency along with the feedback resistance connected with graphene-based nano-patch and nano-dipole antennas acquired seeing that perform on the antenna size, edge geometry and strength[5]. Some sort of GNR can be used for any nano-patch antenna the 2-D antenna whilst CNT employed for the nano-dipole antenna virtually the 1-D antenna. New atomically accurate types will be achievable in the near future[6].

IV. ANTENNA DESIGN EQUATION AND SIMULATION TOOL

A. Microstrip Rectengular Patch antenna at 2.6 THz:

To simulate the graphene based antenna we at first design a micro strip patch antenna has resonant frequency of 2.6THz.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

The length and width of the antenna depends on the following equations [10] given below:

Antenna length and widthfor rectangular patch antenna,

$$L = \frac{c}{2f_r}\left(\frac{1}{\sqrt{\varepsilon}}\right) \quad (1)$$

Where, f_r=resonance frequency

The width of the patch antenna,

$$W = \frac{c}{2f_r}\sqrt{\frac{1}{\varepsilon+1}} \quad (2)$$

The design specification we followed to design the patch antenna is given below:

From eq. (1) and (2) by putting, frequency f_r =2.6 THz, permittivity, ε =2.3 and c=3×10^8 m/s we get, length, L= 11µm and width, W =14.76µm approximately. The rest of the measurement parameters are found from Figure.2they are given below at Table. I.

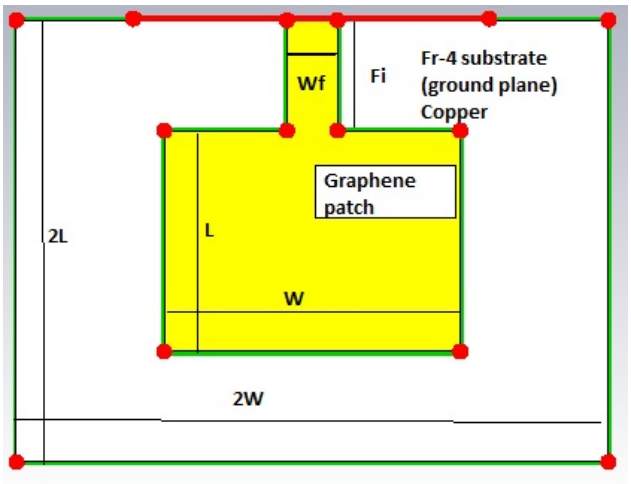

Figure 2.The model followed for designing rectangular patch antenna

B. Circular patch antenna at 2.6 THz

Circular patch antenna consists of a single circular metallic patch. But here we used graphene patch instead. The radius of the patch can be calculated from the empirical formula [10]

Patch radius

$$a = \frac{F}{\sqrt{\{1+\frac{2\times h}{\pi\varepsilon F}[\ln(\frac{\pi F}{2h})+1.7726]\}}} \quad (3)$$

Where h is the thickness, ε is the dielectric constant of the substrate material and F is related by the following equation:

$$F = \frac{8.791\times10^9}{f_r\sqrt{\varepsilon_r}} \quad (4)$$

Here a circular shapedmicro strip patch antenna is designed at resonant frequency of 2.6 THz. The proposed antenna is constructed using single circular patch of radius 11.26 □m.The proposed antenna shape is shown in Figure.3. Thesubstrate of thickness 1.305µm is used on which the structure is mounted. Dielectric constant is chosen 2.3 while the loss tangent is 0.025.The opposite side of the substrate contains the copper plate that act as the reflecting ground plane. The graphene is used as the radiating material. The thickness of both the radiator and ground plane are 0.0489 µm.The substrate we used is square of dimension 29.34 µm.Co-axial feed is used to excite the antenna.

C. Simulation tool

There are different types of simulation tool. But the most important problem is that the graphene simulator which work on mainly on the theory of Density functional theory, Classical potentials, or Extended Huckle theory they are not electromagnetic field solver. So we focus on the EM field solver tools or antenna simulation tools. These tools actually analysis high frequency devices. But the disadvantage of these types of simulator is this type of simulator does not have any model for graphene [3].

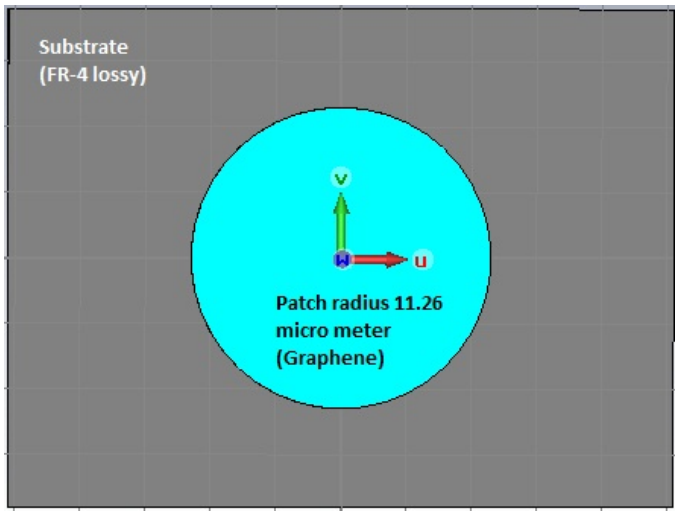

Figure 3.The model followed for designing micro strip circular patch antenna

D. Designing Graphene material for Graphene patch

Because of the absent of graphene model we followed two models to design and simulate graphene based nano antenna on this type of simulator. The models are complex permittivity model which accounts for intraband and interband transitions of electrons [11].And the second model is Drude approximation which only accounts for intraband transitions of electrons [12]. So for using graphene patch antenna we have at first designed graphene material. First, we considered the complex conductivity model by using the numerical values. CST simulates the structures which have length, width and thickness. But graphene is an one atom thick material. So for simulating graphene based antennas we make the thickness of the structures close to zero. [3].

E. Antenna design(Rectengular Patch)

The graphene nano ribbon based microstrip patch antenna is designed which has dimension in order of few micrometers. Conventionally the micro strip patch antenna consists of a

radiating patch where graphene is used as the material by editing the conductive and dispersion parameters of the drude material. The patch and the ground plane is separated by a thin dielectric substrate. We used the rectangular shape of the patch for ease in the analysis procedure. As indicated in Fig.2, the graphene nano ribbon is used as the patch where the patch thickness is much smaller than the wavelength. The radiating patch and ground plane is separated by a 1.305 µm thin substrate.

TABLE I. GNR BASED TERAHERTZ RECTANGULAR PATCH ANTENNA DESIGN PARAMETER[16]

Parameter	Description of the parameters		
	Symbol	***Value***	***Unit***
Patch length & width	L×W	11×14.76	μm^2
Resonant frequency	F	2.6	THz
Substrate length,width and thickness	2×(L×W×h)	2×(11×14.76×1.305)	μm^3
Dielectric constant	ε_r	2.3	-

The circular patch and the ground plane isalso separated by a thin dielectric substrate. We used the circular patch for comparing the performance characteristics with the rectangular patch antenna. Also the shape of the patch gives ease in the analysis procedure. As indicated in Figure. 3, the graphene nano ribbon is used as the patch where the patch thickness is much smaller than the wavelength. The radiating patch and ground plane is also separated by a 1.305 µm thin substrate.

TABLE II. GNR BASED TERAHERTZ CIRCULAR PATCH ANTENNA DESIGN PARAMETER[16]

Parameter	Description of the parameters		
	Symbol	***Value***	***Unit***

V. SIMULATION AND EXPERIMENTAL RESULT

A. Simulation Results

The designed antenna is resonant at 2.6THz. The excitation signal is supplied by a 50Ω source. The simulation results mainly consist of the return loss, the directivity, and gain and radiation pattern of the patch antenna.

B. Return Loss,gain and Voltage standing wave ratio

The proposed rectangular patch antenna is designed and its radiation characteristics are investigated in the band of 2.45-2.98 THz, using the CST simulation tool. We have measured the return loss (S_{11}) and the voltage standing wave ratio for the patch antenna from Figure.4 & Figure5 it can be observed that the return loss at the resonant frequency is -15.179 dB and the voltage standing wave ratio at the resonant frequency is 1.421.

The proposed circular patch antenna is designed and its radiation characteristics are investigated in the band of 2.45-2.98 THz, using the CST simulation tool

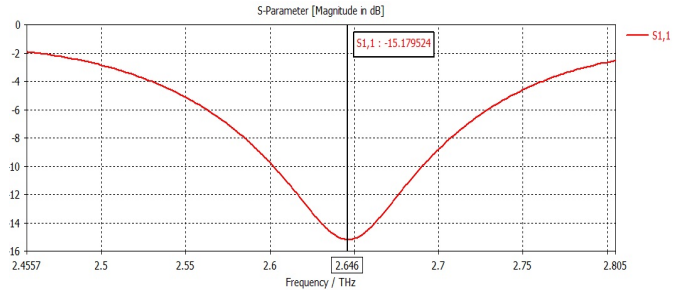

Figure 4.Return Loss for rectangular patch antenna

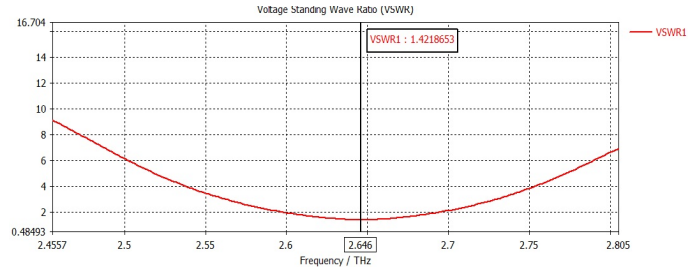

Figure 5.Voltage standing wave ratio for rectangular patch antenna

We have measured the return loss (S_{11}) and the voltage standing wave ratio for the patch antenna. From Figure.6 and Figure.7 can be observed that the return loss at the resonant frequency is -14.82 dB and the voltage standing wave ratio at the resonant frequency is 1.64.

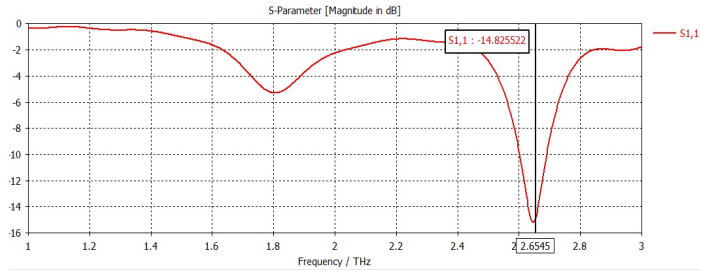

Figure 6.Return loss for circular patch antenna

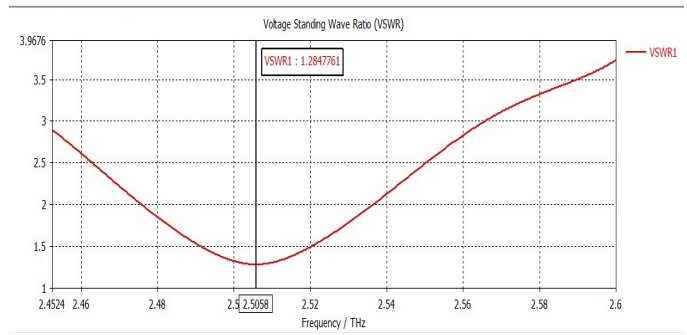

Figure 7.Voltage Standing wave ratio for circular patch antenna

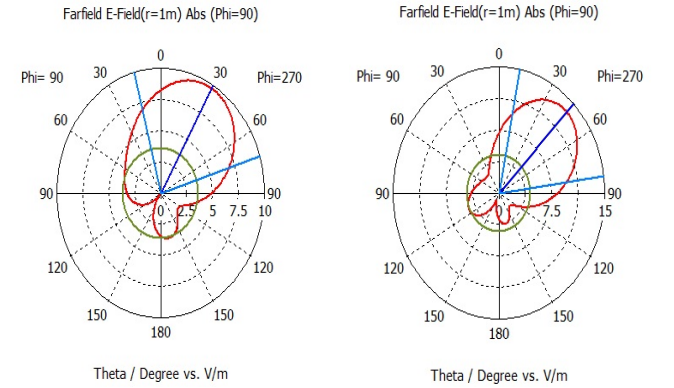
The E and H planes far-field radiation patterns of the proposed rectangular and circular antennas in the range of 2.515 THz are visualized in Figure 8(a)-(b) and 9(a)-(b). The E-plane radiation plot demonstrates that the antenna has least back flap radiation in the craved band. So better front to back projection proportion is accomplished, and examined in Table III. It is seen from Figure.10, GNR based rectangular patch antenna has yielded a farfield increase of 19.8dB and the

circular patch has yielded a farfield addition of 34.3dB at 2.6 THz.

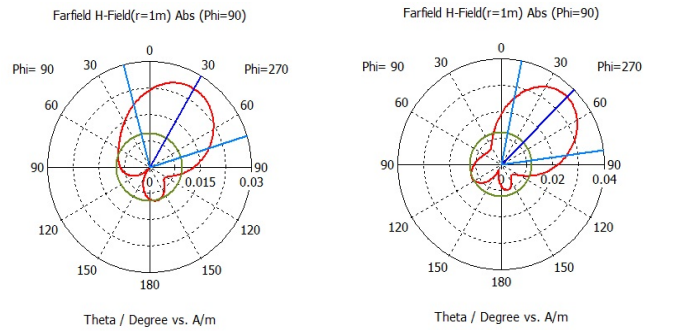
The Gain for the circular and rectangular patch antenna are shown in Figure. 10 (a)-(b) in the polar radiation pattern. For observing the gain we used linear scaling in the far field plot.



(a) (b)

Figure 8.E-plane (solid line) far field radiation patterns of the proposed antenna (a) Rectangular patch antenna (b) circular patch antenna

The visualization of far field gain as 3D radiation patterns of the proposed rectangular and circular patch antenna are shown in Figure 11(a) and 11(b) respectively.



(a) (b)

(a) (b)

Figure 10.Farfield gain (solid line) patterns of the proposed antenna (a) Rectangular patch antenna (b) circular patch antenna

The radiation qualities of the proposed antenna are contrasted and that of the already reported graphene based and ordinary antennas working in terahertz band is compressed in Table III. The proposed GNR based patch antenna is not optically transparent. So this outcome will utilize graphene based patch antenna to be utilized as a part of future THz band correspondence framework.

Figure 11.3D radiation patterns of the proposed antenna (a) Rectangular patch antenna (b) circular patch antenna

TABLE III. PERFORMANCE COMPARISON OF THE GNR BASED ANTENNA WITH THE EXISTING ANTENNASIN THE CONTEXT OF RADIATION CHARACTERISTICS.

Parameter	GNR based antennas			Conventional antenna	
	Proposed antenna	*[16]*	*[13]*	*[14]*	*[15]*
Resonant Frequency(THz)	2.6	0.750	0.800	1.425	2.15
Gain(dB)	13.4(rectengular),7.96(circular)	5.09	-	1.65	4.97
Directivity(dB)	10.74(rectengular),9.76(circular)	5.71	0	-	-
Front To back Lobe ratio	78.3(rectangular),73.31(circular)	70.27	-	-	-

VI. CONCLUSION

In this paper, the radiation attributes of grapheme nanoribbon based nano scale strip rectangular and circular patch antenna have been explored in the 2.45-2.98 THz band. Graphene nanoribbon based terahertz patch antenna is reproduced by utilizing the finite component system based test system CST. The proposed antenna has appeared to create the top increase of 13.4dB for rectangular patch and 7.96dB for circular patch at 2.515 THz .The antenna has likewise the most astounding directivity in the desired band. The design parameters of the proposed rectangular and circular patch antenna is listed in Table I and Table II, and the proposed antenna is compared contrasted with the already reported graphene based antennas,

furthermore with ordinary patch antennas in Table III. It shows that although we used a higher resonant frequency for our proposed antenna, the gain, directivity and front to back lobe ratio have improved significantly.

***Abstract*— Use of renewable energy is the key to produce electricity from limited resources. Solar cells appear as promising candidates for this purpose. Research on third generation quantum dot solar cells have drawn much attention. Solar cells made of wide bandgap materials that utilize quantum dots have the potentials for being ideal solar cells of future. Quantum dots have a tunable bandgap, so they can be designed to absorb light from the entire solar spectra. Proper tuning of the quantum dots in the absorber layer is the key factor for absorbing solar photons. Here we have optimized Indium Gallium Nitride quantum dots for absorbing photons from most of the solar spectra. It covers the entire range of visible light along with a significant portion from ultraviolet (UV) and Infrared (IR) light . In this theoretical approach, the bandgap of Indium Gallium Nitride and the radii of the quantum dots were varied throughout the simulation. At an optimal mole fraction of Indium & Gallium, we tuned the quantum dots to absorb wavelengths from 142 nm to 1565 nm.**

Keywords—Quantum dots; tuning; intermediate band solar cells; solar spectra; Brus Equation.

I. INTRODUCTION

In solar cells, atomic level conversion of light into electricity takes place in two steps- 1) Atoms of solar cells get hit by the photons and absorb the energy transferred from the photon 2) This absorbed energy is used to free electrons. These free electrons produce electric current when they are driven in an orderly way. Light is absorbed by a semiconductor material producing an electron-hole pair known as exciton. This pair is separated by an internal electric field. It results in flow of electrons and holes. This is how and electric current is produced. In case of conventional silicon based solar cells the efficiency is limited to 30%. They have limited operation range because they can work within a limited range of solar spectra that includes visible light only. Photons only with energies higher than the bandgap of the material can free electrons and contribute to current. Those with lower energies cannot contribute to produce electricity [1], [2]. Solar spectra consists of 3 to 5% Ultraviolet (wavelength < 400 nm) , 42 to 43% Visible (400-700 nm) and 52 to 55% Infrared (wavelength > 700) light (Fig. 1) . So if the Infrared (IR) and Ultraviolet (UV) range are also utilized for energy harvesting, more of the solar energy will come into use. A solution to this problem is the intermediate band (IB) solar cell. Intermediate bands are formed by addition of a narrow band of states in the middle of the band gap of a photovoltaic material .

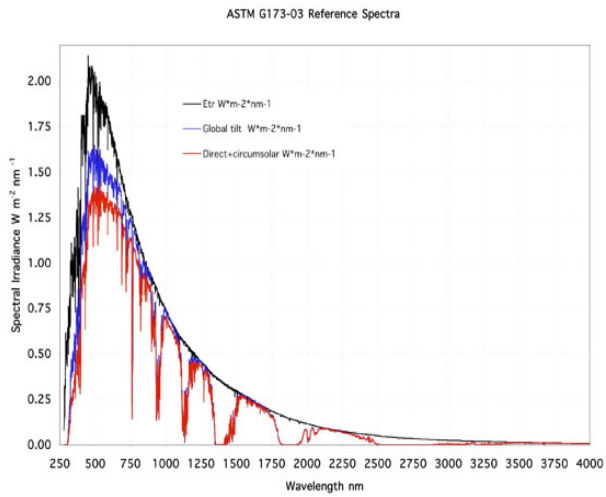

Fig. 1. AM 1.5 solar spectra [22], [23]

Electrons can jump from valence band to intermediate band being excited by a low energy photon, then jump to conduction band by another low energy photon. Thus photons with lower energies are also utilized. This can be achieved by insertion of Quantum dots as the absorbing material into the bulk semiconductor. These are nano sized particles where carriers in the semiconductor are confined by potential barriers . Quantum dot solar cells promise conversion efficiency upto 86% by using multiple junctions . Quantum dots have a tunable bandgap depending on their size. So QD (Quantum Dot) solar cells can be designed to work in any part of the solar spectra. This lets the whole spectra to be utilized [3]-[10] . Gallium Nitride (GaN) based solar cells with Indium Gallium Nitride (InGaN) quantum dots are promising candidates for ideal wide spectrum solar cells. Indium Gallium Nitride itself has a tunable bandgap which is determined by the mole fraction of Indium and Gallium present in the alloy. It can be varied from 0.7 eV to 3.42 eV corresponding to a wide range in solar spectra. This feature of InGaN along with flexible bandgap of

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

quantum dots provide an excellent scope for tuning InGaN quantum dots to any desired wavelength region [11]-[14]. At a particular mole fraction of constituent elements, the radii of the embedded quantum dots in the different layers of the intrinsic region can be varied in such a way that dots in different layers absorb different wavelengths (Fig. 2).

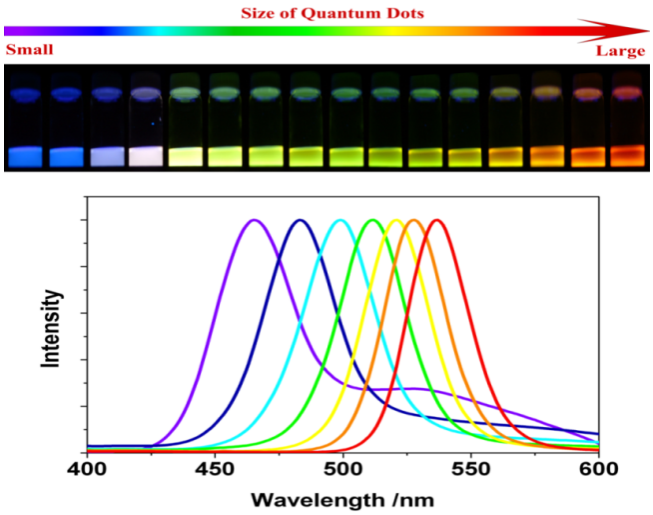

Fig. 2. Change in wavelength of quantum dots with change in size [24]

In that case, photons with energies corresponding to the quantum dots' bandgap energies will be absorbed by that layer. For designing such an efficient wide spectrum QD solar cell, the optimum bandgap of the dot material and also the required confinement radii must be known. This needs specific study on these criteria. Researchers have varied the size of Zinc Oxide (ZnO), Cadmium Selenide (CdSe), Zinc Sulphide (ZnS) and Gallium Arsenide (GaAs) QDs and calculated the resulting bandgap, emitted wavelength etc. using Brus equation which match pretty well with experimental data [15]-[18] . But no specific study on optimizing InGaN quantum dots to match the solar spectra has been reported in literature. We have varied the mole fraction of Indium (In) and Gallium (Ga) and calculated the effective bandgap of Indium Gallium Nitride. Then using the Brus equation and we have varied the size of QDs at an optimal mole fraction to absorb specific wavelength from 142 nm to 1565 nm. It covers the range of existing wavelengths of solar spectra starting from 280 nm to 1565 nm. This covers the whole range of UV and visible light from AM 1.5 solar spectra and a significant portion of IR region [23].

II. Theoretical Framework

Being a ternary compound, the bandgap of InGaN depends on the mole fractions of the constituent elements. Bandgap energy of the quantum dots depends on the effective mass of excited electrons and holes as well as the size of the dot. Absorbed wavelength can be found from the relationship between energy and wavelength (i.e. E=hc/λ). So a number of factors need to be considered to reach the optimum condition.

A. Bandgap of InGaN as a function of mole fraction

The bandgap of InGaN varies with the mole fraction of Indium (In) and Gallium (Ga) in the alloy as well as temperature. If X be the In doping relative to Ga, E_{InN} is the bandgap of Indium Nitride (InN), E_{GaN} is the bandgap of Gallium Nitride (GaN) , b is the bowing parameter of $In_xGa_{1-x}N$, then the bandgap of the alloy is given as-

$$E_{g,InGaN}(X) = XE_{InN} + (1-X)E_{GaN} - bX(1-X) \qquad (1)$$

By varying X in (1), the bandgap of InGaN can be adjusted to any desired value within 0.7 to 3.42 eV [19].

B. Brus Equation

L. E. Brus in 1984 first developed an equation for size dependence of lowest excited electronic state in case of small semiconductor crystallites [15] . With some moderations, the equation named after him is written as-

$$E(QD) = E_g(bulk) + \frac{h^2}{8R^2}\left(\frac{1}{m_e^*} + \frac{1}{m_h^*}\right) - \frac{1.786e^2}{4\pi\varepsilon_0\varepsilon_r R^2} \qquad (2)$$

Where E(QD) is the bandgap energy of quantum dot, the first term in right hand side of the equation represents the bandgap energy of bulk semiconductor, ε_0 is the permittivity of vacuum, ε_r is the relative permittivity of the semiconductor, m_e^* is the effective mass of excited electron, m_h^* is the effective mass of excited hole, R is the radius of spherical quantum dot. The second additive term in the right hand side, is dependent on inverse of square of the radius. It accounts for the additive energy due to quantum confinement. The third term in the right hand side is due to the coulombic interaction energy of exciton and is negligible for materials with high dielectric constants [16], [17]. So the overall Brus Equation to be used in this work is-

$$E(QD) = E_g(bulk) + \frac{h^2}{8R^2}\left(\frac{1}{m_e^*} + \frac{1}{m_h^*}\right) \qquad (3)$$

Varying R in (3) at a certain mole fraction, quantum dots can be tuned to absorb any specific wavelength. Quantum dot confinement region must be smaller than or comparable to their De Broglie wavelength or to the Bohr radius of excitons .

C. Calculation of electron and hole effective mass

As can be seen from (3), electron effective mass m_e^* plays an important role in determining the bandgap of the QD. It changes with varying mole fraction. Effective mass of electron in *InGaN* can be calculated using the following equation which utilizes the interpolation formula[20] , [21] –

$$m_{e,InGaN} = m_{e,GaN} + X(m_{e,InN} - m_{e,GaN}) \qquad (4)$$

The value of hole effective mass can be calculated in same way using the equation below-

$$m_{h,InGaN} = m_{h,GaN} + X(m_{h,InN} - m_{h,GaN}) \quad (5)$$

D. Condition for varying Quantum dot radius:

For the confinement effects to be prominent, the radius of the quantum dot must be kept less than the exciton Bohr radius of the quantum dot material [3]. The exciton Bohr radius of a semiconductor material can be calculated as-

$$a_B = \frac{4\pi\varepsilon_0\varepsilon_R\hbar^2}{m_{eff}q^2} \quad (6)$$

Where m_{eff} is the effective mass of the electron-hole pair, q is the charge of a carrier. If the radius of the dots exceed the exciton Bohr radius of the material, the quantum confinement effects will not hold any more and Bandgap energy of the quantum dots will not practically resemble the Brus equation. Exciton Bohr radius for InGaN is very small, it can be as small as 3 nm for less indium concentration [25] . If indium content is increased in the alloy, the exciton Bohr radius increases like 7 nm for indium concentration, X=0.75 [26]

III. PARAMETERS AND SIMULATION

Value of InN, GaN bandgap, bowing parameter of InGaN have been adapted from [12] . Interpolation formula has been used where necessary. The values of the basic parameters used in the simulation have been listed in Table I. Here, m_0 is the rest mass of an electron.

TABLE I. PARAMETER VALUES

Parameter name	Value
Bandgap of InN at 300K	0.7 eV
Bandgap of GaN (wurtzite) at 300K	3.42 eV
Bowing parameter for InGaN alloy	1.43
Electron effective mass of GaN, $m_{e,GaN}$	0.2 m_0
Hole effective mass of GaN, $m_{h,GaN}$	1.25 m_0
Electron effective mass of InN, $m_{e,InN}$	0.05 m_0
Hole effective mass of InN, $m_{h,InN}$	0.6 m_0

MATLAB version 7.10.0499 (R2010a) has been used as the simulation software throughout this work.

IV. RESULTS AND DISCUSSIONS

At first, the possible bandgaps for InGaN were calculated by varying the mole fraction of Indium, X . As can be seen from Fig. 3., it could be tuned from 3.37 eV for X = 0.01 to 0.713 eV for X = 0.99. As the mole fraction of Indium increases, the bandgap of InGaN tends to decrease because of low bandgap of InN [19].

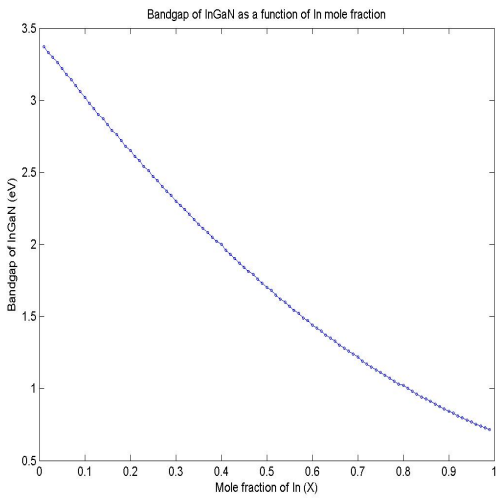

Fig. 3. Bandgap of InGaN with changing mole fraction of In

By calculating the exciton Bohr radius for various mole fraction of the constituents, it was found that as the Indium concentration in the alloy increases, exciton Bohr radius of InGan alloy increases too. Fig. 4 shows that, for X = 0.01, calculated exciton Bohr radius was 2.77 nm. The exciton Bohr radius reached its highest value of 10.75 nm for X = 0.99. This is the optimal mole fraction where the radius of the quantum dots can be varied over a wide range to cover the whole spectra. With this value of X, calculated bandgap of InGaN alloy was 0.713 eV.

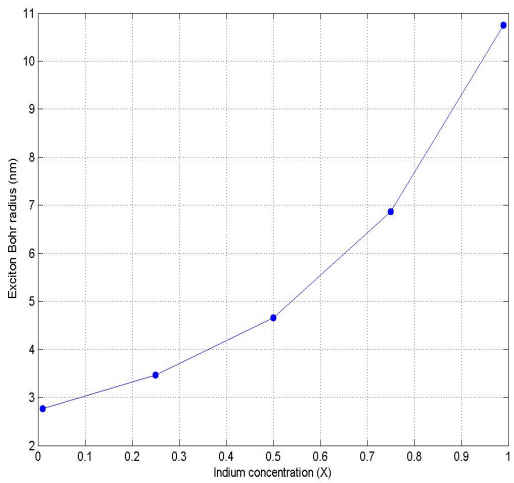

Fig. 4. Exciton Bohr radius of InGaN alloy at different In concentration

The optimum bandgap is chosen such that varying the dot size only gives an absorption range that covers as much portion as possible from UV, visible and Infrared region . For tuning the dots to absorb UV light with Indium composition X = 0.99, radius of the dots were varied from 1 nm to 1.83 nm. It gave an absorption range starting from 142 nm wavelength to 400 nm as shown in Fig. 5.

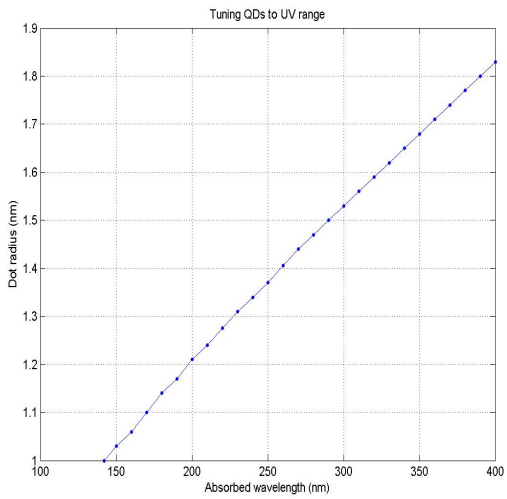

Fig. 5. Dot radius versus absorbed wavelength plot for UV region

By varying the dot radius from 1.83 nm to 2.75 nm, wavelengths from 400 to 700 nm can be absorbed which covers the whole visible range. This is shown in Fig. 6. If the dot radii are further increased, and varied from 2.75 nm to 10.05 nm, it gives an absorption range from 700 nm to 1565 nm in the Infrared region as shown in Fig. 7. Observations show that as the In mole fraction in the alloy is increased, the bandgap of the alloy gets lower. To design quantum dots for absorbing higher energy photons Indium concentration in the alloy must be reduced .

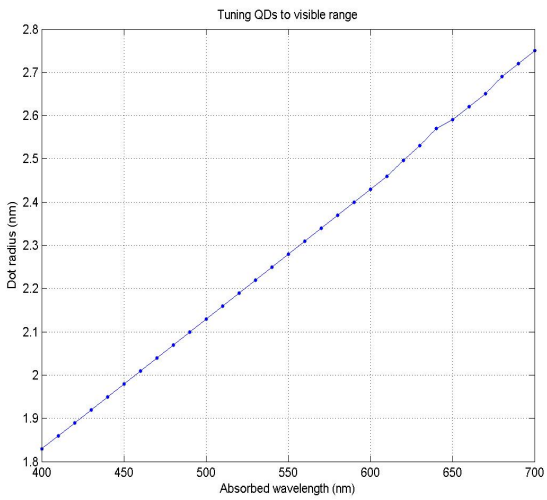

Fig. 6. Dot radius versus absorbed wavelength plot for visible region

Another thing apparent from the observation is that, smaller quantum dots with greater energy gap are able to absorb shorter wavelength photons which contain much energy. As the quantum dot radius is increased and their size gets bigger, the confinement strength gets reduced. That is why larger quantum dots have smaller bandgap energies. These quantum dots absorb photons with larger wavelengths and less energy.

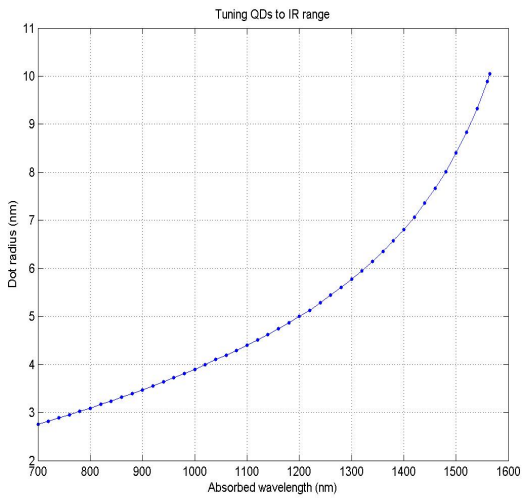

Fig. 7. Dot radius versus absorbed wavelength plot for IR region

The optimum bandgap for tuning InGaN quantum dots was found to be 0.713 eV with Indium composition X = 0.99. If the dot radius is varied from 1 nm to 10.05 nm, they can absorb wavelengths starting from 142 nm to 1565 nm which covers the whole UV and visible range along with significant portion of Infrared region of AM 1.5 solar spectra as can be seen from Fig. 8.

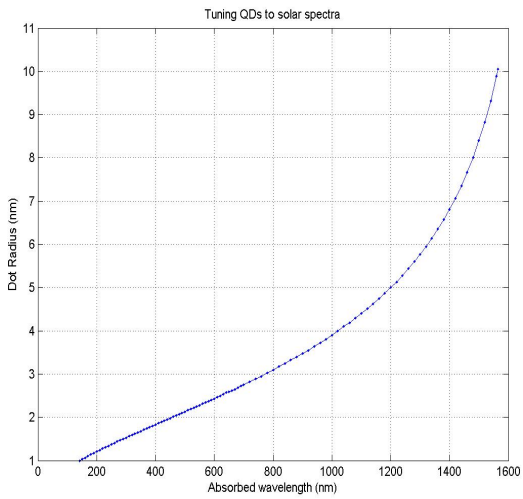

Fig. 8. Dot radius and absorption range with X = 0.99

V. CONCLUSION

InGaN quantum dots have a wide range of tunable bandgap and absorption spectra. This feature can be used to absorb almost any wavelength within the AM 1.5 solar spectra. InGaN quantum dots can be used to design an efficient wide spectrum solar cell. Solar photons over a wide range of wavelengths will be absorbed and utilized. Future work may include the investigation of the confinement effects for different shapes of InGaN quantum dots like pyramid, hexagonal, cubic etc. Effects of changing shape on the absorption spectra should also be studied.

***Abstract*— Using numerical simulation, the performance of organic light emitting diode (OLED) based on modified indium tin oxide (ITO) has been investigated. The effects of ITO surface modification in energy barrier reduction at anode side which increase charge carrier injection, transport and recombination have been explained quantitatively. Calculated current balance factor from simulation results also confirmed the efficiency enhancement of bilayer OLED by the ITO work function modification technique.**

Keywords*— *indium tin oxide (ITO); hole current density; numerical simulation; current balance factor; carrier recombination

I. INTRODUCTION

As an optoelectronic device, OLED has been covered most of the area in the field of lighting and displays technologies over other existing lighting sources like light emitting diodes (LEDs) and liquid crystal displays (LCDs) because of their low turn on voltage, low input power, fast turn on response time, wide viewing angle (~180^0), thin and light weight, low cost, non-toxic materials and emitting light spectrum near to sun [1, 2]. After the demonstration of first bi-layer OLED by C. W. Tang and S. A. Vanslyke group in 1987 [3], the research on modification of OLED structures has been expanded dramatically. As a result, graded and mixed host based devices have been modeled and fabricated to improve the OLED lifetime and efficiency limitations [2, 4, 5]. However, these structures based devices increased complexity during fabrication. To overcome device fabrication complexity and increase charge injection rate into the device for improve device performance, ITO work function modification by O_2 and Cl_2 plasma treatment [6], post annealing treatments, adding buffer layer [7, 8] and UV-ozone treatments [9] are the most efficient and effective processes. Since, ITO commonly used as anode in most optoelectronic devices especially in OLEDs, hence device performance can be enhanced significantly using these ITO surface modification process which reduce the energy barrier for carriers to cross the ITO/organic interface [8].

H.-W. Lu, C.-W. Huang, P.-C. Kao, S.-Y. Chu, and Y.-D. Juang. [7] recently reported a work function modification technique of ITO by soaking in 1 wt%, 5 wt% and 10 wt% concentration of caesium fluoride (CsF) solution where the work function of ITO modified from normal work function of 4.78 eV to 4.95 eV, 5.01 eV and 5.11 eV correspondingly. They tried to explain the effects of ITO surface modification on the ITO/CsF/NPB/Alq_3/LiF/Al based bilayer OLED performance by analysis the current density- luminance - voltage (J-L-V) characteristic curves and surface morphology. However, that works unable to explain how ITO surface modification effects on the internal carrier distribution, electric field and recombination of device those are key factors for device modeling.

Motivating from this point, the effects of ITO surface modification on device J-L-V and efficiency have been explained through this numerical simulation in terms of charge carrier distribution, hole current density and carriers recombination. Moreover, the calculation of current balance factor which is proportional to the experimental quantum efficiency, able to justify this modified ITO based OLED performance. By the systematic study of the device performance of OLED, it is possible to explain some effects qualitatively. But, without numerical simulation, it is difficult to explain these effects quantitatively [10]. Numerical simulation is more viable to get any analytical results directly from the OLEDs where complicated working process and several interfaces are involved [11]. Therefore, this work led by numerical simulation which treated as powerful method to retrieve detailed information such as the charge carrier injection, distribution of electric field and recombination those are difficult to measure directly through experiments, investigate the underlying device mechanism and their amplitude which can affect the device performance.

II. ELECTRICAL MODEL

To analysis the effect of ITO work function modification on the underlying physics and performance of bi-layer OLED,

drift-diffusion electrical model has been implemented using a numerical simulator called 'SETFOS' (Semiconducting Thin Film Optics Simulation Software). Poisson equations and continuity equations as presented in "(1)," and "(2)," correspondingly considered in that electrical model to solve the electric field distribution and time evaluation of the system.

$$\frac{dE}{dx} = \frac{q}{\varepsilon\varepsilon_0}(p-n) \tag{1}$$

$$\frac{dn}{dt} = \frac{dJ_n}{qdx} - R - T \tag{2}$$

where, E is the electric field inside the OLED, q the elementary charge, □ the dielectric permittivity of the organic materials, □$_0$ the dielectric constant, p and n are the hole density and the electron density respectively, J_n the electron current density, R the recombination rate and T the trapping rate for free carriers. The carrier density distribution can be obtained by solving the drift and diffusion equation based on the Langevin recombination (R) process those are calculated using "(3)," and "(4)," respectively. The conventional electric filed dependent 'Poole-Frenkel mobility (PFM)' model as expressed in "(5)," applied for carrier mobility calculation in the device. The current balance factor (b) in "(6)," used to measure the device quantum efficiency [12] which is defined as the recombination current with the total current density.

$$J_n = qp\mu_n E + qD_n \frac{dn}{dx} \tag{3}$$

$$R = \frac{q}{\varepsilon\varepsilon_0}(\mu_p + \mu_n) \tag{4}$$

$$\mu(E) = \mu_0 \exp(\gamma * \sqrt{E}) \tag{5}$$

$$b = \frac{\int_0^L qR(x)dx}{J_T} \tag{6}$$

Here, μ_p and μ_n are the hole and electron mobility respectively, D_n the diffusion constant, $\mu(E)$ is the charge carrier mobility under electric field (E), μ_0 is the mobility under zero electric field, γ is the Poole-Frenkel field dependent factor, J_T is the total current density and L is the total device thickness.

III. Device Structure And Input Prameters For Simulation

The OLED structure as shown in "Fig. 1," used for simulation where the HOMO and LUMO levels of NPB (Alq_3) are 5.4 eV (5.7 eV) and 2.3 eV (3.0 eV) and the work function of LiF/Al is 3.0 eV [4, 7]. Before, surface modification, the usual work function of ITO is 4.78 eV which is modified after soaking in different concentration of CsF solution. The work functions of modified ITO become 4.95 eV (1 wt% CsF solution), 5.01 eV (5 wt% CsF solution) and 5.11 eV (10 wt% CsF solution). The work functions of ITO and organic materials parameters obtained from the UV- photoelectron spectrometer [7] and time of flight (TOF) measurement [13, 14] correspondingly, used as input during simulation. Considering the normal work function based ITO as reference, the effects of modified ITO work function using different concentrations of CsF solutions on hole injection efficiency, carrier recombination rates and current balance factor have been analyzed in the next section.

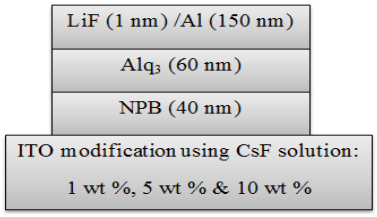

Fig. 1. Modified ITO based OLED Structure

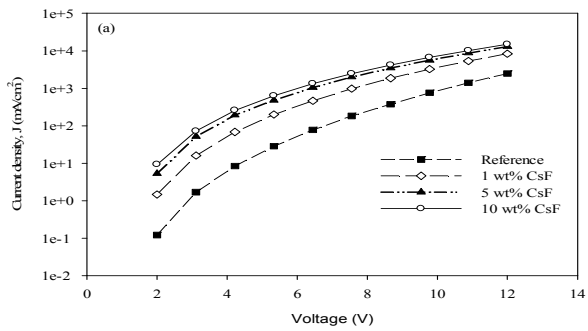
IV. Results and Discussions

A. J-L-V Characteristics and Efficiencies

Figure 2 shows the current density-voltage (J-V) and the luminance-voltage (L-V) characteristics curves of four OLEDs where one OLED based on unmodified ITO as reference and others OLEDs based on modified ITO by CsF solution. 1 wt%, 5 wt% and 10 wt% solutions of CsF improved the work function of ITO from normal value of 4.78 eV to 4.95 eV, 5.01 eV and 5.11 eV respectively. These work function improvement of ITO increased the hole injection rate by which the J-L-V curves influenced significantly. At a constant operating voltage of 6 V (Fig. 2(a)), the current density of OLEDs based on reference, 1 wt%, 5 wt% and 10 wt% CsF solutions are 46 mA/cm^2, 356 mA/cm^2, 751 mA/cm^2 and 928 mA/cm^2. On the other side, at 500 cd/m^2 (Fig. 2(b)), the operation voltage of reference, 1 wt%, 5 wt% and 10 wt% CsF solutions based OLEDs are 6.9 V, 4.7 V, 3.7 V and 3.3 V correspondingly. 10 wt% CsF solution based OLED shows the highest current density and luminance due to higher hole injection rate which also result of higher efficiency as evidence as presented in Fig 2(c). The improved values of electroluminescence (EL.) efficiency, γ (power efficiency, η) of modified ITO based OLEDs by 1 wt%, 5 wt% and 10 wt% CsF solutions are 4.79 cd/A (4.68 lm/W), 5.28 cd/A (5.38 lm/W) and 5.39 cd/A (5.89 lm/W) over without ITO modification based OLED where the value of EL. efficiency (power efficiency) is 4.4 cd/A (4.52 lm/W). These significant performance improvements of OLEDs using ITO surface modification by CsF solutions can be visualized and explained form the carrier distribution and recombination profiles.



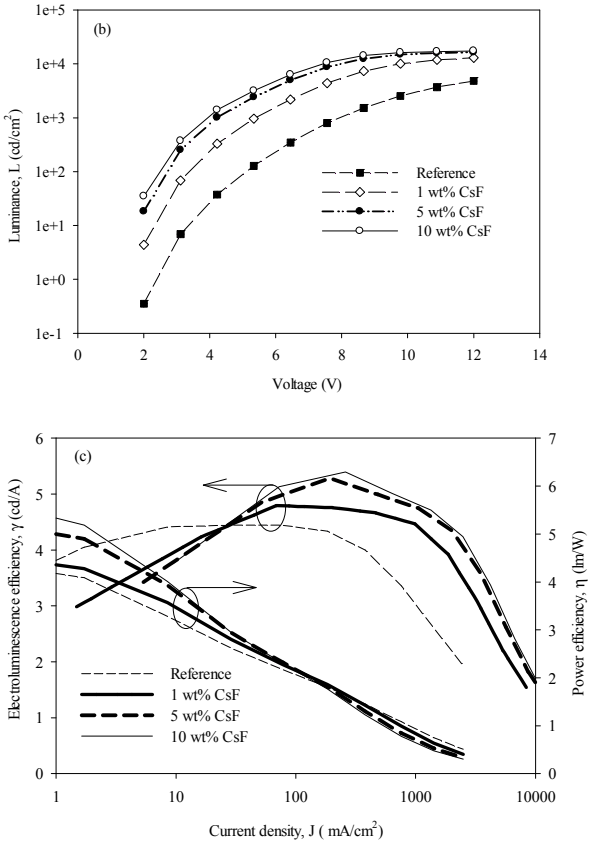


Fig. 2. Characteristics curves of OLEDs in terms of (a) Current density-Voltage, (b) Luminance-Voltage and (c) Electroluminescence and Power Efficiency-Current density

B. *Effects of ITO surface modication on current balance and recombination*

From the carrier concentration profile as shown in Fig. 3 (a), it is observed that at operation voltage of 6 V, the hole density increased around 1, 1.7 and 2 orders due to ITO surface modification by 1 wt%, 5wt% and 10 wt% CsF solutions respectively, when the interfacial energy barrier between ITO (4.95 eV, 5.01 eV and 5.11 eV) and NPB (HUMO=5.4 eV) reduced from 0.62 eV (in unmodified condition (4.78 eV)) to 0.45 eV, 0.39 eV and 0.29 eV correspondingly. Therefore, these significant reduction of interfacial energy barrier increased the hole current density in the NPB layer (Fig. 3(b)) around 5, 9 and 11 times which linked to increase the total current density of the modified ITO based OLEDs over unmodified ITO based OLED. Moreover, the electric field distribution along the device as shown in Fig. 4(a) increased steadily from anode/NPB interface to NPB/Alq_3 interface due to this CsF solution based ITO surface modification technique which harmoniously influenced the recombination rate at that organic layers interface. The highest calculated values of current balance factor in Fig. 4(b) of modified ITO based OLEDs with 1 wt%, 5wt% and 10 wt% CsF solutions are 0.68, 0.77 and 0.90 respectively where ITO surface modification based OLEDs reached steady state position before unmodified ITO based OLED (0.61).

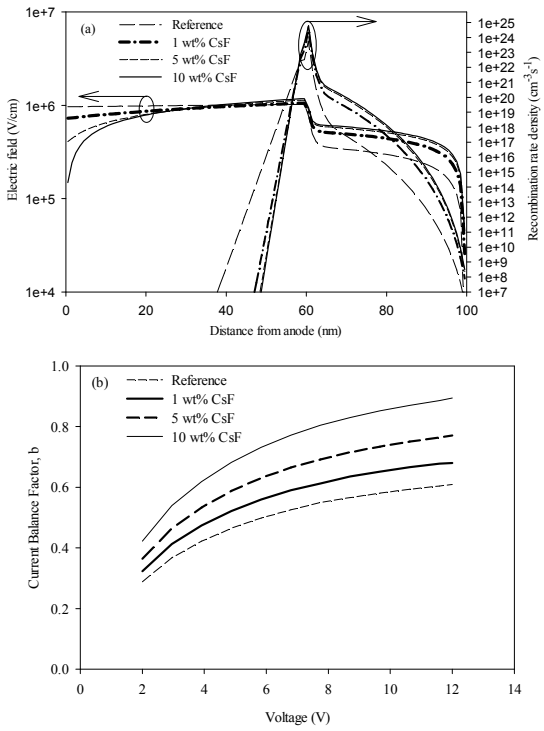

Fig. 4. (a) Distribution of Electric field and Recombination zone at 6V and (b) Current Balance Factor for treated and untreated ITO based OLED

C. Discussions

Through this numerical simulation, the influence of CsF solution on ITO work function modification and device performance have been explained from the hole current density, recombination rate and current balance factor. Due to the ITO surface modification by ITO soaking in 1 wt%, 5wt% and 10 wt% CsF solutions, the energy barrier at anode/organic interface reduced by 0.17 eV, 0.23 eV and 0.33 eV respectively from the original value (0.62 eV) and hence increased the hole injection rate. Therefore, the device EL. efficiency and power efficiency correspondingly improved by 1.08, 1.20 and 1.23 times, and 1.03, 1.19 and 1.30 times. Due to this CsF solution based ITO surface modification technique, a summary of performance improvements of all modified devices in terms of their efficiencies and CBF have been presented in TABLE I. Around 1.5 times improvement (10 wt% CsF solution) in current balance factor over normal condition also confirmed the improvement of device quantum efficiency.

TABLE I. COMPARISON OF OLEDS PERFORMANCES WITH AND WITHOUT ITO MODIFICATION.

Work function of ITO	**Simulation Results (Experimental Results [7])**					
	Max. EL. Efficiency, γ (cd/A)	***Max. Power efficiency, η (lm/W)***	**CBF**	**Improvement over unmodified ITO based OLED**		
				γ (cd/A)	**η (lm/W)**	**CBF**
4.78 eV (Reference)	*4.4 (2.81)*	*4.52 (1.47)*	*0.61*	-	-	-
4.95 eV (1 wt% CsF Sol.)	*4.79 (2.85)*	4.68 (1.51)	0.68	1.08 (1.01)	1.03 (1.02)	1.11
5.01 eV (5 wt% CsF Sol.)	*5.28 (2.62)*	5.38 (1.37)	0.77	1.2 (0.93)	1.19 (0.93)	1.26
5.11 eV (10 wt% CsF Sol.)	5.39 (3.0)	5.89 (1.58)	0.90	1.23 (1.06)	1.3 (1.08)	1.47

V. CONCLUSIONS

The effects of CsF solution based ITO surface modification technique on OLED performance have been analyzed from the 'SETFOS' based numerical simulation results. Due to ITO surface modification with 10 wt% CsF solution, the energy barrier for hole injection reduced more than 2 times (from 0.69 eV to 0.29 eV) which significantly increased hole injection rate at anode, accumulation of holes and recombination at the NPB/Alq_3 interface. Therefore, both EL. and power efficiencies increased around 1.23 and 1.30 times respectively. The value of current balance factor also improved from 0.61 to 0.90 (around 1.5 times) which is proportional to the experimental quantum efficiency. Moreover, the quantitative results of OLEDs performances by this numerical simulation comparable with experimental results [7].

Abstract—**This paper numerically explores the possibility of high efficiency, ultrathin and stable ZnCdTe (CZT) polycrystalline solar cell using well accepted simulator AMPS-1D. The base line structure of the ZnCdTe cell (Glass/ITO/CdS/ZnCdTe/Back Contact) was the beginning point of this work and further this base line structure was modified to achieve ultrathin, higher efficiency and stable solar cell. In modified structure, CdS window layer has been replaced by a wide band gap material $Zn_xCd_{1-x}S$ which increase the spectral response in the blue region as well as $Zn_xCd_{1-x}S$ window layer was reduced to the extreme limit with insertion of a suitable buffer layer of ZnO in between ITO and window layer to check forward leakage current of ultrathin window layer. To lessen the back surface recombination loss and barrier height at back contact another extra layer (BSF p-Sb_2Te_3) has been inserted in between p-ZnCdTe layer and back contact (BC). Then the thickness of the window layer and absorber layer of the modified structure has been optimized. The modified structure with back surface field (BSF) layer (Glass/ ITO/ZnO/$Zn_xCd_{1-x}S$/$Zn_xCd_{1-x}Te$/Sb_2Te_3/BC) shows the highest efficiency of 23.17% (*Jsc*=33.50 mA/cm^2, *FF*=0.77% and *Voc*= 0.98V). Finally the temperature effect on cell parameters was investigated and the overall temperature coefficient (TC) of the proposed cell is found to be 0.085%.**

Keywords—TFSC, CZT solar cell, ZnCdS, Photovolatic, BSF.

I. INTRODUCTION

Polycrystalline thin film solar cells such as Cu(InGa)Se_2 (CIGS), $CuInSe_2$ (CIS) and CdTe compound semiconductors are important for global application because of their high efficiency, long term stable performance and prospective for low cost production. Because of the high absorption coefficient (~10^5 cm^{-1}) a thin layer of ~2 μm is enough to absorb the useful part of the spectrum [1]. Highest recorded efficiency of 19.2% for CIGS [2] and 16.5% for CdTe [3] solar cell has been achieved. However there are rooms to improve the thin film solar cell (TFSC) performance by reformed cell design and using simple deposition technique to increase any one of cell performance parameters.

. Materials with high energy conversion efficiency have attracted substantial attention in the recent year. In this regards semiconductors having band gaps in the visible region of the electromagnetic spectrum are of commercial interest due to their valuable application in optoelectronic devices [4]. Silicon (Si) and germanium (Ge) are simplest and conventional semiconductors used in these devices but the problem with these semiconductors are their brittle nature as well as fixed and indirect band gap. CdTe is a direct band gap semiconductor with a fixed 1.45 eV band gap which is not good enough to involve wide range of energy from near infrared to near-ultraviolet. That's why the best replacement of these semiconductors in terms of efficiency and operating temperature is CZT due to its wide band gaps and high absorption rate at room temperature. In this work, a new TFSC structure is planned, where Zinc Cadmium Sulfide ($Zn_xCd_{1-x}S$) was used as window layer and Zinc Cadmium Telluride ($Zn_xCd_{1-x}Te$) was used as absorber layer with an extra benefit of variable band gap. As the spectral region sensitivity of the material depends on its band gap which depends on the controlled composition x in $Zn_xCd_{1-x}S$ and $Zn_xCd_{1-x}Te$, hence the value of x is varied symmetrically in the range $0<x<1$ to involve wide range of energy from near infrared to near ultraviolet [4]. In consideration to fabrication challenges, simulation results and resistivity of $Zn_xCd_{1-x}S$ film, in this work x=0.1 [5] is selected which showed low resistivity and high conversion efficiency in comparison to other value of x. The band gap E_g=1.57 eV is selected for ZnCdTe because it is in the range of optimum band gap. Moreover this band gap of $Zn_xCd_{1-x}Te$ can be obtained practically using the composition of x=0.1 in $Zn_xCd_{1-x}Te$ [6]. In the following text, $Zn_xCd_{1-x}S$ window layer and $Zn_xCd_{1-x}Te$ absorber layer has been written to $Zn_{0.1}Cd_{0.9}S$ and $Zn_{0.1}Cd_{0.9}Te$ respectively.

Now a day's one of the main goal of solar cell research is using a lesser amount of semiconductor material by making the cell thinner. Thinning will not only save material but also decrease layer deposition time as well as the energy requirement of production. All of these aspects will decrease the production cost of cell. In this work to reduce the cell thickness, modified cell structure (Glass/ITO/ ZnO/$Zn_xCd_{1-x}S$/$Zn_xCd_{1-x}Te$/Sb_2Te_3/BC) has been proposed and optimized the cell thickness without compromising the cell performance using Sb_2Te_3 BSF. Eventually, the modified CZT cell was investigated and achieved the maximum efficiency of 23.17% (*Jsc*=33.50 mA/cm^2, *FF*=0.77% and *Voc*= 0.98V).

II. Device Design And Simulation

Thin film solar cell can be grown in both substrate or superstrate configuration, but the uppermost efficiency is achieved in the superstrate configuration [1]. In this work superstrate configuration is used and the usual superstrate structure of baseline CdS/ZnCdTe solar cell and modified ZnCdS/ZnCdTe solar cell is shown in Fig. 1. It is apparent from Fig. 1(a) that in the baseline structure of CZT solar cells, SnO_2 with 500 nm thickness is used as TCO or front contact, CdS with 100 nm thickness is used as window layer and ZnCdTe with 4000 nm thickness is used as absorber layer. It is also clear from Fig. 1(b) that the modified structure has an additional layer (ZnO) in the middle of TCO and n-$Zn_{0.1}Cd_{0.9}S$ layer to achieve ultrathin $Zn_{0.1}Cd_{0.9}S$ layer and another extra layer (BSF p-Sb_2Te_3) in between p-$Zn_{0.1}Cd_{0.9}Te$ layer and back contact. The key purposes of the BSF are to shrink the back surface recombination loss and to reduce the barrier height at BC. The specific BSF material selected to investigate in this work is Antimony Telluride (Sb_2Te_3).

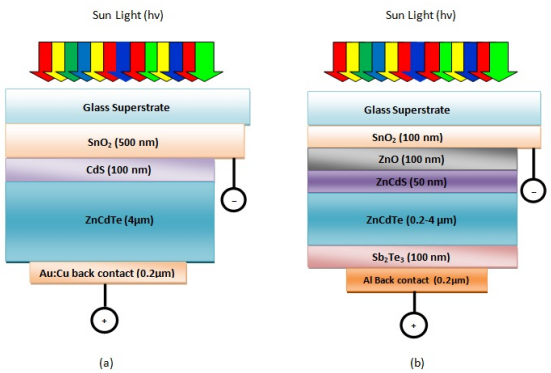

Figure 1. Schematic view of the CZT solar cell (a) baseline structure (b) proposed modified structure.

In this study, AMPS 1D [7] was used to explore the CZT baseline solar cell and modified structured solar cell for achieving ZnCdTe and ZnCdS layer with higher conversion efficiency. This simulation program has been developed to simulate faithfully the electrical characteristics of thin film heterojunction solar cell. That's why the four basic layers that have been emphasized in this modeling are the buffer layer (ZnO), n-$Zn_{0.1}Cd_{0.9}S$ window layer, p-$Zn_{0.1}Cd_{0.9}Te$ absorber layer and Sb_2Te_3 BSF layer. Table 1 displays the material parameters used in this work, which were selected based on literature values, theory or in some case, reasonable guesstimates. In this analysis, $Zn_{0.1}Cd_{0.9}Te$ absorber layer thickness has been varied from 0.2 µm to 4.0 µm and $Zn_{0.1}Cd_{0.9}S$ window layer thickness has been varied from 25 nm to 200nm by kept all other parameters at fixed value as stated in table 1 aiming to get efficient and thinner CZT solar cell.

III. Results And Discussions

A. Analysis of Baseline CZT Cell Structure

The baseline structure of CZT solar cell has shown in Fig. 1(a). The performance parameters of the baseline structure of CZT solar cell are: efficiency, η=21.63%; short circuit current density, Jsc=33.7mA/cm^2; open circuit voltage, Voc=0.96 V and fill factor, FF=0.73%. The thickness of the baseline structure cell was 4600nm. Further modifications have done to increase the cell performance as well as reduce the cell thickness to achieve an ultrathin solar cell. In the modified structure (Fig. 1(b)) of CZT cell, the window layer CdS was replaced by a wide band gap alloy ZnCdS which provide a more transparent window layer. As a result the spectral response at blue region and photocurrent generation has been increased. It is clear from the Fig. 2 that, the quantum efficiency of 50 nm thick ZnCdS shows better quantum efficiency than 100 nm thick CdS window layer. Lessening of ZnCdS thickness causes pinhole, which was reduced by insertion of 100 nm thick n-ZnO buffer layer in between TCO and n-ZnCdS window layer. Another layer has been introduced in modified structure which is called BSF to overcome rollover effect, to reduce the loss due to minority carrier recombination at back contact as well as to improve the stability of the cell at high operating temperature. All these modifications turn into increment of cell efficiency (21.63% to 23.17%). The J-V characteristics curve of the baseline structure and modified structure of CZT cell has shown in Fig. 3.

Table I. Materials properties used in AMPS-1D simulation

Typical cell properties		
Parameters	**Front contact**	**Back contact**
Φ_b [eV]	Φ_{bn} = 0.05	Φ_{bp} = 1.0 (Cu) and 0.1 (Sb_2Te_3)
S_e [cm/s]	1×10^7	1×10^7
S_h [cm/s]	1×10^7	1×10^7
R_f [I]	0.01	0.99 (Al) and 0.99 (Cu_2Te)

Layer properties				
Parameter	**ZnO**	**$Zn_xCd_{1-x}S$ (x=0.1)**	**p-$Zn_xCd_{1-x}Te$ (x=0.1)**	**p-Sb_2Te_3**
W (µm)	0.1	0.05-0.2	0.2- 4.0	0.5
$\varepsilon/\varepsilon_0$	9.0	9.3	9.5	55
μ_e (cm^2/Vs)	100	95	250	1094
μ_p (cm^2/Vs)	25	35	70	320
n, p (cm^{-3})	10^{19}	2.5×10^{16}	5×10^{14}	7.5×10^{21}

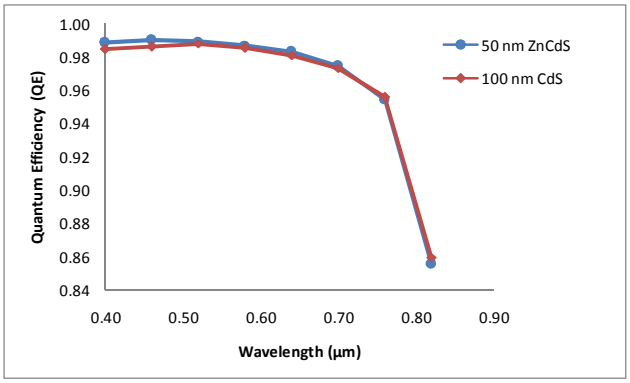

Figure 2. Spectral responses of ZnCdS and CdS window layer.

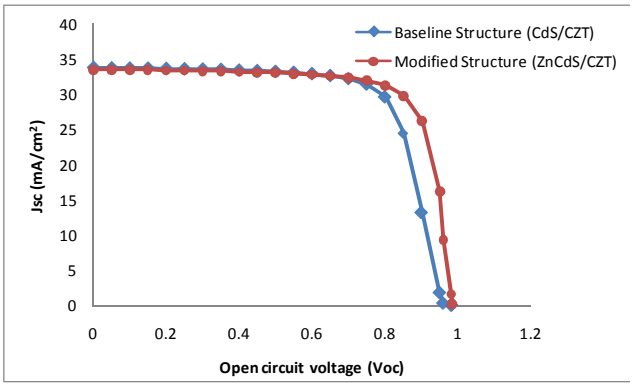

Figure 3. J-V characteristics curve of baseline and modified CZT solar cell.

Table II. Comparison of performance parameters between baseline case and modified cell

Performance parameters	Baseline case structure of CZT cell	Modified structure of CZT cell
η (%)	21.63	23.17
FF (%)	0.73	0.77
Jsc (mA/Cm^2)	33.71	33.50
Voc (V)	0.96	0.98

B. *Optimization of window and absorber layerthickness*

In this part, $Zn_{0.1}Cd_{0.9}S$ window layer thickness and $Zn_{0.1}Cd_{0.9}Te$ absorber layer thickness are optimized to form an ultrathin solar cell without affecting the cell performance. The thickness of window layer is changed from 25 nm to 200 nm.

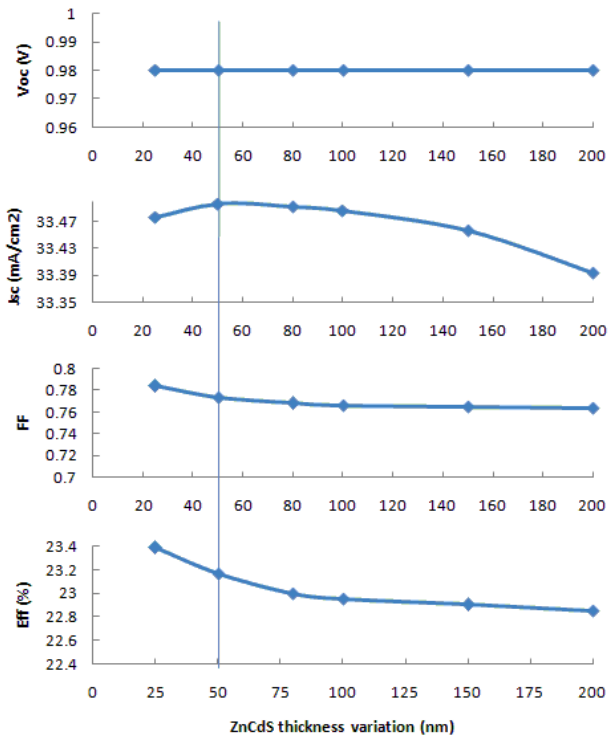

Figure 4. Effect of ZnCdS window layer thickness on cell performance parameters.

Fig. 4 shows the effect of window layer thickness variation on cell performance parameters. It is investigated that by decreasing the thickness of window layer the cell efficiency (η), current density (*Jsc)* and fill factor (*FF*) has been increased. Efficiency is increased due to increase of *Jsc* and *Jsc* is increased due to the use of wide band gap window layer as well as insertion of additional layers of ZnO and Sb_2Te_3. ZnO reduced the pinhole creation in ZnCdS layer and prevent forward leakage current. Whereas BSF layer reduced the loss due to minority carrier recombination at back contact as well as improved the stability of the cell at high operating temperature. However, by decreasing the thickness of window layer *FF* is increased a bit, because thinner window layer decreases overall cell resistance. But there is no change in *Voc* due to reduction of window layer thickness. The thickness of window layer is reduced from 200nm to 25nm and as a result the efficiency increases from 22.85% to 23.38%. Still to date it is impractical to fabricate good quality devices with ZnCdS film thickness below 50nm. Consequently the optimum thickness of window layer has been set to 50nm with conversion efficiency 23.17%.

In this work the thickness of absorber layer is varied from 0.2 µm to 4.0 µm. The effect of thickness variation of $Zn_{0.1}Cd_{0.9}Te$ absorber layer has shown in Fig. 5. It is evident from Fig. 5 that, efficiency almost follows the short circuit current trend. It can be seen that by decreasing the absorber layer thickness from 4.0 µm to 1.0µm the magnitude of *Jsc* decreases slightly. But *Jsc* decreases rapidly with the change of thickness from 1.0µm to 0.2µm. This is because of less absorption of light photon by reduced absorber layer thickness. That's why the efficiency decreases with lessening of absorber layer thickness because of the shrinking of *Jsc*. The increase of CZT layer thickness causes big area of p-n junction as the main

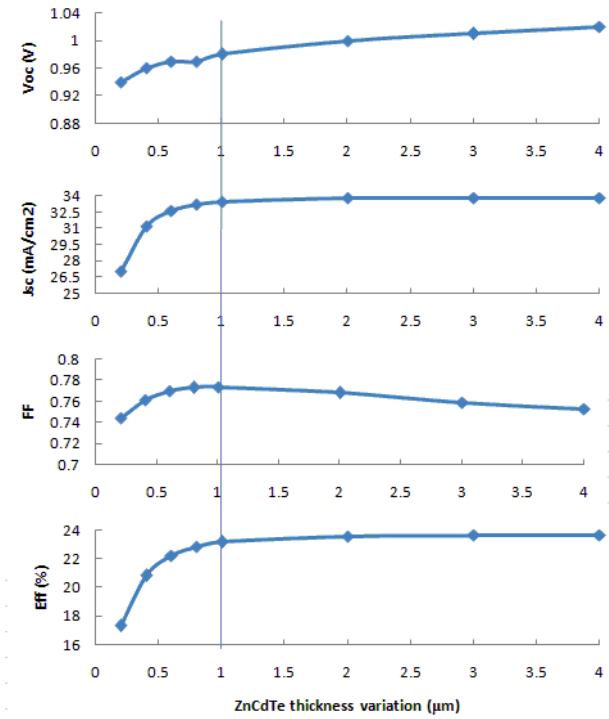

Figure 5. Effect of $Zn_{0.1}Cd_{0.9}Te$ absorber layer thickness on cell performance parameters.

part of p-n junction is formed in CZT layer. It is evident from Fig. 5 that by changing absorber layer thickness *Voc* increases gradually due to the increment of layer series resistance. On the other hand *FF* is increased with the reduction of absorber layer thickness. It is also noticed from Fig. 6 that the cell output parameters gradually decrease from 4.0µm to 1.0µm thick ZnCdTe layer. Where, all performance parameters decrease dramatically with the thinning of absorber layer thickness from 1.0µm to 0.2µm. It was also investigated that in this work the thickness of absorber layer is reduced from 4.0µm to 0.2µm and as a result the efficiency changes from 23.67% to 17.33%. Though efficiency decreases a little bit (only 0.5%) for thickness reduction from 4.0µm to 1.0µm, thus 1.0µm thick absorber layer is proposed for modified CZT cell with a little sacrifice of efficiency but grater saving of absorber layer material ($Zn_{0.1}Cd_{0.9}Te$).

C. *Effect of temperature on cell performance*

To investigate the temperature effect on cell performance of modified cell, temperature is changed from 25°C to 100°C. Temperature effect on different performance parameters has been shown in the Fig. 6. With the increment of temperature from 25°C the cell efficiency and *FF* has slightly increased up to 50°C after then it started to decrease for further temperature increment. As temperature rises, the band gap of semiconductor decreases and *Voc* decreases with a temperature dependency factor q/kT. Solar cells therefore have a negative temperature coefficient of *Voc* (β). That's why *Voc* decreases with the increase of temperature. On the other hand, as temperature rises the band gap of semiconductor shrinks meaning more incident energy is absorbed because a greater percentage of the incident light has enough energy to increase

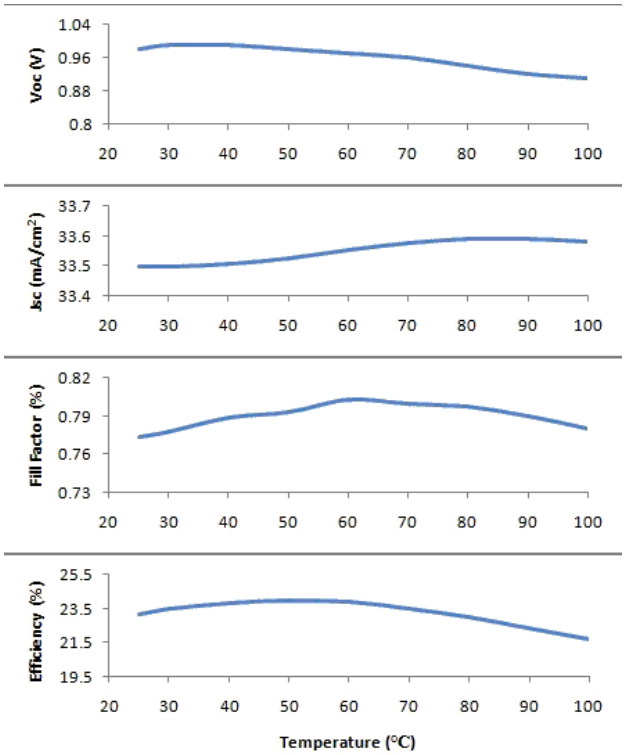

Figure 6. Effect of temperature on cell performance parameter of modified CZT cell.

charge carriers from the valance band to the conduction band. In effect, a larger photocurrent results; thus, *Isc* increases for a given insulation and solar cells have a positive temperature coefficient of *Isc* (α). Thus *Jsc* increases with the increment of temperature which is clear from the Fig. 6. The efficiency of the proposed cell at T=25°C is 23.17%, and when temperature is increased to T=50°C the efficiency become 23.83% and finally 21.68% is obtained at T=100°C. The overall temperature coefficient (TC) of the proposed cell is found 0.085% which means that this cell has good stability at higher temperature.

IV. Conclusion

From this numerical analysis it has been substantiated that the proposed modified CZT solar cell structure became thinner (1350 nm) than the reference CZT solar cell structure thickness (4600 nm) using Sb_2Te_3 BSF. It is clearly apparent that almost 70% less material will be used in this modified solar cell structure which was one of the main targets of this study. On the other hand the proposed solar cell performance has been risen (η=23.17%, *Jsc*=33.50%mA/cm^2, *Voc*=0.98V and *FF*=0.77%) due to few authentic effective modifications in the starting baseline structure. As well as the proposed cell also shows better stability (TC=0.085%) with Sb_2Te_3 BSF at high operating temperature. Thus this study clearly brings out a good prospect of the ZnCdS/ZnCdTe solar cells using Sb_2Te_3 BSF.

***Abstract*— A numerical approach is presented to calculate crystal orientation-dependent effective mass of heavy hole, light hole and spin-orbit split-off hole of III-V semiconductors (GaAs, InAs, InP, GaSb, and InSb etc.) at Gamma-point by envelope approximation using *k.p* method. Unitary transformation is used to modify the wave vector and eight-band k.p Hamiltonian is applied in conventional (100) crystal orientation. The simulation is carried out for conventional crystal orientations (100), (110) and (111) as well as non-conventional orientations (113), (131) and (201). It is found that there is a substantial correlation between the effective mass and the crystal orientation. The results obtained from conventional crystal orientations are compared with that of estimated by well-established PBE, HSE and MBJLDA methods and found to have within good agreement. This indicates that the proposed technique can be applied to evaluate effective mass in arbitrary orientation of III-V semiconductors. It is also found that (113) orientation possesses lowest effective mass than other orientations. The outcome of this paper would be a boost to design high-speed optoelectronic devices with improved performance by introducing non-100 oriented epitaxial layers.**

Keywords*— *Crystal orientation, Effective mass, Tensor rotation, k.p method, III-V semiconductors

I. INTRODUCTION

The zinc-blende (ZB) III-V semiconductors have received considerable attention in the last decades due to its unique characteristics such as high electron mobility and superior carrier saturation velocity [1]. Consequently, its application scope broadens up to the operation in the active region of different optoelectronic devices [2-4]. Recently, it has become apparent that energy band dispersion profile of III-V materials is strongly co-related with crystal orientations. High performance optoelectronic devices can be realized in non-conventional orientation having favorable band structure [5-6].

Modern fabrication techniques such as molecular beam epitaxy (MBE) and metal-organic chemical vapor deposition (MOCVD) enables the growth of non-(100)-orientated crystal structure. High quality epitaxial layer on (201)-oriented GaAs substrate using MBE was cited by Woolf et al. [7]. In another research work, Nötzel and Ploog reported AlAs/GaAs multilayered structures on (210)-oriented substrate [8]. The orientation-dependent emission profile of InGaSb as well as InGaAs lasers were studied and found that non-(100) oriented laser structures show excellent performance with orientation-dependent tunable characteristics [9]. In another study, Ahmed and Debbichi showed that InAsN/GaSb quantum well laser diode in (110) and (111) orientation had better optoelectronic properties than the habitual (100) growth direction [10]. Oshima et al. reported orientation dependent features of recessed gate InGaAs/AlGaAs HEMT [11]. In a separate research, Lee and Zucca showed crystal orientation effect on planer InGaAs Schottky barrier field effect transistors [12].

To explore and explain the orientation-dependent performance of III-V semiconductor based electronic and optoelectronic devices, it is very much essential to know the orientation-dependent effective mass. Extensive researches have already been carried out experimentally and theoretically to calculate effective mass of heavy hole and light hole, paying particular attention to their fundamental properties and band topologies. The band structures and effective mass of ZB III-V semiconductor are studied using the Perdew, Burke and Ernzerhof (PBE) method, the Heyd, Scuseria, and Ernzerhof hybrid functional (HSE) method, and modified Becke-Johnson combined with the local-density approximation (MBJLDA) [13]. In these studies, the masses were evaluated numerically by fitting the calculated dispersion curves around the Γ-point along the directions (100), (110) and (111). However, these methods require an extensive fitting to experimental data, which are often scarce and possibly inaccurate. Moreover, for arbitrary crystal orientation such as, (113), (131) and (201) etc., considerable uncertainty still exists for the above mentioned methods due to unavailability of experimental effective masses [13-18].

In this paper, a general mathematical model based on tensor rotation technique is developed to determine effective mass of heavy hole (HH), light hole(LH) and spin-orbit split off hole(SH) in arbitrary (hkl) crystal orientation for ZB III-V semiconductor (GaAs, InAs, GaSb, InSb, InP) at Γ-point. The electronic band structure is calculated using an eight-band ***k.p*** Hamiltonian including spin-orbit coupling which enables us to have a good model for the non-parabolic dispersion of topmost valence band. Tensor rotation technique is used to modify wave vector and Hamiltonian for conventional (100) crystal orientation. The conduction and valence band wave functions and Eigen energies are evaluated using the finite difference method. The average heavy hole, light hole and spin-orbit split-off hole masses are obtained by exploring the orientation dependent parameters and addressing the energy separation from conduction band to heavy hole and light hole valence bands over all possible directions of wave vector. To confirm the validity of the results obtained from the proposed model, they are compared with the experimental and simulation

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

results reported in previous studies for (100), (110) and (111) orientations.

The layout of this proposal is outlined as follows: the theoretical details to calculate electronic band structure and valence band effective masses of the ZB III-V semiconductor are illustrated in section 2. Results and discussions on the valence band structure in arbitrary orientation, Hole effective masses, and optical gain are presented in section 3. Finally, a conclusion is depicted in section 4.

II. THEORY

A. The k.p Method of Band-Structure Calculation near Γ-point

The electronic band structure is solved in envelope approximation using eight-band $\boldsymbol{k}\cdot\boldsymbol{p}$ Hamiltonian, H_0. The Kane's 8×8 Hamiltonian matrix can be asserted by [19]:

$$H\psi_h(z) = E\psi_h \tag{1}$$

The components of the Hamiltonian matrix are:

$$H_0=\begin{bmatrix} A & 0 & V^* & 0 & \sqrt{3}V & -\sqrt{2}U & -U & \sqrt{2}V^* \\ 0 & A & -\sqrt{2}U & -\sqrt{3}V^* & 0 & -V & \sqrt{2}V & U \\ V & -\sqrt{2}U & -P+Q & -S^* & R & 0 & \sqrt{\frac{3}{2}}S & -\sqrt{2}Q \\ 0 & -\sqrt{3}V & -S & -P-Q & 0 & R & -\sqrt{2}R & \frac{1}{\sqrt{2}}S \\ \sqrt{3}V^* & 0 & R^* & S & -P+Q & S^* & \frac{1}{\sqrt{2}}S^* & \sqrt{2}R^* \\ -\sqrt{2}U & -V^* & 0 & R^* & S & -P+Q & \sqrt{2}Q & \sqrt{\frac{3}{2}}S^* \\ -U & \sqrt{2}V^* & \sqrt{\frac{3}{2}}S^* & -\sqrt{2}R^* & \frac{1}{\sqrt{2}}S & \sqrt{2}Q & -P-\Delta & 0 \\ \sqrt{2}V & U & -\sqrt{2}Q & \frac{1}{\sqrt{2}}S^* & \sqrt{2}R & \sqrt{\frac{3}{2}}S & 0 & -P-\Delta \end{bmatrix} \tag{2}$$

The wave function $\Psi_h(z)$ can be given by:

$$\Psi_h(z) = \begin{bmatrix} \Phi_{1/2,1/2}(z) \\ \Phi_{1/2,-1/2}(z) \\ \Phi_{3/2,1/2}(z) \\ \Phi_{3/2,-1/2}(z) \\ \Phi_{3/2,3/2}(z) \\ \Phi_{3/2,-3/2}(z) \\ \Phi_{1/2,1/2}(z) \\ \Phi_{1/2,-1/2}(z) \end{bmatrix} = \begin{bmatrix} g^{(1)}(z) \\ g^{(2)}(z) \\ g^{(2)}(z) \\ g^{(4)}(z) \\ g^{(5)}(z) \\ g^{(6)}(z) \\ g^{(7)}(z) \\ g^{(8)}(z) \end{bmatrix} \tag{3}$$

where, ϕ_{j,m_j} or $g^{(j)}$ is the conduction and valence band wave function component and E is the energy of conduction band and three valence bands.

The matrix elements are [19]:

$$A=E_c-\frac{\hbar^2}{2m_0}(k_x^2+k_y^2+k_z^2) \tag{4}$$

$$P=-E_v-\gamma_1\frac{\hbar^2}{2m_0}(k_x^2+k_y^2+k_z^2) \tag{5}$$

$$Q=-\gamma_2\frac{\hbar^2}{2m_0}(k_x^2+k_y^2+k_z^2) \tag{6}$$

$$R=\sqrt{3}\frac{\hbar^2}{2m_0}[\gamma_2(k_x^2-k_y^2)-2i\gamma_3k_xk_y] \tag{7}$$

$$S=-\sqrt{3}\gamma_3\frac{\hbar^2}{2m_0}k_z(k_x-ik_y) \tag{9}$$

$$U=\frac{-i}{\sqrt{3}}p_0k_z \tag{10}$$

$$V=\frac{-i}{\sqrt{6}}P_0(k_x-ik_y) \tag{11}$$

P_0 is the coupling between the conduction and valence bands, E_c and E_v are the (unstrained) conduction and valence band energies respectively, and Δ is the spin orbit splitting. The γ_i's are modified Luttinger parameters.

The energy dispersion profile along (100) orientation is calculated as a function of k for the 8-band $\boldsymbol{k.p}$ theory by diagonalizing the Hamiltonian using finite difference scheme.

B. Crystal orientation dependent Energy Band

As the conduction band wave function does not change exclusively with crystal orientation, here we are interested about the modification in the valence band Hamiltonian matrix owing to crystal orientations. If the working region is grown on arbitrary crystal orientation, the wave vectors on (100) crystal can be attained by the subsequent formula [20]:

$$\begin{pmatrix} k_1 \\ k_2 \\ k_3 \end{pmatrix} = O_R \begin{pmatrix} k_x \\ k_y \\ k_z \end{pmatrix} \tag{12}$$

where, k_x, k_y, k_z are the wave vectors along (hkl) direction. The expression of the rotation matrix is as follows [21]:

$$O_R = \begin{pmatrix} cos\theta cos\emptyset & -sin\emptyset & sin\theta cos\emptyset \\ cos\theta sin\emptyset & cos\emptyset & sin\theta sin\emptyset \\ -sin\theta & 0 & cos\theta \end{pmatrix} \tag{13}$$

where, $\theta = \tan^{-1}\left(\frac{\sqrt{(h^2+k^2)}}{l}\right)$ and $\phi = \tan^{-1}(k/h)$

Practicing the wave vector in the (100) crystal orientation, the Hamiltonian matrix for (100) crystal orientation can be calculated using eqn. (2). Then the Hamiltonian matrix in (hkl) orientation can be obtained by [22]:

$$H^{hkl} = U H^{(100)} U^* \tag{14}$$

where, $U = R(\theta)R(\phi)$

In this equalization, $R(\theta)$ and $R(\phi)$ are symbolized as rotations which transform the (100) orientated valence band Hamiltonian to arbitrary crystal orientated Hamiltonian matrix. The argument of $R(\theta)$ and $R(\phi)$ can be defined by [21]:

$$R(\theta)=\begin{pmatrix} \alpha^2 & -\sqrt{3}\alpha^2\zeta & \sqrt{3}\alpha\zeta^2 & \zeta^3 \\ \sqrt{3}\alpha^2\zeta & \alpha^3-2\alpha\zeta^2 & -2\alpha^2\zeta+\zeta^3 & \sqrt{3}\alpha\zeta^2 \\ \sqrt{3}\alpha\zeta^2 & 2\alpha^2\zeta-\zeta^3 & \alpha^3-2\alpha^2\zeta & -\sqrt{3}\alpha^2\zeta \\ \zeta^3 & \sqrt{3}\alpha\zeta^2 & \sqrt{3}\alpha^2\zeta & \alpha^3 \end{pmatrix} \tag{15}$$

$$\alpha = \cos\frac{\theta}{2} \text{ and } \zeta = -\sin\frac{\theta}{2}$$

$$R(\phi) = \begin{pmatrix} e^{i(3/2)\phi} & 0 & 0 & 0 \\ 0 & e^{i(1/2)\phi} & 0 & 0 \\ 0 & 0 & e^{-i(1/2)\phi} & 0 \\ 0 & 0 & 0 & e^{-i(3/2)\phi} \end{pmatrix} \tag{16}$$

C. *Crystal orientation dependent Effective Mass:*

A general mathematical model based on tensor rotation technique is proposed to determine average heavy hole (m^*_{hh}), light hole (m^*_{lh}) and spin-orbit split off hole (m^*_{so}) effective masses for Zinc blende III-V semiconductors in arbitrary (*hkl*) crystal orientations over all possible directions of wave vector k considering the wrapped spheres of valence band energy surface figured out by 8×8 k.p Hamiltonian. The formulations can be given by [23]:

$$(1/m^*_{hh}) = \frac{-2A + 2B(1+ 2C^2/15B^2)}{\hbar^2} \quad (17)$$

$$(1/m^*_{lh}) = \frac{-2A - 2B(1+ 2C^2/15B^2)}{\hbar^2} \quad (18)$$

$$(1/m^*_{so}) = 1-(2/3)\left(\frac{M^2}{m_0(E_0+\Delta_0)} + \frac{2N^2}{m_0(E_0+\Delta_0)}\right) \quad (19)$$

The constants A, B, C (in units of $\hbar^2/2m$) are related to momentum matrix element between conduction band and valence band and energy band gaps and can be given by [23]:

$$\frac{2m_0}{\hbar^2}A = 1-\frac{2}{3}\left[\left(\frac{M^2}{m_0E_0}\right) + \left(\frac{2N^2}{m_0E_0'}\right)\right] \quad (20)$$

$$\frac{2m_0}{\hbar^2}B = \frac{2}{3}\left[\left(\frac{-M^2}{m_0E_0}\right) + \left(\frac{2N^2}{m_0E_0'}\right)\right] \quad (21)$$

$$\left(\frac{2m_0}{\hbar^2}C\right)^2 = \frac{16M^2N^2}{3m_0E_0m_0E_0'} \quad (22)$$

E_0= energy separation between conduction and heavy hole band
E'_0 = energy separation between conduction and light hole band
Δ_0= Spin-orbit splitting of valence band

M and N is the orientation dependent wave vector that can be given by [23]:

$$M=\left(\frac{\hbar^2\gamma_1}{2m_0}\right)(k_x^2+k_y^2+k_z^2) \quad (23)$$

$$N=\left(\frac{\hbar^2\gamma_2}{2m_0}\right)(k_x^2+k_y^2 - 2k_z^2) \quad (24)$$

Since change in crystal orientation changes the splitting between valence bands; knowing the energy separation E_0 and E'_0 and orientation dependent M and N parameters, Valence band effective masses in any arbitrary (hkl) orientation can be calculated.

III. RESULTS AND DISCUSSIONS

Following the mathematical model presented in section II, effective mass of heavy hole, light hole and spin-orbit split-off hole of ZB III-V semiconductors (GaAs, InAs, InP, GaSb, InSb etc.) at Γ-point for arbitrary (hkl) crystal orientation are determined. The simulation is carried out in MATLAB environment at room temperature. The valence band dispersion profiles of GaAs are evaluated in (100), (110), (111) and (113) orientations and shown in Fig. 1(a)-(d) respectively. To compare the orientation-dependent band dispersion profiles, the figures are plotted as a function of wave vector in the same scale. It is demonstrated that, for nonzero value of k (wave vector in the plain direction), the increasing conduction and spin-orbit split off band coupling gives rise to strong non-parabolicities in the valence band structure at (111) and (113) orientations. For (113) orientation, larger energy spacing between heavy hole and light hole is found so hole effective mass may reduce. From Fig. 1, it is demonstrated that crystal orientation exclusively changes the topmost valence band curvature which explains effective mass has an orientation-dependent characteristic.

The effective mass of heavy hole, light hole and spin-orbit split-off hole is determined from eqns. (17-19).The related parameters are extracted from the orientation-dependent band dispersion profiles. The results estimated from the proposed technique are listed in Table I for (100), (110) and (111) orientations at the Γ-point.To confirm our results; they are compared with the results obtained from the well-established

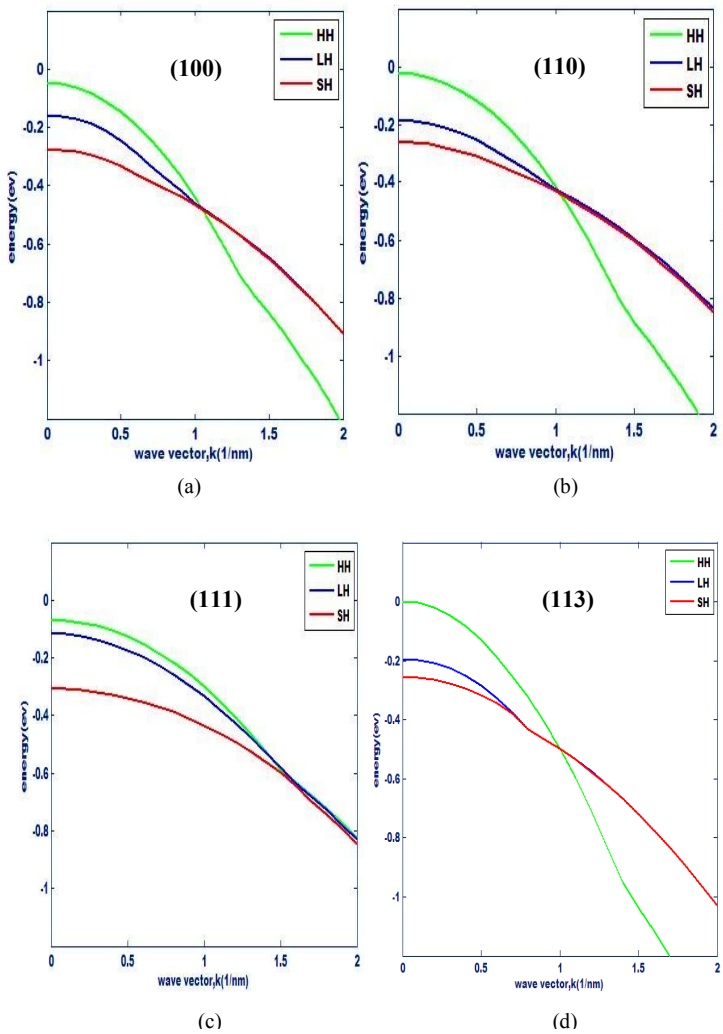

Fig. 1: Valence band dispersion profiles of (a) (100), (b) (110), (c) (111), and (d) (113) - oriented GaAs

PBE, HSE and MBJLDA methods. It is noted here that, in previous studies, the masses were evaluated numerically by fitting the calculated dispersion curves around the Γ-point for the conventional directions (100), (110), and (111) [Ref. 18]. It is seen from Table I that there is a good agreement between our results and the results obtained from the well-established methods. Fig. 2 demonstrates the correlation of heavy hole effective mass of GaAs obtained from well-established HSE, PBE, MBJLDA methods and our proposed formulations along (100), (110) and (111) orientations. It is observed that from our proposed formulations, effective mass of heavy hole of GaAs along (100), (110) and (111) orientations is found to be $0.345m_0$, $0.528\ m_0$, $0.823\ m_0$ whereas, from HSE method, they are found to be $0.3257m_0$, $0.5571\ m_0$ and $0.7299\ m_0$ which shows a reasonable agreement. From this motivation, we calculated effective mass of these materials along arbitrary (hkl) crystal orientations such as (113), (131) and (201) etc. The results are listed in Table II. From Table I and II, it can be seen that lowest heavy hole effective mass for GaAs, InAs and InSb is found in (113) orientation. So it is quite visible that the smallest effective masses in (113) orientation leads to have high performance (113)-oriented optoelectronic devices than the habitual crystal growth orientations like (100) and (111).

IV. CONCLUSION

A general mathematical model based on tensor rotation technique is proposed to understand the impact of crystal orientation on valence band effective masses of ZB III-V semiconductors at the Γ-point. The theoretical results depict that the curvature of topmost heavy hole and light hole bands changes exclusively with crystal orientation. Addressing the splitting between energy bands and exploring the orientation dependent parameters over all possible directions of wave vector, the average heavy hole, light hole and spin-orbit split-off hole masses are obtained which show that lowest effective masses are obtained in (113) orientation for GaAs, InAs and InSb crystals. However, this results are not consistent for GaSb and InP materials and also for light hole and split off hole masses. This simulation results demonstrate that our proposed formulations will be a boost for the fabrication of novel optoelectronic devices along other crystallographic orientations than the conventional [100] or [111] growth direction.

***Abstract*—Graphene nanoribbons (GNRs) are predicted to be essential components in future graphene nanoelectronics. Recent studies show that atomic scale edge structures of GNRs consist of armchair and zigzag edges with some other defects. Here we probe systematically the details of the phonon properties of GNRs with realistic edge structures combining the armchair and zigzag edges along with some vacancies using the forced vibrational method. We have calculated the phonon density of states (PDOSs) and typical mode patterns of GNRs considering the effects of the mixture of the different directional armchair edge and zigzag edge with some vacancy type defects. We find that in-plane longitudinal and transverse optical (LO) and (TO) mode phonons of realistic edge shaped GNR are non-degenerate and shifted down with the decrease of ribbon width. The PDOS at low frequency region changes significantly for the realistic edge structures. We observe a strongly localized eigenmodes of in-plane transverse optical phonon (iTO) near the armchair edges and defect sites which are conceptually very good agreement with the Raman D peak comes from the armchair edges or the defects of GNRs activated by the iTO phonons.**

Keywords—Graphene nanoribbons, realistic edge strucures, phonon density of states, vacancy defects, strong localization.

I. INTRODUCTION

High expectations are set for graphene electronics [1] due to its incomparable properties. However, the electronic applications are crippled by the absence of energy band gap in the pristine graphene. If graphene sheet is patterned into a narrow ribbon, it opens a band gap by quantum confinement [2]-[6]. It is envisaged that the large band gap opening in the nanoribbons depend on the nature of the edge structures and their orientations. The edge geometry is the preeminent parameter which determines the electronic properties of the nanoribbons. For example, localized states appear at the edge with energies close to the Fermi level [7]-[8] in the graphene nanoribbons with zigzag edges. In contrast, edge states are away for ribbons with armchair edges. It has been suggested that armchair edges give rise to intervalley backscattering, which is suppressed at zigzag edges [9]. The research of the edge dependent fundamental and application oriented properties are thus of indispensable prerequisite for tomorrow's graphene-based electronics.

Recent studies [10]-[11] on edge structures of graphene nanoribbons (GNRs) perceive that although the edge may be mainly armchair or zigzag at the microscopic scale, it is not perfect armchair or zigzag at the atomic scale, but a mix of them with some other defects. It is also believed that the armchair edge of GNRs act as a crystalline defects. As electrons and phonons are strongly coupled in graphene related materials, the electron transports of GNRs strongly depend on the nature of edge-phonon modes in addition to the roughness of the ribbon edge [12]-[13]. Because of the scattering by disorders, phonons have the finite lifetime and localization length, which is one of the main contributions to the natural line width of the Raman spectra, the widely used tool for the investigation of graphene related system. We thus require a detailed understanding of the effects of various types of edges, their orientation, and the defects on the phonon modes which noticeably change the electron transport properties.

Over the last few years, many approaches have been employed to estimate the vibrational properties of graphene nanoribbons including force constant fittings [14]-[15], density functional theory [16]-[17] and the first-principles calculations [18]-[19]. In contrast to the intensive research on the ribbons with perfect edges, there is no studies on the vibrational properties of GNRs having realistic edge structures. The disordered edges of GNRs may induce the symmetry breakdown of elemental topological arrangements [12], which generate more complex lattice structures. Therefore, the dynamical matrix technique needs enormous computational resources. These long computational times and convergence problems in the dynamical matrix calculations restrict the systems of interest to benchmark molecules. Nonetheless, a considerably larger scale model is essential for an in-depth understanding of vibrational properties of disordered atomic structures. It is thus indispensible to develop a reliable model to observe the phonon modes of GNRs with realistic edge structures directly.

In this work, we explore systematically the details of the phonon properties of GNRs consist of realistic edge structures combining the armchair and zigzag edge with some vacancy defects. We have estimated the phonon density of states (PDOSs) of GNRs considering the effects of the mixture of the various directional armchair and zigzag edges with some

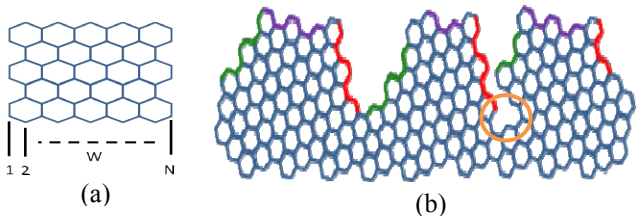

Figure 1. Graphene nanoribbons with (a) perfect armchair edge on both sides(b) realistic edge combining the armchair and ziga edges along with some point defects. The dimer and red lines indicate the ribbon width and different directional armchair edges, respectively. Orange circle shows the vacancy defects.

vacancy type defects. For all calculations, we employed the forced vibrational method [20], which is based on the mechanical resonance to extract the vibrational eigenmodes for very complex and large disordered systems by numerical simulation. Due to the defects, the phonon modes lie outside of the allowed frequency range of the pristine crystal. These are called localized modes as the mode energy is concentrated near the defect site. Since localization virtually immobilizes phonons and makes them non-conducting, these phonons lose their nature as heat carriers. In spite of graphene related systems have the excellent thermal conductance, disordered regions may interrupt the crystallinity and impede the flow of thermal energy. To study the localized eigenmodes, typical mode pattern of GNRs considering different directional real edges and defects has also been calculated. Here, we mainly concentrate on the K-point of the in-plane optical mode phonons as they have significant effects on the Raman spectra of GNRs.

II. Computational Details

All the calculations in this work were carried out using the forced vibrational (FV) method introduced by Williams and Maris [20]. The FV method is an efficient scheme for computing spectral densities, eigenvalues and eigenvectors of complex and large disordered physical systems. The algorithm utilizes a principle of Hamilton mechanics: a linear lattice dynamical system driven by a periodic external force of certain frequency will respond with large amplitudes in those eigenmodes close to this frequency. Specifically, the eigenvalue analysis is reduced to solve the time development of the equations of motion in the presence of an external periodic force. In general, the equation of motion of the system consists of N atoms which are coupled together with linear springs, with the scalar displacement of the lth mass, $u_l(t)$ is:

$$M_l \ddot{u}_l(t) + \sum_{l'} \phi_{ll'} u_{l'}(t) = 0 \qquad (1)$$

For time t > 0, a random force $F_l = F_0\sqrt{M_l}\cos(\varphi_l)\cos(\Omega t)$ is applied to each atom l at rest. Where, F_0 is a constant amplitude, the phase φ_l and Ω are a random variable with respect to the site number l and a frequency of the external force, respectively. Thus, for large times the periodic external force excites only those modes whose frequency is close to Ω. When we average all possible values of φ_l and use the orthonormality of the eigenvectors, the averaged total energy of the system after time T becomes:

$$\langle E(\Omega,T)\rangle \approx \frac{\pi t F_0^2}{8}\sum_{\lambda}\delta[(\omega_\lambda - \Omega) = \frac{\pi t F_0^2 N g(\Omega)}{8} \qquad (2)$$

where $g(\Omega)$ is the phonon density of states (PDOS). Thus:

$$g(\Omega) = \frac{8\langle E(\Omega,T)\rangle}{\pi t F_0^2 N} \qquad (3)$$

In order to obtain the PDOS, our task is to compute the averaged total energy $\langle E(\Omega,T)\rangle$. Moreover, the mode patterns can also be obtained by applying iteratively the external periodic force proportional to the displacements of atoms at each step. The calculations start with the GNRs having perfect armchair edges on both side. Following the previous convention [12]-[13], the GNRs with armchair shaped edges on both sides are classified by the number of dimer lines (N) across the ribbon width W. The structural model of GNRs with perfect armchair edge and realistic edge combining the armchair and zigzag edge along with some point defects is shown in Fig. 1a and 1b, respectively. The maximum width of up to 4 nm (~32 AGNR), while the length is about 120 nm long in the total of 17,474 atoms are considered. The simulations are performed under the free boundary conditions (FBCs). Only interactions up to the fourth nearest neighbor atoms are used and the force constant tensor between two carbon atoms is taken from Jishi et al. [21]. For atoms near an edge, only the force constant of actual atoms is included in the calculation under the FBC.

III. Results and Discussions

Fig. 2 shows the width dependent PDOSs of pure armchair GNRs in comparison with that of the GNRs consist of realistic edges combining the armchair and zigzag edges along with some vacancy type defects. There are more fine structures (peaks) in PDOS curves for the wider GNRs, and the PDOS approaches that of infinite graphene sheet with the increase of

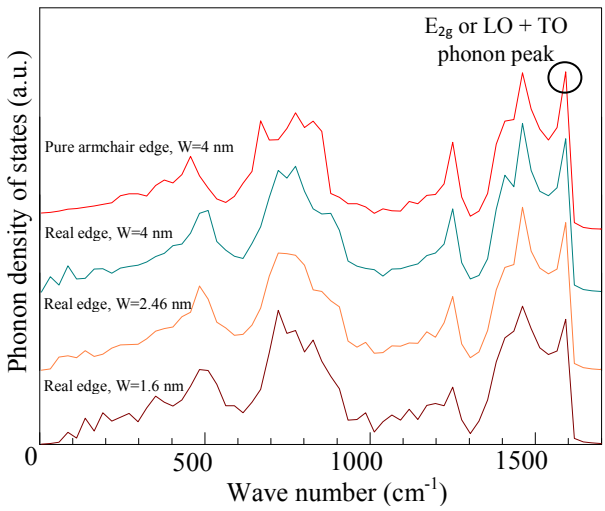

Figure 2. Width dependent phonon density of states of GNRs with realistic edge structures.

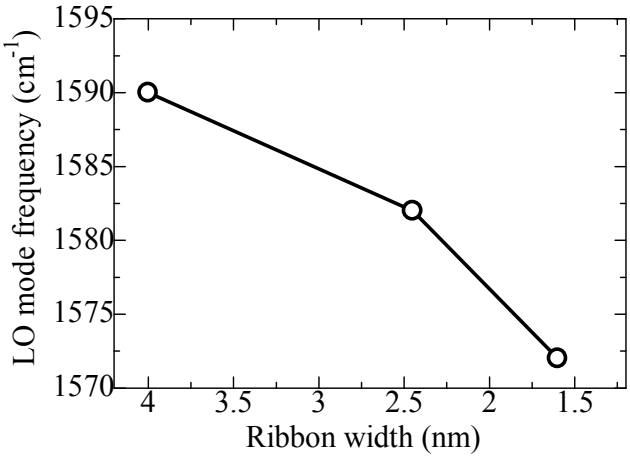

Figure 3. Longitudinal optical mode phonon as a function of ribbon width for the realistic edge structures of GNRs.

the GNR width of about 4 nm. The simulation results reveal that the PDOS of GNR with realistic edge shapes are distorted, non-degenerate and softened with the decrease of ribbon width. Generally, a group of six Γ point phonon modes are observed for GNRs. The physical origin of the G peak (around 1590 cm^{-1}) of Raman spectra comes from the scattering of a doublydegenerate longitudinal optical (LO) and transverse optical (TO) phonon at the Brillouin zone center. It is found that the Γ point of the LO and TO mode phonons of realistic edge shaped GNR are non-degenerate and shifted down with the decrease of ribbon width. The other noteworthy characteristic of the PDOS is the vanishing of fine structure (peaks) at high frequency region, while some fine peaks appear at low frequency region with the decrease of ribbon width as shown in Fig. 2. The shift of the PDOS towards the low frequency region may be induced by the increase of the numbers of the unsaturated C atom with some dangling bonds because the increase of the unsaturated C atoms in the ribbons cause to decrease of the density of high frequency modes.

In armchair graphene nanoribbons (AGNRs), only the LO phonon modes are Raman active, and the G band Raman spectra near the edge shows a down shift of the LO mode. Due to the conical shape of the energy spectrum, momentum conservation notifies that a direct electron–hole pair can couple to the Γ point LO phonon modes, thus shows a down shift of the LO mode [13]. Nevertheless, the TO phonon modes are decoupled from electron–hole pairs. Consequently, the frequency of the TO mode remains same as the original Γ point (LO and TO mode) frequencies of infinite graphene sheet [13]. These effects indicate that the LO phonon mode has the significant contribution to the electron transport in comparison with the TO phonon mode. We have extracted the LO phonon frequencies for various width of GNRs having realistic edge shapes. As can be seen from Fig. 3, the LO frequencies of the nanoribbons are shifted down. It is envisaged that the disorder edges incite the phonon non-degeneracy and move down the LO phonon frequency. The force constant tensors of carbon atoms at the disordered edges are less than that of the pure graphene nanoribbons. Therefore, the phonon frequency decreases compared with that of the ribbon with perfect edges.

The calculated typical mode pattern for the realistic edge structure of GNR is shown in Fig. 4. Here, each circle denotes an atom, and the color denotes the displacement. We mainly focus on the K point of the in plane optical modes (iTO branch) phonon of the eigenmodes due to the dominant effect of these modes on the large D band features of the Raman spectra, especially for defective states of the sample. Due to the defects, the phonons propagations are constrained into a particular region. We observe a strongly localized eigenmodes near the armchair edges and defect sites which are conceptually very good agreement with the Raman D peak comes from the armchair edges or the defects of crystals. These strongly localized states originate from the resonant vibration of the randomly arranged atoms in the disordered edges. In spite of showing the localized vibration of the mode patterns, the centers of the localized modes are not in the same places for different time development. To take out the eigenmodes, a random force has been applied to the each atom of the systems. It is thus expected that the centers of the localized modes are traveled with the each time development. However, in all time development, the centers of the localized modes stay asymmetrically near the armchair edges or the vacancies.

IV. Conclusion

In conclusions, the effect of realistic edge structures on the vibrational properties of graphene nanoribbons has been studied systematically. The forced vibrational method which is

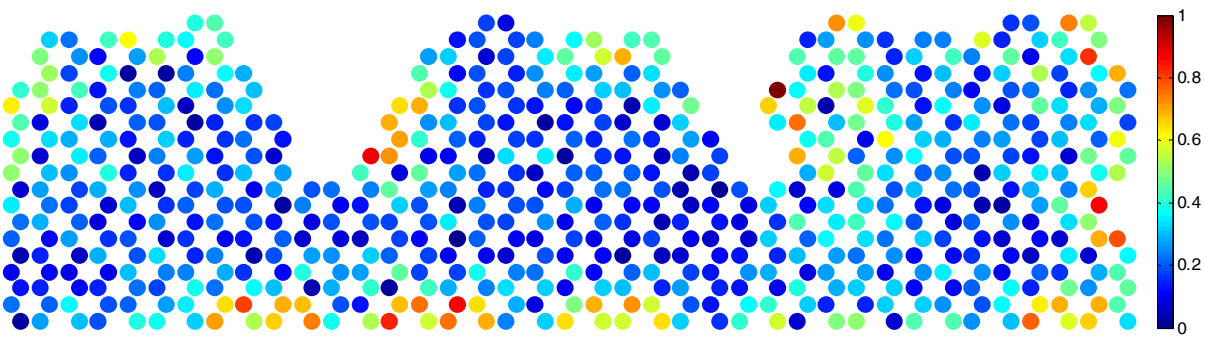

Figure 4. Typical mode pattern for in-plane transverse optical mode phonons of GNRs at 1355 cm^{-1}.

based on the mechanical response to extract the pure vibrational eigenmodes has been employed to perform the numerical experiment. We have calculated the phonon density of states (PDOSs) and typical mode patterns of GNRs considering the effects of the mixture of the different directional armchair and zigzag edges with some vacancy type defects. Our results show that the vibrational properties strongly depend on the realistic edge structures and the width of the ribbons. The PDOSs at low frequency region change significantly for the realistic edge structures. We observe a strongly localized eigenmodes of k-point iTO mode phonon near the armchair edges and defect sites which are conceptually very good agreement with the Raman D peak comes from the armchair edges or the defects of GNRs induced by the iTO mode phonon. These analyses are important not only in fundamental science, but also in advanced nanoelectronics, where the non-ideal realistic edges of GNRs affect the electronic properties significantly.

***Abstract*—Crosstalk induced overshoot/undershoot effects in Multilayer Graphene Nano Ribbon interconnects (MLGNRs) are investigated using ABCD parameter matrix approach for intermediate level interconnects at 8 nm technology node. The worst case crosstalk induced peak overshoot voltage for perfectly specular doped multilayer zigzag GNR interconnects is comparable to that of copper interconnects. It is observed that the performance of neutral GNR interconnects is better than that of its doped counterpart in terms of peak crosstalk induced overshoot voltage. But from the perspective of effective electric field across the gate oxide, the multilayer doped GNR interconnects outperform neutral ones and copper interconnects for all the cases. Finally, our analysis has shown that from the gate oxide reliability perspective, the perfectly specular doped multilayer zigzag GNR interconnects are significantly advantageous to copper interconnects for future generation Integrated circuit technology.**

Keywords*—Crosstalk ; Overshoot/Undershoot ; Graphene Nano Ribbon (GNR) ; Interconnects ; ABCD parameter ; Specular ; Neutral ; Gate oxide reliability ; Integrated circuit.

I. Introduction

The ever increasing circuit complexity led by Moore's law with the continuous scaling of CMOS technology has made the role of interconnects in nanometer technology nodes very prominent. However conventional copper wires face tremendous challenges of the nanometer technology where the requirement is of reliable high speed wires with minimal crosstalk effects. Graphene has been regarded as a suitable material for nanometer technology [1], [2] because of its tolerance to higher maximum current density, lower resistivity and lower capacitive effects compared to copper at nanometer dimensions [2]. Moreover, compared to multi-walled carbon nanotubes (MWCNT), Graphene is suitable for its simpler fabrication processes, better material control and reproducibility. Recently, a CMOS Ring oscillator with graphene interconnects is fabricated to operate at a frequency of 1.3 GHz [3].

Xu et. al. have studied the performance of GNR interconnect in [5]. Naeemi and Meindl has proposed a physics based circuit model for GNR interconnect in [4]. Crosstalk effects in MLGR interconnects have been studied in [7], [8], [6]. In all these works, the crosstalk induced effects are analyzed using SPICE simulations. However Simulation tools like SPICE is computationally expensive at the full-chip level [9]. Therefore, a non-SPICE based model is necessary for analyzing crosstalk effects in dense high performance ICs. The ABCD parameter matrix based model has been proposed for analyzing crosstalk induced effects in SWCNT bundle interconnects [10], MWCNT bundle interconnects [11] and MLGNR interconnects [12]. In this work, ABCD parameter based model is used to analyze crosstalk induced overshoot/undershoot effects in multilayer neutral and doped zigzag GNR interconnects of various specularity at 8 nm technology node. The impact of overshoot/undershoot on the gate oxide reliability is also estimated. It is found that 100 μm long, doped perfectly specular MLGNR interconnects have gate oxide failure rate (AFR) of three orders lesser than copper interconnects for 8 nm technology node.

The paper is presented in the following sequence. Section II presents the equivalent RLC model for multilayer GNR interconnects. Section III discusses the proposed ABCD parameter matrix based approach in details. Section IV describes how crosstalk induced overshoot/undershoot impacts the gate oxide reliability of CMOS devices. Section V presents simulation results. Finally the conclusions are drawn in Section VI.

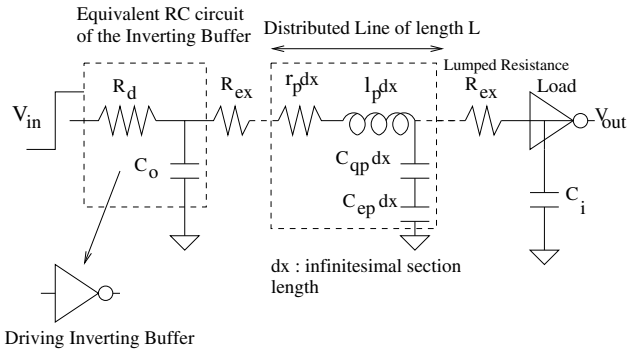

Fig. 2: Equivalent RLC model of a typical multilayer GNR interconnect system.

zigzag based on the arrangement of carbon atoms. Chirality differs the conductive property in zigzag and armchair GNR. For interconnect applications, zigzag GNR is proposed due to its metallic property. Multi-layer zigzag GNR structure is utilized in modeling the nanoscale interconnects here because of the low conductivity of the mono layer GNR interconnects. Fig. 1 shows a typical MLGNR interconnect structure [5]. The interconnect dimensions are represented as t (thickness), w(width), ht(height from ground plane), and s(spacing between the interconnects) and δ (= 0.34 nm) (spacing between each graphene layer known as the Van der Waal's gap). The interconnect dimensions have been considered according to latest ITRS-2013 data [1] as shown in Table I. The number of graphene layers is given by,

$$N_{layer} = 1 + \lfloor \frac{t}{\delta} \rfloor \tag{1}$$

Fig. 2 depicts the equivalent RLC model of a typical MLGNR interconnect system. In the figure, L is the interconnect length, R_{ex} is the lumped resistance (i.e., consists of GNR-electrode contact resistance(R_C) and quantum resistance(R_Q), $R_{ex} = (R_C + R_Q)/2$), r_p is per unit length (p.u.l) distributed resistance, l_p is p.u.l self inductance (consists of kinetic inductance, L_k and self inductance, L_s), C_{qp} is p.u.l quantum capacitance, C_{ep} is p.u.l electrostatic ground capacitance. The quantum resistance is defined as [5],

$$R_Q = \frac{\frac{h}{2q^2}}{N_{ch}N_{layer}} = \frac{12.94K\Omega}{N_{ch}N_{layer}} \tag{2}$$

where, N_{ch} is the number of conducting channels (modes) in one layer, N_{layer} is the number of GNR layers, h is the Plancks constant (=6.626×10^{-34} J.s), and q is the electronic charge (=1.6×10^{-19} C). The number of conducting channels in mono-layer graphene (i.e., N_{ch}) is given by [5],

$$N_{ch} = \sum_{j=1}^{n_C} \left[1 + e^{\frac{(E_{j,n} - E_F)}{K_B T}} \right]^{-1} + \sum_{j=1}^{n_V} \left[1 + e^{\frac{(E_{j,h} + E_F)}{K_B T}} \right]^{-1} \tag{3}$$

where, j (=1, 2, 3, ...) is a positive integer, E_F is Fermi energy, K_B is the Boltzmann constant, T is absolute temperature, and n_C and n_V are the number of conduction and valence subbands, respectively. $E_{j,n}$ and $E_{j,h}$ are the energies of electron and hole in j^{th} subband as given by [4],

$$E_j = \frac{h\nu_F}{2w} |j + \frac{1}{2}| \tag{4}$$

TABLE I: Global-level Interconnect Parameters (ITRS-2013)

Parameters \ Year	2024	2027

C_i (in fF)	0.036	0.021

where, j(=1, 2, 3, ...) is an integer. The p.u.l resistance (r_p) of the MLGNR interconnect is calculated according to the method explained in [5].

The per unit length quantum capacitance (C_{qp}) is expressed as ,

$$C_{qp} = N_{ch}N_{layer}\frac{4q^2}{h\nu_F} = N_{ch}N_{layer} \times 193.18aF/\mu m \tag{5}$$

where, ν_F is the Fermi velocity = 8×10^5 m/s for GNR [4]. The per unit length kinetic inductance(L_k) is expressed as [5],

$$L_k = \frac{\frac{h}{4q^2\nu_F}}{N_{ch}N_{layer}} = \frac{8.0884}{N_{ch}N_{layer}} nH/\mu m \tag{6}$$

The self inductance (L_s) and electrostatic capacitance (C_{ep}) of GNR are assumed to be same as that of Cu with equal dimensions [5]. The total p.u.l inductance of the MLGNR interconnect is expressed as $l_p \approx (L_k + L_s)$. Inverting buffers are used to implement both the driver and load. The load capacitance, C_i in Fig. 2, denotes the gate capacitance of the load inverting buffer. The parameters of the buffers are R_d(equivalent switching resistance), C_o(equivalent diffusion capacitance) and C_i(equivalent gate capacitance). The RC parameters (i.e., R_d, C_o and C_i) for the driver/load buffer at 8 nm technology node are calculated from ITRS-2013 roadmap [1] as shown in Table II. The analytical equations used to calculate distributed RLC parameters of copper interconnect are taken from [13].

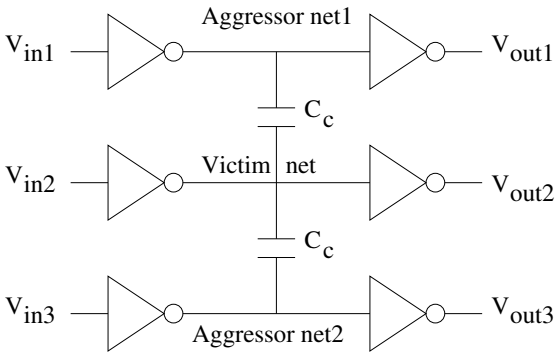

Fig. 3: How the overshoot/undershoot effects occur through coupling capacitance?

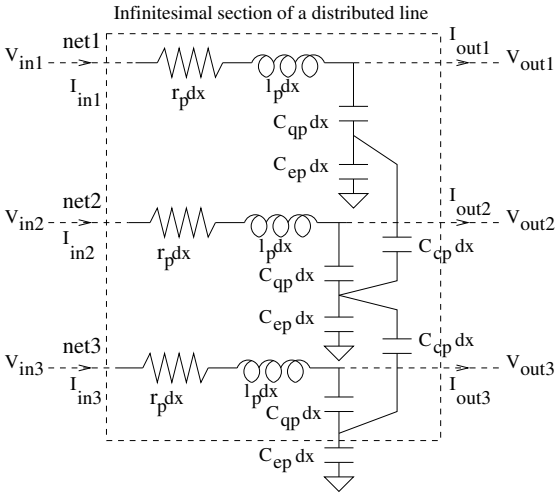

Fig. 4: Infinitesimal section of an identically coupled three conductor multilayer GNR interconnect system.

III. Modeling of Crosstalk induced overshoot/undershoot effects

Fig. 3 shows how coupling capacitance induces overshoot and undershoot in victim net. With victim net at logic high level if aggressor nets(net1 and net2) switch from logic low to high then overshoot occurs in the victim net. Whereas, for victim net kept at logic low level if both the aggressor nets switch from logic high to low then undershoot occurs.

An efficient computational model for crosstalk induced overshoot/undershoot analysis in identically coupled multilayer doped GNR interconnect systems is presented. In our proposed methodology first, we develop an analytical expression for the crosstalk induced overshoot/undershoot in Laplace domain. Then we adopt the inverse Laplace transform to find out its time-domain response. Our methodology is as accurate as SPICE but computationally much faster [10], [11]. The proposed methodology is illustrated as follows.

A. ABCD parameter based approach

An infinitesimal lumped RLC section of an identically coupled multilayer doped GNR interconnect system is shown in Fig. 4. The Kirchhoff equation for an infinitesimally small segment of these three identically coupled interconnects is given by the following equation [14],

$$\phi_{in} = P\phi_{out} \tag{7}$$

where,

$$\phi_{in} = [V_{in1}, V_{in2}, V_{in3}, I_{in1}, I_{in2}, I_{in3}]^T \tag{8}$$

$$\phi_{out} = [V_{out1}, V_{out2}, V_{out3}, I_{out1}, I_{out2}, I_{out3}]^T \tag{9}$$

and, matrix P is shown in (12). The matrix P may be diagonalized as $P = VWV^{-1}$, where,

$$V = \begin{bmatrix} Z_1 & -Z_1 & Z_2 & -Z_2 & -Z_3 & Z_3 \\ Z_1 & -Z_1 & -2Z_2 & 2Z_2 & 0 & 0 \\ Z_1 & -Z_1 & Z_2 & -Z_2 & Z_3 & -Z_3 \\ 1 & 1 & 1 & 1 & -1 & -1 \\ 1 & 1 & -2 & -2 & 0 & 0 \\ 1 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \tag{10}$$

and, W is a diagonal matrix as shown in (13). Here, dx is the length of the infinitesimal line and θ_1, θ_2 and θ_3 are the propagation constants of the decoupled interconnects. Z_1, Z_2 and Z_3 are the characteristic impedances of the decoupled interconnects. These parameters are defined as: $dx = L/n$, $\theta_1 = \sqrt{s(\alpha.C_{qp})(r_p + sl_p)}$, $\theta_2 = \sqrt{s(\beta.C_{qp})(r_p + sl_p)}$, $\theta_3 = \sqrt{s(\gamma.C_{qp})(r_p + sl_p)}$, $Z_1 = \sqrt{\frac{(r_p+sl_p)}{s(\alpha.C_{qp})}}$, $Z_2 = \sqrt{\frac{(r_p+sl_p)}{s(\beta.C_{qp})}}$ and $Z_3 = \sqrt{\frac{(r_p+sl_p)}{s(\gamma.C_{qp})}}$. Here, n is the number of infinitesimal sections. Other parameters are defined as, $\alpha = (1-2g-h)$, $\beta = (1+g-h)$ and $\gamma = (1+2f-g-h)$, where, $f = \frac{a^2}{ab^2+b^3-2a^2b}$, $g = \frac{ab}{ab^2+b^3-2a^2b}$ and $h = \frac{b^2}{ab^2+b^3-2a^2b}$ with $a = \frac{C_{cp}}{C_{qp}}$ and $b = \frac{C_{ep}+C_{qp}+C_{cp}}{C_{qp}}$. Using, $P^n = (VWV^{-1})^n = (VW^nV^{-1})$ and the identity, $\lim_{n\to+\infty}(1+\frac{x}{n})^n \to e^x$, P^n can be written as shown in (14), where, $ta = \cosh(L\theta_1)$, $tb = \cosh(L\theta_2)$, $tc = \cosh(L\theta_3)$, $td = \sinh(L\theta_1)$, $te = \sinh(L\theta_2)$,and $tf = \sinh(L\theta_3)$. Here, P_{dr} and P_{dc} are the ABCD matrices of the driving buffer, P_{Rf} is the ABCD matrix representation of the lumped resistance R_{ex} and P_{load} is that of the capacitive load. The final Kirchoff equation for the coupled interconnects can be written as,

$$\Phi_i = P_{dr}P_{dc}P_{R_{ex}}P^nP_{R_{ex}}P_{load}\Phi_o \tag{11}$$

By solving (11), the final output voltages V_{o1}(s), V_{o2}(s) and V_{o3}(s) can be represented in terms of the inputs V_{i1}(s), V_{i2}(s) and V_{i3}(s) in matrix form as shown in (15). The exact expressions of H_1(s), H_2(s) and H_3(s) in (15) are shown in (16), (17) and (18) respectively where, $A = (1 + sR_dC_o)$ and, $B = (R_d + AR_{ex})$. H_1(s), H_2(s) and H_3(s) are the transfer functions of the decoupled interconnects. Here, The transfer function for the crosstalk induced overshoot/undershoot evaluation in the victim net will be denoted as H(s) throughout the paper. H(s) can be derived from (15) for different evaluation conditions (i.e., crosstalk induced overshoot/undershoot). We consider a fifth-order Padé expansion for approximating hyperbolic functions in (16), (17) and (18) with high degree of accuracy [15]. So the transfer function H(s) will be of the form as follows [given in (19)] after the Padé expansion.

$$H(s) = \frac{1}{1 + sb_1 + s^2b_2 + s^3b_3 + s^4b_4 + s^5b_5 + s^5b_5 + s^6b_6 + s^7b_7} \tag{19}$$

where, the coefficients are shown below,

$$b_1 = \frac{L^2r_pC}{2} + R_d(C_o + C_i) + 2R_{ex}C_i + (R_d + R_{ex})LC + LC_ir_p \tag{20}$$

$$\begin{aligned} b_2 = {} & 2R_{ex}R_dC_oC_i + \frac{L^2l_pC}{2} + C_iLl_p + \frac{C_iL^3r_p^2C}{6} + \frac{L^4r_p^2C^2}{24} \\ & \frac{L^2r_pC(R_dC_o + R_dC_i + 2R_{ex}C_i)}{2} + \frac{(R_d + R_{ex})r_pL^3C^2}{6} + \\ & LR_{ex}C(R_dC_o + R_dC_i + 2R_{ex}C_i) + LC_iR_dC_or_p \end{aligned} \tag{21}$$

$$P = \begin{bmatrix} 1 & 0 & 0 & (r_p + sl_p)dx & 0 & 0 \\ 0 & 1 & 0 & 0 & (r_p + sl_p)dx & 0 \\ 0 & 0 & 1 & 0 & 0 & (r_p + sl_p)dx \\ sC_{qp}(1-(g+h-f))dx & -sC_{qp}.g.dx & -sC_{qp}.f.dx & 1 & 0 & 0 \\ -sC_{qp}.g.dx & sC_{qp}(1-h)dx & -sC_{qp}.g.dx & 0 & 1 & 0 \\ -sC_{qp}.f.dx & -sC_{qp}.g.dx & sC_{qp}(1-(g+h-f))dx & 0 & 0 & 1 \end{bmatrix} \tag{12}$$

$$W = \begin{bmatrix} (1+\theta_1 dx) & 0 & 0 & 0 & 0 & 0 \\ 0 & (1-\theta_1 dx) & 0 & 0 & 0 & 0 \\ 0 & 0 & (1+\theta_2 dx) & 0 & 0 & 0 \\ 0 & 0 & 0 & (1-\theta_2 dx) & 0 & 0 \\ 0 & 0 & 0 & 0 & (1+\theta_3 dx) & 0 \\ 0 & 0 & 0 & 0 & 0 & (1-\theta_3 dx) \end{bmatrix} \tag{13}$$

$$P^n = \begin{bmatrix} (\frac{ta}{3}+\frac{tb}{6}+\frac{tc}{2}) & (\frac{ta}{3}-\frac{tb}{3}) & (\frac{ta}{3}+\frac{tb}{6}-\frac{tc}{2}) & (\frac{td.Z1}{3}+\frac{te.Z2}{6}+\frac{tf.Z3}{2}) & (\frac{td.Z1}{3}-\frac{te.Z2}{3}) & (\frac{td.Z1}{3}+\frac{te.Z2}{6}-\frac{tf.Z3}{2}) \\ (\frac{ta}{3}-\frac{tb}{3}) & (\frac{ta}{3}+\frac{2tb}{3}) & (\frac{ta}{3}-\frac{tb}{3}) & (\frac{td.Z1}{3}-\frac{te.Z2}{6}) & (\frac{td.Z1}{3}+\frac{2te.Z2}{3}) & (\frac{td.Z1}{3}-\frac{te.Z2}{3}) \\ (\frac{ta}{3}+\frac{tb}{6}-\frac{tc}{2}) & (\frac{ta}{3}-\frac{tb}{3}) & (\frac{ta}{3}+\frac{tb}{6}+\frac{tc}{2}) & (\frac{td.Z1}{3}+\frac{te.Z2}{6}-\frac{tf.Z3}{2}) & (\frac{td.Z1}{3}-\frac{te.Z2}{3}) & (\frac{td.Z1}{3}+\frac{te.Z2}{6}+\frac{tf.Z3}{2}) \\ (\frac{td}{3Z1}+\frac{te}{6Z2}+\frac{tf}{2Z3}) & (\frac{td}{3Z1}-\frac{te}{3Z2}) & (\frac{td}{3Z1}+\frac{te}{6Z2}-\frac{tf}{2Z3}) & (\frac{ta}{3}+\frac{tb}{6}+\frac{tc}{2}) & (\frac{ta}{3}-\frac{tb}{3}) & (\frac{ta}{3}+\frac{tb}{6}-\frac{tc}{2}) \\ (\frac{td}{3Z1}-\frac{te}{3Z2}) & (\frac{td}{3Z1}+\frac{2te}{3Z2}) & (\frac{td}{3Z1}-\frac{te}{3Z2}) & (\frac{ta}{3}-\frac{tb}{3}) & (\frac{ta}{3}+\frac{2tb}{3}) & (\frac{ta}{3}-\frac{tb}{3}) \\ (\frac{td}{3Z1}+\frac{te}{6Z2}-\frac{tf}{2Z3}) & (\frac{td}{3Z1}-\frac{te}{3Z2}) & (\frac{td}{3Z1}+\frac{te}{6Z2}+\frac{tf}{2Z3}) & (\frac{ta}{3}+\frac{tb}{6}-\frac{tc}{2}) & (\frac{ta}{3}-\frac{tb}{3}) & (\frac{ta}{3}+\frac{tb}{6}+\frac{tc}{2}) \end{bmatrix} \tag{14}$$

$$\begin{bmatrix} V_{o1}(s) \\ V_{o2}(s) \\ V_{o3}(s) \end{bmatrix} = \begin{bmatrix} (\frac{1}{3}H_1(s)+\frac{1}{6}H_2(s)+\frac{1}{2}H_3(s)) & \frac{1}{3}(H_1(s)-H_2(s)) & (\frac{1}{3}H_1(s)+\frac{1}{6}H_2(s)-\frac{1}{2}H_3(s)) \\ \frac{1}{3}(H_1(s)-H_2(s)) & (\frac{1}{3}H_1(s)+\frac{2}{3}H_2(s)) & \frac{1}{3}(H_1(s)-H_2(s)) \\ (\frac{1}{3}H_1(s)+\frac{1}{6}H_2(s)-\frac{1}{2}H_3(s)) & \frac{1}{3}(H_1(s)-H_2(s)) & (\frac{1}{3}H_1(s)+\frac{1}{6}H_2(s)+\frac{1}{2}H_3(s)) \end{bmatrix} \begin{bmatrix} V_{i1}(s) \\ V_{i2}(s) \\ V_{i3}(s) \end{bmatrix} \tag{15}$$

$$H_1(s) = \frac{1}{(A(1+sC_iR_{ex})+sC_iB)\cosh(\theta_1 L)+(\frac{B}{Z_1}(1+sC_iR_{ex})+AsC_iZ_1)\sinh(\theta_1 L)} \tag{16}$$

$$H_2(s) = \frac{1}{(A(1+sC_iR_{ex})+sC_iB)\cosh(\theta_2 L)+(\frac{B}{Z_2}(1+sC_iR_{ex})+AsC_iZ_2)\sinh(\theta_2 L)} \tag{17}$$

$$H_3(s) = \frac{1}{(A(1+sC_iR_{ex})+sC_iB)\cosh(\theta_3 L)+(\frac{B}{Z_3}(1+sC_iR_{ex})+AsC_iZ_3)\sinh(\theta_3 L)} \tag{18}$$

$$\begin{aligned} b_3 = {} & \frac{L^2 l_p C(R_dC_o+R_dC_i+2R_{ex}C_i)}{2} + Cr_pL^2R_dR_{ex}C_oC_i + \\ & \frac{C^2r_pl_pL^4}{12} + l_pLC_iR_dC_o + \frac{C^2r_p^2L^4(R_dC_o+R_dC_i+2R_{ex}C_i)}{24} \\ & + CLC_iR_{ex}^2R_dC_o + \frac{C^2r_pL^3R_{ex}(R_dC_o+R_dC_i+R_{ex}C_i)}{6} + \\ & \frac{Cr_p^2L^3R_{ex}C_iC_o}{6} + \frac{Cr_pl_pC_iL^3}{6} + \Big(\frac{Cl_pL^3}{6}+\frac{C^2r_p^2L^5}{120}\Big) \\ & (C(R_d+R_{ex})+r_pC_i) \end{aligned} \tag{22}$$

$$\begin{aligned} b_4 = {} & Cl_pL^2R_dR_{ex}C_oC_i + \frac{C^2l_p^2L^4}{24} + \frac{C^2r_p^2L^4(R_dC_oR_{ex}C_i)}{12} + \\ & \frac{C^2r_pl_pL^4(R_dC_o+R_dC_i+2R_{ex}C_i)}{12} + \frac{Cr_pl_pC_iL^3R_dC_o}{6} + \\ & \frac{C^2r_pC_iL^3(R_dC_oR_{ex}^2)}{6} + \frac{C^2r_pl_pL^5}{60}(C(R_d+R_{ex})+rC_i) + \\ & \Big(\frac{Cl_pL^3}{6}+\frac{C^2r_p^2L^5}{120}\Big)(CR_{ex}R_dC_o+CR_{ex}C_i(R_d+R_{ex})+ \\ & r_pC_iR_dC_o+l_pC_i) \end{aligned} \tag{23}$$

$$\begin{aligned} b_5 = {} & \frac{C^2l_p^2L^4}{24}(R_dC_o+R_dC_i+2R_{ex}C_i) + \Big(\frac{Cl_pL^3}{6}+\frac{C^2r_p^2L^5}{120}\Big) \\ & (CR_{ex}^2C_iR_dC_o+l_pC_iR_dC_o) + \frac{C^2l_p^2L^5}{120}(C(R_d+R_{ex})+rC_i) + \\ & \frac{C^2r_pl_pL^4(R_dC_oR_{ex}C_i)}{6}(CR_{ex}R_dC_o+CR_{ex}C_i(R_d+R_{ex})+ \\ & r_pC_iR_dC_o+l_pC_i) + \frac{C^2r_pl_pL^5}{60} \end{aligned} \tag{24}$$

$$\begin{aligned} b_6 = {} & \frac{C^2l_p^2L^4(R_dC_oR_{ex}C_i)}{12} + \frac{C^2r_pl_pL^5}{60}(CR_{ex}^2C_iR_dC_o+ \\ & l_pC_iR_dC_o) + \frac{C^2l_p^2L^5}{120}(CR_{ex}R_dC_o+CR_{ex}C_i(R_d+R_{ex})+ \\ & r_pC_iR_dC_o+l_pC_i) \end{aligned} \tag{25}$$

$$b_7 = \frac{C^2l_p^2L^5}{120}(CR_{ex}^2C_iR_dC_o+l_pC_iR_dC_o) \tag{26}$$

Similarly, H_2(s) and H_3(s) can be represented in a form as given in (19). The parameter C in the coefficients b_1 to b_7 varies according to the transfer function of the decoupled interconnect and it is represented as αC_{qp}, βC_{qp} and γC_{qp} in $H_1(s)$, $H_2(s)$ and $H_3(s)$ respectively. The other parameters correspond to the distributed parameters of the copper interconnect, length of the interconnect, driver and load RC parameters.

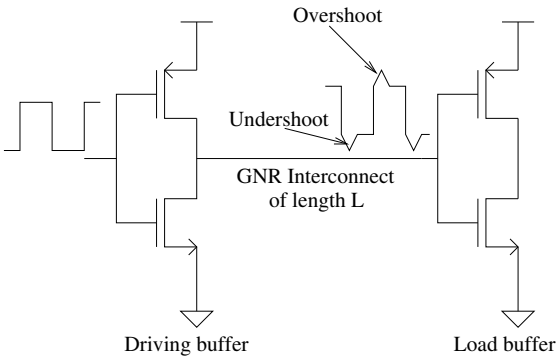

Fig. 5: Crosstalk induced overshoot/undershoot effects.

IV. Gate oxide reliability of CMOS devices

Fig. 5 depicts how overshoot stresses the NMOS gate oxide and undershoot stresses the PMOS gate oxide. As understood from the figure that, gate oxides of MOS transistors are operated under pulsed conditions. Thus the gate oxide faces an ac electric field. However, to estimate the impact of this electric stress on the oxide, an effective electric field is defined as follows [16],

$$E_{avg} = \frac{1}{\psi}\ln\Big[\frac{1}{T}\int_0^T e^{\psi E_{ins}(t)}dt\Big] \tag{27}$$

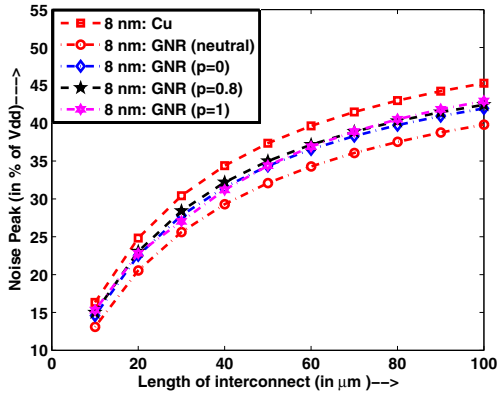

Fig. 6: Comparison of crosstalk induced peak overshoot voltage at 8 nm node

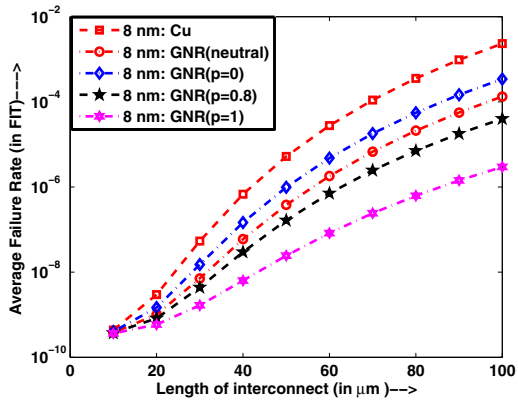

Fig. 8: Comparison of average failure rate of MOS gate oxide at 8 nm node.

where, ψ is the field acceleration factor. In [17], it is shown that the impact of the overshoot/undershoot induced electric field can be estimated by calculating the average failure rate (AFR) of the MOS gate oxides. Information about failure rates of gate oxides is already gathered under various electric stress conditions (i.e., varying oxide thickness, applied gate voltage etc.) using a reference oxide area and reference temperature. The AFR [16] of a MOS device having gate oxide area A is then expressed as below,

$$AFR = \frac{AFR_{const}}{A_{const}} A e^{\psi W_S (E_{avg} - E_{const})} \tag{28}$$

where, AFR_{const} is the reference failure rate, A_{const} is the reference area of the sample used for calculating reference failure rate, W_S is the Weibull slope, E_{avg} is the effective electric field across the gate oxide, and E_{const} is the reference electric field. Using (28), we calculate the AFR of the MOS devices. For this purpose, we consider parameters such that the failure rate of a chip operating at nominal voltage is 10 FIT, assuming one billion transistors in a chip.

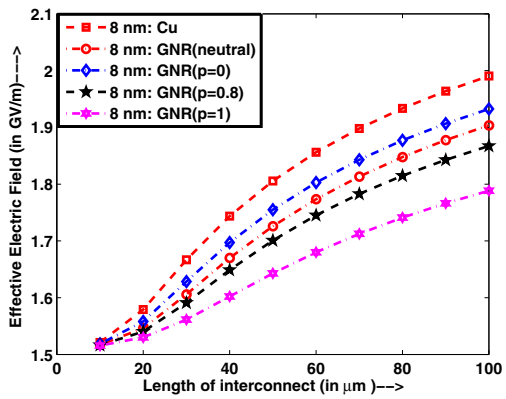

Fig. 7: Comparison of effective electric field across the gate oxide at 8 nm node.

V. Simulation Results

The proposed analytical model is implemented in MATLAB 7.1 running on standard desktop with 1.6 GHz Intel Core 2 Duo processor with 2.5 GB memory. The crosstalk induced overshoot values are calculated for different RLC values of the intermediate level multilayer GNR interconnect at 8 nm technology node with length ranging from 10 μm to 100 μm. Driving and load inverter buffer sizes are chosen as 50 times the minimum sized buffer. The individual GNR layer-electrode contact resistance is considered as 100 KΩ. Fermi levels are set as 0 eV and 0.3 eV respectively for neutral and doped GNR interconnects [5]. Perfectly specular (i.e., $p = 1.0$) GNR edges are assumed for neutral zz-GNR, whereas specularity index (i.e., p) is varied from completely diffusive edges ($p = 0.0$) to completely specular edges ($p = 1.0$) for AsF_5 intercalation doped zz-GNR interconnects [5]. Further Mean free path (i.e., λ) is considered here as 419 nm and 1.03 μm for neutral and AsF_5 doped MLGNR interconnects respectively [5].

A. Analysis of crosstalk induced overshoot effects

Fig. 6 delineates the worst case peak crosstalk induced overshoot for copper and GNR interconnects of various specularity viz. $p = 0.0, 0.8$ and 1.0 for both the technology nodes. It is a fact that the peak crosstalk induced overshoot voltage depends upon the coupling ratio (C.R.) where, C.R.=$\frac{C_{cp}L}{SC_i + C_{cp}L + C_{ep}L}$. At smaller interconnect lengths, due to smaller coupling ratio, peak overshoot is dependent upon the time constant of the interconnect system. Copper interconnects induce the maximum overshoot amongst all. While the perfectly specular GNR interconnects induce the maximum overshoot amongst the GNR counterparts (i.e., of various specularity) due to its least time constant. Being of larger time constant, the neutral GNR interconnect induces the least amount of overshoot.

B. Analysis of gate oxide reliability

Fig. 7 depicts the effective electric field produced because of this excess electric field over the gate oxide. As observed from the figure, copper interconnect again is the victim of producing maximum electric field across the gate oxide irrespective of technology nodes. Interestingly though doped perfectly specular MLGNR interconnect induces higher overshoot but produces the least effective electric field in both the technology nodes with others producing electric field in between. The reason behind this is that because of its least

time constant amongst all, it induces least amount of overshoot area (i.e., $\frac{1}{2} \times overshoot\ peak \times overshoot\ width$). Finally, Average failure rate (AFR) is plotted in Fig. 8. As observed from (28) that effective electric field is the marker for how reliable will be the interconnect and this is quantified through Average failure rate (AFR). It is seen that 100 μm long, doped perfectly specular MLGNR interconnects have an AFR of three orders smaller than copper interconnects for 8 nm technology node respectively. Further it is inferred from the figure that with higher interconnect length AFR increases, which can also be intuitively understood.

VI. Conclusions

In this work, an ABCD parameter matrix based model for crosstalk induced overshoot/undershoot has been proposed for multilayer Graphene Nano Ribbon interconnects for intermediate level interconnects at 8 nm node. The worst case crosstalk induced peak overshoot/undershoot voltages have been derived for both neutral and doped zigzag MLGNR interconnects and compared to those of conventional copper interconnects. The worst case crosstalk induced peak overshoot voltage for near specular, doped multilayer zigzag GNR interconnects is comparable to that of copper interconnects. It has been observed that the performance of neutral MLGNR interconnects is better than that of its doped counterpart with respect to peak crosstalk induced overshoot, but from the perspective of effective electric field across the gate oxide, doped MLGNR interconnects outperform neutral ones and copper interconnects for all the cases. Finally, our analysis has shown that from the gate oxide reliability perspective, perfectly specular, doped multilayer zigzag GNR interconnects are significantly advantagious compared to copper interconnects for future IC technology generations.

***Abstract*— A physics based analytical model for double gate metal oxide semiconductor graphene field effect transistor (GFET) has been presented. We have derived the expression of drain to source current using the general physics of conventional silicon MOSFET. The explicit expression of drain current is very simple and few fitting parameters have been considered to obtain the I-V characteristics. This model is also applicable for top gated GFET. Results using our analytical model show very good agreement with the experimental results and result using NANOHUB tool. This model can be integrated in circuit simulation tools.**

Keywords-graphene, field effect transistor, model, fitting parameters.

I. INTRODUCTION

GRAPHENE is a promising material for high performance RF and analog electronics [1]-[3] for next generation. It has got excellent electrical properties such as high carrier mobility (2×10^5 cm^2/V.s) at room temperature [4] and high saturation velocity (6.3×10^7 cm/s) which is six times higher than silicon [5]. Due to absence of bandgap, the ON/OFF current ratio is very small, so there are certain limitations for digital application but for analog or RF application, researchers have focused on zero bandgap graphene material where high ON/OFF current ratio is not required. Device designers have shown the figure of merit of RF devices in Gigahertz range for gapless large area graphene channel MOSFET. The cutoff frequencies as high as 427 GHz have been presented in [6].

The schematic of the GFET structure is shown in Fig. 1. The double gate transistor is considered here, where top gate oxide is hafnium oxide and back gate oxide is silicon oxide. The back gate oxide has been deposited on doped silicon. Thus device models need to be developed to gauge the applicability of G-FETs for various applications as sensors, VLSI interconnects or devices.

978-1-4673-9257-0/15/$31.00©2015 IEEE

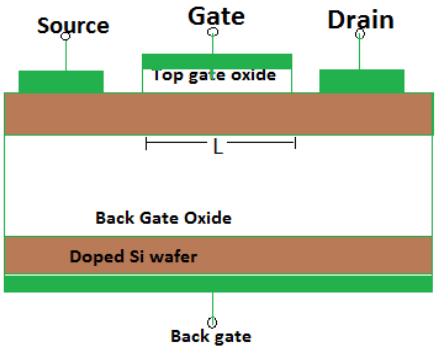

Figure 1. Schematic of GFET

Different types of models may be categorized either as physical model or empirical model. Physical model of GFET has already been developed previously [7-10] based on device physics. Empirical or semi empirical models are mostly acceptable for implementation on standard EDA tools because they achieve moderate accuracy with far lesser computational burden than very accurate physical centric models. Most of the physical models focus on the first principle based calculation of band structure, tunneling effect and carrier transport. GFETs with gapless, large area graphene channel are modeled using a quasi analytical approach in [11]. Another compact physical model for GFET has been presented in [12],[18]. Conventional MOSFET models [13]-[15] form the basis of this model. The models are only validated with experimental data for long channel GFETs ($L_G > 1\mu$m) [18]. Drift diffusion based model [16] has been used here to obtain explicit drain current model. Virtual source model [17] has been utilized for obtaining the I-V characteristics. In previously developed models, the expression of drain to source current is a function of channel potential making it more complicated than our model where, drain current expression is directly related to front gate, back gate & drain bias with few fitting parameters. The model I-V behaviors show very good agreement with experimental and simulation results.

The drain to source current expression is valid for both double and single gate technology. For positive or negative gate biases the drain current can be determined very easily, so this model is highly applicable for circuit simulation using standard EDA tools.

The paper is organized as follows. Section II discusses, about the model description of GFET. Section III discusses establishment of the drain to source current equation with the fitting parameters. The analytical results of I-V characteristics of model have been compared with the experimental and simulation results, for the same GFET configuration, and values of fitting parameters have been discussed in section IV. Finally the conclusions are drawn in section V.

II. GFET MODEL

The large area graphene channel [18] has been deposited on a thick SiO_2 layer that is grown on a heavily doped silicon wafer. The source and drain electrodes are contacting the graphene channel. The SiO_2 layer forms back gate oxide capacitance and silicon acts as a back gate. The conductivity type of the channel can be changed by applying constant back gate voltage. The top gate oxide is HfO_2 form top gate capacitance which controls the carrier charge density.

The drain current I_D of a conventional field effect transistor can be expressed as

$$I_{DS} = -q\rho_{CH}(x)v(x).W$$
$$= -q\rho_{CH}[V(x)]v[V(x)].W \quad (1)$$

where q = charge of electron.

$\rho_{CH}(x)$ = carrier density in the channel at position x

$v(x)$ = carrier drift velocity.

W = gate width

Channel sheet density and saturation velocity is function of x. The local potential $V(x)$ exist across the channel from source to drain so right hand side of equation is substituted by $V(x)$ at the position of x. Now channel sheet density and saturation velocity is function of $V(x)$.

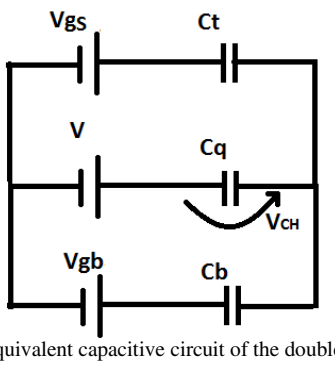

Figure 2. Equivalent capacitive circuit of the double gate GFET.

The concept of the electrostatic of dual gate GFET can be understood from equivalent capacitive circuit from figure.2. The top gate oxide and bottom oxide capacitance are Ct and Cb respectively and the quantum capacitance is Cq. The channel potential V_{CH} is the voltage drop across quantum capacitace Cq.

Here, we have considered the quantum capacitance directly depends on gate bias and drain bias. The expression of quantum capacitance is [19].

$$Cq = \left(e^2/\sqrt{\pi}v_F\hbar\right)\begin{pmatrix}\rho_{CH0}{}^2 + ([Cb(Vgb - Vgb0) + \\ Ct(Vgs - Vgs0)]/q)^2\end{pmatrix}^{1/4} \quad (2)$$

where v_F = Fermi velocity

ρ_{CH0} = residual carrier sheet density

Here, Ct=top gate capacitance, Cb= back gate capacitance. Vgs and Vgb are top gate and back gate bias respectively. Vgs0 and Vbs0 are top gate voltage and back gate voltage at Dirac point. In Dirac point the charge carrier density is minimum. This is similar to the flat band voltages in conventional silicon MOSFET.

Applying Kirchhoff's circuit law in fig.2 we get the following relation

$$V_{CH} = (Vgs - V(x))\alpha + (Vgb - V(x))\beta \quad (3)$$

where $Vgs = Vgstop - Vgs0$

$Vgb = Vgback - Vgb0$

$$\alpha = \frac{Ct}{Ct + Cb + \frac{1}{2}Cq} \quad \text{and} \quad \beta = \frac{Cb}{Ct + Cb + \frac{1}{2}Cq}$$

The α and β is treated as fitting parameter depends on top gate, back gate, and quantum capacitances used to adjust the channel potential. The voltage drop across the graphene channel is $V(x)$ which is zero at source end at x=0 and equal to drain source voltage Vds at the drain end at x=L.

The calculation of the approximate value of graphene sheet charge carrier density is defined as the [11], [20]

$$Q_{CH} = q\rho_{CH} = -\int CqV_{CH} = -\frac{1}{2}CqV_{CH} \quad (4)$$

As we consider here parallel plate capacitor, so Q_{CH} not equal not equal to $-CqV_{CH}$ but half of it. From equation (4) we get the carrier sheet density as

$$q\rho_{CH} = \theta V_{CH} \quad (5)$$

where $\theta = -(Cq/2)$

Here, θ is considered as fitting parameter, used to control the carrier sheet density in the channel region.

III. DRAIN CURRENT MODEL

The carrier velocity v=$v(x)$ has been defined in (1) is important parameter to derive the drain current expression. The steady state velocity field characteristics of graphene have been shown by Monte carlo simulations which is a soft saturation [20] that can be approximated by the expression,

$$v = \frac{\mu E}{1 + \mu E/v_{sat}} \quad (6)$$

where E = electric field

μ = low field carrier density

v_{sat} = saturation velocity

Remote interfacial phonon scattering [21] is important phenomena and the saturation velocity is affected by this

scattering. Two surface optical phonons of SiO_2 are involved in this process. With considerable accuracy, the process can be described by only one phonon with an effective energy $\hbar$. Saturation velocity depends on the effective energy and also on sheet carrier density(ρ_{CH}) and the expression is given below,

$$v_{sat} = \frac{\phi}{\sqrt{\pi \rho_{CH}}} \tag{7}$$

where, ϕ=phonon energy

Applying $E = -\frac{dV(x)}{dx}$ and combining (6) & (7) the drain current becomes,

$$Id = -q\rho_{CH} \frac{\mu\left(-\frac{dV}{dx}\right)}{1+\mu\frac{(-dV/dx)}{v_{sat}}} W \tag{8}$$

The left hand side of (8) is integrated w.r.t device length using boundary conditions x=0 to x=L and right hand side w.r.t V from V=0 at x=0 to V=V_{DS} at x=L. The resulting expression for drain current is,

$$Id = \frac{q\mu W \int_0^{Vds} \rho_{CH}\, dV}{L - \mu \int_0^{Vds} \frac{1}{v_{sat}} dV} \tag{9}$$

Integrating (9) using V as a integral variable, the explicit expression for Ids can be finally obtained,

$$Ids = \frac{\mu W \theta}{Leff}[(\alpha Vgs - \beta Vgb)Vds - (\alpha+\beta)(Vds^2/2)] \tag{10}$$

where,

$$Leff = L - \left(\frac{2}{3}\sqrt{\frac{\pi}{q}}\right)\cdot\left(\frac{\mu\sqrt{\theta}}{(\alpha+\beta)\,\phi}\right)\left[\begin{array}{l}((\alpha Vgs - \beta Vgb) - (\alpha+\beta)Vds)^{3/2} \\ -(\alpha Vgs - \beta Vgb)^{3/2}\end{array}\right]$$

IV. Result And Discussion

To compare with the experimental I/V characteristics, the voltage drop at source and drain region has to be considered. The relationship between external drain voltage $Vdsext$ and the internal drain voltage Vds is given by the corresponding equation,

$$Vds = Vdsext\left(1 - \frac{Ids}{\zeta}\right) \tag{11}$$

where $Vdsext$=External applied drain voltage

$$\zeta = \frac{Vdsext}{(Rs + R_D)}$$

Rs = Source resistance

and R_D = Drain resistance

The parameter ζ is treated as a fitting parameter which depends on external applied drain voltage and source and drain resistance.

To verify the model validity, we have benchmarked the resulting current voltage characteristics with experimental results. The model has been tested against two different experimental environments. First test (TEST A in Table I) parameters have been extracted from Meric et.al [18] and second and third test (TEST B and TEST C in Table I) parameters from Kedzierski et. al [19].

Fig. 3 shows the plot of I-V characteristics of GFET (TEST A parameters are considered) . The experimental [18] value of mobility(μ) is 550 $cm^2/V.s$, source and drain resistance value is Rs=700Ω and R_D=700Ω respectively. A good agreement between experiment and our model (as expressed in (10)) is obtained with μ=600 $cm^2/V.s$, Rs=800Ω and R_D=800Ω. So for best fit, the mobility value of 9%, source and drain resistance of 14% higher than experimental value have been chosen. The fitting parameters have been used to derive the final expression of drain current in our model. The values of the parameters are, α=0.2, β=0.004, θ= - 0.02, and ζ=-0.0025.

In the second experiment [19], the design of GFET is different, only top gate technology has been used. Fig. 4 (TEST B parameters are considered) displays the plot of output characteristics. For the best fit with the experiment, the mobility of holes and electrons agree with experiment, only resistance values Rs=400Ω and R_D=400Ω, have been considered which is 33% higher than measured value. The fitting parameters are, α=0.3, β=0,θ= - 0.01, and ζ= - 0.003.

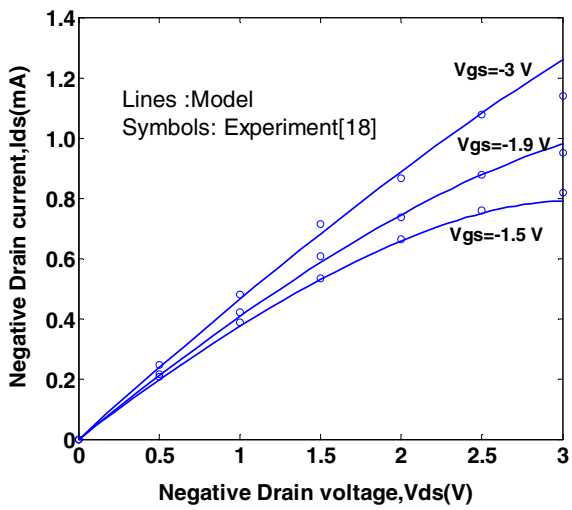

Fig. 3. Drain current as a function of drain source voltage for Vgs =-1.5V,-1.9V, and -3V, (from bottom to top) with α=0.2, β=0.004, θ= - 0.02, and ζ=-0.0025.

TABLE I. DIMENSIONS AND PARAMETERS OF THE MODELED GFET

MODEL PARAMETERS	TEST A	TEST B	TEST C	TEST D	TEST E
Channel Length, L (μm)	1	10	10	1	0.6/2
Channel Width, W (μm)	2.1	5	5	1	1
Top gate oxide Thickness, $t_{ox\text{-}top}$ (nm)	15	40	40	8/12	8
Back gate Oxide Thickness, $t_{ox\text{-}back}$ (nm)	285	…	…	300	300
Flat band voltage at top gate,Vgs0 (V)	1.45	0.85	0.65	0	0
Flat band voltage at back gate,Vbs0 (V)	2.7	…	…	…	…
Residual charge density, ρ_{CH0} (cm^{-2})	5×10^{12}	1×10^{12}	1×10^{12}	0	0
Source Resistance , Rs (Ω)	800	400	400	1	1
Drain Resistance , R_D (Ω)	800	400	400	1	1
Electron Mobility, μ_n (cm^2/V.s)	600	6500	1500	3000	3000
Hole Mobility, μ_h (cm^2/V.s)	600	6500	1500	3000	3000
Phonon energy, $\hbar$ (meV)	55	99	99	78	78
External back gate voltage (V)	-40	…	…	…	…

The plot in fig. 5 (TEST C parameters are considered) shows the transfer characteristics for two different drain biases *Vdsext*=0.1*V*, and *Vdsext*=1*V* respectively. The graph matches with the experiment taking all previously values for output characteristics, only *Vgs0*=0.65*V* have taken for final tuning with the fitting parameters α=0.2, β=0, θ= - 0.01, and ζ=-0.002.

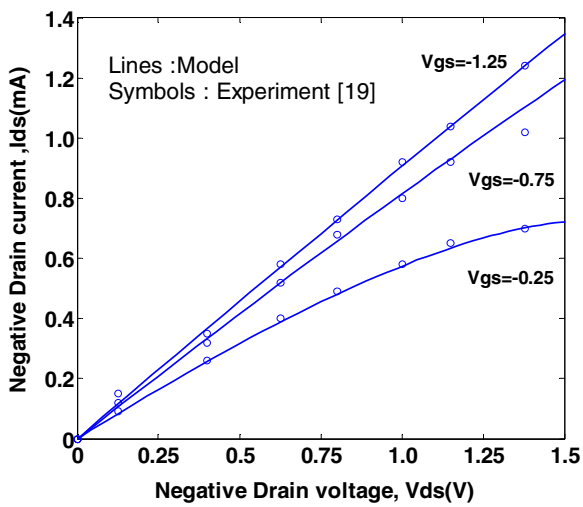

Fig. 4. Drain current as a function of drain source voltage for Vgs =-0.25V, -0.75V, and -1.25V (from bottom to top) with α=0.3, β=0,θ= - 0.01, and ζ= - 0.003.

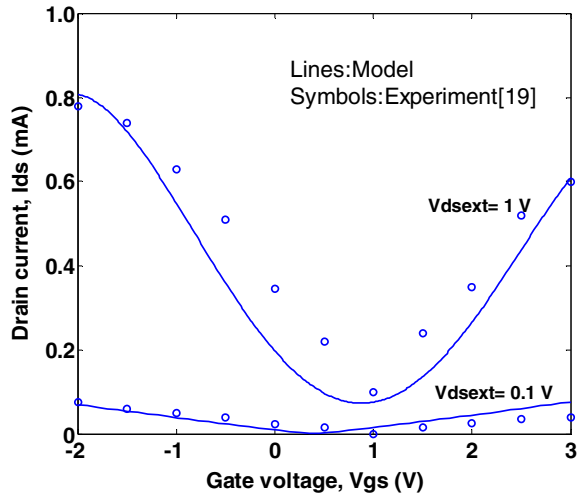

Fig. 5. Drain current as a function of gate source voltage for Vdsext= 0.1V and Vdsext= 1V with α=0.2, β=0, θ= - 0.01, and ζ=-0.002.

Finally, we have verified our model, against a known simulation tool, GFET tool from nanoHUB. In this simulation tool, the drift diffusion transport mechanism has been used to obtain the output characteristics. The dielectric material is silicon dioxide for both top gate and back gate oxide. Graphene mobility is characterized as a function of carrier density at temperature from 300 K to 500 K.

The model has been tested in two different conditions. For the first test (TEST D in Table I), channel length and width are kept fixed and top gate oxide thickness is varied. The parameters used in simulation are mentioned in Table I. Fig. 6 shows the output characteristics with this test setup.

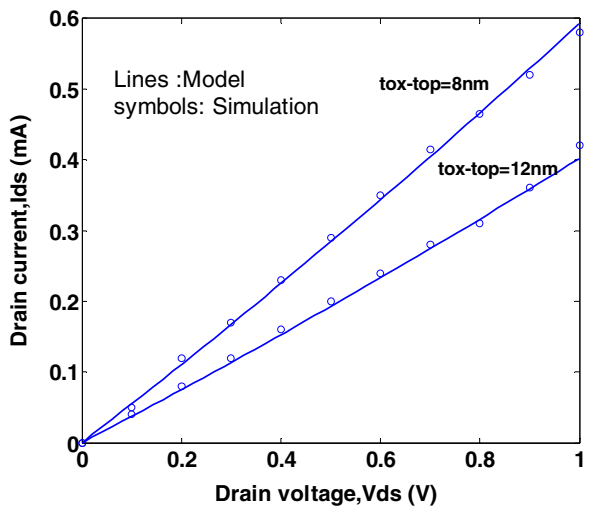

Fig. 6. Drain current of the GFETs with different top gate oxide thickness, tox-top =8nm with α=0.08, β=0,θ= - 0.02, and ζ= - 0.50 and tox-top =8nm with α=0.07, β=0,θ= - 0.01, and ζ= - 0.50 for Vgs = 0.6 V.

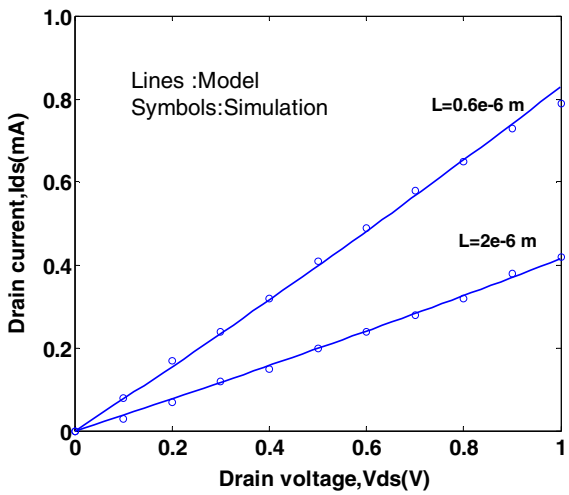

Fig. 7. Drain current of the GFETs with different channel length, L =0.6μm with α=0.08, β=0, θ= - 0.02, and ζ= - 0.50 and L =2μm with α=0.07, β=0,θ= - 0.01, and ζ= - 0.5 for Vgs = 0.6 V.

In the second test (TEST E in Table I), the channel length of GFET has been varied, for fixed channel width and top gate oxide thickness. Simulation parameters are shown in Table I. Fig. 7 shows the output characteristics with this test setup.

V. Conclusion

We have presented a compact drain current model of GFET, based on conventional transport equation for large channel area GFET, with double gate bias configuration. From saturation velocity and channel carrier density, we have determined the explicit closed form expression of drain current, using few fitting parameters. The analytical expression of drain to source current is very simple. Results using our model match very well for both experimental and simulation results and also it is valid from long channel regime (L=10μm) to short channel (L=600nm) regime. The circuit design engineers use the drain current and drain voltage characteristics to simulate different circuits. The GFET model in this paper is suitable for circuit simulation tools.

Abstract— **A simple analytical approach is presented to investigate the energy band structure of graphene under the application of shear strain. The strain-induced deformation in the unit cell in terms of the angle between two unit vectors is taken into consideration in the framework of nearest neighbor tight binding model. The proposed approach is applied to evaluate the energy band gap in graphene structure under shear strained condition. The results obtained from the proposed approach are compared with those of reported by DFT calculation and they are found to be in good agreement. This demonstrates that the proposed approach can be applied to calculate the band gap energy in shear strained graphene.**

Keywords— Graphene, shear strain, tight binding model, analytical approach, band structure.

I. INTRODUCTION

Graphene [1] is a name given to a flat single layer of carbon atoms tightly bonded into a two dimensional (2D) honeycomb lattice and is a fundamental building block for graphitic materials of all other dimensionalities [2]. Graphene is considered to be the strongest material ever [3]. As the graphene has excellent electronic structure [4]-[6] and transport property [7], researchers are having great interest in graphene. Since graphene is very thin having excellent electronic properties, it may be used in future logic devices to face the challenge of Gordon Moore's law, that is, the number of logic components per integrated circuit would double every 2 years. But the main problem with graphene is its zero band gap[1,8], which reveals that it cannot be used in logic circuits as well as other electronic applications. Scientists are working to find out the way to open the energy gap in graphene. Different methods have been proposed to create band gap in graphene, such as using quantum confinement effect in graphene nanoribbon (GNR) [9]-[11], applying external electric fields, introducing symmetry breaking of regular hexagonal structure[13],[14], by the process of doping [15]-[17], and by the process of external strain [18],[19]. To calculate the band gap in strained graphene, several techniques were applied [18-20] such as first principal calculation, tight binding model, K.P method, density function theory (DFT) etc. Most of them are performed by numerical simulation techniques which have huge computational complexity and hence needs high capacity super computer [18]. Some analytical works have also been done on strained graphene and GNR using tight binding approximation which mainly focuses on the strength of strain and spin polarization interaction [19]. In a recent study [20], we have reported an analytical approach to calculate strain-dependent energy band gap in uniaxially strained graphene. In this study a simple analytical approach is presented to determine the energy dispersion of graphene under the application of shear strain. In the proposed technique strain-induced unit cell deformation is incorporated in the framework of tight binding model. Using the proposed approach the band gap is determined for different values of shear strains. The results obtained from the proposed technique are compared with the results published by the DFT [19] and found to be in good agreement.

II.PROPOSED APPROACH

In symmetrically strained graphene, the band structure remained unchanged just like unstrained graphene. To introduce band gap in graphene structure asymmetrical strain (shear /uniaxial) could be applied that breaks the symmetry in the lattice structure. This leads to localize the delocalized electron and hence to create band gap in the graphene. The strain-induced lattice structure deformation under the application of shear strain along with unstrained lattice structure is shown in Fig. 1.

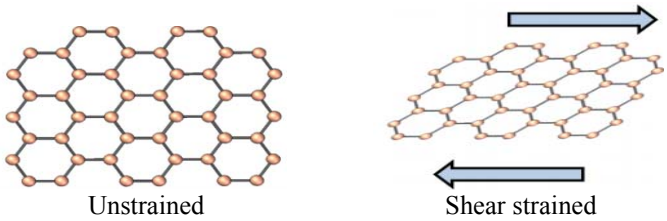

Figure 1. Unstrained and shear strained graphene structure [21].

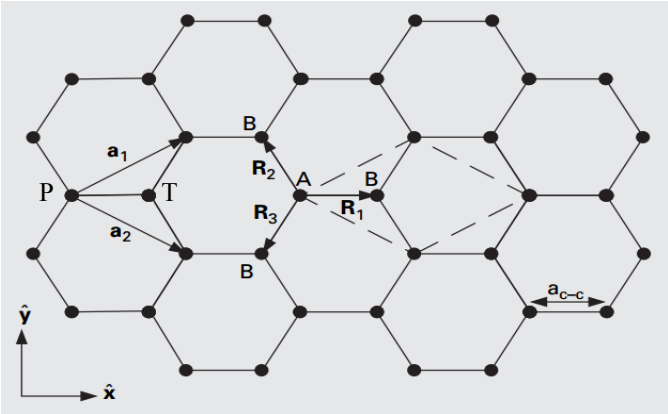

Figure 2. The honeycomb lattice of graphene. The primitive unit cell is the equilateral parallelogram (dashed lines) with a basis of two atoms denoted by A and B.

In our study, we have used the nearest neighbor tight binding model. Here the type-A atom in the graphene lattice is bonded with three of its nearest neighbors of type-B atoms as shown in fig. 2, where the primitive unit cell is also shown by dashed line. In unstrained graphene the angle between the unit vectors $\mathbf{a_1}$ and $\mathbf{a_2}$ is 60^0, which with respect to a unit vector and the reference line PT is 30^0. However, under the application of shear strain the unit cell will be deformed. As a result, the angle between the unit vectors $\mathbf{a_1}$ and $\mathbf{a_2}$ will be changed. A typical deformation of unit cell due to shear strain is shown in Fig. 3, where α and β are the angles between the line PT and unit vectors $\mathbf{a_1}$ and $\mathbf{a_2}$, respectively.

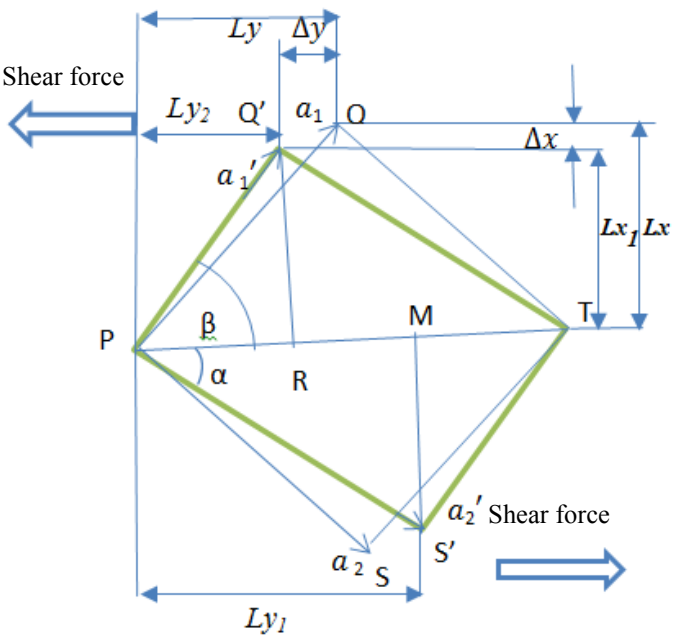

Figure 3. The un-deformed and shear strain-induced deformed primitive unit cells with their primitive unit vectors.

When shear strain is applied the points Q and S is shifted to points Q' and S' due to unit cell deformation, assuming that the points P and T are fixed as seen in Fig. 3. Using trigonometric relationship in $\Delta PQ'R$ the angle β can be expressed by

$$\beta=\tan^{-1}\frac{L_{x1}}{L_{y2}}=\tan^{-1}\frac{L_x-\Delta x}{L_y-\Delta y} \quad (1)$$

where $\Delta x = L_x - L_{x1}$ and $\Delta y = L_y - L_{y2}$. Δx and Δy represent the deformation in the primitive unit vectors due to shear strain.

Similarly from $\Delta PMS'$,

$$\alpha=\tan^{-1}\frac{L_{x1}}{L_{y1}}=\tan^{-1}\frac{L_x-\Delta x}{L_y+\Delta y} \quad (2)$$

Due to the strain-induced deformation of primitive unit cell the vectors $\boldsymbol{a_1}'$ and $\boldsymbol{a_2}'$ become

$$\boldsymbol{a_1}' = [a_1'\cos(\beta), a_1'\sin(\beta)],$$
$$\boldsymbol{a_2}' = [a_2'\cos(\alpha), -a_2'\sin(\alpha)] \quad (3)$$

Here a_1' and a_2' represent magnitude of the vectors. It is found in "Fig. 2" that there are three nearest neighboring atoms. The separation of these atoms can be represented by three vectors $\boldsymbol{R_1}$, $\boldsymbol{R_2}$, and $\boldsymbol{R_3}$.

$$\boldsymbol{R_1} = (\tfrac{2}{3}a_1'\cos\beta, 0) = \tfrac{2}{3}a_1'\cos\beta\,\mathbf{x} \quad (4)$$

$$\boldsymbol{R_2} = -\boldsymbol{a_2}' + \boldsymbol{R_1} = \left(\tfrac{2}{3}a_1'\cos\beta - a_2'\cos\alpha\right)\mathbf{x} + a_2'\sin\alpha\,\mathbf{y} \quad (5)$$

and $\boldsymbol{R_3} = -\boldsymbol{a_1}' + \boldsymbol{R_2}$

$$\boldsymbol{R_3} = \left(-\frac{1}{3}a_1'\cos\beta - a_2'\cos\alpha\right)\mathbf{x} + (a_2'\sin\alpha - a_1'\sin\beta)\,\mathbf{y} \quad (6)$$

From tight-binding energy dispersion model the formula of energy dispersion can be given by

$$E(k) = \pm\sqrt{H_{AB}(k)H_{AB}^*(k)} \quad (7)$$

where $H_{AB}(k)$ is the Hamiltonian matrix. For unstrained graphene the Hamiltonian matrix element reduces to a sum of three terms:

$$H_{AB(k)} = \gamma e^{-ikR_1} + \gamma e^{-ikR_2} + \gamma e^{-ikR_3} \quad (8)$$

When shear strain is applied " (8)" becomes

$$H_{AB(k)} = \gamma_1 e^{-ikR_1} + \gamma_2 e^{-ikR_2} + \gamma_3 e^{-ikR_3} \quad (9)$$

and its conjugate is

$$H^*_{AB(k)} = \gamma_1 e^{ikR_1} + \gamma_2 e^{ikR_2} + \gamma_3 e^{ikR_3} \quad (10)$$

Here γ is a fitting parameter which is often called the nearest neighbor overlap energy. In unstrained graphene, $\gamma_1 = \gamma_2 = \gamma_3 = \gamma = -2.8\, eV$[22]. When shear strain is applied, the change of three bond length with three nearest neighbor become different. As a result, the values of γ_1, γ_2, and γ_3 become different [22]. Now

$$H_{AB}(k)H^*_{AB}(k) = (\gamma_1 e^{-ikR_1} + \gamma_2 e^{-ikR_2} + \gamma_3 e^{-ikR_3}) * (\gamma_1 e^{ikR_1} + \gamma_2 e^{ikR_2} + \gamma_3 e^{ikR_3}) \quad (11)$$

Putting the value of $\boldsymbol{R_1}$, $\boldsymbol{R_2}$, $\boldsymbol{R_3}$ and $\boldsymbol{K} = k_x\boldsymbol{x} + k_y\boldsymbol{y}$ and after some mathematical manipulation we get

$$\mathrm{H}_{AB}(k)H^*_{AB}(k) = \gamma_1^2 + \gamma_2^2 + \gamma_3^2 + 2\gamma_1\gamma_2 c_1 + 2\gamma_2\gamma_3 c_2 + 2\gamma_3\gamma_1 c_3 \quad (12)$$

where $c_1 = \cos[-a_2^{'}\cos\alpha k_x + a_2^{'}\sin\alpha k_y]$

$$c_2 = \cos[-\, a_1^{'}\cos\beta\, \mathrm{k_x} - a_1^{'}\sin\beta\, \mathrm{k_y}] \quad (13)$$

$$c_3 = \cos[(a_1^{'}\cos\beta + a_2^{'}\cos\alpha)\mathrm{k_x} + (a_1^{'}\sin\beta - a_2^{'}\sin\alpha)k_y)]$$

Substituting "(12)" into "(7)" we have

$$E(k) = \pm\sqrt{\gamma_1^2 + \gamma_2^2 + \gamma_3^2 + 2\gamma_1\gamma_2 c_1 + 2\gamma_2\gamma_3 c_2 + 2\gamma_3\gamma_1 c_3} \quad (14)$$

This is the generalized equation for the energy dispersion relation of graphene under shear strain condition.

III.RESULTS AND DISCUSSION

We have studied the electronic band structure of shear strained graphene. Application of shear strain leads to create bandgap. The strain-induced deformation of unit cell causes change in angles (α and β) between vectors ($a_1^{'}$ and $a_2^{'}$) and reference line PT asymmetrically. These angular changes are taken as parameters to calculate the band structure of graphene under shear strained condition. Using "(1)" and "(2)" values of α and β are evaluated 29.66^0, 29.01^0, 27.75^0, 26.93^0 and 30.29^0, 30.99^0, 32.25^0, and 33.07^0 respectively, for the change in strain values 0.48% , 1.86% , 4.17%, and 5.58%. Using "(13)" the band gap energies are estimated

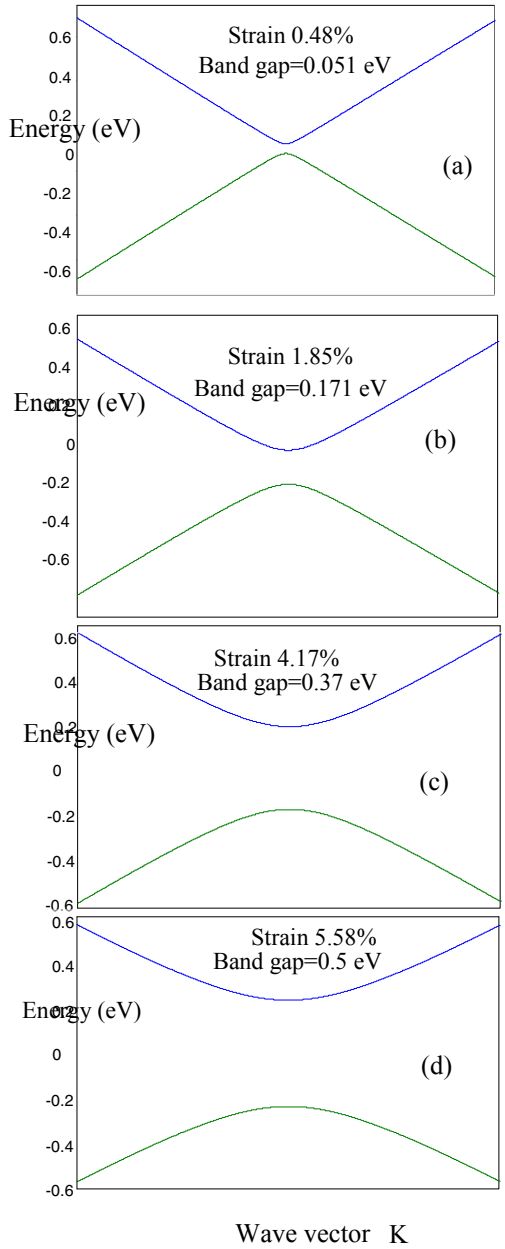

Figure 4. Bandgap opening under the application of shear strain (a) 0.48 % (b) 1.85 %(c) 4.17 %, and (d) 5.58% strain

and are found to be 0.051, 0.171, 0.37 and 0.50 eV for the corresponding percentage of strain. Due to the application of shear strain the symmetry of the regular hexagonal structure is broken, as a result, energy bangap created in shear strained graphene. The results are shown in Fig. 4 (a), (b), (c), and (d). To observe the results clearly, the dispersion profiles are extended near the K-point of the Brillouin zone.

IV. CONFIRMATION OF THE PROPOSED TECHNIQUE

In order to confirm the proposed analytical approach, the results obtained from the present study is compared with the previously published results. A comparison is shown in Table 1. It is found that the results obtained from the proposed technique agree with the results evaluated from DFT calculation, upto the 5.6 percents of applied strain [19]. This demonstrates that the proposed technique can be applied to determine the bandgap in shear strained graphene structure.

TABLE I. COMPARISON OF SHEAR STRAIN-DEPENDENT ENERGY GAPS OBTAINED FROM THE PROPOSED TECHNIQUE AND DFT CALVULATION [19]

L_{x1} (nm)	L_{y1} (nm)	L_{y2} (nm)	DFT (eV)	Proposed approach (eV)
0.12397	0.21769	0.21219	0.0489	0.051
0.12559	0.22650	0.20902	0.196	0.171

0.12803	0.24029	0.20489	0.401	0.321
0.12845	0.24414	0.20359	0.435	0.37
0.13045	0.25680	0.20034	0.583	0.5

V. CONCLUSION

In this study, a simple analytical approach is proposed to evaluate the energy dispersion in shear strained graphene on the basis of nearest neighbor tight binding model. The strain-dependent change in the angle between the two primitive vectors of a unit cell of graphene is taken into consideration. It is found that the angles between two primitive vectors with respect to a reference change asymmetrically due to shear strain. It is found that with the increase in strain the energy band gap increases and it is evaluated to be 0.5 eV for the value of strain 5.58%. Finally, to confirm the proposed technique our results are compared with those of reported by DFT calculation and found to be in good agreement.

***Abstract*—Based on equivalent single conductor (ESC) model, an appropriate RLC equivalent circuit model for multi layer zigzag graphene nanoribbon (zz-MLGNR) interconnect is presented. The values of different circuit parameters (i.e resistance, inductance and capacitance) are calculated. The impact of various interconnect parameters (e.g., dimension of interconnect, number of GNR layers, Fermi energy) on the circuit parameters are discussed. The per unit length resistance of zz-MLGNR interconnect is compared with other interconnect materials [e.g., copper (Cu), tungsten (W) and carbon nanotubes (CNTs)]. The analysis revealed that zz-MLGNR can offer lower resistance than Cu, W and even single-walled carbon nanotubes (SWCNs). Time delay of zz-MLGNR interconnect is analyzed using the RLC equivalent circuit model and it is shown that intercalation-doped zz-MLGNR can outperform Cu.**

Keywords—GNR interconnect, multilayer graphene nanoribbon (MLGNR), interconnect delay.

I. INTRODUCTION

To keep up with the Moore's law both transistor and interconnect dimensions are scaled down rapidly. The continuing exponential reduction in feature size on electronic chips, leads to ever larger number of faster devices at lower cost per device. The decrease in minimum feature size of devices has led to a proportional decrease in interconnect cross-sectional area and pitch, as a consequence the delay associated with the transistors, gate delay, has continuously decreased with decrease in minimum feature size, while the delay associated with interconnect, the parasitic resistance, capacitance and inductance delay has increased significantly. International Technology Roadmap for Semiconductors (ITRS) [1] has pointed out that, due to this scaling down, traditional semiconductor material, silicon (Si) and interconnect material, copper (Cu) are reaching their threshold limit, so the industry is in search for viable alternatives; and carbon based materials are the protagonist in this endeavour.

Graphene, an atomic layer of carbon atoms arranged in a two dimensional (2D) honeycomb lattice, has recently emerged as a potential candidate for nanoelectronics due to its promising electronic properties [2]. The high mobility and carrier velocity in graphene promises ballistic devices with high switching speeds. The fabrication of the first field-effect graphene-based transistor [3], led to an explosion of interest in the electronic properties of graphene. Nowadays, graphene is considered to be a viable alternative to Si and Cu [4]. If graphene sheet is patterned into narrow strips then it is called graphene nano-ribbon (GNR). GNR can conduct much larger current densities than Cu, due to its strong sp^2 hybridize bonds and absence of severe reliability problems that plague Cu, particularly for future interconnect geometries [3, 5-8]. Thermal conductivity of GNR is much larger than Cu [9-11]. Moreover, compared to Cu, GNR has larger carrier mean free path (MFP), which leads to larger electrical conductance [12-14]. Physically graphene can be metallic or semiconducting according to its chirality. For example zigzag edge GNR (zz-GNR) is always metallic, while armchair-GNR (ac-GNR) can exhibit both semiconducting and metallic behaviour depending on the number of carbon atom along its width [15]. The potential performance of GNR transistors has been studied in several publications, and it has been projected that such transistors can potentially outperform Silicon transistors because of the large carrier mobility and the better electrostatic control of gate on channel [16, 17]. GNR interconnects can potentially be used as intracell interconnects linking GNR transistors in a seamless fashion [3, 18, 19] or in a multilevel interconnect network like conventional interconnects [20]. The former would reduce the number of metal-to-graphene connections and, therefore, would improve the circuit performance by eliminating some contact and quantum resistances. Although the maximum current-carrying density up to *108 A/cm*^{2} (*~100* times of Cu) was reported, current density of SLGNR is limited by its 2D atomically-thin geometry, sensitivity to ambient, poor noise tolerance, and conductance degradation due to edge-related effects [21, 22]. 3D nano-carbon, or vertically stacked multilayer graphene (MLGNR), can potentially be employed to address this challenge, yielding an ultra conductive material system as shown in Fig. 1. Multilayer graphene has received significant amount of theoretical and experimental attentions in recent years [23]. The in-plane conductivity of graphite can be several tens of magnitude by intercalation doping, which involves an insertion of one dopent layer between each pair of graphene layers [24]. Intercalation doping can increase the carrier density due to increased layer spacing [25].

In this paper we have presented a RLC equivalent circuit model for multi layer zigzag graphene nano-ribbon (zz-MLGNR) based on equivalent single conductor (ESC) model [26]. Per unit length resistance, capacitance and inductance of zz-MLGNR are calculated using the proposed model. The effect of interconnect width, number of layers and Fermi energ-

y on different parameters are discussed. Resistance of zz-MLGNR is benchmarked against other traditional interconnect materials. Finally 50 percent delay of zz-MLGNR interconnect is calculated and benchmarked against Cu.

II. CIRCUIT MODELING

Let's consider a N layer zz-MLGNR interconnect of length L, width w ($w << L$), thickness t as shown in Fig. 2(a). The per unit length equivalent circuit of zz-SLGNR is shown in Fig. 2(a). In Fig. 2(a), R_Q is the quantum resistance which is expressed as [27]

$$R_Q = h/2e^2 N_{ch} \approx 12.9\ k\Omega/N_{ch} \quad (1)$$

Where h is Plank's constant and N_{ch} is the number of conduction channel, which is a function of GNR width w, chirality, temperature and Fermi energy. N_{ch} is calculated by [28]

$$N_{ch} = \Sigma 1/[1+exp((E-E_F)/k_BT)] + \Sigma 1-1/[1+exp((E-E_F)/k_BT)] \quad (2)$$

Magnetic inductance (L_M) and electrostatic capacitance (C_E) are determined by the geometry and the materials surrounding the interconnects. Kinetic inductance (L_K) represents the kinetic energy of the electrons and because of small density of states in GNR, its value is substantially larger than the magnetic inductance [29]. Unlike magnetic inductance, kinetic inductance has no mutual component and its value decreases linearly with increase in N_{ch} ($8\ nH/\mu m/N_{ch}$) [30]. Quantum capacitance is also the consequence of small density of states and increases linearly with N_{ch} ($200\ N_{ch}\ aF\ /\mu m$). The scattering resistance per unit length is represented by r which can be expressed as $r = R_Q / l_D$. Here l_D the mean free path which is around $1\mu m$ in graphene [31]. zz-MLGNR can be considered as a arrangement of N zz-SLGNR, Fig. 2(b) shows the per unit length equivalent circuit of MLGNR, and the multiconductor transmission line (MTL) representation of it is shown in Fig. 2(c), here R_c is terminal contact resistance, L_m is magnetic inductance and C_m is mutual capacitance. In order to reduce the computational effort of the complex MTL approach, zz-MLGNR can be analyzed using an equivalent single conductor (ESC) model [32]. The ESC model is represented in Fig. 3(a). R_{ESC} can be calculated by,

$$R_{ESC} = h/2e^2\ N_{ch}\ N\ l_D \quad (3)$$

L_{ESC} and C_{ESC} are calculated from Fig. 3(b) and Fig. 3(c) respectively.

III. RESULTS AND DISCUSSIONS

In the process of modelling zz-MGNR interconnect various physical properties were investigated. Fig. 2(a) shows the schemata of the considered structure. The number of conduction channel (N_{ch}) is obtained using closed from expression Eq. 1 and plotted versus width for different Fermi energy in Fig. 4. Increasing width and Fermi energy populates more subbands and therefore, increases the number of conduction channel. Knowing the number of conduction channel the per unit length resistance of zz-MLGNR are calculated from ESC model and plotted versus width for different number of layers and Fermi energy in Fig. 5. For reference, the per unit length resistance of Cu and W wires with unity aspect ratio and monolayer single walled nanotube (SWCNT) interconnect with random chiralitiy are also plotted. The analysis reveals that the per unit length resistance of neut-

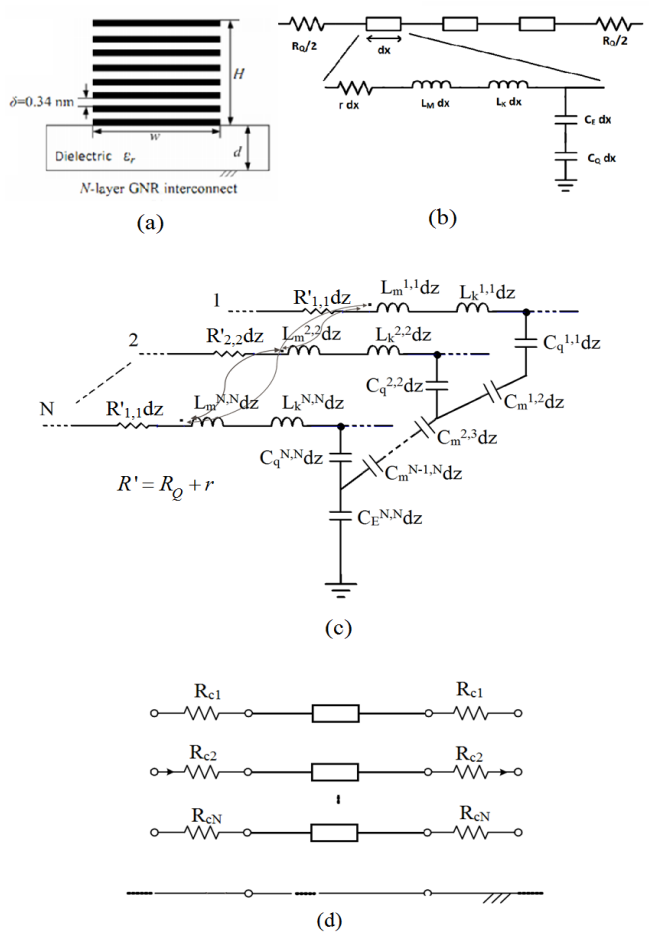

Figure 2. (a) Geometry of a N layer zz-MLGNR along with, (b) per unit length equivalent circuit model of zz-SLGNR, (c) per unit length equivalent circuit model of zz-MLGNR and (d) multiconductor representation of zz-MLGNR including terminal resistance.

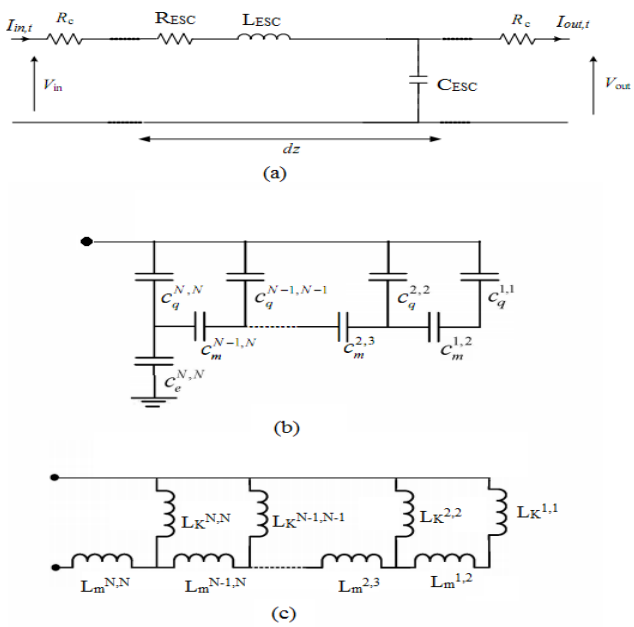

Figure 3. (a) ESC circuit of an MLGNR interconnect and per unit length equivalent network for (b) capacitance; (c) inductance.

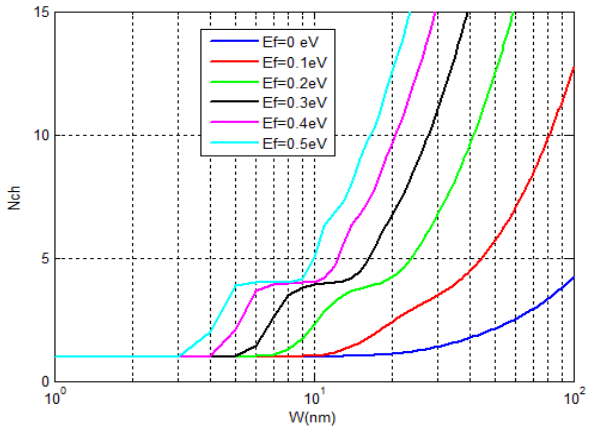

Figure 4. Number of conduction channel (N_{ch}) versus width for different Fermi energy is shown.

ral (E_F = 0) zz-MLGNR is higher that Cu and SWCNT. But at higher Fermi energy it can offer significantly less per unit length resistance than both Cu and SWCNT. The per unit length capacitance of zz-MLGNR is calculated using the ESC model and plotted. Fig. 6 (a) shows the per unit length capacitance as a function of width and Fig. 6 (b) shows the per unit length capacitance as a function of layer number for both *14nm* and *22nm* technology nodes. Fig. 6 reveals that, capacitance increases with increase in width but shows little variation due to change in Fermi energy or number of GNR layers. This is because, all the components of C_{ESC} i.e C_Q, C_m and C_E increases with width but among them only C_Q changes with Fermi energy and whose value is much-much larger than C_m or C_E.

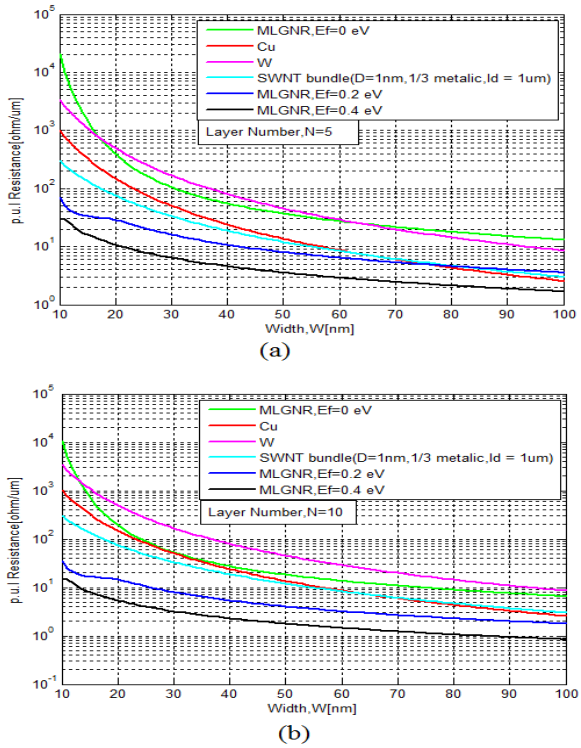

Figure 5. Per unit length resistance of zz-MLGNR shown for (a) 5 layers and, (b) 10 layers. Per unit length resistance of Cu, Wires with unit aspect ratio and monolayer SWNT (D = 1nm) with random chirality is also shown for comparison.

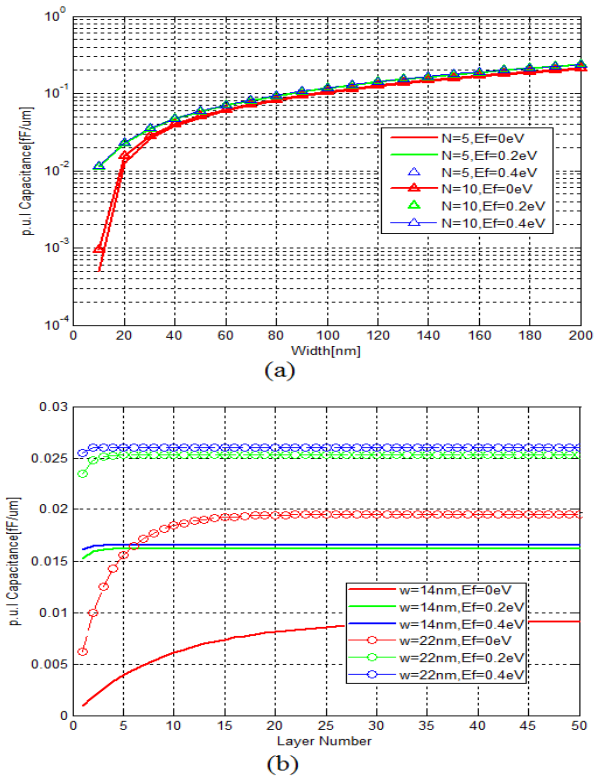

Figure 6. Per unit length capacitance of zz-MLGNR as (a) function of width (b) function of number of GNR layer.

Fig. 7 shows the per unit length inductance as a function of width and number of GNR layer . L_k decreases with increase in width, Fermi energy and number of GNR layer and L_m decreases with increase in GNR width, so the total inductance decreases with increase in width, Fermi energy and number of layers.

For delay calculation a driver-GNR interconnect as shown in Fig. 8 is studied. Based on the proposed RLC model, simulations were implemented using HSPICE. The driver equivalent resistance and capacitance are obtained from the ITRS [1]. Fig. 9 shows the 50% delay of zz-MLGNR of width *14nm* consisting of 10 layers with respect to Cu interconnect of same dimension. It is evident from Fig. 9 that the performance of neutral zz-MLGNR is much worse than Cu but it can outperform Cu when its Fermi energy is raised at 0.6 eV, which can be achieved by intercalation doping [33].

IV. Conclusion

We have developed an RLC equivalent circuit for zz-MLGNR based on ESC model. We have investigated all the lumped elements in zz-MLGNR based on the proposed model and compared with that of Cu, W and SWCNT interconnect. The analysis revealed that, zz-MLGNR can provide lower per unit length resistance than Cu, W and SWCNT it also offers lower per unit length capacitance but in the expense of higher inductance. We have analyzed interconnect delay of zz-MLGNR using the proposed RLC equivalent circuit. It is concluded that the performance of zz-MLGNR can match or become better than Cu only if it is intercalation doped.

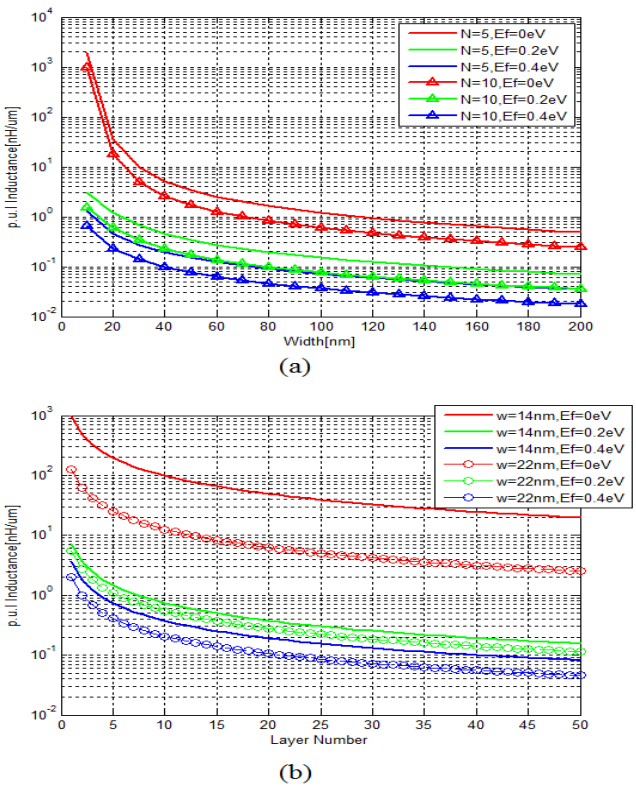

Figure 7. Per unit length inductance of zz-MLGNR as (a) function of width and, (b) as a function of number of GNR layer.

***Abstract*—**In this research work, ferrites with compositions of $Ni_{0.60}Zn_{0.40-x}Re_xFe2O4$ where x=0.05, 0.10, 0.15 were prepared by double sintering ceramic technique. The samples were pre sintered at 1000^0 C for 4 hours in air and sintered at 1250^0 C for 3 hours. The influence of Yttrium (Y) substitution on various properties of Ni-Zn ferrites have been studied in this work. Investigations were carried out by the measurements of AC resistivity, Permeability and Curie temperature of the sample. AC resistivity shows the nature of the semiconductor of the samples. The initial magnetic permeability remains constant from low frequency to 10 MHz thenceforth sharply fall to very low values at higher frequencies and again remain constant onward to Zn deficient of Ni -Zn ferrites with substituting of Y. At T = T_c the sharp directress of permeability indicates the samples are good homogeneity.

Keywords— Permeability, Curie temperature, Rare Earth metal and Sintering etc.

Introduction

Iron and its alloys were used as magnetic materials in order to serve the need of the electrical industry at the beginning of the industrialization. With the advent of higher frequencies, the standard techniques of reducing eddy current losses, using lamination or iron powder cores, were no longer efficient or cost effective. S. Hilpert in Germany in 1909, first reported this realization stimulated a renewed interest in "Magnetic Insulators". By 1945 Snoek had laid down the basic fundamentals of the physics and technology of practical ferrite materials [1]. In 1948, the Neel theory of ferromagnetic provided the theoretical understanding of this type of magnetic material. Soft ferrites polycrystalline prepared from metal oxides are magnetic semi conductors and have made important role, both technological and theoretical to the development of electronics. These soft ferrites still remain the best magnetic materials and cannot replaced by any other magnetic materials with respect to their very high frequency application because they are inexpensive, more stable, easily manufactured [2].The most important progress were made in ferromagnetism in the field of magnetic oxides (ferromagnetic). The progress of high frequency ferrites was initiated by the work done by J. L. Snoek [3], who found that connected with excellent properties in the high frequency range, Mn-Zn and Ni-Zn ferrites provide a family of magnetic materials helpful for radio and TV sets as well carrier telephony as cores of inductors transformer and so forth. The most well-liked combination are Ni-Zn [4], Ni-Cu-Zn [5-7], Mg-Zn [8] and Mg-Cu-Zn [9] a ferrites. Ferrite crystallizes with two magnetic sub-lattices i.e. tetrahedral (A) site and Octahedral (B) site based on Neel's model. Magnetic and electrical properties of ferrites are strongly dependant on distribution of cation in A and B sites and their valance state [10]. The properties of Ni-Zn ferrites can be modified by substitutions them with different metals ions such as Co^{2+},Mg^{2+},Mn^{2+},Cu^{2+}etc. The addition of rare earth metal in Ni-Zn ferrite composition is known to play a crucial role in increasing the sintering density and lowering the sintering temperature. Various additives such as V_2O_5, Bi_2O_3, PbO, MoO_3, WO_3, E_2O_3 P_2O_5, La_2O_3, W_2O_3, LiO etc. having low melting point, facilitated to reduce the sintering temperature of these oxides materials due to liquid phase either due to the melting of the additives or due to the eutectic liquid phase formation between the additives and the ferrite. Amount of liquid phase increase with increasing amount of sintering aids which results in increased densification. However excessive amount of sintering additives' will deteriorate electromagnetic properties of the ferrite. So, optimum content of sintering aids is necessary to achieve good sinter ability as well as better electromagnetic properties. Till now researches have not yet been able to formulate a rigid set of rules for ferrites about a single property. Among these La_2O_3,Y_2O_3 and E_2O_3 were the most effective sintering for Ni-Zn ferrite the systematic research is still necessary for effects has been under taken to prepare Ni-Zn ferrite doped with La_2O_3,Y_2O_3 and Eu_2O_3. Scientists still continue their efforts to find out optimum parameters of ferrites, like high saturation magnetization, high permeability, high resistivity, etc. In the present research work we prepared $Ni_{0.60}Zn_{0.40-x}Y_x$ Fe_2O_4 (x=0.05, 0.10, 0.15) Ferrites. We studied the variation of electrical resistivity and magnetic permeability in both temperature and frequency dependent cases.

EXPERIMENTAL

Double Sintering Ceramic Technique: In this method, the required composition is usually prepared form the appropriate amount of raw mineral oxides or carbonates by crushing, grinding and milling. The most common type of grind is the ball grind but instead of ball grind we performed it by hand grind. Grind can be carried out in a wet medium to increase the degree of mixing. The solid state inter-diffusion between

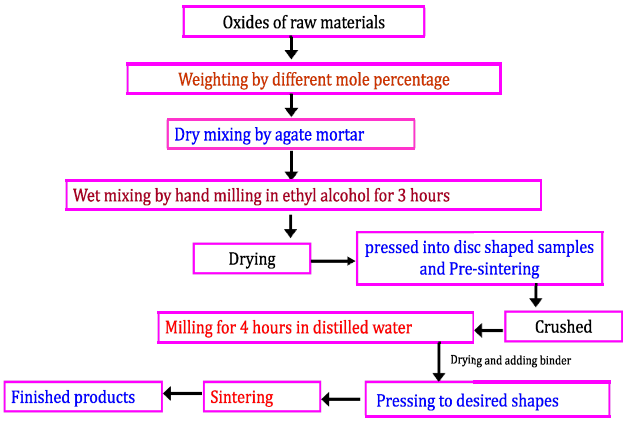
the raw materials play crucial role in this method. Normally, solids do not react at room temperature over normal time scales. Hence it is necessary to heat them at higher temperatures for the diffusion length $(2Dt)^{1/2}$ to exceed the particle size, where t is the firing time , and D is the diffusion constant for the fast-diffusing species. At temperature above 1000^0C, the grind powders are then calcined in air or oxygen. For some time, this process is continued until the mixture is converted into the correct crystalline phase. These powders are again crushed into fine powders. Using hydrostatic pressure the tablet and ring shaped samples are prepared from these fine powders. Pre sintering is carried out at temperature 1000^0C for (3) three hours and sintering at the temperature 1250^0 C for (4) four hours. The general solid state reaction leading to a ferrite MFe_2O_4 may be represented as

$$MO + Fe_2O_3 \rightarrow MeFe_2O_4$$ where M is the divalent ions.

Table of 20 gm compositional details of $Ni_{0.6}Zn_{0.4-x}La_xFe_2O_4$ [x = 0.05, 0.10, 0.15] ferrites

Content,x	NiO	ZnO	La_2O_3	Fe_2O_4
0.05	3.756	2.387	0.473	13.384
0.10	3.731	2.033	0.940	13.296
0.15	3.707	1.683	1.401	13.209

A flow chart of preparation of sample is presented below



As a whole the preparation procedure generally represents:

- A mixture of materials was prepared with the cations in the ratio corresponding to that in the final product.
- Pre sintering the mixture at temperature 1000^0C to form ferrite.
- Converting the raw ferrite into powder and pressing the powder using hydrostatic pressure into the required shapes.
- Sintering at 1250^0C to produce a highly densified product.

Results and discussion

Table-1 Resistivity at room temperature of Ni0.60 $Zn_{0.40-x}$ $La_xFe_2O_4$ ferrites

Content,x	Resistivity at room temperature(30^0C)
0.05	7.562
0.10	13.112
0.15	129.08

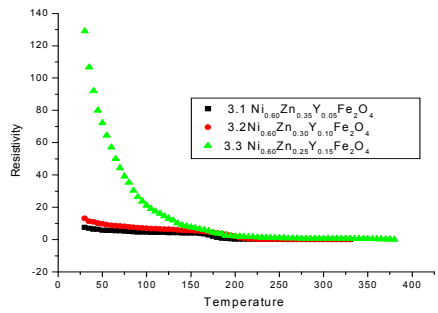


Figure-1: Temperature dependence of resistivity, as a function of Temperature of $Ni_{0.60}$ $Zn_{0.35}$ $Y_{0.05}$ Fe_2 O_4, $Ni_{0.60}$ $Zn_{0.30}$ $Y_{0.10}$ Fe_2 O_4, and $Ni_{0.60}$ $Zn_{0.25}$ $Y_{0.15}$ Fe_2 O_4, sintered at 1250^0C

In figure -1 the rectangular black sign indicates the sample $Ni_{0.60}$ $Zn_{0.35}$ $Y_{0.05}$ Fe_2 O_4.The curve of sample $Ni_{0.60}$ $Zn_{0.35}$ $Y_{0.05}$ Fe_2 O_4 shows that with increasing the temperature from room temperature the resistivity decreasing up to 180^0C. After that with increasing the temperature the resistivity becomes constant and almost temperature independent. In figure-1 the circle shaped red sign indicates $Ni_{0.60}$ $Zn_{0.30}$ $Y_{0.10}$ Fe_2 O_4 which indicates that with increasing the temperature the resistivity decreasing up to 185^0 C and becomes constant and almost temperature independent onward. In figure-1 triangular green sign indicates sample $Ni_{0.60}$ $Zn_{0.25}$ $Y_{0.15}$ Fe_2 O_4 which shows that with increasing temperature the resistivity decreasing gradually and after 190^0C becomes almost temperature independent. All the samples show the nature of the semiconductor.

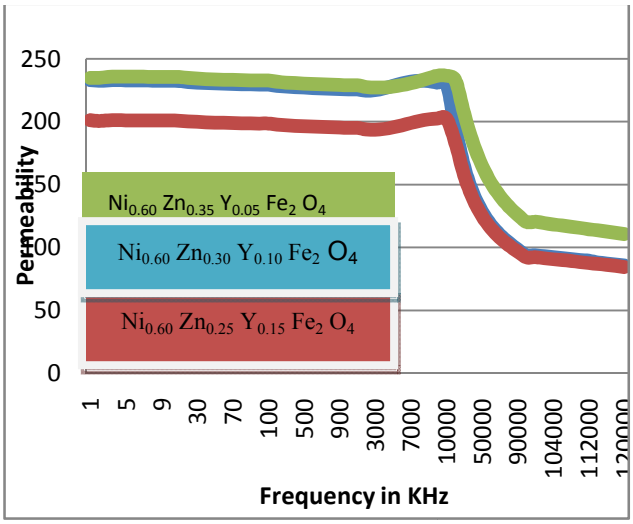

Figure-2: The real part of the permeability dependant on frequency of $Ni_{0.60}$ $Zn_{0.35}$ $Y_{0.05}$ Fe_2 O_4, $Ni_{0.60}$ $Zn_{0.30}$ $Y_{0.10}$ Fe_2 O_4, and $Ni_{0.60}$ $Zn_{0.25}$ $Y_{0.15}$ Fe_2 O_4, sintered at 1250^0C

Figure-2 describes the change of permeability with the change of frequency. For sample $Ni_{0.60}$ $Zn_{0.35}$ $Y_{0.05}$ Fe_2 O_4, $Ni_{0.60}$ $Zn_{0.30}$ $Y_{0.10}$ Fe_2 O_4, and $Ni_{0.60}$ $Zn_{0.25}$ $Y_{0.15}$ Fe_2 $O_4Ni_{0.60}Zn_{0.35}La_{0.05}Fe_2O_4$ it is seen that the initial permeability is as same as up to a very high frequency 10 MHz i.e., initial permeability is constant up to 10 MHz thenceforth the initial permeability sharply decreases up to 100MHz after that it remains constant on wards. At high frequency greater than 100 M the permeability becomes frequency independent.

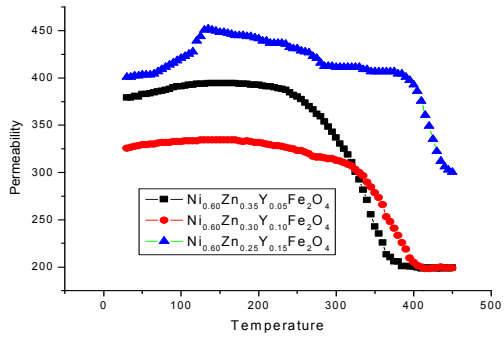

Figure-3: The real part of the permeability dependant on temperature of $Ni_{0.60}$ $Zn_{0.35}$ $Y_{0.05}$ Fe_2 O_4, $Ni_{0.60}$ $Zn_{0.30}$ $Y_{0.10}$ Fe_2 O_4, and $Ni_{0.60}$ $Zn_{0.25}$ $Y_{0.15}$ Fe_2 O_4, sintered at 1250^0C

Table-1 Data of Curie temperature (T_C) ($Ni_{0.60}$ $Zn_{0.40-x}$ $Y_xFe_2O_4$)

Zn- deficient content , x	$T_s = 1250^0$C
	T_c^{0C}
2.1 $Ni_{0.60}Zn_{0.35}Y_{0.05}Fe_2O_4$	340
2.2 $Ni_{0.60}Zn_{0.30}Y_{0.010}$ Fe_2O_4	355
2.3 $Ni_{0.60}Zn_{0.25}Y_{0.15}Fe_2O_4$	395

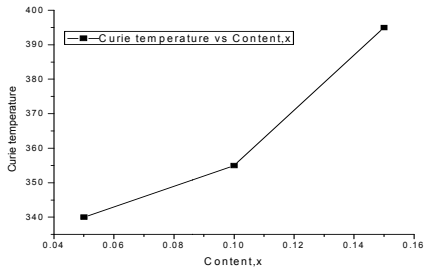

Figure-4: Curie temperature dependence of the content, as a function of Temperature of $Ni_{0.60}$ $Zn_{0.35}$ $Y_{0.05}$ Fe_2 O_4, $Ni_{0.60}$ $Zn_{0.30}$ $Y_{0.10}$ Fe_2 O_4, and $Ni_{0.60}$ $Zn_{0.25}$ $Y_{0.15}$ Fe_2 O_4, sintered at 1250^0C

Figure-4 shows the variation of Curie temperature, T_c with contents. Curie temperature gradually increases with increasing the contents mainly depends upon the strength of A-B exchange interaction.

Conclusion

Effect of electrical and magnetic properties of $Ni_{0.60}Zn_{0.40-x}Y_x$ Fe_2O_4 has studied thoroughly on the Yttrium (Y) substitution where x = 0.05, 0.10, 0.15. Temperature dependence resistivity was measured to identify the nature of the samples. Initially resistivity decreases gradually at lower temperature region and with further increasing the resistivity decreases sharply and at higher temperatures region it becomes almost independent of temperature. Initial permeability dependant on frequency was studied to fathom the frequency response initial permeability. Temperature dependence permeability has been used to measure the Curie temperature of $Ni_{0.60}Zn_{0.40-x}$ Y_x Fe_2 O_4 (x=0.05, 0.10, 0.15) Ferrites. Curie temperature of Ni-Zn ferrite increases with the decrease in Zn-content. There is much scope for further research in controlling the magnetic characteristics by changing composition and heat treatment certain important parameters like temperature dependence magnetization, anisotropy and magnetostriction can be study in detail for a better understanding of micro structure properties of the samples.

Abstract—**Effect of source/drain contact resistance on the DC characteristics of large area Graphene Field Effect Transistor (GFET) is reported here. As graphene has been identified as a potential candidate for replacing silicon based devices, their performance has been thoroughly investigated. In practical devices, the contact resistance at the interface of channel and Source/Drain (S/D) contact is inevitable; therefore a compact model is proposed taking them into account. In the simulation, Ti, Au, Pt and Ni are considered as contact metals. The result shows the DC characteristics of GFET greatly depends on the contact resistance. Drain current reduces with increasing contact resistance and saturation in the current voltage characteristics disappears at high value of the contact resistance.**

Keywords- Graphene; GFET; Contact Resistance; DC characteristics; Compact modeling

I. INTRODUCTION

In order to sustain Moore's law, the size of silicon (Si) based field effect a transistor has been being reduced for last four decades. As they reached at 22 nm node, they are almost at their physical limit [1, 2]. Enhanced short channel effects (SCEs) as well as diminutive control of gate over the channel leads severe performance variation from the intended design [3]. To solve this problem, Si needs to be replaced from the channel with some material having superior transport properties. One of the most promising materials is graphene mainly due to its wide spread availability as well as low cost along with its excellent physical and electronic transport properties. The sp^2 bonded carbon atoms organized in hexagonal lattice format makes graphene 200 times stronger than steel. The enhanced elastic constant further leads to better thermal conductivity. For electron transport, graphene offers carrier mobility at the range of 3000 cm²/Vs to 27000cm²/Vs [4] [5]. However, the only problem is the semi-metal band structure, i.e. graphene possesses no band gap that forbids its application in logic devices. Nevertheless, its outstanding transport properties have led to many comprehensive studies on the applicability in various fields such as nanoelectronics and high frequency electronics [6], energy storage and conversion [7], field emission display [8], transparent conductors [9] and so on.

However, most of the studies are done for ideal graphene based devices. In real devices, when a channel material is connected with contact, it forms an inherent resistance at the channel-contact interface. In this study, we report the large signal model of GFET and a simple mathematical expressions to analysis the DC characteristics in presence of contact resistance. The basic model given in [10] is modified under the postulates given in [11]. And they are done by adding the effect of contact resistance (R_C) of graphene-metal contact. The values of R_C vary from a few hundred to a few thousand Ω-μm, and depends on the metal used, fabrication procedure, gate bias and measurement conditions [12]. A gate-dependent nickel-graphene contact resistance of 500 Ω μm has been reported at 300 K [13]. For a titanium–graphene system, an R_C of less than 250 Ω μm has been reported at liquid helium temperatures, and an R_C of greater than 1,000 Ω μm at 300 K [13]. These experimental values are used in the elucidation of our proposed model.

II. LARGE SIGNAL MODEL NEGLECTING R_C

Large signal model of graphene FET (GFET) is shown in Fig. 1. It consists of drain, source, graphene channel and an insulated top gate. The effect of R_C between drain/source and graphene has been neglected in this section.

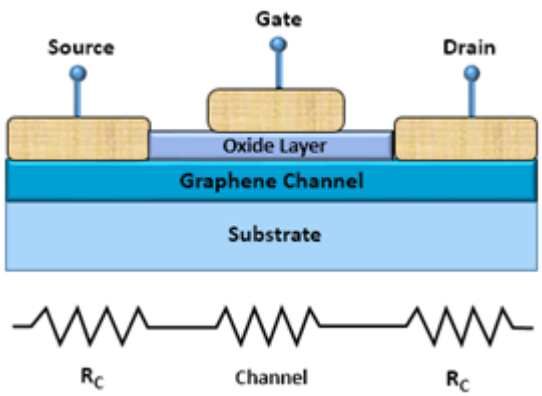

Fig. 1: Schematic diagram of graphene field effect transistor (GFET), and equivalent circuit including the contact resistance.

A. Drain Current Modeling

The expression of drain current of top gated GFET is [10, 11]-

$$I_D = \mu W \frac{\int_0^{V_D}(|Q_{net}| + n_{puddle})dV}{L + \mu|\int_0^{V_D}\frac{1}{v_{SAT}}dV|} \quad (1)$$

Where μ is the carrier mobility, W is the width of the graphene sheet, L is the channel length, and V_{SAT} is the saturation velocity in the graphene layer, Q_{net} is the net mobile charge, e is electron charge and n_{puddle} is the residual carrier density which is induced by spatial in homogeneity within the graphene layer. It is given as [14]-

$$n_{puddle} = \frac{\Delta^2}{\pi\hbar^2 v_f^2}$$

Δ represents the spatial in homogeneity of the electrostatic potential, $\hbar$ is the reduced Planck constant, and v_f is the Fermi velocity. Equation (1) can be written as:

$$I_D = \frac{Num_1 + Num_2}{Den} \quad (2)$$

where,

$$Num_1 = \frac{\mu W}{4\beta}\int_0^{V_D}\left[-C_T + \sqrt{C_T^2 + 4\beta|C_T(V_{eff} - V) + eN_f|}\right]^2 dV \quad (3)$$

Here the factor $\beta = \frac{e^3}{\pi\hbar^2 v_f^2}$. C_T is the top oxide capacitance, V is the potential variation along the channel due to drain voltage V_D and N_f is a term that accounts for the net acceptor/donor concentration. The effective gate-source overdrive voltage, $V_{eff} = V_G + V_{TH,0}$. Where V_G is top gate voltage and $V_{TH,0} = eN_f/C_T$ is zero bias threshold voltage for GFET devices. Equation (3) contains integration of absolute function. It can be expanded as followed:

$$Num_{1\,(V_{eff} \geq V_D)} = -\frac{\mu W}{\beta^2 C_T}\left[\frac{-\beta C_T^3 V_D}{2} + \frac{\beta^2 C_T^2}{2}\left\{(V_{eff} - V_D)^2 - V_{eff}^2\right\} + \frac{C_T}{12}(C_T^2 + 4\beta C_T V_{eff})^{3/2} - \frac{C_T}{12}\left(C_T^2 + 4\beta C_T(V_{eff} - V_D)\right)^{3/2}\right] \quad (4)$$

$$Num_{1\,(V_{eff} < V_D)} = -\frac{\mu W}{\beta^2 C_T}\left[\frac{\beta C_T^3 V_D}{2} - \frac{\beta^2 C_T^2}{2}\left\{(V_{eff} - V_D)^2 + V_{eff}^2\right\} + \frac{C_T}{12}(C_T^2 + 4\beta C_T V_{eff})^{3/2} + \frac{C_T}{12}\left(C_T^2 - 4\beta C_T(V_{eff} - V_D)\right)^{3/2}\right]$$

The second term of numerator is given by:

$$Num_2 = \mu W \int_0^{V_D} en_{puddle} dV = \mu W e n_{puddle} V_D \quad (5)$$

The denominator in equation (2) can be expressed as:

$$Den = L + \mu\left|\int_0^{V_D}\frac{1}{v_{SAT}}dV\right| \quad (6)$$

This can be simplified assuming an average V_{SAT} given by [10]:

$$v_{SAT,AV} = \frac{\omega}{\sqrt{\pi\frac{|Q_{net,AV}|}{e} + n_{puddle}}} \quad (7)$$

Where ω is obtained from the surface phonon energy of the substrate ħω and $Q_{net,AV}$ is the average charge [10] given by:

$$Q_{net,AV} = \frac{1}{4\beta}\left[-C_T + \sqrt{C_T^2 + 4\beta\left|C_T\left(V_G - \frac{V_D}{2}\right)\right|}\right]^2 \quad (8)$$

The model is simulated in MATLAB using numerical parameters given in table-1. Fig. 2 shows the simulated I_d-V_D characteristics considering no contact resistance.

TABLE I

Symbol	Description	Value
μ	Mobility	$7000\ cm^2V^{-1}s^{-1}$
C_{TOP}	Top oxide capacitance	$3.6 \times 10^{-3}\ \mu Fcm^{-2}$
Δ	Spatial inhomogeneity	8.65×10^{-21}meV
e	Charge of electron	1.6×10^{-19}C
$\hbar$	Reduced plank constant	1.055×10^{-34}J/s
ω	Angular frequency	$8.5 \times 10^{13}\ s^{-1}$
L	Channel length	1μm
v_f	Fermi velocity	$960000\ cm^{-1}$
W	Channel width	$1\ \mu$m

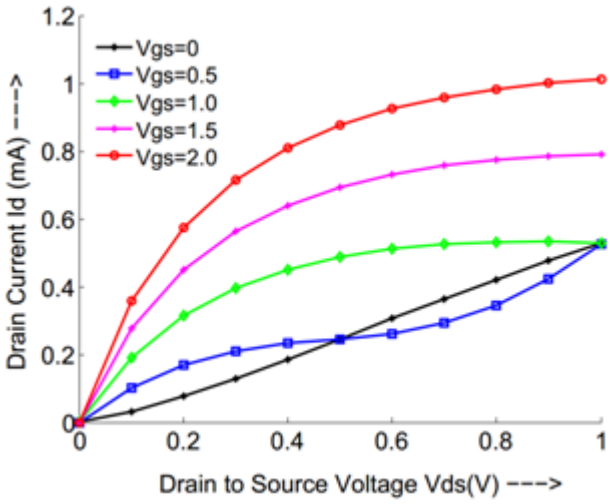

Fig. 2: I_D-V_D characteristics of large area GFET when no contact resistance is taken into account.

B. Transfer Characteristics

The voltage in gate terminal creates electric field in graphene channel that changes or controls the conductivity of the graphene channel. It also controls the number of electrons that can pass through the channel. From the equation (1), it is clear that the I_D is proportional to the polynomial of gate voltage V_G. It is seen in the I_D-V_G characteristics in Fig. 3 that both for positive and negative gate bias, the drain current is positive. Also note that drain current of GFET never goes to zero, it becomes minimum at certain gate bias called the "Dirac point". Left to the Dirac point, current is carried by hole and right to that point, it is carried by electron. That also means the Dirac point distinguishes the point of bipolar conduction.

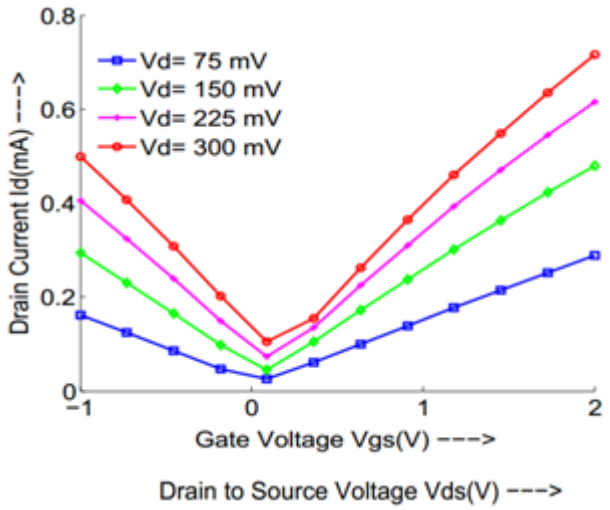

Fig. 3: I_D-V_G characteristics of large area GFET when no contact resistance is taken into account.

III. GFET MODEL CONSIDERING R_C

For a complete model of GFET, the contact resistances R_C cannot be neglected where R_C is in the order of few hundred ohms. The contact length of 0.5 μm is considered. The complete model is shown in Fig. 4.

A. Effect of R_C on Drain Current

When voltage is applied between drain to source (V_D), a portion of it drops across each R_C. In that case, the V_D is given as-

$$V_D = V_{Ch} + 2I_D R_c \qquad (9)$$

The limit used in the integrals in equation (1) is the potential extremes at the channel region. That is why when contact resistance is added, they must be modified as follows:

$$I_D = \mu W \frac{\int_{I_D R_C}^{V_D - I_D R_C} (|Q_{net}| + n_{puddle}) dV}{L + \mu \left| \int_{I_D R_C}^{V_D - I_D R_C} \frac{1}{v_{SAT}} dV \right|} \qquad (10)$$

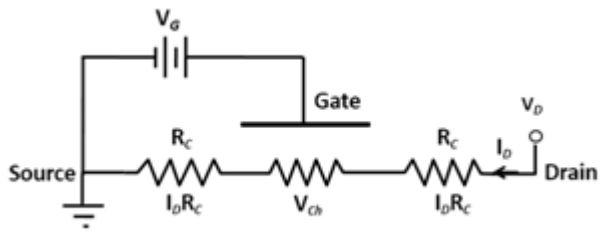

Fig. 4: The complete GFET model with the voltage drops in channel and in contact resistances.

The further calculations are same as described in section II. The equation (10) is a polynomial of drain current I_D and it cannot be solved directly. That is why it is solved by numerical root finding methods. From several available techniques, Bisection method is used here.

The simulation results of $I_D - V_D$ characteristics for different R_C are shown in Fig. 5. It is observed that the I_D decreases with the increase of R_C. Also the saturation regions of $I_D - V_D$ characteristics disappears for the higher values of R_C.

B. Effect of R_C on Transfer Characteristics

The transfer characteristics with the contact resistance can be simulated in the same way explained in preceding section, and are shown in Fig. 6. It is observed that at zero contact resistance (R_C=0), the I_D–V_G curves are linear before and after Dirac point. This linearity disappears and I_D–V_G curves get saturated for higher values R_C. However, no change in position of Dirac points is observed.

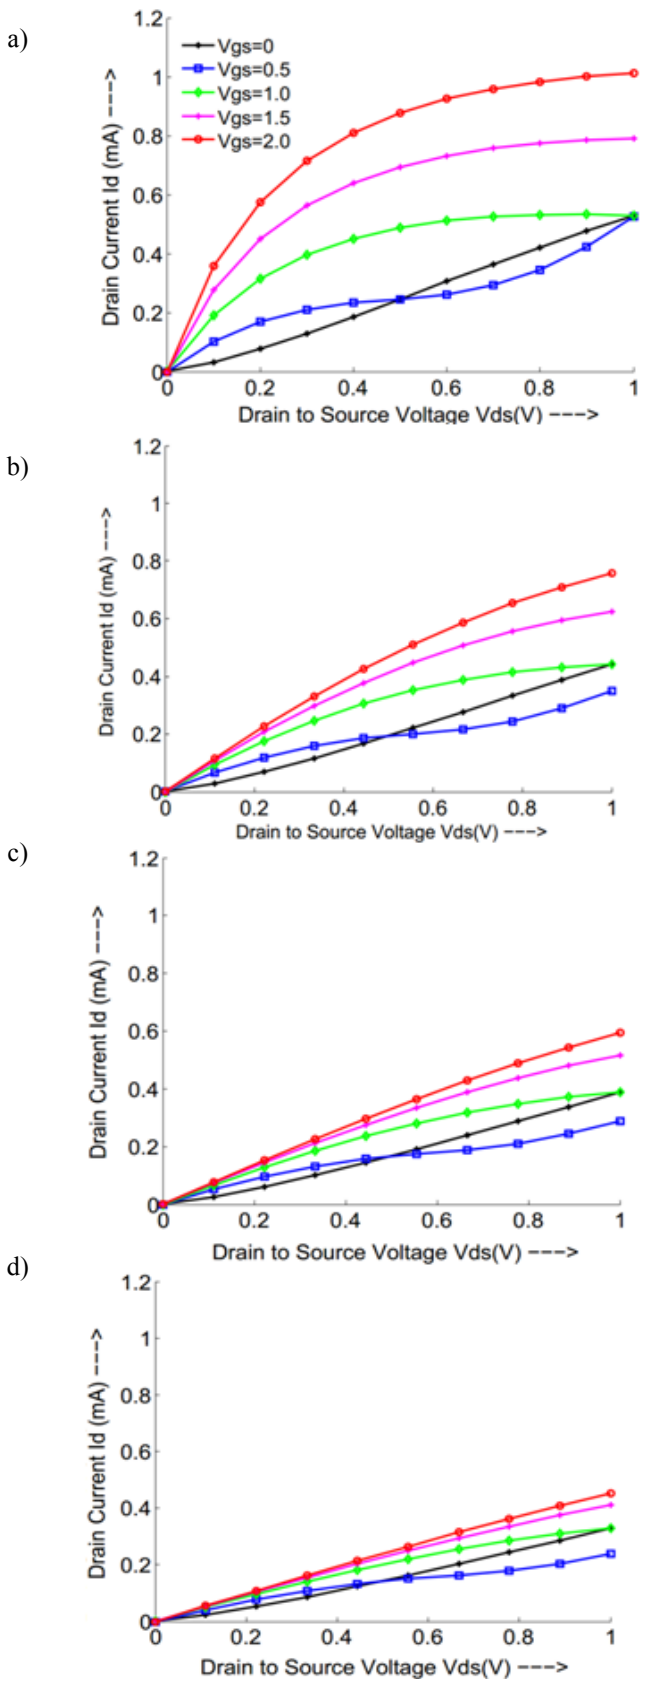

Fig. 5. The effect contact resistance R_C on I_D–V_D characteristics of GFET. (a) without R_C; (b) with R_C = 300 Ω; (c) with R_C = 600 Ω; (d) with R_C = 900 Ω

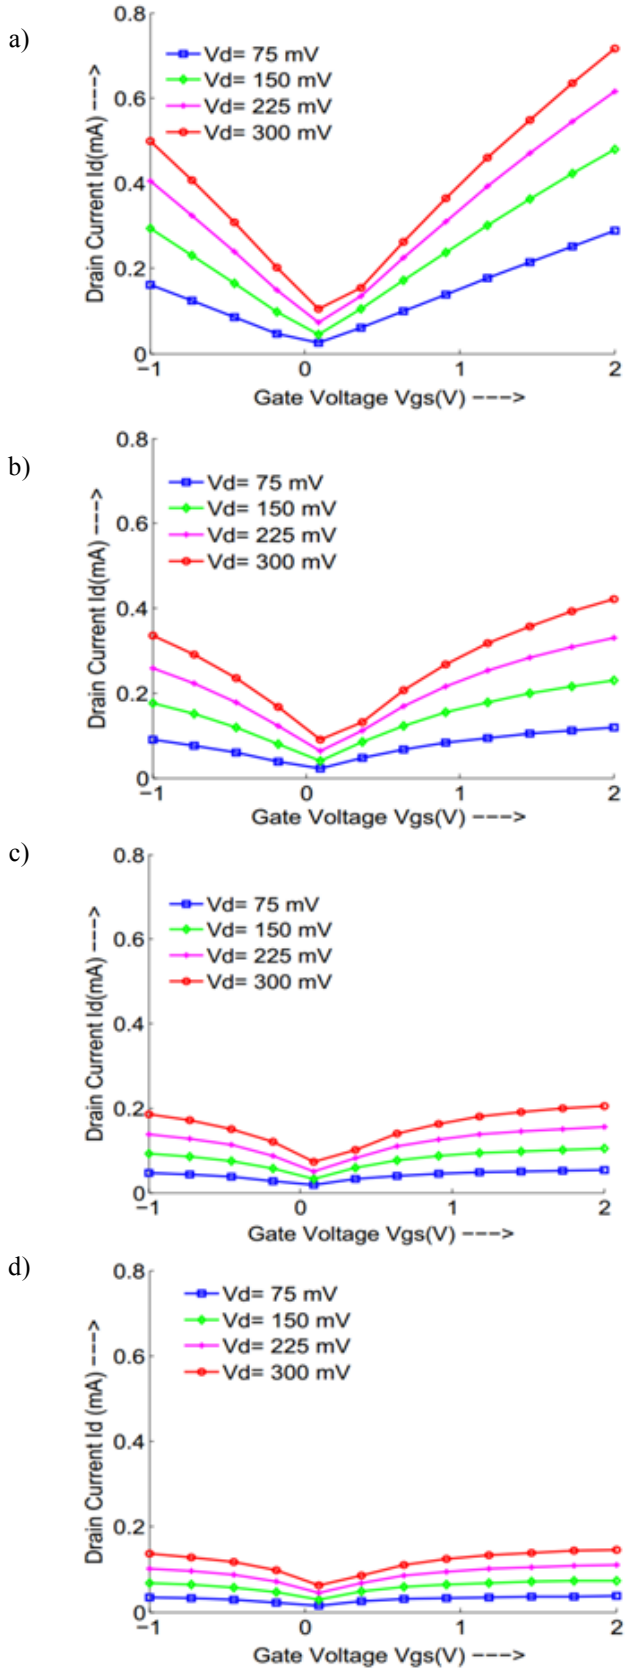

Fig. 6. The effect contact resistance R_C on I_D–V_G characteristics of GFET. (a) without R_C; (b) with R_C = 300 Ω; (c) with R_C = 600 Ω; (d) with R_C = 900 Ω

IV. CONCLUSION

In this research, we present a compact model for large signal characteristics for top-gated graphene FET with no band-gap engineering of the graphene channel. Because of zero band-gap, GFET cannot be used as logic device, but it can be used in RF (Radio Frequency) applications. Taking into account the contact resistance, an analytical expression is provided for the drain current I_D which is a polynomial function of all relevant parameters. Simulation result shows that the contact resistance has a significant effect on the $I_D - V_D$ and transfer characteristics. When contact resistance is neglected, the saturation region $I_D - V_D$ is flat enough to make the device compatible for analogue application. However, with increasing resistance, I_D decreases significantly and When R_C increases, the voltage drops in drain and source terminals increases. So for a fixed value of drain voltageV_D, the channel potential decreases. The expression of I_D is a very complex function of V_D, V_G and R_C. So it is difficult to explain the disappearance of saturation region.

***Abstract*— In this paper, a thermal model of an embedded system consisting of MOSFET, MESFET and HFET is presented in nano-electronic system by using FEM (Finite Element Method) . This model is used to analyze the thermal effects of an embedded system and to solve the associated thermal problems by using graphene heat spreader on different positions of the embedded system. This paper also suggests the best position of graphene heat spreader to ensure maximum reduction of temperature of the electronic devices. As high temperature sets a limit to the reliability of the devices, such modeling is very useful for the optimization of an embedded system to guarantee a longer lifespan and a better reliability.**

Keywords*— *Graphene, Heat Spreader, Embedded System, Thermal Management.

I. INTRODUCTION

Self-heating is a severe problem for the high-power related electronic, optoelectronic and photonic embedded devices [1]–[3]. Average temperature rise and non-uniform distribution of dissipated power in embedded systems consist of MOSFETs, MESFETs and HFETs individually or combination of these transistors, leading to the emergence of hotspots nears the device channels. These hotspots bring about degradation of the drain current, gain and output power, and can cause thermal breakdown [4]–[6]. Furthermore, the down-scaling of devices and higher circuit speeds lead to further increase in heat generation, power densities and temperature rise [7-8]. Temperature rise to an abrupt level also causes an increase in gate-leakage current and results in a poor reliability [9]. Various thermal management solutions, for example, conventional heat spreaders (HS) like Copper or Aluminum results poor improvement in thermal management for FET devices. To overcome these shortcomings, a newly invented material named Graphene, the 2-D allotrope of carbon atoms arranged in hexagonal pattern with superior thermal conductivity, ranging from 3000-5300 W/m.K at room temperature can be a potential candidate. It has very high electron mobility as well as very low resistivity. It also provides lower thermal contact resistance due to its flat geometry. The heat propagates in a lateral direction within the graphene plane that increases the area of the heat dissipation, increases the removal of heat flux from hot spots, reduces temperature and thus high heat flux thermal management becomes more efficient [10] .

In this work we carry out two dimensional thermal modeling in order to study the effect of graphene heat spreaders in thermal management of an embedded system.

II. MODEL FOR HEAT CONDUCTION

To find out the best position for adding graphene heat spreader, we simulated the embedded system with Graphene heat spreader (a) at the drain region of every FET devices (b) at only two drain terminals of the whole embedded system (c) at the junction of GaAs and SiC substrate region.

The simulated embedded system consists of 5 FET devices with a separation of 5μm between two consecutive FET transistors (cf. Fig. 1).

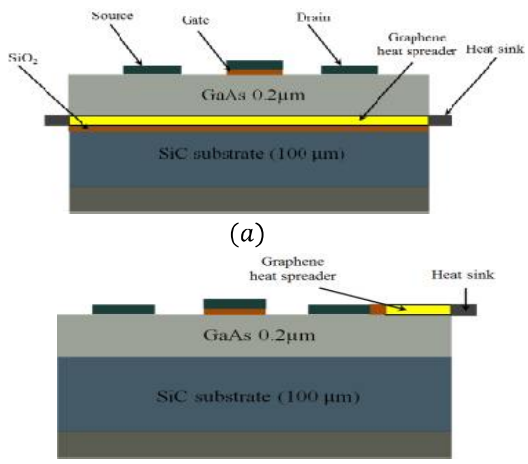

Fig. 1 Heat removal technique using graphene heat spreader (a) when graphene HS is connected to the substrate level and (b) when graphene HS is connected to the drain region. (One of the five FETs of the embedded system is shown in the figure.)

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

The whole device width is 26μm. For MOSFET and MESFET, the thicknesses of SiC substrate, epitaxial GaAs film and graphene heat spreader are 100μm, and 0.2μm , and 1nm, respectively while their thermal conductivities are 490W/m.K, 46W/m.K and 2000W/m.K, respectively for different embedded systems simulated here [11-12]. A SiO_2 is used as an insulator with a thermal conductivity of 1.4 W/m.K and thickness of 10nm. For AlGaAs/GaAs HFETs, the thickness of SiC substrate, GaAs, AlGaAs and SiO_2 layers were 100μm, 192nm, 8nm and 10nm, respectively. Their corresponding thermal conductivities at the room temperature are taken from the literature to be 350W/mK, 160W/mK, 120W/mK and 1.4W/mK, respectively [13]-[15].

The whole simulation is carried out with FEM (Finite Element Method) using COMSOL software [16]. A conventional heat sink is attached to the device structure at the bottom. A graphene heat spreader, when used, is connected- at first case, at drain region of each FET devices; in the second case, at the drain region of the two terminal FET devices only; and in the third case, at GaAs and SiC layer for heat escaping. The heat spreader is insulated from the drain terminal by a thin SiO_2 layer. In our proposed device structure the size of the graphene layer is in micrometer range which is much larger than phonon mean free path of graphene (775 nm). Hence in our work, the thermal transport is considered to be diffusive and does not reveal any edge dependence[17]-[20].

In this paper, the thermal profiles have been simulated by using the Fourier's law expressed as:

$$-\nabla \cdot (k\,\nabla T) = Q \qquad (1)$$

and the Ohm's law given by:

$$J = \sigma E + J_e \qquad (2)$$

Here Q is the heat source, defined as the heat energy generated within a unit volume per unit time, T is the absolute temperature and k is the thermal conductivity of material, J is the current density, σ is electrical conductivity and E is the electric field. The operator $\nabla = \partial/\partial x + \partial/\partial y + \partial/\partial z$. The bottom surface of the substrate and the far end of the graphene heat spreader were kept at a constant temperature T = 300 K. The external boundaries were considered to be adiabatic and given by $\nabla \cdot (k\,\nabla T) = 0$ i.e. the temperature gradient across the boundary is zero. All the heat sinks were considered to be held at a constant room temperature and were described as $T = T_0$, where T_0 = 300K. The external surfaces were modeled as insulated from the environment.

III. Simulation and Results

Thermal issue is more critical in embedded systems and we get a clear picture of this phenomenon from the simulation results shown in Fig. 2. The maximum temperature in integrated chip is very high without the heat spreader. By using graphene heat spreader,maximum temperature is reduced by a significant amount.

An embedded system is energized by a drain voltage and an electric current. Maximum heat is generated in the channel region. The hot spot temperature was obtained using 2D simulation, using COMSOL multiphysics software. With the graphene heat spreader, heat generated from the hot spot can be propagated to a larger area, and dissipated by natural convection, thus a temperature drop of the embedded system's hot spot was observed. The reduced hot spot temperature suggests improved temperature uniformity across the chips and enhanced performance and lifetime for electronic devices.

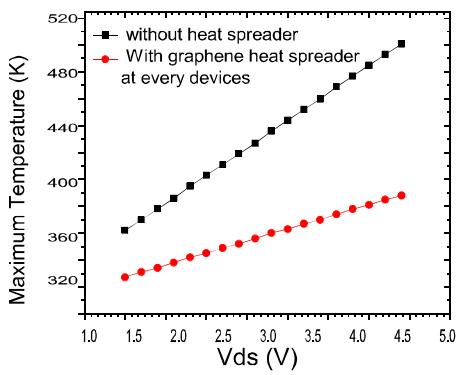
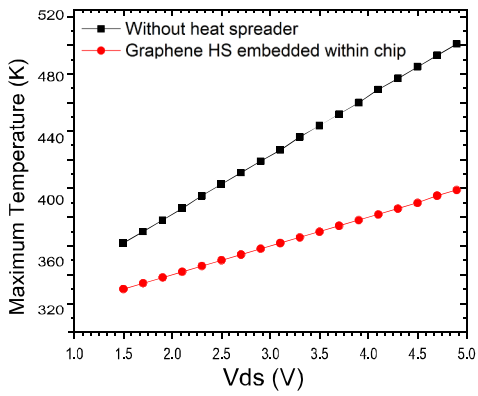
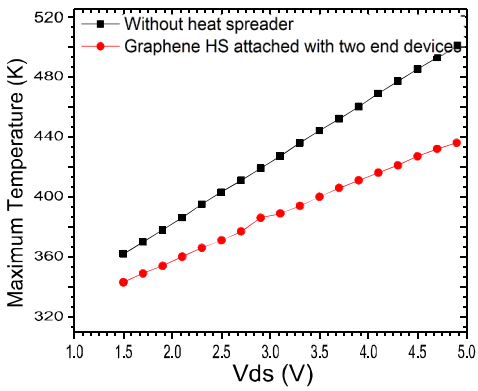
Fig.2. Temperature distribution in simulated 2-D embedded MOSFET system (a) without and (b) with graphene heat spreaders attached to the side heat sinks. (Zoomed view of one of the five MOSFETs).



(a)



(b)



(c)

Fig.3. Temperature profile for a MOSFET embedded system with Graphene HS (red colored line) (a) at drain region of each MOSFET, (b) at SiC substrate level in another words as embedded within chip and (c) only at two MOSFETs located at the ending terminals of the embedded system. All the figures compared with respect to same system having no heat spreader (black colored line).

Fig. 3(a) represents the temperature effects on a MOSFET embedded system when no heat spreader is used (black colored line) and with graphene heat spreaders used at the end of drain terminals of each device (red colored line). We observed that graphene HS reduces temperature of the embedded system by a great extent. Fig. 3(b) and Fig. 3(c) represent the temperature effects on a MOSFET embedded system without any heat spreader and with graphene heat spreaders used at substrate levels and only at the end of two Terminal devices, respectively.

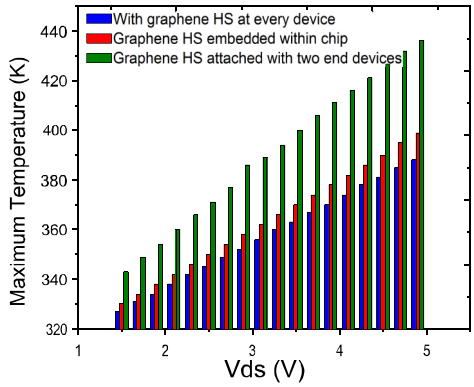


Fig.4. Comparison among three different positions of the graphene HS for the MOSFET embedded system.

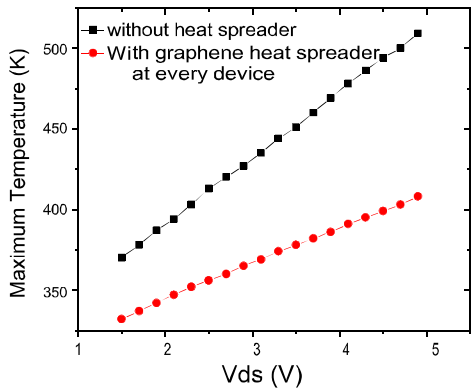
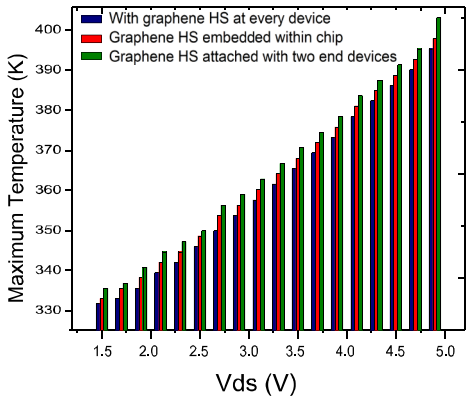
Fig. 4 represents the comparison among thermal improvement of a MOSFET embedded system when graphene heat spreaders connected at different positions of the system. As it is clear from the graph that, graphene HS, if connected to each drain terminals of the system, gives the best improvement in devices; and when graphene HS is connected only at two endmost terminal devices, it gives poor result; and moderate thermal improvement occurs when graphene HS is connected at substrate level. For instance, for a given gate voltage $V_{gs} = 1.5V$ and drain voltage $V_{ds} = 3.0V$, maximum temperatures of the MOSFET embedded device are 427K, 357K, 362K and 389K in case of without heat spreader, graphene HS at every device, graphene HS at the substrate level and graphene HS at only two terminal devices, respectively.



(a)



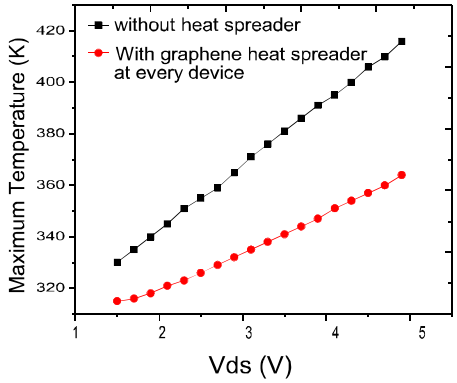
(b)

Fig.5.Temperature profile for a MESFET embedded system with graphene HS (red colored line) (a) at drain region of each MESFET, of the embedded system. The figure is compared to same system having no heat spreader. (b) Comparison among three different positions of the graphene HS.

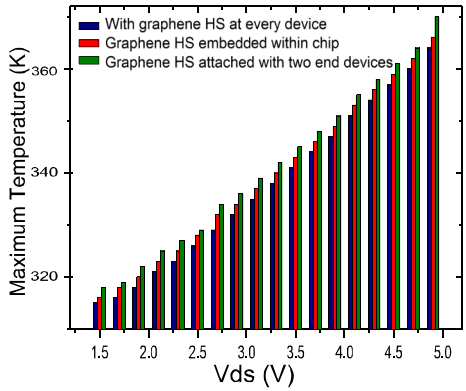
Fig. 5(a) demonstrates the thermal improvement of a MESFET embedded system when graphene heat spreader is incorporated to device terminals with respect to without heat spreader. As it is clear form the figure that with the increment of drain to source voltage, thermal improvement is quite significant with graphene HS.

Fig. 5(b) compares the thermal improvements for different drain to source voltages for incorporation of graphene HS at different positions of the embedded system. When graphene heat spreaders are connected to the drain region of the each MESFET of the system, it gives the best result in terms of temperature reduction as well as increasing of system lifetime, while graphene HS embedded within the chip, in another words at substrate level gives a satisfactory thermal improvement and graphene HS at only terminal most two MESFET of the system gives least improvement among three possible ways of heat escaping as demonstrated here.

For a given gate voltage $V_{gs} = 1.5V$ and drain voltage $V_{ds} = 3.0V$, temperature improvements of the MESFET embedded device are 66K, 63K and 59K with respect to without HS and when graphene HS at every device, graphene HS at substrate level and HS at only two terminal devices is used to the system respectively.



(a)



(b)

Fig.6.Temperature profile for a HFET embedded system with Graphene HS (red colored line) (a) at drain region of each HFET, of the embedded system, with the results being compared with that having no heat spreader(black colored line). (b) Comparison among three different positions of the graphene HS

As for a HFET embedded system, using of graphene heat spreader gives an outstanding thermal improvement with respect to using no heat spreader, depicted in Fig. 6(a). The maximum temperatures of the system are 371K and 335K for without heat spreader and for the case of using heat spreader respectively, at $V_{gs} = 1.5V$ and $V_{ds} = 3.0V$. Fig. 6(b) reveals the best option for incorporating of graphene heat spreader to the embedded system. It shows that graphene HS at the end of each HFET gives the best improvement and HS at only two end devices of embedded HFET system gives the least thermal improvement among three possible paths for heat escaping.

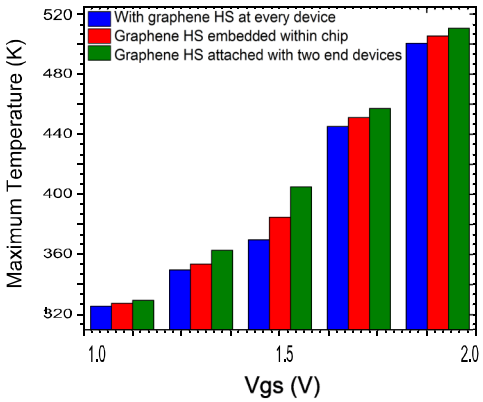


Fig.7.Temperature profile for an embedded system with Graphene HS at different positions of the MOSFET embedded system with the variation of gate to source voltage.

Fig. 7 shows the temperature variation of an embedded system with the variation of gate to source voltage. It is clear from the graph that graphene heat spreader connected at every device reduces the maximum temperature of the system to a significant amount.

IV. CONCLUSION

We carried out a feasible study of the use of graphene as the material for lateral heat spreading in embedded chips. Although our results show that the amalgamation of graphene or FLG (few layer graphene) at the drain terminal of each FET devices gives the best thermal improvement,this is a less feasible solution for fabrication perspectives. Graphene heat spreader embedded within chip,in another words graphene HS at the interface of the insulating and the substrate layer can lead to substantial reduction in temperature of the hot spots which is very close to the thermal improvement for HS connected to each device with more feasible fabrication process.Graphene HS only at the end of two endmost FET devices carried out the poorest result among these three possible positions of incorporation of graphene a HS at embedded FET devices. Hence we suggest embedded graphene heat spreader as the most pragmatic and convenient means of improving thermal issues of FET devices. The efficiency of the hot spot removal with graphene depends on the specifics of the device structure, geometry, and position of the heat spreader. The obtained results can lead to a new type of possibility of thermal management of nano-electronic circuits.

***Abstract*—This work reports on development of an optimized analytical model to investigate the current-voltage (J-V) characteristics of a lightly doped CdTe-based thin film solar cell considering voltage-space dependency of electric field in the absorber region. Following the theory of perturbation, the intractable mathematical equations have been solved analytically. Finally, changes in J-V characteristics curve are observed in various conditions such as effect of stress, life time of holes and electrons and varying series resistance. The proposed model is proven to be helpful in giving better physical insight of Cds/CdTe solar cell.**

Keywords— CdS/CdTe Solar Cell, J-V Characteristics, non-uniform electric field , Perturbation Theory, stress effect.

I. INTRODUCTION

Thin-film CdS/CdTe solar cells fabricated on glass substrates have been recognised as one of the most potential candidates for the development of cost-effective and reliable solar cells in large-scale photovoltaic applications. The documented experimental efficiency of these cells is about 16%–17% and the consequent theoretical values are more than 28% [1]. The advantages of using CdTe include high absorption capability for being a direct bandgap material and the simplicity of device processing [2]. It can be deposited on glass typically a few micrometers deep as absorber layer with a very thin layer of CdS (0.1µm) in the emitter side [2], [3]. In Cds/CdTe solar cells, higher percentage of incident light is absorbed in first few micrometers of lightly doped CdTe layer. The photo-generated carriers in this region are collected by the voltage-dependent electric field [4]–[6].

A number of numerical as well as analytical models [4] – [7] have been introduced in the literature to model the current-voltage (J-V) characteristics of Cds/CdTe solar cells. All these models used a lot of fitting parameters. Anjan *et al*. [8] and Mannan *et al*. [9] developed their models with minimum number of fitting parameters. In [8] electric field is considered as uniform throughout the absorber layer, whereas the same is considered as space-dependent in [9]. Both models used the voltage-dependency of the electric field; but these models used numerical iterations to model the J_L-V_L characteristics, although they deduced the photo-generation current analytically. Later Haque *et al*. [10] derived the J_L-V_L characteristics analytically using the concept of perturbation method. But this model considered the electric field in the absorber layer as constant.

This work focuses on developing a model that removes the abovementioned limitations. In the proposed model, the electric field across absorber layer is considered nonuniform. Furthermore, the theory of perturbation has been applied in order to solve the intractable major differential equations which are proven to be more time effective and acceptable than that of typical lengthy iteration methods. The variations of J-V characteristics under different parameters, i.e., before and after stress, life time of holes and electrons and series resistance have been analysed.

II. ANALYSIS

The load current density (J_L) against the load voltage (V_L) of any solar cell including the effect of series resistance can be expressed as

$$J_L(V_L) = -J_{ph}(V_L) + J_0(V_L)(e^{\frac{V_L - J_L R_s}{nV_T}} - 1) \quad (1)$$

Where, J_{ph} is the photogenerated current density, J_0 is the dark saturation current density, n is the ideality factor and V_T is the thermal voltage. Since the band-gap of CdS (E_g = 2.42 eV) is comparatively higher than that of CdTe (E_g = 1.5 eV), the dark saturation current at the emitter region caused by diffusion is negligible and hence, is dominated by the recombination process in the absorber region. In [9], the expression for J_0 is given as

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

$$J_0(V_L) = \frac{qn_iW_a}{2\sqrt{\tau_n\tau_p}} \quad (2)$$

where, q is the electronic charge, n_i is the intrinsic carrier concentration and τ_n and τ_p are the lifetimes of electron and hole respectively for CdTe, and W_a is the width of the absorber layer .

The photogenerated current can be obtained by adding the average electron current density ($J_{n,avg}$) and average hole current density ($J_{p,avg}$) in the absorber layer and can be expressed as

$$J_{ph} = J_{n,avg} + J_{p,avg} \quad (3)$$

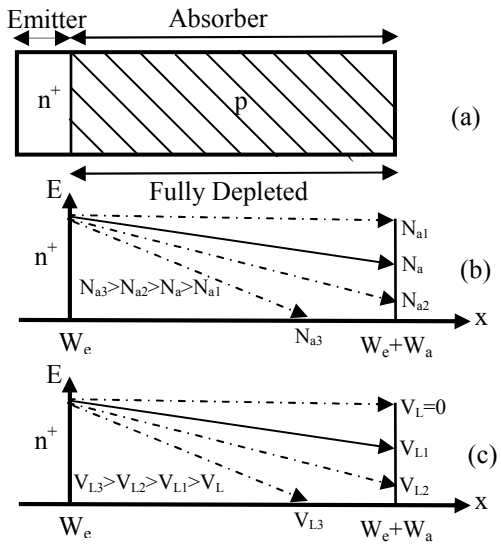

Fig. 1. Electric Field (E) Profile

where, $J_{n,avg}$ and $J_{p,avg}$ can be calculated according to [8], [9] as

$$J_{n,avg} = \frac{1}{W_a}\int_0^{W_a} J_n(x)dx \quad (4)$$

$$J_{p,avg} = \frac{1}{W_a}\int_0^{W_a} J_p(x)dx \quad (5)$$

where, $J_n(x)$ and $J_p(x)$ stands for electron current density and hole current density respectively. The basic equations needed to deduce the $J_n(x)$ and $J_p(x)$ are as follows

$$J_n(x) = qn(x)\mu_n E(x) \quad (6)$$

$$J_p(x) = qp(x)\mu_p E(x) \quad (7)$$

$$\frac{dJ_n(x)}{dx} = \frac{qn(x)}{\tau_n} - q\alpha(\lambda)G_0(\lambda)e^{-\alpha(\lambda)x} \quad (8)$$

$$\frac{dJ_p(x)}{dx} = -\frac{qp(x)}{\tau_p} + q\alpha(\lambda)G_0(\lambda)e^{-\alpha(\lambda)x} \quad (9)$$

Where, n(x) and p(x) is electron and hole density, E(x) for electric field at any point x in Fig. (1), μ_n and μ_p represents electron and hole mobility, α for wavelength-dependent absorption coefficient of the material and G_0 for the optical generation rate given by

$$G_0(\lambda) = (1 - R(\lambda))\frac{\lambda I_0(\lambda)}{hc} \quad (10)$$

Where, h is Planck's constant, c is the velocity of light, $I_0(\lambda)$ is the intensity of light, $R(\lambda)$ is the reflection coefficient and λ is the wavelength of the incident light.

In the thin film hetero-junction structure of CdS/CdTe-based solar cell deposited on the glass substrate, the base (CdTe) region is lightly doped. So, the entire absorber layer will be depleted. For intrinsic or very lightly doped absorber, the electric field can be considered as constant. Previous analysts [2-5] have used this approximation in their analytical approach; but in practical cases for a little increase in the absorber doping results in a linearly-decreasing electric field. However, the electric field in the depletion region close to the emitter side is considered negligible due to its very narrow width. If the absorber layer is fully depleted under short circuit condition, then increase in the absorber doping level [Fig. 1(b)] or in the load voltage [Fig. 1(c)] decreases the field at the right of the absorber layer. Since the electric field is linear throughout the absorber layer and non-zero at the edge, solving Poisson's Equation this field can be calculated as [9]

$$E(x) = \frac{V_{bi} - (V_L - J_L R_S)}{W_a} + \frac{qN_a}{\varepsilon}\left(x - \frac{W_a}{2}\right) \quad (11a)$$

where, ε is the permittivity of absorber material (CdTe), W_a is the absorber width which is equal to the metallurgical base width and V_{bi} is the built-in voltage across the absorber layer. However, if the absorber doping level or the load voltage is further increased, the depletion edge moves towards the left. Hence, the depletion width is no longer equal to the base width and the electric field becomes zero before the base edge. Under this situation, the expression for the electric field can be expressed as found in the standard text books [11]:

$$E(x) = \frac{qN_a}{\varepsilon}(x - W_a) \quad (11b)$$

Combining (6), (8) and (7), (9) gives the first order differential equations of n(x) and p(x) in the absorber layer as

$$\frac{dn}{dx} + \left[\frac{1}{E(x)}\frac{dE}{dx} - \frac{1}{\tau_n\mu_n E(x)}\right]n(x) = -\frac{\alpha(\lambda)G_0(\lambda)}{\mu_n E(x)}e^{-\alpha x} \quad (12)$$

$$\frac{dp}{dx}+\left[\frac{1}{E(x)}\frac{dE}{dx}+\frac{1}{\tau_p\mu_p E(x)}\right]p(x)=\frac{\alpha(\lambda)G_0(\lambda)}{\mu_p E(x)}e^{-\alpha x} \quad (13)$$

Since electrons and holes are swept out by the electric field from the absorber layer in the opposite direction, it can be assumed that $p(W_e) \approx 0$ and $n(W_e+W_a) \approx 0$. Using these boundary conditions, the solutions for the electron and hole concentration can be obtained as

$$n(x)=\frac{\alpha(\lambda)G_0(\lambda)}{\mu_n IF_n(x)}\int_{W_e+x}^{W_e+W_a} e^{-(\alpha+f_n(x))}dx \quad (14)$$

$$p(x)=\frac{\alpha(\lambda)G_0(\lambda)}{\mu_p IF_p(x)}\int_{W_e}^{W_e+x} e^{-(\alpha+f_p(x))}dx \quad (15)$$

where, $IF_n(x)=Ee^{-f_n(x)}$, $IF_p(x)=Ee^{-f_p(x)}$,

$$f_n(x)=\int\frac{dx}{\mu_n\tau_n E(x)},\ f_p(x)=\int\frac{dx}{\mu_p\tau_p E(x)}$$

Now putting the values of n(x) and p(x) from (14) and (15) to (6) and (7) gives the electron and hole current densities as

$$J_n(x)=qG_0(\lambda)\alpha(\lambda)e^{f_n(x)}\int_{W_e+x}^{W_e+W_a} e^{-(\alpha+f_n(x))}dx \quad (16)$$

$$J_p(x)=qG_0(\lambda)\alpha(\lambda)e^{f_p(x)}\int_{W_e}^{W_e+x} e^{-(\alpha+f_p(x))}dx \quad (17)$$

Putting the value of Jn(x) and Jp(x) at (4) and (5), $Jn,_{avg}$ and $Jp,_{avg}$ can be solved.

From (1) it is observed that the load current (J_L) at any load voltage (V_L) can only be determined using numerical methods due to the presence of unknown J_L on both sides. However, using the concept of the perturbation theory this J_L can be determined analytically. According to this theory, if J_L at any V_L is known then, the same at $V_L+\delta V_L$ can be determined using this value, provided that $\delta V_L \rightarrow 0$. Proceeding in the same manner, currents at $V_L+2\delta V_L$, $V_L+3\delta V_L$ …….. can be determined from the current values at $V_L+\delta V_L$, $V_L+2\delta V_L$ …… respectively. Photo-generated current calculated without considering R_s can be used as the initial guess of this process.

III. Results and Discussions

Simulation results based on the proposed model are presented and discussed in this section. The incident photon flux is the air mass (AM) 1.5 global spectrum, which is obtained from the ASTM G-173-03 standard [12]. The absorption coefficients for CdS and CdTe are obtained from the absorption curves in Ref. [13]. The thickness of CdS and CdTe layers are 0.1 and 3.5 µm respectively.

The current-voltage (J_L-V_L) characteristics curve simulated using the proposed model has been shown in Fig. (2). It is noteworthy that the open circuit voltage (0.84 v) and the short circuit current density (17.82 mA-cm^{-2}) obtained in the proposed model are in well agreement with that obtained in the work of Hegedus *et al.* (Fig. 9 of [7]), for R_s = 1.2 Ω cm^2 and n =1.7 and J_0=8×10^{-8} mA-cm^{-2}.

Fig. (3) shows the nature of J_L and V_L with respect to different values of series resistance, R_s. It is observed from the simulation result that though both J_L and V_L decrease slightly in the middle region with the increase in R_s, neither J_{sc} nor V_{oc} changes due to change in R_s.

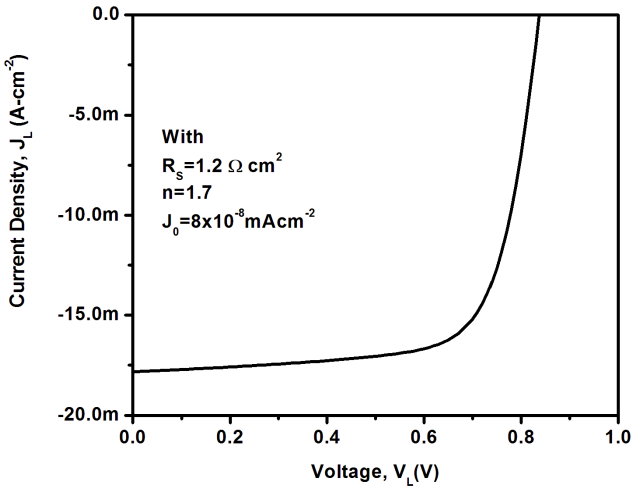

Fig. 2. J_L-V_L Characteristics of the proposed model

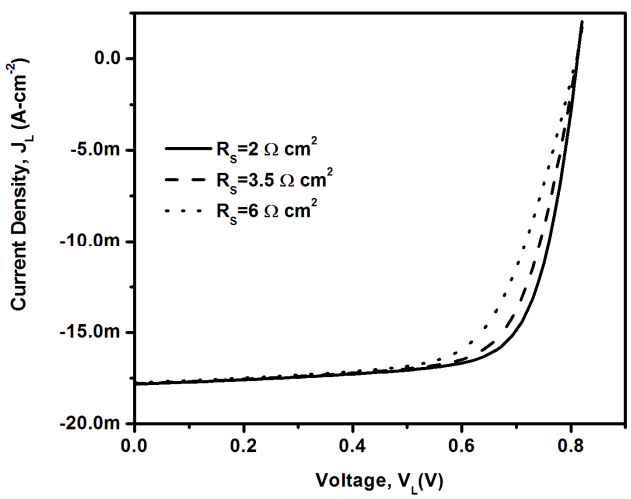

Fig. 3. J_L-V_L characteristics curve under the variation of series resistance (R_s)

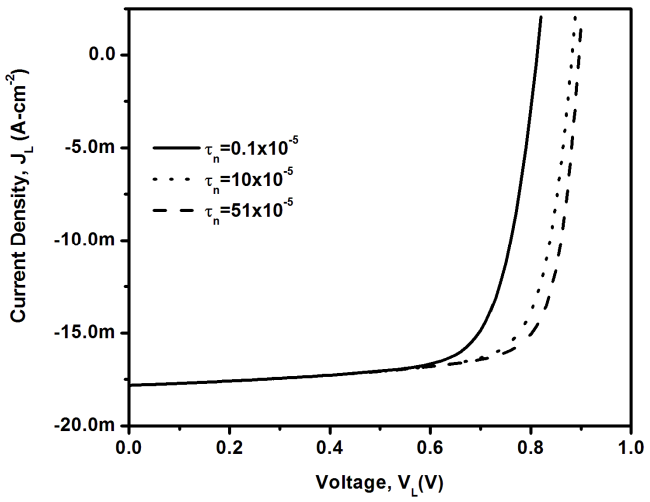

Fig. 4. J_L-V_L characteristics curve against the variation of electron lifetime (τ_n).

J_L-V_L curves have been shown for different lifetimes of electrons (τ_n) in [Fig. (4)] and of holes(τ_p) in [Fig. (5)]. It is found that J_L increases with the increase in any of τ_n or τ_p. This is quite normal, but interestingly, variation in τ_p has a noticeably greater impact on current than that in τ_n has. This phenomenon is quite logical. In fact, most of the photons are absorbed near the emitter side of the n-p junction. Since the fully depleted p-region is much longer than the n-region, it can be argued that the most of the absorption and hence the generation of electron-hole pairs is occurred in a region, which is more distant from bottom contact than from the top contact [Fig. (1)]. The built in electric field then drives the electrons towards the top and the holes towards the bottom of the cell. The holes have to travel a longer way than the electrons do before leaving the cell, holes experience more recombination than the electrons. Hence, the impact of change in τ_p is greater than that in τ_n on J_L.

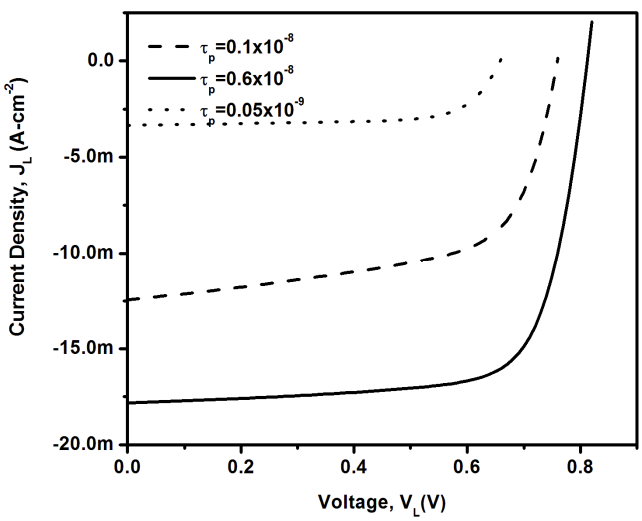

Fig. 5. J_L-V_L characteristics curve against the variation of hole lifetime (τ_p)

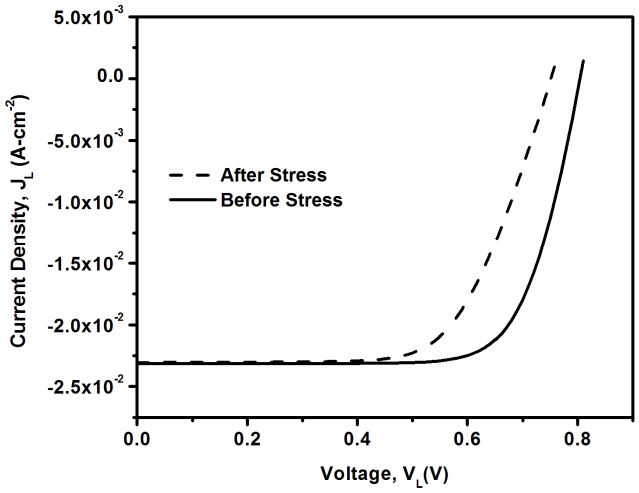

Fig. 6. J_L-V_L characteristics curve before and after applying stress.

Fig. (6) shows the behavior of J_L and V_L of CdTe based solar cell of 7 μm thick CdTe layer and with a Cu/Ni bilayer contact (15 nm/50 nm) of before and after stress, as mentioned in [6], to observe the degradation effects of contact materials over time. The cell was stressed by keeping it at 85^0 C in dry air under 100% sun illumination and open circuit condition for 15 days. Simulation has been done for n=1.66, R_s= 2.4 Ω cm^2 and J_0=1.5×10^{-10} mA cm^{-2} before stress while for n=1.58, R_s= 5.1 Ω cm^2 and J_0=2×10^{-10} mA cm^{-2} after stress. The results i.e., J_{sc} (before stress 23.16 mA cm^{-2} and after stress 23.06 mA cm^{-2}) and V_{oc} (before stress 0.8 v and after stress 0.75 v) has a good agreement with those stated in [6]. The increased value in R_s and J_0 reflects the increased recombination due to degradation, which results in a decreased value in V_{oc}.

IV. Conclusion

The current-voltage characteristics including the series resistance of a CdS/CdTe-based thin film solar cell deposited on the glass substrate have been analytically modeled and analyzed using perturbation theory. The proposed model assimilates both the voltage and the space dependency of the electric field in the absorber region. The model is able to include the stress effects due to contact, explains the more sensitivity of the solar cell to the hole transport than to the electron transport and shows the effects of series resistance. Consequently, the proposed model will be helpful for the better understanding of the physics of the thin-film solar cells.

***Abstract*—In this study the effect of dislocation density on the performance of InGaN based multi junction solar cell has been calculated analytically. It is found that dislocation density adversely affects the open circuit voltage, short circuit current density and conversion efficiency of a solar cell. Efficiency is found to be improved with the increase in the number of junction (24.4-43.56% for single-six junction solar cells) while considering no dislocation. Whereas it is found that the efficiency is affected when dislocation density (10^{01}-10^{13}m^{-2}) is incorporated for analyzing the performances of either single junction (24.47-8.25%) or multi junction solar cell (43.56-15.25% for six junctions). The effect of dislocation density on minority carrier life time is also been anticipated in this study.**

Keywords— Dislocation density, Multi Junction (MJ), Minority carrier diffusion length, Recombination center

I. INTRODUCTION

The ternary InGaN alloy, a direct band gap material can cover most parts of solar spectrum owing to its tunable bandgap (0.64-3.4eV) [1]. It has some unique properties such as high mobility, high absorption coefficients, and low effective mass of carriers which make it promising especially in photovoltaic (PV) applications [2]-[5]. Since single junction (SJ) InGaN solar cell is not able to convert full spectrum to electrical energy, MJ solar cell is being studied widely all over the world during the last few years. However this approach has some challenges. One of the most critical issues is the higher density of threading dislocations (TD) prevailing in III-nitrides epilayers at levels of ~1×10^{9}cm^{-2} [6]. It is found that a large lattice and thermal expansion coefficient mismatches exist between the layer and substrate. These introduce higher dislocations which lead to the degradation of material quality and consequently the performance of its constituent devices [7]–[9]. For InGaN single junction solar cell the edge, screw, and mixed type misfit dislocations are found [10]. A higher density of TDs incorporates in InGaN based MJ solar cell during hetero-epitaxial growth due to higher lattice mismatch. These dislocations emerge as scattering centers and mid bandgap states, which act as recombination centers and decrease the minority carrier lifetime.

Exploration is going on the improvement of the performances of InGaN based MJ solar cells. In available theoretical works that have been performed for analyzing InGaN solar cells, there is no such work showing the effect of dislocation density on the performances. InGaN based high efficient MJ solar cell has been projected in the literatures without considering the effect dislocation density [11]-[13]. Efficiency of InGaN-based solar cell is found to be 24.24% and 43.56% for single and six junctions respectively [11]. Theoretical investigation on InGaN/InGaN/Si three-junction tandem cell has also been performed without dislocation [13]. Moreover, literatures reviews show the discrepancy between the theoretical and practical performances of InGaN-based solar cell. In this study, dislocation density has been attributed for this disparity in projected and practical performances for InGaN-based MJ solar cell. The impacts of dislocation density, minority carrier diffusion length, and surface recombination velocity on the performance parameters of InGaN based MJ solar cells have been simulated analytically.

II. MODELING

Dislocations play a dominant role in determining the electrical and PV characteristics of thin-film InGaN based SJ and MJ solar cells acting as recombination centers. The recombination losses at dislocations which reduce short-circuit current and enhance excess leakage current is the predominant loss mechanism in thin-film InGaN solar cells. The transport of minority carrier to the dislocation can be found from one dimensional continuity equation solved by Yamaguchi and Amano [14].

$$\frac{\partial n}{\partial x} = \frac{D\partial^2 n}{\partial^2 x} \tag{1}$$

Using the following boundary conditions

$$n = 0 \text{ at } x = 0$$

$$\text{and } \frac{\partial n}{\partial x} = 0 \text{ at } x = X_c = 1/(\pi N_{dis})$$

Where n is the excess minority carrier concentration, X_c is the unit cell radius, and N_{dis} is the dislocation density. With these conditions the continuity equation can be satisfied for:

$$n = n_0 e^{-t/\tau} \sin\left(\frac{x\pi}{2x_c}\right) \tag{2}$$

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

Here n_0 is the equilibrium concentration of minority carrier and τ is the minority carrier lifetime. This solution includes only the first order sine function that gives a best case result for the effective diffusion length approach. By combining (1) and (2), the minority carrier diffusion length limited by recombination at the dislocations is found to be:

$$\frac{1}{L_{dis}^2} = \frac{\pi^3 N_{dis}}{4} \tag{3}$$

With a reciprocal rule the effective minority carrier diffusion length as follows.

$$\frac{1}{L_{eff}^2} = \frac{1}{L_0^2} + \frac{1}{L_{dis}^2} \tag{4}$$

Here L_0 is the minority carrier diffusion length where dislocations are not present. The short circuit current density (J_{SC}) has been calculated from one dimensional steady state continuity equation for electron in p-type and hole in n-type semiconductor. The J_{SC} being dependent on minority carrier diffusion length has been calculated for different dislocation densities. Efficiency calculation includes the total number of photons in solar spectrum per unit area per unit time and band gap is selected in each junction so that equal number of photon can be absorbed. The bottom junction band gap energy is optimized and the other junction's band gap energy is chosen accordingly. When a light of wavelength λ is incident on semiconductor the generation rate of electron hole pairs (EHPs) at a distance x' from the semiconductor surface is given by [15]:

$$G(\lambda, x') = \alpha(\lambda) F(\lambda)[1 - R(\lambda)] e^{[-\alpha(\lambda)x']} \tag{5}$$

Where, $\alpha(\lambda)$ is the absorption coefficient, $F(\lambda)$ the number of incident photons/cm^2/s per unit bandwidth and $R(\lambda)$ is the fraction of these photons reflected from the surface.

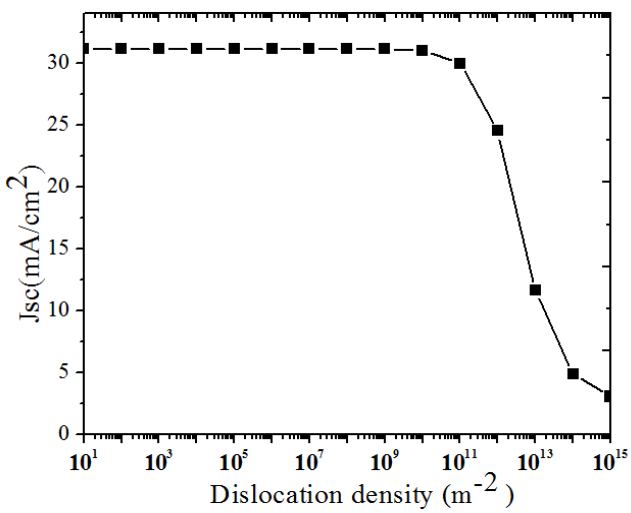

Figure 1. Dependence of short circuit current density (J_{sc}) on dislocation density.

One dimensional steady-state continuity equations for holes in n-type semiconductors under low injection condition are:

$$G_p - \frac{p_n - p_{no}}{\tau_p} + \frac{1}{q}\frac{dJ_p}{dx'} = 0 \tag{6}$$

The current density equation for hole can be expressed as:

$$J_p = q\mu_p p_n \xi - qD_p \frac{dp_n}{dx'} \tag{7}$$

Here, D_p = Diffusion coefficient for p-type. Combining the equation (5), (6) and (7) yields the expression:

$$D_p \frac{d^2 p_n}{dx'^2} + \alpha F(1-R) e^{(-\alpha x')} - \frac{p_n - p_{no}}{\tau_p} = 0 \tag{8}$$

Solving the equation (8) and using two boundary conditions at the surface, $x' = 0$ and at the edge of the depletion region $x' = x_j$ the resultant hole density can be calculated. The resultant photocurrent density due to hole collected at the depletion region, J_p has been calculated. Similarly electron photocurrent density collected at the depletion edge, J_n is evaluated. Total photocurrent density at a given wavelength:

$$J(\lambda) = J_p(\lambda) + J_n(\lambda) + J_{dr}(\lambda) \tag{9}$$

The efficiency expression is given by:

$$\eta = \frac{J_{ph} V_{oc} FF}{\Phi_0} \tag{10}$$

Finally open circuit voltage and efficiency have been calculated at a fill factor FF=0.85 and the incident irradiance Φ_0 = 96.366 mW/cm^2 [16].

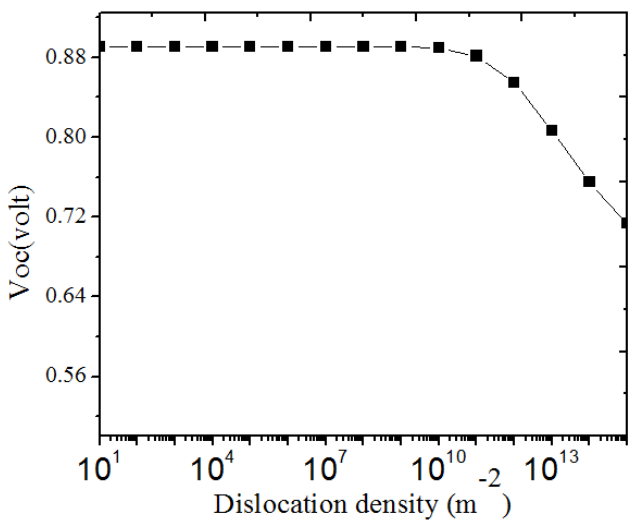

Figure 2. Dependence of open circuit voltage (V_{oc}) on dislocation density.

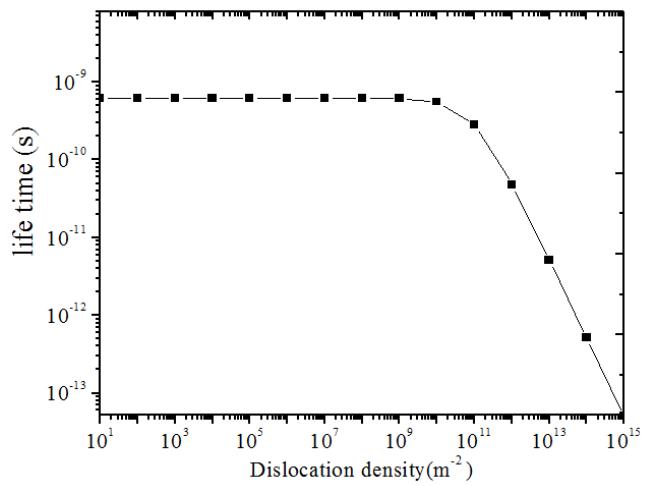

Figure 3. Change of minority carrier lifetime with the variation of dislocation density in $In_{0.51}Ga_{0.49}N$ single junction solar cell.

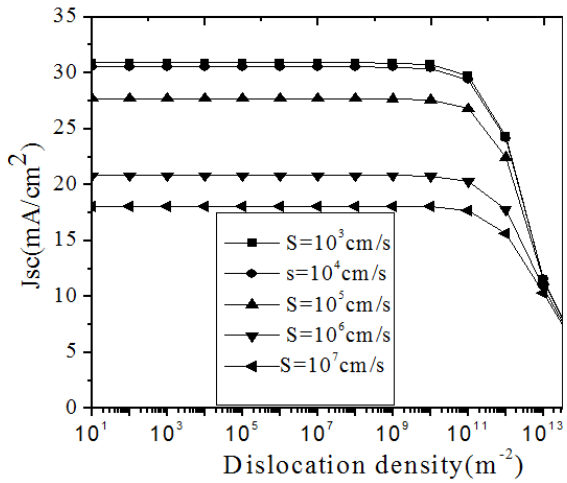

Figure 4. Variation of short circuit current density (J_{sc}) with the change of dislocation density at different values of surface recombination velocity.

III. Result and Discussion

A. Performance evaluation for Single Junction Solar Cell

Fig. 1 depicts the short circuit current density (J_{SC}) at different dislocation densities. The J_{SC} falls significantly above the dislocation density $10^{11}m^{-2}$. Fig. 2 shows that the V_{oc} decreases gradually with the increase of dislocation density above $10^{11}m^{-3}$. The V_{oc} decreases from 0.887v to 0.67v with the increase of dislocation density from 10^{01} to 10^{15} m^{-2} for a fix value of recombination velocity S=10^3cm/s in a single junction solar cell considering band gap 1.38862eV. The optimized value of band gap is 1.38862 eV when we choose x=0.514. The variation of the minority carrier lifetime with the dislocation density in above n on p-$In_xGa_{1-x}N$ solar cell is depicted in Fig. 3. The minority carrier lifetime of electrons in p-$In_{0.51}Ga_{0.49}N$ base layer is 6.25E-10s when the dislocation density is lower than 10^8 m^{-2} and starts to decrease rapidly to 10^{-13}s as the dislocation density increases above 10^9m^{-2}. Since minority carrier life time is important parameter to determine the performances of solar cell, it should be increased in order to enhance the performances. The calculated value of J_{sc} at different dislocation densities with different values of surface recombination velocity (S) are illustrated in Fig. 4. The J_{sc} decreases as the recombination velocity increases for a same set of dislocation densities. All the values of J_{sc} were plotted at finite value of S. The J_{sc} of solar cell is significantly lowered by increasing S. The S generally increases with increasing dislocation density.

The S of direct band gap semiconductor, such as GaAs, InP, GaN, InN etc. is very high. Change in efficiency is observed when the S increases at a constant dislocation density. The change in efficiency with change in S is shown in Fig. 5. A negligible variation in efficiency is observed for S when it is bellow 10^4cm/sec and efficiency falls as S increases above 10^4cm/sec. Efficiency is an important parameter to

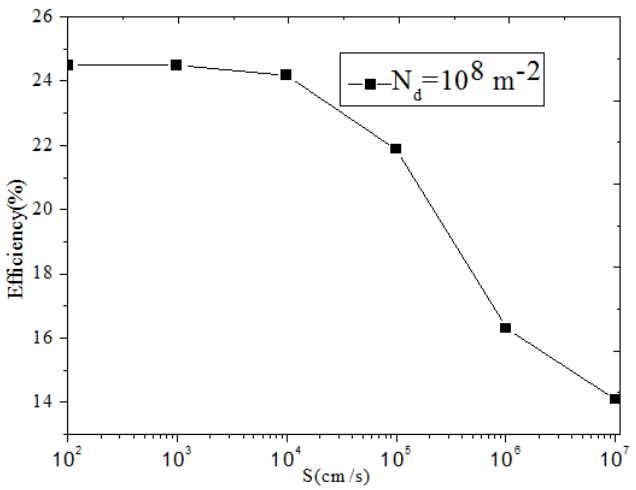

Figure 5. Dependence of efficiency on recombination velocity at a fixed value of dislocation density.

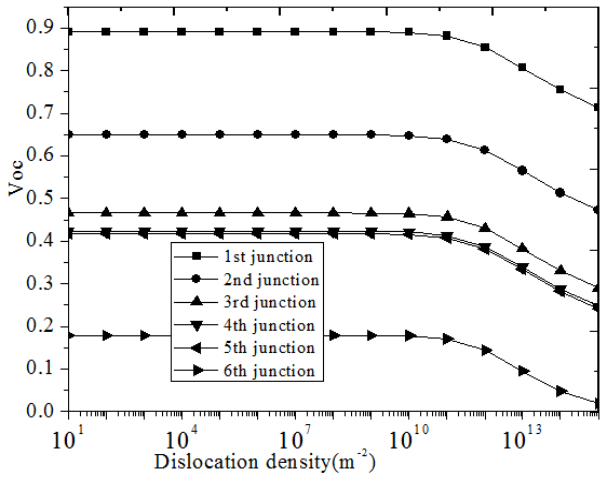

Figure 7. Change in open circuit voltage with dislocation density for individual junction.

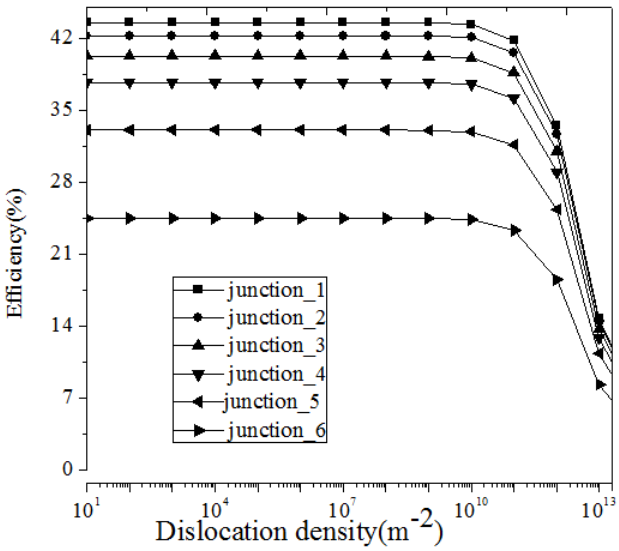

Figure 9. Dependence of Efficiency on dislocation density up to six junctions.

investigate the performances of solar cells. The efficiency of InGaN based SJ solar cell decreases as the dislocation density increases depicted in Fig. 6. There is a marginal change in cell efficiency when the dislocation density increases from 10^{10} to $10^{13}m^{-2}$ at a fixed surface recombination velocity. The efficiency remains nearly constant up to $10^{10}m^{-2}$ at a fix value of surface recombination velocity which is good agreement with [11]**.** result for SJ solar cell. There is a rapid decrease in efficiency when the dislocation density goes above $10^{10}m^{-2}$.

B. Performance evaluation for MJ

The effect of dislocation on V_{oc} for individual junction is represented in Fig. 7. The optimum band gap energies are taken as 1.381eV, 1.15eV, 0.974eV, 0.938eV, 0.938eV, 0.7eV respectively for single-to-six junctions. The open circuit voltage is found to be 0.894 V and 0.18 V, respectively for the

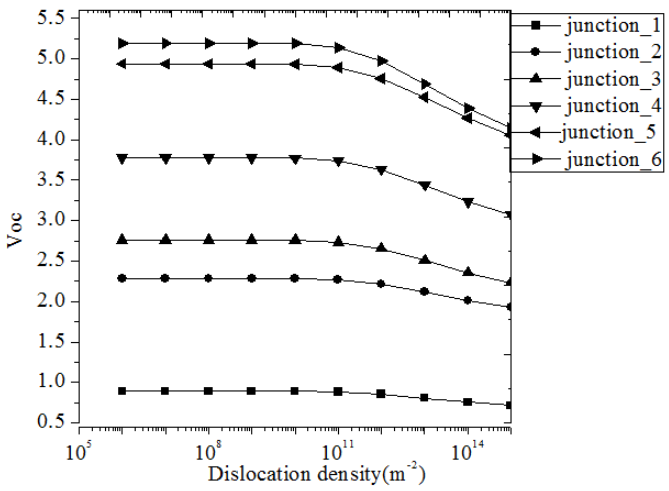

Figure 8. Open circuit voltage up to six junctions with the variation dislocation density.

1st and 6th junction individually at dislocation density below $10^{10}m^{-2}$. The variation of V_{oc} with respect to dislocation density is shown in Fig. 8. The V_{oc} is plotted as the summation of individual junction. Fig. 9 shows the efficiency of InGaN based MJ solar cell up to six junctions at different dislocation density. From the figure it is evident that the efficiency remains nearly constant up to dislocation density $10^{10}m^{-2}$. The efficiency falls dramatically above the dislocation density 10^{11} m^{-2}. The efficiency is found to be varied 24.47% to 8.25% for single junction and 43.56% to 15.25% for six junctions with the increase in dislocation density from 10^{01} to $10^{13}m^{-2}$.

It is found from the simulation results that for InGaN based MJ solar cell, the overall efficiency degradation starts to occur when dislocation density is greater than $10^{10}m^{-2}$. It is evident that the edge, screw, and mixed type misfit dislocations are found to be occurred 4.69×10^{10}, 4.53×10^{9}, and $4.03\times10^{11}cm^{-2}$ in InGaN [10], [17]. Hence, if we want fabricate InGaN-based high efficient MJ solar cell we should go through the steps that can reduce the dislocation density.

IV. CONCLUSION

The effects of dislocation density on the performance of InGaN based solar cell have been investigated analytically. It is found that higher dislocation density has negative impact on the performance of either SJ or MJ solar cells. It is seen that due to higher dislocation density, surface recombination velocity increases which results in fall in efficiency. The outcomes of our simulation depicts that the performance parameters are intensely affected when dislocation density is above $10^{11}m^{-2}$ and remains approximately persistent bellow this value. Furthermore, in comparison with previous simulation based investigations without considering the dislocation density, it is informed that the calculated efficiency is somewhat lower for each junction.

Abstract— **The main drawback of currently used photovoltaic cell is it's low conversion efficiency. Among the single junction solar cells, cells with GaAs material offers the maximum efficiency.For direct bangap material like GaAs photon recycling is an exciting approch.Benefication to solar cell properties due to photon recyling(PR) has been speculatively and carefully investigated in a p+ n structure of GaAs. In this study all the concentration has been made on the effect of PR that enhance the functioning of the cell. This study is also focused on the effect of architechtural and substantial parameters reliance on the magnitude of PR effect. For the PR effect short circuit current density, open circuit voltage of the cell is found to be increased which in turns increases the efficiency. PR is largely effected by high surface recombination velocity, emitter thickness, doping density.**

Keywords—Solar cell, Photon Recyling (PR), GaAs, p+n strcuture, Surface recombination velocity (SRV), Doping Density, Emitter thickness.

I. INTRODUCTION

Energy is major concept of economic development. World need more energy to provide the growing population with increase standard of living. Fossils fuels such as, oil, gas etc. are the major sources of energy and contribute to a bigger portion of world's energy supply. There are other source of energy, known as renewable energy source, fulfill a small portion of world's energy demand. It's importance is increasing and it is expected that it will become more important in future. The common renewable energy sources are biomass, geothermal, wind, solar etc. Among these sources solar energy is very important because it does not require any fuel cost and it is plentiful in nature. Most importantly, solar technologies are environmental friendly. Solar cell does not produce any environmental waste during it's operation and no noise is produced, if produced it is very small.

With respect to other available energy sources,the efficiency of solar cell is coparatively low. Besides the cost of solar energy is more than the conventional energy. There are many factors which affect the cost of solar energy. The cost of solar cell can be reduced by improving the performance of solar cells. Among the performance parameters, the efficiency of solar cell is very important. There are many approaches to increase the efficiency. Although most of them provide high efficiency but their fabrication process and control is much difficult and costly. An important role in the cost minimization is played by single junction cell. It's fabrication is comparatively less difficult and it provides higher efficiency with minimum cost. Among all the single junction solar cell GaAs offers maximum efficiency.

Among all the exciting approch to increase the efficieny of solar cell photon recyling is an encouraging step.The efficiency of semiconductor solar cell is dependent on minority carrier parameters.The efficiency is high if the minority carrier charge density can be increased. Minority carrier charge density is dependent on photon recycling and increased due to photon recycling in direct bandgap semiconductors.During the radiative recombination process re-absorption of photons emitted is referred to as photon recycling(PR).PR utilizes the photon emitted during the recombination of electron with hole. It minimizes the loss due to recombination. Minimization of the loss due to recombination is a contribution to the increase of efficiency. As a consequence of this process new electron–hole pairs are generated and the minority carrier charge density increases. One of the main factors that contribute to the improvement of efficiency of solar cell is short circuit current. Short circuit current increases with the increase of minority carrier charge density. So utilization of recycled photon is the best way to improve the efficiency of solar cell. As GaAs is a direct bandgap semiconductor, band-band recombination with accompanying photon emission and subsequent photon reabsorption at another location in the cell may occur [3]. Previously many scientists explored the effect of PR in the improvement of cell.Very recently Alexandre et al. has shown the current–voltage characteristics of the cells [11].This model is founded on Shockley–Read–Hall lifetimes based on internal quantum efficiency measurement.Gilt edge design of the cell has been done for the variation of base thickness and Shockley–Read–Hall lifetime using reflector. It is shown in the paper that the doping concentration is insignificant in the enhancement of open circuit voltage. Some other factors of a solar cell that have on authority in the improvement of efficiency is not considered in their model. The other factors that can grease the efficiency is considered in this paper like the surface recombination velocity, emitter thickness and the doping concentration.

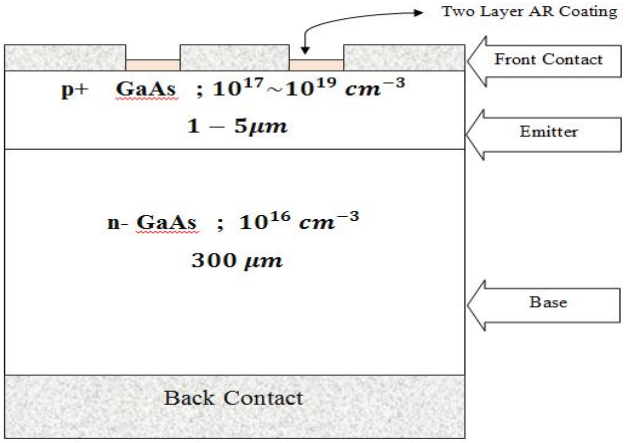

Figure 1: Structure of the p+ n solar cell used

II. MATHEMATICAL EXPRESSION FOR PHOTON RECYLING MODEL

To model PR effects, a number of different approaches have been made. Hypothesis was proposed by Asbeck regarding radiative lifetime multiplication factor to explain lifetime measurements in GaAs. Due to PR effect additional generation of minority carrier has incorporated. In order to enumerate the one dimensional photon recycling generation rate the basic formulation of Kuriyama et al. has been used in this paper. The cell model of fig.1 has been used. At first applying the boundary condition distribution of excess minority carrier density, without photon recycling is found. There will be a short circuit current density. As there are two layers in solar cell, emitter and base. Short circuit current is generated in each layer and also within the depletion region. The total short circuit current is the sum of the contribution from the emitter, base and depletion region. This will be

$$J_{sc} = J_{psc} + J_{nsc} + J_{dr} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(1)$$

Where,

Short circuit current due to holes collected at the depletion edge

$$J_{psc} = q(1-R_o)F\frac{\alpha_0^2 L_p^2}{\alpha_0^2 L_p^2 - 1}\left\{\frac{1+{\xi_p}/{\alpha_0 L_p}}{\cosh\left({x_j}/{L_p}\right)+\xi_p \sinh\left({x_j}/{L_p}\right)}\right\} \quad \ldots\ldots..(2)$$

Short circuit current due to electrons collected at the depletion edge

$$J_{nsc} = q(1-R_o)F\frac{\alpha_0^2 L_n^2}{\alpha_0^2 L_n^2 - 1}\left\{\frac{1+{\xi_n}/{\alpha_0 L_n}}{\cosh\left({x_j+w}/{L_p}\right)+\xi_n \sinh\left({x_j+w}/{L_n}\right)}\right\}\ldots(3)$$

Short circuit current generation takes place within the depletion region.

$$J_{dr} = qF(1-R)\exp(-\alpha x_j)\left[1-\exp(-\alpha W)\right] \quad \ldots\ldots\ldots..(4)$$

Where, τ is minority carrier lifetime, α_o is absorption coefficient of the excitation light, R_o is reflectivity, F is photon flux density, d is thickness of emitter and L is the diffusion length of minority carrier. ξ is the normalized surface recombination velocity defined by $\xi = {SL}/{D}$, S is surface recombination velocity and D is the diffusion constant. W is the width of depletion region.

Now during recombination a new photon will be emitted. From a certain point within the cell a photon will be emitted. By absorbing the photon energy a new pair of electron-hole will generate. Thus increase the minority carrier density. Including the photon recycling process the expression for short circuit current density will be:

$$J_{t,sc} = J_{pr} + J_{sc} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(5)$$

Where,

$$J_{pr} = J_{pr,psc} + J_{pr,nsc} + J_{dr,pr} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots..(6)$$

From the hole density distribution the resulting hole short circuit current density due to photon recycling at the depletion edge is,

$$J_{pr,psc} = q\frac{1}{\cosh\left({x_j}/{L_p}\right)+\xi_p \sinh\left({x_j}/{L_p}\right)}\left\{\int_0^{x_j} g_{pr,k}(\xi_p)\cosh\left({\xi_p}/{L_p}\right)d\,\xi_p + \int_0^{x_j} g_{pr,k}(\xi_p)\sinh\left({\xi_p}/{L_p}\right)d\,\xi_p\right\} \quad \ldots\ldots\ldots(7)$$

The short circuit current due to electrons by photon recycling collected at the depletion edge is,

$$J_{pr,nsc} = q\frac{1}{\cosh\left({x_j+w}/{L_p}\right)+\xi_n \sinh\left({x_j+w}/{L_n}\right)}\left\{\int_0^{x_j+W} g_{pr,k}(\xi_n)\cosh\left({\xi_n}/{L_n}\right)d\,\xi_n + \int_0^{x_{j+W}} g_{pr,k}(\xi_n)\sinh\left({\xi_n}/{L_n}\right)d\,\xi_n\right\} \quad \ldots\ldots\ldots..(8)$$

The short circuit current density due to photon recycling in the depletion region is as follows:

$$J_{dr,pr} = q\int_{x_j}^{x_j+W} g_k(z)dz \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots(9)$$

From the value of diode saturation current J_0 and short circuit current the value of open circuit voltage can be calculated. The open circuit voltage due to photon recycling, $V_{t,oc}$ will be,

$$V_{t,oc} = \frac{kT}{q}\ln\left(\frac{J_{t,sc}}{J_o}+1\right) \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots..(10)$$

In order to determine the efficiency fill factor is to be calculated. It is known that fill factor,

$$V_m J_m = FF \times V_{t,oc} \times J_{t,sc} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots..(11)$$

Efficiency of the cell due to photon recycling,

$$\eta = \frac{FF \times V_{t,oc} \times J_{t,sc}}{P_{in}} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots.....(12)$$

III. SIMULATION RESULTS

Photon recycling takes place within the cell. It's performance will obviously rely on the structural and material parameter of the cell. Moreover recombination are dependent on the material of the cell, doping level and the structure. So this factor will have influence upon the magnitude of photon recycling effects. In the following section graphical representation of the dependence of photon recycling on different parameters will be shown.

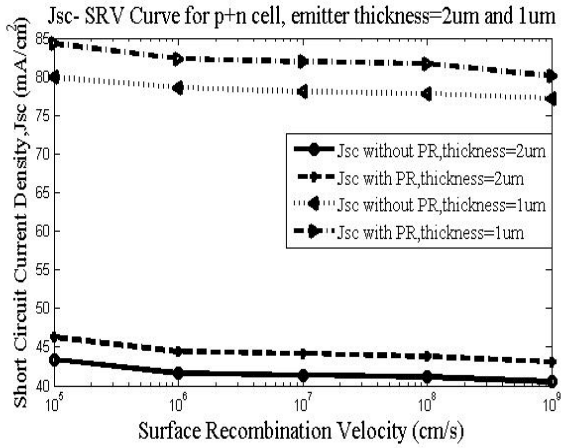

Figure 2. J_{sc}– SRV curve for p+ n cell at emitter thickness,2μm and 1μm

A. *Varying the surface recombination velocity :*

Fig 2 shows the variation of the short circuit current density with the surface recombination velocity. Two different cases has been considered. One is for emitter thickness of 1μm and the other one is for 2μm.In both the cases due to PR effect the short circuit current density has increased. But it has been found out that when the emitter thickness is reduced the PR effect increases. So one can come to conclusion that the lower the emitter thickness higher will be the PR effect. Due to increase in minority carrier density the increase in current density is observed. As the current density is increased, the open circuit voltage and the efficiency of the cell is increased in turns, shown in fig.3 and fig.4. Average increase of efficiency is 10.9% for emitter thickness of 2μm and for emitter thickness of 1μm this is 5.7%.The average increase in the two cases is different but overall increase of efficiency is higher for emitter with lower thickness. This may be due to the fact that the diffusion length of the minority carrier remain almost constant for different emitter thickness. At lower thickness the contribution of minority carrier density is more than at higher thickness.

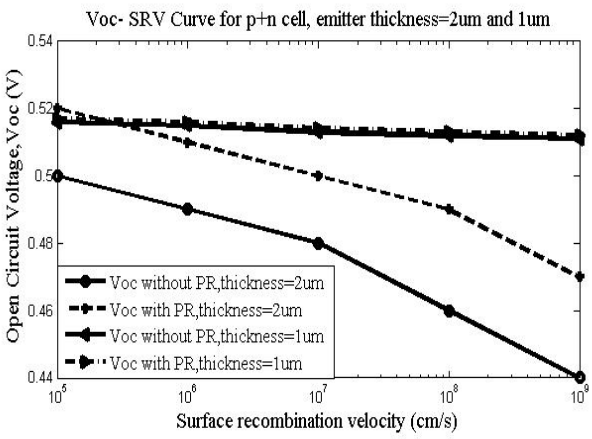

Figure 3. V_{oc}– SRV curve for p+ n cell at emitter thickness2μm and 1μm

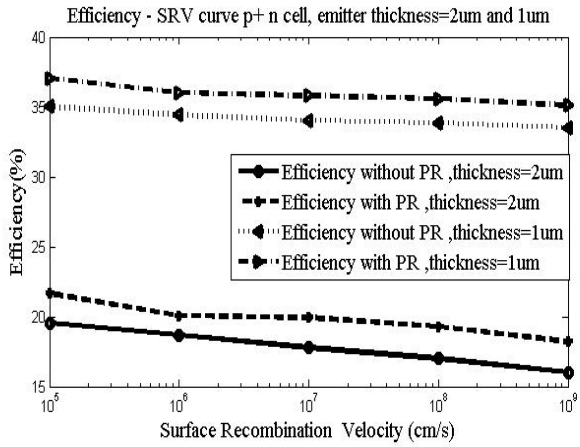

Figure 4. Efficiency– SRV curve for p+ n cell at emitter thickness 2μm and 1μm

B. *Varying the emitter thcikness :*

In the second case emitter thickness is varied taking two surface recombination velocity fixed .From fig.5 it can be easily said that the PR effect is largely dependent on the thickness of emitter. PR effect increases the short circuit current density but short circuit current density goes on decreasing with the increase of emitter thickness. At large surface recombination velocity the effect is lower. As because at higher surface recombination velocity recombination take place quickly. So the photon with minimum energy required for the generation of electron-hole pair do not emit. As the short circuit current density goes on decreasing so does the open circuit voltage and the efficiency of the cell decreases, shown in fig 6. and fig 7. The average increase of efficiency for surface recombination velocity of $10^5\ cm/s$ is 17%. On the other hand for surface recombination velocity of $10^7\ cm/s$ increase of efficiency is 15%.

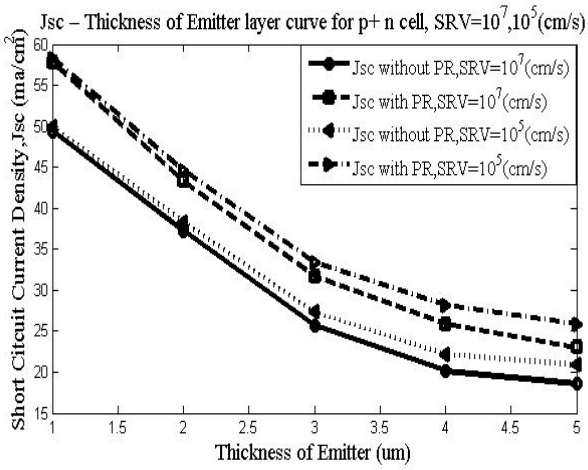

Figure 5. J_{sc}– thickness of emitter curve for p+ n cell at SRV, 10^7 cm/s and 10^5 cm/s

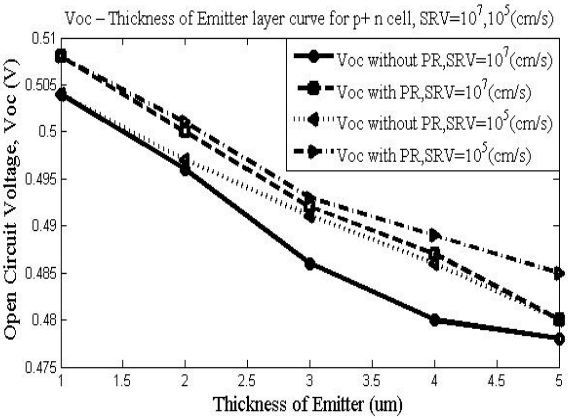

Figure 6. V_{oc}– thickness of emitter curve for p+ n cell at SRV, 10^7 cm/s and 10^5 cm/s

C. *Varying the doping density :*

In the third case keeping the surface recombination velocity and thickness of emitter constant, the doping density of the emitter is varied. From fig 8. it is clear that with the increase of doping density the short circuit density goes on decreasing. But the PR effect increases the current density for all the doping densities. As the short circuit density increases due to PR effect, the open circuit voltage and the efficiency of the cell also increases. Difference of efficiency is observed for with and without PR. At higher doping density the PR effect is more. Because the probability of radiative recombination increases with the increases of doping density .So minority carrier density in the p+ base decreases. The average increase of efficiency is 12% due to PR effect due to increase of doping density.

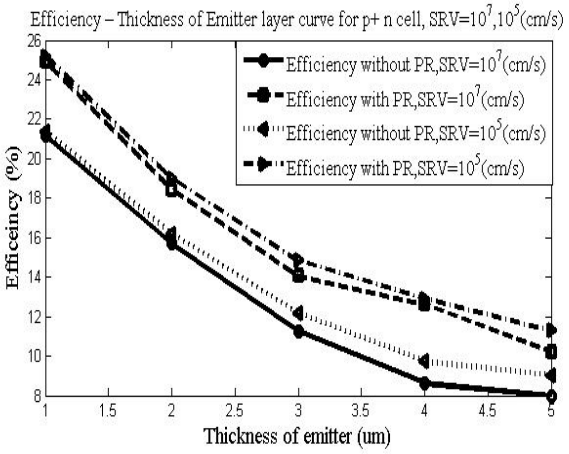

Figure 7. Efficiency– thickness of emitter curve for p+ n cell at SRV, 10^7 cm/s and 10^5 cm/s

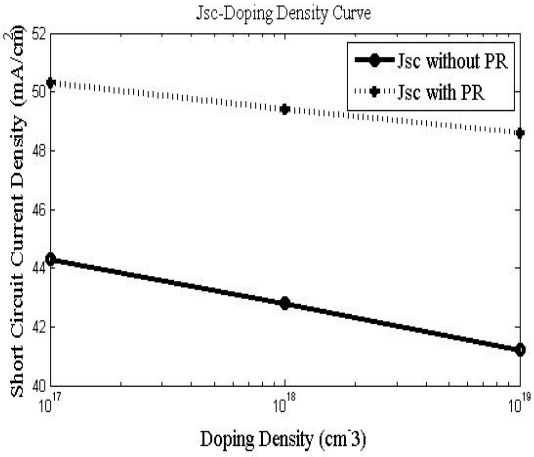

Figure 8. J_{sc}– Doping density of emitter curve

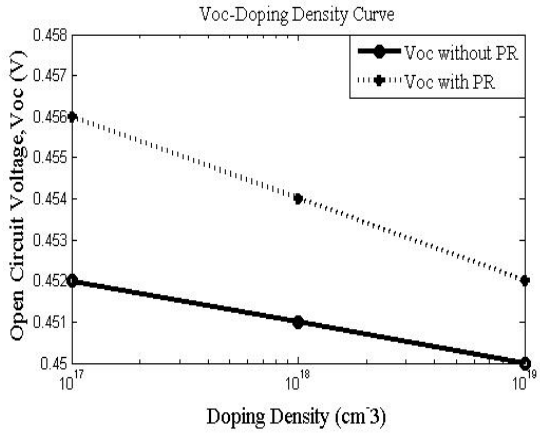

Figure 9. V_{oc}– Doping density of emitter curve for p+ n cell

IV CONCLUSION

In order to find out the prominent factors for PR in GaAS solar cell structures, research has been done on p+ n cell using the method schemed by Kuriyama et al. PR effect is actuated by thickness of emitter , surface recombination velocity and

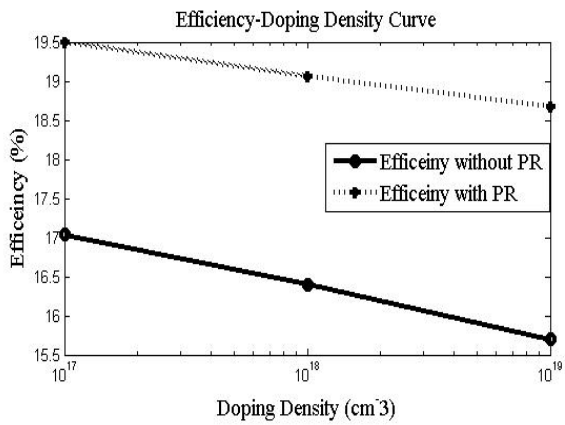

Figure 10. Efficiency– Doping density of emitter curve for p+ n cell

doping density of p+ emitter. Effect of base n-layer is negligible on PR effect. Among the three dominant factor thickness effects the PR more. The lower the thickness the better will be the efficiency of the cell. PR effect accelerate the cell performance in the positive direction. While designing a cell with PR different factors must be taken into consideration.

***Abstract*—This paper investigates the smart grid infrastructure with an upgradation of existing electricity networks and advanced information and communication technologies (ICT), intelligent devices & system. Considering the energy utilities play an increasingly important role in our daily life, smart grid technology introduces new security challenges that must be addressed. This paper has focused on the implementation of smart grid architecture to develop a real time situation and study the impacts of cyber-attacks on its communication infrastructure. A micro grid structure with particular generation and distribution specification along with its relevant communication infrastructure is designed to analyze the security challenges. The studies are performed based on a digital computer simulation approach using Power Factory 14.1. Some dynamic system events are formulated linking the change in different system parameters and effects of these changes are examined on the smart grid generation and distribution network.**

Keywords— Smart grid, communication infrastructure, microgrid, cyber attacks, generation power, power system, load demand, frequency respsonse, control center, system frequency.

I. INTRODUCTION

Smart grid is an electricity supply network which is based on a digital technology. It uses a two way digital communication to establish a communication path between the supplier and consumers. This allows the smart grid system to monitor, analysis and control the efficiency, cost, reliability and the sustainability of the production and distribution of electricity [1]. As this next generation power grid strongly depends on digital technology, it is vulnerable to different types of security issues. In recent time different research have been conducted to explore and solve the security issues and challenges of smart grid network. The concept of smart grid consists of its infrastructure, components, framework etc. The infrastructure of smart grid mainly consists of two major systems; the management system and the protection system. The management system provides advanced management and control services such as improving energy efficiency, demand profile, utility, cost and emission, based on the infrastructure by using optimization, machine learning, and game theory. The protection system provides advanced grid reliability analysis, failure protection as well as security and privacy protection services. The security of the smart grid infrastructure is very crucial to ensure uninterrupted and reliable power supply to the users during emergency situations. As this communication infrastructure highly depends on information and cyber technologies, it is highly vulnerable to cyber interruption and which can cause failure of any critical power system component and eventually lead to devastating physical impacts [2], [3]. In order to protect this infrastructure from any kind of security threats and to maintain stable and reliable power supply operations, the power grid must be modernized and incorporated with special features like advanced metering and monitoring system, advanced electricity generation and distribution, dedicated devices and software, highly secured control center etc. Another effective way of developing the security issues of smart grid is to divide a large power grid system into several microgrid structures. A microgrid system consists of interconnected set of electricity sources and loads that fall under a common control center. Microgrid system has the ability to separate and isolate itself from the utility grid manually or automatically using a switch during any kind of disturbances faultlessly with little or no disruption to the loads within the microgrid. After islanding, a microgrid remains operational in a self-directed mode and functions as an island. After the separation, a microgrid is permitted to reconnect with the utility grid only when the restoration of the main system and the microgrid is achieved. System voltages and frequencies must be either returned to normal range or maintain in a normal range for a reasonable period of time to achieve the grid restoration. The foremost objective of this paper is to identify the growing threats of cyber based attacks on nation's electrical grid and other critical infrastructure and also analyzing the changes in the real time data in different parts of the system after various faults, analyzing the fault conditions and monitors the values of these fault conditions with the help of a graph based simulation. This paper is based on a specific microgrid test system and a specific simulation tool has been used to run and analyze the test system.

II. SMART GRID COMPONENTS

A. Power System Components

Electrical power system is now one of the most effective components of the infrastructure on which modern society depends. They are used to deliver electrical energy to

978-1-4673-9257-0/15/$31.00 ©2015IEEE

industrial, residential and commercial consumers to meet the increasing demand [4]. Main components of modern electric power system are consists of: power stations, bulk generators, transformers, conductors, reactors, power utility equipments, capacitors, electronics and general load [5].

B. Communication Components

It is essential to digitize communication systems on power line in order to provide secure, profitable, reliable, proficient, environmental friendly power grid system. Communication components that are crucial for next generation power grid are: incorporated communications, measurement and sensing, advanced power devices, highly developed control methods and highly improved appliances.

C. Advanced Communication Components

The smart grid's behavior can be determined by using advanced components. These next generation power system devices will apply the latest research in materials, superconductivity, power storage, power electronics and microelectronics. Some advanced components regarding power electronics devices are dynamic volt amp reactive (DVAR), unified power flow controller (UPFC), distribution static compensator (DSTATCOM), static VAR compensator (SVC), medium voltage static voltage regulator (MV SVR), solid state transfer switch and AC/DC inverter [6].

III. CYBER SECURITY OF SMART GRID

Implementation of cyber security system and protection of a smart grid system from any sort of cyber threats or cyber intrusion has become much challenging nowadays. As the communication infrastructure of smart grid greatly depends on digital technologies, it has several vulnerabilities. These vulnerabilities can easily allow a cyber hacker to break into a network, gain access to the control center, spread malware to affect software and alter load conditions to destabilize the grid in unpredictable ways [7]. Developed cyber security strategies are required to eliminate these types of rapidly evolving threats and also to give flexibility to the manufacturers, utilities, and grid operators so that they can respond quickly and decisively during any kind of emergency situations. The basic concept of smart protection is to ensure first that the power grid has the ability to monitor, analysis, control and communication capabilities to the national electricity delivery system. Smart protection of power grid is also needed in order to maximize the output of the system and to reduce energy consumption. The reliability, security, and efficiency of the electrical grid is improved by the smart grid technologies which can be automatically adjusted by intelligent devices connected to the system and changing conditions to prevent blackouts and increase the capacity. Seven major features must be applied in a smart grid to make it self-aware and self-protective from any kind of cyber-attacks:

- Ensure customer security by protecting consumer's private information, activities and devices.
- Provide maximum security to power generation and distribution areas which may be targeted as attack entry points.
- Enable new and upgraded devices, products, technologies and services in order to fight against new types of cyber incursions.
- Maintain power quality to ensure reliable and stable electricity supply to the consumers.
- Optimize the intelligent devices which can increase the operating efficiency of the power grid.
- Implement a security system which can anticipate and respond quickly to any kind of system disturbances in a self healing manner.
- Operate resiliently against physical and kinds of natural disasters [8].

A cyber attacker can penetrate a smart grid using variety of attacks which can be classified into three categories; component wise, protocol wise and topology wise. Component wise cyber attack targets the field components and protocol wise cyber attack targets the communication protocol while topology wise cyber attack targets the topology of the smartgrid. Some other types of attacks are discussed below;

A. Spreading Malware

Malware can be developed by an attacker and spread to infect and corrupt different software which can damage smart meters or company servers. Malware can also be used to replace or add any function to a device or a system to send wrong information to the control center.

B. Exploiting The Control System Network

Activities are recorded by the control system network then mirror the logs into the business network. If the database management systems are not properly secured, a cyber hacker can easily gain access to the business database exploiting the control system network.

C. Compromising Communication Equipment

Some of the communication equipments such as multiplexers or sensors can be compromised by an attacker by injecting false information into these devices such as wrong data, false tripping information and fake emergency event causing direct damage to these devices.

D. Traffic Analysis and Network Protocol

Internet protocol (IP) and transmission control protocol (TCP)/IP stacks are used by the smart grid system which can be subjected to denial of service attacks (DoS). If these vulnerabilities are exploited by a cyber hacker then it can cause delay, block, or corruption of information transmission. A hacker can monitor the network traffic and can also obtain sensitive information by doing this.

IV. RESULTS AND ANALYSIS

A. Test System and Simulation Tool

The system shown in Fig. 1. is composed of a 13.8-kV, three-feeder distribution subsystem which is connected to a large network through a 69-kV radial line. The 13.8-kV substation busbar is radially connected to the main grid through the substation transformer and a 69-kV line. The network at the end of the 69-kV line is represented by a 69-kV, 100-MVA short-circuit capacity bus. A combination of linear and nonlinear loads of Load 1, Load 2, Load 3, Load 4 and Load 5 are supplied through three radial feeders of the subsystem. The system also includes two distributed energy resources (DER), i.e., DER1(3.5 MVA) and DER2 (3.5 MVA) on feeders F3 and F1 respectively. DER2 is a synchronous rotating machine equipped with excitation and governor control systems. DER1 utilizes a voltage-sourced converter (VSC) as the interface medium between its source and the power system. It also represents a dispatchable source with adequate capacity to meet the real/reactive power commands, within pre-specified limits. Such a dispatchable source may also include energy storage interfaced at the converter DC bus. DER1 also provides control on its output of real and reactive power components independently.

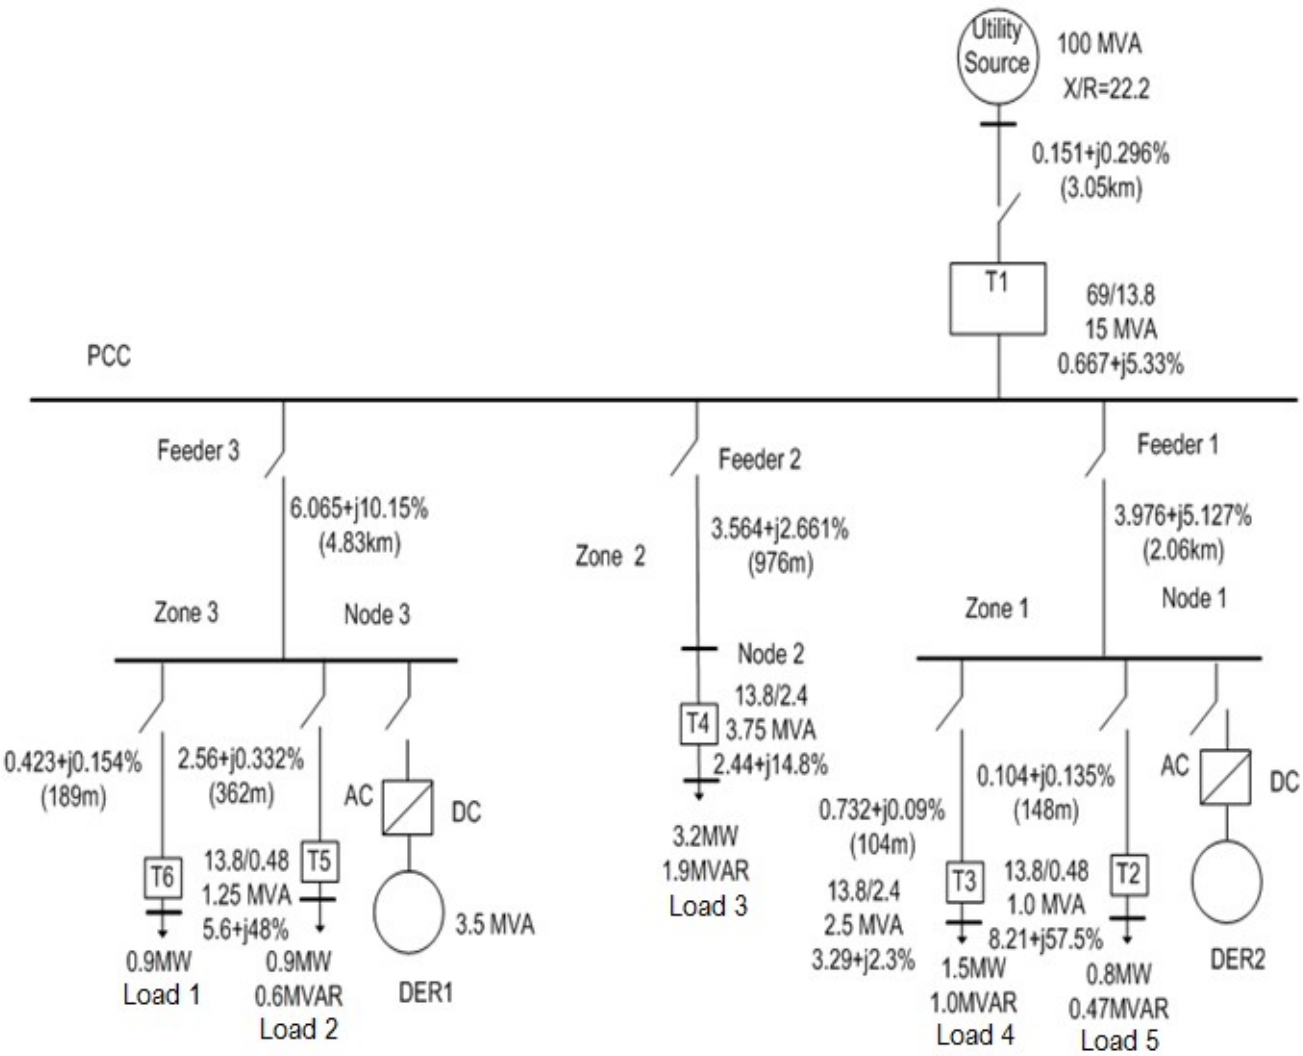

Fig. 1. Single-line diagram of the studysystem

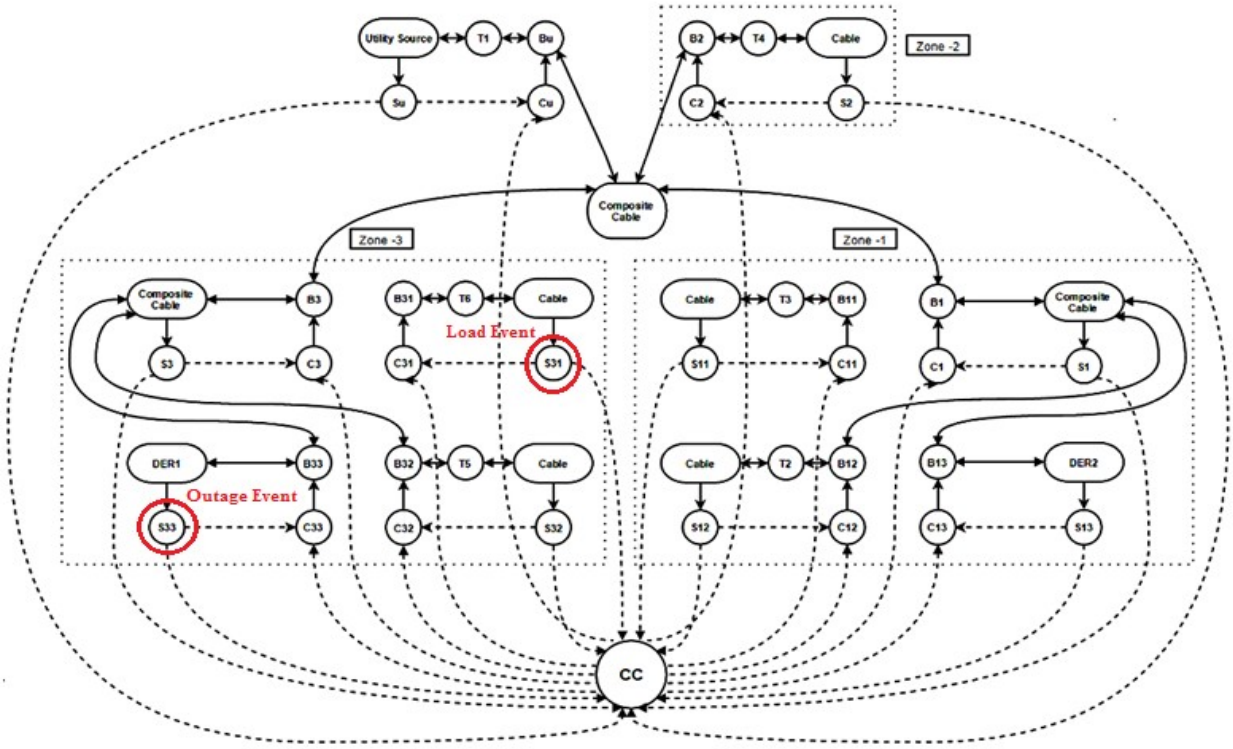

Fig. 2. Electrical and cyber graphs for system of Fig. 1. in islanding mode. Nodes are comprised of DERs, circuit breakers *Bi*, cables, transformers *T* of the electrical network and sensors *si* and actuator controls *ci* of the cyber network.

B. Simulation Results

Here the results are presented in pertaining to the graph and dynamic systems modeling of cause-effect relationships of a cyber-attack on the test system as proposed in [9]. A graph-theoretic formulation of distributed control is well-suited to this smart-grid representation. Using DigSILENT Power Factory 14.1 two types of simulation events are performed for this system; the single load event and the outage event. The utility source of this test system has a generation capacity of 3.17 MW and 3.04 MVAR. Load shedding or tripping off of generator will be occurred if an individual or the combined load demand exceeds generation. The impacts of cyber-attack on smart grid can be observed by creating events on different components of the system. The system frequency is 50Hz and the threshold value for generator under-frequency is set at 48Hz (4%); that means when the system frequency drops under 48Hz, the generator will be tripped out. Preliminary results can also be found in [9].

1) *Single Load Event*

The generator of this test system serves five general loads of different rating. If the load demand on a system suddenly increases the generation limit, this will cause frequency drop to the system and eventually the generator may trip out as the generation is not compatible with the increased demand which may apparently increase load demand on several sections of the system. Intentional load events are performed here in order to differentiate the before and after effect of increasing load demand on the system. For single load event Load 1 has been targeted where real power and reactive power are increased.

Load 1 has the rating of 0.9MW. In the simulation at 0s the load is assumed to come on along with all other loads in the system. The cyber-attack is applied at the time 1.2 sec on the sensor element by adding a load event which increases the load demand to 200% of its initial active power value and 50% of its initial reactive power value and the simulation has been performed for 400 seconds. If load demand increases suddenly, the system frequency drops from 50Hz as showed in Fig. 3. to 47.736 Hz at t=191.092 sec and after that it becomes constant as showed in Fig. 4. The under frequency relay is tripped after sensing the frequency drop in the system (at 4% mismatch of the nominal value). In normal condition when no event has taken place i.e. system is running smoothly, total generated power equals to the total load demand. If this situation remains the same, no load shedding or generator trip will take place. But the scenario changes when sudden increase on load demand takes place. This sudden change can be performed by cyber attack which has become a very common issue nowadays.

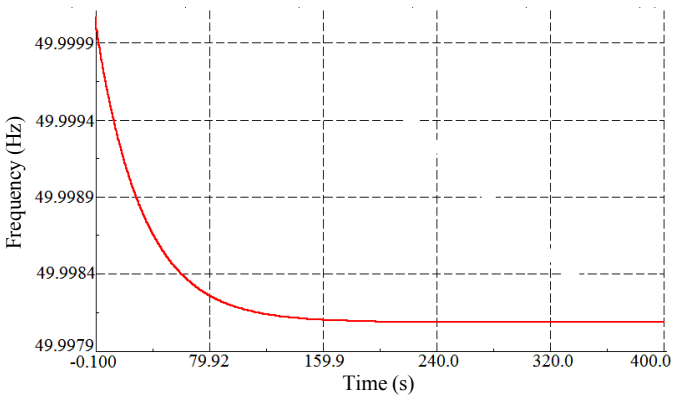

Fig. 3. The overall system frequency before any type load event taking place

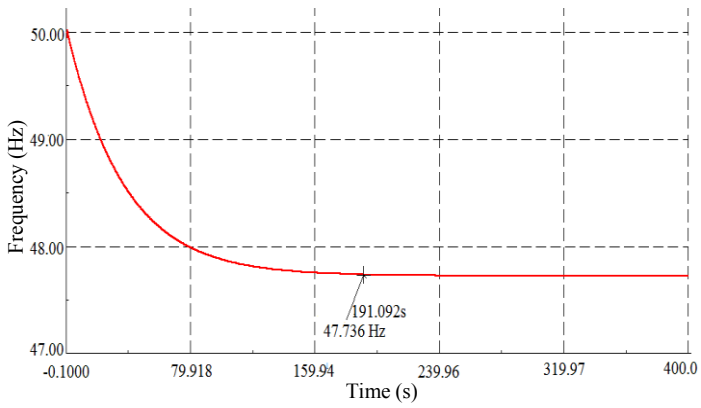

Fig. 4. Frequency plot for the sudden increase on load demand when Load 1 is increased

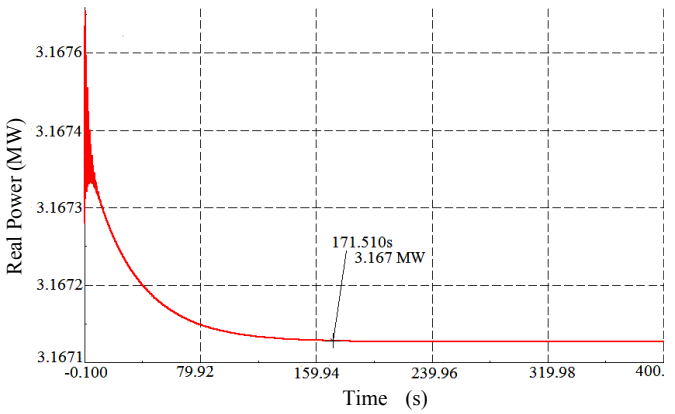

Fig. 5. Total power generation in the external grid before load event.

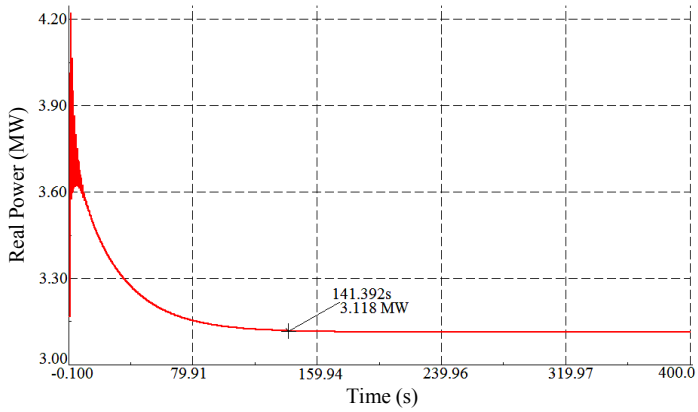

Fig. 6. The power generation at the external grid after load event takes place on Load 1

If any sensor gets wrong information due to the attacks, it may influence the control center to make a wrong decision as shown in Fig. 2 which represents an electrical cyber graph for system of Fig. 1 [6]. In case of single load event where Load 1 is suddenly increased by cyber attacks, sensor S31 is targeted. Control center, cc communicates all control signals at a particular time. For this general load, control signal C31 denotes whether a particular breaker B31 is open or close. Control center, cc collects information through sensor S31 and employs some algorithm to ideally avoid an unexpected situation if some unusual incidents occurs which make the system frequency unstable. When an attack is superimposed, sensor S31 is misinformed and this sensed information is collected by control center. It then performs necessary algorithms and makes quick decision for the whole system. If the sensed information shows that the load demand exceeds the generation power, system frequency will fall from its nominal value. An engine powered generator has a device on it named governor. In order to maintain speed it looks at the speed of the generator and controls the fuel going to the engine. The engine starts to slow down as the load increases. By increasing fuel, the governor keeps it from drifting too far out. If the requirement for electrical power is larger than what the engine can deliver, the governor can't make the engine put out more horse power that it's capable of. Then it slows down and can't maintain the frequency. If the frequency goes too slow, by using control signals the load management sheds one or more loads to avoid frequency deviation by opening their corresponding switches. In large interconnected system if this happens, sometimes we may experience cascading blackout.

2) *Outage Event*

For outage event two individual attempts have been performed, where two different system elements i.e. synchronous generator (DER1) and Load 1 of the test system have taken out of service separately in order to observe the after effect on the system frequency. For both case simulation has run for 400 seconds and elements have taken out of service from the system at t=1s. In order to take DER1 out of service, its corresponding sensor S33 becomes point to object. Fig. 7. displays the frequency response of the system after DER1 is taken out of service. This frequency plot asserts that system frequency falls from 50Hz to 43.65Hz at t=204.45s and after that it becomes constant. When DER1 is targeted by cyber-attack, corresponding sensor S33 senses the sudden change. At any time t, for a switch i, the control center, cc communicates with all control signal $C_i(t)$ where $C_i(t) = 0$ indicates open switch and $C_i(t) = 1$ indicates close switch. When sensor S33 is misinformed due to attack, corresponding

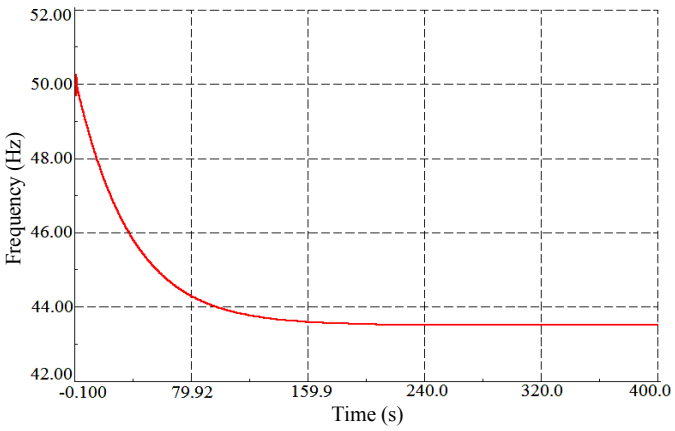

Fig. 7. Frequency plot for synchronous generator(DER1)

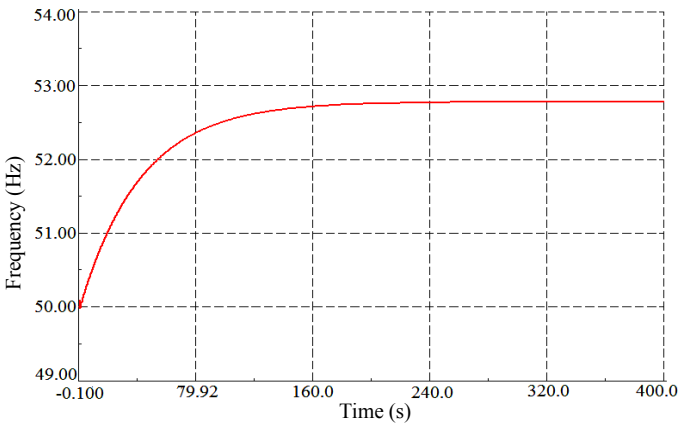

Fig. 6: Frequency plot for Load 1

control signal C33 helps control center, cc to collect this information so that it can perform necessary algorithm to make a quick decision for the whole system. DER1 is a dispatchable source of 3.5MVA rated power with adequate capacity to meet the real/reactive power demands. Due to its outage generation power will be less than total demand and consequently system frequency will fall. As the system frequency falls from its nominal value, load management sheds one or more loads by opening corresponding switches or in extreme condition it may cause system black out. Load1 has been intentionally taken out of service on the next attempt. Likely before, corresponding sensor of this load S31 is misinformed as shown in Fig. 2. This information is collected by control center, cc via control signal C31 and by performing some necessary algorithm a very fast decision is made. The frequency plot due to outage of Load 1 is shown in Fig. 8. System frequency rises from 50Hz to 52.76Hz at t= 255.41s as load demand decreases due to outage of Load 1. Studies showed that electrical equipment designed for any rated frequency may damage if they run above that rated frequency and to solve this problem some backup loads can be reserved so that system frequency remains constant.

V. CONCLUSION

A smart grid is an advanced power grid system that carries out the ever growing electricity demand in a reliable and sustainable manner. It is built on a modern communication infrastructure and adjusted to make the integration of all kinds of power utilities easier. Compared to current grid infrastructures, smart grid infrastructures adds significant complexity including security issues. As a result this increased complexity will require more effort to understand the system and will also provide numerous opportunities for the cyber hackers to exploit it. From the perspective of the defender, more complex systems require more effort to analyze and defend the system. Current approaches to secure cyber infrastructures are: techniques for key management, secure communication, secure code execution, intrusion detection systems, etc. These approaches model the malicious behaviors as components failures, fake information, false inputs and noises. Then analyzing their effects it will design counter measures to defend the attacks. However, the simulation world is modeled with estimation whereas the physical world is more complex, which can result in a deviation of any model to the reality. Therefore, theoretic approaches are mostly based on approximations compared to the physical world's unpredictability. As discussed in this paper, smart grid system demands additional security requirements, such as continuity of power delivery and accuracy of dynamic events. Such requirements are closely related to the models and states of the system, which are difficult to represent only by cyber security. Therefore, both cyber security and theory based security are essential to securing smart grid systems, offering exciting research challenges for many years to come.

ACKNOWLEDGEMENT

We would like to show our deepest gratitude to our respected and honorable supervisor Dr. Tareq Aziz, Associate Professor, Department of EEE, Ahsanullah University of Science and Technology for his unbounded guidance, encouragement, inspiration and valuable assistance in completion of this work.

Abstract*— The energy is running out with the increase of demand of people in the world day by day. So accomplish this crisis alternative energy source can be weapon of this demand. In our project "from biogas to methane i.e. vehicle gas" can be a substitutive way to minimize this assertion. The target of this paper to produce biogas from saturated organic waste for example cow dung and pig slurries, food wastes i.e. municipal solid waste (MSW). To use as vehicle fuel, it has to be updated. In biogas contain CH_4, CO_2 and lean amount of H_2S. CO_2 is detrimental for our environment and atmosphere and H_2S have corrosive in nature. For better quality of fuel, the percentage of CH_4 have to be increased which is our main aim. By reducing CO_2 from the biogas, it is possible to increase the calorific value of the fuel and this fuel less emissive than that of fossil fuel i.e. diesel, petrol. On the other hand sources of fossil fuel are very limited in our country and it is not environmentally friendly, it causes greenhouse effect in the atmosphere. But by using biofuel, greenhouse effect is less than the fossil fuel and it is less costly and production is easy and improves local air quality compared to the other fuel. This paper is focused on preparation of available biogas production technology. This paper is going to disclose how the biogas is converted into transportation fuel to save the environment and atmosphere and to make the world green.

Keywords*— *Municipal solid waste; Biogas plant; Biogas; Impurities removals; Compress natural gas.

I. INTRODUCTION

Energy sources are decreasing gradually with the enhancement of assertion. Municipal solid waste is another form of Biomass. With fast socio economic and industrial development, the municipal solid waste increases rapidly in recent years. We have to look over alternative energy source to fulfill our challenge. Biomass is one of the major sources in present world. Every year about 140 billion metric ton of biomass is generated all over the universe [1]. Landfill gas which is produced from biomass contains about 36% to 44% carbon dioxide, 45% to 55% Methane, 17% to 19% Nitrogen, 2% or nil Oxygen, saturated with moister and H_2S is about 25ppmv to 1,000 ppmv+ [2].

Biogas is produced form biomass. Biomass recovers from residual stalks, straw, leaves, roots, husk, nut, seed shells, waste wood and animal husbandry waste. By using biofuel greenhouse effect is 21% less than the fossil fuel.

Now-a-days, Vehicle fuel is one of the important issues in present world. In this paper we are focusing about conversion

Fig. 1. Integrated Waste management of municipal solid waste

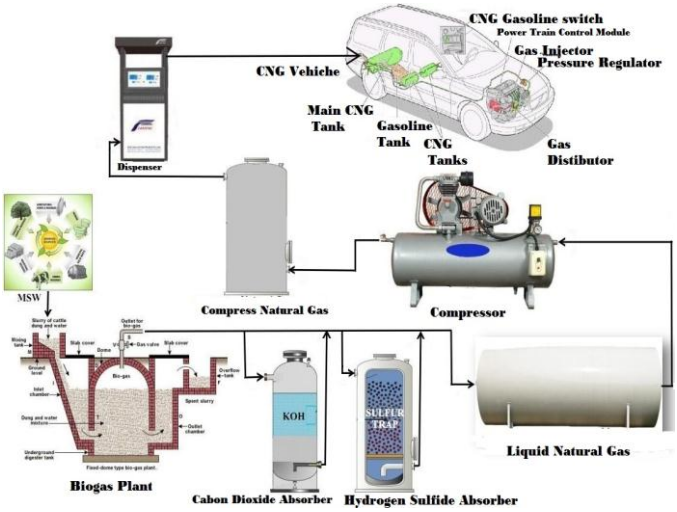

Fig. 2. Schematic view of municipal Solid waste to vehicle fuel.

from biogas to vehicle fuel. Landfill Gas can be produced from this biomass by proper utilization and it can be used in house hold works, industrial purposes. In our country, maximum vehicle are confined on fossil fuel for example Diesel, Petrol, Natural gas and Furnace oil. Diesel and Petrol is costly and not environmental friendly. It also more and emissive which is responsible for greenhouse effect and environmental pollution. Besides The Natural gas is more environmental friendly but resource of it is very limited in our country. Those resources are gradually diminished and it is a very threat full for our next generations.

By removing of carbon dioxide from landfill gas it can be used as vehicle fuel which impacts a major effect in our country. By using converted landfill gas, we can reduce extraction of natural source. After converting Landfill Gas into vehicle fuel that means it will be converted into compressed natural gas.

Volume fraction of biogas produced by controlled anaerobic digestion produces Bio-Compressed Natural Gas and there Methane (CH_4) contains 95.0% or more, Carbon dioxide (CO_2) contains 2.5% or less, Water (H_2O) contains 4 mg/ Nm^3 or less, Hydrogen sulfide (H_2S) contains 5 mg/Nm3 or less, Oxygen (O_2) contains 100 ppm or less, Hydrogen (H_2) contains 6% or less, Nitrogen (N_2) is no more [3]. This Compressed natural gas is usable for vehicle fuel.

There are different methods of managing MSW. The Integrated Waste Management (IWM) technique developed by the EPA is one such methodology in which use of different practices is made to safely and effectively handle the solid waste.

II. LITERATURE REVIEW

In ancient cities, wastes were thrown into streets and roadways, where they were left to accumulate. At that time, a system for waste removal began to evolve in Greece and in the Greek-dominated cities of the eastern Mediterranean. Disposal methods were very crude, involving open pits located just outside the city walls. As populations increased, efforts were made to transport waste farther out from the cities. In 1714 at first the city in England was found the waste management system. Toward the end of the 18th century in America, municipal collection of garbage was begun in Boston, New york city and Philadelphia [4].

The U.S Environmental Protection Agency (EPA) encourages consumers to reuse and recycle these valuable products to keep them out of the waste stream [5]. With this in mind, waste management has partnered with several companies, like LG Electronics, to recycle electronics for reprocessing [6].

There are large quantities of the biomass available in Bangladesh. Huge amount of Landfill Gas is produced from biomass by removing of CO_2 and H_2S from Landfill Gas, Landfill gas is composed of a mixture of hundreds of different gases. By volume, landfill gas typically contains 45% to 60% methane and 40% to 60% carbon dioxide. Landfill gas also includes small amounts of nitrogen, oxygen, ammonia, sulfides, hydrogen, carbon monoxide, and non-methane organic compounds (NMOCs) such as trichloroethylene, benzene, and vinyl chloride. Landfill gas produced by Bacterial decomposition, volatilization and Chemical reactions [8]. It can be easily converted into Liquid natural gas(LNG) and finally compress LNG will converted into CNG which can be used vehicle fuel.

A work on solid waste management was found that the management system and energy recovery system does not work for proper management of solid wastes because of financial resources, institutional weakness, improper selection of technology, transportation systems and disposal options, public's lack of concern towards environmental cleanliness and sanitation have made this service unsatisfactory. Wrong attitudes and perceptions of the people about sanitation issues contributed to solid waste management problems of the respective City Corporations.

III. METHODOLOGY

By bacterial decomposition of organic material contained in municipal solid waste (MSW), Landfill gas (LFG) is produced. Some factors influence the quantities of gas that a MSW landfill produces are organic compounds in the waste, and the moisture content and temperature of the waste. Temperature and moisture levels are influenced by the surrounding climate.

Landfills often accept waste over period of 20 to 30 year and large scale Landfill gas is produced by Bacterial decomposition. Natural process of bacterial decomposition of landfill waste consists of four sequential stages.

First stage: At the beginning of the first stage of decomposition, aerobic bacteria which live only in the presence of oxygen, consumes oxygen while breaking down the long molecular chains of complex carbohydrates, proteins, and lipids that comprise organic waste. The primary byproduct of this process is CO_2. In this stage, depending on the presence of oxygen, decomposition can last for days or months.

Second stage: After introducing oxygen in the landfill Gangrene starts. Bacteria is converted into compounds created by aerobic bacteria into acetic, lactic, and formic acids and alcohols such as methanol and ethanol by using an anaerobic process. The landfill becomes highly acidic. The gaseous byproducts of these processes are CO_2 and H_2.

Third stage: Initialization of decomposition depends on the consumption of organic acids produced in second stage by the certain types of anaerobic bacteria. Hence production of the landfill gas becomes more neutral environment in which methane-producing bacteria begin to establish themselves.

Fourth stage: Mortification starts in this stage, when both the production rates and the composition of landfill gas remain relatively constant. In this stage landfill gas usually contains approximately 45% to 60% CH_4 by volume, 40% to 60% CO_2 and 2% to 9% other gases for examples sulfides.

Gas is produced at a stable rate about 20 years. If greater amounts of organics are present in the waste, such as at a landfill receiving higher than average amounts of domestic animal waste [8].

The raw gas contains several impurities like water, dust, H_2S, CO_2, siloxanes, Hydrocarbons, NH_3, oxygen and several other elements that must be removed in order to reach certain standards of quality [14]. From Biogas plant firstly collect Landfill gas and burnt off in a controlled manner (flaring) in order to destroy pollutants. While flaring LFG will largely mitigate the negative effects of these emissions, the strategy can also be seen as a lost opportunity for converting the gas into a useable form of energy. LFG can be used for many energy recovery projects [7].

A. Removal of water: Possible impact of water is corrosion in compressors, gas storage, tanks and engines due to reaction with H_2S, CO_2 and NH_3 to the acid. Untreated or raw biogas is usually saturated with water and the absolute water quantity depends on the temperature (according to chemical equilibrium) and water is removed by Physical separation of condensed water or chemical drying [8].

B. Hydrogen sulfide (H_2S): It is a foul odor of rotten eggs colorless, very poisonous, flammable gas with the characteristic. It is removed by two ways [9]

i. Removal of H_2S during digestion:

$$2H_2S+O_2 \rightarrow 2S+2H_2O$$

$$2Fe^{2+}+3S^{2-} \rightarrow 2FeS+S$$

$$Fe^{2+}+S^{2-} \rightarrow FeS$$

ii. Removal of H_2S after digestion:

$$Fe_2O_3+3H_2S \rightarrow Fe_2S_3 + 3H_2O$$

$$2Fe(OH)_3+3H_2S \rightarrow Fe_2S_3 + 6H_2O$$

C. Carbon dioxide (CO_2) Removal: At the contemporary there are several alternative technologies which are adopted for CO_2 removal from gases. Many of them encouraged by the recent interests of segregation of CO_2 from power plant flue gases for the aspect of CO_2 sequestration. Various sophisticated commercial CO_2 removal technologies have been in use for several decades to produce CO_2 catherses for processed food for example soft drinks, for natural gas purification and for tertiary oil recovery. However, at the present time various researches are going on for the removal of CO_2 from gas, which is applicable to begin upgrading. CO_2 removal by using potassium carbonate solutions is now obsolete technology which were mixed with other chemicals to facilitate the process. For CO_2 catharses from the gas, recent proposed process uses refrigeration. However these process are highly sophisticated, precise researches are need to improve the process. Though there are some process of CO_2 removal, the entire world searching for "game changing" technologies for CO_2 removals from power plant and industrial emissions.

Potassium hydroxide (30 % w/v) to absorb CO_2 and cuprous chloride in hydrochloric acid to absorb CO [9]. Potassium hydroxide' solution (250g KOH in 500mL of boiled distilled water), and it absorbs only CO_2. A hydrocarbon is burnt with excess air. The Orsat analysis of the flue gas shows 10.81% CO_2, 3.78% O_2 and 85.40 N_2. Calculate the atomic ratio of C:H in the hydrocarbon and the % excess air [10].

A thin film membrane used which only allows particular molecules to pass through it and allowed molecules will affect the conductivity of the thermocouple system which send signal proportional to the chemical molecules. Based on chemical absorption principle, typical flue gas analyzers measures the quality of CO_2. On depending absorption factor of this components their bulb component, when flue gas is passed through the bulb, components are separated that helps to know the volume drop from initial flue gas volume. By absorption, water vapors in the flue gas removed on solid $CaCl_2$ and then passed a pipettes. The sequence should start from CO_2, if the reagent in the analyzer is KOH in the absorption solution. To absorb, gas then passed into KOH solution pipette to form K_2CO_3 by the following reaction.

$$2KOH+CO_2 \leftrightarrow K_2CO_3 + H_2O \text{ at ambient conditions [11]}$$

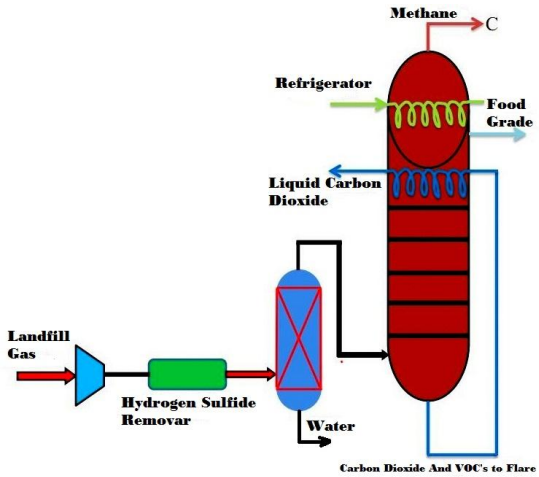

Fig. 3. Schematic view of Removal of CO2 from biogas.

TABLE. 1. TIME OF BIODEGRADABLE [12]

Item	Time to Degrade	Item	Time to Degrade
Paper towel	2-4 weeks	Normal paper	1-2 weeks
Newspaper	6 weeks	Ply wood	1-3 years
Cardboard box	2 months	Wool gloves	1 year
Apple core	2 months	Cotton gloves	1-5 months
Waxed milk carton	3 months	Photo-degradable beverage holder	6 months

TABLE 2. CONSTRUCTION COST ACCORDING TO SIZE [13].

Size (m3)	Operational hours per day	Cow dung requirement per day (kg)	Poultry litter requirement per day (kg)	Approximate construction cost (BDT)
1.6	3-4	43	23	26,000
2.0	4-5	54	28	32,000
2.4	5-6	65	34	36,000
3.2	7-8	87	45	43,000
4.8	10-12	130	68	52,000

IV. ECONOMIC ASPECTS IN BANGLADESH

The diagram depicts that, in the year of 2005, no of biogas plant was 30 and in the year of 2008 no of biogas plant was 4621. This shows within a short time establishment of biogas plant increased rapidly. In the year 2014 no of established biogas plant is 30291. From this diagram it is clear within a difference of 10 years, about 30,000 biogas plant established in Bangladesh. This also indicates that adeptness of biogas plant is increasing and it can be forecast that about 1,00000 biogas plant will be established in the next decade. Thus dependency on biomass will be increased rapidly in the upcoming decades and this introduced method will be fruitfull to compensate this energy demand specifically in transportation sector.

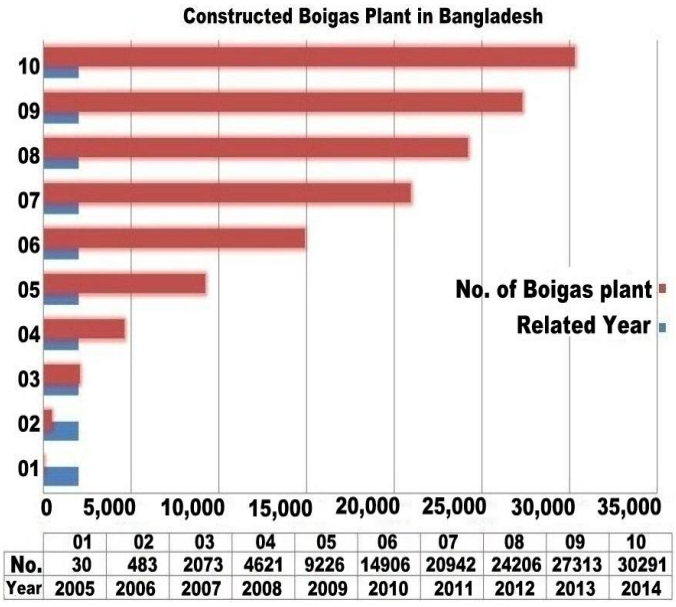

Fig. 4. Biogas plant Construction in Bangladesh previous ten years [14].

V. CONCLUSION

We are extracting energy for different purpose. Now-a-days the diesel, petrol, natural gas are used to appease our pretention. But those energy sources are tethered and diminishing day after day by the increasing amount demand. So to minimize this problem bio-fuel may be an effective source. In our under developing country bio-fuel can play a vital role in our transportation system. Because of less cost it would be popular and most useable fuel in our country. The environmental pollution occurs for food wastes, paper wastes and different organic elements. By using this pollutant elements the environment pollution is reduce considerably and by proper utilization of this toxic element bio-fuel can be produce which affix our energy source and become environmental friendly and greenhouse effect free. For under developing country, the municipal waste, food wastes is available compare to another source and it create pollution negatively. So by constructing dustbin where maximum amount of food wastes ,municipal wastes produce such as hospital where organic wastes can be found, food industry and maximum amount of biomass can be found from dairy farm, poultry farm . By using of this wastes bio-fuel can be produced that will mitigate pollution and will construct green world. If a biogas plant is set-up in every municipal area and all biomass is gathered in biogas plant. Large amount of biogas is produced form each area and it can be converted into CNG to use in vehicle. By this process we can decrease the pressure on natural gas and environment will be pollution free.

Abstract— **Battery performance of a proposed solar car has been investigated under different road conditions while the car makes a trip in one of the longest routes in Dhaka city, using a model developed in Matlab Simulink. A significant reduction in energy consumption is observed when the car runs at lower speed, which is attributed to lower air drag at lower speed. Energy consumption further reduces with the increase in number of stoppages. Thus the solar/electric car will be an ideal mode of transport for a city like Dhaka, where traffic congestion is a daily occurrence.**

Keywords— **Solar car, SIMULINK, Batteries, Battery modelling, State of charge.**

I. INTRODUCTION

In Dhaka city, a major mode of transportation for daily office commuters is fuel driven cars. However, emissions from such cars pose serious environmental and health hazards, especially during office hours when cars are caught in traffic congestion causing more and more toxic emissions. Solar powered clean cars can be of great advantage to the public and environment and can go a long way to alleviate this problem. On these premises, a solar powered light-weight economically affordable clean car for the daily office commuters of Dhaka city was proposed in [1] which is able to run on solar power alone during sunny days of summer and spring, and with complementary charging of the batteries from other sources during winter and under overcast sky.

Batteries are an indispensable and critical part of the electric drive system of a solar car. A healthy battery will ensure a longer battery life and a safe driving of the car. Further, unlike fuel driven car, there is no rapid recharging system for solar car. Therefore, it is imperative to have a prior understanding of how the battery will perform on the road under different road conditions. With this objective, this paper aims to investigate the battery performance while the car is making a trip from home to office in Dhaka city, considering one of the longest trips, Uttara to Motijheel, which is about 18 km long, under different traffic conditions.

Performance analysis is carried out using a model developed in Simulink assuming the batteries to be fully charged. The simulation has been conducted using the specifications of the solar car that is being built in the Robotics Workshop of BRAC University [2]. In this study, the discharge characteristics, mainly the variation in the state of charge (SOC) and the terminal voltage (V_t) of the battery with travel distance and time under different traffic conditions are observed and analysed. Role of the solar panels is excluded from the study as the purpose of this paper is solely to study the battery performance. Effects of temperature and aging have been ignored in the analysis. In the subsequent sections, sections II and III, models used for the battery, charge controller and the motor power are described, followed by their implementation in Simulink. Section IV provides the simulation results on the battery performance under different road conditions. Finally section V concludes the findings of this work.

II. MODELING OF SOLAR CAR

Fig. 1 shows the block diagram of the electric drive system of the solar car consisting of solar panels charging the battery through the charge controller. Charge controller also controls dissipation of energy to the motor to ensure healthy battery life. Following subsections discuss the modelling of different modules of the electric drive system, except the PV panel.

A. *Modelling of Battery*

The model used for battery is based on Thévenin battery model [3]. In Thévenin battery model (Fig. 2), the resistance R_0 and capacitance C_0 between electrodes and electrolyte of the battery is considered along with the series resistance R_S. V_{OC} is the open circuit voltage and I_L is the load current. Experiments on battery suggest that the voltage drop, V_d across R_0 or C_0 is almost constant for a particular SOC [4]. All the three parameters namely V_{OC}, R_S and V_d in Fig. 2 are functions of SOC.

The load current, I_L for a load which draws out power P can be calculated as,

$$I_L = \frac{(V_{OC} - V_d) - \sqrt{(V_{OC} - V_d)^2 - 4R_S P}}{2R_S} \quad (1)$$

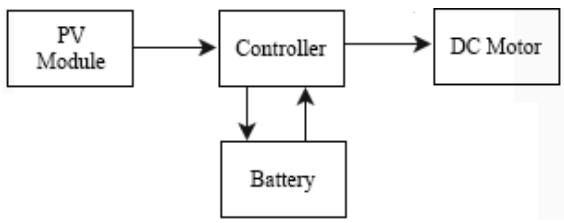

Fig. 1 Block diagram of electric drive system of solar car

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

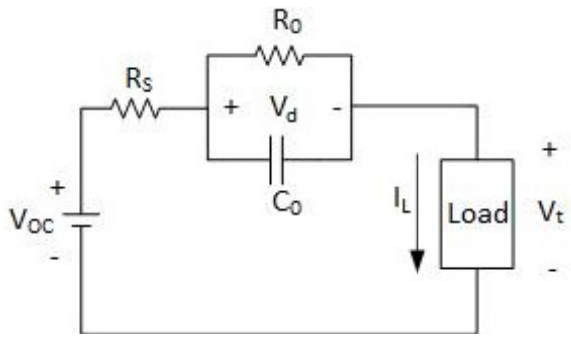

Fig. 2 Thévenin battery model

Once the current is known, the terminal voltage V_t can be determined using (2).

$$V_t = V_{OC} - I_L R_S - V_d \tag{2}$$

The total charge dissipated from battery for time t is calculated using (3).

$$Q_{dis} = I_L \mathrm{t} \tag{3}$$

In case, battery is being charged by I_{CH} current, the overall current flowing out of the battery is reduced to $(I_L - I_{CH})$.

The SOC of the battery after supplying P power for t seconds is calculated as,

$$SOC(new) = SOC(old) - \frac{Q_{dis}}{C} \tag{4}$$

where C is the capacity of the battery.

With this new SOC, V_{OC}, R_S and V_d are re-evaluated according to the following relations which were determined experimentally in [5].

$$V_{OC} = 1.4667SOC - 11.0233 \tag{5}$$

$$V_d = 0.086SOC - 0.011 \tag{6}$$

$$R_S = -0.0531SOC + 0.066 \tag{7}$$

Then the algorithm recurs with the calculation of I_L until SOC gets low enough for the process to cease.

B. *Power Calculation of DC Motor*

A motor draws out power from battery to give the solar car a driving force. The total drive force to make the vehicle move or keep it moving can be estimated by adding together individual force components that arise from different physical effects.

The major three forces are the rolling resistance force F_R, aerodynamic drag force F_D and the force of acceleration F_A. Summing up them, total driving force, F_T is obtained as [6].

$$F_T = F_R + F_D + F_A \tag{8}$$

The rolling resistance force, the frictional force that resists the motion when a vehicle rolls on a surface, is given by,

$$F_R = \mu_R mg \tag{9}$$

where μ_R is the coefficient of rolling resistance, m is the mass of the car and g is the gravitational acceleration.

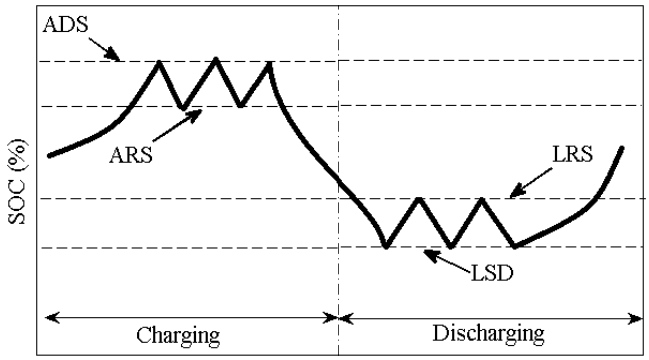

Fig. 3 Charge Controller set points

Aerodynamic drag force is the force exerted by the air against the movement of the car and is given by,

$$F_D = \frac{1}{2} C_D \rho A_{CROSS} v^2 \tag{10}$$

where ρ is the air mass density, A_{CROSS} is the cross sectional area of the car, v is the velocity of the vehicle, and C_D is the coefficient of aerodynamic drag force.

The force of acceleration is given by,

$$F_A = ma \tag{11}$$

where a is the acceleration and is accounted for when the car is accelerating. When the car moves at constant speed, the force of acceleration is zero.

If the car is running at velocity v then the power exerted by the shaft of the motor can be expressed as,

$$P_T = F_T v \tag{12}$$

If the efficiency of the motor is η_m, the power to be supplied by the battery to the motor is given by,

$$P = \frac{P_T}{\eta_m} v \tag{13}$$

C. *Mechanism of charge controller*

There are four set points in a charge controller, two to avoid overcharge and two for overdischarge as in [7]. The maximum SOC the batteries are allowed to reach and above which solar panels are disconnected from the battery is array disconnect SOC (ADS). Then the battery may discharge to a SOC level low enough to start charging again; the level is array reconnect SOC (ARS). Similarly, the load is disconnected at the minimum SOC, namely low SOC load disconnect (LSD), after which more discharging may damage the battery. Then the battery may charge for some time, the SOC rises and the load is connected again at a level of load reconnect SOC (LRS). The points are depicted in Fig. 3.

III. Implementation in Simulink

The implementation of the aforementioned models of battery, motor power and charge controller are described in the following subsections.

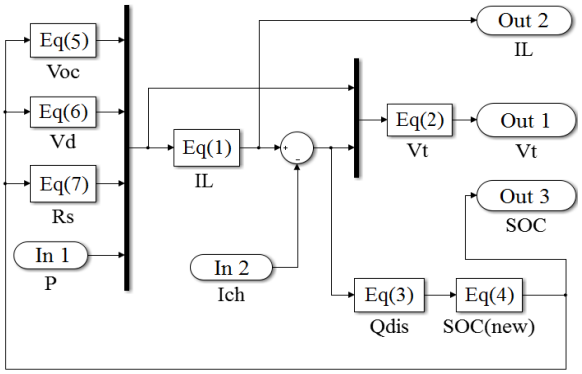

Fig. 4 Implementation of Battery model in SIMULINK

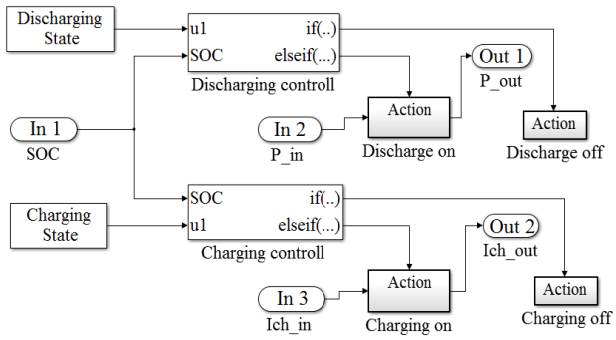

Fig. 5 Implementation of charge controller model in SIMULINK

A. *Implementation of Battery Model*

Fig. 4 shows the battery model in Simulink where the power required P and charging current I_{CH} are the inputs to battery. It calculates I_L, V_t and SOC after dissipating power for a certain time and gives out as outputs. Eq(1), Eq(2) etc. labelled in the diagram refer to the corresponding equation numbers in this paper. The time interval after which the model calculates dissipated charge and records a new SOC can be fixed by the mask parameter dialog box along with the nominal capacity of the battery, initial state of charge, temperature and number of batteries in series.

B. *Implementing Load Block in SIMULINK*

The Simulink block of Load, named 'Load' in Fig. 6, takes inputs of variable velocity on different time frames and some invariants related to the car e.g. its weight, frontal area. If the car moves at velocity v_1 kilometer per hour (kph) for t_1 minutes, comes to a halt and rests for t_1^r minutes, and then starts again at v_2 kph at which it runs for another t_2 minutes, the input format is $v = [v_1 \quad 0 \quad v_2]$ and $t = [t_1 \quad t_1^r \quad t_2]$. Time t_1 consists of the time at which the car accelerates from static position to reach v_1, the time it runs at constant v_1 kph, and fall time when the car decelerates to halt. The inputs are transferred to a MATLAB program which gives a timeseries variable P using the equations (8) to (13). The signal building block of load has some presets e.g. Busy road, Highway, Empty road etc. to select easily or the users may produce one according to their concern.

C. *Implementation of Charge Controller*

Fig. 5 implements the charge controller in SIMULINK. There are two 'if' blocks in the diagram; upper one is controlling the discharging state and lower one the charging state. If the SOC goes below the given level to turn off discharging, and the discharging process is not switched off yet, the upper if block commands the Discharge off block to disconnect the load. On the other hand, if the SOC is high enough to turn on discharging, the same if block triggers Discharge on action block to connect the load and deliver input power to the output. Same mechanism applies for the charging state controller 'if' block except, this time, the input charging current flows to output when charging is turned on.

D. *Combining the Components*

All the components portrayed in earlier sections are packed inside subsystems and combined together to build a complete model of vehicle as in Fig. 6. As mentioned earlier, the concern here studying discharging characteristics, and hence charging current is considered zero. All data found by the simulation are transfered to the MATLAB workspace to plot and analyze the results.

IV. RESULTS AND DISCUSSIONS

An itinerary is assumed for a Dhaka city dweller from his home to office, which is 18 km long. For the sake of convenience, it is assumed that the person leaves his home in the morning with his car fully charged and reaches his office by driving 10% of the distance at 10 kilometer per hour (kph) and rest of the road either 30 kph or 60 kph depending on the road condition. In the afternoon, he returns by the same route with same speed characteristics.

Fig. 7 shows the plots of power required P, SOC and V_t with respect to time as the car travels at different velocities from its origin to destination. The top most plot shows the different velocities of the car during its trip which starts with 10 kph at its origin covering 5% of the distance, goes at after that for 15% of the road, then goes at 60 kph for 60% of the road, after which it goes at 30 kph and 10 kph for the rest of

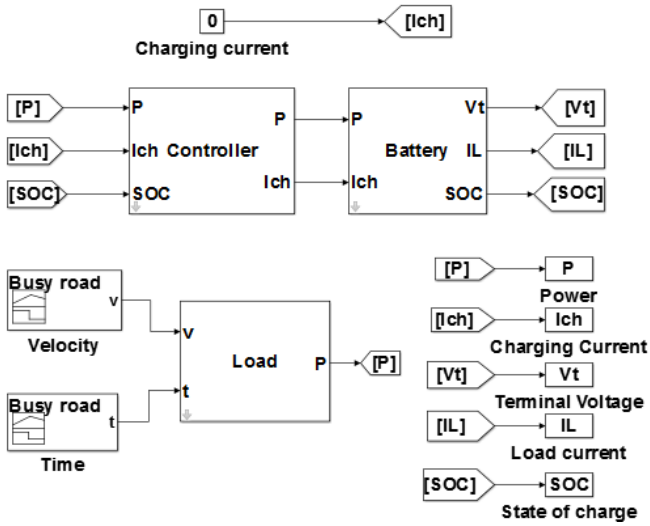

Fig. 6 The Model of the solar car combining all individual components

TABLE I
PROPERTIES OF SOLAR CAR

Components	Parameters	Value
Battery [5]	Capacity of the Battery, C (AH)	40
	Number of Batteries in Series	5
Vehicle Platform [1]	Mass of the car, m (kg)	500
	Maximum velocity, v_{max} (kph)	60
	Time to get max. velocity, t_{max} (min)	1.5
	Frontal Area, A_{CROSS} (m^2)	1.1
Environment [6]	Coeff. of Rolling Resistance, μ_R	0.01
	Coeff. of Aerodynamic drag force, C_D	0.035
	Air Density, ρ (kg/m^3)	1.2

15% and 5% of the road, respectively, before it reaches the destination. For the sake of simplicity we assumed a constant acceleration with which the car reaches the maximum speed from its rest position and a constant deceleration with which it comes to a halt from its maximum speed. For higher speed higher acceleration and deceleration are assumed than those at lower speed. The required power increases gradually with the increase in car speed as can be seen from the power plot below the velocity plot in Fig. 7. The power drops abruptly whenever the velocity reaches target speed because as the driver releases the accelerator, force of acceleration becomes zero requiring less power to drive. SOC plot shows gradual decrease in SOC with a faster drop when the car runs at the peak speed of 60 kph.

Fig. 8 shows how the SOC varies when the car travels at the top speed of 60 kph for different lengths of the road. As can be seen from this figure, SOC drops to almost 67% when the car runs 90% of the road at the top speed, indicating about 33% consumption of battery charge at this speed. However, SOC drops to only 81% when the car runs only 30% of the road at the top speed with 60% at half the top speed and the rest 10% at 10 kph, indicating more that 40% reduction in energy consumption at this slower speed. The higher energy requirement at higher speed is due to the higher aerodynamic drag force which increases as the square of the velocity according to (10). Energy requirement is further reduced if the trip is accompanied with frequent breaks (topmost plot in Fig. 8) during heavy traffic congestion which is a common phenomenon in the city of Dhaka.

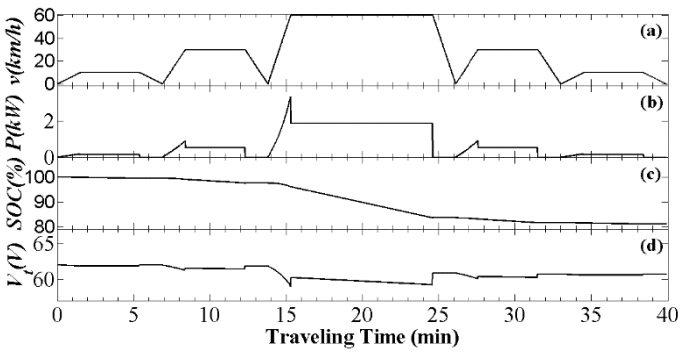

Fig. 7 Variation in (a) car speed, (b) motor power, (c) SOC, and (d) terminal voltage, V_t of the battery during one full trip as the car travels from origin to its destination.

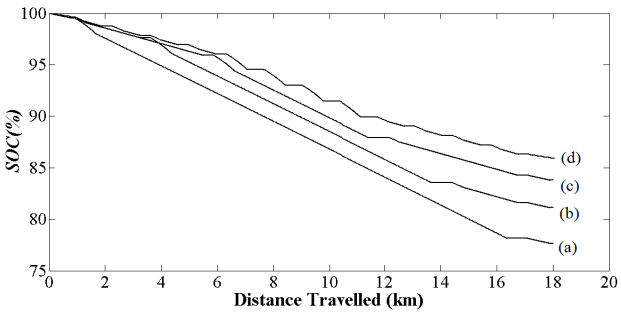

Fig. 8 Variation in SOC with the car traveling (a) 90%, (b) 60%, and (c) 30% of the road at the top speed. Plot (d) is that for 30% with 20 number of stoppages.

Consumption of less energy at slower speed will be an added advantage of the solar car over the fuel driven cars which consume more fuel at slower speed to cover the same distance due to inefficient burning of the fuel.

V. CONCLUSION

Battery performance of a propsed solar car has been investigated while the car makes a trip from home to workplace of an office commuter under different road conditions, using a model developed in Matlab Simulink. It has been observed that energy requirement decreases significantly when the car runs at a slower speed due to lower air drag force at lower velocity. Thus for a city like Dhaka, where traffic congestion is a daily occurrence, solar/electric car will be a perfect mode of transportation as it is not only emission free but also consumes less energy under heavy traffic congestion, unlike the fuel driven cars which consumes more energy and emit more toxic gases under such condition. A detailed performance study of the proposed solar car under different traffic and weather conditions that also includes the solar panels is currently under way.

Enhancement of Device Performance with Optimized Absorber Layer in CIGS Solar Cell

Sharmin Aktar Chowdhury, Md. Shah Alam
Department of Applied Physics, Electronics & Communication Engineering
University of Chittagong
Chittagong-4331, Bangladesh
Sharmin_apece1291@yahoo.com, shah.alam@cu.ac.bd

***Abstract*— Numerical simulation of CIGS solar cell has been carried out in this study to investigate the performance of the solar cell with different band-gap and thickness of the absorber layer. In this paper, we also introduce the effect of Ga content on solar cell material parameters. The aim of this work is to check the device performance like open circuit voltage, short circuit current density, fill-factor and efficiency with the change of thickness and band-gap of the absorber layer. It is shown that, by optimizing the CIGS absorber layer it is possible to achieve an AM 1.5G conversion efficiency of greater than 22% which is an increased value than presently reported.**

Keywords—CIGS, band-gap, thickness, Solarcell, simulation.

I. INTRODUCTION

A solar cell is a form of photoelectric cell which generates electrical power by the photovoltaic effect. It is done by converting the sunlight into electricity directly [1]-[2]. Photovoltaic industry has grown rapidly in the last several years. Now, worldwide total installed capacity of photovoltaic reached at least 178 GW at a cost less than $1/W till date. The total output power is now greater than 200 billion kWh, which represents 1 percent demand of worldwide electricity [3]-[4]. So it is strongly desirable to raise the power conversion efficiency while reducing the costs also. It is predicted that the installation rate will grow at a double digit of 16-25 percent and in the range of 55-57 GW at the end of 2015.

Thin film PV cell is a second generation solar cell which uses <1% of the expensive raw materials compared to other wafer based solar cell. So significant price drop can be gain by per watt peak capacity. It is made on a substrate like glass, plastic or metal by depositing one or more thin layer or thin film of photovoltaic material on it [5]. Thin film solar cells are commercially used in several technologies like CdTe, CIGS, and amorphous Si etc. Thin film PV technology is for more than 90% based on silicon as source material and these are low-cost alternatives [6]. Again, CIGS is one of the most promising I-III-VI_2 chalcopyrite photovoltaic materials for thin film solar cell technology [7]. These are highly attractive because of their tunable band-gap, radiation hardness and excellent outdoor stability on the earth. Copper Indium Gallium Deselenide ($Cu(IN_{1-x}Ga_x)se_2$) based solar cell exhibits superior conductivity and higher efficiencies due to native defects [8]-[9]. Recently, CIGS solar cell efficiency has been claimed a record value of 21.7% [10]. CIGS is a compound semiconductor material which has a high absorption coefficient of more than 10^5/cm for 1.5eV band-gap. CIGS solar cell has the advantage of presenting a thin active layer due to direct band-gap of the material. Much information is available in the literature regarding single-junction CIGS solar cell. To improve the overall performance of the solar cell, increasing the open circuit voltage V_{OC} and fill-factor (FF) is highly desirable. Because increased open-circuit voltage (V_{OC}) minimizes the interconnection losses in the manufacture of cell modules. [11]. The optical band-gap of CIGS increases with the use of Gallium which finally increases the open-circuit voltage (V_{OC}) and lowers costs as compared to pure CIS. Again, Cu deficiency increases the majority carrier concentration by increasing the number of Cu vacancies. Because when the films are Cu deficient, its surface layer form an ordered defect compound (OVC) by forming a p-n homo-junction at the interface [12]. To reach the band-gap of 1.5ev which is ideal for a single junction CIGS, a [Ga/(Ga+In)] of 0.7 is optimal. But device performance drops off when the ratio exceeds 0.3 [13].

In this study, we tried to optimize the band-gap as well as the thickness of the absorber layer and enhanced the solar cell device performance.

II. SIMULATION METHODOLOGY

A. Cell Structure

The structure of the studied solar cell based on Copper Indium Gallium Deselenide (CIGS) consists of the following layers: Soda lime glass substrate (SLG) of about 1-3mm thickness which has shown a substantial increase in open-circuit voltage (V_{OC}), Molybdenum back contact generally deposited by sputtering which reflects most unabsorbed light back into the CIGS absorber, a p-type CIGS absorber layer and n-type CdS buffer layer deposited on top of the absorber layer. Next the buffer layer is overlaid with a thin, intrinsic ZnO layer (i-ZnO) which is capped by Al doped ZnO window layer. The Al doped ZnO serves as a transparent conductive oxide to collect and move electrons out of the cell [14]-[15]. The schematic diagram for a typical ZnO/CdS/CIGS solar cell structure is illustrated in Fig 1.

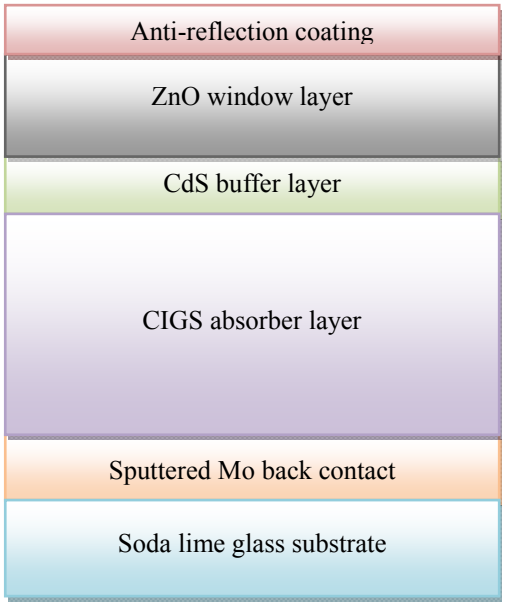

Fig. 1. CIGS solar cell structure used for the simulation

B. Numerical Simulation

In our present work, numerical simulation of CIGS thin film solar cell has been investigated by using the latest version 3.3.0.1 of SCAPS i.e. Solar Cell Capacitance Simulator. This is a 1D solar cell simulation program which developed in the University of Gent at the department of EIS, allows the definition of thin film solar cell devices stacks of layers with a large set of parameters [16]-[17]. SCAPS is originally developed for devices or the solar cell structures specially CdTe and $CuInSe_2$ family [18]. The objective of the numerical method is to test the device performance without fabrication, for analysis of the effect of material parameters variations and finally determining optimal values for the best solar cell performance. SCAPS solves the fundamental solar cell equations like Poisson's equation, the continuity equation for electrons and the continuity equation for hole in one-dimension and in steady-state condition. Generally, Poisson's equation for semiconductor device is [19]

$$\frac{\partial}{\partial x}\varepsilon(x)\frac{\partial}{\partial x}\psi(x)=q\left(p(x)-n(x)+N_D-N_A+\rho_{def}\right) \quad (1)$$

Where, n, p are the concentrations of free electrons and holes, n_t, p_t are the concentration of trapped electrons and holes, N_D, N_A are the concentrations of the ionized donors and acceptors, ε is the dielectric permittivity of semiconductor, q is the electron charge and ψ is the electrostatic potential. Here, the drift-diffusion approach is used as a function of device length, x.

Again, the continuity equation in steady state conditions for electrons and holes are:

$$\frac{1}{q}\frac{d}{dx}J_n=R_n(x)-G(x) \quad (2)$$

$$\frac{1}{q}\frac{d}{dx}J_p=G(x)-R_p(x) \quad (3)$$

Where, q is the electron charge, J_n and J_p are the electrons and holes current density, R_n and R_p are the electrons and hole recombination velocities and G is the optical generation rate.

The photocurrent which flows in opposite direction to the dark current I_D is the maximum current when the voltage across the solar cell is absolutely zero. It is caused by the generation and collection of light generated carriers. I-V characteristics of a p-n junction solar cell under illumination can be expressed as:

$$I=I_{ph}-I_{01}\left(qV/k_BT-1\right) \quad (4)$$

Where, I_{01} is the saturation current and I_{ph} is the photocurrent.

At V=0, short-circuit current is equal to the photo-generated current [20] i.e.

$$I_{sc}=I_{ph} \quad (5)$$

For removing the dependence of the solar cell area, it is usually defined short-circuit current I_{SC} as the short circuit current density J_{SC}. The equation for the short-circuit current density J_{SC} for the solar cell with perfectly passivated surface and uniform generation is as follows [21]:

$$J_{sc}=qG\left(L_n+L_p\right) \quad (6)$$

Again, open-circuit voltage V_{OC} is the maximum voltage available through the solar cell when the current is absolutely zero. Open-circuit voltage can be expressed as:

$$V_{oc}=V_T\ln\left[\frac{I_{sc}}{I_{01}}+1\right] \quad (7)$$

Where, V_T is the thermal voltage and is equal to K_BT/q. the open-circuit voltage can be increased either by increasing substrate doping density or increasing the minority carrier lifetime in the solar cell. High shot-circuit current density J_{SC} is very desirable because it can also enhance the open-circuit voltage V_{OC}, hence we can get an enhanced performance of the device. Typical values of open-circuit voltage V_{OC} ranges from 0.5 to 0.7V [20]-[21].

The fill-factor of the solar cell is the parameter in which in conjunction both the operating points corresponding to I_{SC} and V_{OC} determines the maximum power output from a solar cell. It is a measure of the squareness of the I-V characteristics and is expressed as:

$$F.F.=\frac{P_m}{V_{oc}I_{sc}} \quad (8)$$

Where, P_m is the maximum power output of the p-n junction solar cell and is equal to V_mI_m. Fill-factor depends on the series and shunt resistances and the diode ideality factors. For solar cell, fill-factor is always less than 1 [1], [20], [22].

The ratio between the output electrical power at the maximum power point on the I-V curve to the input electrical power is called the efficiency of the solar cell and is defined as:

$$\eta = \left(\frac{P_{out}(\max)}{P_{in}} \right)\% \qquad (9)$$

Where, P_{in} is the input power from the sunlight, P_{max} is the maximum power output and is equal to $V_{OC}I_{SC}FF$ and η is the solar cell efficiency [20], [21].

III. SIMULATION PARAMETERS

For the calculation of device performance, we need to know the values of the parameters. In this work, we used three layers for the simulation. These are: 1) p-type CIGS absorber layer, 2) n-type CdS buffer layer and 3) ZnO window layer. Here, the surface recombination velocities were set at 10^7 cm/s for both electrons and holes. The AM 1.5G solar spectrum is used and the temperature is set at 300k for this numerical simulation.

The CIGS absorber layer has adjustable band-gap by tuning ratio [12]. Here, band-gap of the CIGS absorber layer was varied from 1.04 to 1.69eV as the Ga content varied from x=0 to x=1, according to the equation:

$$E(x) = 1.02 + 0.67x + 0.11x(x-1) \qquad (10)$$

This band-gap alteration ability makes them perfect candidates for high performance thin film device [23]. Varying the ratio in material affects various parameters in the absorber such as band-gap, optical absorption and defect concentration which influence the solar cell performance. In our simulation, solar cell performance was examined by varying the absorber layer thickness and band-gap and keeping all other parameters at a fixed value.

TABLE I gives the summary of different layer parameters used in this paper.

TABLE I. MATERIAL PARAMETER VALUES FOR THE SIMULATION

Properties	p-CIGS	n-CdS	i-ZnO
W(μm)	variable	0.050	0.200
E_G(eV)	variable	2.4	3.3
X(eV)	4.5	4.2	4.45
Dielectric Permitivity	13.6	10	9
N_C(cm^{-3})	2.200E+18	2.200E+18	3.100E+18
N_V(cm^{-3})	1.800E+19	1.800E+19	1.800E+19
V_n(cm/s)	1.000E+7	1.000E+7	1.000E+7
V_p(cm/s)	1.000E+7	1.000E+7	1.000E+7
μ_n(cm^2/V-S)	100	100	100
μ_p(cm^2/V-S)	25	25	25

IV. RESULT AND DISCUSSION

A. *Effect of absorber layer band-gap:*

The resulting performance parameters are determined by using current-density voltage characteristics.

The simulation results of the solar performance corresponding to different band-gap of the absorber layer are given in TABLE II.

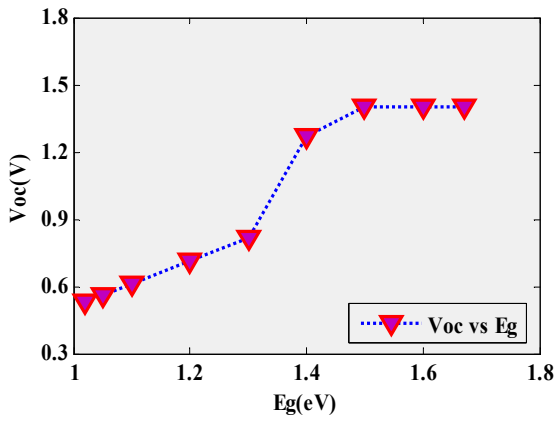
TABLE II. SIMULATED RESULT FOR VARYING BAND-GAP

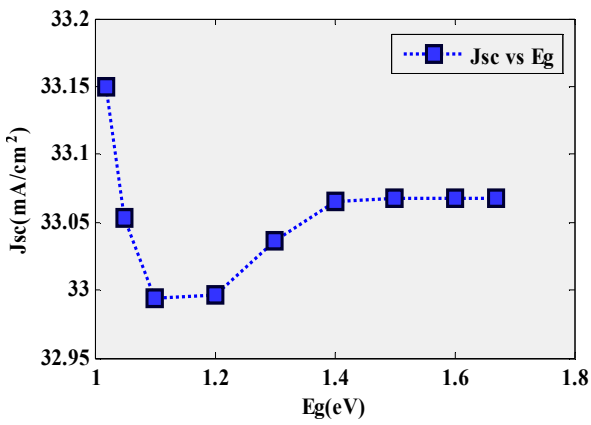
Eg(eV)	V_{OC}(V)	J_{SC}(mA/cm^2)	FF(%)	η(%)
1.02	0.53	33.15	79.14	13.99
1.05	0.56	33.05	79.67	14.81
1.1	0.61	32.99	80.59	16.25
1.2	0.71	33.0	82.03	19.22
1.3	0.81	33.04	82.52	22.18
1.4	1.27	33.06	57.35	24.05
1.5	1.40	33.07	52.43	24.24
1.67	1.40	33.07	52.31	24.25

From our simulation it is originated that, the efficiency of solar cell increases with the increase of band-gap of the absorber layer. As the band-gap of CIGS absorber layer varied from 1.02 to 1.5eV, the solar cell efficiency increased from 13.99 to 24.24% and the open-circuit voltage (V_{OC}) is also increased from 0.53 to 1.40V as the recombination current falls. It is mainly depends on the saturation current I_o. Further increase in CIGS band-gap has no significant effect on these parameters. Again, it has very little effect on short-circuit current density (J_{SC}).

However, band-gap of the CIGS absorber layer affects the fill-factor of the cell. As the band-gap increased beyond 1.3eV, fill factor decreased sharply. Because increased Ga content causes higher recombination rate and lower carrier lifetime, for which recombination in SCR may overweight the recombination outside of this region. So, ideality factor in accordance with the FF will be decreased due to defect in SCR. This is a key parameter in evaluating solar cell performance. Solar cell with a high fill factor is very desirable, because small amount of the current is dissipated by internal losses [13].

Fig 2 shows the effect of band-gap variation on the performance of CIGS solar cell.





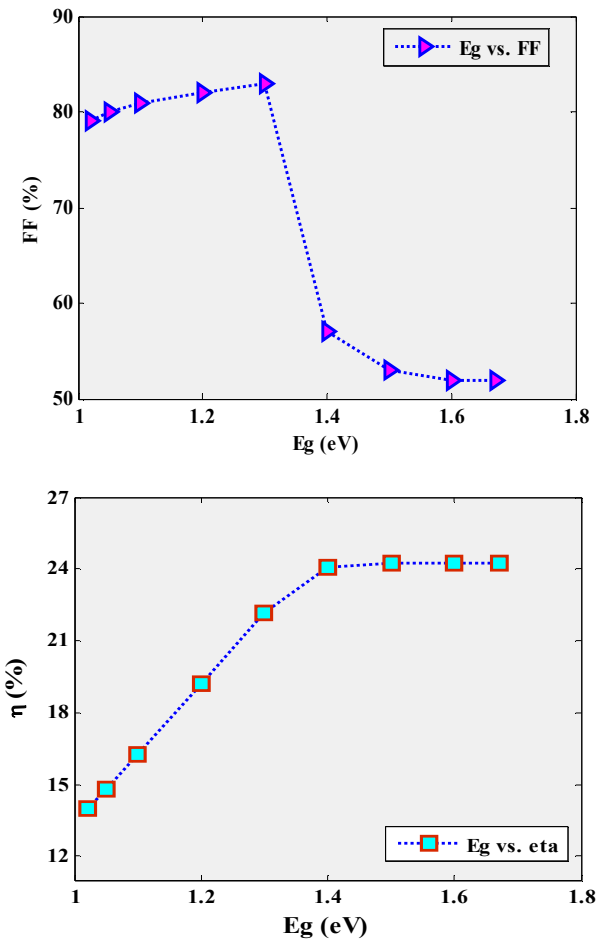


Fig. 2. Band-gap effect on solar cell performance

The trade of among these phenomena is that, an optimum band-gap of 1.3eV is proposed in which the device have a high fill factor without sacrificing its V_{OC} or J_{SC}. The result yields a maximum efficiency of 22.18%.

B. *Effect of absorber layer thickness:*

CIGS solar cell has an absorption which is more than 10 times better than for crystalline silicon. Hence, it is possible to make a solar cell which is very thin compared to well known silicon solar cell. Various researches have reported the impact of the thickness of CIGS absorber layer on solar cell performance parameters. In our simulation, CIGS layer thickness was varied from 0.3µm to 3µm, where the band-gap was kept in the optimum value at 1.3eV and all other layer parameters were kept the same as before. The simulation results for varying thickness of the absorber layer are given in TABLE III.

TABLE III. SIMULATED RESULT FOR VARYING THICKNESS

W(µm)	V_{OC}(V)	J_{SC}(mA/cm^2)	FF(%)	η(%)
0.3	0.69	26.14	69.09	12.54
0.5	0.75	27.30	77.65	15.93
0.7	0.77	28.94	79.70	17.75
0.9	0.78	30.10	80.81	18.99
1.1	0.79	30.94	81.58	19.90
1.5	0.80	32.11	82.43	21.16
2.0	0.81	33.04	82.52	22.18
2.5	0.83	33.66	82.22	22.86
3	0.84	34.10	81.80	23.35

Fig 3 shows the effect of thickness variation on the performance of solar cell.

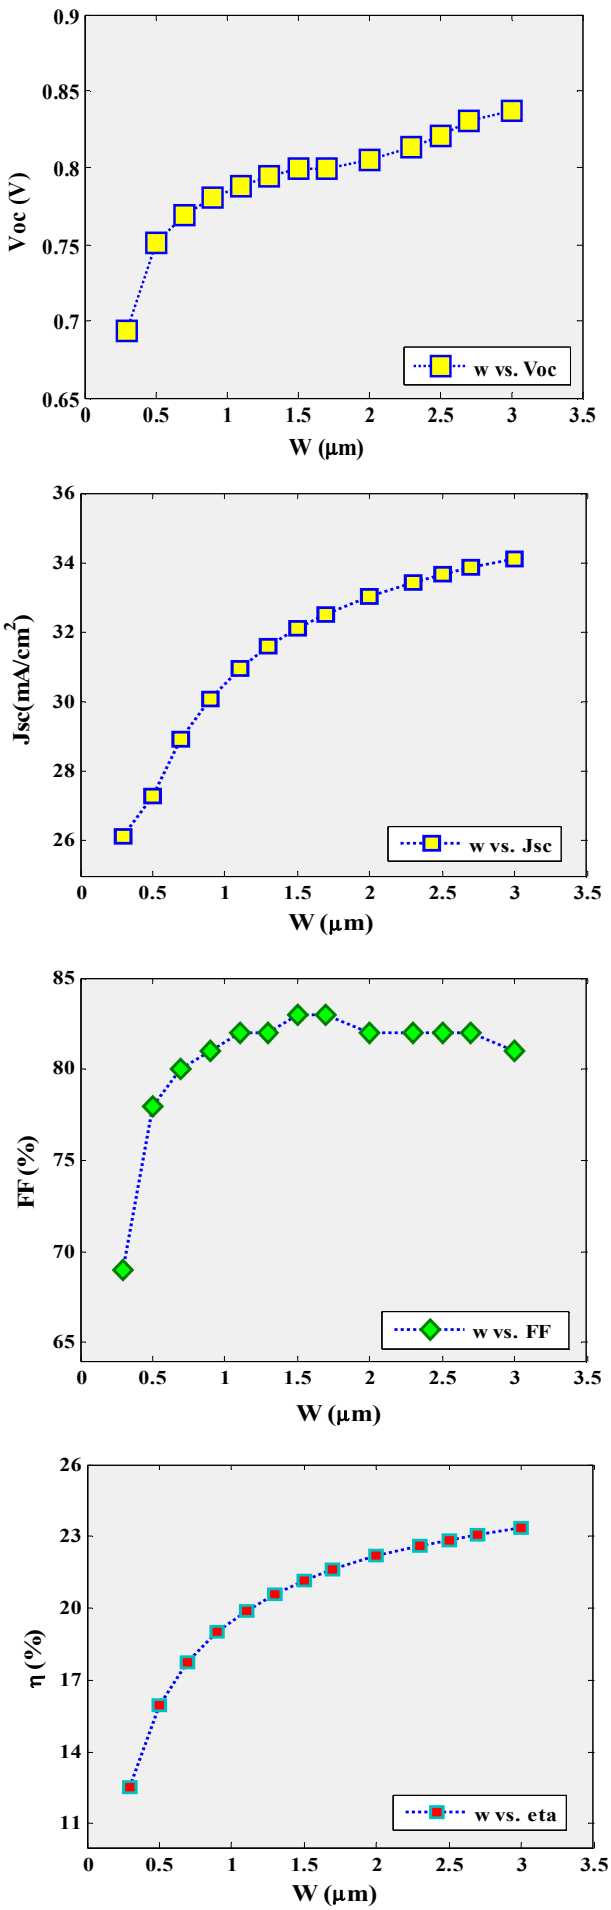

Fig. 3 Thickness effect on solar cell performance

Based on the simulated result it is seen that, device performance was considerably influenced by the absorber layer thickness. The J-V curve reveals that as the thickness of the absorber layer CIGS increases from 0.3 to 2µm, V_{OC} increases from 0.69 to 0.81V due to decreased recombination probability of photon-generated carriers. Again, when the thickness of CIGS increases beyond 2µm, V_{OC} increases very slowly.

Again, in the case of $J_{SC,}$ it follows the same trend with the increasing thickness of the absorber layer. As in fig, Fill-factor increases with the thickness from 0.3 to 2µm and after this it decreases slowly. So, we considered the optimum value of the CIGS absorber layer at 2µm in which the efficiency was 22.18%.

V. CONCLUSION

In this study, numerical optimization has been performed by adjusting parameters like thickness and band-gap of the absorber layer CIGS and it is shown that this parameters has crucial effect on solar cell performance. Simulation results exhibit that, increased solar cell efficiency is obtained by increasing the thickness and band-gap. Other performance parameters like V_{OC}, J_{SC} and FF is also enhanced by optimizing CIGS absorber layer thickness at 2µm. In the case of band-gap it is seen that, after 1.3eV fill-factor drops significantly. So we `optimized the band-gap of the absorber layer at 1.3eV and it is demonstrated that a maximum efficiency of 22.18% can be obtained by CIGS solar cell, where the presently reported best efficiency is 21.7%.

Abstract—**In this paper, a new prediction model for solar irradiance has been proposed using ant colony optimization (ACO) and neural network (NN), called as ACOSIP. In ACOSIP, the most salient climatological features are selected in order to enhance the solar irradiance prediction (SIP) accuracy. To implement such idea, ACO search technique utilizes the advantages of the combined activities of the features by considering the correlation information among the features and the outcome of NN. Thus, ACOSIP introduces the wrapper and filter approaches in its feature selection process. To make an effective ACO search, two sets of new rules have been designed for pheromone update and heuristic information measurement. To evaluate the performance of ACOSIP, 12 solar irradiance data samples in between the year of 2000-2013 were collected from Bangladesh Meteorological Department (BMD). Experimental results show that ACOSIP can select six most salient features easily with increasing the prediction accuracy, which are longitude, latitude, day light hour, max temp., min temp., and humidity. In addition, the averaged prediction accuracy of ACOSIP for 35 stations of BMD in testing case is 99.74% including the MAPE of 0.26%. The proposed ACOSIP also represents high correlation of 99.93% in between the actual and forecasted data.**

Keywords—Solar radiation forecasting, Artificial neural network, Ant colony optimization and Feature selection .

I. INTRODUCTION

Solar energy research is based on solar radiation data, but is not available for most of the sites due to non-availability of solar radiation measuring equipments at the meteorological stations. Therefore, it is essential to predict solar radiation for a location using several climatic variables. Furthermore, the application of solar energy among the different types of renewable energy sources has more attentions nowadays throughout the whole world that might be increasing in the following days.

A number of works has already been published in the literature related to modeling and prediction of solar radiation for various solar energy applications [1]. Analytic formula [3], numeric simulation or statistical approaches [4] are developed two or three decades before to predict solar irradiance. But, these prediction models resulted in large errors. To overcome these limitations, NN-based models [3-9] has been introduced in the recent years for predicting the solar irradiance.

Mohandas proposed a model in [5] where solar irradiance data was collected from different 41 stations in Saudi Arabia to train the NN for finding the irradiance prediction accuracy. The incorporated input variables are latitiude, longitude, altitude and sunshine duration. The results for the testing stations are within 16.4%. In [6], NN-based model used 12 various Indian weather stations with different climatic conditions. The results of RMSE in NN model is in between 0.0486-3.562 for Indian region. On the other hand, S. Rahman's proposed model [7] used data for Abha city of Saudi Arabia in NN training where the result of MAPE is 4.49%. S. Quaiyum proposes a SIP model [8] for Bangladesh obtained the result of MSE is 0.29%. Hasni proposes a SIP model [9] for south-western region of Algeria where the MAPE obtained is 2.9971%. In [3], Kalogirou has reviewed the use of NN in the applications of renewable energy systems. In addition, Mellit [4] has shown NN for sizing of PV systems.

According to the afore-mentioned proposed models for predicting the solar irradiance, it has been observed that, NN-based models cannot perform well in predicting the solar radiation using all the available features. The reason is that, the performance of NN always degrades if some irrelevant features exist in the available feature set [10]. Therefore, selecting those irrelevant features from the original set is a crucial work in the NN-based SIP process. In this regard, Will tries in [11] to select climatic variables for 14 weather stations in North Argentina using niching genetic algorithm.

However, in this paper, an ACO-based SIP model has been proposed to select the most relevant features to increase the prediction performance of NN. ACO here incorporates two techniques in its weight update rules, which are wrapper and filter approaches.

The remainder of this paper is organized as follows. ACOSIP are broadly discussed in Section 2. Simulation results, comparison to other methods, are reported in Section 3. Short conclusions with few remarks are given in Section 4.

II. PROPOSED ACOSIP MODEL

To determine the best climatological features in increasing the solar irradiance accuracy, ACOSIP uses hybrid ACO based search technique. Furthermore, to obtain a small subset of salient features, the ants are guided at its traversal period upon the feature space. For comprehensibility, the proposed ACOSIP model can be discussed by the flowchart shown in Fig. 1, which is described as follows:

i) Let D is a given data set with n distinct features. Initialize the pheromone trails τ and the heuristic information η of all n features by giving equal values to τ and η.

ii) Measure the correlation data of individual n features using correlation measurement scheme. The reason is to select more distinct features by ants. Thus, the ants are guided to select the features which are less correlated among the original features.

iii) Motivate the ants to choose location information (i.e., latitude and longitude) at each iterations.

iv) Generate a set of artificial A ants equivalent to n, i.e. $A = n$.

v) Subset size, s is determined prior to SC for each of the A ants. By using the conventional probabilistic transition rule [13] for selecting features with which to construct the subsets as follows:

$$P_i^A(t) = \begin{cases} \dfrac{[\tau_i(t)]^\alpha [\eta_i(t)]^\beta}{\sum_{u \in j^A} [\tau_u(t)]^\alpha [\eta_u(t)]^\beta} & if \;\; i \in j^A \\ 0 & otherwise \end{cases} \quad (1)$$

where j^A is the set of effective features, τ_i and η_i are the pheromone and heuristic values for the feature i (i= 1, 2,…..,n). The relative importance of the pheromone value and heuristic information is decided by α and β. Eq. (1) shows random behavior in subset construction initially, since the initial value of τ and η for all individual features are equal.

vi) After completion of subset construction by all ants, then system move forward, on the other hand system will back to Step 4.

vii) The subsets $R^A(t)$ is evaluated and measure the performance using MAPE $M(R^A(t))$. Here, $R^A(t)$ refers to the effective sets constructed by A ants at iteration t.

Step 8) The $R^l(t)$ (local best subset) among all $R^A(t)$ and the R^g (global best subset) among all $R^l(t)$ is selected with the searching methodogy. Here, t = 1, 2,3,…….,I where I is a number of iterations.

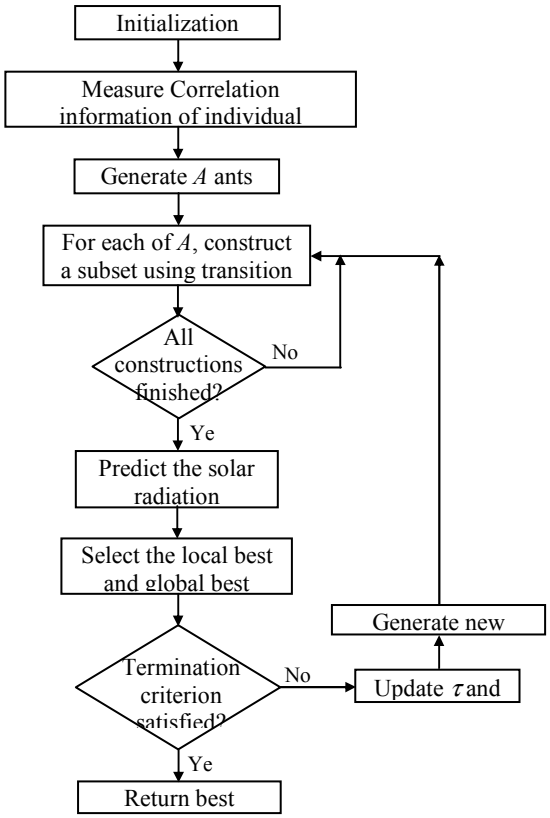

Figure 1. Flowchart of ACOSIP

Step 9) Check whether $R^l(t)$ attains a predefined SIP performance, or the algorithm execution reaches an iterative limit I_{th} and then terminate the selection process. Note that, at iteration I_{th} the model cannot find anymore variation in R^g. Otherwise continue the FS and save the evaluation results of all local best subsets, $M(R^l(t))$ for further use.

Step 10) The values of τ and η for all the features will be updated according to the rules of pheromone update and heuristic value measurement, respectively.

Step 11) A new set of artificial A ants will be generated and proceed the scheme similarly.

Clearly, the idea behind ACOSIP is straightforward, which used ACOFS algorithm to guide the ants in bounded region (between 3 to 6) of search space and providing mixed technique to the ants search. To select the distinct features which is helpful for effective learning of NN, a correlation information measurement procedure has been integrated, so performed only once throughout the FS process.

III. HYBRID SEARCH PROCESS

In ACOSIP, a hybrid search technique has been introduced that is composed by wrapper and feature approaches. These

approaches are embedded in the newly designed two sets of rules, which are pheromone update and heuristic value. Note that, these both rules are involved with correlation information measurement of individual features, which are further described as follows:

A. Pheromone Update Rule

On basis of random and probabilistic phenomena, a set of two pheromone update rules are introduced from the original one mentioned in [10] as follows:

Random case: The rule presenting in Eq. 2 is selected from [10], in which case second term is divided by f_i. The features are selected to construct subsets randomly according to their experiences. This enhances the exploration capability of ants. The rule has been accepted as follows:

$$\tau_i(t+1) = (1-\rho)\tau_i(t) + \frac{1}{f_i}\sum_{A=1}^{n}\Delta\tau_i^A(t) + e\Delta\tau_i^g(t) \tag{2}$$

$$\Delta\tau_i^A(t) = \begin{cases} M(R^A(t)) & if\ i \in R^A(t) \\ 0 & otherwise \end{cases},$$

$$\Delta\tau_i^g(t) = \begin{cases} M(R^l(t)) & if\ i \in R^l(t) \\ 0 & otherwise \end{cases}$$

Here, i refers to the number of feature (i = 1, 2,……n),and f_i is the count for the specific selected feature i in the current iteration. $\Delta\tau_i^A(t)$ is the value of pheromone taken by the local update for feature i, which is included in $R^k(t)$ at iteration t. Similarly, the global update, $\Delta\tau_i^g(t)$,is the value of pheromone for feature i that is included in $R^l(t)$. Finally, ρ and e are the pheromone decay value and elitist parameter, respectively.

Probabilistic case: Eq. (3) shows the updated pheromone rule (probabilistic case).

$$\tau_i(t+1) = (1-\rho)\tau_i(t) + \sum_{A=1}^{n}\Delta\tau_i^A(t) + e\Delta\tau_i^g(t) \tag{3}$$

$$\Delta\tau_i^A(t) = \begin{cases} M(R^k(t)) \times C_i & if\ i \in R^A(t) \\ 0 & otherwise \end{cases},$$

$$\Delta\tau_i^g(t) = \begin{cases} M(R^l(t)) \times C_i & if\ i \in R^l(t) \\ 0 & otherwise \end{cases}$$

Here, feature I is renown by the global update. The $\Delta\tau^g$ is provided only to those features that are actually efficient, because, global update has an important part in selecting the effective features in ACOSIP.

B. Heuristic Value Measurement

In this paper, we propose a set of new heuristic value estimation rule depending on two basic phenomena in SC. To describe the attractiveness for each features heuristic value, η, is important. So, to overcome the greediness η, is therefore necessary [12], and finally an effective solution may be appeared.

Random case: In the initial stage, the ants are involved to construct the feature subsets randomly, and the heuristic value of all features i can be estimated as follows:

$$\eta_i = \frac{1}{f_i}\sum_{A=1}^{n} M(R^A(t))(1+\phi e^{-\frac{|R^A(t)|}{n}})$$
$$if\ i \in R^A(t) \tag{4}$$

Probabilistic case: In the following iterations, after constructing subsets on the basis of the probabilistic behavior, the following formula is used to estimate η for all features i:

$$\eta_i = f_i\varphi_i\sum_{A=1}^{n} M_a(S^k(t))C_i(1+\phi e^{-\frac{|S^k(t)|}{n}})$$
$$if\ i \in S^k(t) \tag{5}$$

In these two rules, φ_I refer to the count of a particular selected feature I from previous iterations to the current iteration, except for the initial iteration. C_i refers to the correlation value for feature i. The aim of including C_i is based on the following two factors:(a) to select the more distinct features during SCs, and (b) enhancing the robustness of learning model. Thus, best features may be selected in the SC for different iterations, thus of course enhancing the prediction accuracy of the ACOSIP.

C. Correlation Value Measurement

In order to measure relationship between the climatological features which are used as the input pattern in ANN and to choose distinct features correlation information (CI) is important and useful statistics. To reduce the effect of features to each other and to increase the learning power of ANN we need more uncorrelated features set in training purpose. This information is providing to heuristic information measurement η of all individual features. In this work, Pearson product-moment correlation coefficient is used. The correlation coefficient, r_{ij} between two features, i and j is,

$$r_{ij} = \frac{\sum_p (x_i - \bar{x}_i)(y_j - \bar{y}_j)}{\sqrt{\sum_p (x_i - \bar{x}_i)^2}\sqrt{\sum_p (y_j - \bar{y}_j)^2}} \tag{6}$$

The correlation coefficient is computed for all possible combinations of features then ACOSIP computes the correlation of each feature. The correlation, Cor_i, of any feature i is

$$Cor_i = \frac{\sum_{j=1}^{n}|r_{ij}|}{n-1} \qquad i \neq j \tag{7}$$

where n is the number of features used. Then to find the uncorrelated features we use C_i, which is

$$C_i = 1 - Cor_i \tag{8}$$

IV. DATA COLLECTION

The significance of ACOSIP has been evaluated in this section on twelve well known climatological features as longitude (Ln), latitude (Lt), elevation (ev), year (y), month (m), station constant (sc), day light hour (DL), relative humidity(Rh), maximum temperature (Mat), minimum temperature (Mit), rainfall(Rf) and wind speed (Ws), and the solar radiation data is used as the target. These features have been used in many of solar radiation prediction models using ANN. In this study we use 14 years (2000 - 2013) monthly averaged data, for 35 stations, which are collected from Bangladesh Meteorological Department (BMD), Weather office.

V. METHODOLOGY

To verify the effectiveness of ACOSIP for FS and RP, a number of experiments have been carried out on ACOSIP. To justify the FS and RP task suitability in ACOSIP, one basic step need to be considered, namely, giving values for user-specified parameters such as $\eta, \tau, \alpha, \beta, \rho$ and ϕ, which are common for the all datasets. These parameters have been chosen after some runs. To achieve a level of balance between exploitation and exploration proper selection of the values of parameters is helpful of ants to select feasible features.

VI. EXPERIMENTAL RESULTS

The effectiveness of ACOSIP model is verified by a succession of experiments. To prove the strength of the proposed model 35 ACOSIP models have been designed for 35 stations and then results are being averaged to show the global strength of the model – shown in Table 1. As Table 1, the avg. results of PA and MAPE for 35 stations are 99.60 % (training), 99.49% (testing) and 0.42% (training), 0.49 (testing), respectively validated the ACOSIP structures for predicting solar irradiance.

TABLE I. AVERAGED PERFORMANCE RESULTS OF 35 MODEL OF ACOSIP

Local Investigated Data					
DATA	**Avg. PA (%)**	**Avg. MAPE (%)**	**Avg. RMSE (%)**	**Avg. MSE (%)**	**Avg. R (%)**
Training	99.60	0.42	0.244	0.077	99.81
Testing	99.49	0.49	0.289	0.104	99.72

TABLE II. PERFORMANCE RESULTS FOR WELL PERFORMED STATIONS

Station Names	**DATA**	**Avg. PA (%)**	**Avg. MAPE (%)**	**Avg. RMSE (%)**	**Avg. MSE (%)**
Chittagong	Training	99.79	0.21	0.0366	0.00135
	Testing	99.67	0.33	0.0576	0.00332
Dhaka	Training	99.86	0.14	0.0244	0.00059
	Testing	99.74	0.26	0.0454	0.00206
Khulna	Training	99.76	0.24	0.0419	0.00175
	Testing	99.66	0.34	0.0593	0.00352

Table 2 shows the results for different ACOSIP model of each station. The model of Dhaka region found to be best among the 35 models.

The effectiveness of FS algorithm and the prediction ability of ANN have been ascertained using the data for Dhaka region. In this respect the 15 independent runs for ACOSIP model for Dhaka have been performed and then averaged the results – shown in Table 3.

As Table 3, the PA and MAPE for training and testing case are 99.84%, 0.16% and 99.70%, 0.3%, respectively.

And as the value of R is higher (99.90%), so it can be easily understood that the ACOSIP model has stronger prediction capability.

Table 4 depicts the positive effect of feature selection strategy. PA is 99.74% with selected features.

Determination of the best solution in ACOSIP can be seen in Fig. 2, it can be showed that, the PAs varied with the size of those subsets and for the performances of the local best subsets.

The PAs were maximized in various points, but the best solution was selected (indicated by circle) by considering the reduced size subset.

How the selection of salient features in different iterations progresses in ACOSIP, Fig. 3 and Fig. 4 shows the scenario of such information for a single run.

We can see that, features 1, 2, 12, 7, 8 and 4received maximum values of τ and η so these features have a higher priority of selection.

Ultimately, a successful evaluation function NN model is used to find high- quality solutions for ACOSIP in prediction. As training process progresses and converges to a certain limit up to 40 epochs (Fig. 5(a)). However, the training is terminated, because at this instant validation error increases due to over training (Fig. 5(b)).

At the termination epoch we also observed that the number of hidden neuron is 3. Table 5 shows the correlation information that the selected features are highly uncorrelated.

TABLE III. PERFORMANCE OF ACOSIP MODEL AND RESULTS WERE AVERAGED OVER 15 INDEPENDENT RUNS.

Local Investigated Data For Dhaka Region For 15 Independent Run					
DATA	Avg. PA (%)	Avg. MAPE (%)	Avg. RMSE (%)	Avg. MSE (%)	Avg. R (%)
Training	99.84	0.16	0.027941	0.000781	99.90
Testing	99.70	0.3	0.052889	0.002745	99.82

TABLE IV. PERFORMANCE (AVERAGED) OF ACOSIP MODEL FOR FEATURE SELECTION OVER 15 INDEPENDENT RUNS.

Avg. Result for all features				Avg. Result for selected features			
N	SD	PA (%)	SD	ns	SD	PA (%)	SD
12	0.00	95.5	1.12	6.13	0.82	99.74	0.40

TABLE V. CORRELATION INFORMATION (CI) OF SELECTED FEATURES

Features	Ln.	Lt.	DL	Rh	Mat	Mit

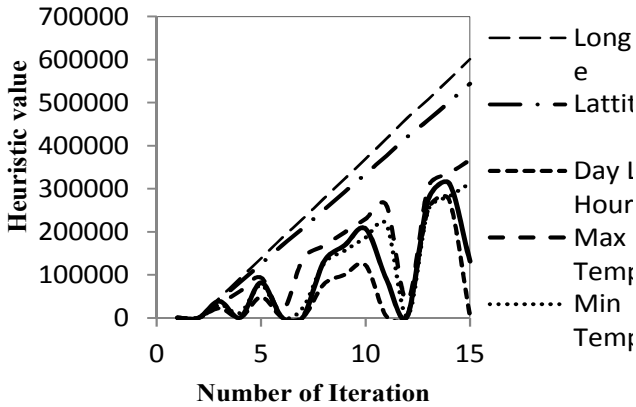

Figure 4: Distribution of heuristic level in different iterations for a single run.

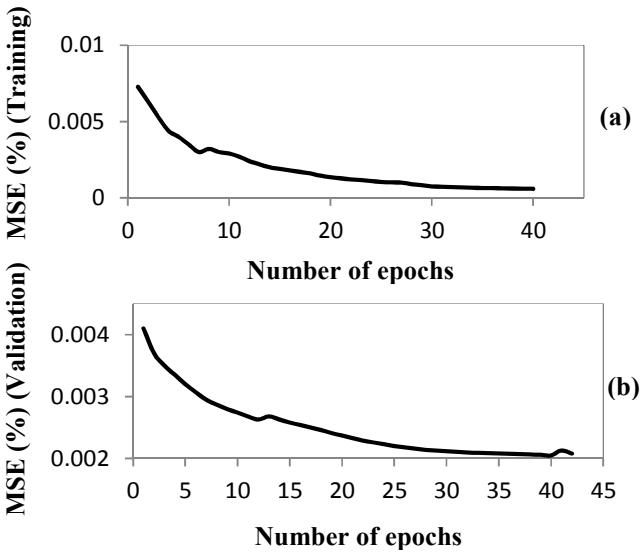

Figure 5. Training process to evaluate the constructed subsets by ants: (a) training error, (b) validation error.

It can be seen from Fig. 6 that the high correlation is present between actual and predicted data.

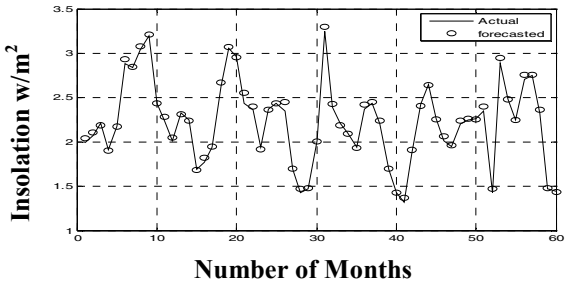

Figure 6. Actual and predicted insolation curve

VII. COMPARISON WITH OTHER WORKS.

Theoretically, a huge amount of attempts have been carried out in designing solar radiation prediction models. The proposed model is quite different from those discussed in [3 – 9], where the prediction models use the features, based on knowledge or availability with no attempts to search the best feature subset. From Table 6 it can be seen that, the proposed ACOSIP perform better with feature selection strategy.

TABLE VI. COMPARISON WITH OTHER WORKS

Name of Authors	MSE (%)	PA (%)	MAPE (%)
Proposed Model	0.000598	99.86	0.14
Amit Kumar Yadav [6]	0.0024		0.2783
Shafiqur Rahman [7]			4.49
Salman Quaiyum [8]	0.29		

VIII. CONCLUSION

This work represents a new model (ACOSIP) for predicting solar irradiance using ACO and NN. In ACOSIP, the most salient climatological features are selected in order to improve SIP accuracy. To facilitate the activity of ACOSIP, two sets of new rules have been designed for pheromone update and heuristic value measurement, where the correlation information technique and the outcome of NN are embedded. Experiment results show that, ACOSIP performs well in 12 solar radiation data samples collected from BMD, where it selected six most salient features easily with better prediction accuracy. The selected features are longitude, latitude, day light hour, max temp., min temp., and humidity. Furthermore, the averaged prediction accuracy of ACOSIP for 35 stations of BMD in testing case is 99.74% including the MAPE of 0.26% (Table 2). The proposed ACOSIP also represents high correlation of 99.93% (Table 1) in between the actual and forecasted data. On the other hand, the results of the low standard deviations of prediction accuracies exhibit the robustness of this model. Comparison results presented in Table 6 show that, ACOSIP can perform well comparing to other existing models. Thus, it can be said that, the proposed ACOSIP model may have capability to select the relevant features and to predict solar radiation at any location in the world, provided that the proper data from the locations are available.

***Abstract*—Smart meter, the core part of smart grid system, is becoming an active field of research for its immense potential in efficient power distribution and load management. It is expected to have potential applications in Bangladesh as well. Efforts are already underway from distribution companies to introduce intelligence in the meter system. This paper proposes several smart meter assisted economic energy consumption schemes for consumers and power outage reduction scheme for distribution utility companies that will enhance the quality of service. Necessary analyses have been included to verify the proposed schemes. Real-life electric power demand and supply data from various substations under Dhaka Electric Supply Company (DESCO) have been used to validate the power outage reduction scheme. Results show that the schemes provide economic benefit to the consumer and an effective load management strategy for distribution companies. Operating issues related to the proposed schemes have also been detailed to highlight the practicality of the proposed schemes**

Keywords-Smart meters, power management, power outage reduction, implementation factors)

I. INTRODUCTION

Smart grid is being increasingly seen as an efficient and effective power transmission and distribution system. Smart meters at customer premises represent the core part of the intelligence and automatic control system of smart grid infrastructure [1]-[2]. Smart meters present themselves as enablers for cost-effective energy management strategies for consumers and power distribution companies [3]-[4]. An estimated 62% Bangladeshi people is connected to the electric grid. The electricity supply is not reliable and peak demand cannot be met. In the rural areas, where more than 70% of the population lives, only about 30% of them have access to electricity supply [5]. In the context of energy scenario in Bangladesh where there is a large deficit between energy generation and demand, smart meters offer the potential of providing economic usage of energy for customers and smart management of distribution system so as to minimize the impact of the energy deficit [6]. Dhaka Electric Supply Company (DESCO) in an attempt to introduce intelligent metering keeping in line with smart meter concept conducted a pilot project to introduce prepaid meters with limited feature for residential customers. Extension of such approaches will form the future of electric power distribution and consumption strategies by relying on smart meters with advanced algorithms and reliable two-way communications between the meter and the central control located at the distribution center. With increase in energy tariff coupled with energy deficit, customers will look for avenues to reduce their electricity expenses while expecting a good quality of service from the distribution companies. With a smart meter installed at the customer premise, customers can avail various options to optimize electricity usage and minimize energy expense.

This paper proposes several energy management strategies that are applicable at customer and distributor end. This includes keeping the monthly bill within a pre-set limit and being notified of tariff slabs as energy is being consumed. The proposed techniques further include energy consumption within the assigned load limit or sanctioned load. Additionally, it is possible through implementation of the proposed techniques to alleviate the existing power outage crisis and to provide uninterrupted power at a useful level. It may be worthwhile to draw differences with research that address smart meter applications at customer premises [3]-[4] and [6]. The cited research focuses on actual hardware details of a household smart meter, wider range demand side management or configuration of appliances to match the peak-hour in demand. In contrast, the research presented in this paper provides an in-depth analysis of load management scheme and addresses the practical issues that arise from such schemes. Moreover, the proposed schemes have the potential of mutually reinforcing the efficacy of load management technique. Recorded data of supply and demand over time from DESCO has been used to analyze the performance of the proposed power outage reduction scheme [7]. It is expected that the research presented in this paper will provide a practical direction for technically and economically feasible deployment.

The organization of the paper is as follows. Section II presents smart meter enabled smart electricity consumption management for customers. Section III proposes power outage reduction scheme while Section IV addresses practical issues related to the proposed management schemes. Section V touches upon the communications infrastructure to support the proposed schemes followed by concluding remarks.

II. SMART METER FOR ECONOMIC ENERGY USAGE

Consumers can regulate his/her energy usage through smart meter based usage management: (A) Fixed budget for electric bill. (B) Electricity cost management according to price slabs, and (C) Sanctioned load monitoring. These are described in details in the following subsections.

A. Fixed budget for electric bill

A smart meter can be used to help the consumer plan a monthly budget for electricity usage. The consumer will give his/her allocated budget as an input to the meter and the meter will calculate the available energy units based on the existing tariff rate. Based on the available units, the meter will calculate the daily average allowed unit. For each day, the meter will determine the consumed energy units for that day and raise an alarm if that consumed energy is higher than the average value. Thus, the consumer will be informed of his/her daily status on consumed energy units and will adjust the energy consumption for the remaining days of the month so that the total consumed energy is within the allotted budget set at the beginning of the month. An example of variation of daily consumed energy is shown in Figure 1 along with the meter computed the average daily energy unit. Here it is assumed that the allocated budget allows 570 units (i.e., kW-Hr) of energy for a given month and the resulting per day allowable energy use is about 18.8 units. Thus, whenever the consumed load exceeds the preset average value, the smart meter will raise an alarm and generate a message about exceeding the average and the remaining allowable energy units. The customer then lowers the energy consumption below the allowable daily limit.

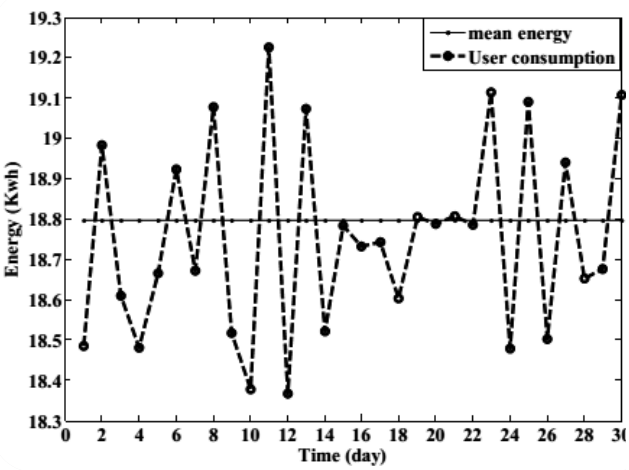

Figure 1: Energy consumption pattern following fixed budget plan.

Figure 2 shows the cumulative energy consumption from the budgeted limit (straight line representing mean energy) and from smart meter assisted user regulated scheme. The plots reveal that the proposed scheme enables the user to closely approximate the preset limit and to keep within the budget.

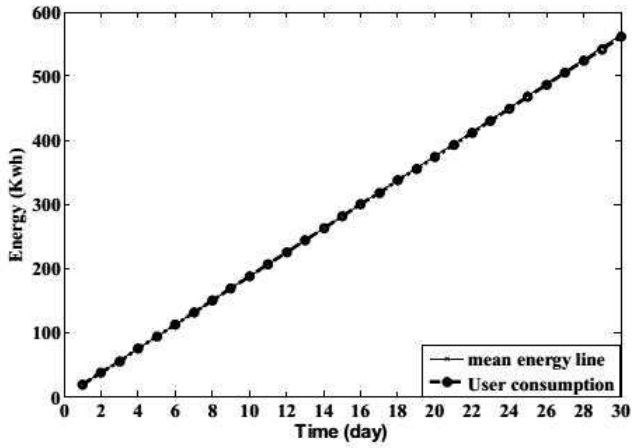

Figure 2: Allocated and daily energy consumption lines for a month.

B. Electricity cost management according to price slabs

The Dhaka electric supply company (DESCO) has implemented new tariff rates from 01 September 2012 in accordance with Bangladesh Energy Regulatory Commission (BERC) [7]. Figure 3 shows only the residential component of the tariff structure. This tariff rate is flat throughput the day irrespective of the peak demand hours.

TABLE 1: PRICE SLABS FOR RESIDENTIAL AREA IN BANGLADESH [5]

Category	Per unit Rate (BDT)
Life Line : From 1 to 50 units	3.33
First Step : From 1 to 75 units	3.53
Second Step : From 76 to 200 units	5.01
Third Step : From 201 to 300 units	5.19
Fourth Step: From 301 to 400 units	5.42
Fifth Step: From 401 to 600 units	8.51
Sixth Step: Above 600 units	9.93

As per this tariff structure, the consumer pays increasingly higher tariff as his energy consumption increases and crosses over to the higher price slabs. A smart meter can help customers become more energy-conscious as it can alert them when the energy consumption is approaching the slab with the next higher tariff rate. This will help the customers to keep the energy consumption within an affordable limit. Various algorithms can be devised to keep track of the energy consumption, the related total cost and to implement the user control (manual or automatic).

C. Sanctioned load monitoring

The customers of power distribution companies are assigned various levels of allowable sanctioned loads based on their demands whenever they subscribe to a particular company. The sanctioned load implies a tacit agreement that customer will not cross the sanctioned load. However, there is no

provision for monitoring operating customer loads and penalty for exceeding the sanctioned load. Only recently, DESCO is deploying energy meters on a small scale with instantaneous load monitoring capability and applying penalty in case of exceeding the limit. That monitoring scheme turns off the meter should there be a first-time violation of sanctioned load and the user can turn on the meter. If the violation occurs second time, the user is still allowed to turn the meter on; however, with the next violation, the meter turns off and cannot be turned on except from official intervention along with a penalty. A better and more customer-friendly approach can be adopted where the meter will alert the consumer whenever the current load limit is within a certain percentage of the sanctioned load (e.g., within 5% or if the operating load is around 950W when the sanctioned load is 1kW). Thus, with this alert in mind, the consumer will plan his energy consumption and prioritize appliances so that overall load is kept below the sanctioned load. For the case when the operating load does exceed the sanctioned limit, then the smart meter will turn off and will not turn back on until the operating load is reduced below the sanctioned load limit.

D. Operational Aspects

Hardware implementation of smart meter based energy management is an important operational aspect [8]. The proposed schemes (A-C) can be implemented through a smart meter, user interface and supporting communication system installed within consumer premises. For tracking energy consumption cost management (schemes A, B), a smart meter can be programmed to monitor daily usage and generate alert messages and alarms as needed. For implementing sanctioned load monitoring (C), the smart meter can play the role of load monitoring and generating alert messages and alarms. However, for consumer responses to the alerts and alarms, some additional features can be provided through indoor short range communication link between the smart meter and the appliances that can be controlled by the smart meter. It can be safely assumed that high-wattage appliances have major impact on operating load, pushing energy cost into higher price slabs. Thus, if the electrical outlets for these appliances are fitted with switches or relays (smart switches) controlled by smart meters through Zigbee based communication links, the operation of these devices can be controlled as per requirements from sanctioned load settings and tariff structures. For example, if the consumer would like to turn on a high-power appliance, he/she will press the smart switch and the smart switch will request the smart meter to enable it. The smart meter will monitor the parameter settings for a particular application (i.e., sanctioned load monitoring or energy cost reduction), will issue a command accordingly to the smart switch. For sanctioned load monitoring, the smart meter will not enable the smart switch till the load is reduced below the sanctioned limit. For energy cost reduction, the smart meter will disable the switch when an alert condition is encountered; however, the user can press the smart switch second time that will enable that switch and turn on the appliance.

III. POWER OUTAGE REDUCTION

There is an acute shortage of electricity production at the national level in Bangladesh and the gap between production and demand has to be compensated by power outage. In the metropolitan areas, the power outage is usually scheduled by the electricity distribution companies where an alternating hourly pattern of availability of electricity and power outage (termed load shedding) is maintained. The outage scenarios in rural areas is even worse as generated electricity is mainly channeled to city and industry areas giving less priority to rural areas. A typical hourly pattern for electricity supply, demand and the resulting amount of load shedding for a specific zone (Dhanmondi zone under DESCO) is shown in Figure 4. From the figure it can be seen that the demand is higher than the supply throughout the day with the peak demand occurring at 5 pm onwards. The peak amount of load shedding is somewhat higher than 15 MW while the peak available supply is about 22 MW.

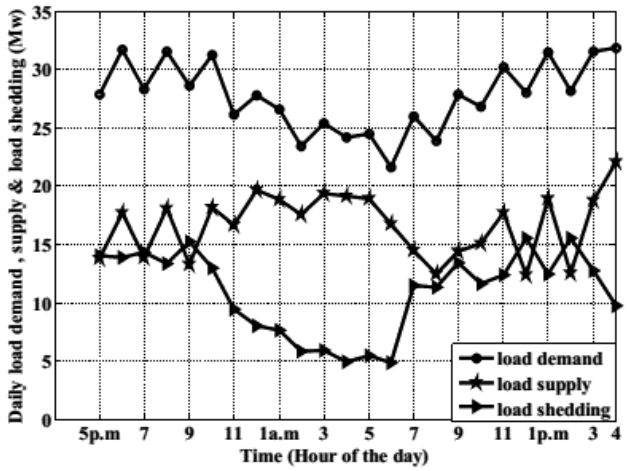

Figure 3: Load demand, supply and load shedding patterns of Dhanmondi zone in a metropolitan city Dhaka [1]

A. Proposed load management scheme

As per the current practice of load shedding, the 11 KV feeders coming out of a substation are selectively switched off in a pre-determined schedule. Thus, a group of consumers belonging to a set of feeders faces power outage in specific one hour duration while in the next hour the feeders are switched on. Thus, there is an hourly "on-off" pattern for available electricity to the consumers. The consumers usually respond to power outages by installing IPS for home use and diesel generators for high-rise residential apartments and offices and educational institutes.

Smart meters in combination with appropriate control mechanism at the distribution substation side can enable an alternative strategy where electricity can be made available to the consumers throughout the day albeit at a reduced level. The distribution companies will predict the load demand D(t) at a given time t for a given day and will

estimate a "load meet" factor *LM(t)*based on the available electricity supply S(t) allotted to it from the national grid as follows.

$$LM(t) = \frac{S(t)}{D(t)} \quad (1)$$

The central control system at the distribution substation will then relay this value to the smart meters for individual consumers and instruct the smart meters to reduce to a level as per the computed value of LM (t). A plot of LM (t) for the hourly patterns of demand and supply from figure 3 is shown in Figure 4.

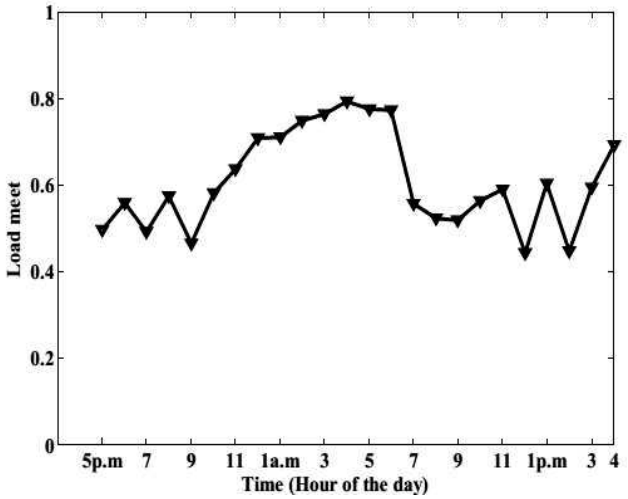

Figure 4: Variation of load meet factor with the period of time in a day.

It is instructive to compare the proposed scheme of offering energy all the time at a reduced level with the existing "on-off" hourly pattern of electricity supply.

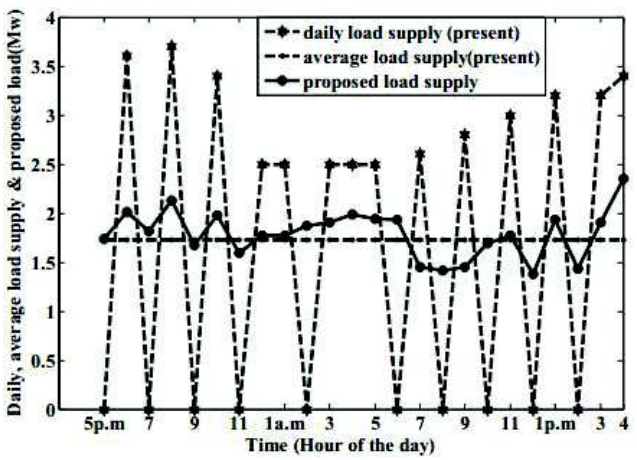

Figure 5: Existing power supply scheme and the proposed outage management scheme.

Figure 5 shows the hourly pattern of existing load shedding for a given day at a given feeder at the Dhanmondi zone for DESCO. The figure shows that except for midnight to early morning load shedding occurs regularly at alternating hours. The average available load from this load shedding approach is also shown as a straight line. The proposed load management scheme offers uninterrupted electricity supply at a reduced level of 1.5 to 2.4 MW. It can be seen that the proposed load management scheme behavior is relatively stable and is close to the average load supply from the existing load shedding technique. This shows that the proposed outage management scheme provides average energy supply to the customers that is similar to that from the present on-off scheme while maintaining continuity of service.

The different feeders of the same substation (Dhanmondi zone, DESCO) can also be studied for their allowable load variation throughout the day. The temporal patterns for the allowable load for the individual feeders for the same substation are shown in Figure 7. It can be seen that the variations are correlated depicting common residential customer energy consumption pattern. The variation in peak load supply can be attributed to individual feeder capacity.

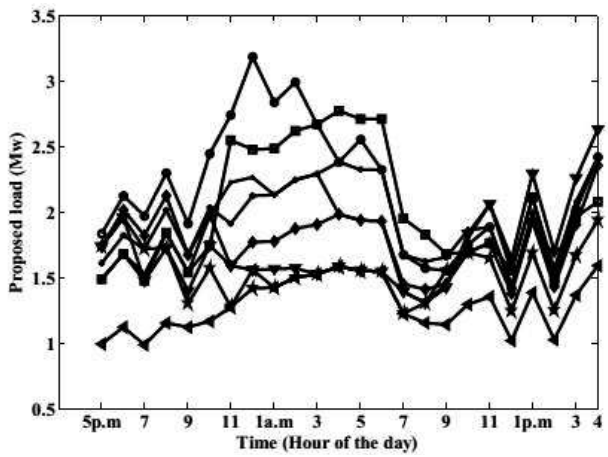

Figure 6: Variation of proposed load across different feeders of the same substation.

Let be the supplied load in a $d_1(t)$, $d_2(t)$, ⋯⋯ $d_N(t)$ substation and be the load demand of substation where N is the total number of feeders in that substation. Then total load-meet factor for a given substation can be expressed as

$$LM(t) = \frac{\sum_{n=1}^{N} P_n(t)}{\sum_{n=1}^{N} d_n(t)} \quad (2)$$

Load-meet actors for different substations (Shyamoli, Dhanmondi and Paribagh) have been computed from data available from DESCO web page. Figure 8 shows the variation of LM(t) for these substations. The plots in Figure 8 reveal that there is a strong correlation of the patterns across the substations. Thus, load distribution at different substations will follow the general pattern from applying the proposed power outage management scheme.

IV. Important Implementation Factors

The proposed load management schemes aim at more efficient and economic electricity consumption for customers. Additionally, it offers the distribution companies to provide uninterrupted electricity supply to their customers. One issue may arise and needs to be addressed is that the uninterrupted service occurs at lower load level. The main effects of that are:

- Individual consumers will need to lower their load level below the sanctioned load. Thus, the consumer needs to plan electricity appliances usage to be within the assigned load level. Thus, for a consumer with 1kW sanctioned load, he/she may be allowed minimum of 450W (45% load meet value in Figure 5) and maximum of 800W (80% load meet level in Figure 5). This can be accommodated by using more efficient electric appliances coupled with smart usage strategy implemented through smart meter.
- The availability of uninterrupted electricity will lead customers to do away with IPS and battery charging system. The charging of battery during "on" period in the current load shedding scheme can put significant burden on the available supply. Generally batteries designated for use with IPS tend to have shorter charging period by consuming higher current. For example, a 100AH battery at 12 volt can be designed to be completely charged in 3 hours; this implies that with a charging current of 100AH/3H 33 A,, the IPS system will consume 33 12 = 396 WH within the „on" time of 1 hour of the period. This can constitute a significant impact on the customer load and contribute to increase in demand during peak load.
- For high-rise apartment systems, the supply to lift/elevator and water motor can be left out of the proposed reduction scheme. Since the motors for these heavy electric devices cannot be operated at a reduced supply, the smart meters connected to these devices will be allowed to operate at their rated required capacity. This will reduce the operating expenses of the residents by excluding generators.
- Hospitals and emergency services can be left out of proposed load reduction scheme. Alternately, they can be guaranteed certain amount of supply throughout the day and difference between this supply and requirement can be compensated by installing generators.
- Since monitoring of sanctioned load does not take place currently, there is more energy consumption than the allowable limit from the consumer's side placing an increasing demand on the system. The proposed load management scheme offers monitoring of sanctioned load, and it is expected that this will bring down the demand on the distribution system with more energy aware consumers.
- These proposed load management schemes will also drive entrepreneurs to offer green energy solutions at customer premises or at the distribution centers. With additional energy from non-conventional renewable sources, the load management scheme will become more efficient and consumer friendly.

V. Communication Links for the Proposed Schemes

The proposed schemes will need a reliable two-way communications link between the smart meter and central substation [9] and between the smart meter and home appliances for automatic control. The communication link to support power outage management can be implemented via wireless or wired infrastructure. For wireless implementations, modems are needed at the smart meters to set up the link, a local concentrator to aggregate the data from multiple smart meters and relays to channelize the data to the central substation. Since the data rate is expected to low to support the scheme, the link can be designed to be small bandwidth systems. The wireless system can also be implemented through a mobile operator where data and control information can be communicated via mobile operator network so that the overall design can be made relatively simple [10]. As an alternative to the wireless systems, wired communication links can be established that will use the existing power distribution lines from the distribution substation to customer premises. This can be implemented using broadband over power lines (BPL) or power line communication (PLC) techniques [11]. Devices that are needed in this case are PLC modems at customer premises, extractor to concentrate the incoming signals, repeaters to keep the signal strength at a satisfactory level and injectors. Except for the cost of these additional devices, the PLC based implementation is expected to be economic since the existing power line network can be used as the communication infrastructure. As for energy consumption regulation at customer end (schemes A-C), customer response to smart meter alerts and alarms can be either manual or automatic. For scheme A and B, the customer can respond to alerts by planning energy consumption on his own without the need for any smart device. For scheme C, smart switches can be used for heavy load appliances to respond to alarms. In this case, low to moderate data rate links based on Zigbee systems will be sufficient for automatic control of the appliances.

VI. Conclusions

The research presented in this paper focuses on smart meter assisted energy consumption management for consumers and load management for distribution companies. Necessary analysis has been presented to verify the schemes. Analyses reveal that the proposed schemes have the potential to benefit the consumer and also assist distribution companies to provide a better quality of energy supply. The practical operational issues that can result from the proposed load outage reduction scheme have been discussed in details. The existing communications network in Bangladesh is adequate to support the proposed schemes. Thus, the proposed schemes can bring the much needed benefits and quality of electric energy supply and can be implemented through off-the-shelf components using the existing communication infrastructure.

ACKNOWLEDGMENT

The authors are grateful to Md. Faruk Hossain, Assistant Engineer, 70 MW Peaking Power plant, Bera, Pabna, for his thoughtful comment on power distribution and load shedding scheme.

***Abstract*—The increasing energy demand has enhanced the use of renewable energy as the source of fossil fuel cannot meet up this demand. The photovoltaic cell converts sunlight to electricity without any pollutant emission. A complete analysis on Photo Voltaic system is required to get the maximum output. But because of some external and internal factors, the generation of maximum output power is disrupted. Shading, temperature, irradiance as external factors and series and parallel resistance as internal factors change the maximum power point of a Photo Voltaic system. In this research, the generalized model for Photo Voltaic system was implemented in MATLAB interface. According to the change of the values of irradiance, shading, temperature, series and parallel resistance. The I-V and P-V characteristics are analyzed for the best case. On the basis of the analysis, effective Photo Voltaic system is built which gives approximately 5000W output by using the best values for the above mentioned factors. The proposed system is built to serve the purpose of an industry.**

Keywords—Irradiation; temperature; shading effect; bypass diode; maximum power point.

I. INTRODUCTION

The excessive demand for energy as a result of the industrial development and rapid population growth has lead to the necessity for alternative energy. The dwindling fossil fuel reserve has emphasized on this quest for alternative energy. Renewable energy is a great contribution to meet up the energy crisis. Solar energy is one of the candidates which has replaced fossil fuel by 20% to 25% over the past 20 years [1]. The use of solar power is growing at a rate of 60%. With no pollutant emission, low cost, availability, research in this topic has gained popularity. Bangladesh is also heading towards the use of solar energy in mass level in order to balance the insufficient supply of energy. In this country the duration of sunshine is 3 to 11 hours daily and the solar irradiation varies from 3.8 KWh/m^2/day to 6.4KWh/m^2/day. So there is high potential to implement solar system in the country. As a result Bangladesh Government has a target of 650 MW electricity generations by 2020. All this causes lead to the proper implementation of PV system with great performance.

The efficiency of PV system can be improved by variation of temperature, solar irradiance, shading [2, 3]. Series and parallel resistance are another factors that influence the losses.Previously some researchers gave importance on generalized PV model without considering partial shading [4].Again Partial shading [5] or MPPT [6, 5] was main focus of other authors. While the series resistance R_s and the parallel resistance R_p are discussed in others [7, 8, 9].

The focus of the paper is to develop an effective and complete PV system to manipulate important factors (shading, irradiance, temperature) and investigate a Simulink model with best values of them.

In section II, formation of a PV array is elaborated. Section III consists of the analysis of effect of irradiance, shading and temperature on cell, module and array respectively. The effect of parallel and series resistance on cell are also explained here. Section IV gives a short discussion on the analysis of section III.

II. STEP TOWARDS PV ARRAY

A. Operating Mechanism

The smallest unit of PV array is the PV cell. In a semiconductor material, electron in the valance band excites when it is irradiated and the energy of the photon exceeds the band gap energy of the material creating a hole. The n-type region gets rich of electrons and p-type region of holes because of the depletion region. This leads to a photo generated current flow if the PV cell is connected to an external circuit as shown in Fig. 1.

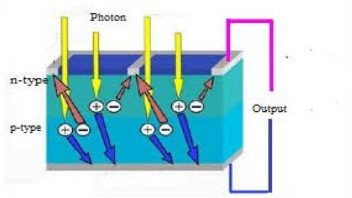

Figure 1. Process of producing photo-generated current and voltage.

B. Equivalent model of a PV cell

An equivalent model is developed to simulate a PV cell which contains a current source representing the photo generated current I_L with a diode connected in parallel can replace a PV cell. The p-n junction is represented by the diode. The external behaviour of the model is represented by a resistance in parallel named Rp and in series named Rs as shown in Fig. 2.

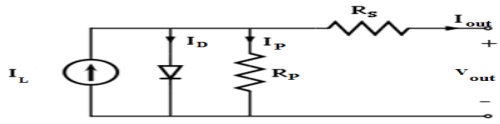

Figure 2. Equivalent model of a PV cell.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

The output voltage and current equations of a PV cell for this model are given below.

$$I_{out} = I_L - I_0(e^{\frac{qV_d}{mkT}} - 1) - \frac{V_d}{R_p} \quad (1)$$

$$V_{out} = V_d - I_{out}R_s \quad (2)$$

Here, output current is represented by (1) and output voltage by (2). In this equations above I_{out} is the output current, I_L is the photo generated current, R_s is the series resistance, R_p is the parallel resistance, I_0 is the Reverse saturation current is the electron charge (1.602 X 10^{-19}C), m is the diode ideality factor (for an ideal diode its 1), k is the Boltzmann constant (1.38 X 10^{-23}J/°K), T is the Temperature, V_d is p-n junction diode voltage. The output current is dependent on the series and parallel resistance, short circuit current and open circuit voltage, irradiation and reverse saturation current. Newton-Raphson method is very useful for solving non-linear equation which depends on numerical approximation. So V_d can be calculated by using Newton-Raphson method by using the best values of R_p and R_s randomly. The numerical process is done following the given flow chart in Fig. 3.

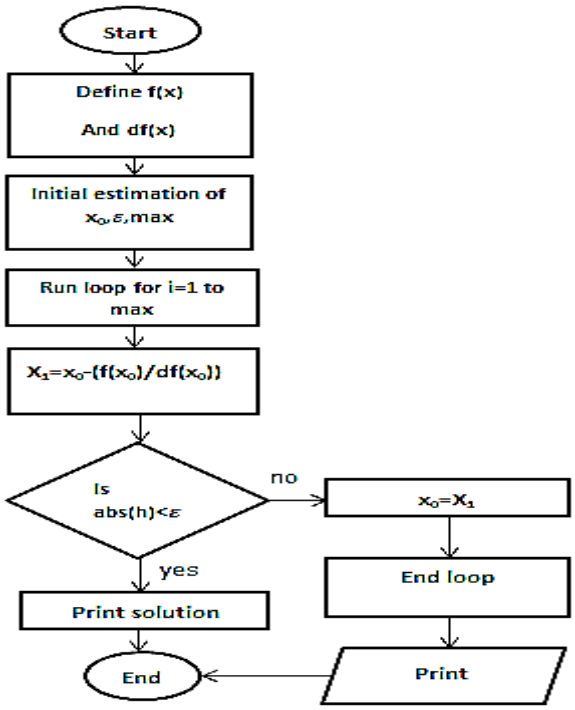

Figure 3. Algorithm of Newton-Raphson method.

C. Construction of PV module and array

To increase the total amount of voltage, PV cells are connected in series. A PV module is formed by connecting 28 to 36 PV cells as shown in Fig. 4. The total voltage is equal to the summation of the individual voltages. A PV array fulfills a desired amount of voltage as in Fig. 5 by connecting the modules in series and parallel forms. Each series branch in array is called a string.[15].

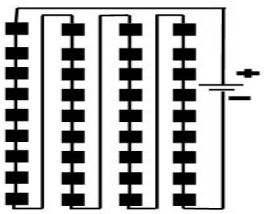

Figure 4. PV module scheme

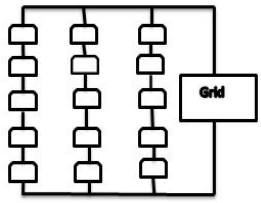

Figure 5. PV array diagram.

III. SIMULATION AND ANALYSIS

A. Cell analysis

1)Effect of series and shunt resistance on single PV cell: The performance of a cell is determined by the accuracy of series and parallel resistance. The two types of losses in the equivalent model of PV cell are leakage current loss and the losses of the semiconductor. These losses are to be minimized. Fill factor known as curve factor is the ratio of maximum power and the product of short circuit current and open circuit voltage. A large fill factor is expected.It usually ranges from 0.5 to 0.88[14-16].

$$F.F. = \frac{P_{max}}{V_{oc}.I_{sc}} = \frac{V_{max}.I_{max}}{V_{oc}.I_{sc}} \quad (3)$$

A method by which the values of R_s and R_p can be determined is using (4).

$$R_p = \frac{V_{out} + I_{out}.R_s}{I_L - I_{out} - I_0[e^{\frac{q(V_{out}+I.R_s)}{mkT}} - 1]} \quad (4)$$

Best values of R_s and R_p were assumed in order to analyze the effect of resistance. The value of V_d was estimated by using (1) and (2) on the basis of taking initial value zero. The algorithm of Newton-Raphson method used for this purpose is as Fig.3. For the required analysis, in the first case parallel resistance is taken approximately 6 Ω and series resistance is given as 0 Ω. In the second case, Rp and Rs are given as 6 Ω and 0.006 Ω respectively. In the third case, the value of R_p is made 0.06 Ω keeping R_s 0.006 Ω. The short circuit current increases but power decreases as series resistance and also parallel resistance increases as shown in Fig.6 and Fig.7. The fill factor also increases in this case.

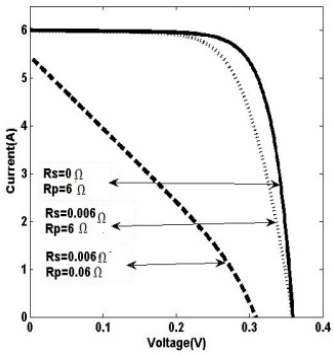

Figure 6. The influence of series and parallel resistance on I-V curve for a cell.

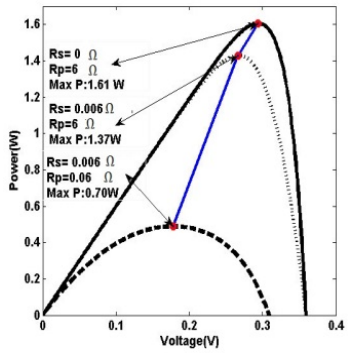

Figure 7. The influence of series and parallel resistance on P-V curve for a cell.

2)Effect of temperature on single PV cell: The reverse saturation current depends on temperature [14,15]. The performance of the PV cell is highly dependent on temperature variation. The reverse saturation current decreases with increasing temperature as from (1).

$$I_L = I_L(T_1) + K_0(T - T_1) \tag{5}$$

$$K_0 = \frac{I_{sc}(T_2) - I_{sc}(T_1)}{T_2 - T_1} \tag{6}$$

$$I_0 = I_0(T_1) \times \left(\frac{T}{T_1}\right)^{3/n} \times e^{\frac{qV_d T_1}{nk\left(\frac{1}{T} - \frac{1}{T_1}\right)}} \tag{7}$$

$$I_0(T_1) = \frac{I_{sc}(T_1)}{e^{\frac{qV_{oc}(T_1)}{nkT_1}} - 1} \tag{8}$$

The relation between photo generated current of T_1 and T can be expressed by (5). MATLAB was used to implement these equations. T is 25°C and T_1 is 75°C. The ratio of difference between short circuit current at T_1 and T_2 and the difference between the corresponding temperatures is K_0. I_0 is the reverse saturation current.

Concerning the temperature variation in Bangladesh, the variation is observed at 15°C, 25°C and 35°C and thus I-V and P-V characteristics curves are drawn as in Fig.8 and 9. These curves match with the ideal characteristics. At fixed irradiation=1000W/m^2, the reverse saturation current decreases with increasing operating temperature and so the open circuit voltage decreases but the short circuit current increases slightly.

With increasing temperature, the current increases but it cannot minimize the effect of decreasing short circuit voltage. As a result as temperature increases, MPPT seems to decrease. As shown in Fig.9, the maximum power point shifts up-ward. The MPPT was calculated 1.68W, 1.46W and 1.16W respectively at 15°C, 25°C and 35°C by MATLAB simulation. It is better to keep the temperature low. For the PV system described in this paper, temperature is chosen 25°C.

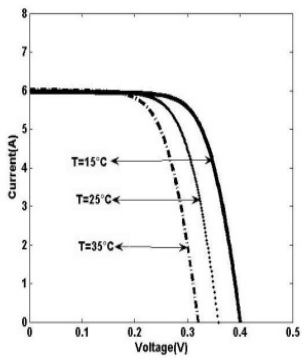

Figure 8. The influence of temperature on I-V curve for a cell.

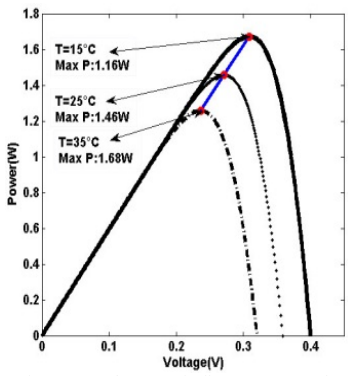

Figure 9. The influence of temperature on P-V curve for a cell.

*3)Effect of different solar irradiation on single PV cell:*Irradiation is an important effect to analyze. As it causes photo generated current to flow and at high irradiation [13, 14, 15].

$$I_L(T_1) = I_{sc}(T_1, G_{nom}) \times \frac{G}{G_{nom}} \tag{9}$$

The equation of photo generated current is given above where $I_L(T_1)$ is the photo generated current at $T_1$where T_1 is 25°C, G is the irradiance of 1000W/m^2 and G_{nom} is the irradiance which was varied. I_L is the photo generated current at 25°C and I_{sc} is the short-circuit current at 25°Cand at 1000W/m^2.

I-V and P-V curves are found by using equation (9) in MATLAB. The irradiances are taken as 1000 W/m^2, 1500 W/m^2, 2000 W/m^2. As irradiation increases, current is produced as seen in Figs. 10 and 11 which increases the open circuit voltage. This occurs because photo generated current increases at high solar irradiation. The power also increases as 0.89W, 1.38W, 1.86W shifting the maximum power point upward. So irradiance is kept at 1000 W/m^2 throughout.

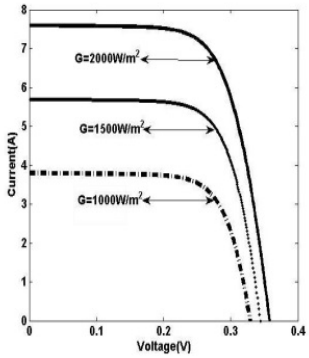

Figure 10. The influence of irradiance on I-V curve for a cell.

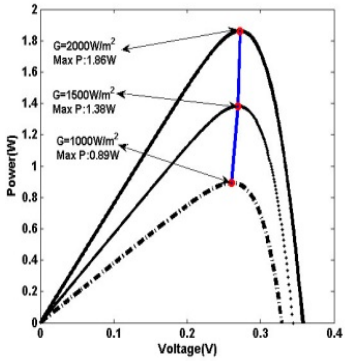

Figure 11. The influence of irradiance on P-V curve for a cell.

B. Module Analysis

By connecting 36 PV cells in series, PV module is constructed for better and accurate result. So total voltage is multiplied cell number times but the current remains constant. The cell number may be varied.

1) Effect of shading on PV module: When uneven shading is taken into account, I-V and P-V curves are slightly different. Because the heat produced by the shading effect affects the module. Shaded cells act as load. It draws current from fully illuminated cell and reduces the output power significantly. The operations are carried out on the basis of the following equations:

$$I_c = (1 - p_i)I_L - I_0\left(e^{\frac{qV_{di}}{mkT}} - 1\right) - \frac{V_{di}}{R_p} \tag{10}$$

$$V_{ci} = V_{di} - I_c.R_s \tag{11}$$

$$V_s = V_{c1} + V_{c2} + ... + V_{c(n-1)} + V_{cn} \tag{12}$$

Here, V_{di} and V_{ci} are the p-n junction diode voltages and output voltages of the *i*th PV cell, I_L is the full sun photo generated current and pi is the shading factor of the ith cell. By varying the p_i, the shading effects are taken as 0%, 40% and 80% for uneven shading.

More power is consumed and the terminal voltage is also changed when the charge carriers of the un-shaded cell flow through the shunt resistance of the shaded cell. To make the electrons flow through the shaded cells, more voltage is consumed and so the terminal voltage decreases during each kind of shading but the short circuit current remains constant. The output power decreases with the increasing shading factor because current is constant and terminal voltage decreases. During 0% shading, output power is maximum. The output maximum powers obtained are 45.68W, 50.38W and 52.54W for 80%, 40%and 0% shading respectively by simulating the equations in MATLAB. The characteristics are shown in Figs. 12 and 13.

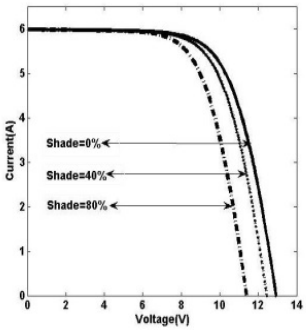

Figure 12. The influence of shading on I-V curve for a module.

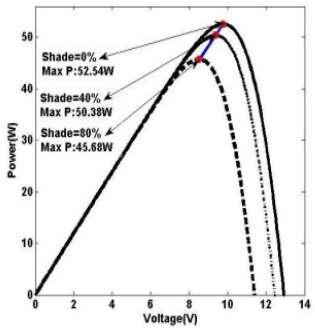

Figure 13. The influence of shading on P-V curve for a module.

2) Effect of Bypass Diode on PV Module: Bypass diode is connected in parallel with PV cells in opposite direction to reduce the impact of shading analyzed previously. Normally a bypass diode is connected in parallel with the series PV cells as in Fig**.** 14. This creates a bypass way for the current generated in the other unshaded cell [13]. The equations used for simulation are given below:

$$I_{ci} = (1 - p_{ij})I_L - I_0(e^{\frac{qV_{di}j}{mkT}} - 1) - \frac{V_{dij}}{R_p} \quad (13)$$

$$V_{pdi} = V_{ci1} + V_{ci2} + ... + V_{ci(n-1)} + V_{ciL} \quad (14)$$

$$V_{cij} = V_{dij} - I_{ci}.R_s \quad (15)$$

$$I_s = I_{ci} + I_0(e^{-qV_{pdi}/mkT} - 1) \quad (16)$$

$$V_s = V_{pd1} + V_{pd2} + ... + V_{pd(m-1)} + V_{pdM} \quad (17)$$

Here, V_{dij} and V_{cij} are p-n junction diode voltage and PV cell output voltages of the *j*th PV cell within the *i*th bypass diode group, p_{ij} stands for the shading factor relevant to the full sun condition for the *j*th PV cell within the *i*th bypass diode group, I_{ci} is the output current of the series PV cells within the *i*th bypass diode group, and V_{dpi} represents the voltage applied to the *i*th bypass diode. i is the number diode and j is the number of cell and L=N/M is the number of PV cell group where one bypass diode is connected.

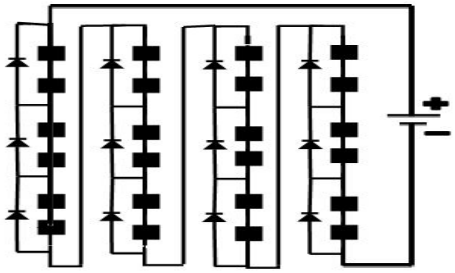

Figure 14. PV array diagram where 3 series branches, containing 6 PV modules, are connected in parallel to complete the array.

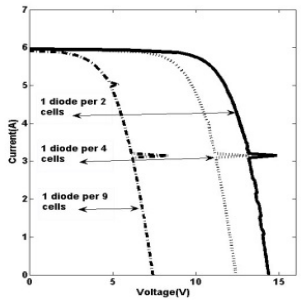

Figure 15. The influence of bypass diodes on I-V curve for a module.

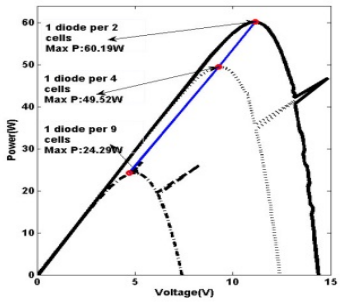

Figure 16. The influence of bypass diodes on P-V curve for a module.

From Fig**.**16**,** the less the PV cells are under one bypass diode, the less is the power consumption as seen from simulation. Because the shaded power absorption is reduced in this case and so bypass diode is added for 2, 4 and 9 PV cells respectively. The open circuit voltage increases with the maximum output power increase when less PV cells are under one bypass diode as in Fig. 15. Maximum output power obtained are 24.29 W, 49.52 W and 60.19 W when 9, 4 and 2 PV cells respectively are connected under one bypass diode. While adding one diode with each 4 PV cells maximum output power is 49.13 W. This output is increased at 60.19 W in case of reducing PV cells to 2.So better output can be produced by reducing the number of cells under one diode.

3) Effect of temperature and irradiance on PV module: The effect of temperature on the output current, voltage and power of PV module matches with that on PV cells. As voltage decreases, the power decreases with the increase of temperature. Short circuit current is constant and the simulation is done according to section III. The maximum powers are 60.33W, 52.55 W and 45.32W for the above temperatures respectively. The I-V and P-V curves with the variation of temperature are shown in Figs.17 and 18. [13,14,15] when irradiance is kept constant at 1000W/m^2.

Greater irradiance gives better results in case of PV module. This is verified by simulation as done in section III using Equation (9). The irradiance is changed as 1000W/m^2, 1500W/m^2 and 2000W/m^2 while both the short circuit current and open circuit voltage increases as in Fig. 19. The cause of increasing photogenerated current is same as explained in

section III. The maximum power point shifts upward as 32.9W, 49.91W, 66.41W.

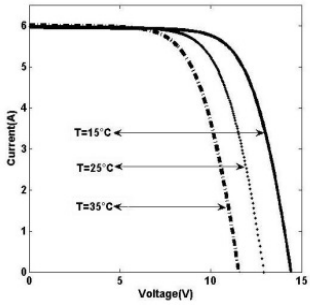

Figure 17. The influence of temperature on I-V curve for a module.

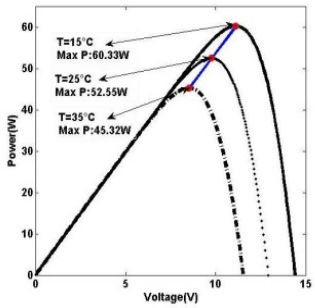

Figure 18. The influence of temperature on P-V curve for a module.

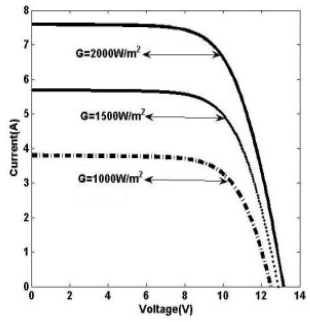

Figure 19. The influence of irradiance on I-V curve for a module.

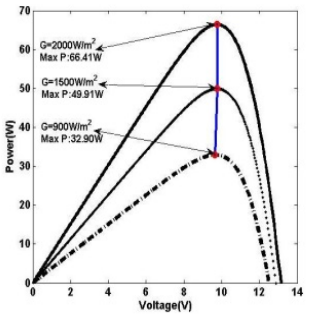

Figure 20. The influence of irradiance on P-V curve for a module.

C. Array Analysis

PV array and module shows similar characteristics.3 strings are connected in parallel consisting of 6 modules to design a 1KW PV system in the array.

*1) Effect of shading and bypass diode on PV array:*Maximum power is obtained for shading of PV array when shading is 0%. For increased shading, the output powers are 945.8 W, 906.91W and 822.24 W respectively at 0%, 40%, 80% as in Fig. 22. As seen in Fig. 21 the open circuit voltage decreases and this can be improved by using bypass diode as in Fig. 24. Power increases as 0.35 KW, 0.81 KW and 1.01 KW for 9,4 and 2 PV cells respectively under each bypass diode. By reducing the cell number by half under one bypass diode, the maximum power increases from 0.81 KW to 1.01 KW as shown in Fig. 24.

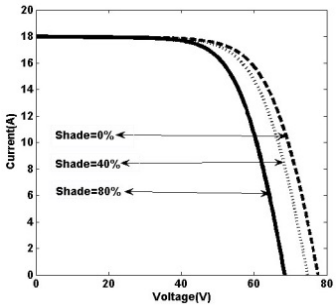

Figure 21. The influence of shading on I-V curve for an array.

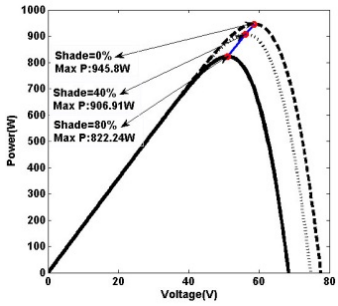

Figure 22. The influence of shading on P-V curve for an array.

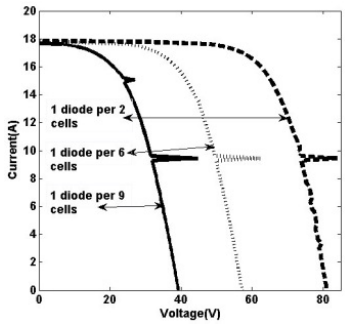

Figure 23. The influence of bypass diodes on I-V curve for an array.

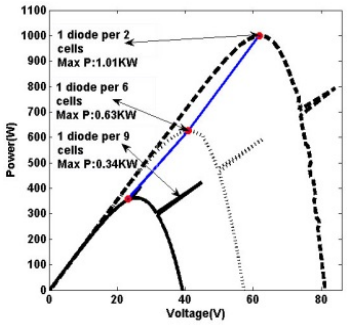

Figure 24. The influence of bypass diodes on P-V curve for an array.

*2) Effect of temperature and irradiance on PV array:*The maximum output powers are 1.09 KW, 0.95 KW and 0.82 KW for 15°C, 25°C, 35°C are obtained by simulating the equations of section III in MATLAB. This is shown in Fig. 26. With the increase in temperature, the open circuit voltage decreases as shown in Fig. 25. The theory used here matches with section III. The irradiances are considered as 2000W/m^2, 1500W/m^{2}and 1000W/m^2 for convenience and the corresponding output powers are 1.19 KW, 0.9 KW and 0.59 KW obtained from MATLAB simulation. These effects are well understood from the curves in Fig. 27 and 28.

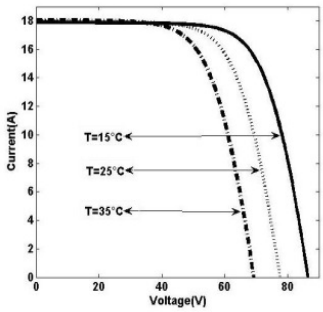

Figure 25. The influence of temperature on I-V curve for an array.

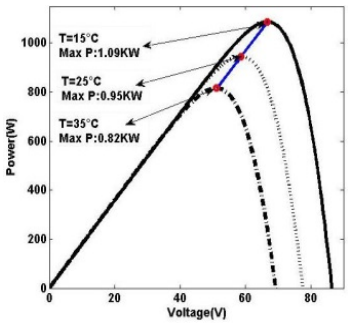

Figure 26. The influence of temperature on P-V curve for an array.

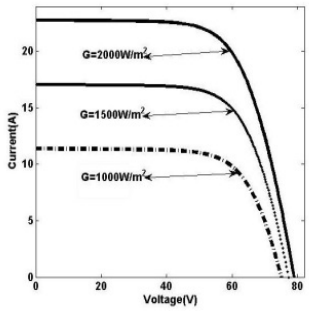

Figure 27. The influence of irradiance on I-V curve for an array.

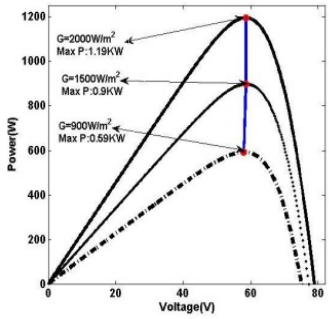

Figure 28. The influence of irradiance on P-V curve for an array.

3) Simulink Model of an array: A Simulink model is built to get around 5000 watt output power from a PV array. Built in PV cell of MATLAB was used in this purpose. A PV module of 20 PV cell is taken. It generates 250 W. And 1 string is prepared taking 4 modules in series. 2 such strings are

connected in parallel. The output is taken at solar irradiance of 1000W/m^{2}at 25°C. The Simulink model is shown in Fig.29.

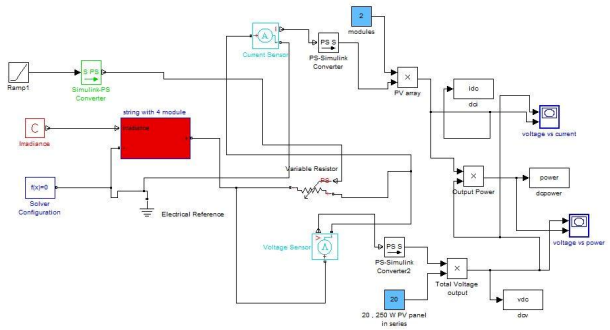

Figure 29. Simulink model for almost 1KW maximum power output.

After developing the Simulink model, the graphs are obtained as shown in Fig. 30 and Fig. 31. Analyzing the graphs it is seen that maximum output power is obtained as 5.05 KW. Under this condition V_{out} is 1129 volt and I_{out} is 5.87 Amp. R_s of 0.006Ω and R_p of 6 Ω are used. For developing the Simulink model, solar irradiation of 1000 W/m^2 and temperature of 25°c is considered.

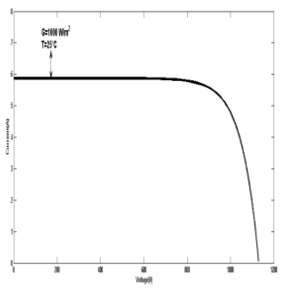

Figure 30. I-V characteristics curve for the Simulink model.

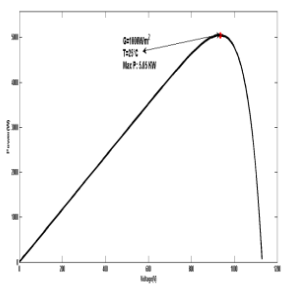

Figure 31. P-V characteristics curve for the Simulink model.

A table showing all the Electrical characteristic data of the Simulink model is as following:

TABLE I. ELETRICAL CHARACTERISTICS DATA OF THE SIMULINK MODEL

Electrical Characteristics	Values
Maximum Power	5.05 K Watt
Voltage at Maximum Power	931.2 Volt
Current at Maximum Power	5.41 Amp
Open Circuit Voltage	1129 Volt
Short Circuit Current	5.87 Amp
Series Resistance	0.006 Ω
Parallel Resistance	6 Ω
Fill Factor	0.76

IV. CONCLUSION

In the preceding sections, simulation in MATLAB was done to analyze the behavior of PV cell completely, module and array. With a view to this, different influencing factors such as temperature, irradiance, shading, series and parallel resistance are varied to observe the change in the output power. And thus the methods of improving the output performance are mentioned. All the analyses are done using the best values in MATLAB. Along with the above works, a solar panel with an output of 5 KW is designed. This work can further be used to get the maximum output from a solar panel eliminating the effects of various internal and external factors. The analyses done in the paper may be expanded in hardware side too for further study, implementation and improvements.

***Abstract*—As a tropical country Bangladesh receives a substantial amount of solar insolation suitable for PV application. Being an agricultural economy, the irrigation need is increasing day by day. Use of diesel run pumping system is neither cost effective nor environment friendly. Even though 47.8% of the total irrigation pumps are diesel run which emits a huge amount of CO2 and other toxic gases. In this paper a typical year round irrigation load has been modelled and used to analyze the feasibility of replacing diesel irrigation pumps with solar PV powered motor-pump systems in HOMER. It was found that stand alone operation of diesel powered pumps are not at all cost effective. PV powered pumps are more feasible than a hybrid PV-Diesel Generator-Battery powered pump systems if it has a larger storage tank. If storage tank is not available then excess electricity fraction rises up to 84% which can be used in residential needs or can be used in other agricultural needs.**

***Keywords*—Feasibility of solar irrigation; Sustainable irrigation; Photovoltaic pumping; Green farming; Green energy.**

I. Introduction

Agriculture is the vital component of the economy of Bangladesh in terms of GDP share and also lifestyle. The rural economy contributes 60% of the GDP [1] which mostly comes from the agricultural sector. Irrigation is an essential component of this agriculture. Proper irrigation at proper time increases the yield of crop significantly. Due to climate change and intensive agricultural practices of changing crops and cropping patterns the demand for irrigation water increased a lot [1]. Besides this, expansion of High Yielding Variety (HYV) rice cultivation increased the need for groundwater irrigation which is 73% of the total irrigation need [2]. To lower the cost of energy (COE) and increase the renewable fraction in the energy basket we have to use renewable solutions like solar photovoltaic energy, wind energy or other type of renewable energy in the irrigation sector as well.

A design and analysis of low cost solar water pump for irrigation in rural Bangladesh was done by researchers of Bangladesh University of Engineering & Technology [16]. Some researchers have also studied the prospect of hybrid solar irrigation system in Bangladesh [17]. Practical set up of solar irrigation pump system was done by various groups from industry and local people. Direct coupling of pump with solar panel for sustainable irrigation is also investigated by Bangladesh University of Engineering & Technology [18]. Application of photovoltaic array for water pumping as an alternative to diesel engines is investigated by various researchers of the world [12-15, 19-20].

In this work, a pre-feasibility study was done to see the optimal condition to replace the diesel powered irrigation pumps with solar PV powered motor-pumps in Bangladesh.

II. Present Irrigation Scenario of Bangladesh

Presently, in 2013-14 there were around 1630866 unit irrigation pumps in operation among which 96% are Shallow Tube Well (STW) and 2% Deep Tube Wells (DTW) and 2% Low Lift Pumps (LLP) [3]. The average elevation of Bangladesh from sea level is very low and static head of surface water is less than 20-30 m in most of the places [3]. Figure 1 shows the present ground water depth in different areas of Bangladesh.

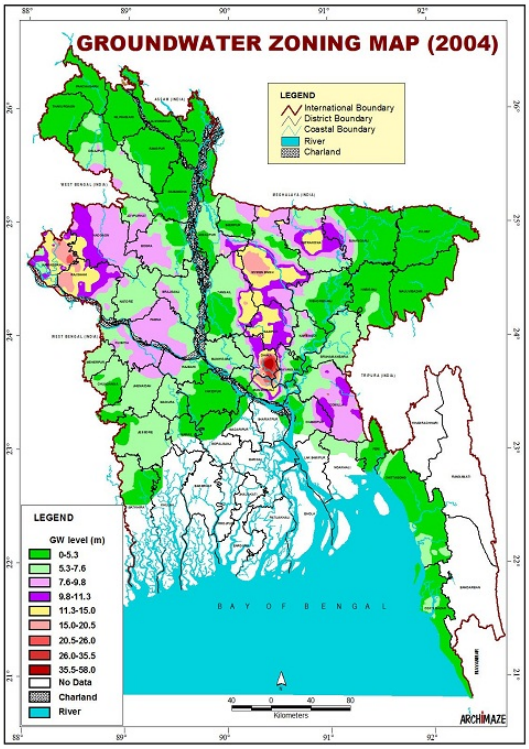

Fig. 1. Groundwater zoning map of Bangladesh [4].

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

Because of this low ground water depth STWs are most popular in irrigation systems of Bangladesh. Figure 2 illustrates the irrigation pump units in 2012-13 and 2013-14 and their fuel mix. Number of irrigation pump units increased 58.8% in 2013-14 than that of 2012-13 and the number of electricity run units were very small in numbers in 2012-13 but in 2013-14 it increased 5 times. The reason behind this is governments declaration of low price of electricity for irrigation (2.51 BDT/unit) and high demand for irrigation water [5]. Whereas number of diesel run units decreased only 8% in 2013-14. From this scenario it is clear that the demand for irrigation water will increase significantly in the next upcoming years and satisfying this stepper demand with grid electricity will be quite impossible. As diesel run pumps cannot be a sustainable solution of this problem we need to find renewable sources to satisfy this demand as well as to replace the diesel run machines to ensure a sustainable irrigation system for future Bangladesh.

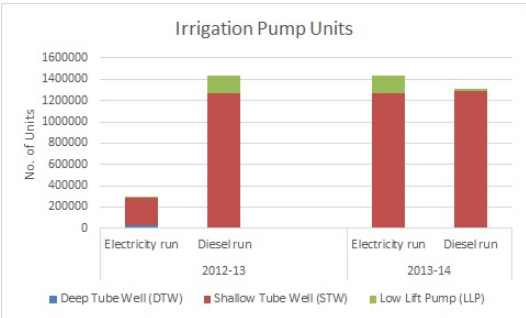

Fig. 2. Distribution of irrigation pump units according to their fuel consumption [3].

III. Characteristics of Solar PV powered motor-pumps

To calculate the working water head of the pump Koner [13] has given the following formula :

$$h = K_1(w^p)^2 - K_2(w_0 - w^p)^2 \tag{1}$$

where,
h: working water head, (m), w_p: pumping speed $(rads^{-1})$
K_1: voltage dependent water head constant, $m(rads^{-1})^{-2}$
K_2: flow rate dependent water head constant, $m(rads^{-1})^{-2}$
w_0: the speed of motor-pump system at no-flow condition, $(rads^{-1})$

The relation of water discharge to water head of the pump was given by Braunstein and Kornfield [14] as:

$$Q = K_3(h_0 - h)^{1/2} = K_3K_2^{0.5}(w_0 - w^p) \tag{2}$$

where,
Q: flow rate of a pump (ls^{-1}),
h_0: water head of a pump at no-flow condition, (m),
K_3: flow speed constant, $(ls^{-1}m^{-0.5})$
The speed-torque relationship is given as:

$$T^p = K_4(w^p)^2 \tag{3}$$

where,
T^p: pump torque, (Nm), K_4: flow-water head constant of a pump, $(ls^{-1}m^{-1/2})$
The equations for DC series motor was deduced by Hsiao and Blevins [15] as follows:

$$V^m = MI^m w^m + I^m R_t \tag{4}$$

$$T^m = M(I^m)^2 \tag{5}$$

$$M = M_0(w^m/(w_0^m)) \tag{6}$$

where,
V^m: motor terminal voltage, (V),
M_0: motor constant, (NmA^{-2})
I^m: armature current of a motor, (A)
w^m: motor shaft speed, $(rads^{-1})$
R_t: Field coil and armature resistances of motor, (ω)

Finally, the efficiency of the motor pump is given by Kolhe, Joshi, and Kothari [12] as:

$$\eta_{mp} = \frac{\rho g Q H}{VI} \tag{7}$$

and the overall efficiency as:

$$\eta = \eta_e \eta_{mp} \tag{8}$$

where,
η_e: PV array efficiency, Q: flow rate, (m^3s^{-1})
H: head of water, (m), g: constant of gravity $(9.81ms^{-2})$
ρ: density of water, (kgm^{-3})

IV. Availability of Solar Energy and Precipitation in Bangladesh

The requirement of irrigation for crops depends on mostly two factors- amount of rainfall and solar insolation. Bangladesh receives most of its rainfall (around 90%) in the monsoon from June to September [6] as shown in fig. 3. In the other months due to lack of rainfall crop production is hampered. So we need to irrigate the crops from surface water in those months.

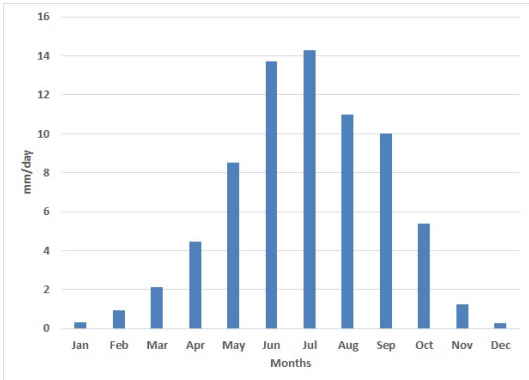

Fig. 3. Monthly Averaged Yearly Precipitation: 22 years average (1983-2005) [7].

On the other hand solar insolation level is pretty high from 4-5 kWh/day around the year [7] which ensures the potential

of solar power harvesting for irrigation in Bangladesh. In fig. 4 the 22 years average of monthly averaged daily solar insolation and clearness index is shown. The effectiveness of solar powered irrigation pump mostly depends on the solar radiation received and thus Bangladesh is a very suitable place for solar irrigation. Besides this, we can use a storage tank to harvest rain water.

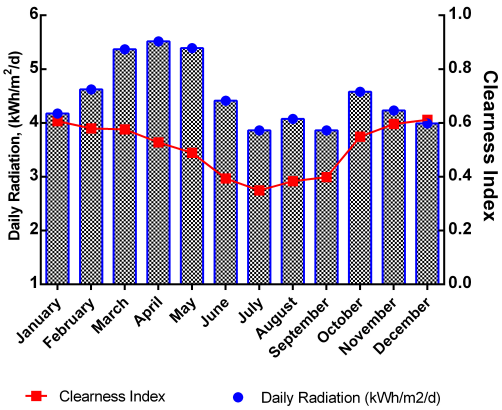

Fig. 4. Monthly averaged daily solar insolation with superimposed clearness index [7].

V. Modeling the Irrigation Pump System in HOMER

HOMER is a micropower optimization and simulation software developed by National Renewable Energy Laboratory (NREL), USA. The word HOMER came from the abbreviation of "Home Energy". It simulates the operation of a system by calculating energy balance equations for 8,760 hours in a year and compares the solutions with different possible configuration and finds the best possible and economically suitable solution [8].

As irrigation water requirement is not a primary load and can be deferred for a later time the load was modelled as a deferrable DC load in HOMER. The deferrable load, PV arrays and a battery element was connected in the DC bus, and a diesel powered AC generator was added in the AC bus coupled with a converter to power the DC bus. The schematic diagram is shown in fig. 5.

A. Modeling the deferrable load

Irrigation for crops can be delayed for 1-3 days without any disturbance in the production process [4]. Therefore we have assumed our load to be a deferrable load. A deferrable load is an electrical load that must be met within some time period, but the exact timing is not important [9]. Loads are normally classified as deferrable because they have some storage associated with them. In irrigation system we can use a storage tank, pond or canals as the storage system for the deferrable load.

Three different crops were taken to find the average water requirement per hectare land. The average water need was calculated as shown in the table 1 [10].

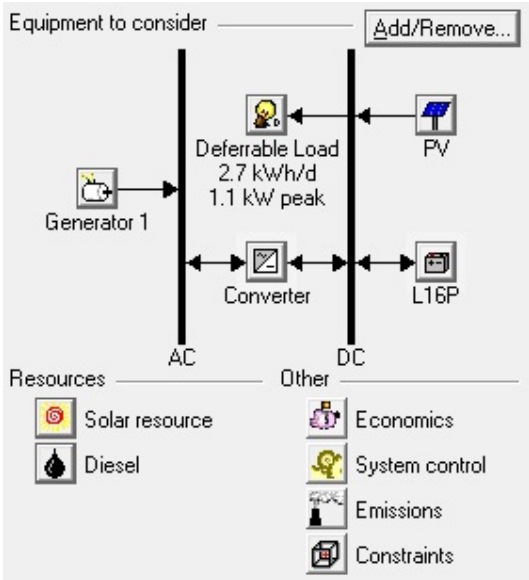

Fig. 5. Schematic diagram of the simulation in HOMER

TABLE I
Average monthly water need for crops

Name of the crops	Required Water Volume (m3/hectare)	Average (m3/hectare/year)	Average (l/hectare/month)
Rice	850		
Wheat	700	750	62500
Cotton	700		

A typical 1.1 kW solar pump has a flow rate of 55 LPM with 20m water head [11]. So, at rated power the solar pump can lift 3300 lit/hour. Ten hectares of sample land was taken to irrigate per day and therefore taking these values and the amount of precipitation approximate values of monthly averaged daily water pumping load was calculated as shown in table 2.

As the time of rainfall over the year is uncertain so 0.5 kWh/day load was added for supplementary irrigation need during May September. Figure 6 shows the daily load profile of our deferrable load.

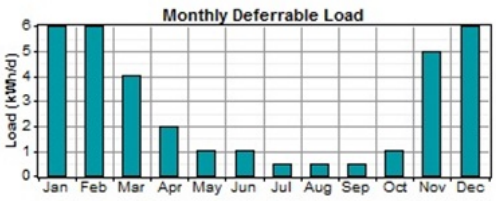

Fig. 6. Monthly average daily deferrable water pumping load modeled for HOMER.

B. Other input parameters

The present market condition was analyzed to find the current prices of PV arrays, diesel generator set, converter and batteries. Table 3 lists the other input values given in HOMER.

TABLE II
CALCULATION OF MONTHLY AVERAGED DAILY WATER NEED AND ENERGY REQUIREMENT.

Month	Average water requirement (l/hectare/month)	Rainfall (l/hectare/month)	Average irrigation requirement (l/hectare/month)	Average irrigation requirement (l/10hectare/day)	Average Energy need, kWh/day
Jan	62500	300	59500	19833.33	6.01
Feb	62500	9200	53300	17766.66	5.38
Mar	62500	21300	41200	13733.33	4.16
Apr	62500	44400	18100	603.33	0.18
May	62500	85100	-22600	-7533.33	0
Jun	62500	137000	-74500	-24833.3	0
Jul	62500	143000	-80500	-26833.3	0
Aug	62500	110000	-47500	-15833.3	0
Sep	62500	100000	-37500	-12500	0
Oct	62500	53800	8700	2900	0.87
Nov	62500	12500	50000	16666.66	5.05
Dec	62500	2800	59700	19900	6.03

TABLE III
DIFFERENT INPUT VALUES OF DIFFERENT COMPONENTS

Name of the Component	Cost ($/kW)	Replacement Cost ($/kW)	Operation & Maintenance Cost	Sizes to consider
PV array	1000	900	$ 0 (/year)	0,1-10 kW
Diesel Generator	600	500	$ 0.05 (/hr)	0,1,2,4,6,8 kW
Converter	500	400	$ 50 (/year)	0,2,4,6,8 kW
Trojan L16P Battery	300 (per piece)	200 (per piece)	$ 30 (/year)	0,2,4,6,8

C. Sensitivity Variables

A sensitivity analysis can be performed by HOMER by entering multiple values for a particular input variable. An input variable for which multiple values are specified is called a sensitivity variable [9]. HOMER repeats its optimization process for each value of that variable and lets you see how the results are affected.

As we want to see the feasibility of replacing diesel generator with PV powered motor-pump system several sensitivity variables was used to find the best possible solutions. Table 4 lists all the sensitivity variables used in HOMER.

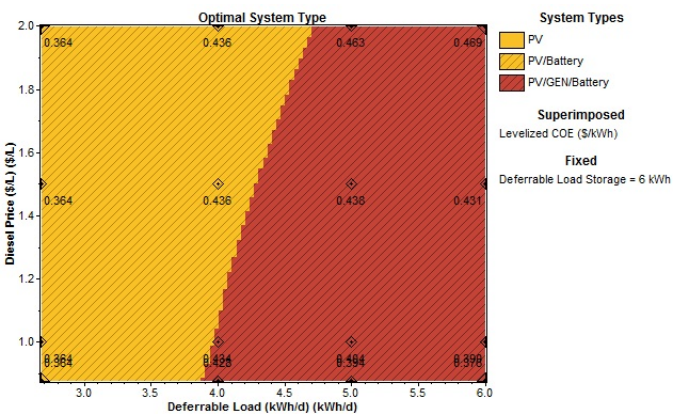

Fig. 8. Effect of diesel price.

VI. ANALYSIS AND RESULTS

After doing the analysis HOMER gives the optimal system type graph superimposed with levelized Cost of Energy (COE)

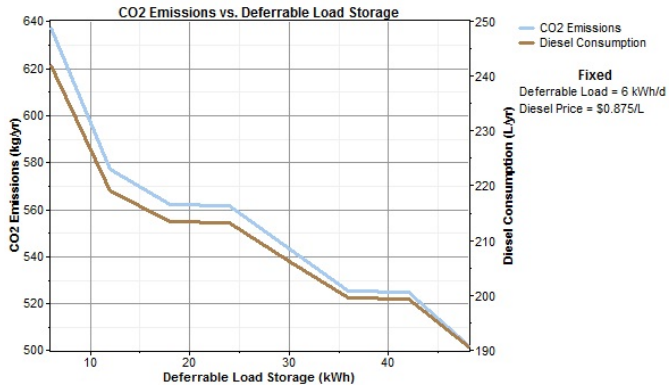

Fig. 9. CO_2 emission vs. deferrable load storage.

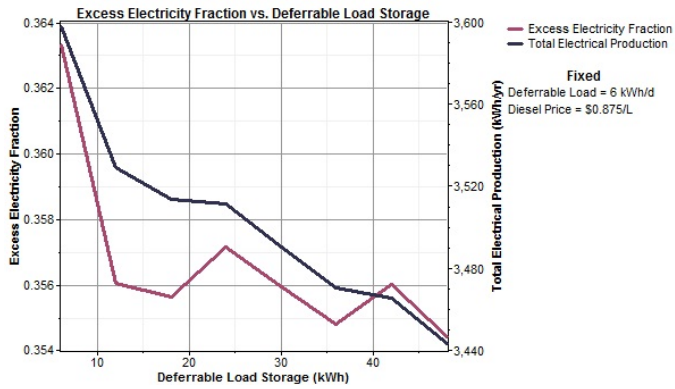

Fig. 10. Excess electricity fraction Vs. Deferrable load storage.

TABLE IV
SENSITIVITY VARIABLES

Sensitivity Variable	Input Values	Reason why this sensitivity variable was used
Deferrable Load (kWh/day)	2.67 (scaled annual average), 4, 5, 6	To find the optimum system with variable load.
Deferrable Load Storage Capacity (kW)	6, 12, 18, 24, 30, 36, 42, 48	To see how water storage capacity affects the output of the system
Diesel Price ($)	0.875 (present cost), 1, 1.5, 2	To find optimum system with a higher diesel price.

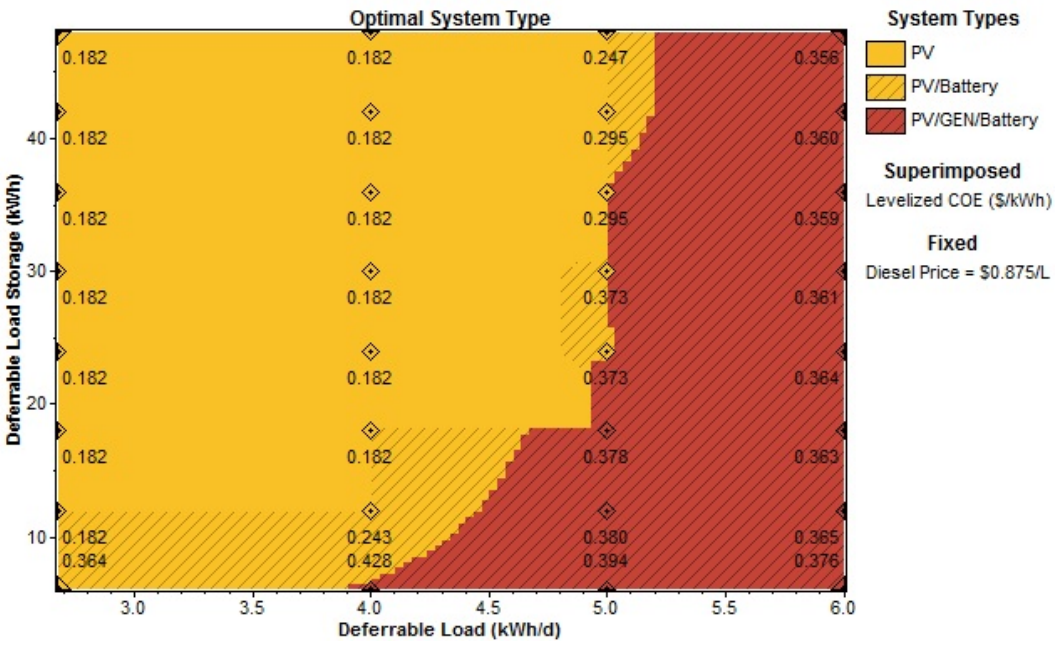

Fig. 7. Optimal system type superimposed with Levelized COE.

as shown in fig. 7. It is evident that PV has the most dominant portion in the graph. With low deferrable load storage PV needs battery backup but with high storage PV itself is sufficient. The levelized COE is as low as $0.182 with PV in operation. Interestingly using only diesel generator is not at all feasible as there is no portion of the graph with only generator shown.

By changing the axis in HOMER we can also find the graph of optimal system type with variable diesel price as shown in fig. 8. It is evident that as the diesel price increases PV becomes more feasible.

Using the line graph option fig. 9 10 shows the CO2 emissions and excess electricity fraction with the change of deferrable load storage. It is very clear from the graph that if there is low deferrable load storage which is water storage tank in our case, there will be a frequent need for diesel generator operation. PV arrays need solar insolation which is not a continuous source of energy and therefore use of a larger storage tank is important. With a larger storage tank added in the pump system will give higher system stability with lower possible COE.

Besides this, lower storage capacity will increase the excess electricity fraction significantly which can be as high as 83.2% of the total production. To lower this excess electricity fraction either we have to use larger storage tank or we can supply this excess electricity to local consumers or can run other agricultural equipment.

VII. CONCLUSIONS

From the above analysis the following conclusions can be made:

01. Stand-alone operation of diesel generator for irrigation purposes is not at all feasible in Bangladesh. So, diesel generators should be replaced with PV powered motor-pump systems as soon as possible.

02. Use of a larger water storage tank is very important. CO2 emissions and excess electricity fractions can be lowered to 0% if a larger storage tank is used.

03. If a larger storage tank is not available then the excess electricity can be supplied to the local consumers or can be used in other agricultural energy need.

ACKNOWLEDGMENT

We would like to express our gratitude to Institute of Energy, University of Dhaka for aiding with technical support. We would also like to thank Bangladesh Meteorological Department (BMD), Bangladesh Agricultural Development Corporation (BADC), Bangladesh Agricultural Research Council (BARC), and Dhaka Electric Supply Company Limited (DESCO) for their data and support.

***Abstract*—Rural Distribution Systems (RDSs) are expanding abruptly day by day. With this continuous expansion, the distribution loss is increasing deliberately as a coherent parameter. Constructing single phase HT (high tension) line, it becomes more alarming with respect to loss as well as system management. This paper highlights the advantages of three phase tap lines for the reduction in line loss compared to single phase. A cost analysis is carried out by designing all HT lines of RDSs with three phase taps instead of single phase taps and the obtained result is compared with the single phase tap line. Then, an optimum length of single phase tap line is determined using simplex method for linear programming considering the cost of three phase tap line as a standard. The results show that more area can be electrified using three phase tap lines compared to the single phase tap line with the same cost.**

Keywords—cost analysis; power loss; rural distribution system (RDS); single and three phase tap line; simplex method.

I. INTRODUCTION

The primary objective of a distribution power system design is to deliver reliable power to the remotest consumer with maximum efficiency and minimum cost [1]-[3]. As consumer, so load, is increasing, to meet the objective it is essential to think about the restructuring of power distribution systems [4]-[9].

Bangladesh Rural Electrification Board (BREB), among all the Electricity Distribution Utility of Bangladesh, is the largest having 2,70,000 Km of distribution line with 1,22,00,000 nos. of different category consumers purchasing 18,80,000 MWhr energy per month. The average sales per month is 16,10,000 MWhr to the consumers. Therefore, 2,70,000 MWhr of energy waste as system loss [10], which is 12.92% of the total purchased energy. This loss includes mostly technical loss, as well as minor non-technical loss. One of the important factors to increase technical loss is the design standards and considerations for the construction of HT (High Tension) and also LT (Low Tension) lines adopted so far.

As it is known that from the very beginning BREB follows the standard to construct three phase backbone distribution HT lines of 11 kV voltage with both three phase and single HT taps of 11 kV and 6.35 kV voltage, respectively and both three phase and single phase LT lines of 0.415 kV and 0.23 kV voltage, respectively. Single phase HT and LT lines are taken into consideration considering the lower construction cost for rural people. If we construct a single phase line, we do not have any option to construct other than single phase line until it is renovated or converted. When we start with a few span of single phase line, due to Area Coverage Rural Electrification (ACRE) [11], it becomes a line of fifty spans, even hundred-fifty spans, of single phase line, which ultimately creates operational problem, unbalance system and at the same time increases line loss, consequently system loss.

It is obvious that for the same load, line loss is lesser for a three phase system than that of a single phase [11]. However, the line construction and maintenance cost in a three phase system is higher than that of a single phase system. With the practical hazard for operation management, system management, and loss management, a narrow thinking was started-'Are single phase distribution lines cost effective with all respect?' To be clear from a misty thinking, this research has conducted over both single phase and three phase lines considering line loss, construction and maintenance cost for their whole life, which is normally considered as 30 years for a rural distribution line.

Traditional tapping lines of BREB are single phase which produce an unbalance system due to the loading in phases individually and it is not expected from system management and economical viewpoints. Therefore, three phase power distribution systems may be the right choice for their superior power carrying capability at a reduced cost. However, it needs a rigorous investigation before implementing three phase taps to avoid unnecessary cost.

In this paper, a RDS is designed with single phase and three phase taps for a comparative analysis. Moreover, an Excel Solver [12, 13] is used to calculate the optimum length of the single phase tap lines which determines the area coverage by tap lines in the RDS. The system is optimized using simplex algorithm for linear programming (LP). In the next of this paper, following topics are discussed: Why three phase?, losses in power distribution system, costs considered, Excel solver algorithm, case study and conclusion.

II. WHY THREE PHASE?

A three phase line generates three individual "waves" of power which joins three alternating waves of the same frequency, each 120 degrees out of phase with each other. The power in a three phase power supply never goes down to zero, but in single-phase the power goes down to zero 3 times for every cycle as shown in Fig.1. Thus, in a three phase power supply, the power delivered is constant [14]. To fulfill the requirement of balance system and to avoid neutral **c**urrent in grounded Y-connected line, which incur additional loss, three phase lines are better choice for transmitting power.

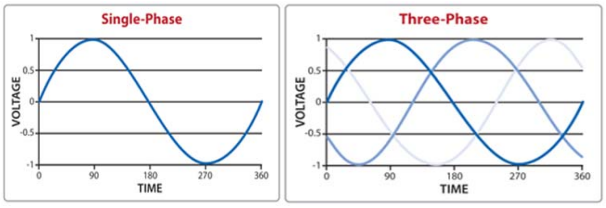

Fig.1. Single phase and three phase wave shape [14].

III. LOSSES IN POWER DISTRIBUTION SYSTEM

Losses in power distribution system is a term which may express as the difference between the total power received by a 11 kV feeder and total power delivered to the individual consumer. If P_R is the power received and P_D is the total power delivered to the consumer connected to this feeder; then power loss P_{loss} will be [11]

$$P_{loss} = P_R - P_D \quad (1)$$

A. Categorization of Losses:

The power distribution losses are commonly classified into two categories: 1) technical loss and 2) non-technical Loss.

1) Technical Losses: Technical losses are internal to the distribution power system and occur in the equipment installed in that system. In RDS, it occurs for the power dissipation in the lines (HT/LT), distribution transformers, junctions and joints, service drops, etc. [15].

2) Non-Technical Losses: Non-technical losses occur due to actions external to the power system, which includes primarily of electricity theft, not running meters and errors in accounting and record-keeping [15].

B. Mathematical Representation of Technical Losses:

In a system, technical loss means the power losses incurred by the physical properties of components connected to it. The power loss, P_{loss} (kWh) is proportional to the total line resistance (R_T) of the conductor and the square of the current (I) flows through that portion of line in Amps [11].

So, power loss is [11]

$$P_{loss} \text{ /Month} = (I^2 \text{ x } R_T \text{ x LsF x Total Hour})/1000 \text{ kWh} \quad (2)$$

where, R_T = No. of phase x R_p x line length in Km
R_p= Resistance per phase per Km of line.
Ls.F. = Loss Factor
= 0.85*(Load factor)^2+0.15*(Load factor) (3)

Load factor is defined as the ratio of average power delivered to the peak load of a certain period. The value of load factor for a 11 kV feeder of the RDS varies between 40% to 60%.

IV. COSTS CONSIDERED

Rural Distribution lines are constructed by both wooden poles and SPC (Spun Pre-stressed Concrete) poles with wooden cross-arms, GI hardware and ACSR (Aluminum Conductor Steel Reinforced) conductors. Taken geographical condition into account, the life of constructed distribution lines is considered to be almost 30 years.

In this paper, to optimize the design cost, following costs are considered [15]:

1) Cost of technical loss unit: The total cost for technical loss is calculated multiplying the technical loss unit (kWh) by per unit rate (Tk.), which occurs for whole of the life if the line is under energized condition.

2) Cost of distribition line construction: The costs for construction of distribution lines include material costs and labour costs, which occur once in its life.

3) Cost of maintenance: The maintenance cost of lines is to maintain the line in working condition which includes reparing, ROW (Right of Way) clearing, etc. This cost also occurs over whole life of the line until it becomes idle.

V. EXCEL SOLVER AS OPTIMIZATION TOOL

The Microsoft Excel Solver is very popular and the most widely used general purpose optimization tool. The Microsoft Excel Solver combines the functions of a graphical user interface (GUI), an algebraic modeling language like general algebraic modeling system (GAMS) or a mathematical programming language (AMPL), and optimizers for linear, nonlinear, and integer programs [12, 13].

The flowchart of the proposed methodology is shown in Fig. 2. The algorithm is described below.

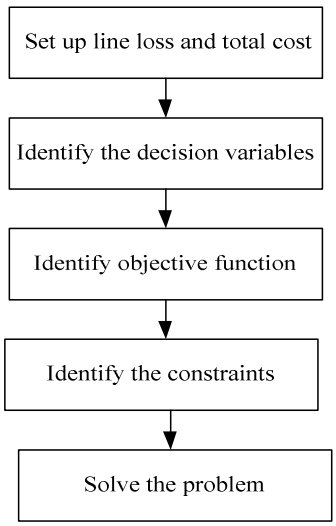

Fig. 2. Flowchart of the proposed methodology.

• *Data set up:* The first step of the proposed method is to set up distribution line loss data and total cost which includes line loss cost, construction cost and maintenance cost of the line.

• *Decision variables:* The decisions of the problem are represented as decision variables. The length of single phase tap is considered here as a decision variable.

• *Objective function:* The objective of the problem is to minimize the total cost incurred by line loss, construction and maintenance cost. For this purpose, the target value is set up which is the difference between the cost of three phase and single phase tap line.

• *Constraints:* The limitations or requirements of the problem are expressed as inequalities or equations in decision variables. The upper and lower limit of the considered tap line is specified as constraints.

The Excel Solver builds a representation of the model suitable for an optimizer by extracting the optimization problem from the spreadsheet formulas. For a linear programming (LP) problem, the focus of this model representation is the LP coefficient matrix, which in general terms, is the Jacobian matrix of partial derivatives of the problem functions (objective and constraints) with respect to the decision variables. For a linear problem, the matrix entries are constant and only need to be evaluated once at the start of the optimization [13].

The Excel Solver uses finite differences and supports all of Excel's built-in functions as well as user-written functions. In calculating finite differences, the [*i,j*]-th element of the Jacobian matrix is approximated by the formula [13].

$$\frac{|f_i(x+\delta e_j)-f_i(x)}{\delta} \quad \text{where } \delta = eps\,|1+x_j| \qquad (4)$$

The solver perform linearity test after it had obtained a solution using the simplex method. It uses these solution values x^* and the initial values x^0 for the variables, to check that the objective and each constraint function $f_i(x)$ until satisfied the following condition [13].

$$|f_i(x^*)-(f_i(x^0)+\nabla f_i(x^0)(x^*-x^0))| \le tol \qquad (5)$$

where $\nabla f_i(x^0)$ is the function gradient and ≥ is the precision value in the solver options dialog box with a default value of 10^{-6}.

The Solver results dialog box is displayed whenever the solver stops and allows the user to keep the solution or restore the original values of the variable cells to generate one or more reports.

VI. CASE STUDY

Let us consider a distribution line feeding from a sub-station, which we shall call as three phase back bone line. Line to line voltage of the backbone line is 11 kV. The line is constructed by # 4/0 ACSR conductor. The feeder backbone line distributes 1.6 MW load. We observe in the next study what will happen, what is the effect on system loss if tap lines from the backbone are constructed single phase and three phase.

A. *When All Taps are Single Phase:*

Consider 10 Km of backbone line for loss calculation. Current feeding at starting point for R-phase is 110 Amps, Y-phase is 85 Amps & B-phase is 75 Amps. For single phase tap the system is unbalance at the starting. A phase balancing is critical for this type of long and loaded single phase tap.

Here in R-phase there are two single phase tap. First tap is 5 Km and second tap is 10 Km apart from the starting point. First tap carries 30 Amps current, second tap carries 60 Amps. In Y-phase there are also two single phase tap. First tap is 3 Km and second tap is 8 Km apart from the starting point. Here, first tap carries 30 Amps current, second tap carries 45 Amps. In B-phase there are two single phase tap. First tap is 4 Km and second tap is 9 Km apart from starting point. First tap bears 30 Amps current, second tap carries 36 Amps. The connection and currents are shown in Fig. 2 given below:

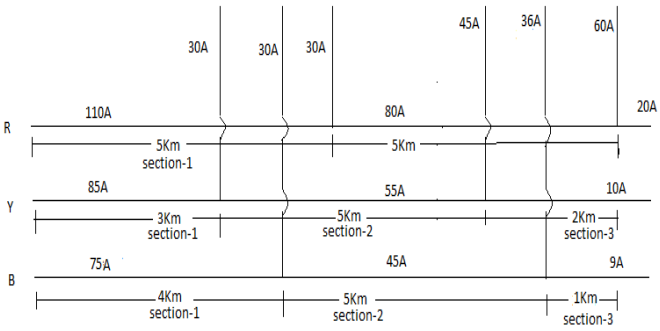

Fig. 2. Three phase system with single phase tap

For simplicity we consider load factor=0.5 for all over the line. Also, consider all tap lines (single phase & three phase) are constructed by #3 ACSR bare conductor. Resistance per Km per phase of #4/0 ACSR & #3 ACSR is R_p & R_t , value of which is 0.3522 Ohm & 1.3946 Ohm, respectively.

So, loss factor = 0.85*(Load factor)^2+0.15*(Load factor)
= 0.85*(0.5)^2+0.15*(0.5)
= 0.2875

Sample loss calculation for Section-1, Tap-1 is given below:

R-phase, Section-1:

Line Length : 5 Km
Current thru the section , I_1 : 110 Amps
Line Conductor : # 4/0

So, P_{loss} /Month = (I_1^2 x R_T x L.F x Total Hour)/1000 KWh
Here, R_T = 1 x 0.3522 x 5 Ohm=1.761 Ohm
P_{loss} /Month = [(110)^2 x 1.761 x 0.2875x720)]/1000 KWh
= 4410.77 KWh

R-phase, Tap-1:

Line Length : 5 Km
Current thru the section , I_{rt1} : 30 Amps
Line Conductor : # 3 ACSR

So, P_{loss} /Month = (I_{rt1}^2 x R_T x L.F x Total Hour)/1000 KWh
Here, R_T = 1 x 1.3946 x 5 Ohm=6.973 Ohm
P_{loss} /Month = [(30)^2 x 6.973x0.2875x720)]/1000 KWh
= 1299.07 KWh

Calculation for other sections and taps have summarized in Table I considering construction cost of three phase line of #4/0 ACSR per Km is Tk. 13,00,000, single phase line of #3 ACSR per Km is Tk. 9,00,000.

B. *When All Taps are Three Phase:*

Consider the same 10 Km of backbone line. Total load flowing through the phases was (110+85+75) = 270 Amps. So, the average load per phase is 90 amps. If all the taps or minimum the long and loaded taps are three phase, then we can get balance system, which was not easily possible for the single phase system. So, we can consider in this case, per phase current is equal and the value is 90 amps.

18					42244.71	15208097.07	91248582.44		61600000.00	1414000.00
19									Total cost,1-0	154262582.44

For the first, we consider the tap which was connected in Y-phase in the single phase tapping. The load was 30 amps. If the tap was constructed in three phase, we can get balanced load of 10 Amps per phase. With the same consideration, second tap which is 4 Km apart from the starting point, carries 10 Amps per phase. Thirdly, the tap is 5 km apart from starting point and carries balanced load of 10 amps per phase. Fourth tap which is 8 Km apart from starting point, carries balanced load of 15 amps per phase. For fifth and sixth tap which are apart 9 Km & 10 km from the starting point and carries balanced load of 12 Amps & 20 Amps per phase. The connection and currents are shown in Fig. 3 given next.

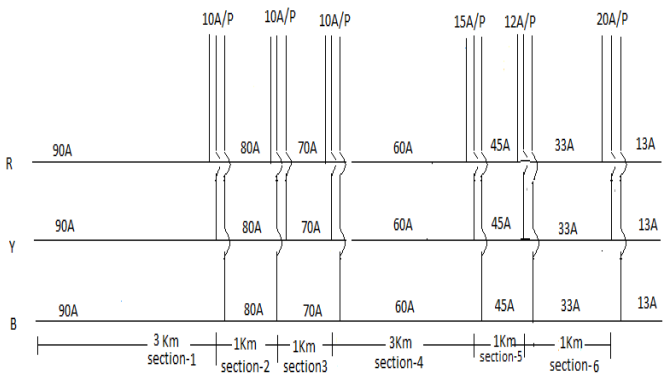

Fig. 3. Three phase system with three phase tap.

Sample loss calculation for Section-1, Tap-1 is given below:

Section-1:

Line Length : 3 Km
Current thru the section , I_{r1} : 90 Amps
Line Conductor : # 4/0

So, P_{loss} /Month = $(I_1^2 \times R_T \times L.F \times \text{Total Hour})/1000$ kWh
Here, R_T = 3 x 0.3522 x 5 Ohm=5.283 Ohm
P_{loss} /Month = $[(90)^2 \times 5.283 \times 0.2875 \times 720)]/1000$ KWh
= 5314.80 kWh

Tap-1:

Line Length : 5 Km
Current thru the section , I_{t1} : 10 Amps
Line Conductor : # 3 ACSR

So, P_{loss} /Month = $(I_{t1}^2 \times R_T \times L.F \times \text{Total Hour})/1000$ kWh
Here, R_T = 3 x 1.2673 x 5 Ohm=19.0095 Ohm
P_{loss} /Month = $[(10)^2 \times 19.0095 \times 0.2875 \times 720)]/1000$ kWh
= 393.50 kWh

Calculation for other sections and taps have summarized in Table II given below.

17									Total cost,3-Ø	122886244.00

Analyzing two costs mentioned in Table I and Table II, it is clear that the cost for three phase line with single phase tap is higher than that of all three phase tap. However, another objective of this paper is to compare the area covered by the three phase tap and single phase tape considering the cost of Table II as standard.

If the cost of single phase line becomes same as that of three phase line i.e. cost difference reduced to '0' (zero), then that will be the optimal design with single phase. This can be done by Excel Solver Program. To obtain objective function, the target cell (J22) is set as '0' and this zero may be achieved by changing the length of single phase line i.e. cell no. D5, D7, D9, D11, D14, D16 assuming the constraints of this cell value not below zero i.e. no negative value is allowed. Maximum value is set as the exact length of single phase line. Table III shows the optimized length of single phase tap line in Column D.

Figure 4 shows the original and optimized lengths of the single phase tap lines from which it can be seen that lengths of all the single phase taps are reduced after optimization. These results signify that single phase taps will cover less area compared to three phase tap lines. Thus, three phase taps are cost effective for covering the whole area of the considered RDS.

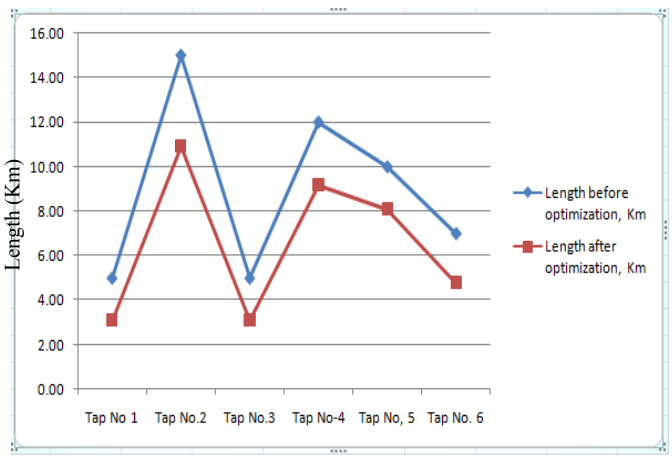

Fig. 4. Length of single phase tap before and after optimization.

VII. CONCLUSION

This paper concentrates on the analysis of the RDS with different tap lines and verifies the effectiveness of three phase tap line over single phase. An optimization model for single phase taps is developed considering the cost of all three phase taps as a standard. It is found that three phase taps provide the cost effective solution to reach all the consumers in terms of length of the considered distribution network. Therefore, to keep the door open for further expansion of reliable distribution line cost effectively, which is the main objective of the area coverage rural electrification, this paper may be an initiator of future days' design. Ultimately, this may contribute in the process of overall national development by electrifying more rural area.

Abstract— **Due to the different types of conversion purposes lots of harmonic creates in DC operated power system. Our goal is to minimize the harmonics at a certain level. The main focus of this research is to explain the effects of harmonics in a 12-pulse High Voltage Direct Current (HVDC) transmission network and take corresponding steps to reduce those effects. It includes harmonic reduction technique to improve the power quality of the HVDC transmission system. This paper also explains how harmonic distortion in HVDC network is one of the important problems associated with power quality and creates several disturbances to the overall power system. In this paper, simulation results were developed on the basis of bus no 1 and 2 of an ideal HVDC transmission Link where there are a lot of harmonics created primarily both in voltage and current due to the presence of Transformer, Converter Devices and Nonlinear Loads. After using passive filter, this harmonic level will be minimized at a certain point which is explained in details on this paper with practical justification.**

Keywords—Harmonics, Total Harmonic Distortion (THD), Transmission network, HVDC Transmission, Passive Filter, Harmonic Reduction

I. INTRODUCTION

In a High voltage direct current (HVDC) system, from the transmitting station AC voltage is being converted into DC voltage with the help of a rectifier and then DC power is transmitted through the transmission line. After that at the receiving station DC power is being reconverted into AC power through an inverter and the power is supplied in the system [1]. When compared to the AC transmission, it is robust against a disturbance and improves a dynamic characteristic of AC power system and lowers the short circuit capacity as voltage, current and transmission power in the DC transmission can rapidly be controlled [1, 2]. But due to various conversion purposes and the rapid uses of nonlinear loads & power electronic devices the harmonic current distortion of the DC transmission system is a highly concerned issue.

In power system design and operation, controlling and eliminating such harmonics have been a great concern for the power engineers. Therefore, in power system planning, control, and operation the HVDC power system harmonic analysis is essential [3]. Harmonic Studies are also important in respect to avoid damages due to excessive harmonic currents in transformers and capacitor banks, to ensure that due to excessive harmonic voltage distortion sensitive electronic equipment will not malfunction and to satisfy the utility's voltage and current harmonic distortion requirements.

Previously, researches have been conducted research on load behavior and harmonic contribution in various sectors of HVDC power system. For instance Capacitor behavior on harmonic distortion is investigated [2]. HVDC Transmission Systems and HVDC Power System Harmonic Analysis were discussed in [3, 4, 5 and 6]. Harmonic characteristics of new HVDC transmission system based on new converter transformer were analyzed in [7]. Harmonic reduction methods using active filters for HVDC networks were introduced in [8, 9]. Different control topologies of the HVDC network have been further developed in [15, 16 and 17].

This paper represents the results of a simulation study of Passive filter on a 12 pulse HVDC (High Voltage Direct Current) Transmission network using a system design in SimPowerSystems tools of Matlab. The objective of the study is to investigate the performance of the system's harmonic contents with and without the presence of Passive Filters. This paper is organized as follows: Section II presents a brief overview of sources of harmonics on HVDC Transmission network and their effects on the overall Power System. A brief introduction to Passive filter technique for harmonic reduction used in this study has been presented in section III. Simulation results along with the influence in harmonic contents with the appearance of Passive filters have been discussed in section IV. Some discussions and explanations of the findings have also been provided finally in section V conclude the work highlighting the major contributions.

II. HARMONICS ON 12-PULSE HVDC TRANSMISSION NETWORK

Among all power transmission systems, HVDC utilized direct current (DC) for high voltage bulk transmission of electrical power contrary to the more common alternating current (AC) systems [3, 10]. A constitutional task occurred in an HVDC system when the conversion of electrical current from AC to DC (rectifier) and from DC to AC (inverter) at the transmitting end and the receiving end respectively.

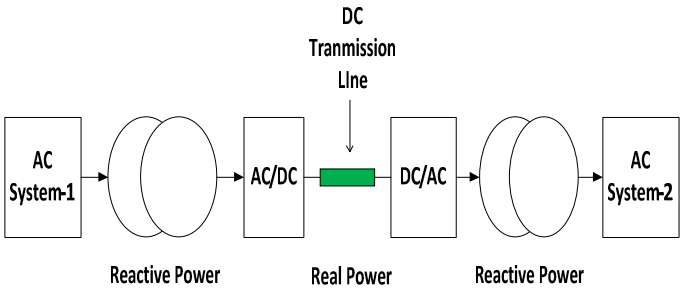

Figure.1: Simple mono polar HVDC Transmission System

HVDC transmission may be performed in two ways, mono polar and bi-polar. Mono-polar HVDC transmits power in one way whether bi-polar HVDC can transmit power in a bi - directional path.

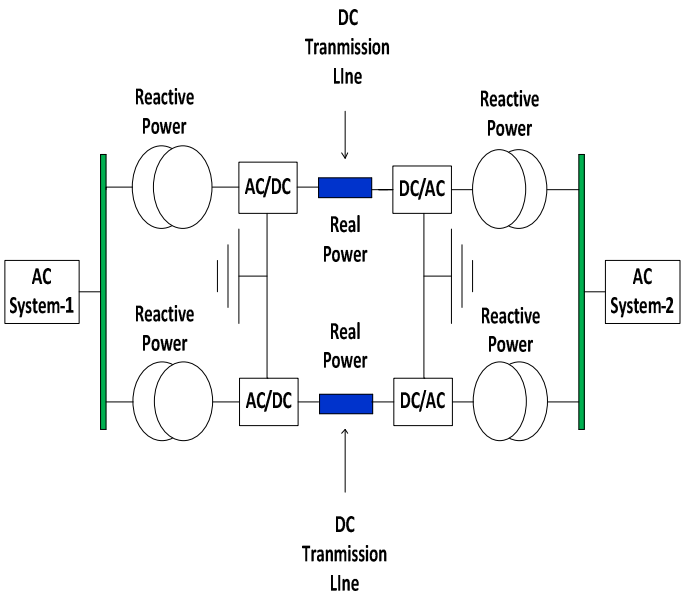

Figure.2: Bipolar HVDC Transmission system

The performance of HVDC power system is being affected by the harmonics created by the higher use of non-linear devices. Due to the presence of solid state drives or electric furnaces and capacitor banks in the HVDC power system, harmonics are generated frequently. Just as high blood pressure can cause stress and serious problems in the human body, high levels of harmonic distortion could result in problems for the utility's transmission system, the plant's distribution system, as well as the equipment under that transmission system. Most familiarize sources of HVDC harmonics and their effects are described in details below.

A. Sources of HVDC Harmonics

Since electrical signal is scrutinized, matter of harmonic is considered also. Harmonic is defined as the content of the signal whose frequency is an intrinsic multiple of the radical system frequency assembled by the generators. In HVDC power system, harmonics are assembled by some system elements which have non-linear characteristics, such as transformers, generators, power converters and electrical machines [11, 12 and 13]. Specifically, converters are the considerable sources of harmonic in an HVDC network during a steady state operation and engender harmonics on both AC and DC sides of their valve groups. The valve operation in converters of a 12 pulse HVDC link changed the original shape of voltage and current in a steady state condition, as a result of system harmonics. In HVDC power system, the interaction of primary currents and characteristic harmonic in non-linear components assembles sum as well as the difference in frequencies. The secondary voltage harmonics to the primary three phase voltage waves fetch the voltage zeros from the zeros of the primary waves unescorted and these fetches of zeros cause asymmetrical firings of the valves and non-characteristic AC harmonics are engendered.

Transformers are other acceptable source of harmonics, and this harmonics are incorporated with their design and operation. Besides, throughout the large disturbances transformers can substantially increase their contribution of harmonic and the transfer current accommodated both odd and even harmonics in an unbalanced condition. Generators such as electric machines are another acceptable source of harmonics also in HVDC power systems because of their economical as well as practical design. A machine has not operated in the saturation region if the magnetic flux of a machine has a perfectly sinusoidal distribution around the air gap. In machines, the magnetic saturation can also be contributed to the generation of harmonics like as transformers [3].

B. Effects of Harmonics

In HVDC system, harmonics reduced the efficiency of power generation and transmission. They lower the efficiency of power utilization and damage the insulation of system components also. If the system has high harmonic contents, the plant malfunction can be occurred after that the harmonics are entering the ark network and the DC line may result in the overheating of generators and capacitors, the interference with communication circuits and the instability of the system controls. The unwanted signal induced by a power system on a communication circuit degrades the transmission quality of the communication signals [11]. Harmonic resonances genesis excessive currents and over voltages which dramatically increase the losses of system devices and even can damage them. Effects of HVDC power system harmonics have been seen in rotating machines, which introduced losses [14]. The pierce of harmonics in a network cause additional network losses due to the increase of the effective values of current. Harmonic currents increased the harmonic voltage drops across circuit impedances. When the electric power is transmitted by cables, harmonic voltages increased dielectric stress in proportion to their crest voltages. The high dielectric stress shortens the useful life of the cables. The harmonics also have effects on the corona. The corona starting and extinction levels depend on peak-to-peak voltages, which are affected by

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

harmonics. These types of scenario are seen in converter stations.

III. PASSIVE FILTER TECHNIQUES FOR HVDC HARMONICS REDUCTION

Due to the commutating process of the converter bridge, several characteristic and non-characteristic harmonics are generated on the 12-pulse HVDC transmission system [7].There are many ways to reduce harmonics in HVDC power system. Such as- using phase controlled thyristor rectifier, using larger DC or AC inductor, using Tuned single or multiple arm passive filter, External active filter etc. To maintain the power quality of an HVDC transmission system Active and passive filters is essential [9]. Filtering is currently the most common method used for limiting the effects of harmonics to the rest of the system [8]. Filters typically consist of Tuned Series L-C circuits and its impedance is negligible with respect to the rest of the transmission network [14].

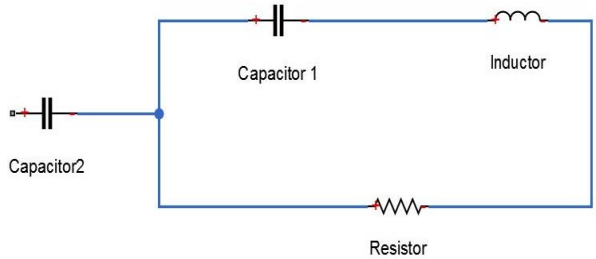

Figure.3: Basic representation of C-type high pass passive filter

Passive filters consist of resistors, inductors and capacitors. They are not expensive and are often used to restrict the harmonic currents from entering the power system thereby minimizing the effect of harmonics. Also, the passive filters are kept close to the source of harmonic generated loads. Doing so, in reducing the harmonic effect the passive filters produce better results. The passive filters create a resonance frequency in order to reduce the harmonic effect. This resonance frequency is kept away from the harmonic distortion of the nonlinear loads.

IV. DESIGN AND SIMULATION RESULTS

The peak demand of Bangladesh is of the order of 4200-5500 MW and the peak deficit is about 1000-1500 M [14]. The HVDC interconnection between the electrical grids of India and Bangladesh would facilitate transfer of 500 MW Power in either direction [14]. This section deals with the design and implementation of a Software Based system where SimPowerSystems tools of Matlab were used as the simulation tool. The proposed Simulink model consists of several parts. The block representation, including the overall system is shown in Figure 4 below.

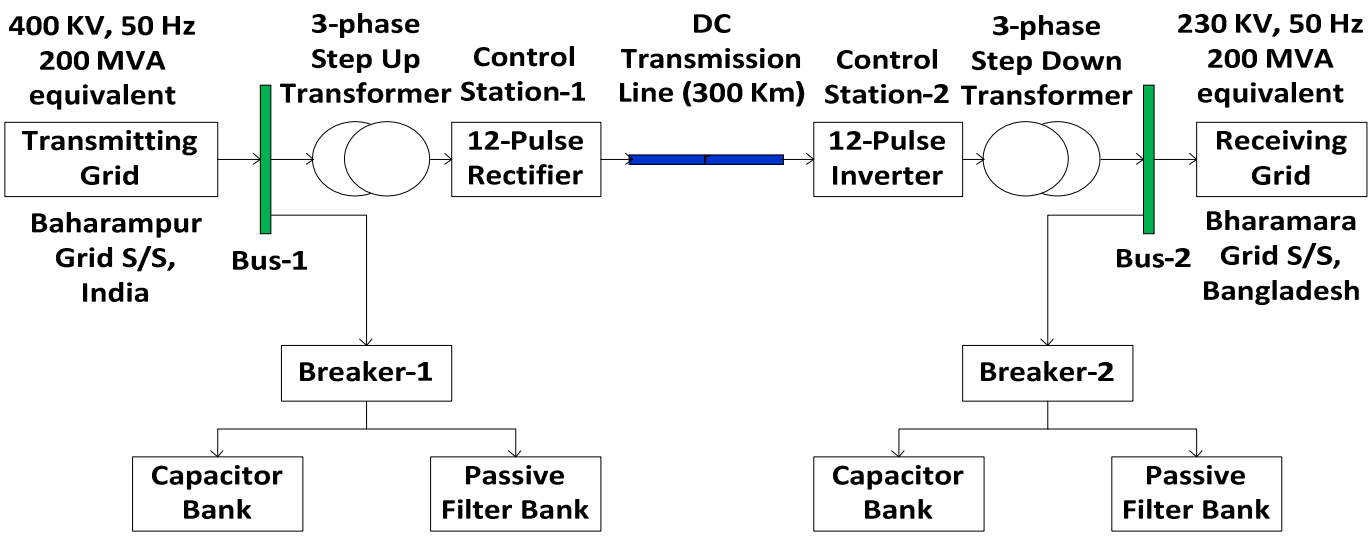

Figure.4: Test System

In the above HVDC system design in figure 4, 500 MW Power is transmitted from a 400 KV network to a 230 KV network. Both the network has a power rating of 200 MVA and frequency of 50 Hz. The converter is connected to the system with a 200 MVA Three-Phase transformer (three windings). The rectifier and the inverter are 12-pulse converters using two 6-pulse thyristor bridges, are interconnected in series through a 300 km distributed parameter line and two 30 mH smoothing reactors. Two three-phase Circuit Breakers (CB-1 & CB-2) are separately used to connect the filters set on the AC bus. The filter sets connected to Bus-1on the transmitting grid through Circuit Breaker-1 are made of the following components - one

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

capacitor banks of 75 Mvar, 3x75 Mvar tuned low pass filters for removing the lower order harmonic (11th, 12th and 13th) and one 75 Mvar high pass damped filter for higher order (24th) harmonic reduction using the three-phase harmonic filter modeling. The total Mvar rating of the filter sets connected to Bus-2 is then 455 Mvar. The filter sets connected to Bus-2 on Load side through Circuit Breaker-2 are made of the following components - one capacitor banks of 91 Mvar, 3x91 Mvar tuned low pass filters for removing the lower order harmonic (11th, 12th and 13th) and one 91 Mvar high pass damped filter for higher order (24th) harmonic reduction using the three-phase harmonic filter modeling. The total Mvar rating of the filter sets connected to Bus-2 is then 455 Mvar.

From the design, four parameters Vabc_B1, Iabc_B1, Vabc_B2 and Iabc_B2 and their corresponding harmonic components (both voltage harmonics and current harmonics) has been observed for three phases. With the help of SimPowerSystems under SimScape division in Matlab results of THD have been measured for with and without passive filter connections. Simulations have been carried out with two different conditions. Condition 1 calculates the existing THD of the 12-pulse HVDC transmission network without any filter in the system. Condition 2 represents the improved THD value of the HVDC network after adding passive filters into. The results of this design and implementation considering phase sequence A are described briefly for a better comparison scenario.

Condition-1: When both the Breakers were open (Without Passive Filter)

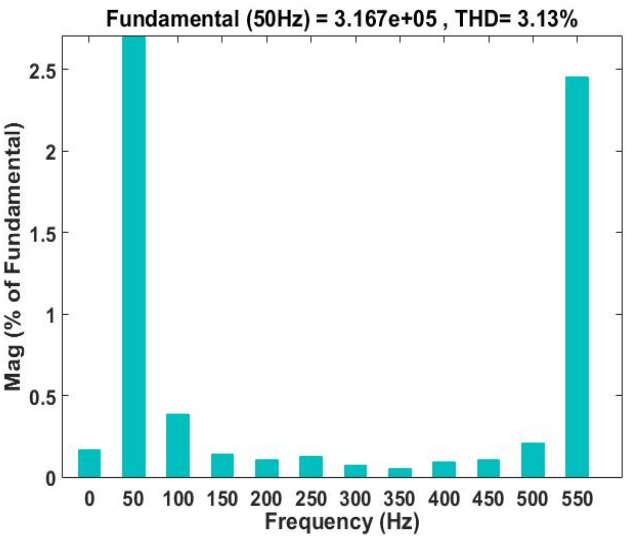

Figure.5: Voltage Harmonics (THD_V) – At Phase A of Bus 1.

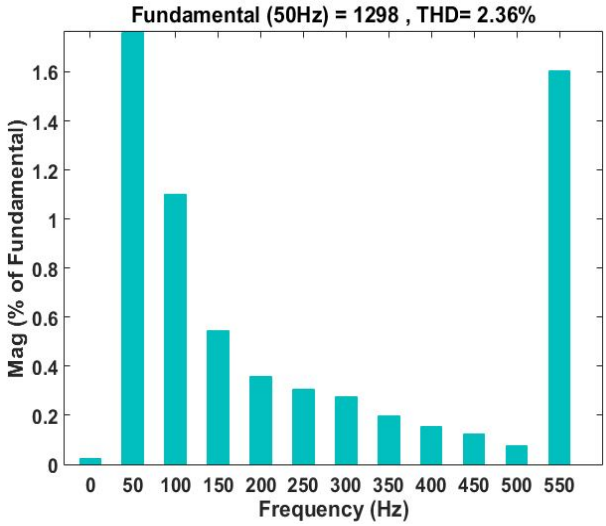

Figure.6: Current Harmonics (THD_I) – At Phase A of Bus 1.

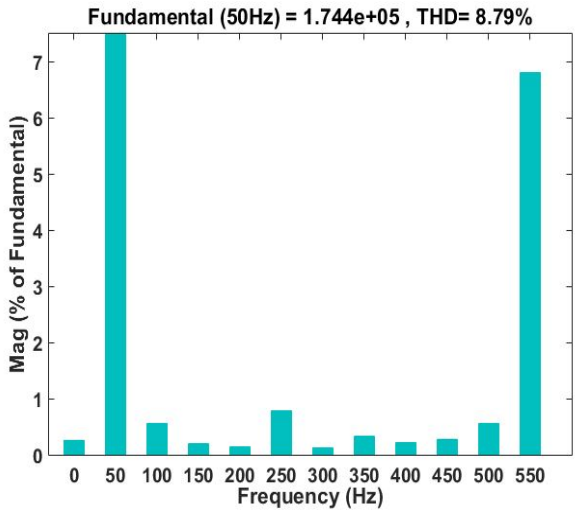

Figure.7: Voltage Harmonics (THD_V) – At Phase A of Bus 2.

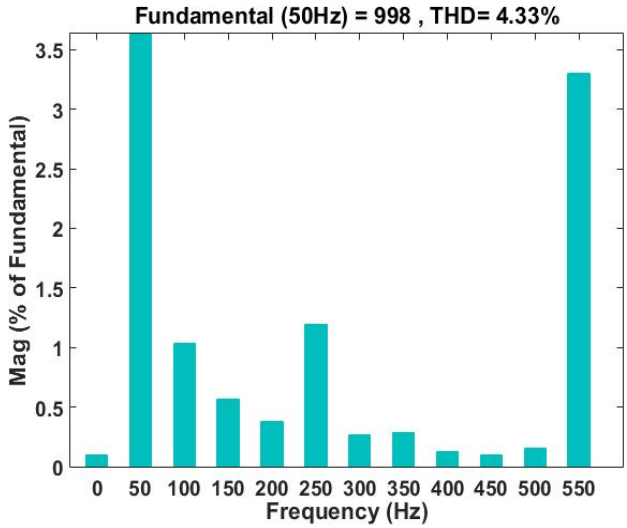

Figure.8: Current Harmonics (THD_I) –At Phase A of Bus 2.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

In the above figures (5, 6, 7, 8), THD of the system without harmonic filter has been demonstrated and found that design's THD is much higher without harmonic filter installation. At fundamental frequency, the Voltage (THD_V) & Current (THD_I) harmonic distortion level at Bus-1(phase A) are 3.13% and 2.36% respectively. And at Bus-2 (phase A), Voltage (THD_V) & Current (THD_I) harmonic distortion level are 8.79% and 4.33% respectively. That's why a second case study was performed by designing passive harmonic filter on the HVDC transmission network to examine the performance of the system and harmonic distortion level.

Condition-2: When both the Breakers were closed (With Passive Filter)

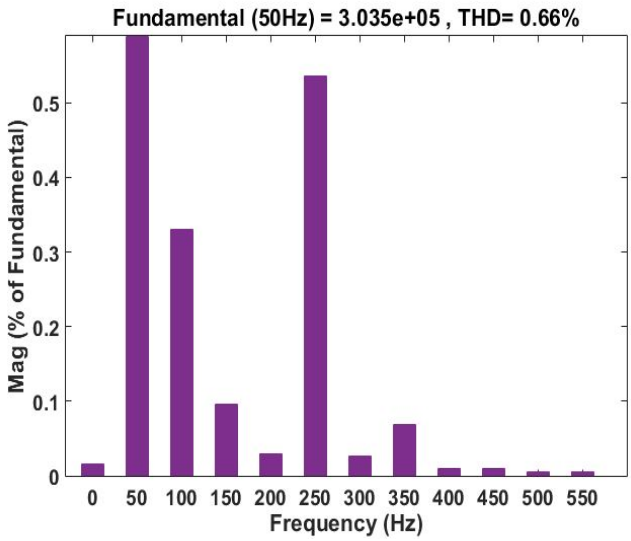

Figure.9: Voltage Harmonics (THD_V) – At Phase A of Bus 1.

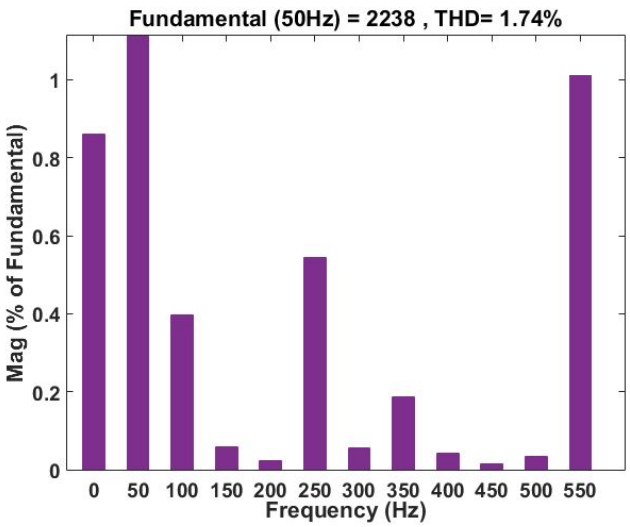

Figure.10: Current Harmonics (THD_I) – At Phase A of Bus 1.

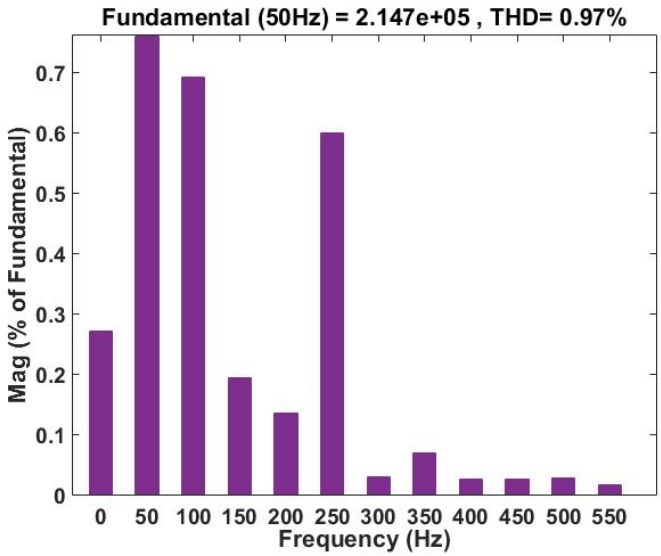

Figure.11: Voltage Harmonics (THD_V) – At Phase A of Bus 2.

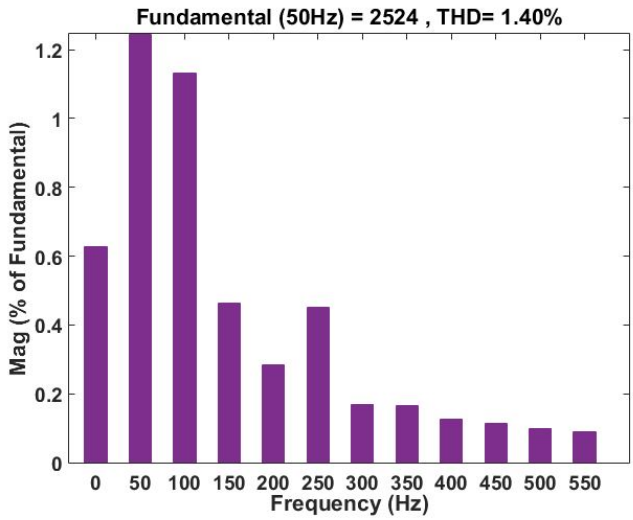

Figure.12: Current Harmonics (THD_I) – At Phase A of Bus 2.

In the above figures (9, 10, 11, 12), THD of the system with passive harmonic filter has been demonstrated. At fundamental frequency, the Voltage (THD_V) & Current (THD_I) harmonic distortion level at Bus-1(phase A), are 0.66% and 1.74% respectively. And at Bus-2 (phase A), Voltage (THD_V) & Current (THD_I) harmonic distortion level are 0.97% and 1.40% respectively. All the findings of the proposed design and simulation results of two different conditions are tabulated in Table-1.

The above results are about time domain simulation. The findings of the above discussions are demonstrated in the table below.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

Table.1: Value of THD for fundamental component of 50Hz with and without passive filter

Bus No.	Phase	THD(%) without passive filter		THD(%) with passive filter	
		Voltage	Current	Voltage	Current
1	A	3.13	2.36	0.66	1.74
2	A	8.79	4.33	0.97	1.40

From the above comparison, the harmonic limit is under the IEEE std. 519 after using the passive harmonic filter. The observation was that the harmonic filters almost eliminate the harmonics generated by the converter.

V. CONCLUSION

When large amounts of power are to be transmitted for long distances, HVDC is considered an economically beneficial because of their low electrical losses. But the impact of harmonics in HVDC network might be detrimental and redundant to both loads and grid. With the use of Passive harmonic filters are ways of mitigating the effects of such. To determine harmonic distortion levels and filtering requirements harmonic studies with passive filter on the HVDC transmission network were performed. Designing proper implementation with the help of the Simscape division of Matlab was performed with practical system and data's. This study determines if harmonic voltages and currents are at acceptable levels. An evaluation of the harmonic voltage and current limits is completed to determine the effectiveness of the proposed filter installation. The founding's of this work concludes that Harmonic analysis with passive harmonic filter is a very important discussion on the modern day's power system which reduces excessive current flow on the non-linear load. The application of Passive harmonic filters will significantly alter the frequency response of the power system. After completing the task, it will be minimize the wasteful impact of unnecessary power conversion, which saves more energy in the system. With the rapid conversion of AC to DC system more and more filters will be required to keep the harmonic limits within the acceptable range. So in future, further studies can be performed for improved implementation based on this research work.

Harmonic Analysis on LVDC Distribution System and Passive Filter Techniques for Harmonic Reduction

Sanjib Kumar Nandi, Md. Siddikur Rahman, Ridown Rashid Riadh

American International University-Bangladesh, Dhaka, Bangladesh

sanjib.eee.aiub@gmail.com, rahman.siddikur286@gmail.com, rashidridown@gmail.com

Abstract— **Usages of DC power instead of AC power on the secondary distribution system creates a lot of harmonics. Our goal is to eliminate the harmonics onto the system and due to the limited specification of filter it has not been possible to reduce all the harmonics in the secondary distribution system. But we must be more focused to achieve this goal, because large shares of household loads are turning into DC in recent years. If this trend continues, the impact of harmonics on customer end will reach a level which might be detrimental and redundant to both loads and grid. The main objective of this research is to explain the effects of harmonics on the low voltage direct current (LVDC) distribution system and measure the harmonic content present in the network and proposed a recovery method by inserting filter. Due to additional non-linear loads on the LVDC distribution system, a sufficient amount of harmonics will be created. To solve this issue, use of passive harmonic filter is recommended for the DC operated secondary distribution system. After using a passive filter into the LVDC network, the system harmonics are being reduced into the acceptable limits and almost eliminate the harmonics generated by the converter and nonlinear loads.**

Keywords—Harmonics, Total Harmonic Distortion (THD), DC Power, LVDC Distribution System, Passive Filter, Harmonic Reduction

I. INTRODUCTION

Among all the existing network technologies, LVDC system is one of the emanating technology renovations for Smart Grid application to the distribution of electricity and a highly interesting challenge [1]. The salient purposes beyond this development of the LVDC network is to enhance the power quality and furnish security experienced by the end users of the electricity for ameliorating the distribution economy [1]. This pledge flexible and robust coupling point for small scale generation and evolve infrastructure for interactive and intelligent distribution network [1, 2]. The distribution transformer is one of the key parts of LVDC system [3]. The nonlinear nature of the load has generated harmonic currents which may cause problems in the power system and overheating transformers. Nonlinear loads have generated harmonic currents which are flown from the load towards the power source, following the least impedance paths [4].

Modern electrical system consists of a vast amount of nonlinear loads which causes disturbances in DC current. Commercial buildings often have a large amount of nonlinear electronic loads such as lighting, computers, monitors and adjustable-speed drives for air conditioning. Due to this huge presence of nonlinear loads, electromagnetic-compatibility and power quality problems may occur [5]. For which power system suffers from unfavorable consequences and may damage electrical equipment's. IEEE Standard 519-1992 specifies limits for each harmonic up to the 35th and limits the total harmonic distortion (THD) to 5% [6]. EN 50160 limits the THD to 8% and the unbalance to 2% [7].

This problem can require special consideration to serve non-linear loads with a reduce amount of harmonic distortion. Using various techniques power distribution system's Harmonic distortion might be restrained [2]. Previously, researches have been conducted on load behavior and harmonic contribution in various sectors of the power system. For instance, The LVDC power distribution network concept is presented [8]. Harmonic analysis and DC operated electrical system with distributed resources for recovery from the effects of harmonics and closely relevant criteria have been proposed in [9, 10, 11 and 12]. The LVDC distribution system concept has been developed in [13]. Passive filter installation for reducing harmonic in single phase motor, varying load has been introduced in [4].

Analysis of harmonics and measuring simulation based results is helpful for preparing data based efficient models of the LVDC distribution system. Investigation of harmonic content present in low voltage direct current (LVDC) power distribution network has been demonstrated in this article. This paper mainly focuses on the effects of the increase amount of harmonics in a LVDC distribution network and possible solution to overcome. The primary objective is to measure harmonic contents on the LVDC distribution system. And the secondary objective of this work is using an active harmonic filter to improve the system performance of the LVDC distribution system. For investigation, simulation environment at SimPowerSystems tool of Matlab Simulink is used. The organization of the paper is set as: in Section II, a brief overview of LVDC distribution network was introduced. Sources of harmonics in LVDC network and their effects in distribution feeders have been discussed in section III. A brief introduction to Passive filter technique for harmonic reduction used in this study has been presented in section IV. Simulation

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

results along with the influence in harmonic contents of LVDC system with the appearance of Passive filters have been discussed in section V. Some discussions and explanations of the findings have also been provided finally in section VI conclude the work highlighting the major contributions.

II. LVDC DISTRIBUTION SYSTEM

The LVDC distribution system is an advanced revolution in the field of electricity distribution. Recently, power electronic constituents have developed in the way of economic and technological, which enabled to apply power electronics in LV network. A basic conviction of LVDC distribution system concentrated at the DC/AC interface focused on implementation of customer-end inverter [13]. The LVDC distribution system builds of power electronic converters and DC link between the converters. A LVDC distribution system can have different types of topologies that the AC/DC conversion can be placed at various locations [14].

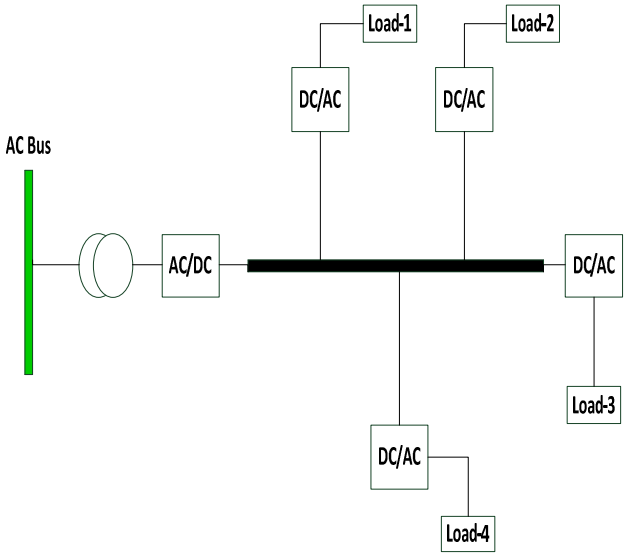

Figure.1: Simple LVDC Distribution system

LVDC system consists of a distribution transformer, a DC link, a rectifier, DC/AC inverter units, customer loads and filters [15]. In LVDC distribution system, DC connection is used to avoid the need to build a medium voltage branch line as well as traditional low voltage AC grid to furnish electricity to a group of low power customers [16, 17]. In LVDC distribution grid, DC grid is powered by a front-end rectifier. The front-end rectifier includes of two 6-pulse thyristor bridges. Thyristor bridges are powered by phase shifting transformer with two secondary windings to form a 12-pulse rectifier. The customer-end inverters loaded the DC system. The bipolar DC power distribution network serves as the power supplier of the inverters. Both single phase and three phase inverters can be used to energize the consumer end AC network. Due to high ±750 VDC voltage used in the LVDC network, inverters are generally connected in between the zero pole and plus or minus DC pole. Customer's coupling point can also be located in the DC side in some special cases [18].

III. HARMONICS ON LVDC DISTRIBUTION NETWORK

Using a DC distribution system makes it easier to incorporate more local energy storage and sources. To connect an energy source with a DC system only the voltage has to be controlled, as opposed to the AC system where voltage magnitude, frequency and phase must be matched [9]. An indispensable deliberation when estimating the smash of harmonics is their effect on power system constituent and loads [16]. Higher consumption of reactive power causes more system losses and malfunction the protection of the power system [5]. The current harmonics found in the grid components may sustain impairments in distinct devices which are fastened to the same grid [16].

The converters used in the LVDC distribution system produce flexible harmonic contents. The distortion of voltages and currents can cause extra losses in system components [17]. Generally, industrial electronic devices and nonlinear loads are the considerable source of harmonic generation. When sinusoidal voltage is applied to a nonlinear load, then the resulting current is distorted. So, non-linear loads are the leading source of harmonic distortion in power system. Modern personal computer's power supply is a familiar example of nonlinear load. It's switching action results in distortion of the current waveform [19]. With the increase use of PV grid integration also causes harmonics problem inside the power system [20].

Distribution transformer is one of the vital constituents of LVDC system. Harmonic load currents consequence heating inside and cause eddy current losses in transformer. The escalated depletions due to harmonic distortion can seed excessive depletions as well, hence the anomalous temperature rise. The assessment of iron depletions and copper depletions of transformers is the prime in particular for transformers feeding nonlinear loads [16].

Whenever there is a large number of a nonlinear load, more harmonics are observed in the LVDC distribution system. Harmonic currents which are engendered by nonlinear loads are flown from the load toward the power source, shadowed the ways of minimal impedance. Due to greater percentage of harmonics many more unnatural situation may occur such as - overheating of electrical distribution system wiring, transformer overheating which shortened transformer service life, false circuit breaker tripping, power factor correction capacitor failure etc. [21] The likelihood of experiencing problems increases with the increase of harmonic levels. In Rising temperature and creating Skin Effect harmonic is an important factor. Both the electrical distribution systems and equipment have consequences due to heating effect. Problems in neutral conductors, unpredictable operation of relays and breakers, presence of distinct magnetic fields near transformers and switchgear etc. are also the outcomes of harmonics. Harmonics may also results in electronic instrument's reading errors, false instruction, excessive line loss, thermal loading of motors, malfunction of transformers, generators, electronics equipment like computers, air conditioning systems, PLCs, remote monitoring systems etc.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

IV. HARMONICS REDUCTION BY PASSIVE FILTER

A lot of harmonics are generated on the LVDC distribution system due to different types of conversion process and nonlinear loads. There are many ways to reduce LVDC power system harmonics. Such as- using phase controlled thyristor rectifier, using larger DC or AC inductor, using Tuned single or multiple arm passive filter, External active filter etc. To maintain the power quality of an LVDC distribution system Active and passive filters is essential. Filtering is currently the most common method used for limiting the effects of harmonics to the rest of the system. Filters typically consist of Tuned Series L-C circuits and its impedance is negligible with respect to the rest of the distribution network. Passive filters are used to restrict the harmonic currents by providing a low impedance path to enter the power system. Resistors, inductors and capacitors are the main components for designing of the passive harmonic filters [22]. A basic structure of a Passive Shunt Filter with Load connection has been shown in figure.2.

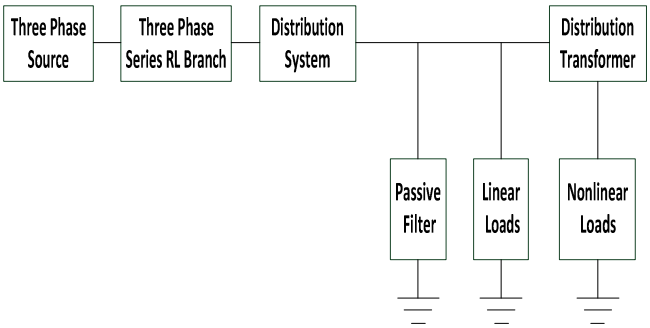

Figure.2: Passive Shunt Filter with Load connection

By using Passive filter as a harmonic reduction technique, power quality of the distribution network can be improved [4, 23]. Passive harmonic filter reduces harmonics which are existed due to nonlinear loads in the power system by injecting equal current or voltage distortion [4]. Passive filters are not expensive and often used to restrict the harmonic currents from entering the power system thereby minimizing the effect of harmonics. Also, the passive filters are kept close to the source of harmonic generated loads. Doing so, in reducing the harmonic effect the passive filters produce better results. The passive filters create a resonance frequency in order to reduce the harmonic effect [4]. This resonance frequency is kept away from the harmonic distortion of the nonlinear loads.

V. SIMULATION RESULTS

When designing a system, several things need to be addressed in order to observe the Impact of increased share of DC load. LVDC grid requires 1500 VDC Medium-voltage fretwork and 20 KV voltages have to be laid down by a transformer to low AC voltage like 1 KV in power distribution. When ripple voltage is not more than 10 % of the nominal voltage, is to be known as DC voltage, but the real scenario of the ripple voltage has considerably underneath the margin of losses in DC cables. For analyses of a bipolar LVDC network ± 750 VDC distribution systems is considered. The proposed Simulink model block diagram representation is shown in Figure 3 below that presents the overall system where a simple LVDC system is designed.

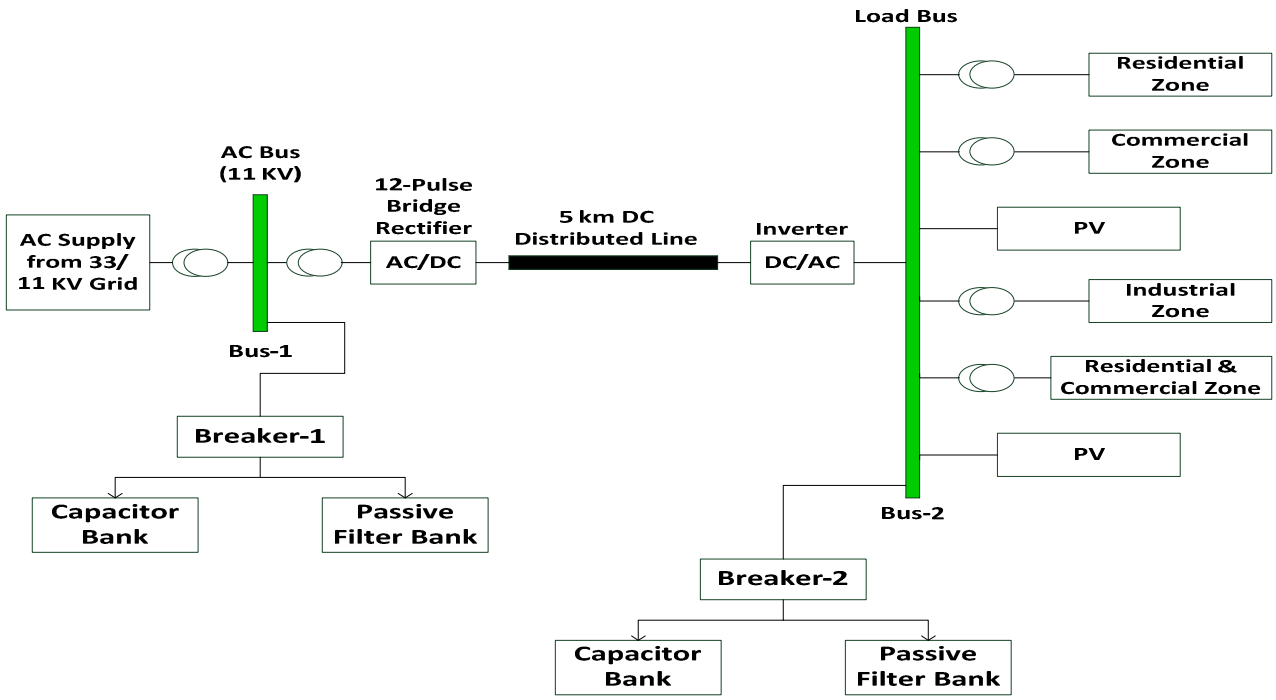

Figure.3: Test System

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

The Simulink model consists of a LVDC distribution system along with Passive Harmonic Filters connected to the adjacent AC Bus. It is important to get familiarized with the components needed to observe the impact of increased share of DC loads. The components used for observing the impact of increased share of DC loads are Three-Phase Source, Series RLC Branch, Three-Phase Transformer, 12 pulse Thyristor controlled bridge rectifier, inverter, linear and nonlinear loads and Three-Phase Harmonic Filter. Designing and implementing of this Software Based system is followed by the implementation using SimPowerSystems Tool of Matlab. The Harmonic Filter uses a Phase Locked Loop to generate a reference sinusoidal source current which is in phase and has the same RMS gain as the load current.

A 5 km DC interconnection is used to transmit power from an 11 KV, 50 Hz distribution Grid to load side. The converter is connected to the system with Three-Phase transformer windings. The rectifier is a 12-pulse converter using two 6-pulse thyristor bridges. An inverter bridge is used in the load side for DC/AC conversion which is interconnected in series through a 5 km distributed parameter line. Six individual feeders carrying on different types of loads (both linear and nonlinear) are connected to Bus-2 through individual transformer. Here, along with residential, commercial and industrial loads, Photovoltaic (PV) was also inserted to have a better scenario. 8 MW load in residential feeder, 2.5 MW load in Commercial feeder, 4.5 MW load in (Residential + Commercial) feeder, 5 MW load on Industrial feeder and 2 MW load in each PV individually were considered and connected to the system. Total load connected to the LVDC network was amounted to be 24 MW. Two Passive filters were connected to Bus 1 and 2 The filter sets are made of the following four components – one capacitor banks of 91 Mvar, one C-type high-pass filter of 150 Mvar, two single-tuned filter of 2x150 Mvar for reduction of odd harmonics, one high-pass damped filter of 150 Mvar modeled using the three-phase harmonic filter. The total Mvar rating of the filters set was 455 Mvar at individual Bus. A three-phase circuit breaker was used with each filter block to connect the filters set on the AC bus separately.

The most important part of this design was to observe the impact increased share of DC load. From the design, four parameters Vabc_B1, Iabc_B1, Vabc_B2 and Iabc_B2 and their corresponding harmonic components (both voltage harmonics and current harmonics) has been observed for three phases. With the help of SimPowerSystems under SimScape division in Matlab results of THD have been measured for with and without passive filter connections. Simulations have been carried out with two different conditions. Condition 1 calculates the existing THD of the LVDC distribution network without any filter in the system. Condition 2 represents the improved THD value of the LVDC network after adding passive filters into it. The results of this design and implementation considering phase sequence C of each Bus are described briefly for a better comparison scenario.

<u>Condition-1:</u> When both the breakers were open (without Passive filter)

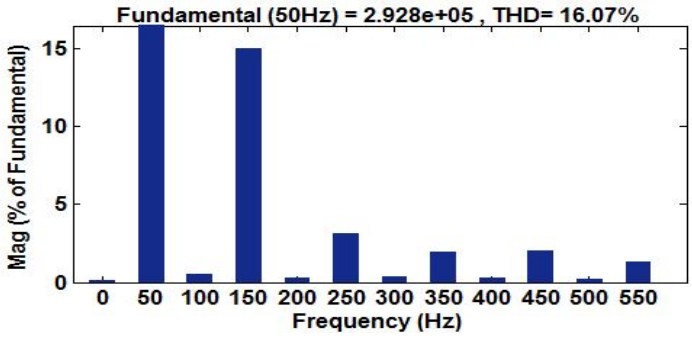

Figure.4: Voltage Harmonics (THD_V) – At Phase C of Bus 1.

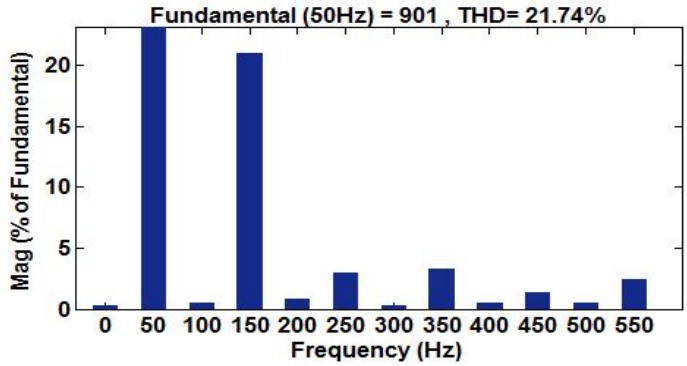

Figure.5: Current Harmonics (THD_I) – At Phase C of Bus 1.

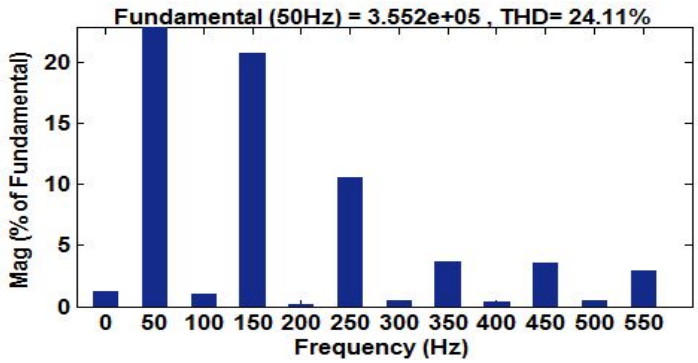

Figure.6: Voltage Harmonics (THD_V) – At Phase C of Bus 2.

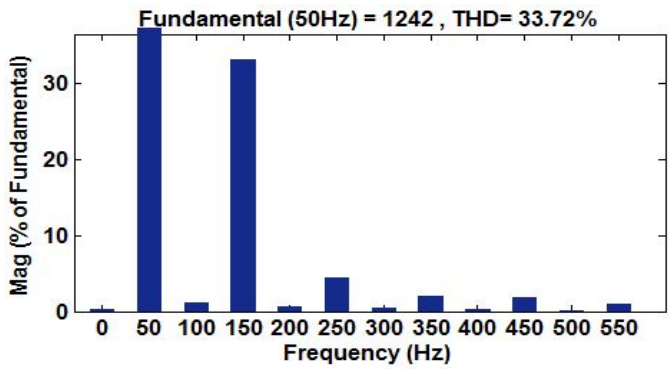

Figure.7: Current Harmonics (THD_I) –At Phase C of Bus 2.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

In the above figures (4, 5, 6, 7), THD of the system without harmonic filter has been demonstrated. It has been found that design's THD is much higher without harmonic filter installation. At fundamental frequency, the Voltage (THD_V) & Current (THD_I) harmonic distortion level at Bus-1(phase C) were 16.07% and 21.74% respectively. And at Bus-2 (phase C), Voltage (THD_V) & Current (THD_I) harmonic distortion level were 24.11% and 33.72% respectively. That's why a second case study was performed by designing passive harmonic filter on the LVDC distribution network to examine the performance of the system and harmonic distortion level.

<u>Condition-2:</u> When both the breakers were closed (with Passive filter)

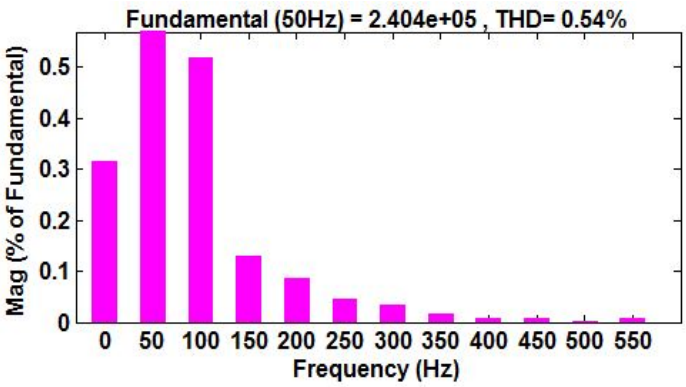

Figure.8: Voltage Harmonics (THD_V) – At Phase C of Bus 1.

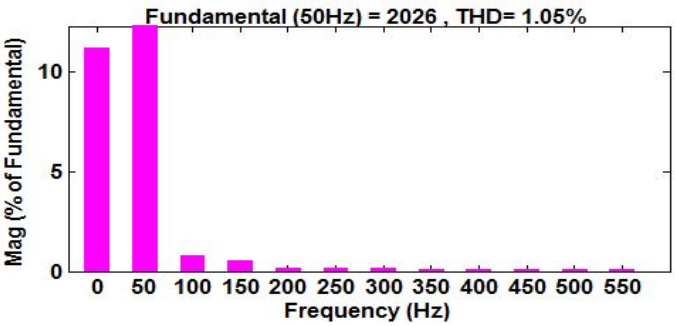

Figure.9: Current Harmonics (THD_I) – At Phase C of Bus 1.

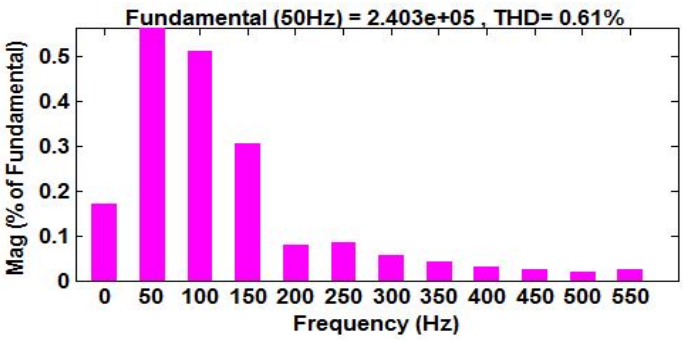

Figure.10: Voltage Harmonics (THD_V) – At Phase C of Bus 2.

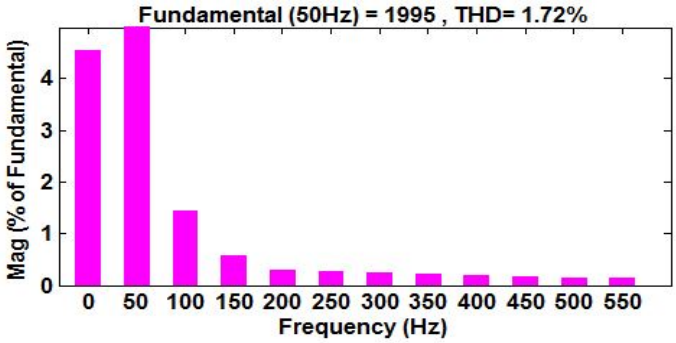

Figure.11: Current Harmonics (THD_I) – At Phase C of Bus 2.

In the above figures (8, 9, 10, 11), THD of the system with passive harmonic filter has been demonstrated. At fundamental frequency, the Voltage (THD_V) & Current (THD_I) harmonic distortion level at Bus-1 (phase C) were 0.54% and 1.05% respectively. And at Bus-2 (phase C), Voltage (THD_V) & Current (THD_I) harmonic distortion level were 0.61% and 1.72% respectively. All the findings of the proposed design and simulation results of two different conditions are tabulated in Table-1.

Table.1: Value of THD for fundamental component of 50Hz with and without passive filter

Bus No.	Phase	THD(%) without passive filter		THD(%) with passive filter	
		Voltage	Current	Voltage	Current
1	C	16.07	21.74	0.54	1.05
2	C	24.11	33.72	0.61	1.72

Analyzing from the First Furrier Transform (FFT) tool of the PowerGui the finding is that the passive harmonic filter reduces the THD of the voltage and current injected into the system.

VI. CONCLUSION

In this work, the wasteful impact of unnecessary power conversion was sought for and recognizes that negative impact of increasing the amount of nonlinear loads. It creates lots of harmonic if the DC power distribution system is used instead of an AC power distribution system. The investigation into power quality and analyzing the harmonics of a LVDC distribution system is performed using Matlab simulation environment. The simulation results are compared by verifications with measurements and practical examples. The effect of system reconfiguration on DC network and transformer harmonic content is determined. The simulated LVDC network with passive harmonic filter is meeting voltage and current harmonic distortion limits of IEEE std. 519. As the amounts of nonlinear loads are increasing day by day throughout the power system, efficient filter designing are required instantly to overcome from the effects of harmonics. The achieved models and results of this paper will be useful in the dimensioning LVDC distribution network components and system designing. This work will be highly applicable on the

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

sight of rural area and different kind of office, bank and where solar panel should be used. After using the proposed filtering, it will be minimize the wasteful impact of unnecessary power conversions, which saves more energy in the system. In future work, using DC power and measurement of maximum tolerable range of DC load integration with the variation of nonlinear load up to which harmonics are tolerable in the secondary distribution system based further analysis can be developed.

Abstract— **The use of renewable energy resources is increasing for the purpose of producing electricity in modern world due to lack of non-renewable sources. As solar panels are becoming more popular day by day, it is a crying need to maximize the solar panel efficiency. The efficiency of solar panels can be increased to a great extent if the solar panels continuously rotate in the direction of sun. Microcontroller and an arrangement of LDR sensors can be used for the purpose of tracking the sun. But the system is less efficient because of the low sensitivity and disturbance of light dependent resistors. In this paper, a methodology of an automatic solar tracker is proposed by means of both sensors and image processing simultaneously. The mechanism of solar tracking was implemented by the use of an image processing software which combines the effect of sensors and processed image of sun and controls the solar panel accordingly. The methodology is a combination of hardware and software which can be used to control hundreds of solar panels in a solar power plant with more accuracy. It can be concluded that the proposed system is more accurate and efficient than the conventional solar tracking systems which can optimize the power requirement.**

Keywords—Photovoltaic cell, Solar tracker, Light dependent resistor, Microcontroller, Servomotor.

I. INTRODUCTION

While thinking about the development of a nation, the prime factor comes to mind is 'energy'. Huge amount of nonrenewable energy is extracted, distributed, converted and consumed in the global society daily. Almost 85% of energy production depends on fossil fuels. The resources of the fossil fuels are limited and their usage results in global warming because it can be a threat for human being by the emission of greenhouse gases. If we want to provide a sustainable power production and safe world to the future generation, we have to utilize the growing demand for energy from renewable sources like solar energy. Renewable energy sources are considered to be the best sources of energy which means no harm to global environment. Solar energy is a renewable resource which is clean, economical, and less polluted compared to other resources and energy [1].

Photovoltaic module is one of the efficient sources by which solar energy is converted in the form of electricity. Different semiconductor materials are used to make a solar panel. If Si is used to make solar panel, it becomes approximately 24.5% efficient [2]. Solar panel engrosses the energy from the sun and the energy can be stored in the battery which can be used for different purposes. Solar tracker is a system by which a solar panel can actually follow the sun to increase the power [3]. The main objective of this system is to develop a standard model of solar tracking system which consists of image processing using C++ programming language and sensor simultaneously. Thus it can increase the efficiency of solar panel at a great extent compared with the conventional systems.

The paper is organized as follows: Section II describes the photovoltaic technology and methods to improve efficiency of solar panel. Section III illustrates the proposed system. The hardware implementation is described in section IV. The methodology and developed prototype are briefly described in section V and VI respectively. The experimental result and discussion is described in section VII. Finally, section VIII concludes the paper.

II. PHOTOVOLTAIC TECHNOLOGY AND IMPROVING EFFICIENCY OF SOLAR PANEL

Researchers are trying to develop various methods whereby maximum power can be obtained from the solar panel. Maximum power point is the point where the maximum power from the system can be obtained by tracking that point during the sunshine hours. Fig. 1 represents the short circuit current versus voltage and power versus voltage characteristics of a photovoltaic cell [4].

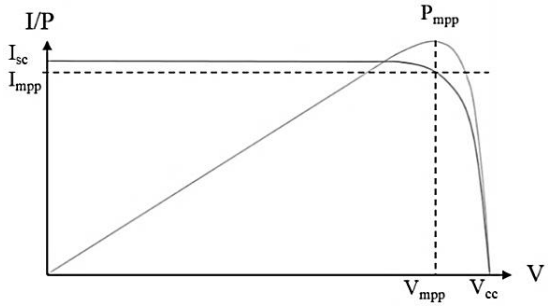

Figure 1. I_{sc}-V and P-V characteristics of solar cell

Researchers developed many Maximum power point tracking (MPPT) algorithms to maximize the output power from solar panel [5]. A solar tracker can increase the efficiency of the

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

solar panel by tracking the sun. This mechanism can increase the power output of solar panel 30% to 60% than the fixed solar panel system [6]. Researchers developed different solar tracking algorithms recently [7, 9].

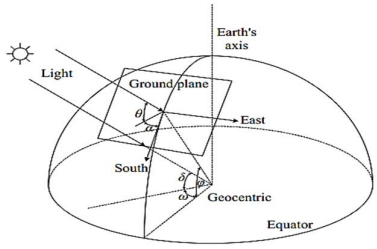

Figure 2. Geometric model of solar position

The sun trajectory tracking mode can work normally till the panel's azimuth and elevation angle change in accordance with the current solar azimuth and elevation angle [10]. From astrophysical knowledge, the solar azimuth and elevation angle at any given time can be calculated [11] [12].

The solar azimuth α and the elevation angle θ can be calculated using (1) and (2):

$$sin\theta = sin\varphi sin\delta + cos\varphi\ cos\delta\ cosw \quad (1)$$

$$sin\alpha = \frac{cos\delta\ sinw}{cos\theta} \quad (2)$$

Where, φ indicates the latitude angle, δ indicates the declination angle, ω indicates solar hour angle. The meanings of the parameters used are presented in Fig. 2 [10].

The declination angle δ and the solar hour angle ω can be calculated using (3) (Cooper Equation) and (4) [11].

$$\delta = 23.45° sin\frac{360°(284+d)}{365} \quad (3)$$

$$\omega = (h + E) \times 15 + \psi - 300° \quad (4)$$

In (3) and (4), h signifies the Beijing time, E indicates jet lag, ψ indicates the local longitude, d indicates the date, for example, d=2 stands for January 2nd, d=364 stands for December 30th [12]. Let, solar position is (α_t, θ_t) at t. Now, after interval T, the position changes to $(\alpha_{t+T}, \theta_{t+T})$. During this time, the variation of solar position can be expressed by $\Delta\alpha=\alpha_{t+T}-\alpha_t$, $\Delta\theta=\theta_{t+T}-\theta_t$.Let the panel has been aligned at t, if it is still aligned from t to T, the panel should rotate Δα in the horizontal direction and Δθ in the vertical direction respectively. In this way, sun trajectory can be explored.

III. Proposed System

The block diagram of the proposed system is presented in Fig. 3. The LDR sensor first takes the solar panel to a desired position. Then image processing is applied to track the sun coordinate. The servo motors are adjusted such that the canter of sun is always at the middle of the scaled camera window. By the iterative method it frequently checks the position of the sun and thus adjusts it to that particular position. The combined effect of LDR sensors and image processing operates simultaneously which gives better performance and efficiency.

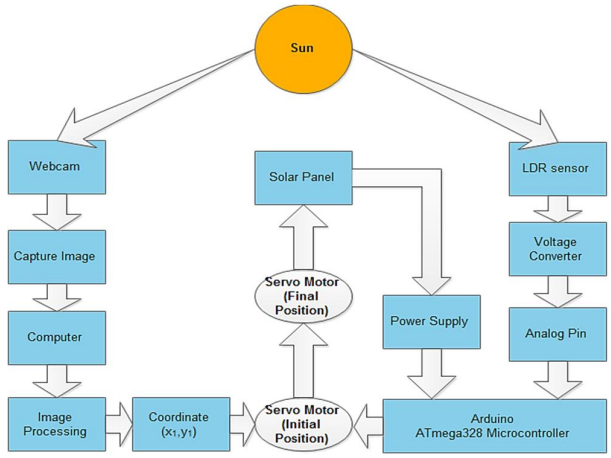

Figure 3. Block diagram of the system

IV. Hardware Design

The hardware consists of an Arduino UNO, two servo motors and four LDR sensors. The LDR sensors sense the sun light and the Arduino UNO takes decision to whether to rotate the vertical servo or horizontal servo motor. The circuit diagram of the system is shown in Fig. 4.

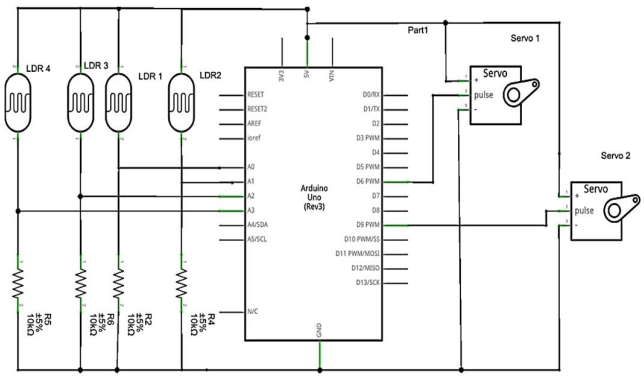

Figure 4. Circuit diagram of the system

V. Methodology

The sun is tracked in two stages- using the sensitivity of LDRs and then the adjustment of camera in new position by shifting the origin. Firstly, LDR sensors with the shadow arrangement compares the intensities fall on them and thus adjust the solar panel at an initial position. If the solar panel is out of track or in the opposite direction of sun it is adjusted towards the direction of sun. Secondly, the webcam mounted on the solar panel captures image of the sun and the computer processes the image using image processing algorithm. A new co-ordinate point is calculated by the described process and the two servo motors are controlled such that the sun remains at the center point of the captured image. The two steps occurred repeatedly and position of the sun is tracked accurately by the webcam.

A. Solar Tracking Using LDR Sensor

The resistivity of photo resistor decreases when the intensity of incident light increases. In the dark, an LDR can have a high

resistance like few mega ohms (MΩ). In the light, it can have very low resistance like a few hundred ohms. When we apply a constant voltage across the LDR and the intensity of light is increased, the current starts increasing. There are four LDRs in the proposed system as shown in Fig. 5. The resistivity of the LDRs will vary according to the intensity of light fall on them. LDR sensors are light sensitive. So, we arranged the LDRs in the proposed system in such a position that when the incident light is on the LDRs of one side (east), the LDRs of other side (west) are shaded. When it is afternoon and the sun goes towards the west, gradually the light intensity on the LDRs of the west will be high and the east LDRs will be in the shaded portion.

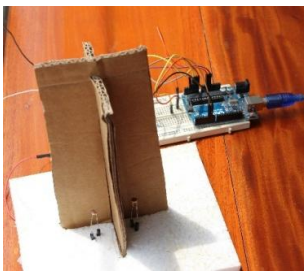

Figure 5. Shadow effect on LDRs

B. Image Processing

The proposed system represents the steps of estimating sun co-ordinates by using image processing. The steps involved in tracking the sun are given in Fig. 6.

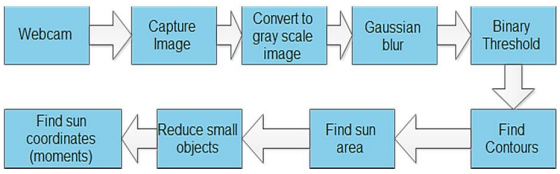

Figure 6. Image processing steps

1) Gray scale conversion and filtering: The captured image consists of the bright sun and blue sky. The processing of image is done in gray scale by extracting the luminescence plane from the RGB plane. Then Gaussian filter is used for the noise reduction of the captured image. The gray scale image is shown in Fig. 7.

Figure 7. Gray scale image with bright sun image

2) Sun detection: In order to extract the bright sun spot, binary thresholding technique is applied on the filtered image. Due to having cloud around the sun, there are some smaller objects detected in the image. Finding the largest contours, the smaller objects are removed. This situation is shown in Fig. 8 (a) and Fig. 8 (b).

(a) (b)

Figure 8. (a) After binary threshold, (b) Estimating the largest area

3) Sun tracking and co-ordinate estimation: After proper segmentation of the blob, the co-ordinates of the sun are estimated by using the centroid formula for irregular objects. The center position of the image is also calculated. Sun co-ordinate point is compared with the image center co-ordinate as shown in Fig. 9 for proper controlling of the servomotors.

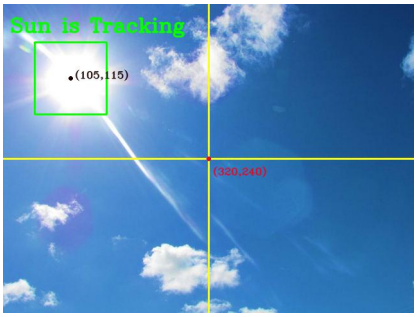

Figure 9. Sun co-ordinates calculation

C. Axis Transformation

1) Transformaton of origin with respect to change of axis: If the origin $O(x_0, y_0)$is shifted at $O'(x_1, y_1)$but the direction of axes remain unchanged, then in the transformed coordinate the origin to be shifted by $(x_1 - x_0)$distance in the x direction and $(y_1 - y_0)$distance in the y direction. The axis transformation is shown on Fig. 10.

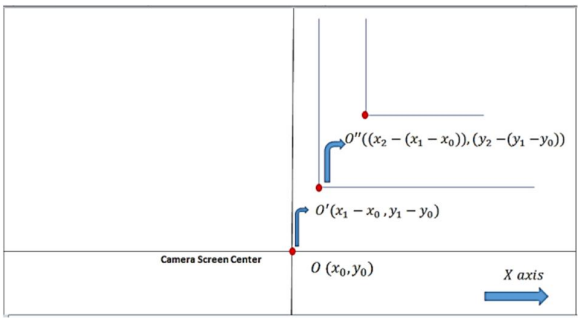

Figure 10. Transformation of origin

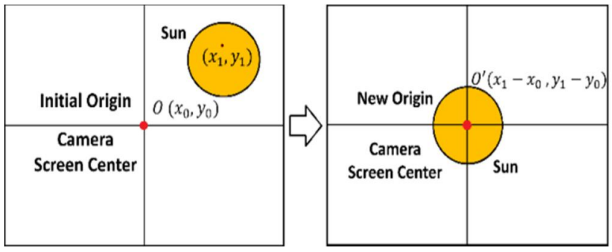
2) Adjustment of the solar panel position by tracking the cordinates of the sun: The webcam captures the images of the

sun and the coordinates of the sun is calculated. Now, the initial camera screen center point is adjusted such that the sun always remains at the center point which is shown in Fig. 11. Then proper transformation formulas are used to get the distance from the initial origin point to the sun coordinates. The two servo motors are controlled to get the proper position.



(a) (b)

Figure 11. Camera position control (a) camera detect sun at (x_1, y_1) point (b) camera screen center is shifted to that point

VI. Developed Prototype

The hardware for LDR based solar tracking system consists of an Arduino UNO, two servo motors and four LDR sensors. The LDR sensors are arranged such that the shadow effect works on them. The image processing based solar tracking system consists of a webcam and a personal computer. The system was tested on a core i5 2.60 GHz processor, 4GB memory running on Windows 7, 64-bit Operating system. The webcam installed on the solar panel had a resolution of 2 mega pixels. The developed prototype for real time sun tracking is shown in Fig. 12.

(b)

Figure 12. Developed Prototype (a) solar panel with webcam (b) LDR arrangement with Arduino and image processing using PC

VII. Experimental Results and Discussion

In this proposed system we used a mono crystalline BX-5W solar panel. The technical specifications were rated power of 5W, 17.4V rated voltage and 0.29A rated current. The open circuit voltage was V_{oc} =21.6V and short circuit current was I_{sc} =0.32A. The normal operating cell temperature of solar panel was45 ℃. The experimental data was recorded in Khulna University of Engineering & Technology (KUET) campus, Khulna-9203, Bangladesh at different times of the day. The experimental data is shown in Table 1.

While working using fixed solar panel, we found the maximum short circuit current of 0.2420A and maximum open circuit voltage of 19.170V at 1pm. Then the experiment was done using same solar panel and with the LDR based solar tracking system. In this case we found the maximum short circuit current of 0.2443A and maximum open circuit voltage of 20.016V at 12pm. Finally, the solar tracking system was implemented using both LDR arrangement and using webcam. In this case, we found the maximum short circuit current of 0.2497A at 2pm and maximum open circuit voltage of 20.456V at 11am. The short circuit current versus the day time was plotted in Fig. 13. The open circuit voltage versus the day time curve is shown in Fig. 14. The power versus the day time curve was plotted in Fig. 15.

This literature describes a novel system of solar tracking mechanism which repeatedly uses LDR sensors and image processing to track the sun. The image processing was done in C++ using OpenCV library. This mechanism is more efficient than the previous solar tracking mechanisms. From the power versus day time curve in Fig. 15, the maximum power was 4.89W at 12pm when we used only LDR sensors in the solar tracker. The maximum power was found to be of 4.96W at 12pm when we used the LDR sensors and webcam simultaneously. Of course the LDR based solar tracking system power curve was above the fixed system. So, it was better than the fixed solar panel system. But the LDR arrangement and webcam based solar tracking system was more efficient during morning and evening but it was quite difficult for the LDR arrangement alone. It was because of the low intensity of the sun light during this period. This system is much preferable compared with the conventional systems.

The sun can be tracked solely by either using Image processing of sun or using LDR sensors. When the LDR sensors are inactive or disabled or become obsolete, the solar tracker can track the sun using image processing spontaneously. On the other hand, if the webcam becomes obsolete or a fault occurs to it, the solar panel can easily operate using the sensitivity of LDRs. After the sun sets, the power supply to the system is disconnected and the system again operates in the next morning.

VIII. CONCLUSION

To conclude, it can be said that the proposed system increased the efficiency of the solar panel by tracking the sun in appropriate direction. The mechanism can be more effective if more LDR sensors are used and every solar panel in a particular area has a webcam. But for minimizing cost, thousands or hundreds of solar panel can track the sun using a single arrangement of LDR and a single webcam. The greater the resolution of the camera the better will be the performance of the solar tracking system. Thousands of solar panel can be operated by using this mechanism in the solar power plant. PLC can be used for the controlling purpose of thousands of solar panels. The more cameras be used; the efficiency of solar trackers will be more high. For minimizing cost, Raspberry Pi can be used instead of computer. The motors and microcontroller can be fed through the power produced by the solar panel itself. After all, we can say that the proposed system can optimize the power requirement by tracking the sun more appropriately.

***Abstract*—This paper represents the effect of solar radiance on the efficiency of GaInP$_2$/GaAs/Ge based multi junction solar cell. Solar radiation changes with the different wavelength and air mass. With the change in the irradiance data, the theoretical efficiency of the multi junction solar cell changes. The whole calculation is based on a modified version of spectral p-n junction solar cell model. The three sub layers are lattice matched and connected in series so that optical transparency and maximum current conductivity through the top and bottom cell can be produced. Short circuit current density, open circuit voltage, maximum current density, maximum power, fill factor and efficiency change with the variation of irradiance for the different air mass. For the simplicity of calculation, there are some assumptions which are necessary. The analysis is done under one sun condition. The J-V curves is also plotted for different layers under different air mass condition.**

***Index Terms*—multijunction solar cell, efficiency, air mass, current density, irradiance**

I. Introduction

Power crisis has been one of the most significant issues all over the world. Scientists and researchers have been working relentlessly to find a solution for this problem. Most of them are doing their work on renewable energy. Because the amount of energy that can be generated from coal, gas or any other petroleum materials is limited. So scientists are more encouraged to work on the renewable energy sources for its unlimited availability. Among all the renewable energy sources, solar energy has got more popularity than all the others. Many works have been done to increase the efficiency of the solar cell.

Single junction solar cell was first introduced. But the efficiency of this solar cell is very low because the maximum efficiency depends on the incident spectrum [1]. The reason working behind that is, there is a good amount of solar spectrum remains unabsorbed due to the single junction. As the absorption is done by only one layer, the energy of the photon greater than the band gap cannot be absorbed by the single junction.

The researchers then developed an idea of converting different parts of solar spectrum that will be incident to the cell. This idea was considered since 1995 [2] [3]. So to reduce the losses and to increase the efficiency of solar cell, multi junction solar cell is introduced. With the innovation of multi junction solar cell, different solar spectrum now can be absorbed by the different layer of the multi junction solar cell. So the losses are reduced that results in increasing the efficiency.

In the figure: 1, it is clearly seen the solar spectra for different air mass [4]. From the figure it is seen that in multi junction solar cell it is possible to absorb most portions of solar radiation by choosing the band gap of different layers.

For the calculations of different parameters of solar cell, many scientists have given different models. First modern silicon solar cell with efficiency of 6 % has been developed in Bell Laboratory in 1954 [5]. In 1961,William Shockley and Hans Queisser reported the maximum theoretical efficiency of 33.7% for a single junction solar cell [6]. Spectral p-n junction model was published both for single junction cell and tandem

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

cell for infinity thickness cell that is the thickness absorbed all incident irradiance equal or greater than thecorresponding band gap of the material [7]. Considering the thickness and modifying the reversesaturation current density equation, a theoretical model for tandem solar cell was reported [8].

For different value of air mass (AM) condition such as AM0,AM 1.5D and AM 1.5G the efficiency of $GaInP_2$/$GaAs$/Ge based multijunction solar cell has been calculated in this paper.

In this paper, section II depicts the discussion about solar cell and renewable energy, section III describes the multi junction solar cell model parameters, section IV gives the idea about the assumptions that are made for the calculations as well as the optoelectronic parameters of the different layer materials, section V shows the results for three air mass conditions and then the paper is concluded in the next section.

II. Solar Cell

Renewable energy is derived from naturally regenerative sources like solar, wind, geothermal or hydroelectric actions. Among these sources the demand of solar energy is increasing rapidly for its feasibility in developing countries. A solar cell is an electrical device by which light energy can be converted into electricity. The electrical characteristics of this photoelectric cell vary due to the different intensity of light [9]. There are various types of solar cells. Single crystalline i.e. monosilicon solar cell having commercial efficiency of about 22% is mostly used in integrated circuits and processing units of computers.

Thin film solar cells have semitransparent nature with lower efficiency of about 12-20%.The third generation PV cell or Organic PV cell are used for light absorption or electrical charge transport [10]. Single junction solar cells usually have lower efficiency. Increasing short circuit current density by better light trapping the efficiency can be improved for single junction solar cells [11].

III. Multijunction Solar Cell Model

Single junction solar cells have lower efficiency. Increasing the efficiency of PV cell is the main motto of current generation that is why multi junction solar cell is introduced into modern technology. Multijunction solar cells are constructed by connecting two or more p-n junction layers in series. Multijunction solar cells can generate power over a larger spectrum of sunlight having a higher efficiency than single junction solar cells. The lattice of the materials must be matched with each other to produce the same current in the different layers of multijunction solar cell. Thus the design for this kind of solar cell becomes complex with an increasing cost [12].The efficiency can be increased due to the reduction of top cell thickness. Cells with low surface recombination velocities can also help to increase open circuit voltage, resulting in higher efficiency [1]. The irradiance changes with the change in air mass coefficient. Thus the efficiency can be varied by using different air mass coefficient (AM).

The short circuit current density J_sc can be calculated by using irradiance data [13].

$$J_{sc} = eF \tag{1}$$

Where, F is the photon flux and e is the charge of an electron. Again,

$$F = \frac{\lambda I}{hc} \tag{2}$$

Where, is the wavelength, I is the irradiance, h is the Planck's constant and c is the speed of light.

The reverse saturation current density can be expressed as [1] [7] [8],

$$J_0 = e\sqrt{\frac{D_e}{\tau_e}}\frac{n_i^2}{N_A}\left(\frac{S_e\sqrt{\frac{\tau_e}{D_e}}\cosh\left(\frac{x_p}{\sqrt{D_e\tau_e}}\right)+\sinh\left(\frac{x_p}{\sqrt{D_e\tau_e}}\right)}{S_e\sqrt{\frac{\tau_e}{D_e}}\sinh\left(\frac{x_p}{\sqrt{D_e\tau_e}}\right)+\cosh\left(\frac{x_p}{\sqrt{D_e\tau_e}}\right)}\right) + e\sqrt{\frac{D_h}{\tau_h}}\frac{n_i^2}{N_D}\left(\frac{S_h\sqrt{\frac{\tau_h}{D_h}}\cosh\left(\frac{x_n}{\sqrt{D_h\tau_h}}\right)+\sinh\left(\frac{x_n}{\sqrt{D_h\tau_h}}\right)}{S_h\sqrt{\frac{\tau_h}{D_h}}\sinh\left(\frac{x_n}{\sqrt{D_h\tau_h}}\right)+\cosh\left(\frac{x_n}{\sqrt{D_h\tau_h}}\right)}\right) \tag{3}$$

Where, D_e and D_h are the diffusion current constant for electron and hole respectively. $N_A$is acceptor concentration, N_D is donor concentration, S_e and S_h are the surface recombination for electron and hole respectively, n_i is the intrinsic carrier concentration, τ_e is the minority carrier lifetime for electron and τ_h is the minority carrier lifetime for hole, x_p and x_n are the thickness of p-layer and n-layer respectively.

For the ease of calculation the above equation can be simplified as,

$$J_0 = eS_e\frac{n_i^2}{N_A} + eS_h\frac{n_i^2}{N_D} \tag{4}$$

The diffusion constants can be calculated from the Einstein Relationship,

$$D_e = kT\frac{\mu_e}{e}$$
$$D_h = kT\frac{\mu_h}{e}$$

Where, k is the Boltzmann's constant, μ_e is the electron mobility and μ_h is the hole mobility. The equation for minority carrier lifetime for electron and hole are:

$$\tau_e = \frac{1}{\frac{1}{\tau_{SRH}} + BN_D}$$
$$\tau_h = \frac{1}{\frac{1}{\tau_{SRH}} + BN_D}$$

B is the direct band-band recombination coefficient and is the Shockley-Read-Hall lifetime. The surface recombination velocities for electron and hole can be written as:

$$S_e = \sqrt{\frac{D_e}{\tau_e}}$$
$$S_h = \sqrt{\frac{D_h}{\tau_h}}$$

The intrinsic carrier concentration can be calculated from:

$$n_i^2 = 4M_cM_v\left(\frac{2\pi kT}{h^2}\right)^3 (m_e^* m_h^*)^{\frac{3}{2}} \exp\frac{-E_g}{kT}$$

Where, M_c and M_v are the densities of states in the conduction and valance band, T is the temperature, E_g is the energy gap of the material, $^*_e$ and m_h^* are the effective mass of electrons and holes respectively, M_c and M_v are the number of equivalent minima in the conduction and valance band. The open circuit voltage can be expressed as:

$$V_{oc} = \left(\frac{kT}{e}\right)\ln\left(\left(\frac{J_{sc}}{J_0}\right)+1\right) \tag{5}$$

The maximum voltage is:

$$V_m = V_{oc} - \frac{1}{\beta}\ln(1+\beta V_m)$$

Maximum current density is:

$$J_m = J_{sc}\left(1 - \frac{1}{\beta V_m}\right)$$

The final equation for the efficiency of the solar cell is:

$$\eta = \frac{V_{oc}J_{sc}F.F.}{P_{in}} \times 100\%$$

Where, P_{in} is the input power and F.F. is the fill factor

IV. ASSUMPTIONS AND PARAMETERS

The parameters that are required for calculation of different layers of the semiconductor materials are considered at the temperature of 298K. The input power densities for AM0 is 1353 W/m^2 and for AM1.5G is 1000 W/m^2 and for AM1.5D is 900 W/m^2 [14] [15] [16]. It is also assumed that there are no losses regarding reflection, grid coverage and series resistance. All the calculations are done using the modified versions of standard equations that is the modified version of spectral p-n junction model [1] [8]. The value of irradiance data is gathered from the data provided by ASTM [17].

It has been considered that, there is no carrier generation or recombination in the space charge region, neutral region operates at low injection condition and electric field in neutral region is negligible and photon recycling effects are also negligible.

The optoelectronic parameters are collected for 298K temperature [18] [19] for the different materials used for the three layers.Taking the values of different parameters from the table I, the calculations are done for the various equations that are mentioned in the previous section. The three materials that are chosen for the different layers are lattice matched.

TABLE I
OPTOELECTRONIC PARAMETERS [18] [19]

Parameter	$GaInP_2$	$GaAs$	Ge
Band Gap,(E_g) eV	1.9	1.42	0.67
wavelength,(λ) nm	654.28	875	1775
No of Equivalent Minima in Conduction Band (M_c)	1	1	1
No of Equivalent Maxima in Conduction Band (M_v)	3	1	1
electron mobility (η_e) m^2/Vs	0.4	0.2322	0.39
hole mobility (η_h) m^2/Vs	0.02	0.02	0.19
m_c^*/m_e	0.155	0.067	1.64
m_h^*/m_h	0.460	0.473	0.28
Shockley-Read-Hall Lifetime(T_{SRH}) s	10^{-5}	10^{-5}	10^{-5}
Direct band-band recombination co-efficient(B) s^1m^3	7.5×10^{-16}	7.5×10^{-16}	7.5×10^{-16}
Acceptor Concentration (N_A) m^{-3}	1×10^{23}	9×10^{23}	1×10^{23}
Donor Concentration (N_D) m^{-3}	2×10^{24}	7.8×10^{23}	2×10^{24}
Thickness of p-layer(X_p) m	1×10^{-07}	1×10^{-07}	1×10^{-07}
Thickness of n-layer(X_n) m	2.08×10^{-07}	3×10^{-07}	4×10^{-07}
Lattice constant (a) m	5.660×10^{-10}	5.659×10^{-10}	5.646×10^{-10}

Most of the parameters are dependent on the temperature. So if the temperature is changed, the values of these parameters will change. The thickness of the p layer is kept same for the each layer whereas the thickness for the m layer is different for the three layers of the multi junction solar cell.

V. RESULTS

Using the different equations mentioned in section III the following calculations are done. MATLAB is used for the calculations of the different parameters.

In table II the variations of short circuit current density and the open circuit voltage of the three layers for different air mass condition is shown.

Table III depicts the variations in overall current density, total open circuit voltage, maximum voltage, maximum current density, fill factor and efficiency of the solar cell for different solar radiation spectrum for different air mass.

The total leakage current density vs the open circuit voltage for each multi junction solar cell under different air mass solar radiation spectrum is plotted in the graph.

Figure:2 shows the J-V characteristic for solar radiation spectrum under AM0 condition, figure: 3 shows the J-V

TABLE II
COMPARISON OF DIFFERENT LAYERS

Parameters	AM0	AM 1.5 G	AM 1.5D
Top Layer $GaInP_2$			
Short circuit current density(J_{sc1}), A/m^2	828.9520	744.89	674.0564
Open circuit voltage(V_{oc1}), V	1.4387	1.4300	1.4334
Mid Layer $GaAs$			
Short circuit current density(J_{sc2}), A/m^2	658.5420	652.39	623.859
Open circuit voltage(V_{oc2}), V	1.0418	1.0415	1.0404
Bottom Layer Ge			
Short circuit current density(J_{sc3}), A/m^2	251.3022	163.9747	160.1052
Open circuit voltage(V_{oc3}), V	0.1325	0.1216	0.1210

TABLE III
COMPARISON OF THE TOTAL CELL PARAMETER

Parameters	AM0	AM 1.5 G	AM 1.5D
Short circuit current density(J_{sc}), A/m^2	251.3022	163.9747	160.1052
Total open circuit voltage(V_{oc}), V	2.6129	2.5991	2.5947
Maximum voltage (V_m), V	2.4939	2.4802	2.4759
Maximum current density (J_m), A/m^2	248.7122	162.2754	158.4431
Fill Factor (F.F.)	0.9446	0.9444	0.9443
Power input (P_{in}) , W/m^2	1353	1000	900
Efficiency (η), %	45.8441	40.2482	43.5879

characteristic for solar radiation spectrum under AM1.5D condition & figure: 4 shows the J-V characteristic for solar radiation spectrum under AM1.5G condition.

The total leakage current density is different for different layer and also for different solar radiation spectrum. The reason behind this is the short circuit density is dependent on the irradiance. The value of irradiance varies for the different wavelength. The wavelength is different for different band gap as well as for different layers for absorption. So as the value of irradiance is varying so does the total leakage current density.

For AM0 condition, the value of irradiance data [20] is higher than that of the AM1.5G and AM1.5D.because AM0 is suitable condition for space where the solar radiation is much more than the earth surface. The data that is used is generated by the American Society for Testing and materials (ASTM). It is one of the most accurate and recognized data for multi junction solar cell which is developed by counting one year average weather of United States of America [14]. Efficiency

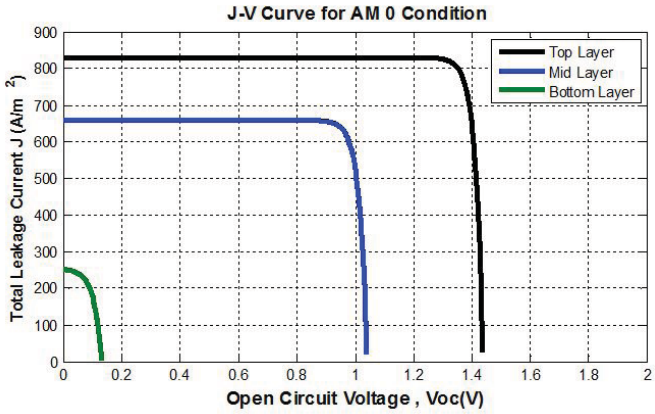

Fig. 2. J-V characteristic for AM0

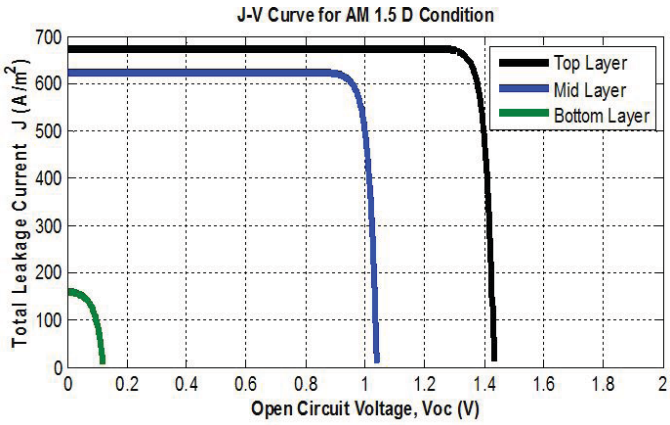

Fig. 3. J-V characteristic for AM1.5D

for AM1.5D is greater than the efficiency for AM1.5G because sunlight hit the solar cell directly in case of AM1.5D and for AM1.5G sunlight hit the solar cell after diffusion.

In the above figures, it is clearly seen that the total leakage current density remains same for a certain increment of open circuit voltage. But after a certain voltage the current density falls. By finding a maximum current and voltage and

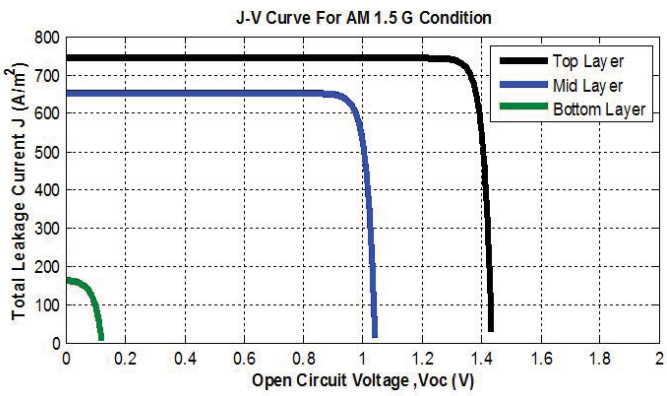

Fig. 4. J-V characteristic for AM1.5G

multiplying them maximum power can found for the solar cell.

In each solar cell, the minimum leakage current is flowing from the bottom layer. So the total cell current density will be the value of the bottom cell current density. So to increase the cell efficiency, the increase of leakage of current density in the bottom cell is necessary.

This characteristic may change in the practical scenario as there are losses. Conditions like carrier recombination in the space charge region, operating injection condition of neutral region, the amount of electric field in the neutral region, effects of photon recycling can cause decrement to the leakage current density and open circuit voltage leads to the reduction in the maximum power resulting in reducing the overall efficiency.

VI. Conclusion

The paper represents the variations in efficiency of GaInP2/GaAs/Ge based multijunction solar cell in different AM conditions such as AM0 , AM1.5D & AM 1.5G. Parameters such as short circuit current density, open circuit voltage also vary in each of the three layers considering change in AM condition. Maximum current density ,maximum voltage & total leakage current for the cell shows a significant change for diverse air mass values. For the three layer solar cell, the minimum current density is found in the bottom cell and it is the current density for the solar cell. As the junctions are connected in series, the open circuit voltage rises as the total open circuit voltage is the summation of three layers open circuit voltages.

***Abstract*— This paper focuses on operation of small scale renewable plants so that the energy produced can be utilized to its highest potential. Energy crisis being one of the main problems is leading the researchers to find fossil fuel replacement which is eventually renewable energy. In most cases, renewable energy is unpredictable as they rely on the nature. Besides, in developing countries it is discouraged to install renewable technology due to their random nature. In order to design a reliable microgrid where renewable resources contribute to its grid power supply, multi-agent system has been incorporated to add intelligence to the system. The various loads to be fed are divided according to importance. The proposed concept also allows sharing of load among utility supply and renewable sources during normal operation.**

***Index Terms*—microgrid, intelligent, multi-agent system, limited renewable resource**

I. INTRODUCTION

Microgrid may be the eventual answer to the present energy crisis that is growing steadily in our world. Implementation of microgrid increases reliability in power distribution system. The utilization of renewable energy in a microgrid though may be a great challenge, this is where the assistance of another system is required which will act as the brain for the microgrid. The multi-agent system (MAS) technology is quite attractive in this respect as it provides a touch of intelligence to the system. There has been significant research on MAS technology in the recent times. MAS use multiple software agents to complete a collective task by dividing and distributing the task among the agents. Renewable energy resources like solar PV, wind turbine etc. contributes a lot to the distributed energy resources (DER) of the microgrid. These renewable energy sources being unpredictable and not always reliable, it becomes a great challenge to utilize them to their highest potential. Hence a system is needed that can adapt to the dynamic behavior of the sources.

Designing agent architecture for microgrid is a complex task. Several studies have been conducted in this field are noteworthy. The research on Intelligent Distributed Autonomous Power System (IDAPS) [1] has discussed on developing architecture for an intelligent system which works in co-ordination with different agents for managing customer owned units in the distribution network. Another research on securing critical loads in a PV-based microgrid with multi-agent system [2] was conducted which basically focused on the design and implementation of a multi-agent system through simulation. There were further discussions on securing critical loads during grid failure. Practical implementation of a multi-agent system was somewhat achieved in [3]. The research concentrated on building hardware modules for the agents. A research on optimization of solar panel output for microgrid based on multi-agent system has been conducted in [4]. Detailed research on scheduling of distributed generation is discussed in [5]. Some more application of MAS in microgrid have been deliberated in [6]-[8].

The sole purpose of this research is to develop a control mechanism for required agents so that they can respond to the changes in the scenario and act accordingly. It is also intended that the power generated from the renewable sources be wisely utilized in order to reduce power consumption from the utility grid supply. In order to make the research as reliable as possible the load profiles for the microgrid is based on the load of Chittagong University of Engineering & Technology (CUET), Chittagong, Bangladesh.

II. OVERVIEW

The first task was to analyze the electrical loading in different feeders of CUET. The microgrid was designed according to the data acquired from the analysis of the loads. The units comprising the DER of the microgrid were selected. This was followed by choosing of different agents that are responsible for managing the DER output. At last model architecture was developed using the agents.

III. LOAD ANALYSIS

A. Collection of data

The data was collected from CUET substation on an hourly basis for a month. There are in total 11 feeders in this educational facility that provides electricity to various loads.

B. Determination of peak load

The data collected was later processed to a load profile of a single day by taking into count the average loadings of working

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

days in the institution. The list of feeders and their peak loads are given in table I.

TABLE I. ESTIMATED PEAK LOAD FOR EACH FEEDER

Feeders	Details	Daily power consumption (kW)	Estimated Peak loads(KW)
Feeder 0	12 floor engineering building, auditorium, Ansar camp	447	50
Feeder 1	Electrical & Mechanical Engineering building Mechanical Engineering Workshop	319	45
Feeder 2	teachers & officer's quarters	1052	70
Feeder 3	Civil & CSE building	510	50
Feeder 4	Vice Chancellor's Bungalow	172	13
Feeder 5	Sufia Kamal Hall	276	18
Feeder 6	Pump , IRP	546	40
Feeder 7	Shaheed Tareq Huda Hall, Shaheed Mohammad shah Hall and Dr. Qudrate Khuda Hall	1169	72
Feeder 8	Pre-engineering building, VC office, library	781	75
Feeder 9	Staff quarter	509	28
Feeder 10	Bangabandhu Hall, canteen, Bank, Mosque, PME Building	414	35

C. *Load curve*

Each feeder was analyzed in order to get a daily load curve that gives an idea on the load behavior of the grid. The load curve gives better prediction on what the demand will be and measures can be taken accordingly.

For simplicity the load curve of all the feeders united is shown in Fig. 1.

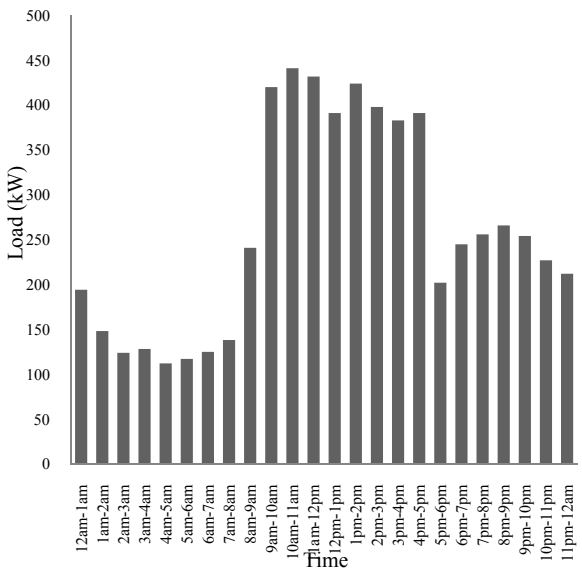

Figure 1. Load curve of the whole system for a single day

From the load curve in Fig. 1 we can observe the electrical activities for a whole day.

IV. MICROGRID MODELING

The microgrid that is intended to design has two parts, the physical part and the virtual part. The virtual part will be discussed later. The distribution system is divided into two parts, (i) utility grid and (ii) DER grid. Considering each feeder as a subsystem that consists of the load, we have 11 subsystems. These subsystems will be powered by utility grid supply and the DER sources. The DER sources include a PV panel and a diesel generator. The different parts of the microgrid are briefly discussed below.

A. *Utility Grid*

Two lines have merged, one from Madunaghat substation and the other from Chandraghona substation supplying 33kV line to the CUET substation.

B. *The subsystems*

The 33kV line is further stepped down to 11kV and then again to 380V. This line is fed to all the feeders. As mentioned earlier, different feeders are considered as subsystems that will denote the loads. The subsystems are further divided into critical and non-critical loads. The selection of critical load depends on the type of load that is to be supplied. Critical loads for residential purpose will differ from that in a class room.

C. *The DER grid*

For efficient distribution of energy, DER grid has been designed to operate isolated from the utility grid. For this research, it is vital fact as the alternative sources which we selected are not able to fully sustain all the critical loads during outage or fault.

The DER grid as mentioned earlier is powered by a PV module and a diesel generator as discussed below:

1) PV module: We assume that a 50kW solar PV panel provided with a battery is existent in our system.

2) Diesel generator: A diesel generator of 67.5kVA is being used for our model.

Each subsystem is provided supply from the DER grid. Another important fact for the diesel generator is that it will only be activated during 'emergency' protocol. The 'emergency' protocol is a manual override during which the diesel generator will be allowed to supply power. The schematic diagram of the whole system is shown in Fig. 2.

V. SELECTION OF CRITICAL LOAD

Selection of critical load is very important for our microgrid design. Critical loads may vary from subsystem to subsystem. At optimum condition, a total of 50 + 67.5 = 117.5 kW (considering power factor unity) can be generated. Owing to the fact that there are several unavoidable losses, the sum is multiplied by a factor of 0.9 which leads to getable power of 105.75kW. Hence while selecting critical loads each subsystem

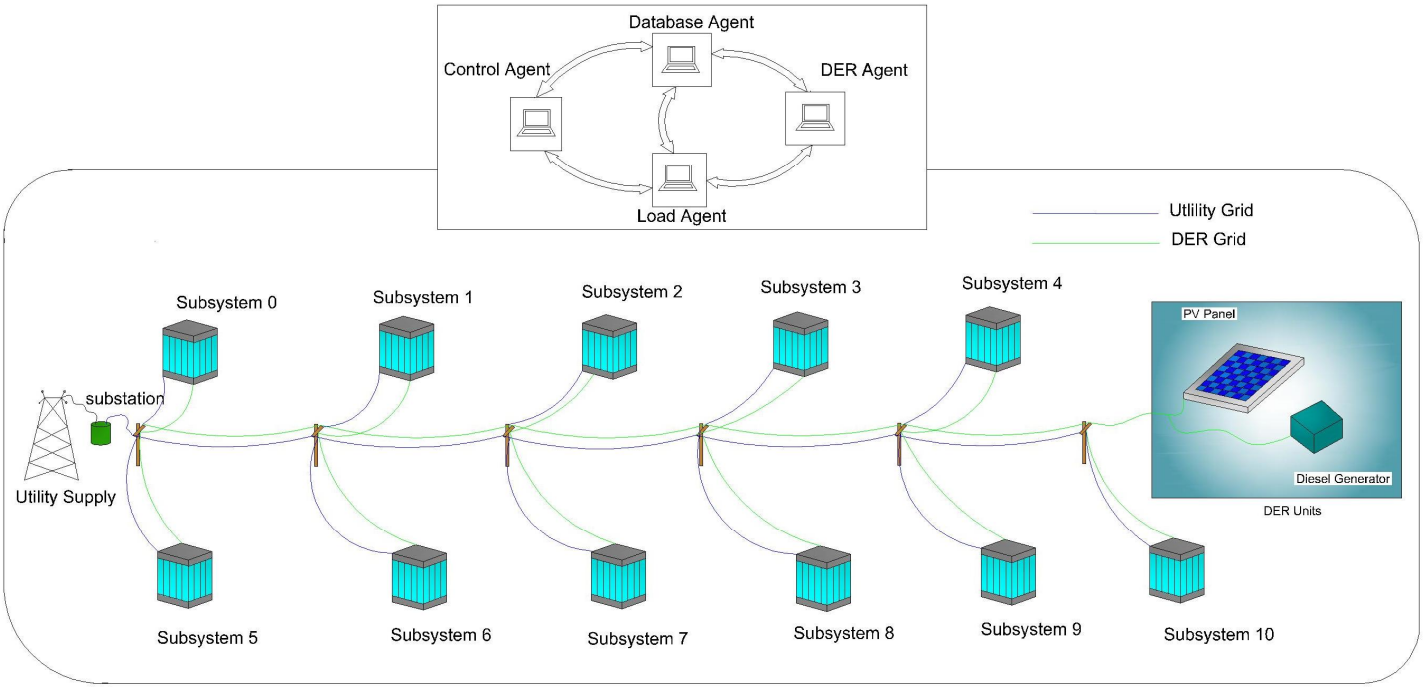

Figure 2. Schematic diagram of the Microgrid in collaboration of MAS

will be assigned a specific amount of loads to gain supply. The selection of load was done according to the need of the subsystem. The allocation of critical loads for each substation is given in table II.

TABLE II. CRITICAL LOAD ALLOCATION

Subsystem	Types of load	Allocated load in kW
0	light, fan, multimedia projectors	12.5
1	light, fan, multimedia projectors, computer	11.5
2	light, fan	18
3	light, fan, multimedia projectors, computer	13
4	light, fan	4
5	light, fan	4.5
6	pump, street lamps	10
7	light, fan	15
8	light, fan, computers	20
9	light, fan	8
10	light, fan , computers	9
	Total	**125.5**

From the table, we observe that a total of 125.5 kW load has been assigned and our total getable power is 105.75 kW. Moreover, the diesel generator is not intended to be used until dire need arises. Hence, distributing the 50 kW PV output among the loads is our main objective.

VI. MULTI-AGENT ARCHITECTURE

According to the requirements of our microgrid the agents are to be selected. The agents must be well defined in order to complete their assigned tasks.

A. Selection of agents

Four agents are required to achieve the goal that has been set. They are,

1) Control Agent: Control agent acts as the actuator of the decisions that are taken. It controls all circuit breakers (CB).

2) Load Agent: Load agent monitors the voltage and frequency of the different subsystem. It sends power request during fault or outages.

3) DER Agent: DER agent monitors the output from the various DER sources. It also checks fuel inventory for diesel generator.

4) Database Agent: Database agent stores data in the form of log.

B. Assign task to the agents

In order to function the agents properly, primarily their tasks and goals have to be set. The tasks are discussed as follows

1) Islanding: This the task performed by the database agent when fault occurs in the utility grid. The other agents are informed about the fault. During islanding the internal grid system is isolated from utility grid.

2) Load shed: This task is performed by the control agent. During islanding all the non-critical loads are shed by invoking this task

3) Emergency: The database agent responds to this task and broadcasts if emergency protocol has been activated

4) Check DER output: The DER agent performs this task by continuously monitoring the output of various DER sources.

5) Check inventory: The DER agent monitors the fuel inventory for diesel generator through this task.

6) Check demand: The load agent checks the voltage and current of various loads through this task.

7) CB open/close: This task is performed by the control agent. Through this task, command signal are sent to the circuit breakers to open or close.

8) Check priority: Priority is a floating number assigned to each subsystem from 0-1. Higher the value the greater the priority.

C. Agent Collaboration

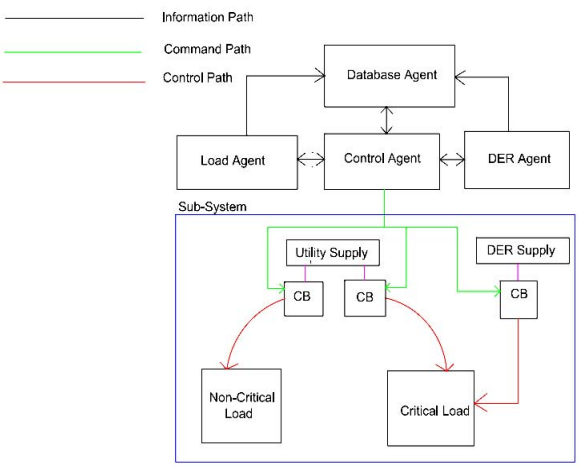

Figure 3. Agent Collaboration

Analogy of a single substation is shown in the Fig. 3. The load agent and the DER agent constantly update the database. The control agent checks for any fault or emergency and acts accordingly. Control agent also controls the circuit breakers that provide power to the loads.

D. Agent Algorithm

The main objective of the agents is to distribute the power output from the DER grid as efficiently as possible. The flow diagram of the control algorithm is shown in Fig. 4.

Suppose an outage occurs, so the grid algorithm will be objected to restore power in the DER grid. At first the subsystem with highest priority is chosen. The output power of the PV panel and the demand of the subsystem are checked. If the demand is less than or equal to the output, circuit breaker to the critical load is closed. If the demand is greater, although being of higher priority the subsystem is ignored. Then the process is repeated for the next priorities until all the subsystem are checked. The system will check if emergency protocol is activated. If not then the system remain as it is until the priority changes or PV output changes.

Next, if there is emergency then the fuel inventory are checked. If there are sufficient supplies, the generator will start. Subsystems those which were ignored will be checked again. If the demand and output match then the critical circuit breaker will close or the system will stay as it is until the priority changes or there is short of supplies.

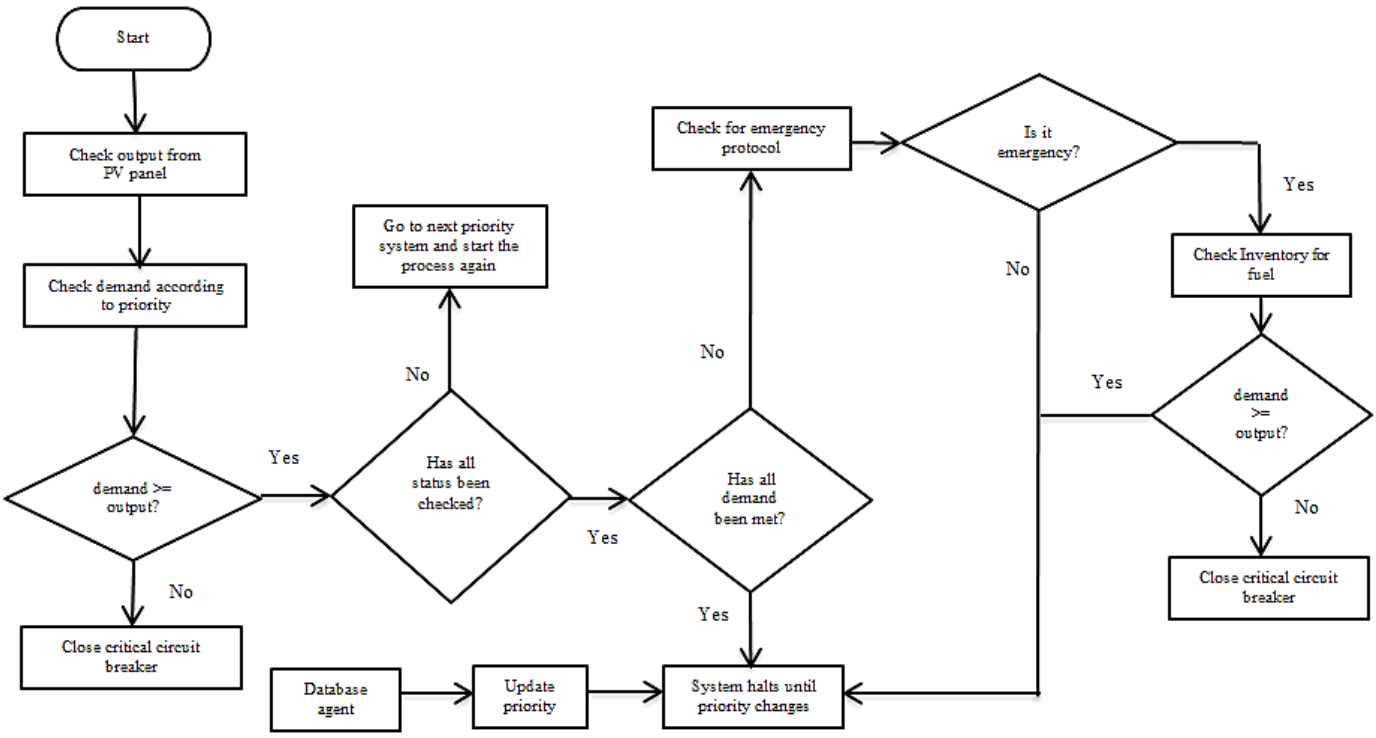

Figure 4. Control analogy for distribution of DER output during outage, fault or load sharing

VII. MICROGRID FEATURES

The designed microgrid has two noteworthy features as discussed below:

A. Islanding Mode

The islanding mode is a very important feature of the microgrid. It protects the microgrid from external fault by isolating it. This feature helps in prevention of blackout, brownout or any other utility grid faults affecting the system.

B. Load Sharing Mode

The designed microgrid not only restores power during outages but also reduces load on utility supply whenever the PV panel is producing enough. The load is at its peak during 9am to 4pm. During this time the PV panel also produces sufficient power. So the critical load which can be sustained by the PV supply are disconnected from the main grid and instead powered by the DER grid. The reduction in power consumption can be shown in Fig. 5.

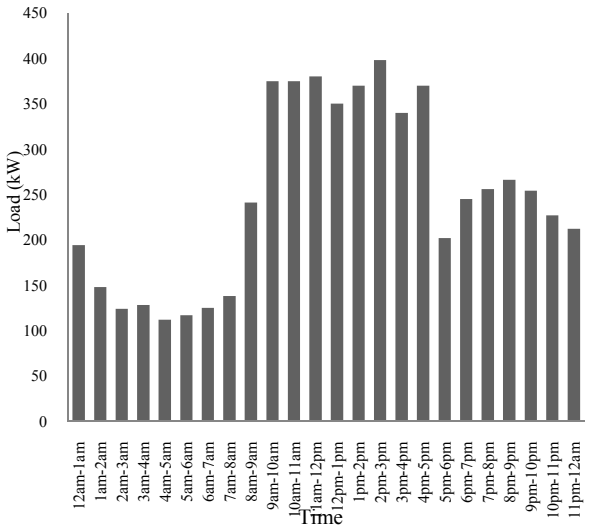

Figure 5. Load curve of the whole system while load sharing

It can be observed that the peak power demand has reduced to 360kW which was around 400kW initially.

VIII. SYSTEM REALIZATION

Multi-agent system realization has been shown in various research works. Some published researches on realization of the system have been mentioned in [9]-[12]. Although system realization is beyond the scope of this research, but a brief process is discussed as follows.

In most of the cases, the microgrid is simulated using MATLAB/Simulink. The loads, sources and other components are available in the library. The agents are developed using agent building toolkit such as JADE [13] and Zeus [14]. The physical system i.e. the microgrid developed in Simulink and the virtual system which are the agents are connected over a TCP/IP connection. The TCP/IP protocol allows computer of different sizes and operating system to communicate with each other [15]. Then a third party software [16] is used to establish the link. The agents communicate among themselves in various ways. For ZEUS based agent architecture, message is exchanged among the agents as a means of communication [2]. In case of IP based network, the agents are placed at single server [12] where they can communicate among themselves easily.

The physical system can be implemented in several ways. In this research, different grid for utility supply and DER supply has been used. The one line diagram of a single system is shown in Fig. 6. The other subsystems also have a similar arrangement. The critical load circuit breakers, non-critical load circuit breakers and the DER control circuit breakers are controlled by the agents while the LV circuit breakeris dependant on fault conditions.

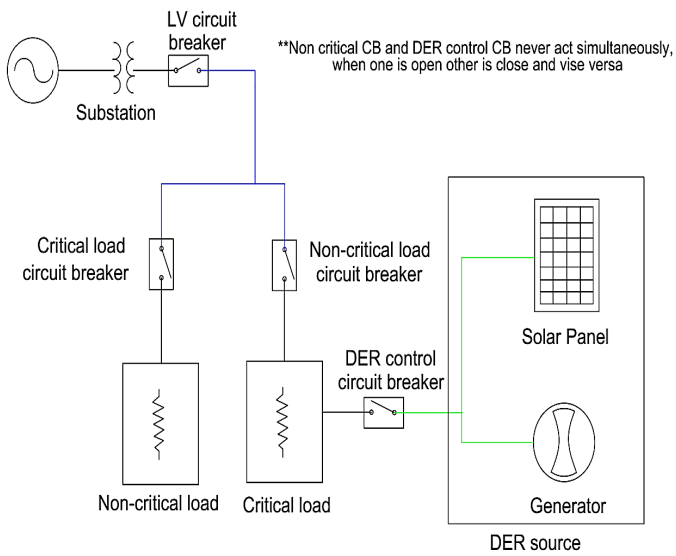

Figure 6. One line diagram of a single subsystem

IX. RESULT AND DISCUSSION

The load analysis revealed that most of the electrical activities are around 9 am to 5pm when the peak load is about 400 kW. For supplying a critical load of 125.5 kW a collective distributed generation of 105 kW is available. In order to distribute the power generated by the PV panel and the generator, the algorithm proposed earlier for scheduling the distributed generation is quite important. Some test conditions are applied to the algorithm and the results are tabulated in table III & table IV.

The four agents as defined earlier are able to function properly to achieve the goal of proper distribution of limited distributed generation. This gives a lot of option and alternative to make an efficient scheduling for distributed generation. Even when there is no sunlight the grid can be supplied by the

generator without taking the machine to overload conditions. If any unit is added or is unavailable the agents will act accordingly to maintain power supply.

Two cases have been shown for visualization of the effectiveness of the algorithm. In the first case only, a PV output of 50 kW is incorporated as shown in table III. In the second case, a combined output of which the PV output of 30 kW and the generator supply of 67.5 kW is considered. For both cases, the priority orders are set as depicted in table III and table IV.

TABLE III. SCHEDULING WHEN PV OUTPUT IS 50 KW AND GENERATOR IS OFF

Sub-system	Priority order	Critical load in kW	State of DER control CB	Power supplied by		
				Grid	PV	Gener-ator
0	1	12.5	closed		✓	
1	2	11.5	closed		✓	
2	3	18	closed		✓	
3	4	13	open	-	-	-
4	5	4	closed		✓	
5	6	4.5	open	-	-	-
6	7	10	open	-	-	-
7	8	15	open	-	-	-
8	9	20	open	-	-	-
9	10	8	open	-	-	-
10	11	9	open	-	-	-
Demand fulfilled by PV				**45.5 kW**		
Demand fulfilled by generator				**0 kW**		

TABLE IV. SCHEDULING WHEN PV OUTPUT IS 30 KW AND GENERATOR IS ON (67.5 KW)

Subs-ystem	Priority order	Critical load in kW	State of DER control CB	Power supplied by		
				Grid	PV	Gener-ator
0	1	12.5	closed		✓	
1	2	11.5	closed		✓	
2	3	18	closed			✓
3	4	13	closed			✓
4	5	4	closed		✓	
5	6	4.5	closed			✓
6	7	10	closed			✓
7	8	15	closed			✓
8	9	20	open	-	-	-
9	10	8	open	-	-	-
10	11	9	open	-	-	-
Demand fulfilled by PV				**28 kW**		
Demand fulfilled by generator				**60.5 kW**		

Power consumption can be reduced up to 10% when running on load sharing mode.

X. CONCLUSION

In this research, a microgrid model is designed for adapting to limited DER supply. The multi-agent architecture is also developed which incorporated with the microgrid helps to develop an autonomous system which is able to adapt to the dynamic behavior of the renewable energy sources. The control algorithm ensured that the system is a reliable and efficient. Successful implementation of small scale renewable power plants will encourage the initiative of making larger plants. Besides, the system is also able to deal with faults and outages and take necessary actions.

Automation of electrification in case of microgrid opens up a lot of scope in research. Meshing up two or three microgrids and sharing power among them is also possible. Hence, a market can be created where power will be the currency. Agent behavior and performance can be greatly enhanced by the use of neural network and fuzzy logic.

***Abstract*—Current power generation scenarios all over the world are not climate friendly as the generation systems are mainly dependent on fossil fuels that produce greenhouse gas (GHG) which contributes to global warming. This paper conducts a feasibility analysis to explore the potentialities of green energy at Kuakata in Bangladesh. The considered renewable energies for investigation are solar and wind. Initially, a hybrid model has been designed with varying the contribution of renewable resources for the considered coastal region of Bangladesh using Hybrid Optimization Model for Electric Renewable (HOMER) software. This model explores a suitable design for mini-grid by varying the capacity of wind and solar units. Also, a comparison has been carried out for different models on the basis of GHG emission. The simulation results show that the proposed grid-PV-wind hybrid power system model with 76% renewable fraction is most suitable, economical and eco-friendly for the considered region.**

Keywords—greenhouse gas (GHG); grid; HOMER; hybrid power system; solar; wind.

I. Introduction

Renewable energy (RE) can play an important role in reducing global warming and high cost of energy [1]. Every sector of modern civilization is dependent on energy which comes from various energy sources such as nuclear energy and fossil fuel (coal, oil and natural gas). The combustion of these energy sources emits huge amount of greenhouse gases (GHG) such as carbon dioxide, sulfur dioxide, nitrogen dioxide that harm the atmosphere and health of the population [2]. Recently, hybrid power systems using RE are becoming popular due to their potential benefits on environment [3].

Presently, the power demand of Bangladesh is about 10,000 MW and it is increasing day by day. As natural gas is used for about 80% energy generation, Bangladesh is responsible for a large amount of GHG emission [4]. Moreover, the present reserve of fuel used for power generation would be depleted by a decade [5]. Therefore, an alternative way of energy generation in Bangladesh is very urgent. RE sources are considered as the best way to meet the energy demand as they are clean and environmental friendly [6].

Although RE sources such as wind and solar have several advantages, a solar or wind generator in a stand-alone system cannot supply the load continuously due to their intermittent nature [7]. As load demands are always changing with time, the changes in solar or wind energy generation do not always match with the time distribution of load [8]. Therefore, there is a need of additional battery storage or other components for providing continuous power supply to the consumer. It has been investigated that a hybrid PV/Wind/battery system is a reliable source of electricity [9]. However, due to the high cost of battery energy storage, a stand-alone system is very expensive [10]. Therefore, it is important to find a suitable combination of different RE sources to maximize the benefit.

Therefore, the main objective of this paper is to quantify the amount of GHG gas emissions from different system models. The economic and environmental feasibility of grid connected proposed model is analyzed. The potential of PV and wind energy is also investigated in the considered region (Kuakata, Bangladesh) and finally, the contribution of renewable energy is determined to get the optimum performance.

The rest of the paper is organized as follows. Section II describes the system description. Methodology is given in Section III. Simulation models are provided in Section IV and results are evaluated in Section V. Finally, conclusions are drawn in Section VI.

II. System Description

In this paper, a number of hybrid power system models with different percentage of renewable energy contribution have been designed to evaluate and determine the cost of different models. GHG emissions from each model are also determined. The analysis is conducted using HOMER software. The HOMER simulation software needs some input data to evaluate the optimization results for different combinations which are described in the next section [11].

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

A. Electricity Demand in Considered Region

The region considered in this paper is Kuakata situated in Patuakhali district in Bangladesh. In this study, after collecting data for load calculation, we assumed that 200 families consumed average 6.6 kWh/d/family, 50 shops consumed 2.5 kWh/d/shop, 15 tourist hotels that consumed 25 kWh/d/hotel, 300 battery run auto rickshaw consumed about 9.66 kWh/d/rickshaw, the total load for the whole area is 4820.87 kWh per day with a peak load of 794.66 kW. The load is grouped in two parts, one is load 1 which consists of houses, shops and hotels loads; another is load 2 which consists of battery run auto rickshaws. The daily average load profile for two types of load is shown in Fig. 1 and Fig. 2, respectively in which 17:00 to 23:00 h time period has been observed as peak demand for domestic load and 23.00 to 06.00 h for charging of the battery of auto rickshaw. The peak value of demand requirement determines the size of the system.

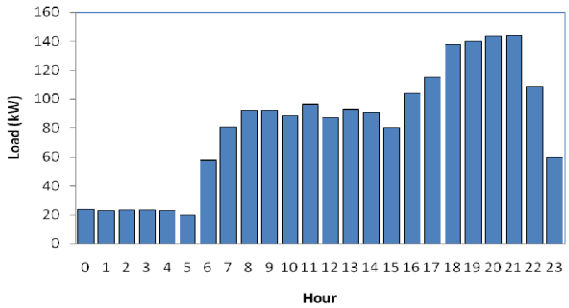

Fig. 1. Daily household load profile.

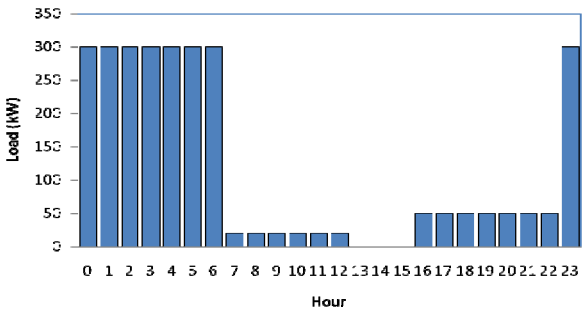

Fig. 2. Daily load profile for auto rickshaw charging.

B. Energy Sources in Kuakata

The coastal area of Bangladesh is suitable for the production of electricity as there is strong wind flow coming from Indian Ocean. This wind blows over Bangladesh form March to September. According to the meteorological department of Bangladesh, monthly average wind speed is observed 3 m/s to 8.3 m/s [12]. The wind speed is high during March to September and other months of a year (October to February) wind speed remains quite low. The peak wind speed occurs during the month of April and May [8]. Fig. 3 shows the monthly average wind speed around the year at Kuakata. Monthly average solar radiation is obtained from NASA surface meteorology and solar energy database and it is shown in Fig. 4. As used in HOMER software, the latitude and longitude of Potuakhali district are 21°49.3´N and 90°7.39´E, respectively. The annual average solar radiation is estimated to be 4.76 kWh/m^2/day [11].

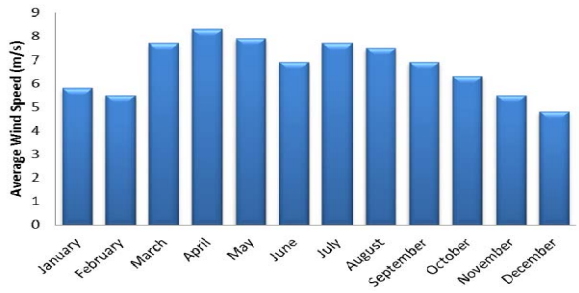

Fig. 3. Monthly average daily wind speed.

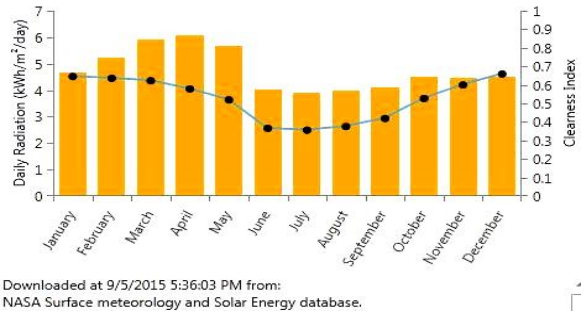

Fig. 4. Monthly average daily solar radiation and clearness index..

III. Methodology

A. HOMER Software

HOMER software is developed by the National Renewable Energy Laboratory (NREL) [13] in the United States (USA). It is generally used for the design and analysis of hybrid power system. In this paper, electrical load, solar radiation and wind speed data, and component details and cost are provided as input information to HOMER.

B. Cost Analysis Procedure by HOMER[2,11,13]

1) Net present cost (NPC): NPC means the present value of al component (operating and maintenance cost) that isinstalled in the plant, minus the present value of all the revenues that it earns over the plant life-span [2,11].

2) Total annualized cost: The total net present cost in a year is called the total annualized cost. It expressed as [2,11]:

$$C_{yr,total} = CRF\ (i, R_{plant\text{-}life}).\ C_{NPC,total}$$

where $C_{NPC,total}$, i, CRF, and $R_{plant\text{-}life}$ represents the total net present cost in dollar, the annual real interest rate, capital recovery factor and the plant life-time in year, respectively.

3) Capital recovery factor (CRF): It is a ratio which is needed to calculate the present value of a series of equal yearly cash flows. It can be expressed as [2,11]:

$$CRF(i,n) = \frac{i \times (1+i)^n}{(1+i)^{n-1}}$$

where, n = number of years and

i = the real interest rate in a year

4) Annual real interest rate: It is the discount rate which is used to convert between one-time costs and yearly costs. It is calculates as follows [2,11].

$$i = \frac{i' - F}{1+F}$$

where, i, i' and F is the real interest rate, nominal interest rate, and annual inflation rate, respectively.

5) Cost of energy (COE): It is defined as the mean value of cost per kWh of useful electrical energy produced by the plant. It is expressed as the ratio of electricity production cost in a year to the total electrical load served by the system. The electricity production cost includes plant installation cost and operation and maintenance cost. Total electrical loads are divided into AC primary load and DC primary load. It is calculated by the following equation [2,11].

$$COE = \frac{C_{yr,total}}{AC_{load} + DC_{load}}$$

where, $C_{yr,total}$ AC_{load} and DC_{load} is the total annualized cost, AC primary load and DC primary load, respectively.

IV. SYSTEM DESIGN

The components are chosen from HOMER to perform the simulation. Fig. 5 shows the grid connected hybrid power system design using HOMER which consists of PV array, wind generator, converter, load, and grid connection.

In order to estimate the system performance under different situations, HOMER simulates the result of the above two arrangements at the same area and same load based on different criteria such as the estimated installation cost, replacement cost, operation and maintenance cost, interest, and cost of energy.

The major components of the different models designed here are wind turbine, PV, battery bank, and a power converter. For economic analysis, the following values are used.

A. PV Array:

In this paper, the initial installation cost of PV arrays is assumed as $3000 per kW and the operation and maintenance cost is zero.

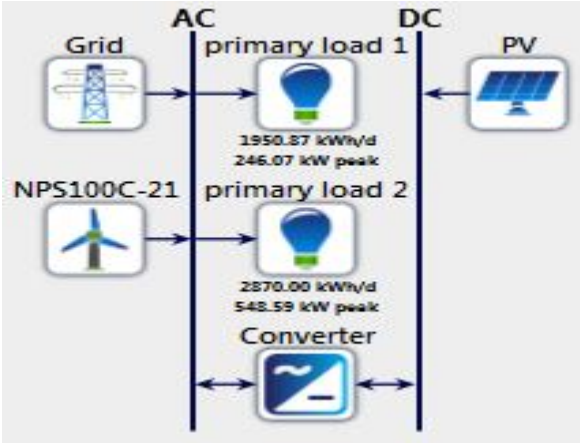

Fig. 5. Grid connected hybrid power system design using HOMER

B. Wind Turbine:

For this study, average wind velocity at 50 m height is 6.73 m/s in Kuakata. It varies from 3 to 8.3 m/s. Here, nine Northern Power NPS100C-21,100 kW wind turbines are used [11]. The wind turbine power output characteristic is shown in Fig. 6. The capital costs are $320000 and also operation and maintenance cost are $2500/yr.

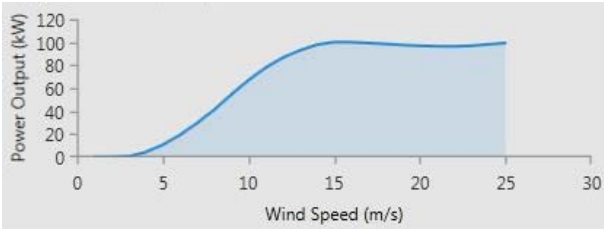

Fig. 6. Wind turbine power curve [11].

C. Power Converter:

In this paper, the capital cost for a 1 kW converter is $300, replacement cost is $300 and operation and maintenance cost practically zero.

D. Battery Bank:

The name of the battery bank is CELLCUBE®FB10-40, manufactured by Gildemeister, with a capacity of 40 kWh, life time 876000 kWh. A battery bank is only used for a stand-alone system design.

E. Grid:

In grid connected design, a grid is used as a backup power component or excess power absorber. The grid supplies power when there is not enough RE power to meet the load demand and grid consumes power when an excessive power is available.

V. SIMULATION RESULTS

The simulation results are described below.

A. Economic Impact

Table I shows the optimization results for the hybrid power system model with different share of renewable energies. For grid connected system, the minimum cost of energy (COE) obtained from the result is $0.0891 whereas for off-grid system it is $0.1588375. Figures 7 and 8 show the COE and NPC values as a function of the number of PV units. It can be observed that the COE and NPC values of the system are increased with the increase in the capacity of PV unit. Also, with the increase of PV capacity, the capital cost of the system is increased. On the other hand, figures 9 and 10 show the graphs of COE and NPC values as a function of the number of wind turbines, respectively from which it can be noticed that COE and NPC values decrease with the increase in the number of wind turbines. It can be also seen that the values of COE and NPC vary from $0.1617027/kWh to $0.0891009/kWh and 5.370379 million dollar to 3.669484 million dollar, respectively. In this paper, size of the plant is considered as 1 MW for which 76% renewable fraction gives the feasible solution. It has to be mentioned that by increasing the size of hybrid power plant the percentage of renewable share can be increased.

TABLE I. SIMULATION RESULT FOR FINDING OPTIMAL DESIGN

Type of the system	PV (kW)	No. of Wind turbine	Battery Bank	COE ($)	NPC ($ million)	Renewable Fraction (%)	CO_2 emission (Tons/yr)
Grid connected	900	1	0	0.1617027	5.370379	52%	269.0764
Grid connected	800	2	0	0.1501716	5.075439	57%	169.8644
Grid connected	700	3	0	0.1403417	4.817061	61%	85.23243
Grid connected	600	4	0	0.1306933	4.583252	65%	1.258075
Grid connected	500	5	0	0.1216871	4.367301	68%	-76.02873
Grid connected	400	6	0	0.1125443	4.16875	70%	-161.3187
Grid connected	300	7	0	0.1040462	3.985773	72%	-245.622
Grid connected	200	8	0	0.0962585	3.818419	74%	-328.4017
Grid connected	100	9	0	0.0891009	3.669484	76%	-410.4542
Off Grid	100	9	8000	0.1588375	3613144	100%	0
Only Grid	0	0	0	0.2000003	4549493	0	1112.077

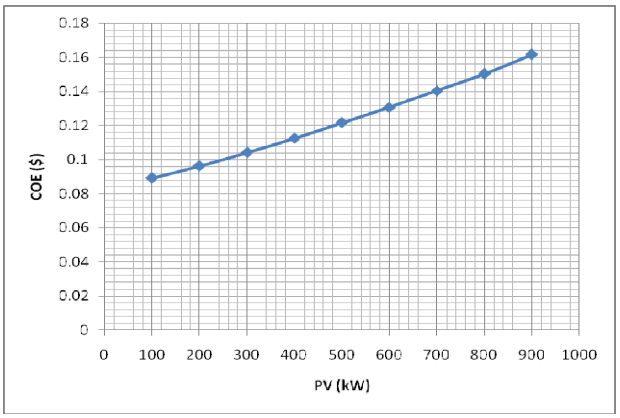

Fig. 7. The COE vs. PV capacity.

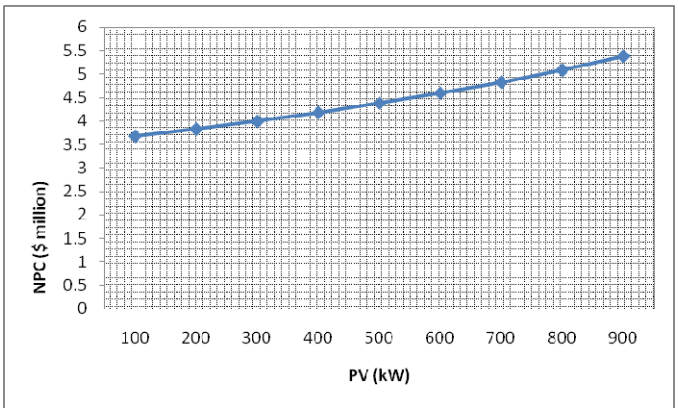

Fig. 8. The NPC vs. PV capacity.

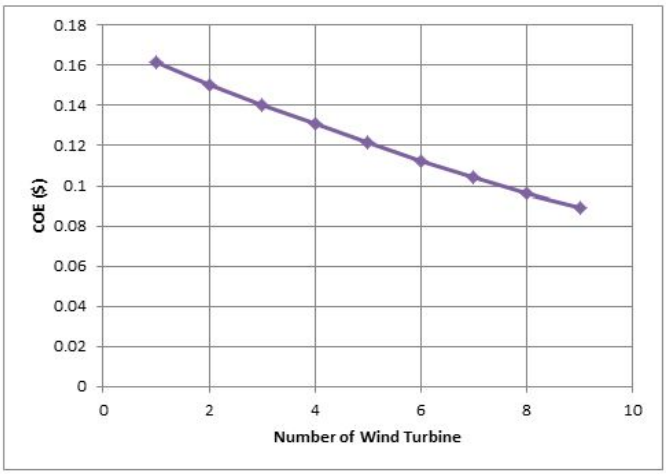

Fig. 9. The COE vs. the number of wind turbines.

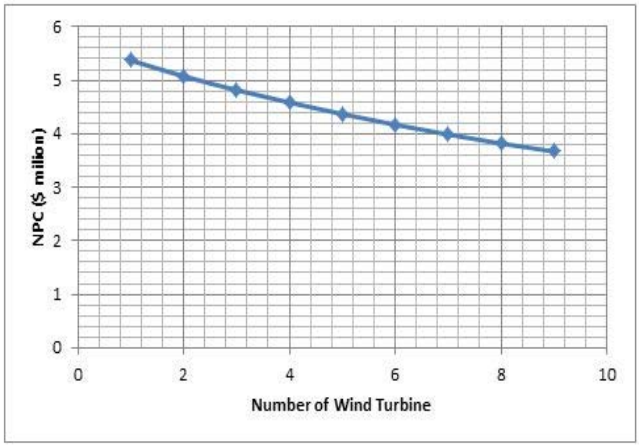

Fig. 10. The NPC vs. the number of wind turbines.

B. *Environmental Impact*

The CO_2 emission with the various contribution of renewable energy is shown in Fig. 11 from which it can be investigated that the emission decreases as the contribution from renewable energy increases. The share of renewable energy can be increased by increasing the number of wind turbines as there is an abundant of wind energy in the considered area compared to solar radiation. The result (Table I) shows that only grid-connected system emitted 11,12077 kg CO_2 per year while wind-PV-grid connected system emitted -410454.2 kg CO_2 per year. Here, the negative CO_2 emission is observed for 76% and some other renewable fraction rate because this system sells more power than it purchases from the grid as it has an excess of electricity. Figure 12 shows the monthly average electric production of various components for 76% renewable fraction rate where the major contribution is coming from wind turbine.

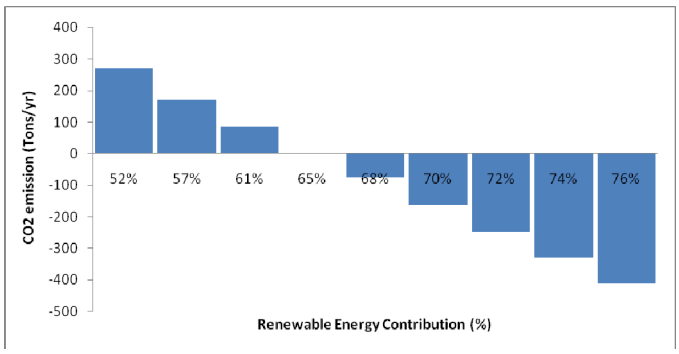

Fig. 11. The CO_2 emission against the various contribution of renewable energy.

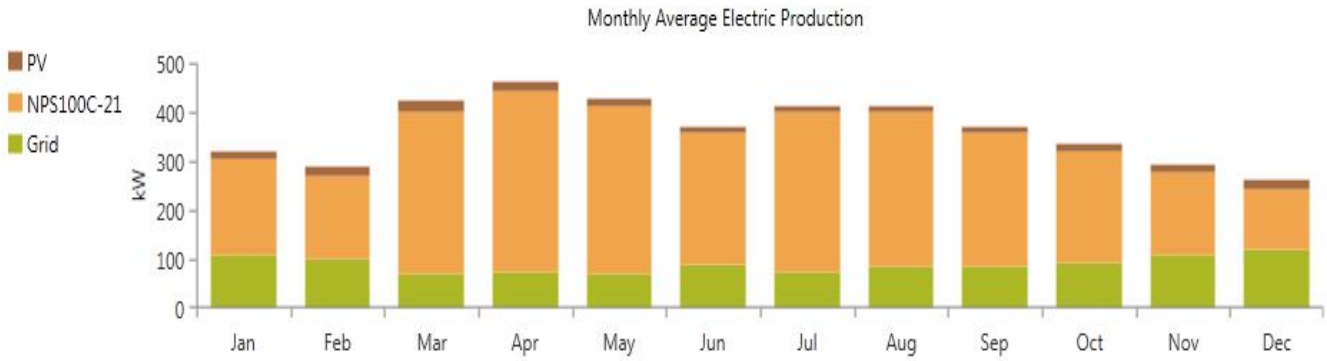

Fig. 12. Monthly average electricity production for final model (renewable fraction 76%)

VI. CONCLUSION

From the analysis it can be concluded that proper utilization of renewable energy reduces an enormous amount of GHG emission in the atmosphere. It is found that the proposed hybrid model with 76% renewable fraction is most suitable, economical and eco-friendly than the other models. It can be concluded that although hybrid model with 100% renewable fraction (off-grid) emits zero kg GHG, it is not always cost effective. The excess output power of the off-grid system goes unused. On the other hand, the proposed grid connected hybrid system does not require an extra battery bank in normal operating condition and excess power that is produced by renewable energy are added to the grid, thereby reducing the total emission.

***Abstract*—This paper investigates the damping performance of power systems through eigenvalue analysis. The analysis is conducted on an IEEE 14-bus test system. The maximum loading limits of the load buses are determined using continuation power flow method and a static synchronous compensator (STATCOM) is installed as an objective to increase the system loadability. Then, the dominant modes and associated states that affect the damping of the system are identified and an oscillation damping controller is designed. The result shows that the proposed damping controller equipped with STATCOM can improve the damping performance of the system significantly.**

Keywords—damping performance; eigenvalue; synchronous generator; static voltage stability; STATCOM.

I. Introduction

Power system is a large interconnected complex network. The main challenges that power system engineers are facing around the world is related to stability [1]-[3]. Reactive power support is a vital issue to improve a power system's performance.

In order to improve the stability of power systems, a static synchronous compensator (STATCOM) is increasingly popular [4, 5]. A STATCOM can dynamically support/absorb the reactive power to/from the power network and hence improves the system voltage profile and angle stability [6]. It can also enhance the overall stability of a power system if it is equipped with some more supplementary control signals.

The effect of different loads and voltage compensation using voltage source converter based STATCOM is presented in [7] which shows that, in some cases, it is hard to maintain the load angle close to unity. Time-domain analysis of a system with and without STATCOM is investigated in [8] for different types of faults in which inadequately damped oscillations are observed under certain critical conditions.

The disturbance in power system is mainly due to the connection/disconnection of large loads, faults, and loss of excitation in the generator [9]. The occurrence of contingencies in power system can cause poorly damped or even unstable oscillations which must be damped to ensure reliable power supply.

A STATCOM is usually used for voltage regulation. However, to achieve satisfactory performance, a proper and efficient control system should be designed for this device. Therefore, the aim of this paper is to investigate the damping performance of power systems through linear and nonlinear simulations. To improve the damping of the oscillatory mode of the system a supplementary controller for STATCOM is designed.

The rest of the paper is organized as follows. The description of the system is given in Section II, static and dynamic analysis is given in Section III and conclusions are given in Section IV.

II. System Description

A single line diagram of the IEEE 14-bus test system considered in this paper is shown in Fig. 1 [10]. It consists of two synchronous generators with IEEE type-1 exciters and three synchronous compensators. All the loads are considered as constant impedance loads and mechanical inputs to the generators are assumed to be constant. A sixth order model of the synchronous generator is used for the analysis. The test system data is given in Appendix.

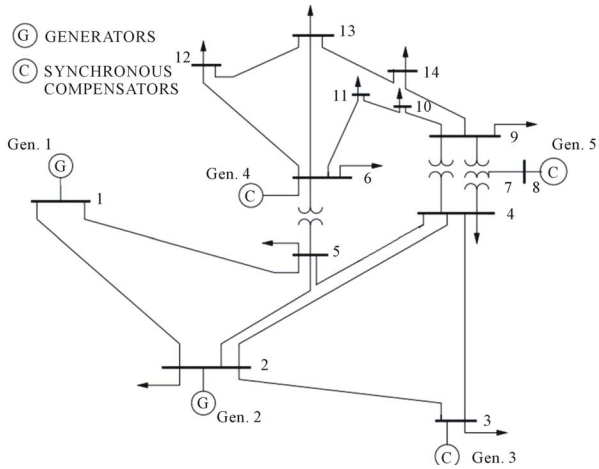

Fig. 1. IEEE 14-bus test system [10].

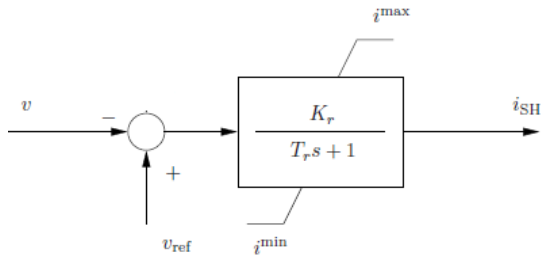

Fig. 2. Block diagram of STATCOM [10].

A STATCOM is used as a Flexible AC Transmission System (FACTS) device in this analysis. Figure 2 shows the block diagram of a STATCOM where v is the measured voltage at the connected bus, v_{ref} is the reference voltage, i^{max} and i^{min} is the maximum and minimum current, respectively, i_{SH} is the total injected current at the connected bus, K_r and T_r is the regulator gain and time constant, respectively. A STATCOM is equipped with a power oscillation damping (POD) controller as shown in Fig. 3 which contains gain, wash-out and compensator blocks.

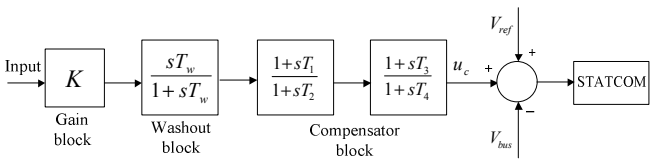

Fig. 3. STATCOM with POD controller

III. Static and Dynamic Analysis

A load flow study for the considered test system is conducted using Newton-Raphson method [11]. To analyze the static voltage stability generally real power-voltage (P-V) or reactive power-voltage (Q-V) curves are used which determine the maximum loading limit of a system [1, 12]. Here, P-V curve has been produced by using a series of power flow solutions (continuation power flow) using power system analysis toolbox (PSAT) in MATLAB environment for different load levels.

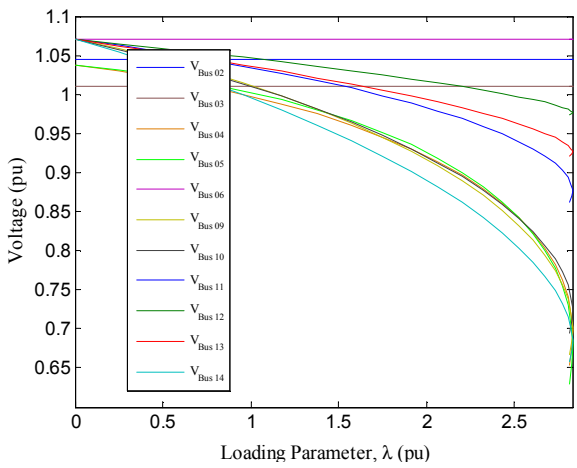

Fig. 4. Loading parameter-voltage curve under base case.

The variations in load bus voltages with the loading factor are obtained and plotted in Fig. 4 from which it can be observed that us-14 is the weakest bus of this network. In this paper, a STATCOM is installed at bus-14 to enhance the static voltage stability of the system.

Next, to understand the inherent dynamics of the system, the test system is linearized and eigenvalues are calculated without STATCOM connection. It is found that the system has a pair of eigenvalue at -0.04654±8.1151 which is the critical mode of this system. Table I shows the participation factors of the dominant states associated with this mode, where e1q_Syn_1 and vf_Exc_1 represents the quadrature axis voltage of synchronous machine 1 and voltage of the exciter 1, respectively; delta_Syn_1 and omega_Syn_1 represents the angle and speed of the generator 1, respectively. This mode has a damping ratio of 0.57%. It is known that the minimum damping requirements for reliable operation of power system is 5%.

TABLE I. Critical Mode of the Considered System

Critical mode	Dominant States and participation factor	Damping ratio (%)
-0.04654±8.1151	e1q_Syn_1=0.22377, vf_Exc_1=0.17139 delta_Syn_1=0.04332,omega_Syn_1=0.04332	0.57

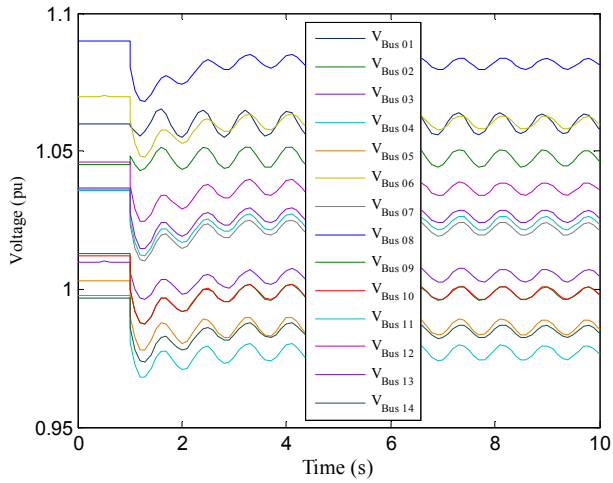

Fig. 5. Bus voltages of IEEE 14-bus test system under disturbance.

To test the dynamic performance of the system, the line between bus 2 and bus 4 is disconnected at 1s. Figure 5 shows the bus voltage profile of the system from which it can be seen that the system suffers from low frequency oscillations. The real power of the sysnchronous generator is shown in Fig. 6. In this analysis, mechanical input to the generator is kept constant. It can be seen from Fig. 6 that the system has large oscillations in its output power.

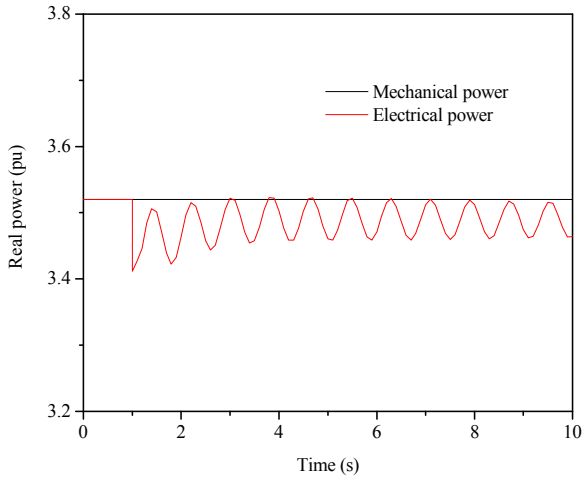

Fig. 6. Mechanical input power and electrical output power of synchronous generator 1.

To solve the above problems, a STATCOM is connected and a POD controller is equipped with it based on the line active power measurement from bus 1. The transfer function of the POD controller is given below [13].

$$H(s) = K\frac{sT_w}{sT_w+1}\left[\frac{sT_{ld}+1}{sT_{\lg}+1}\right]^{m_c} \quad (1)$$

$$\varphi_{comp} = 180^0 - \arg(R_i) \quad (2)$$

$$\alpha_c = \frac{T_{ld}}{T_{\lg}} = \frac{1-\sin(\frac{\varphi_{comp}}{m_c})}{1+\sin(\frac{\varphi_{comp}}{m_c})} \quad (3)$$

$$T_{\lg} = \frac{1}{\omega_i\sqrt{\alpha_c}}, \quad T_{ld} = \alpha_c T_{\lg} \quad (4)$$

where, the phase angle φ_{comp} shows the compensation angle needs to move the eigenvalue direct to the left parallel with the real axis. T_w, T_{ld} and $T_{\lg}$ are the time constant of the wash-out, lead and lag block, respectively, $\arg(R_i)$ is the phase angle of the residue R_i, ω_i, m_c and K is the frequency of the mode of oscillation in rad/s., number of compensation stages and the controller gain, respectively. In this paper, number of compensation stages are 2.

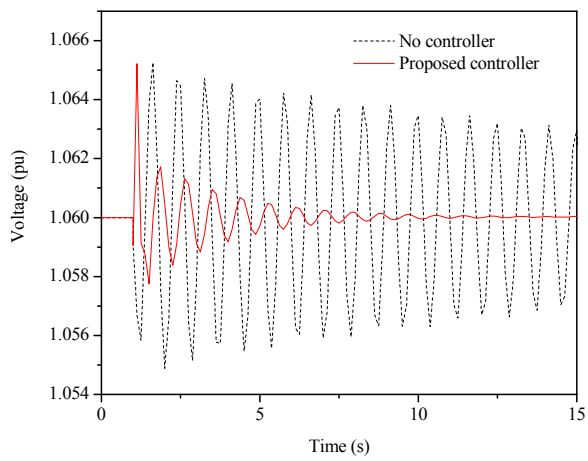

Fig. 7. Bus 1 voltage.

The voltage profile of the test system at bus 1 with and without the proposed controller is shown in Fig. 7 from which it can be clearly observed that the proposed control scheme damps the oscillations quickly. The dominant eigenvalue of the system with the proposed controller is -0.6402±7.6527 with a damping ratio 8.3% which is greater than the minimum limit (5%).

IV. Conclusion

This article investigates the stability improvement problem of a power system considering a STATCOM. The small-signal stability assessment of IEEE 14-bus test system is conducted. It is found that the system has low frequency oscillations with reduced damping. As the weakest bus requires highest reactive power, a STATCOM is connected at the weakest bus of the network. Although a STATCOM improves the static voltage stability of the system, it is not always suitable for damping the oscillatory mode of the system. Therefore, a supplementary controller is designed using the real power deviation as input signal. The result shows that the proposed controller can enhance the damping performance of the system. Thus, this paper proves that an auxiliary control law can be applied to existing devices to enhance the dynamic performance of the system. Determining the optimum size of a STATCOM through static and dynamic analysis is the future aim of this work.

APPENDIX

The line and load data of IEEE 14-bus test system is given in Table II and Table III, respectively [14].

TABLE II. LINE DATA OF IEEE 14-BUS TEST SYSTEM

***Abstract*—This paper describes a set of features along with different classifiers for gender (male, female) identification. Gender identification is the problem to detect the gender of the speaker of the audio content. The proposed method in this study comprises three stages: i) Corpus construction, iii) Input Feature Vector Construction and iii) Identification using a classifier. In this connection, we have constructed a medium scale Bengali speech corpus from The Bengali Daily Newspaper Prothom Alo. The total number of male/female speakers and spoken sentences are eighty and eight thousand, respectively, where the training and test corpus is selected by the 10-fold cross validation. From the experiments it is observed that the accuracies using the most of the classifiers are 100% on audio content duration size 0.7 minutes to 8.4 minutes.**

***Keywords*—Gender identification; Logistic Regression; K-Nearest Neighbor; Decision Tree, Support Vector Machine; Ridge Classifier**

I. Introduction

In modern multimedia information retrieval systems, gender identification has several potential applications. It can be used in audio or video content indexing, gender based classifiers can improve the accuracy of speech recognition [1] and speech coders [2] system. Moreover it can be used in forensic investigations.

In this study, we have proposed a method for gender identification that consists of corpus construction, input feature vector construction, and identification using a classifier. Here, a medium scale Bengali speech corpus is constructed from The Bengali Daily Newspaper Prothom Alo. The originality of this research for Bengali is special features (Energy, Envelope, LPC, etc; in total we used 27 features) extraction from an input speech and use of machine learning tools for this identification. The training and test corpus is selected by the 10-fold cross validation from the eight thousand spoken sentences uttered by eighty male and female speakers. From the experiments it is observed that the accuracies using the most of the classifiers are 100%.

II. Related Works

Gender Recognition based several types of research work have been done for decades. The system described in [3] introduced a new gender identification method using Bootstrapping on audio classification. This paper shows good performance (more than 90%) for Naive Bayes, Decision Trees (C4.5), k-Nearest Neighbors, Logistic regression, Neural Network and Support Vector Machine Classifiers. Content based multimedia indexing using Piecewise Gaussian Modeling with mixture of neural networks was presented in [4]. With one second audio segments, the classification accuracy was 90% regardless of any language and channel of the speech. A system is proposed in [5] where audio classification using multimedia indexing on audio channel having more than 90% accuracy. In [6] a support vector machine (SVM) based gender identification is applied on discriminative weight training. By SVM consisting of optimally weighted mel-frequency cepstral coefficient (MFCC) which is based on minimum classification error (MCE) method, generates a gender decision rule. It outperformed another method mentioned in [7] and has the accuracy almost 100%. Gender Identification based on pitch is proposed in [8], where two stages classifier using Gaussian Mixture Model (GMM) is created to ensure low complexity and high accuracy. Following this method we can get more than 95%. Most of the above described previous works were performed using foreign language (not used Bengali Corpus). But unfortunately for Bengali language, we cannot see much example. The method described in [9] proposed a gender identification method for Bengali consisting of a front end and a back end system. Feature extraction is done using Fast Fourier Transform (FFT) in front end and in back end, a gender model is created using a classifier which produces poor performance around 80%.

III. Methodology

A. Corpus Construction

Different sentences from the Bengali newspaper Prothom Alo uttered by male and female speakers of different regions of Bangladesh are collected. All of the speakers are Bangladeshi nationals and native speakers of Bangla. The age of the speakers ranges from 20 to 40 years. We have chosen the speakers from a wide area of Bangladesh: Dhaka (central region), Comilla Noakhali (East region), Rajshahi (West region), Dinajpur Rangpur (North-West region), Khulna (South-West region), Mymensingh and Sylhet (North-East region). On the other hand, though all of them speak in standard Bangla, they are not free from their regional accent.

Recording was done in a quiet room located at United International University (UIU), Dhaka, Bangladesh. A desktop was used to record the voices using a head mounted close-talking microphone. We record the voice in a place, where ceiling fan and air conditioner were switched on and some low level street or corridor noise could be heard.

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

Jet Audio 7.1.1.3101 software was used to record the voices. The speech was sampled at 16 kHz and quantized to 16 bit stereo coding without any compression and no filter is used on the recorded voice. Duration of the speech files are between 0.7 minutes and 8.4 minutes.

The development of data sets is given as follows.

Data Set-I (D1): This data set consists of 3000 sentences uttered by 30 male speakers (each speaker by 100 sentences). The data is sampled at 16 kHz.

Data Set-II (D2): This data set consists of 3000 sentences uttered by 30 female speakers (each speaker by 100 sentences). The data is sampled at 16 kHz.

Data Set-III (D3): This data set consists of 1000 sentences uttered by 10 male speakers (each speaker by 100 sentences). These sentences are different from D1 data set. The data is sampled at 16kHz.

Data Set-IV (D4): This data set consists of 1000 sentences uttered by 10 female speakers (each speaker by 100 sentences). These sentences are different from D2 data set. The data is sampled at 16 kHz

B. Input Feature Vector Construction

a feature vector is an n-dimensional vector of numerical features that represent some object. In machine learning and pattern recognition, a feature is an individual measurable property of a phenomenon being observed [10]. Choosing informative, discriminating and independent features is a crucial step for effective algorithms in pattern classification. In our experiment we used two steps to construct our feature vector. In first step, we extracted the features from the audio files and in the second step, we normalize the features using different statistical formulas.

1) Feature Extraction: Feature extraction is an essential pre-processing step to pattern recognition and machine learning problems. We extracted time, frequency, coefficient domain features using yaafe - audio features extraction [11]. Followed is the description of each of the features we extracted using the tool:

1) **Amplitude Modulation** [12] is a form of modulation used for radio transmissions for broadcasting and two way radio communication applications. We have used 200 Decimation factor to compute envelope, 32768 output frames size, 16384 steps between consecutive frames are used to calculate the Amplitude Modulation.
2) **Auto Correlation** is used to compare a signal with a time-delayed version of itself. Here, 49 auto correlation coefficients are used. To calculate it we used 1024 output frames size, 512 step between consecutive frames.
3) **Complex Domain Onset Detection** [13] is computed onset detection using a complex domain spectral flux method. Hanning method is used weighting window to apply before FFT, output frames size equals to 1024 and step between consecutive frames equals to 512 is used to calculate the value.
4) **Energy** [14] is computed as root mean square of an audio Frame. We have used output frames size equals to 1024 and step between consecutive frames equals to 512, to calculate the Energy.
5) **Envelope**, extract amplitude envelope using Hilbert transform, low-pass filtering and decimation. Decimation factor equals to 200, output frames size equals to 32768 and step between consecutive frames equals to 16384 is used to calculate the Envelope.
6) **Envelope Shape Statistics** is centroid, spread, skewness and kurtosis of each frames amplitude envelope. Same parameters in calculation of Envelope are used to calculate Envelope Shape Statistics.
7) **Frames** are segment in input signal. Same parameters in calculation of Energy are used to calculate Frames.
8) The **LPC** [15], [16] coefficients are a short-time measure of the speech signal, which describe the signal as the output of an all-pole filter. The first 2 orders of LPC parameters are chosen.
9) **Loudness** [17], [18] coefficients are the energy in each Bark band, normalized by the overall sum.
10) **MFCC** [16] calculation includes discrete Fourier transform of audio frames, followed by filtering by a triangular bandpass filter bank, logarithmic scaling and discrete cosine transform. Here, 13 MFCCs are used.
11) **Magnitude Spectrum** is computed using an analysis window (Hanning or Hamming), or not.
12) **Mel-Spectrum** [19] computes the Mel-frequencies spectrum.
13) **OBSI** [20] or Octave band signal intensity is calculated using a triangular octave filter bank.
14) **OBSIR** computes log of OBSI ratio between consecutive octaves.
15) **Perceptual Sharpness** [17] computes the sharpness of Loudness coefficients.
16) **Perceptual Spread** [17] computes the spread of Loudness coefficients.
17) **Spectral Crest Factor Per Band** computes spectral crest factor per log-spaced band of $1/4$ octave.
18) **Spectral Decrease** [17] computes spectral decrease.
19) **Spectral Flatness** computes global spectral flatness using the ratio between geometric and arithmetic mean.
20) **Spectral Flatness per Band** computes spectral flatness per log-spaced band of $1/4$ octave, as proposed in MPEG7 standard.
21) **Spectral Flux** computes flux of spectrum between consecutive frames.
22) **Spectral Roll off** [21] is the frequency so that 99% of the energy is contained below.
23) **Spectral Shape Statistics** [17] computes shape statistics of Magnitude Spectrum.
24) **Spectral Slope** [17] is computed by linear regression of the spectral amplitude.
25) **Spectral Variation** [17] is the normalized correlation of spectrum between consecutive frames.
26) **Temporal Shape Statistics** computes shape statistics of signal frames.
27) **ZCR** [16] or a zero-crossing is said to occur if successive samples have different signs. The zero-crossing ratio is the number of the time-domain zero-

crossings and total number of samples in a frame. To calculate the value we have kept Minimal distance between consecutive autocorrelation peaks equals to 5, number of autocorrelation peaks equals to 3, number of frames to integrate together equals to 60 and number of frames to skip between two integration equals to 30.

2) Feature Normalization: Feature Normalization is a method used to standardize the range of independent variables or features of data. To normalize the features data we have used mean, variance or standard deviation of the each feature data.

C. Identification Using a Classifier

In this phase we design a classifier using different machine learning approaches [22] and use that classifier to identify gender. Fig-1 describes how we design the classifier and use the classifier to identify gender using unlabeled audio content.

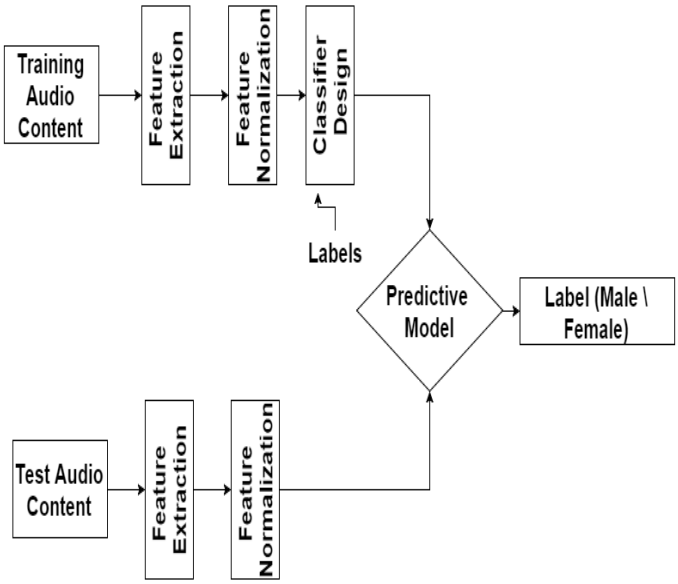

Fig. 1: Gender Identification Using Designed Classifier

Followed we describe about the experimental setup we have used to design our gender identification classifier.

- **Logistic Regression:** [23] For experiment we have used tolerance for stopping criteria=0.0001, C=1.0 and maximum number of iteration is fixed to 100. One vs Rest concept has been used for multi-class classification.
- **Decision Tree:** [24] We have used Gini impurity [25] function to measure the quality of a split, two as minimum number of samples required to split an internal node and one as minimum number of samples required to be at a leaf node.
- **K-Nearest Neighbors (KNN):** [26] For our experimental setup, we used Ball Tree [27] algorithm to compute the nearest neighbors, five as number of neighbors, leaf size = 30, Minkowski is used as the distance metric to use for the tree, where power parameter=2 is used for the Minkowski metric.
- **Ridge Regression Classifier:** [28] For our experimental setup we have used $\alpha = 1.0$ and $tol = 0.001$.
- **Support Vector Machine (SVM):** [29] For our experimental setup we have used, $C = 1.0$, $tol = 0.0001$, max iteration=1000, penalty='l2' and Linear function as kernel function. One vs rest [30] method is used to work for multi-class classification.

IV. Experimental Results

For our experiment we have used the corpus in two different manner: **CS1:** Considering eight thousand speech file and applied 10-fold cross validation and **CS2:** Considering 80 speakers and applied 10-fold cross selection. Moreover we have used three different statistical formula Mean (MN), Variance (VE) or Standard Deviation (SD) to normalize the feature obtain from the feature extraction phase. Therefore, in total we have setup six experiments in this connection: EXP-I)CS1 + MN, EXP-II)CS1 + VE, EXP-III)CS1 + SD, EXP-IV)CS2 + MN, EXP-V)CS2 + VE, EXP-VI)CS2 + SD.

To evaluate our experiments we used Precision (P), Recall (R) and F1-Score(FS) [31].

$$precision = \frac{tp}{tp + fp} \tag{1}$$

$$recall = \frac{tp}{tp + fn} \tag{2}$$

$$f1 - score = 2\frac{precision * recall}{precision + recall} \tag{3}$$

Where, tp equals to true positive, fp equals to false positive and fn equals to false negative.

Here, Table-I, Table-II, Table-III, Table-IV, Table-V and Table-VI show the results of our six experimental setups. From the tables we can observe that KNN gives the best performance for all the six experimental setup and gives a recall equals to 1.0.

Table-I shows result of experimental setup **EXP-I**, where we considered eight thousand speech files and applied 10-fold cross validation(CS1) and Mean(MN) as statistical formula to normalize the extracted features. We got the best recall value for Logistic Regression, KNN and SVM. From the table we can see that, F1-Score is almost same for every classifier.

TABLE I: Result of EXP-I

Classifier	P	R	FS
Logistic Regression	0.999	1.0	0.999
Decision Tree	0.999	0.999	0.999
KNN	0.999	1.0	0.999
Ridge	1.0	0.999	0.999
SVM	0.999	1.0	0.999

Table-II expresses data of experiment setup **EXP-II**, where we considered eight thousand speech files and applied 10-fold

cross selection (CS1). Here we use Variance (VE) as statistical formula to normalize the extracted features and got best recall value for decision tree and KNN classifier which is also same if consider Precision and F1-Score value.

TABLE II: Result of EXP-II

Classifier	P	R	FS
Logistic Regression	0.999	0.999	0.999
Decision Tree	1.0	1.0	1.0
KNN	1.0	1.0	1.0
Ridge	0.969	0.985	0.977
SVM	0.999	0.999	0.999

Table-III demonstrates the consequence of the experiment setup **EXP-III**, where we considered eight thousand speech files and applied 10-fold cross validation (CS1) and Standard Deviation (SD) statistical formula to normalize the extracted features. We got best result for Logistical Regression, Decision Tree and SVM classifier in basis of Recall values.

TABLE III: Result of EXP-III

Classifier	P	R	FS
Logistic Regression	0.999	1.0	0.999
Decision Tree	1.0	1.0	1.0
KNN	1.0	1.0	1.0
Ridge	0.999	0.998	0.999
SVM	0.999	1.0	0.999

Table-IV shows the result of experimental setup EXP-IV. In this setup we consider 80 speakers and applied 10-fold cross selection (CS2) and used Mean (MN) statistical formula to normalize the feature obtained from the feature extraction phase, we got the result that except Ridge classifier, the recall value for every classifier is 1.0.

TABLE IV: Result of EXP-IV

Classifier	P	R	FS
Logistic Regression	0.999	1.0	0.999
Decision Tree	0.999	1.0	0.999
KNN	0.999	1.0	0.999
Ridge	1.0	0.999	0.999
SVM	0.999	1.0	0.999

In Table-V, we mentioned the results of experimental setup EXP-V. Where we considered 80 speakers and applied 10-fold cross section (CS2) and to normalize the extracted feature, we have used Variance. Here we got the best recall value for Decision Tree and KNN classifier.

TABLE V: Result of EXP-V

Classifier	P	R	FS
Logistic Regression	0.999	0.999	0.999
Decision Tree	1.0	1.0	1.0
KNN	1.0	1.0	1.0
Ridge	0.965	0.983	0.973
SVM	0.999	0.997	0.998

Table-VI describes the result of the experiment step up EXP-VI, where we considered 80 speakers and applied 10-fold cross section (CS2) and to normalize the extracted features we have used Standard Deviation (SD) statistical formula. We got best recall value for Logistic Regression, Decision Tree, KNN and SVM classifier.

TABLE VI: Result of EXP-VI

Classifier	P	R	FS
Logistic Regression	0.999	1.0	0.999
Decision Tree	1.0	1.0	1.0
KNN	1.0	1.0	1.0
Ridge	0.999	0.997	0.998
SVM	0.999	1.0	0.999

V. Discussions

In this connection we setup six experiments using our media Bengali speech corpus and for each setup we incorporate five machine learning approaches. Among these experimental setups EXP-IV gives the best performance in terms of recall score and KNN gives the best result among five classification algorithms we used for all the six setups with recall score equals to 1.0.

In this experiment, we were able to produce higher accuracy rate as both the training data and test data are almost know because Data set D1 and D2 is built using the same hundred lines and on the other hand Data set D3 and D4 is built using the same hundred lines. Though we used 10-fold cross validation to split our corpus, the input sentences of audio files are nearly same. Moreover, the age range of the speakers is between 20 to 40 years which may tend to give wrong label for speaker age out of the range. In future we would like to add more speakers of different age groups and also use unique sentences to develop our corpus. In spite of this issue, our experiment is able to identify gender from noisy audio content and also from small size of audio content as we used audio content of duration from 0.7 seconds to 8.4 seconds.

In this paper, we only consider two genders male and female. Third Gender (Transgender) sample is not provided in corpus nor we test with this type of voice. In future we would like to extend our experiments with third gender.

VI. Conclusion

This study has proposed a system for gender identification. The paper concludes the following:

- This study incorporates special features with respect to [9]. These features are Energy, Envelope, LPC, etc.
- This study embeds the machine learning tools, which were not in [9].
- In our method accuracy (recall value) is approximately 100%, but corresponding value of [9] is 80% only.

The author would like to do further experiments for male, female and Trans Gender in near future. Also try to add speaker count and age identification of the speakers.

A Support Vector Regression Model for Forecasting Rainfall

Nasimul Hasan[1], Nayan Chandra Nath[1], Risul Islam Rasel[2]
Department of Computer Science and Engineering
International Islamic University Chittagong, Bangladesh
Email: nasimul_hsn@yahoo.com[1],nayanctg143@gmail.com[1],rasel.kmutnb@gmail.com[2]

Abstract— Rainfall prediction is a very important part of weather forecasting. In countries like Bangladesh; which has several seasons a year, rainfall prediction is really a key factor for many sectors. Rainfall data is a time series data and it changes time to time as climate and season changes. Moreover, rainfall depends on several factors as flow of wind, humidity etc., it is very challenging to make a hundred percent perfect prediction. This paper exhibits a robust rainfall prediction technique in view of the recent rainfall data of Bangladesh utilizing Support Vector Regression (SVR), a relapse methodology of Support Vector Machine (SVR). The collected raw data wasn't prepared for using as input of algorithm, thus it had been pre processed manually to suit into the algorithm, then fed to the algorithm. The evaluation results of the study conducted on the data shows that the projected technique performs higher than the conventional frameworks in term of accuracy and process running time. The proposed approach yielded the utmost prediction of 99.92%

Keywords— Rainfall prediction; timeseries data; windowing operator; sliding window validation; Support Vector Regression;

I. INTRODUCTION

Weather (especially rainfall) has a great influence over cultivation, flood and some other sectors, The cultivation of corps relies mostly on rainfall here and it is important to predict how much rainfall may happen in an upcoming season. A perfect rainfall prediction can help us to take decision what to cultivate and what to not. Since many other things such as drought, tourism, transportation, construction etc. also sometimes depends on rainfall; a good prediction can help to take decisions regarding these sectors. From ancient time people are trying to find the pattern of weather and predict weather for their well-being. From the very beginning of science and technology, weather prediction is a very interesting sector of study. Forecasting rainfall is a tough task due to the complication of the physics and different variable which cause rainfall [1]. It is actually a very noisy and deterministically disordered natural event. Some very important factors as monsoon, wind, moisture, heat, rotation of earth etc. plays a very strong role on the rainfall issue.

A lot of intelligent techniques as Artificial Neural have been used to predict rainfall. Among them Artificial Neural Network (ANN) is a commonly used technique to produce a good prediction [2] [3] [4]. Frequent study shows that ANN can work way better than different regression, MA and EMA. ANN frequently displays conflicting and unpredictable execution on boisterous data [5]. Support Vector Machine (SVM) is a supervised classification and regression algorithm. An SVM model represents the samples as point spaces. It is mainly based of decision plane concept. It separates objects with different class by a visible gap as much as possible between the classes. SVM can perform both linear and non-linear classification with super efficiency. Kesheng Lu and Lingzhi Wang [6] showed in their research that Support Vector Machine can perform an efficient rainfall prediction with a low error rate. Their model can produce almost 99% accurate prediction. A. Mellit, A. Massi Pavan & M. Benghanem [7] developed a SVM model which can produce up to 99% accurate prediction for different models. At the point when utilizing SVM, the fundamental issue is defied: how to pick the appropriate kernel and how to set the best kernel function. The best possible parameters setting can enhance the SVM relapse exactness. Diverse kernel capacity and distinctive parameter settings can bring about huge contrasts in execution. However, there are no investigative strategies on the other hand solid heuristics that can direct the client in selecting a fitting part capacity and great parameter values [6].

In this study, different kernel functions of Support Vector Machine (SVM) and a data preprocessing technique windowing is combined to predict rainfall. Three different models- Total rainfall prediction, maximum rainfall prediction and average rainfall prediction with three different sub models, for 1day ahead, 7 day ahead and 10 day ahead prediction are proposed here for a better rainfall prediction technique.

II. METHODOLOGY

ε-insensitive loss function was introduced by Vapnik and then SVM was developed to solve regression problems as well. The process is known as Support Vector Regression (SVR). SVR has an excellent performance regarding the perfection of solving non-linear regression.

Support Vector Regression: Almost all principals of SVM classification are followed by Support Vector Regression (SVR). As the output is real number and there are unlimited possibilities. To handle this problem, a limitation to the tolerance (epsilon) is set to the SVM which would have effectively asked for from the problem. It minimizes $\|\omega\|^2$ to reduce the model complexity. Here ξ_i and ξ_i^* are slack variables and i= 1, …, n to calculate the difference of training data outside $\varepsilon -$ sensitive zone [8] [9].

Minimize:

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

$$\frac{1}{2}\|\omega\|^2 + C\sum_{i=1}^{n}(\xi_i + \xi_i^*) \quad (1)$$

Subject to:

$$\begin{cases} y_i - f(x_{i,\omega}) \leq \in + \xi_i^* \\ f(x_{i,\omega}) - y_i \leq \in + \xi_\iota \\ \xi_\iota, \xi_i^* \geq 1, \dots, \mathrm{n} \end{cases} \quad (2)$$

The optimization problem can lead to the dual problem and the solution is:

$$f(x) = \sum_{i=1}^{n_{sv}}(\alpha_i - \alpha_i^*)K(x_i, x) \quad (3)$$

Subject to, $0 \leq \alpha_i^* \leq C, 0 \leq \alpha_i \leq C$

Here, n_{sv} denotes the number of Support Vector (SVs).

Kernel Functions:

$$K(x_i, x_j) = \begin{Bmatrix} X_i, X_j & \text{Linear} \\ (\gamma X_i \cdot X_j + C)^d & \text{Polynomial} \\ exp\left(-\gamma|X_i - X_j|^2\right) & \text{RBF} \\ \tan h\,(\gamma X_i \cdot X_j) + C & Sigmoid \end{Bmatrix} \quad (4)$$

Here, $K(X_i, X_j) = \emptyset(X_i, X_j)$ and γ is the adjustable parameter.

A. Time series data:

Rainfall data is time series data. Time series data is a set of values of something where the intervals of the value are listed in such a way that the time period between each attribute is exactly same.

B. Moving Average:

A Moving Average (rolling average or running average) is an estimation to analyze data points by making a progression of midpoints of distinctive subsets of the full data set.

$$\text{MA} = \frac{x_1 + x_2 + \cdots + x_n}{n} \quad (5)$$

Here, $x_1 + x_2 + \cdots + x_n$ are the average values of the monthly rainfall and n is the total number of observation. Moving average of 7 days was considered for all attributes taken as labels in this study

C. Windowing operator:

Windowing operator is an exclusive operator which can perform better for time series prediction. It converts series sample data into single valued data. The series data must be given as Example Set. The parameter "series representation" defines how the series data is represented by the Example Set.

III. Evaluation Process

A. RMSE

Root Mean Square Error is a well-known and commonly used evaluation process for regression models.

$$\text{RMSE} = \sqrt{\frac{\sum_{i=1}^{n}(yt - \widehat{yt})^2}{n}} \quad (6)$$

Here, yt is the original value of a point for a given time period *t*, *n* is the total number of fitted points, and $\widehat{yt}$ is the fitted forecast value for the time period *t*.

B. MAE

Mean Average Error (MAE) is an widely used evaluation formula. Mean Absolute Error (MAE) measures how far predicted values are away from observed values.

$$\text{MAE} = \frac{\sum_{i=1}^{N}|x_i - \hat{x}_j|}{N} \quad (7)$$

Here, x_i is the actual observations time series, is the estimated or forecasted time series, SAE is the sum of the absolute errors (or deviations), N is the number of non-missing data points

IV. Experiment Design

A. Research Data:

6 years Rainfall data (2008-2014) of Chittagong, Bangladesh from the Meteorological Department, Bangladesh were collected to perform experiment and evaluation this study. Here we took only the data of March to October of each year as basically in this period rainfall occurs here normally. Three different models for forecasting maximum, total r and average rainfall were built with the same data. 80% of the data were considered as training data and the rest 20% as testing data. Six attributes, Date, total, avg., max, min, MA included both the training and test data. The 'Date' attribute was selected as id for all three models and another attribute ('max' for maximum rainfall prediction, 'avg.' for average rainfall prediction and 'total' for total rainfall prediction) was chosen as label. Figure 1 shows the actual rainfall (2008-2014)

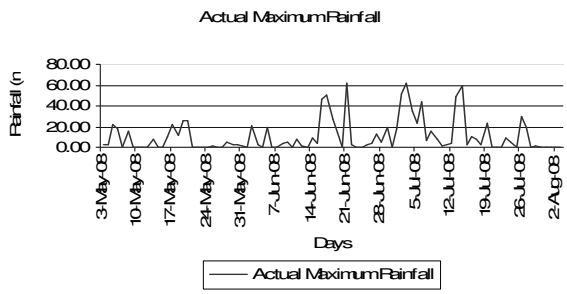

Figure1. Actual Rainfall of Chittagong (Total, 2008-2014)

B. Model construction and analysis:

This step starts with the preprocessing step of data. At the very first Moving Average (MA) technique was applied on the data set. Then windowing operator was used so that it can convert series data to universal dataset and feed the learning process [10]. As learning technique we used Support Vector Regression (SVR). The model structure includes two vital stages, training and testing. Both the stages are continuous process as the main objective of the study was to build a efficient model for rainfall forecasting.

Training and testing stages are mentioned below.

1*) Training stage:*

The training stage starts with the retrieving of data from the repository. The data were processed before entering this stage. After this, the role of the attributes in the dataset was assigned. Then one of the attributes (Date) was selected as the id and another as the label. The selection of label was different for three different models. The next step was to set the windowing operator. The parameters of windowing operator were set and then windowing was performed. A special and efficient validation 'Sliding Window Validation' was performed for validation. Afterwards, the main process was fed and the parameters of the Support Vector Regression. Then the model was set to run.

2) Testing stage:

In this phase the testing data were retrieved from the repository and the role of the attributes of the data was set and then the id and label were selected as done in the training stage. Like the training stage, the parameters of windowing operator were set and run and then the main process was fed. The performance was compared finally.

V. EXPERIMENT RESULT

A. Windowing operator analysis:

At this point we used windowing operator to the time series data to convert it into generic data. Table I shows the windowing operators parameter settings used in this study.

TABLE I. WINDOWING OPERATOR ANALYSIS

Model		Horizon	Window size	Step Size
Total	1 day	1	2	1
	7 day	7	2	1
	10 day	10	2	1
Maximum	1 day	1	3	1
	7 day	7	2	1
	10 day	10	2	1
Average	1 day	1	2	1
	7 day	7	2	1
	10 day	10	2	1

B. Support Vector kernel Analysis:

The parameters selecting of Support Vector Regression is a very crucial and important part. The perfection of prediction depends on best setting of parameters. So that, the parameters were chosen carefully and a log was kept to find the best parameter set. Table II shows the parameter settings for Support vector used in this study. Here, C is the constant of complexity and G is the value of kernel gamma.

TABLE II. SUPPORT VECTOR KERNEL ANALYSIS

Model	Days	Kernel Type	degree	C	G	∈	∈ +	∈ -
Total	1	Anova	1	2000	1	1	1	1
	7		1	1000	1	1	1	1
	10		1	1000	1	1	1	1
Max	1		1	400	1	1	1	1
	7		1	700	1	1	1	1
	10		1	1000	1	1	1	1
Average	1		1	1000	1	1	1	1
	7		1	1000	1	1	1	1
	10		1	1000	1	1	1	1

C. Sliding window validation:

As the validation process for this study sliding window validation was used. It is a special validation for series data. It takes a certain window for training and another window for testing. The window then moves to another window and determine the average of all estimation. The parameter "cumulative training" shows if every single previous sample ought to be utilized for preparing (rather than just the present window) [11]. Table III shows the parameter properties of Sliding Window validation and Table IV shows the result of the study.

TABLE III. SLIDING WINDOW VALIDATION

Model		Training Window Width	Training Window step	Test Window width	Horizon
Total	1	2	1	2	1
	7	2	1	2	7
	10	2	1	2	10
Max	1	2	1	2	1
	7	2	1	2	7
	10	2	1	2	10
Avg	1	2	1	2	1
	7	2	1	2	7
	10	2	1	2	10

TABLE IV. RESULT FOR 1 DAY AHEAD PREDICTION

	Date	Actual Rainfall	Predicted Rainfall 1 day
Total	4-Jul-12	0.1	0.19
	5-Jul-12	2.5	1.76
	6-Jul-12	0.0	0.74
	7-Jul-12	1.6	1.17

	Date	Actual Rainfall	Predicted Rainfall 1 day
Maximum	4-Jul-12	0.1	0.85
	5-Jul-12	2	1.26
	6-Jul-12	0	1.04
	7-Jul-12	1	1.11
Average	4-Jul-12	0.0125	0.76
	5-Jul-12	0.3125	0.76

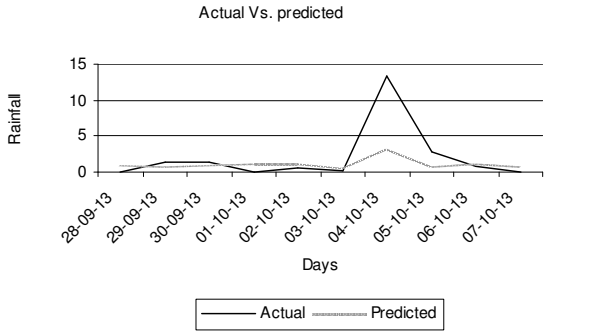

Fig 9 Actual Vs. Prediction (Average, 7 day ahead)

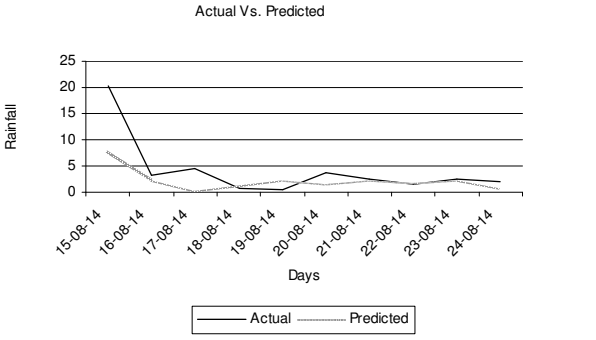

Fig 10. Actual Vs. Prediction (Average, 10 day ahead)

VI. CONCLUSION

A. Discussion

This paper presents a robust rainfall prediction technique using Support Vector Regression. The result of the experiment done with the data of Chittagong, Bangladesh shows that the proposed model can forecast more accurately in comparison with the regular technique used. The proposed model can predict better than any model before one day. The 7 days ahead model also performs very well than conventional processes.

B. Limitation and Future Work

Only Moving Average and Windowing operator were used as data preprocessing step in this study. The data was taken for only Chittagong area of Bangladesh. In future more data preprocessing steps and different algorithms will be used. Data from other stations of different countries and area will be used to get a universal model.

***Abstract*— Software development has been changing rapidly. This development process can be influenced through changing developer friendly approaches. We can save time consumption and accelerate the development process if we can automatically guide programmer during software development. There are some approaches that recommended relevant code snippets and API-items to the developer. Some approaches apply general code, searching techniques and some approaches use an online based repository mining strategies. But it gets quite difficult to help programmers when they need particular type conversion problems. More specifically when they want to adapt existing interfaces according to their expectation. One of the familiar triumph to guide developers in such situation is adapting collections and arrays through automated adaptation of object ensembles. But how does it help to a novice developer in real time software development that is not explicitly specified? In this paper, we have developed a system that works as a plugin-tool integrated with a particular Data Mining Integrated environment (DMIE) to recommend relevant interface while they seek for a type conversion situation. We have a mined repository of respective adapter classes and related APIs from where developer, search their query and get their result using the relevant transformer classes. The system that recommends developers titled automated objective ensembles (AOE plugin). From the investigation as we have ever made, we can see that our approach much better than some of the existing approaches.**

***Keywords*—Adaptation of Object Ensembles, Source Repository, Software Developing Process, Data Mining Integrated Environment.**

I. INTRODUCTION

The Software development process can be enriched by using many processes. Many guidelines are given which influence software development process, especially in the coding stage. Reusing previously completed software repository to enhance the development process is a common phenomenon in the field of Mining Software Repository (MSR). If developers get suggestions in e.g. API recommendations, object usage pattern, class structure or code snippets from the existing projects they might be benefited a lot what they eventually expect while coding. Some of the approaches have integrated web based code, searching in their customized tool like MAC [1] and MAPO [2] before mining the code source abstractions. Although MAC and MAPO are server dependent or online based, by which they are not flexible for a developer. Automated Adaptation of Object Ensembles (AOE) shows a process of adapting the collection frameworks and Arrays, but it is not clear view how to use it as a plug-in tool.

In software development there are different ways available to guide software developers during the development period. A programmer can use programming code in a software system easily by using an automated adaptation of object ensembles. By this process user can find out required data easily. We have used an AOE Plug-in by which a software developer can complete a code in a short time. It takes less time compared to existing approaches. The existing approaches like simply using the Integrated Development Environment (IDE) like Net Beans [3], IntellijIdea [4], and Eclipse [5], is vulnerable to flaws and it is unable to provide us the required interfaces. In essence, it consumes developers' valuable times. We have investigated between the conventional ways and our AOE plug-in approach to evaluate the efficiency of our proposed tool. The study shows that it is able to accelerate the developer's performance and facilitate less time consuming with decreasing code flaws and errors.

Although in MAC [1], MAPO [2], AOE [6]and many others code repository had several limitations such as server dependent searching, either database based or Internet based where data is not preprocessed according to rules of data mining so these are not friendly for a developer. In our methodology we try to show our repository plugin as an offline repository that is filed based instead of a database and it has special source abstraction technique. Adapter classes are the key point in our approach. In AOE the result depends on the resource of the repository of adapter classes. Recently, a number of works are available to guide developers in the field of software engineering. All we have seen is that our approach is comparatively easier to handle than other existing approaches.

The paper is so far structured in the followings: Section II background and related works of this study. Section III shows that full design and proposed approach. The detailed results and evaluation of this paper is presented in Section IV. Section V concludes with the set of observation and future work of this research.

II. BACKGROUNDS AND RELATED WORKS

As the software development process can be influenced by using many techniques, so many researchers try to provide a flexible way that can influence the software development process. Need not to say that previously completed software repository technique enhance the development process is a common framework in the field of mining software repository. The developers can be benefited by following the provided suggestions from various recommendations like API recommendations, object usage pattern, class structure or code snippets from the existing projects. Some of the approaches have integrated web based code, searching in their customized tool like MAC [1] and MAPO [2] before mining the code source abstractions.

There are some processes by which a software system is established by code reusing. But in our approach we use a repository of adapter classes and a tool which adapt this code. By using this AOE plug-in which integrates with the IDE, the user can find the required data type easily. There are some existing efforts such as adapting collection and array by using Automated Adaption of Object (AOE)[6]. Some approaches like Code reusing in MAPO [2], better user recommendation using enhancing software development repository, Scenario Based API Recommendation System [7] and others are also used to accelerate the software development process. As we have proposed that if there have been adapter tools [8] which adapt the given interfaces it will be more helpful for the programmers to find the required interfaces. Mining API Usages from Open Source Repositories (MAPO) [2], [3] was one of the first and MAC [1] was one of the updated triumphs to mine API usage pattern. Other recent works called Enhancing Software Development Process (ESDP) [9] where the developers are highly guided by recommendations from a mined repository is also one of our referral works.

One of the best concepts of test-driven reuse showed by Reiss [10] common test-cases issued as input for a component search engine in [11]. Nevertheless, there exist some problems such as license problem and dependency problem. When the user changes the parameter types, then it might need an even more propagated deep adjustment of type changes. The formal and rule-based language is proposed by Kell [12] that was named Cake for automated wrapper generations. The designing used to define interface relations; transformation object structures are possible by applying these rules. We introduced that transformation should happen automatically but it is most overhead for a developer writing mapping rules, basically for an unknown complex object. It overcame Nita and Notkin [13] by providing an approach which concerned with adapting programs to alternative APIs. When the variations among the APIs are small its schema considers not-straightforward structural respect as out of scope, which is the main challenge, is providing transformation. The work showed by Hummel [14] is depending on the Identity Map Pattern from Fowler [15] and identifies the answer about the problems of the Gang of Four adapter pattern. The approach is integrated into another work by Hummel and Atkinson [14] that supplies relaxed-signature matching for primitive data types.

Recently there have done many works to enhance the software development process. There have applied many tools such as adapter generation tool [6]. In this way a user can find the required method easily. As a result a user can save time and solve any problem easily. The software development process is an easy task for a developer.

In the approach we try to overcome the limitations of existing repository tools. We try to provide as an offline repository tool that are file based instead of a database that has special source abstraction. Adapter and transformer classes are the key point in our approach.

III. PROPOSED APPROACH

In our approach we have developed a plug-in tool that is able to guide software development through suggesting interfaces by using the respective adapter classes. The tool is completely written in java and is executable as a standalone application. It can work with IDE like Net beans [3] and Eclipse [5] as they have the software extensibility.

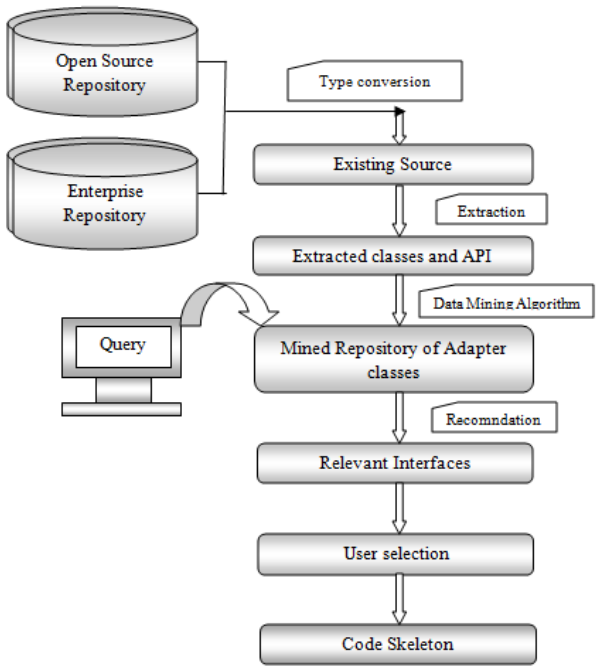

Fig. 1. Automated Object Ensembles (AOE) plugin Framework

Open Source Repository (OSR) is an online software code repository. In this repository many projects problem solving codes are stored. When a programmer stays in online and gets any programming problem, then the programmer can search in this repository for required code. OSP is an Internet based repository. In many software companies, there are stored many projects. It is called the Enterprise Repository.

In repository, there are stored a large number of programs. Many unusual code lines are staying in programs. We take the

only important line for a program. By using type conversion we build up Existing Source where projects are stored without unusual code lines. Programming code is stored in Existing Sources. We extract classes of API from these projects which exist in Existing Sources.

Data Mining Algorithm is used to build up a mined repository of Adapter classes. When a programmer searches any classes, the required classes are shown at first. Then we will find related classes. Programmers, search their needed query in the mined repository of Adapter Classes. Then we get relevant interfaces with the help of a transformer and recommendation interfaces. The user selects the required interfaces and gets code skeleton.

Now a day, there has various tools to increase the optimizing capability in software development field; adapter generation tool is one of them. To overcome mismatches on the signature level a good way is to add an adapter that controls message forwarding from one interface to the other. The adapters allow classes to work together that could not otherwise because of incompatible interfaces. It can also be familiar as a "Wrapper" which wraps the incompatible class into the adapter class, where adapter adapt any types of object, method and interface that helps in the programming fields. There exist projects available the newly integrated ability to transform arrays and collections, which can be executed for verifying the adaptation capabilities. This idea is to describe by Hummel [11], where able to generate a random Array List and a sorted Vector instance the helper class Generator is used. When a client uses an automated adapter class that depends on the interfaces that are provided by collection frameworks then the client needs help to use any plugin.

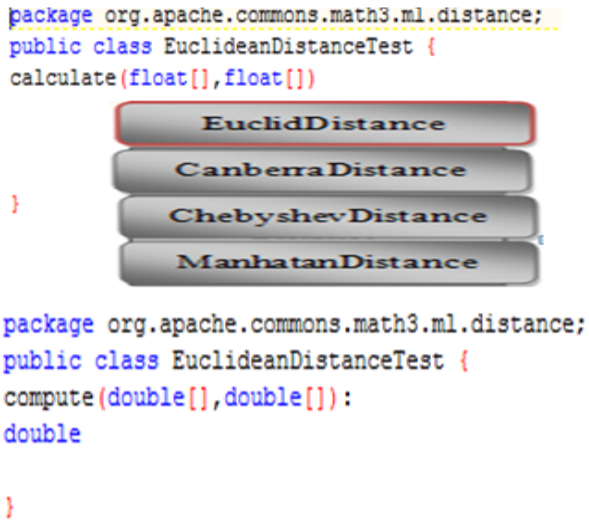

Fig. 2. Adaptation testing overview

For example, when a programmer writes their code in the IDE like as Net Beans they must write the full code to reach the required result, But when they use AOE plug-in by pressing the right button, then the programmer will be guided by the several adapter classes that are shown in the fig. 2., which is remarked by red color box is chosen. Suppose coder write ,calculate (float [], float []) then AOE plaguing suggest Euclid Distance adoptee adapt that generate in D. Seffert and O. Hummel [7] where adapter depends on transformer that transform provided instance to require instance and vice versa. Suppose a client requires a specific data types, then its search in the adapter fields after matching needed data types client can choose any of them. By finishing the process of adaptation successfully the modified test case was executed here using the final adapter instead of the adapter directly. Nevertheless, test case executed full filly the adapter's transformation capability was verified. For example, in the test case the compute method of the selected class from *org.apache.commons.math3.ml.distance* package is tested. That takes as an input two vectors, showed by an array of type double each, and calculates the distance between them. The distance should be zero, if the same vector is provided as the first and second parameter such as in this example. The public double computes (double [], double []) is the interface of the compute method.

```
package org.apache.commons.math3.ml.distance;
public class EuclideanDistanceTest {
final DistanceMeasure distance = new EuclideanDistance();
public void testZero() {
final double [] a = {0, 1, -2, 3.4, 5, -6.7, 89};
Assert.assertEquals(0, distance. compute(a, a), 0d);
```

The array of type double was replaced with a Link List<Float> after the verification of the original test case executed successfully, where the expected name of the method was changed from compute to calculate. The test case is changed to public void double calculate (Linked List<Float>) for the require interfacing. The adapter generator overcome a parameter type and the method name mismatch, namely from Linked List<Float> on double [] and calculate in a computer.

Imagine a client requires one method within two parameters, but there exist more than two parameters in a similar method in the tool then adaptation process solves this complexity. In this paper, we want to describe how easily use collection frameworks as a plug-in tool in software development fields. The collection framework refers the way of implementing interfaces with the help of several classes that are considered as a supported plaguing tool.

We have seen in the approaches [2] [MAPO] that they have used a code search engine to find the desired item following a search query given by a particular client. Like MAPO this paper also enhances the automated adaptation of object ensembles as a repository tool. In this approach the require source may online or offline repository that contain various

kinds of tools. Eventually, the approaches are not only suggesting an adapter class, but also provide its related code implementation to reach the desired goal of a software developer. It works automatically when a client type any code during programing according to their require data types or interfaces. In order to consider the existing paper [6] that shows how to generate an adapter with the help of transforms that can able to solve the matching problems of complex data types. In fig.2. There have given a snapshot of the adapter generation tool. On other existing paper there have no idea about the plugin. But in our paper, we want to use plugin for a user.

A plugin is a software component that adds a specific feature to an existing once. When an application supports plug-in, it enables customization. In our paper we want to provide an adapter plug-in by which any client can complete a task more easily than existing processes. When a client wants to find classes or interfaces, there have given some adapter class options. From these options which is chosen then it finds out the required data by using adapter plug-in.

```
package result;
import java.util.WeakHashMap;

public calss Matrix{

private adaptees Rechteck adaptee;
private static WeakHashMap<adaptees.Rechteck,Matrix>Map=

public Matrix (int param0,int param1,String param2){
    adaptee=new adaptees.Rechteck (param0,param1,param2);
    map.put(adaptee,this);
    }
private Matrix(adaptees.Rechteck adaptee){
    this.adaptee=adaptee;
    map.put(adapte,this);
        }
public adaptees Reckteck getAdaptee(){
    return adaptee;
    }
}
```

Fig. 3. A snapshot 1 of Adapter generation tool (AOE)

IV. Evaluation

There have given a guideline for a programmer to enhance the software development process. An automated adaptation of object ensembles is a process by which any software developer can find the required data easily. There have given some comparison by which we will understand which process is better than another.

a. Environmental setup

In this development process, there have used a repository of adapter classes. How much healthier this repository the development process is more easy. If our adapter class repository is enriched, a user can find the required interfaces in a short time and easily. There have given same adapter class name such as:

SL	Adapter Classes	Line of Code (LOC)
A	EuclidDistance	17
B	CanberraDistance	11
C	ChebyshevDistance	15
D	ManhattanDistance	14
E	OnewayAnova	16

There used an adapter generation tool. Some object oriented language is used. There needs an adapter by which adaptation code is plagued with user. There have given an adapter generation tool such as adaptation tool.zip [6].

b. Time complexity

Time is an important thing when a program is solved. By which a program is solved quickly this process is better than other. When a programmer solves a program in IDE (Net Beans, eclipse) there have needed some times such as 40sec.

TABLE I. TIME COMPLEXITY

Task	IDE with AOE plug-in(no of solved problem)	NetBeans(no of solved problem)
T1	60 sec	120 sec
T2	130 sec	200 sec
T3	150 sec	310 sec
T4	120 sec	360 sec
T5	140 sec	400 sec

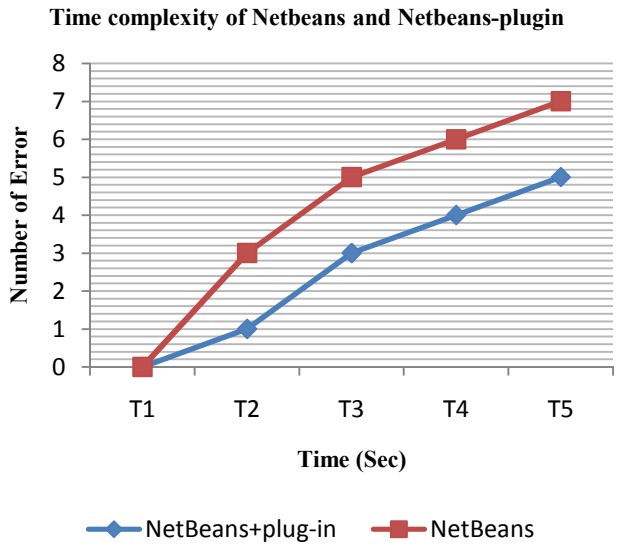

Fig. 4. Time complexity between NetBeans and NetBeans+plug-in

But the same programmer solves this same problem in net beans, but there have plugged-in AOE. As a result, we see that at this time the programmer can solve this problem in 0.20sec. When AOE is plugged-in, they have saved 20sec. There have given a table of how much program is solved without AOE plugged-in and within AOE plugged-in.

c. *Error Vulnerability*

In TABLE II we see that after the total time in IDE with plague-in there have found 13 errors, but at the same time problem solving only in IDE there have found out 21 errors.

TABLE II. Error possibility

Time	NetBeans+plug-in	NeatBeans
T1	0	0
T2	1	3
T3	3	5
T4	4	6
T5	5	7
Total error	=13	=21

As a result, we understand that when the plugin is used error rate is low. So this process is better than another.

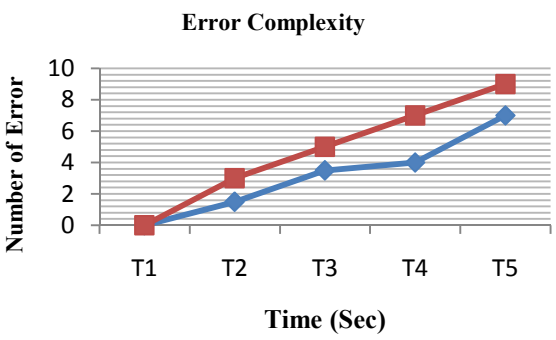

Fig. 5. Error comparison between net beans and NetBeans+plug-in

d. *Thread of the evaluation*

Everything has a limitation. There has some limitation of evaluation. This guideline for software development process is more effective. The evaluation is observed at the same time and same experiment. Such as

a. By having more AOE adapter classes in the repository a user finds more accurate data.

b. A program is evaluated by the same user.

c. It is a lengthy process to plug in a user in an adapter class repository.

d. A user cannot find the mining data.

The results observed in the empirical study may not be applicable to the programming tasks other than those considered in the study, being a threat to the external validity. If the tasks mentioned out there in the study change the results may also be changed. Before we start our evaluation the team members are well trained. The receiving capacity of team members may vary. So the learning curve of these numbers may affect the results.

Within many problems this guideline for a programmer is more effective to develop software process. By this process a user can find any data very quickly. It will keep an important role to enhance the software development process.

V. CONCLUSION

The AOE plug-in approach is more enriched than any other Existing approaches. The approach is able to find out any required data easily and there have needed less time than any other approach. A user finds a data in adapter classes than the AOE plug-in give the required data to the client. The process which we have provided in this paper is different from any other existing process. That is able to enhance the SDP recently.

This paper provided a guideline by which a user can get the required data easily and it is comfortable to use. But these data are not mined. In Future there have used data mining algorithm and find out mined data to enhance software development process.

Abstract— **This paper proposes a fuzzy relational clustering (FRC) to find similar sentences from a set of sentences as well as group them in clusters. For finding similar sentences here FRC used both word-to-word and order similarity. For word-to-word similarity FRC used Jiang and Conrath similarity measure (JnC) with the help of WordNet database. Order similarity is calculated from joint word set. As a sentence may relate to more than one theme so FRC used a fuzzy clustering approach. Here FRC used FRECCA algorithm for the sentence clustering purpose. The algorithm works on Expectation-Maximization where importance of a sentence is expressed by PageRank score which is treated as likelihood. The PageRank scores and mixing coefficients are initialized with Uniform Random Number generation technique. Applying this method on a quotation dataset of different classes we found that it is capable of identifying and grouping similar sentences in a cluster. FRC is also applied on a news article dataset and found admirable results.**

Keywords—Fuzzy Clustering, Sentence Similarity, Relational Data.

I. INTRODUCTION

The amount of data being generated and stored is growing exponentially which presents new opportunities and challenges for unlock the information embedded within this data. Modern field of data mining can be used to extract important knowledge from data [1]. This method only emphasizes on text data. FRC used pre-processed text data of quotes. This method can be further used on pre-processed text data from emails, newspapers, websites, online blogs etc. One of the applications is that, on a certain day many newspapers are published. There are some news articles that are printed in all or most of them but are not written in the same format or language nevertheless the idea of the news is similar. So the main objective is to find similarity between the sentences residing in the news article.

Several works have been done on fuzzy clustering. First one was Relational Fuzzy c-means by Hathaway et al [2]. Then ARCA and K-Medoids [3],[4] was also proposed. But these algorithms had some limitations. In Relational Fuzzy C-means distance between data points couldn't be measured although it could operate on relational data. If the size of data set increased by high number, it causes the ARCA algorithm to fail. K-Medoids were affected by poor initialization which is done randomly.

A sentence is likely to be related to more than one theme or topic present within a document. However, because most sentence similarity measures do not represent sentences in a common metric space, a bag-of-words [5] approach or conventional fuzzy clustering approaches based on prototypes or mixtures of Gaussians are generally not applicable to sentence clustering [6].

Hence there is a need of fuzzy clustering algorithm that operates on relational input data. Relational data are in the form of a square matrix of pairwise similarities between data objects. FRC finds similarities between sentences and puts them into a cluster by calculating the cluster membership values. As the approach is fuzzy, a sentence may reside in more than one cluster with some amount of membership value. The sum of the membership values of a sentence in all clusters is 1. A sentence is considered to be in a cluster for which the corresponding membership value is largest.

This paper has improved the 'Measuring Sentence Similarity' method. The sentence similarity method measures similarity between two sentences based on both Word-to-Word similarity and Order similarity. Word-to-Word similarity measures the similarity between two words with the help of a lexical database known as WordNet [7]. On the other hand Order similarity measures the positioning of a word in a sentence.

The proposed method Sentence-Clustering based on FRC (SBFRC) has improved the 'Initialization' step of the algorithm. The FRECCA algorithm initializes the membership values and PageRank values using simple random number generation technique. FRC implemented 'Uniform Random Number' generation technique.

The rest of the paper is organized as follows. Section 2 summarizes some related works. Section 3 describes the methodology of SBFRC. Section 4 illustrates the experimental studies. Finally Section 5 concludes the paper.

II. RELATED WORKS

Hathaway et al.'s Relational Fuzzy c-Means (RFCM) algorithm [2] is considered as the first successful fuzzy clustering algorithm. Although RFCM operates on relational

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

data input, it does not the express the relation by this data to be Euclidean.

Though having success, the Euclidean requirement in RFCM was considered limited, and various alternatives have been proposed. For instance, the ARCA algorithm [8] uses an attribute-based representation. A limitation of this method is the high dimensionality. It causes by representing objects in terms of their similarity with all other objects.

K-Medoid family is popular in clustering algorithms. Fuzzy versions of k-Medoids have also been introduced. Like k-Means, k-Medoids are also highly sensitive to the initial selection of centroids which is done randomly. And often requires running the algorithm several times from different random initializations.

Many spectral clustering algorithms that can be applied to sentence clustering by Zha [9], and Wang et al. [10]. They have recently applied a closely related nonnegative matrix factorization [11] technique to sentence clustering in the context of multi-document summarization.

Our proposed approach Sentence-Clustering based on FRC (SBFRC) is based on a fuzzy relational clustering algorithm which is known as FRECCA algorithm [6]. Here, Cluster Membership values for each node represent the degree or extent to which the object or a sentence belongs to each of the respective clusters, and mixing coefficients represent the probability of an object being in a cluster [6].

III. SENTENCE-CLUSTERING BASED ON FRC (SBFRC)

To overcome the shortcomings of the above approaches, SBFRC has proposed in this paper that can group similar sentences together in a cluster. It contains several steps which are described as follows. Fig. 1 is the flowchart of the steps of SBFRC.

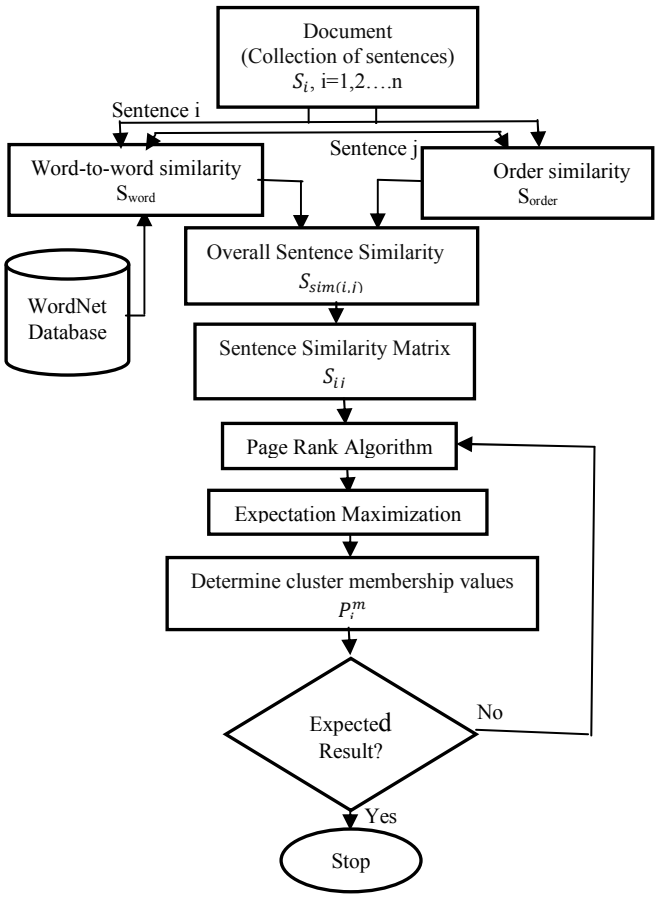

Fig. 1. Flow chart of SBFRC

Step 1: The input set is produced by pre-processing a text document. The sentences are extracted from a paragraph and the numbers of sentences are determined.

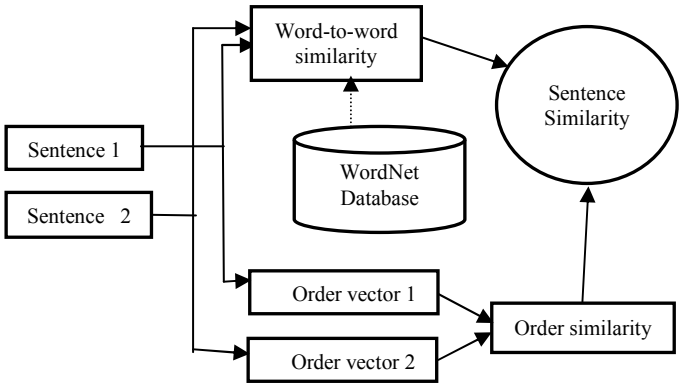

Fig. 2. Measuring Sentence Similarity

Step 2: Second step of SBFRC is to word-to-word similarity measure. Sentence similarity measures play an important role in text-related research. Existing methods for measuring sentence similarity have been adopted from approaches used for long text documents. These methods process sentences in a very high-dimensional space and are consequently inefficient and are not adaptable to some application domains. [12]

The proposed sentence similarity method derives similarity between two sentences using both word-to-word similarity and order similarity. A text is considered to be a sequence of words. The words, along with their combination structure, make a specific meaning.

Unlike existing methods, the proposed method calculates both word-to-word similarity and order similarity to compute final sentence similarity.

For word-to-word similarity the method used knowledge based measures, the WordNet [7] based measure due to Jiang and Conrath[13].

The Jiang-Conrath measure is based on the idea that the degree to which two words are similar is proportional to the amount of information they share. The similarity between words w1 and w2 is defined as equation 1:

$$Sim_{j\&c}(w1,w2) = \frac{1}{IC(w1)+IC(w2)-2*IC(LCS(w1,w2))} \quad (1)$$

Where , $LCS(w1,w2)$ is the word that is the deepest common ancestor of word w1 and w2, $IC(w)$ is the information content of word w, and defined as $IC(w) = -logP(w)$, where $logP(w)$ is the probability that word w appears in a large corpus [12].

Step 3: Third of SBFRC is to measure order similarity. For each sentence, a raw semantic vector is derived [12]. An order similarity is calculated using the two order vectors.

Step 4: The fourth step is to calculate the overall similarity as showed in Fig 2. Word-to-word similarity represents the lexical similarity. On the other hand, word order similarity provides information about the relationship between words: which words come before or after other words. Then, the overall sentence similarity is derived by combining word-to-word similarity and order similarity. And the similarity value is stored in the similarity matrix in respective position.

Overall sentence similarity is calculated using the equation 2 [12]-

$$S_{sim(s1,s2)} = r * S_{word} + (1 - r) * S_{order} \quad (2)$$

Where r <=1 decides the relative contributions of word-to-word and word order information to the overall similarity computation [12]. Since word-to-word similarity is more important and plays a vital role to overall sentence similarity, r should be a value greater than 0.5.

Step 5: Fifth step is to form the similarity matrix. The similarity method is applied between all possible pairs of sentences. After calculating similarity values between all the sentences in a document, the similarity values are stored in a matrix. If there are N sentences in a document then the matrix S_{sim} which size is NxN.

Step 6: Sixth step is to applying the PageRank algorithm [14],[15]. Unlike Gaussian mixture models, which use a likelihood function parameterized by the means and covariances of the mixture components, this method uses the PageRank score of an object within a cluster as a measure of its centrality to that cluster. These PageRank values are then treated as likelihoods. PageRank values are calculated using the equation no. 3:

$$PR_i^m = (1 - d) + d * \sum_{j=1}^{N} w_{ji}^m \left(\frac{PR_j^m}{\sum_{k=1}^{N} w_{jk}^m}\right) \quad (3)$$

Here, PR_i^m is the pagerank score of object i in cluster m. W_{ij}^m is the weight between objects i and j in cluster m calculated previously. And d is the damping factor. The damping factor d that appears in the PageRank calculation affects the fuzziness of the clustering, but generally does not affect the number of clusters, provided that the value is above approximately 0.8. In general, the higher the value of d, the harder is the clustering, with cluster membership values being close to either zero or one. We have used a value of 0.85.

After PageRank scores are calculated, these are treated as likelihoods and then they are used to calculate cluster membership values. Cluster membership values are obtained using the equation 4:

$$P_i^m = \frac{\pi_m * l_i^m}{\sum_{j=1}^{C} \pi_j * l_i^j} \quad (4)$$

Where, π_m is the mixing coefficient for cluster m. And l_i^m is the likelihoods for object i in cluster m which is obtained from the PageRank values. Membership values are normalized so that membership for an object sums to 1 for all clusters [6].

Step 7: Seventh step is the Expectation-Maximization (EM) step. Here there are two steps. The E-step calculates the membership values for each cluster. For each pair of sentences in a cluster weight is calculated using values from similarity matrix and membership values. That is –

$$W_{ij}^m = S_{ij} * P_i^m * P_j^m \quad (5)$$

In equation no. 5, W_{ij}^m is the weight between sentences i and j in cluster m. S_{ij} is the similarity between sentences i and j derived from Sentence similarity matrix. And P_i^m and P_j^m are the respective membership values of sentences i and j in cluster m [6]. With the help of this step once the PageRank scores are calculated they are treated as likelihoods and cluster membership values are calculated afterwards.

In the M-step the membership values are updated until convergence. It actually updates the mixing coefficients based on membership values. The value of mixing coefficient for each sentence in a cluster is same. As in the equation no. 6.

$$\pi_m = \frac{1}{N} \sum_{i=1}^{N} P_i^m \quad (6)$$

Where, π_m is the mixing coefficient for cluster m, P_i^m is the membership values calculated in expectation step and N is the total number of sentences.

Step 8: The eighth and last step is to find the convergence point for the clusters. The convergence is achieved when the membership of the sentences in the clusters is not updating anymore or the difference between the previous values is very little.

IV. Experimental Analysis

A. Experimental Setup

SBFRC has been development under the environment on Intel core i5-2.30 GHz processor with 4.0 GBytes of RAM running on windows 7 operating system. Here SBFRC has been developed in Java. WordNet database has been used while measuring word-to-word similarity. The quotation dataset on Table 1 [16] and news article dataset on Table 3 [6] are partial of the full dataset.

Table 1: Quotation dataset

Knowledge Class
1. Our knowledge can only be finite, while our ignorance must necessarily be infinite. 2. Everybody gets so much common information all day long that they lose their common sense. ……
Marriage Class
11. A husband is what is left of a lover, after the nerve has been extracted. 12. Marriage has many pains, but celibacy has no pleasures. ….
Nature Class
21. I have called this principle by which each slight variation if useful is preserved by the term natural selection. 22. Nature is reckless of the individual. When she has points to carry, she carries them. ….
Peace Class
31. There is no such thing as inner peace there is only nervousness and death. 32. Once you hear the details of victory, it is hard to distinguish it from a defeat. …..
Food Class
41. Food is an important part of a balanced diet. 42. To eat well in England you should have breakfast three times a day. …..

Experimental Results and Comparisons

Table 2 shows the results of applying our method, ARCA, Spectral Clustering, and k-Medoids algorithms to the quotations data set and evaluating using the external measures.

Our method requires that an initial number of clusters must be specified. This number was varied from 3 to 8, running 50 trials for each case, each trial commencing from a different random initialization of membership values. In each case the same affinity matrix was used, with pairwise similarities calculated as described before. However, only three unique clustering were found, each containing a different number of clusters, which ranged from four to seven.

Table 2: Evaluation of quotation dataset

No. of Cluster	Purity	Entropy	Rand	F-Measure
		SBFRC		
4	.350	**.550**	**.750**	**.450**
5	.400	**.500**	**.795**	.400
6	.400	**.445**	.765	**.480**
7	.400	.550	.770	.340
		ARCA

6	.720	.457	.779	.459
7	.740	.425	.805	.461

To demonstrate how the algorithm may perform in more general use in activities related to text mining, the system is also applied to clustering sentences from a news article.
Table 3 shows the sentences from an article about President Barak Obama's presidency.

Table 3: News article dataset

News Articles
1. President Barak Obama on Tuesday championed nuclear energy expansion as the latest way that feuding parties can move beyond the broken politics …… 12. That mission however remains in doubt … 15. In Saginaw Biden insisted the stimulus is working even as he acknowledged it's going to take us a while to get us out of this ditch ….. 27. It includes more direct and rapid response to criticism more events at which the president speaks directly to the public without the filter of the media 28. The intended narrative is one in which Obama hears people's frustrations and is working directly to end them. 29. There is a little doubt the public is angry. 30. A CBS news poll in early February found eighty one percent saying it's time to elect new people to congress

The result from the news article dataset is shown below-

Table 4: Results of News Article dataset

Sentences
3,5,6,9,10,13,14,15,16,17,19,21,24
2,7,12,18,20,22,25,26,27,28,29
1,8,23,30

B. Discussions

The performance measure techniques (Purity, Entropy [17], Rand, F-measure [18]) evaluated our method. The algorithm is run 50 times for the quotation dataset and chosen the best results from it. Since the method is unsupervised, there is no fixed output. As the four performance measures are not always consistent as to which algorithm achieves best performance for a given number of clusters, boldface indication of the value corresponding to SBFRC for which the measure is a maximum. For example, for the Rand Index corresponding to Cluster No =5, our method achieves a value of 0.795, which is greater than that achieved by the other algorithms (0.786, 0.785, and 0.733), and for cluster No. = 6, the proposed method achieves the value of entropy .445 whereas other method has higher value than it (0.451, 0.475 and 0.457) hence these values are represented in boldface. It can be seen from the table that when the number of clusters is 5, the algorithm performs well than when cluster number is 5 or 6 as measured by all five external cluster evaluation criteria.
The result achieved from the news article dataset, it is observed that in 1st cluster, sentence 15 has the highest PageRank score. So the sentence 15 would go in cluster 1. The sentences 3, 5, 6, 9, 10, 13, 14, 16, 17, 19, 21, 24 are also in cluster 1. There PageRank score in close to the PageRank of sentence 15. These sentences are of similar meaning. For 2nd cluster sentence 27 has highest PageRank. Closer to this are the sentences 2, 7, 12, 18, 20, 22, 25, 26, 28, 29. And most of them are similar as they are of negative sense (criticism, angry, frustration).

V. CONCLUSION

An obvious potential application of the algorithm is to document classification and summarization. Like any other clustering algorithm, the performance of this method will ultimately depend on the quality of the input set, and as for the sentence clustering the performance can be improved with better sentence similarity measures. As the cluster number is provided initially the algorithm appears to be able to converge to an appropriate number of clusters. The idea can be expanded to the development of a hierarchical fuzzy relational clustering algorithm as well as the proposed method can also be applied to a cloud trust system to measure its performance by analyzing user feedback comments.

***Abstract*— This paper addresses the performance of a double gate field effect transistor (FET) based nano biosensor in detecting human epidermal growth factor receptor 2 (HER2) which is a key biomarker for detecting breast cancer. At first dimensions of different parameters of a double gate FET were set in order to enhance sensitivity. Then various parameters of HER2 protein were calculated. Various nano biosensor characteristics in terms of settling time, selectivity and sensitivity were simulated. The results demonstrate that the designed nano biosensor has significant prospects of detecting the target.**

Keywords*— *diffussion; hydrophobic; potentiometric; sensitivity.

I. Introduction

In the present world, breast cancer is one the most invasive cancers. It accounts for 16% of all female cancers and 22.9% of invasive cancers in women. 18.2% of all cancer deaths worldwide, including both males and females, are from breast cancer. Research suggests that breast cancers can be divided in four molecular subtypes according to hormone receptor expression (HR±) and/or epithelial cell of origin (luminal or basal). There are two HR+ breast cancers (Luminal A and Luminal B) and two HR- cancers (human epidermal growth factor receptor 2 (HER2)-enriched and basal-like) [1-2]. Gene-expression profiling is not currently standard clinical practice, but, for nearly a decade, testing for joint HR/HER2 status has been a routine part of treatment planning [3]. Breast cancers with HER2 gene amplification or HER2 protein overexpression are called HER2-positive in the pathology report. HER2-positive breast cancers tend to grow faster and are more likely to spread and come back compared to HER2-negative breast cancers [4].

The small size, improved solubility and multifunctionality of nanoelectronics have opened many new research avenues for scientists. Though a lot of research activity has been involved in developing biosensors for various purposes the time has come to bring this technology to the forefront and make it commercially available. Biological signaling mechanism categorizes the types of biosensors. These types are potentiometric detection, amperometric detection, mass detection etc. In this paper a potentiometric detection system is analyzed. Potentiometric biosensors are generally based on ion-selective electrodes (ISE) and ion-sensitive field effect transistors (ISFET) [5-6]. To detect biomolecules, however, ISFET should be immersed and operated in the electrolyte solution to immobilize biomolecules. Thus, it has been pointed out that biosensors based on ISFET showed unreliable operational behaviors, such as drift and hysteresis [7-8]. To overcome these problems a double gate FET biosensor is presented. A Si channel FET is straddled by double gates is demonstrated. The separated double gates allow independent voltage control for channel potential which allows to beat the fundamental Nernst limit and improve sensitivity [9].

II. Modeling of Biosensor

Figure 1 shows the proposed design of a Double Gate Field Effect Transistor based nano biosensor (DGFET). The channel is made of Si. The FET channel is doped with p-type material as our experimental biomarker contains positive charge when acidic solution is used [10]. The front or reference gate is submersed in the solution. It is to be noted that the electrode used in this FET must be faradic electrode. The solution (pH<7) may create an insulator on non-faradic electrode surface which will affect the charge flow.

There are two dielectrics. Top dielectric is the receptor surface. This surface needs to be hydro phobic surface. If hydro phobic surface is not used the surface will not be able to hold on the sample solution. Hydrophobic surface will create a spherical structure of the solution which will help to capture maximum target molecules. Below the drain and source there is a second dielectric whose oxide thickness is much bigger than the front oxide one in order to increase sensitivity. This phenomena will be discussed later. The response time required for minimum number of analyte molecules to be captured to activate the sensor is called the settling time. There is a fundamental limitation for settling time (t_s) for each sensor which is given by the following equation.

$$\rho_0 = N_s * t_s^{-(\frac{3-D_F}{2})} \quad (1)$$

N_s is the minimum number of analyte molecules to activate the sensor which depends on transduction process and ρ_0 is the density of analyte. D_F is the fractal dimension of the surface which is equal to 2 for this sensor.

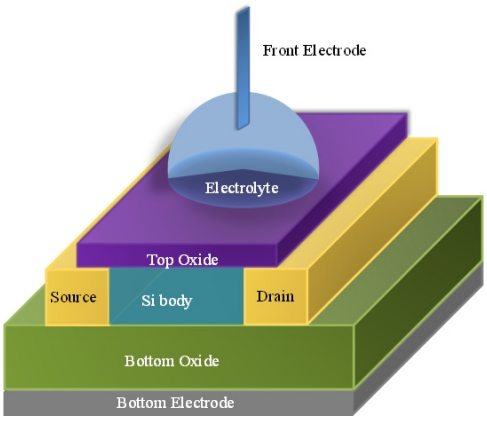

Fig. 1. Structure of DGFET biosensor.

$$N(t) = C_{D(t)}\rho_0 t \quad (2)$$

$$C_{D(t)} = \frac{D}{\sqrt{2Dt}} \quad (3)$$

The number of captured molecules ($N(t)$) in a given time can be calculated from the transient response of biosensor. $C_{D(t)}$ is the diffusion coefficient dependent capacitance. The sensitivity of the biosensor is defined by several ways. In this paper we have worked with the drain current and showed its response. The change in drain current (I_D) with respect to initial current (I_D) is normally called sensitivity (S).

$$S = \frac{\Delta I_D}{I_D} \quad (4)$$

$$S(t) = c_1 \ln(\rho_0) + c_2 \frac{(3-D_F)\ln(t)}{2} - c_3 \ln(I_0) + c_4 \quad (5)$$

c_1, c_2, c_3, c_4 are constants. Several experimental results have shown that sensitivity is non-linear, time dependent and depends on several aspects of the mechanism.

This sensitivity has logarithmic response to density of analyte. Sensitivity is further increased logarithmically with time but decreases logarithmically as we increase the buffer ion concentration. This complex response indicates that all of the parameters should be carefully chosen to design a successful biosensor [11]. One of the fundamental problems of the biosensor is the screening. For screening the salt concentration is generally about 100mM which is very high comparatively when we try to detect biomolecules at a range of µM to nM. From equation (5) we can easily understand how high salt concentration can reduce the sensitivity. There are several ways to beat the screening effect. One of the ways is amplification. This is why double gate is used. The drain current can be amplified by the bottom gate. Top gate and bottom gate produce two drain currents $I_{D,top}$ and $I_{D,bot}$ respectively.

$$I_{D,top} = \mu_1 C_{tox}(\frac{W}{L})V_{DS}V_{G,top} \quad (6)$$

$$I_{D,bot} = \mu_1 C_{box}(\frac{W}{L})V_{DS}V_{G,bot} \quad (7)$$

μ_1 is the carrier mobility, W and L are the channel width and length respectively. $V_{DS}$is the drain to source voltage. C_{tox} and C_{box} are the top and bottom dielectric capacitance respectively. $V_{G,top}$ and $V_{G,bot}$ are two gate voltages. Total drain current (I_D) is denoted by,

$$I_D = \frac{C_{tox}+C_{box}}{C_{tox}+C_{box}+C_{DL}}\nu \quad (8)$$

Q_{MOS} is the deposited charge on FET, ν is the charge velocity and Φ is the extra potential. Equation (8) shows that the total drain current (I_D) on FET operating in accumulation mode is dependent on top oxide capacitance (C_{tox}), bottom oxide capacitance (C_{box}) and capacitance associated with Debye length (C_{DL}). As capacitance is inversely proportional to thickness of oxide layer, in order to increase the sensitivity the bottom oxide thickness is made much bigger than the top oxide thickness. This phenomena helps to beat the Nernst Limit.

The biosensor needs to address two selectivity issues mainly. First one is the binding to wrong molecule. There will be a lot of parasite molecules in the analyte solution. Before the sensing process Polymerase Chain Reaction (PCR) can be used to amplify the number of target biomolecules. The second problem is binding in the empty space. The biosensor surface needs to be hydrophobic and the receptor density should be as much as possible. The signal-to-noise ratio (SNR) of the biosensor can be found by equation (11).

$$SNR = \frac{\sigma_T k_T \rho_T}{\sigma_p k_p \rho_p}\frac{r_T^2}{r_p^2}\frac{\theta}{\theta_{r,p}^{\infty}-\theta} \quad (11)$$

σ_T/σ_p denotes the signal transduction scheme. For example, it could be the ratio of electrostatic charge of the target and the parasitic molecule for electrical detection, or the ratio of the thickness of the target molecular layer to the parasitic molecule etc. k_T and k_p are the association constants of target and parasite molecules. ρ_T and ρ_p are the density of target and parasite molecules respectively. r_T and r_p are the radius surface coverage of each target and parasite molecules respectively. θ is the surface coverage for all target molecules. $\theta_{r,p}^{\infty}$ is the asymptotic surface coverage for a DRSA consisting of receptor conjugation followed by parasitic conjugation. As θ is directly proportional to the receptor density (N_0), the SNR is rapidly increased with higher receptor density [12].

III. HER2 Biomarker

HER2 overexpression and amplification has been linked to augmented cell proliferation, cell motility, tumor invasiveness, accelerated angiogenesis and reduced apoptosis. HER2 positive breast cancers are considered in the "intermediate or high histologic grade," absent of estrogen and progesterone receptors, while including positive lymph node metastases [13-14]. The structure of HER2 can be found in protein data bank. The accepted FASTA sequence of HER2 is given below [15]:

DIQMTQSPSS LSASVGDRVT ITCRASQDVN
TAVAWYQQKP GKAPKLLIYS ASFLYSGVPS
RFSGSRSGTD FTLTISSLQP EDFATYYCQQ
HYTTPPTFGQ GTKVEIKRTV AAPSVFIFPP
SDEQLKSGTA SVVCLLNNFY PREAKVQWKV
DNALQSGNSQ ESVTEQDSKD STYSLSSTLT
LSKADYEKHK VYACEVTHQG LSSPVTKSFN RGEC

The total number of sequence in 214 and the protein weighs 23.45 kilo Daltons. As the charge of the protein will be transduced into signal and the protein charge is associated with the pH of the solution. The pH vs charge relationship is

calculated using protein data bank calculator and is represented in figure 2. The isoelectric point (*pI*) is calculated using Henderson-Hasselbalch equation. The *pI* is found to be 7.70 approximately. This denotes that when pH level is below 7.70 then the protein contains positive charge and vice versa.

IV. Simulation and Results

The modelled DGFET has length and width of 1μm. The bottom oxide is taken 10 times thicker than the top oxide. The channel is a Si body having width of 40nm where the doping concentration is 1e19cm^{-2}**.** The sensor surface is assumed to be highly sticky. So the association and dissociation constant value are taken to be 3e06 and 1 respectively. The protein diffusion coefficient is associated with its size. The diffusion coefficient value for the selected protein is 1.11e06 cm^{2}s^{-1}. The experiment incubation time is set to 180min and temperature is set at 27^{0}C. The receptor density is 1e12 cm^{-2}.

The DGFET response over HER2 was simulated in online biosensor lab from nanohub.org. Figure 3 demonstrates the settling time changing with analyte concentration. The settling time is described in equation (1). It is also to be noted that the settling time increases with the minimum number of captured molecules is increased. But increment of settling time tends to saturate when higher no of molecules to be captured.

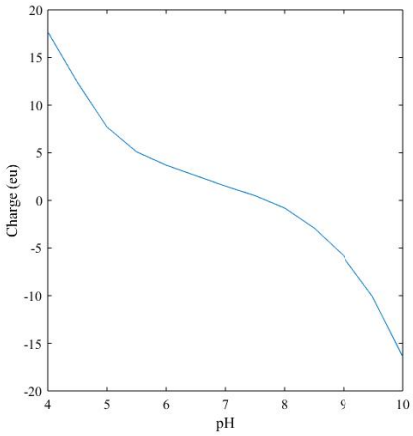

Fig. 2. HER2 charge at different pH level.

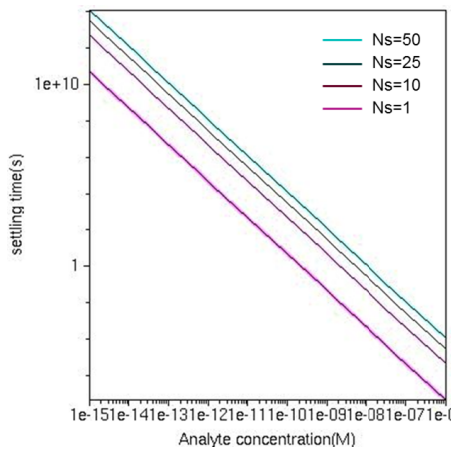

Fig. 3. Effect of analyte concentration on settling time.

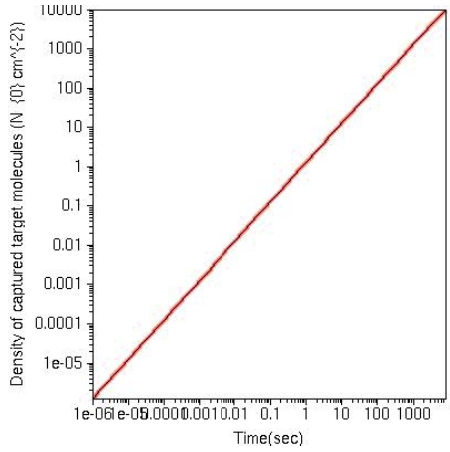

Fig. 4. Time dependency of density of captured molecules.

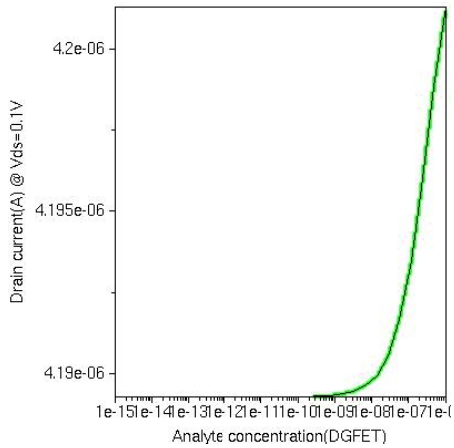

Fig. 5. Drain current response at different analyte concentrations.

The time dependent capture of target molecules is shown in figure 4. The starting time is accounted to be 1e-06sec. it is found that after 1000sec a significant density of captured molecules can be achieved. The sensitivity is assessed by the response in drain current of the FET. Figure 5 depicts the drain current response. A very insignificant response is found when analyte concentration is less than 1nM. The current increases exponentially with analyte concentration. But when the back gate voltage is introduced the response is amplified. From equation (5) we can understand that for a lower buffer ion concentration the drain current is increased with time. But at high concentration due to negative logarithmic effect the increment of current tends to saturate which is shown in figure 6. This is called the screening problem of biomolecule detection where high salt concentration is necessary. This effect can be reduced by using high frequency descreening.

The charge of the biomolecule varies with the pH. With the increase of pH the charge tend to change from positive to negative. So the drain current is also reduced for solution having high pH. Figure 7 clearly indicates that the solution should be acidic and pH level is set to 4 for the biosensor operation. For checking the selectivity it is assumed that the size of the parasite molecules is half of the target molecules. The concentration of parasite molecules is set to be 1μM which is higher than the target molecule concentration of 1nM and 1fM. The maximum surface coverage is 0.54. From figure 8 it

is indicated that SNR increases with the receptor density and if a target molecule is to be detected at 1fM range then the receptor density should be higher. But in reality it is very difficult to achieve receptor density much more than 1e12 cm^{-2}.

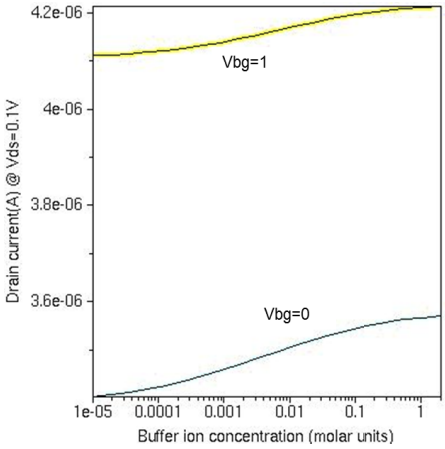

Fig. 6. The effect of buffer ion concentration on drain current.

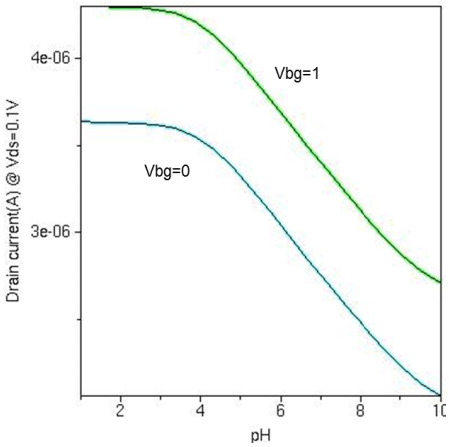

Fig. 7. The change in drain current over pH level.

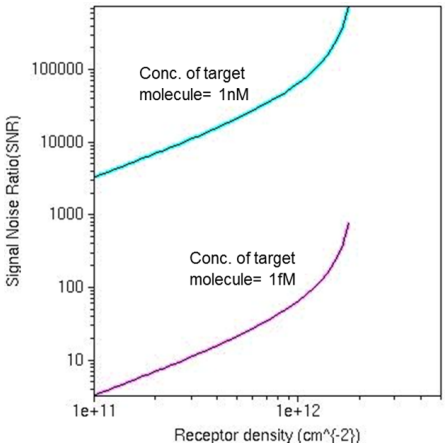

Fig. 8. SNR vs receptor density.

V. Conclusion

The simulated settling time and SNR results clearly indicate that it is possible to detect HER2 biomarker at a minimum concentration of 1nM. The biosensor sensitivity can also be enhanced by back voltage and increased buffer ion concentration. Another way of detection of target molecule can be done by varying the pH level of the solution and checking the difference in drain current. The DGFET biosensor model discussed above for detecting HER2 exhibits satisfactory performance. But several aspects like binding energy of the biomolecule or screening problem should be carefully examined in terms of fabrication of the sensor.

***Abstract*—Software development is getting changed so rapidly. It will be highly benefited if we can accelerate software development process by guiding developers. Appropriate guidelines and accurate recommendations to developers during development process can reduce software development expenses, as well as can save valuable times of developers. There are a number of approaches to speed up the software development process. It can be done through code assistance tools that help developers by recommending relevant items from searching particular repository of Application Programming Interface (API). Some approaches are based on online searching that have some drawbacks due to request and response latency as it has to deal with the extra-large files in a server. Developers generally uses previously completed resources as well as libraries or frameworks to generate relevant snippets which are supplied by the referral repository of APIs. Developers find it hard to choose the appropriate methods as there are thousands of methods in which some are not properly documented. In this paper we have proposed a concept and its respective framework to guide developers that suggests relevant API methods from an offline mined repository. From the investigation we made, we can say that our approach works much better than some of the existing approaches.**

Keywords—Application Programming Inteface (API), Offline Repository, ORBAS, Data Mining Integrated Environment (DMIE).

I. INTRODUCTION

Software development processes for a system is basically done by writing a program based on specific design specification. Nowadays it can be done by using various techniques. To do this development process developers in the software industries generally creates new methods or modifies existing ones or reuses previously defined methods. One of the processes to develop software is the reuse of existing libraries and frameworks. Developers can be highly benefited if they get appropriate guidelines and accurate recommendations. It can decrease development cost and can save valuable time. Application Programming Interface (API) is a process to search relevant items from an existing repository. This process is widely used all over the world. Some approaches of these API search processes are based on online searching. Developers usually searches for API usage pattern using online repositories provided by different tools.

General code search engines often deals with the extra-large files. These extra-large files often contain a large number of API methods. Developers find it very difficult to choose the appropriate API methods to use as there are also duplicate methods. The API methods returned by the search engines are not mined so relevant data cannot be displayed. As the database of the search engines contains a large amount of data; it takes a long time to find appropriate methods. The online search processes for API methods are fully dependent on the server; as it is fully internet based it takes more time to generate the entire API methods thus making it a time consuming process. Normal API library or framework written in object oriented languages and it contains a huge number of methods and classes. If the API methods and classes do not have the meaningful name sometimes even experienced programmers often face a lot of problems. The API methods returned by the search engines are not often well documented. Developers find it challenging to use the most effective and appropriate methods.

To solve these problems we have proposed ORBAS (Offline Repository Based API Searching) thatis an offline repository that contains various API attributes. ORBAS mines API pattern usage methods from the innovative sequences of API in source code. The mined patterns contain less redundant patterns so that the developers cannot find the similar patterns repeatedly. The high coverage usage of API methods should be returned by the patterns to ensure a beneficial achievement to the developers.

In this paper we first plan to make a query in the repository for searching methods. Then the repository returns the associated source files of the matched inquiries. After that there is a code analyzer which extracts API methods from the source files. In the paper we have propose PMD [1] source code analyzer which extracts the API methods from the source code even if the source code is not compilable. The methods are then clustered into groups for mining. Then mining is implemented on the clusters to produce frequent closed sequence. We propose the BIDE [2] algorithm for mining frequently closed API usage patterns. We have again used a clustering technique in the frequent closed sequences. Thus two-step clustering techniques are implemented before and after the BIDE algorithm to produce more accurate usage patterns. Finally the closed API usage clusters are then produced and the related API usage methods are

recommended to the developers. We have come to see that after following this approach ours are more efficient than some of the exiting approach to guide developers for getting API usage patterns.

II. Background and Related works

There exist a number of API usage pattern search theories or tools to find out useful API patterns from source code. Some of these are MAPO[3], MAC[4], ESDP[5], Hipikat[6], ParseWeb[7] etc. Often this search tools are based on online code search repositories such as Koders[8] and Google code search[9]. These code search engines generally evaluate code snippets containing keywords of API methods. Strathcoma[12] is a code snippet recommender, which finds out a set of code snippets by matching the structure of the codes. MAPO is a tool which mines API usage patterns and uses mined patterns for recommending code snippets. MAPO mines API usage pattern which have sequential information among the method calls. But the sequences patterns are not clustered in MAPO. ParseWeb accepts queries from the programmer and generates code samples based on the object type of the source and destination. UP-miner is also a mining tool for mining closed sequences returned from the API methods. It uses two-step clustering technique to find out frequently closed sequences. But it does not use a code analyzer to extract source files from the given result provided by search engines based the programmer query.

Unlike many related works, we have developed ORBAS based on the mining algorithm to mine API methods and a two-step clustering technique to produce frequently closed sequences. As our process searches an offline repository we aim to make it a time consuming procedure.

III. Framework

To mine API usage patterns from an offline based repository we have developed a framework based on the mining and clustering of frequent closed sequences acquired from the source files which are resulted from the query performed in the repository. There are five major components in the framework: an offline repository, a code analyzer, sequence miner, sequence cluster and recommender.The implementation of ORBAS framework is given here. The total procedure works as illustrated in Fig. 1.

Step-1: In the ORBAS framework there is an offline repository in which programmer performs a query.

Step-2: A set of source code is returned from which the code analyzer extracts API methods.

Step-3: A two-step clustering technique is performed before and after mining API sequences.

Step-4: The best API usage cluster is produced and the required methods are recommended to the programmers.

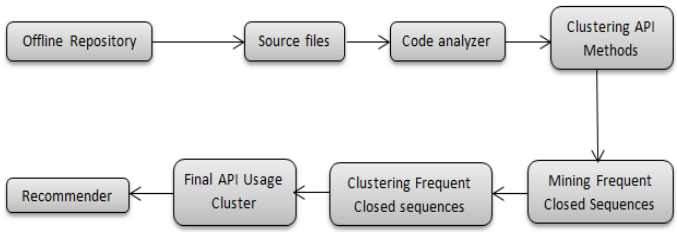

Fig. 1.An overview of ORBAS framework.

IV. Working Approach

A. *Offline repository:*

We have developed an offline repository in which different API methods are being inserted. The repository is organized by using a XML document to store API methods. The repository consists of sections such as search, update and delete. In the search section API methods can be searched by providing the method name. The update section makes necessary steps to add a new API method in the repository. It provides the insertion of methods. The delete section can remove API methods from the repository.

B. *Source files:*

As our framework is based on offline repository so the source files are collected directly from the repository based on the query implemented in the repositories. The repository provides the API methods which matches the input query. If the input method matches with the API methods stored in the repository, the complete source files of the methods are returned by the query.

C. *Code analyzer:*

Code analyzer helps us to extract the API methods from the source files. PMD [1] is a source code analyzer which does not need compilable source files for extracting API methods. PMD search outs common programming flaws like unused variables, empty catch blocks, unnecessary object creations etc. The code analyzer extracts a list of methods for each source files. This is done by collecting class name and full package name for each method. Based on the receiver object name we track the field declarations and local declarations to know the class name of the method calls. For the case of the classes which are exported in the import statement; we keep tracks of import statements to get the full package name of these classes.

D. *Clustering API methods:*

The method sequences returned by the source code analyzer can be two types. One is the frequently used API patterns which have large threshold support and another is less frequently used patterns which has minimum threshold. Clustering technique increases the chance of less frequently used sequence patterns to mine out before mining the frequently closed sequence. *SeqSim* [10] is an n-gram based technique which computes the similarity of two different sequences.

The set G(X) is defined as the n-gram set for a sequence $S(s_1 s_2 \ldots s_n)$ as a collection of unigrams, bi-grams, … , n-gram of *S*:

$(S) = \{s_1, s_2 \ldots, s_n, s_1s_2, s_2s_3 \ldots, s_{n-1}s_n, \ldots, s_1s_2..s_{n-1}, s_2s_3..s_{n-1}s_n, s_1s_2..s_{n-1}s_n\}$

Two situations are considered to evaluate a similarity between two sequences:

i) Sequences are similar if they both equally have a large number of API methods between their representative n-gram sets.

ii) Sequences are similar if they both equally have common subsequences.

If two sequences are s_1 and s_2 then the similarities are:

$$\text{SeqSim}(s_1, s_2) = \frac{\sum i \text{ Weight } (gi\cap)}{\sum i \text{ Weight } (giU)}$$

Where $g^i_\cap$ € $G_\cap = G(s_1) \cap G(s_2)$, g^i_U€ $G_U = G(s_1) \text{ U } G(s_2)$, weight $(g^i_\cap)$ is equal to the length of $g^i_\cap$.

As an example, given s_1 = abc and s_2 = cab, then we will have

$G_\cap$ = {a,b,c,ab}, G_U = {a,b,c,ab,bc,ca,abc,cab} andWeight(ab) = 1, Weight(ab) = 2, SeqSim(s_1,s_2) = 0.33 .

Based on the result of SeqSim, we cluster the API sequences. The remoteness of two clusters is considered as the highest value of remoteness between a pair of items in these two clusters.

E. Mining frequent closed sequence:

BIDE algorithm [11] is used to recognize the frequent API usages for mining frequent closed sequences. A sequence s_1 is a sub-sequence of s_2 and s_2 is a super-sequence of s_1 when s_1 is contained in s_2 and s is a frequent sequence. As there are no appropriate super sequences of s with the same support then s is a frequent sequence in a set of sequence if sup(s) ≥ min_sup. Sup(s) is called the support of sequence which is derived by the ratio of the sequences that are super sequences of s in the sequence set. Min_sup is the minimum threshold support [2].To prepare the frequent closed sequences for the cluster, BIDE algorithm is applied to each cluster originated from the procedure described in the previous section. For example, let us assume there are three sequences is a cluster which are xy, xyz, xyt. If the minimum threshold support is 0.5, BIDE algorithm gives the result of frequent closed sequences xy, where other sequence mining algorithms will provide the result x, y and xy. If xy is frequent then it can be easily noted that x and y will also be frequent. Thus x and y does not need to be enlisted. BIDE algorithm provides the sequences in which there are subsequences of similar support.

F. Clustering frequent closed sequences:

The API method sequences that are clustered using the proposed SeqSim technique in previous section; can be of two types. One is the sequences which are not similar to each other and another is the sequences which are similar. The sequences that are not similar are partitions into clusters. But the sequences that are similar can produce redundancy in the final API usage patterns. To solve this problem, another clustering is performed for the similar sequences. In this process the resulting clusters are considered as usage patterns. For example, we consider two frequent closed sequence xyz and zy which are mined from two distinct clusters. These two sequences are grouped together and shown as xyz after performing the clustering technique. The total number of superfluous sequences can also be removed using the technique. By applying the SeqSim technique; we can measure similarities between two frequent closed sequences.

G. Recommender:

After performing the clustering techniques the frequent closed sequences are produced and the results are shown to the programmers. The programmers can bypass the process of checking code sequences one by one as the recommender returns the mined patterns as an index of sequences. The best API patterns are shown on the top of the index thus providing the programmers a suggestion to select which one is to be used.

V. EVALUATION

A. Environmental Setup:

The implementation of our work requires the usage of severe environmental setups. ORBAS, MAPO and Koders are used as search engine. To produce a graph based result we have implemented our result data in MATLAB. The system platforms in which we developed our framework contain core-i5 processor (2.30 GHz), RAM of 4GB and 3G network.

B. Time Response Evaluation:

Our work in ORBAS is compared to the existing MAPO and Koders search engine for evaluating time response. For example we have consideredWebRequest.create as sequence 1, then we have considered another sequence HTTPWebRequest.getResponse as sequence 2 for both Table I and Table II and so on. By inputting these sequences we generate an output based on the time response of the search tools which is shown in Table I.

TABLE I. TIME RESPONSE EVALUATION

Squ. No.	API Name	MAPO[3]	Koders[8]	ORBAS
1	WebRequest.create	5	7	3
2	HTTPWebRequest. getResponse	7	9	2
3	HTTPWebRequest.create	6	7	4
4	SQLConnection.open	3	5	1
5	SQLDatabase.read	4	6	2
6	SQLConnection.close	2	5	1
7	SQLCommand. parametersAdd	4	8	2
8	SQLDataAdapter.Bill	5	7	1
9	HTTPResponse.setContent	6	5	3
10	HTTPResponse.write	7	5	3

Fig. 2 shows the graphical representation of the response time from the data of Table I. The graph shows result analysis of the time response evaluation of API sequences among ORBAS, MAPO and Koders. The graph is designed in MATLAB by inserting the values of Table I. From the graph it is clear that the time responses for each method are lesser in ORBAS than MAPO and Koders.

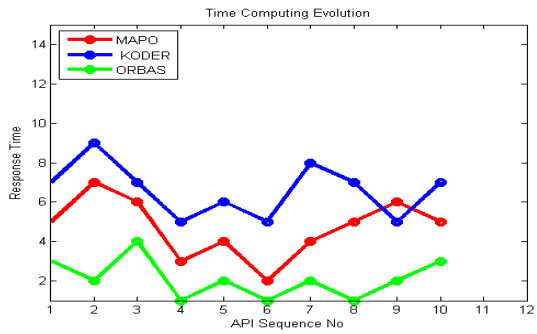

Fig. 2. Response time with different API sequences.

C. Performance Evaluation:

By inputting the sequences into different search engines we have evaluated the performance. Table II shows the performance evaluation based on the methods returned by each search tools. It is shown that ORBAS returns a few number of effective and useful methods compared to MAPO and Koders.

TABLE II. PERFORMANCE EVALUATION

Squ. no.	API Name	MAPO [3]	Koders [8]	ORBAS
1	WebRequest.create	71	110	8
2	HTTPWebRequest.Get Response	58	95	7
3	HTTPWebRequest.cre ate	22	55	4
4	SQLConnection.open	94	105	12
5	SQLDataReader.Read	67	82	10
6	SQLConnection.close	44	50	2
7	SQLCommad.paramet ersAdd	56	70	8
8	SQLDataAdapter.Bill	19	25	3
9	HTTPResponse.setcon tent	8	14	2
10	HTTPResponse.write	5	9	1

Fig. 3 shows the graphical representation of the number of methods returned by per API sequence. The graph shows the result analysis of the number of methods returned for ORBAS, MAPO and Koders. The graph is designed in MATLAB by inserting the data of Table II. It is clear from the graph that ORBAS returns a few but useful API methods than MAPO and Koders.

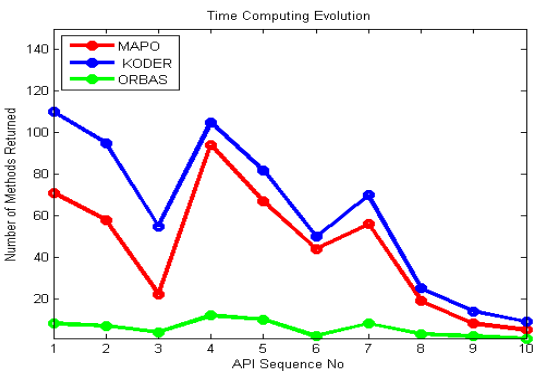

Fig. 3.Methods return from different API sequences.

VI. CONCLUSION AND FUTURE WORK

With a view to helping developers to understand API usages and client code more nicely we have developed a framework called ORBAS which is a supporting tool for mining API usages from anoffline repository. Our experimental results show that ORBAS generates useful API pattern than the existing tools. In future we will try to focus on automatic code generation based on the returned API patterns. Then these automatic generated codes can easily be inserted into developer's code. Our framework ORBAS may require some more data mining techniques. We further need to investigate to confirm whether the selected technique is the best or not. For the purpose of mining API usage patterns we plan to apply other clustering techniques such as k-means clustering. We also have a plan to apply other partial order miner in the mining stage. We plan to include other features such as class structure for clustering. We plan to find out the weights and thresholds value. We will concern other approach and technique and compare with our current process. In our working procedure we do not see the quality of the mined pattern directly. Usually most libraries do not provide usage pattern, there islacking in the field of the usage pattern. We must concern to experiment the quality of the usage pattern. Our framework approach must be applicable to many other object oriented languages. We will try to adapt our supporting tool in other large-scale databases. In our approach we have extracted API usages only for the API client code. In the future we will try to extract to the client code and the implementation code both.

An Experimental Study of Stylometry in Bangla Literature

Prapti Das, Rishmita Tasmim, Sabir Ismail
Department of Computer Science and Engineering
Shahjalal University of Science & Technology
Sylhet-3114, Bangladesh.
prapti.das.06@gmail.com, rishmita.sustcse015@gmail.com,sabir-cse@sust.edu

Abstract— **Every writer has a different style of writing of their own. By analyzing various kinds of features we can identify and specify some characteristics in a writer's writing which is known as stylogenetics. In this paper we gathered Bangla blogs written by four different Bangladeshi writers. Using machine learning methods we tried to identify special Stylometry features in their writing style. We analyzed various features in their writings, for example, percentage of unique words, word length, sentence length, and frequency of some parts of speech, number of suffix, frequency of first word, second word, second last word and last word of a sentence, counting average number of question marks per document, frequency of word by its position in a sentence etc. We gathered statistical data from analyzing those features and tried to find the variance among these writers using the statistical data.**

Keywords— stylogenetics, stylometry, machine learning, unique word, word length, sentence length, parts of speech

I. INTRODUCTION

Now-a-days language technology has reached to a different level of art. This enables the systematic study of the variation of linguistic properties in texts like author detection, find time period of the author, genre of writing, gender of the author etc. In short it helps to detect the characteristic and personality of the author.

Stylogenetics is clustering-based stylistic analysis of literary corpora [1]. It is a way of analyzing written texts to learn about the writer. Some features are often included unconsciously by the writer, for example gender, age, geographic location of the writer, personality characteristics, etc. A writer may use two specific consecutive words most frequently, may start and end a sentence with specific parts of speech, may write using a specific tense most of the time etc. These are some of the features that can be used to identify a writer.

Stylogenetics helps to detect who is the actual author of a specific writing and may assist in identifying fraudulent writing or in cases where multiple authors claim the ownership of a particular writing. Stylogenetics will analyze the writing and find a specific pattern or characteristic of that writing. Through which we can detect the original author.

Stylogenetics is a new area of research in the field of Bangla literature. Researchers in the past have worked with English literature, particularly with worked famous English writers like Shakespeare, Jane Austen, Charles Dickens etc.

However, there has not been any analysis on Bengali writers. There are many talented and skillful writers in our country and we often find interesting style and pattern in their writings. By analyzing their writing we can distinguish among the characteristics and features of individual writers.

Bangla is our mother tongue and Bangla literature is very rich and famous all around the world, which prompted us to initiate the first stylogenetics research in this area.

In this paper we investigated on the writings of four different Bangladeshi writers namely AH, EZ, MZI, SS (Due to Copyright Protection original name of the writers are not used in this paper).The reason behind choosing these four specific writers is the availability and popularity of their writings. We collected the blogs in a random way. A writer may write on a wide range of topics, for example, political issues, educational infrastructure, economical development, critics/novel etc. In this paper, we tried to identify the specific topic used most frequently by a writer.

Through our analysis we found some features that proved to be important to detect an author. But we did not find any absolute way of author detection. So our end-goal is to find a way which can identify an author perfectly.

The methodology we propose is to work with features like unique words used by an author, word length, sentence length which means number of words used in a sentence, number of parts of speech like conjunction and pronoun, number of question mark etc. There are several other possible features, for example, use of punctuations, use of stop words, use of simple/complex/compound sentences etc, which we plan to incorporate into our study in the future. Since in Bangla literature lexical and morphological analyzer is not rich, we could not work with some small details yet.

II. RELATED WORKS

Stylogenetics is the statistical analysis of variations in literary style between one writer or genre and another. Stylogenetics analyzes written texts to learn about the author. In various papers they worked with different features for the purpose of analysis.

Ramyaa et. al. [6] investigated some features like type-

token ratio, mean word length, mean sentence length, standard deviation of sentence length, mean paragraph length, number of commas, question marks, exclamation marks per thousand tokens.

Daelemans et. al [1] adopted a methodology from topic detection research, which included more complex features than the simple lexical features suggested by traditional approaches. They used authors or group of authors as a prediction of class, with clustering methods to indicate the differences and similarities between authors.

On the basis of the stylistic genome of authors, they tried to cluster them into closely related and meaningful groups. They also reported on experiments with a literary corpus of five million words consisting of representative samples of female and male authors.

III. OUR METHODOLOGY

We collected around 50 blogs each written by four different Bangladeshi writers for this study. The features we used and the detail experimental setup are described below.

A. Features Used :

1) Word frequency:

Word frequency means how many times a word was used in a writers writing. We counted frequency of both one word and two consecutive words. This is used as a feature to find the most frequent words used by a writer.

2) Word length:

The distributions of words of different length have been used as a feature. We calculated the frequency of words of different length.

3) Sentence length:

The number of words present in a sentence is used as a feature.

4) Type-token ratio:

The type-token ratio is *N/V*, where *V* is representing the size of the vocabulary of the sample, and *N* is representing the number of unique words. It is a measure indicating the vocabulary richness of an author.

5) Distribution of parts-of-speech:

Syntax-based features are not under the conscious control of the author and therefore it is considered as a feature. We mainly calculated the number of conjunction and pronoun in the texts.

6) Position specific word frequency:

We counted the frequency of words in first, second, last, second last and other random positions.

7) Writer specific unique words:

We created a list of words for each writer containing words which are mainly used by that particular writer. If another writer uses any of those words more than five times, then those words were not be considered as a unique word for that specific writer.

8) Previous and following words of a unique word:

We collected the previous and following words in a sentence for every unique word used by a writer.

9) Frequency of words related with "আমি", "করা","পারা" :

When we considered the word "আমি" we selected words like, আমি, আমরা, আমার, আমাদের etc. For "করা" we selected করা, করর, কররনা etc. And for "পারা" we selected পারা, পারর, পাররনা, etc.

B. Experimental Study:

1) Calculating Word Frequency:

A writer may frequently use some specific words and by calculating frequency of those words we can rank them as words most frequently used by a writer.

2) Frequency of one word:

We have implemented a program using java programming language to calculate the frequency of every word. Fig. 1 shows the words most frequently used by the four writers.

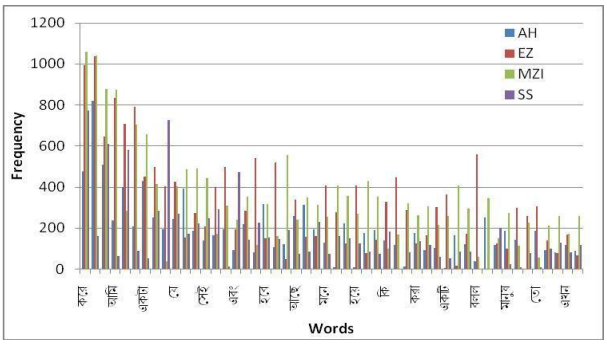

Figure 1. One word frequency of four writers.

As shown in Fig. 1 the words 'বলল' were most frequently used by EZ compared to other writers. So we can say that this can be used as a significant feature in case of EZ.

3) Frequency of two consecutive words:

Writers often use two specific words consecutively. We counted the frequency of two consecutive words using another program implemented in java similar to the program used above. Fig. 2 shows the most frequent two consecutive words used by the four writers.

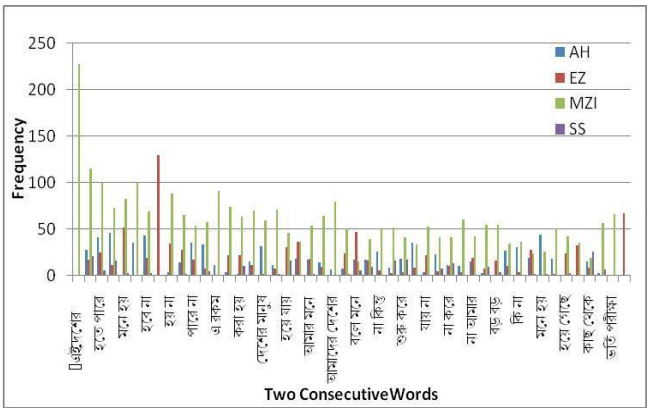

Figure 2. Two consecutive word frequency of four writers.

As shown in Fig. 2 the pair 'এই দেশের' were used in a higher

frequency by MZI than the others. The similar differences are shown in case of other writers.

4) Word Length:

Longer words are traditionally associated with more formal style, whereas shorter words are a typical feature of informal spoken language. Shorter words are also a feature of the modern day writes.

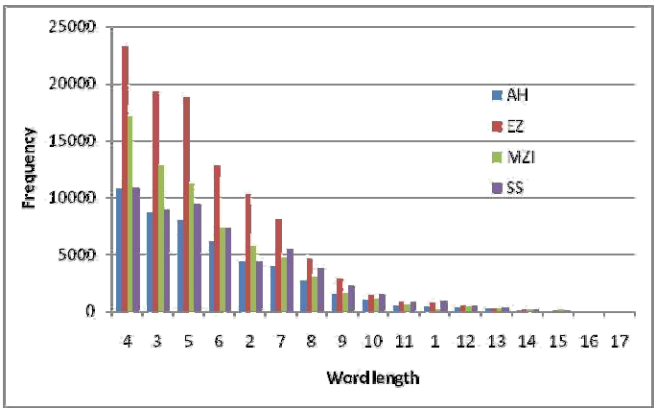

Figure 3. Frequency of words with different lengths.

As shown in Fig. 3 all the writers prefer to use shorter words more frequently than longer words most noticeably the writer EZ.

5) Sentence Length:

While shorter sentences are more indicative of spoken language, longer sentences indicate formal writing. Fig. 4 shows the usage of shorter sentences in a high frequency in case of all four writers.

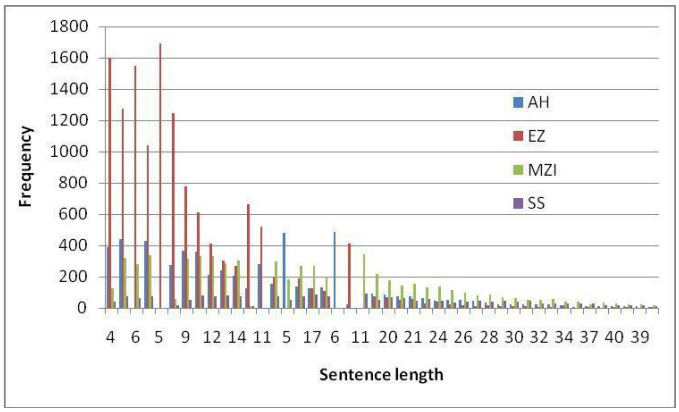

Figure 4. Frequency of sentences with different length.

As shown in Fig. 4 shorter sentences were used most frequently by EZ, while longer sentences were used in a higher frequency in case of MZI.

6) Type-token ratio**:**

The ratio of number of unique words and total number of words present in a document.

$$\text{Type-token ratio} = N/V, \qquad (1)$$

Here, N= number of unique words, V= Total words

Type-token ratio helps to find the richness of the vocabulary of a text. The writer that has the larger ratio has a richer vocabulary. Fig. 5 shows a pie-chart of the type-token ratio of all four writers.

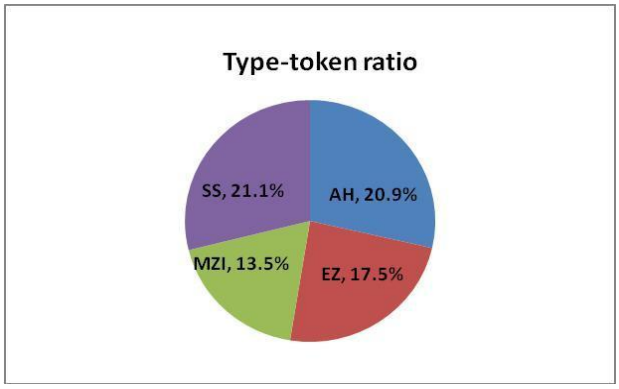

Figure 5. Type-token ratio of four writers.

The pie-chart above shows that SS and AH has higher type-token ratio compared to MZI and EZ. SS has highest type-token ratio, while MZI has the lowest ratio.

7) Distribution of parts-of-speech**:**

As part of identifying the distribution of parts-of-speech, we calculated the number of "conjunction" and "pronoun" in the documents.

Frequency of conjunction indicate continuity in someone's writing. On the other hand frequency of pronoun is indicative of particular pattern or style in writing.

Fig. 6 below shows the comparison of average number of conjunction and pronoun used per document by each writer.

It shows that average number of pronoun used by AH is higher than the others and in case of average number of conjunction is higher for EZ.

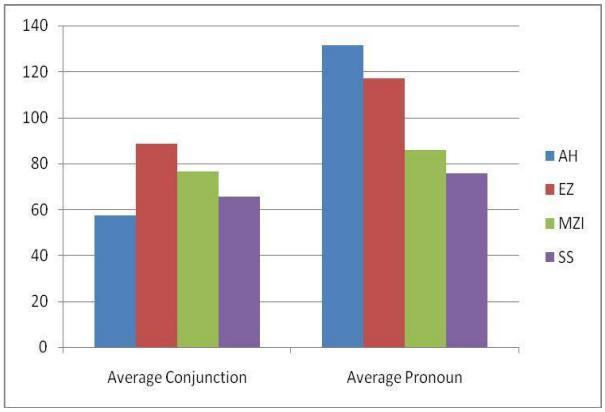

Figure 6. Average number of "Conjunction" & "Pronoun" per document.

8) Position wise word frequency:

Same words can be used in a different position in a sentence by different writers.

9) Writer wise unique words:

These words are especially used by one particular writer. These can be considered as recognizable words for a writer, which indicates the type or category of the text. In our analysis we found some recognizable words of three of the four writers.

In case of EZ, the "Recognizable words" are using different "Names."

Fig. 7 shows the frequency of recognizable words used by EZ comparing to other three writers.

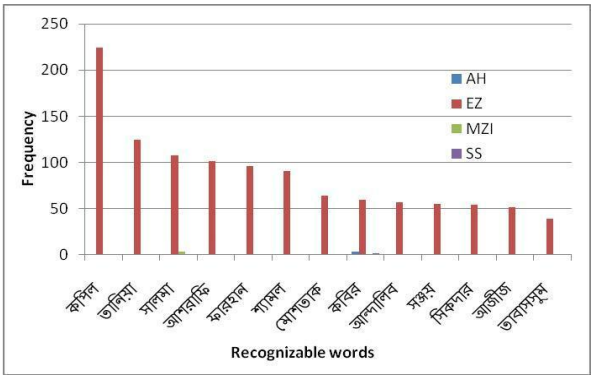

Figure 7. Comparison of "Recognizable words" used by EZ with others.

In case of MZI, the recognizable words are "Educational Words".

Fig. 8 shows the frequency of "Recognizable words" used by MZI comparing to other three writers.

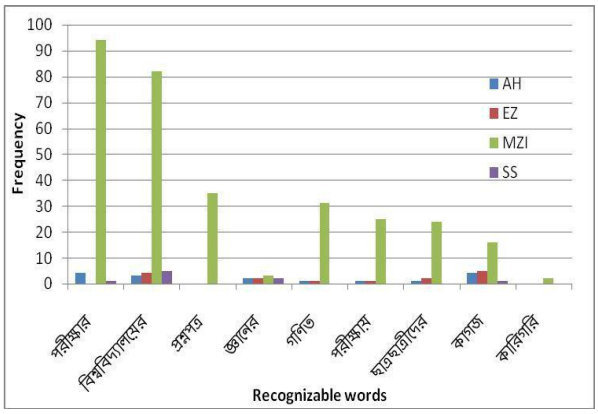

Figure 8. Comparison of "Recognizable words" used by MZI with others.

In case of SS the "Recognizable words" are "Political Words".

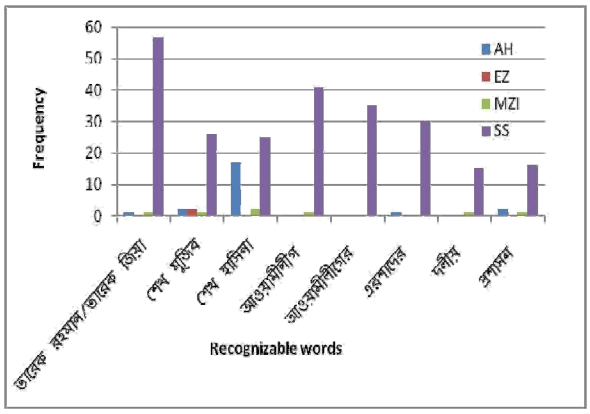

Figure 9. Comparison of "Recognizable words" used by SS with others.

10) Previous and Following words of a unique word:

There might be several words that are used frequently by all four writers. But analyzing the previous and following we can find some difference which could be an important feature.

11) Frequency of words related with "আমি", "করা", "পারা":

If the usage of words related with "আমি" is high in someone's writing, it can indicate that he is more likely to write in first person.

Fig. 10 shows the comparison of using words related with "আমি", "করা", "পারা" among four writers.

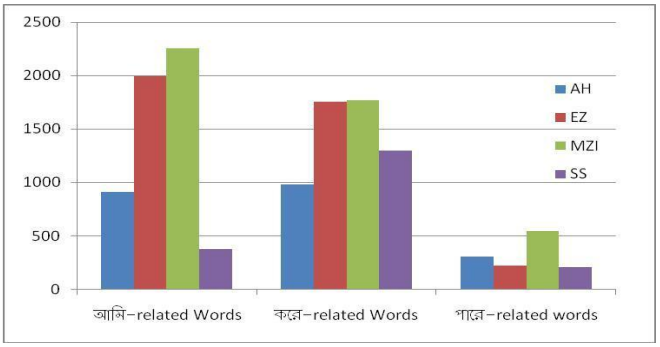

Figure 10. Usage of words related with "আমি", "করা" and "পারা".

We collected training data from these feature analysis. Then we compared the data with some random test data using statistical and machine learning approaches.

A. Standard Deviation:

It is a measure that is used to quantify the amount of variation or dispersion of a set of data values.

We counted the average number of conjunction per document for each writer from our training data. We did the same for test data. Then we calculated the standard deviation between a test data and each of the four writers' training data, e.g. we have test_data_1 and training data of four writers- AH, EZ, MZI and SS. If test_data_1 has the lowest standard deviation with training data of EZ, this indicates that test_data_1 might be the writing of EZ. Fig. 11 shows the standard deviation between test data and training data for average number of conjunction.

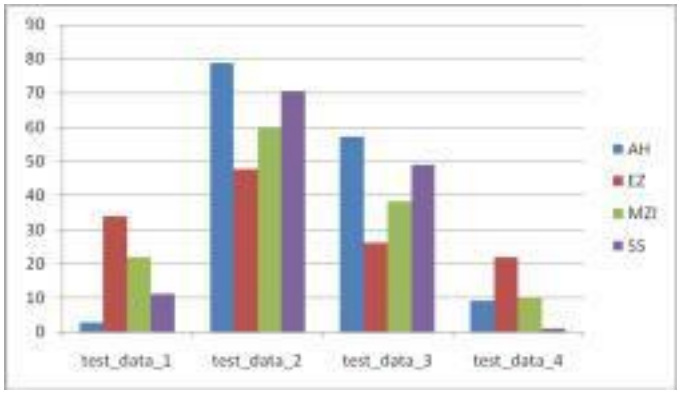

Figure 11. Standard Deviation between "Test data" & "Training data" for average number of "Conjunction".

We applied the same approach for average number of Pronoun.

Fig. 12 shows the standard deviation between test data and training data for average number of pronoun.

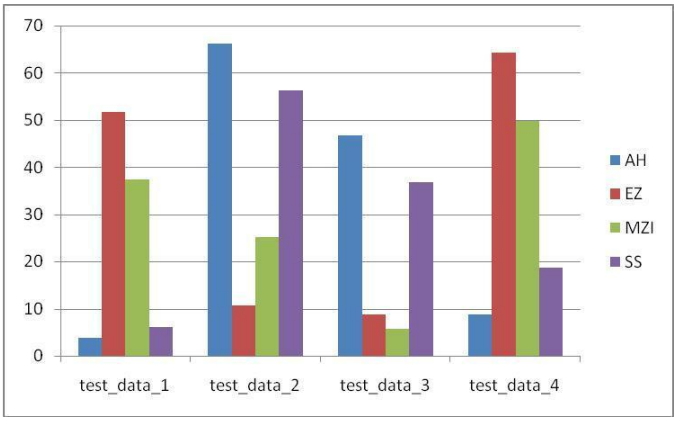

Figure 12. Standard Deviation between "Test data" & "Training data" for average number of "Pronoun".

B. Jaccard Similarity:

Jaccard Similarity is used to find similarity between two data sets. We applied this method for the feature writer wise unique word. We created a vector space model for the training data of unique words of each of the four writers and also for test data. Then we calculated the Jaccard similarity between test and training data, e.g. if test_data_1 has highest similarity value with AH, it indicates test_data_1 is most likely to be written by AH. Fig. 13 shows the Jaccard Similarity between test data and training data for writer wise unique words.

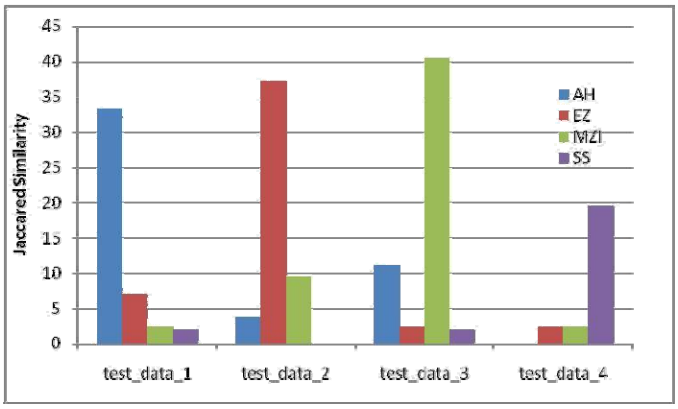

Figure 13. Jaccard Similarity between test data and training data for writer wise unique words.

IV. CONCLUSION

Stylogenetics provides an interesting venue for motivating and demonstrating many standard multivariate statistical techniques. This can be very useful for exploring and analyzing literary data. This paper attempts to recognize different authors based on their style of writing. As our first approach in this paper we analyzed twelve features according to the style of Bangla literature. Both standard deviation and Jaccard similarity can be one of the approaches to find some significant Stylometric features of a writer.

There have been no previous works on Stylometry for Bangla literature. Machine learning methods like Cosine similarity or Clustering can also be used to find some Stylometric features of a writer.

Stylogenetics is quite a new topic in the field of science and literature, especially Bangla literature. We hope our work will inspire others to work with Bangla literature in future.

Designing an Empirical Framework to Measure the Level of Interest of Human

Mizanur Rahman, Minakshi Debnath, ShylaSarmin, Lamia Alam, Safayet Arefin, and Mohammed Moshiul Hoque
Chittagong University of Engineering & Technology (CUET), Bangladesh
* E-mail: mmoshiulh@gmail.com

Abstract— **Human–robot interaction (HRI) is an interdisciplinary research field aimed at improving the interaction between human beings and robots. For effective and prolonged interaction, both interacting partners need to be identified the focus of attention of each other. In other words, need to tracks or determine the each other interest and their level of interest. Interaction between a human and a robot may influence by the proximity and angle between them. In this paper, we proposed a computer vision framework for robots that will determine the level of interest of its human partner in two-party setting. We have used the distance and angle parameters to determine the level of interest in several categories: high, medium, low, and so on. The level of interest information can be used as an indicator of people's willingness to engage in an interaction with a robot. The proposed framework uses depth and visual information, provided by a Kinect sensor. Experimental results show that the system is functioning quite well to measure level of interest of the human with a reasonable accuracy.**

Keywords*—— *Human robot interaction, level of interest, human detection, interest classification, evaluation.

I. INTRODUCTION

Interest may be defined as the cognitive process of selectively concentrating on one thing of the environment while ignoring or giving lower concentration to the other things. Determining someone's interest is the pre-requisite in any human-human and human-robot interactions. Determining human's interest and its level considered also as one of the important features for a social robot. Though human behavior is complex, it is need to be structured along individual and social lines [1]. In order to interact with the human in an uncontrolled environment, the robotic system should able to interpret, predict and respond to the human behaviors appropriately [2]. Thus, to behave in a socially acceptable manner, the robot should be capable of performing a lot of social and cognitive functions [3].

Due to the increased introduction of robots in the human world such as home, offices, shopping mall and so on, the robots are still stumbling to adjust with the social behavior of the human which can be solved by detection of level of interest. For example, considering the scenario of a service robot in a shopping mall where the robot needs to deal with plenty of customers. In that case, the robot needs to understand who is asking for service from it and has to be aware about who is trying to draw its attention. Again, the robot has to serve the customer on a priority basis (i.e. physical positioning of customers in the queue, who comes earlier). In different cases, the robot is required to have the ability to analyze the level of attention of human. Communication between a human and a robot may take several forms, but these forms are largely influenced by whether the human and the robot are in close proximity to each other or not. It also depends on their angular position. Thus, interest can be considered as a function of distance and angle. Depending on the functions, the level of interest varies from high to low. The level of interest can be measured in terms of physical and physiological parameters. In order to measure the level of interest, we consider two parameters: (i) distance between the human and the robot and (ii) angle between the human and the robot (with respect to the camera position of the robot and the line of sight of the human). In this work, we propose an empirical framework to measure the level of interest of human in terms of two parameters that can lead robots with the necessary capability to initiate an interaction episode in a more natural and social manners. After measuring the level of interest of the interacting human, the robot is able to display appropriate behaviors to him/her who are willing to interact with it.

II. RELATED WORK

There are lots of research activities have been conducted on designing several social capabilities of robots such as eye contact [4, 5], joint attention [6, 7], and attention control [8, 9]. However, still there are plenty issues remained unsolved related to developing the social capabilities of robots. In this paper, we focus such one of the important issue: measuring level of attention of human. Miguel et al. [10] estimated the level of attention by analyzing looking response toward the robot. Their system was able to detect the persons in its vicinity by using the stereo system and fuzzy logic is used to define a possibility of interest for the detected persons to interact with the robot. An attention system is proposed by Alcalde et al. [11] for robot-human interaction. This system uses depth and visual information, provided by a Kinect sensor to detect a user when s/he is requiring attention and predict the objects that are suitable for interaction. An approach is presented in [12] for a mobile robot to detect the level of attention of a human (i.e., null, partial, and total) in first-person interactions. Das et al. [13] proposed an attention control mechanism for social robots that attracts and controls the attention of a target person depending on his/her current attentional focus. Their system detects the interest or willingness of the target person to interact with it.

Most of the previous work used expensive color cameras and evaluated only in laboratory conditions. The proposed system uses a comparatively cheaper sensor (i.e., Kinect) that will work in non-laboratory conditions too. The IR color sensor of Kinect will produces better results. Moreover, the most of

the previous works dealt only with analytical dimensions rather than making a system. We propose an empirical framework which can estimate the level of interest of human with better accuracy.

III. PROPOSED FRAMEWORK

Although there are various parameters can be used to measure the level of interest of interacting partner, in this work, we considered two important parameters regarding the detection of human interest visually. First one is the distance between the human and the robot's camera and second one is the angle between the camera and the human. Level of interest of human can be measured by observing these parameters in real environment. We consider depth information by Kinect in this context to estimate the physical distance and angle between the human and the robot's camera.

Initial position of the human head is determined based on the depth image. Positioning is updated frame by frame according to the depth data which results in tracking the human. Distance and angle from the Kinect to the human is then measured by the system. Finally, the level of interest is determined based on the predefined rules. Fig. 1 illustrates the schematic demonstration of the proposed framework.

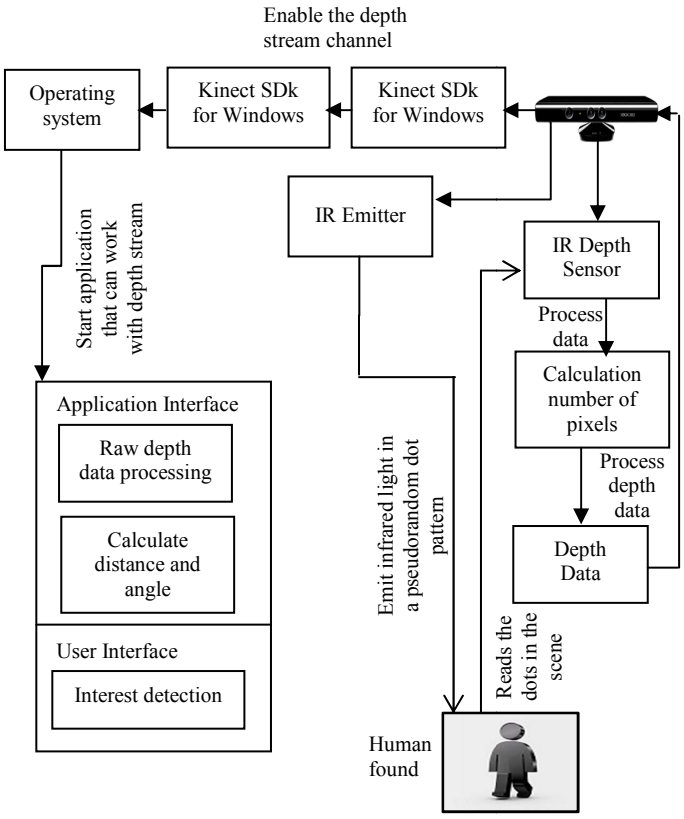

Figure.1: Proposed framework to measure the level of interest.

A. Capturing Depth Data

The infrared (IR) emitter and infrared (IR) depth sensors of Kinnect are used to capture the depth information of human. Kinnect produces a depth image of the human in front of it. The IR emitter and the IR depth sensor are used a combined function to obtain the X, Y and Z co-ordinate values on specific point of the detected human. We considered the head part of the human body to detect the human in our current implementation.

B. Identification of Human and Tracking

We use a model based method for human detection from depth images. Here, human is detected using depth information obtained by Kinect using a 2-stage head detection process, which includes a 2D edge detector and a 3D shape detector. Fig. 2 shows the overview of the human detection process.

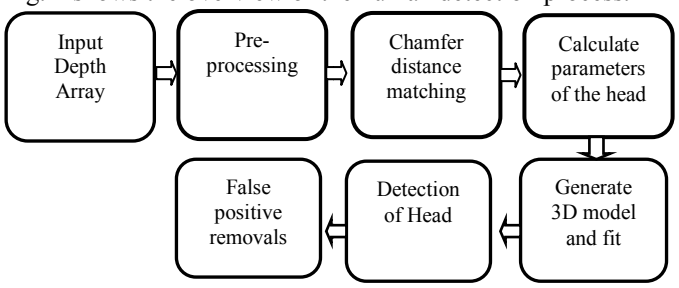

Figure 2: Overview of Human Detection Process

2D chamfer for distance matching algorithm is used. It scans across the whole image and gives the possible regions that may contain people. We examine each of these regions using a 3D head model. We extract the parameters of the head from the depth array and use the parameter to build a 3D head model. Then we match the 3D model against all the detected regions to make a final estimation. From the detection result of 2D chamfer matching, we can get the depth of the head like object from the depth array. In order to generate virtual 3D model of sphere (i.e. head), the only parameter that is required is radius of the sphere has conducted a regression test that have arrived at a cubic equation that gives the relationship between the depth value and the approximate height of head [10]. The cubic equation that fits the geometrical height of the head is computed as Eq. 1.

$$-y = -1.3835\times10^{-9}x^3 + 1.8435\times10^{-5}x^2 - 0.09140x + 189.38 \quad (1)$$

By equation Eq. (1), we calculate the standard height of the head in this depth. Then search for the head within a certain range that is defined by the standard height of the head by the Eq. (2).

$$R = 1.33\,\frac{h}{2} \quad (2)$$

Here, h is the height of the head, R is the search radius. Now, convert the height from millimeter into pixel unit as the matching works pixel by pixel.

$$Radius\ (pixel) = \left(\frac{1}{1.3}\right) \times Radius\ (\text{mm}) \quad (3)$$

Then we fit the model onto the regions detected from previous steps. We extract a circular region with radius R around the detect center and normalize its depth using Eq. (4).

$$En = \sum |\,\text{normalized_real_depth}\ (i,j) - \text{ideal_depth}\ (i,j)\,|^2 \quad (4)$$

We used a threshold value to decide the region is actually a head or not and remove the false positives. If the matching value is within the threshold, then we say the head is detected that in turns means there is a human.

Tracking algorithm is worked based on the movements of the human's head. This Kinect-based head tracking system uses user-specific 3D face template to track head pose. Head movement prediction is used to provide initialization result for ICP tracking, depending on whether or not the previous tracking results are available. The work flow of the human head tracking process is presented in a flowchart [Fig. 3].

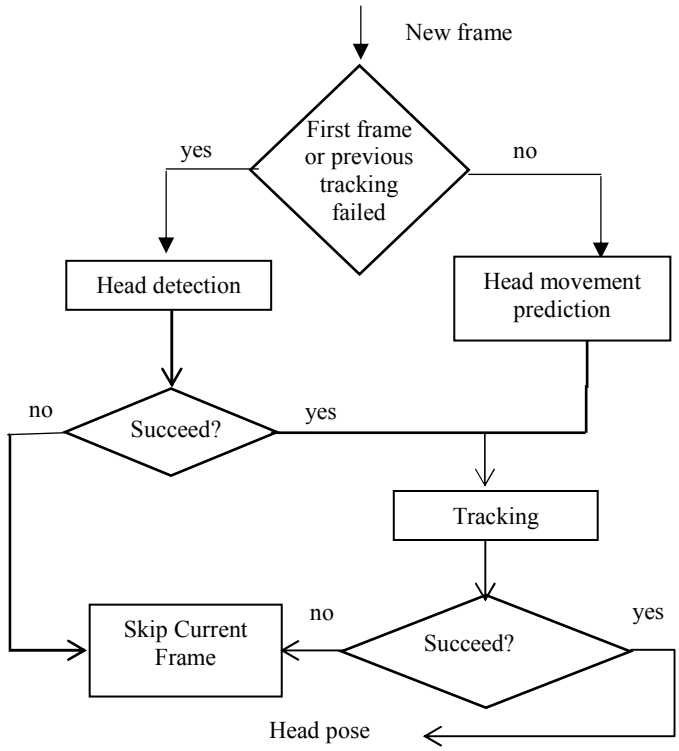

Figure 3: Workflow of the Human Head Tracking System.

Human can be detected either while s/he standing or sitting and facing the Kinect. However, sideways poses could prove to be difficult to be detected because of parts of the human are not visible to the camera.

C. Depth Information Processing

Kinect for windows device is connected to a general purpose PC with an USB cable. When there is a need to capture depth data, the Kinect is turned on and all of its sensors are initiated. Then IR emitter constantly emits infrared light in a random dot pattern over everything in front of it. IR depth sensor that reads the dots in the scene, processes the data, and sends the depth information from which they were reflected.

D. Measuring the Level of Interest Human

Interest can be considered as a function of two parameters distance (D) and angle (θ), $LI(H) = f(D,\theta)$, Where, LI (H) is the level of interest of human, D is the distance between the human and the Kinect sensor, and θ is the angle between the human and the Kinect respectively. Level of interest depends on the distance and varies inversely. Lower distance indicates the higher level of interest and vice-versa. Similarly, interest depends on the angle too. If we consider these two parameters together, then we can calculate interest from the rules below,

$$LI(H) = f(D,\theta)$$

$$LI = \frac{1}{(D+\theta)}; \quad when\ \theta > 0 \tag{5}$$

Here, D is the distance and θ is the angle between the human and Kinect. From the Eq. (5), level of interest is determined with respect to D and θ and varies inversely with them. We classify the level of interests in terms of ten categories based on the measurements of LI. The classification rules of level of interest level are illustrated in Table I.

TABLE I. CLASSIFICATION OF LEVEL OF INTEREST (LI)

Level of Interest (LI)	Classification
If (I = 0)	No Interest
If (I > 0 && I< 10)	Minimum Interest (MNI)
If (I >=10 && I< 20)	Very Low Interest (VLI)
If (I >=20 && I< 30)	Low Interest (LWI)
If (I >=30 && I< 40)	Lower Medium Interest(LMI)
If (4 >=40 && I< 50)	Medium Interest (MDI)
If (I >=50 && I< 60)	Higher Medium Interest (HMI)
If (I >=60 && I< 70)	High Interest (HGI)
If (I >=70 && I< 80)	Very High Interest (VHI)
If (I >=80 && I< 100)	Maximum Interest (MXI)

E. Measuring Parameters (D and θ):

After getting the depth stream data as a succession of the depth image frame the Kinect sensor returns raw depth with 16-bit grey scale format then we can measure distance. Behind the scenes the Kinect sensor runs a series of algorithms on the captured data to give more than an image, which tells how far each pixel in that frame is. Hence the depth pixel contains the distance between the Kinect device and the human in front of the device, in meters. Here we consider the head position of the human, so we measure the distance of the head of the human from the Kinect. The joint positions (here only head) are measured by three coordinates (X, Y, and Z). After getting these coordinate values, finally we calculate the distance between the Kinect and the detected human. The distance between two points (x_1, y_1, z_1) and (x_2, y_2, z_2) in 3-dimensional space can be determined by the Eq. 6.

$$d = \sqrt{\{(x_2 - x_1)^2 + (y_2 - y_1)^2 + (z_2 - z_1)^2\}} \tag{6}$$

Here, we assume that the sensor is in the origin point and another point is the position of the head of the detected human. Then we calculate the angle between Kinect and the human. We consider the angle to the respect of the line of sight of Kinect. In this set up line of sight is the straight line through the sensor. Here x axis is the line of sight and the negative value of θ indicates left side of the human. We use Eq. (7) to calculate the angle (θ).

$$\theta = \tan^{-1}(a/b) \tag{7}$$

Where, a indicates the value along X axis of the head position of human and b indicates the value along Z axis of the head position of the human.

IV. Evaluation Results

In order to evaluate the proposed framework, we have performed several trials in different environments. In each trails, we varied the distance as well as angle to estimate the level of interest. In one trial, a participant is asked at a time to interact with the framework and instructed to move forward and backward to change the distance. The participant also instructed to change their position for varying angle. We have calculated the level of interest of the participant in terms of distance only, angle only, and combined distance and angle respectively.

A. Output of the system

We experiment and analyze the system with different human as input in different real-world environments. We found significant results for most of the cases. We consider the level of interest in three criteria (i.e. IL against distance, angle and distance plus angle) for proper evaluation. A graphical interface is also represented to observe the variation of the interest level over time and to comprehend the significance of distance and angle both for measuring the interest level [Fig. 4].

Figure 4: Graphical User Interface of the System

In Fig. 4, a detected human is seen in the graphical interface of the application, this human stands from Kinect at 1.59 meter distance, and her angle from Kinect is -1.34 degrees. That means, from the equation (3) the level of interest of the participant with respect to distance and angle is 47.38%, which is Medium Interest (MI) according to the table 1.

B. Quantative Analysis of Level of Interest Measurement

To evaluate the level of interest, we have followed a three steps evaluation method. Firstly, we have taken the level of interest (LI) against a single parameter (i.e. distance). Secondly, the level of interest measured against another single parameter (i.e. angle). Finally, the level of interest will measured by combing distance and angles both parameters. We find significant changes among the outcomes that worked with combined parameter than that of single parameter.

Table II shows the summary of the analysis. We considered 10 interaction cases at different positions. Interest level based on single parameter and interest level based on both parameters together is compared. If we consider the first case of the table, here we can see the human in front of Kinect standing at 1.98 meter distance and her angle is 0.01 radian from the Kinect sensor. Therefore, we found that her level of interest is 30.9% which indicates category of Lower Medium. Fig. 5 illustrates this fact.

TABLE II. Measurement of Level of Interest (IL) with Distance, Angle and Combined Distance with Angle.

Case No.	Distance only (D) (m)	Level of interest	Angle only (θ) (rad)	Level of interest	Level of interest (D+θ)
1	1.98	50%	0.01	50%	30.9%
2	2.27	44%	0.07	14.28%	20.72%
3	0.97	100%	0.03	33%	100%
4	0.23	100%	0.16	6.25%	58.23%
5	1.37	73%	0.06	16.66%	9.34%
6	2.2	58%	0.21	4.76%	18.27%
7	2.43	39%	0 .45	2.22%	11.43%
8	1.73	41%	0.5	2%	38.7%
9	1.1	80%	0.04	34%	82.94%
10	4.55	Out of Social Distance	0.39	2.1%	No interest

Figure. 5: Graphical User Interface for case 1. In that case, the distance is 1.98 m, angle is 0.01 (rad), level of interest is 30.9%, and interest category is low medium.

Fig. 6 shows the graphical representation of Interest with respect to D, θ and both of them (D+θ). This Fig. indicates that the level of interest measurement varies both on the parameters D and θ. For example, if the distance is small but the angle is large (i.e., the human is attending the opposite side of the camera), the level of attention can be considered as very low. On the other hand, if the distance is large but the angle is small, then the level of interert can be consideded as the high. Thus, it is better to consider both parameters. In this work, we have proposed to combine the both distance and angle parameters for determining the level of interest of the human partner. Fig. 6 indicates that the level of interest changes

moderately while using combined distance and angle parameters than that of the individual parameter (distance or angle).

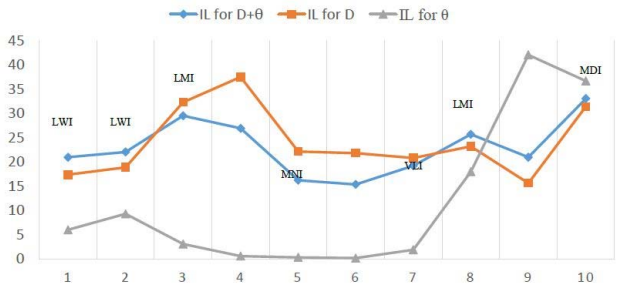

Figure. 6: Graphical representation of level of interest based on D, θ and (D+θ) parameters.

V. CONCLUSION

Measurement of level of interest of human can play a significant role in natural human-robot interaction. In this work, we presented a framework which can primarily measure the level of interest of human based on the distance between the human and camera and angle between them. The system also detects and tracks human as a pre-requisite of the interest measurement. As we worked with depth data rather than that of RGB image processing, performance is quite improved overcoming the environmental effects. Image based processing requires complex algorithm and computational costs. We used simpler algorithm for dealing with depth data. The system was evaluated in different environments with different participants and results reveal that it is able to measure the level of interest of the human with a reasonable accuracy. The proposed system is limited only two parameters. However, more parameters may include such as face area, sound source, attention span, and so on that will enhance the effectiveness of the proposed framework. The system may also extend for estimating the level of interest of multi-person scenario.

***Abstract*—In this paper, we present a bilingual question answering system, BQAS that can generate questions and provide their answers from electronic Bangla and English documents. The system first performs the analysis of the contents of the documents to generate questions based on user provided query. It then generates answers of the questions. The system has been evaluated with real documents. We have found that our system can generate questions and related answers up to a satisfactory level from the documents of two different languages as well as from the documents of the same language.**

***Index Terms*—Bilingual systems, keywords extraction, query execution, clustering.**

I. INTRODUCTION

Question Answering System is system where it produces an amount of questions from one or several documents and justifies users answer. It is one of the popular topics in natural language processing and one of the best ways to retrieve information from the documents. It is very helpful for those students who want to justify his / her learning through putting answer of generated questions.

There are many existing question answering systems. Most of them are unilingual in nature and none of them considers the generation of questions and answers considering the documents of Bangla and English. Considering this fact, in this paper, we develop a bilingual question answering system known as BQAS that can generate questions and their related answers considering the documents of Bangla and English. We implement the system considering users' provided queries and domain information. At first, the system extracts keywords from the documents those are related to the user query. Here, we consider postfix statistics to determine the root words. Then, digit and keyword based questions are generated from those documents. Our translation system then translates those generated questions and stores those questions into the database. A number of questions are shown to the user's screen in users selected language. Later on the system provides the answers of the generated questions.

Our main goal is to generate fact-based questions from the documents of Bangla and English. The importance of the generated is measured in two steps. In the first steps, we identify whether the question is asking something about the topic or something that is very closely related to the topic. For this purpose, we use Latent Dirichlet Allocation (LDA) [1] to identify the sub-topics in the given body of texts and apply the Extended String Subsequence Kernel (ESSK) [1] to calculate their similarity with the questions. In the second step, we judge the syntactic correctness of each generated question. We rank the questions by considering their topic relevance and syntactic correctness scores.The contribution of this paper can be summarized as follows:

The remainder of this paper is organized as follows. Section II provides a brief review of related work. In section III, we detail the computation framework of our proposed approach. Section IV presents the experimental results. Finally, we conclude and sketch future research directions in Section V.

II. RELATED WORK

The idea of automatically generating questions from sentences has been proposed and implemented as early as 1976. Recently question generation has got immense attention from the researchers and hence different methods have been proposed to accomplish the task in different relevant fields.

There are some question answering systems thats operate in English only. Such as, Plamondon et al. [1] developed a system where the question must be asked in English, the document collection is in English and the answer extraction is performed in English. Kaur et al. [2] described a system that first collects the corpus of data or paragraph from encyclopedia to make the questions and find the exact answer. Filho et al. [3] developed a system where they tried to classify the questions in only 4 types ("who", "where", "when" and "how many" questions). Hitomi et al. [4] concerned with a type of infant bilingualism in which children have been regularly exposed to two languages from birth as a result of each of their parent's speaking a different language. Their system produces only negative question in both Japanese and English language and judge the user's response.

Xu et al. [5] focused on the methods for question generation and answer judgement as well as the game implementation. Here they worked with Chinese and English statements. A cross-language question answering system is developed by Plamondon et al. [6]. Here they develop a system that receives questions in English language and show the answer in English for English document collection. They also transformed the system into a bilingual system to allow French speakers to ask their questions in French and get answer in French as well, but using an English document collection.

GistSumm [7] is an automatic summarizer based on a simple extractive method, called gist-based method. QUASAR [8] is

978-1-4673-9257-0/15/$31.00 ©2015 IEEE

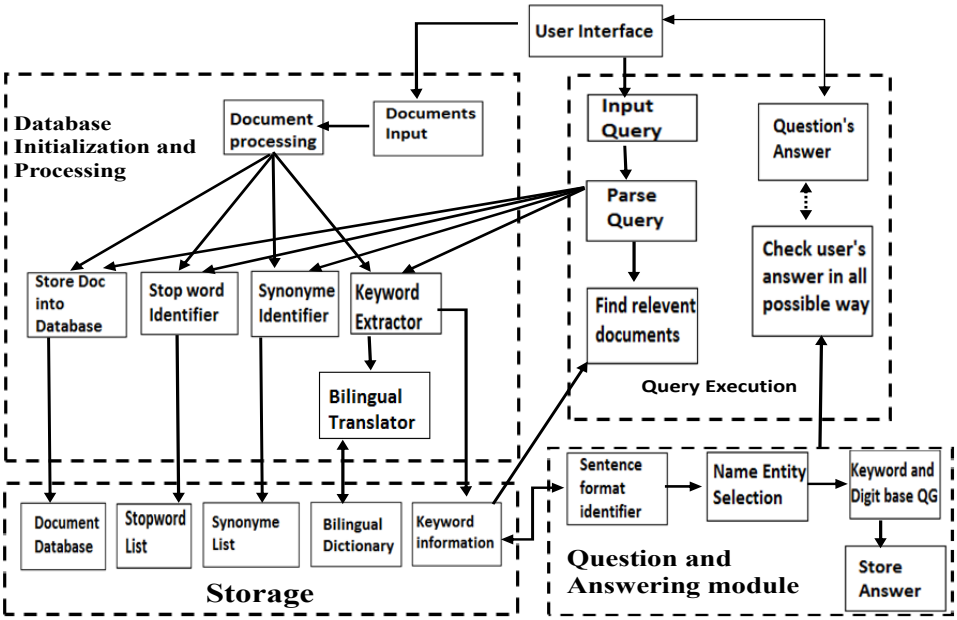

Fig. 1. System architecture of the proposed system

a QA system based on the JIRS1 Passage Retrieval engine, which has been fine-tuned for the QA task, whereas most QA systems use classical PR methods.

A few Banglaa and English question answering system also developed. Haque et al. [9] developed a question answering system based on transliteration and table look-up as an interface for the medical domain. The system is in no way a complete QA system; however, it gives a basis to implement a complete QA system for Bangla. The implementation involves questions from the medical domain only. They also consider only simple questions (wh-question).

There are about 220 million native and 250 million total Bangla language speakers. But there are a few works on Bengali language. So, working with Bangla language is most significant. Besides, Bangla and English question answering system helps students to make their learning more effective.

Considering this fact, in this paper we propose a framework for generating questions and corresponding answers considering the documents of two different languages: Bangla and English.

III. System Architecture and Design

The system architecture of Bilingual Question Answering System comprises four basic modules: Database initialization and processing module, storage module, question and answering module and query execution module. The function of database initialization and processing module is to set up the database from a set of documents for information retrieval. Storage module store all related information to the database. Question and answering module is for generating question and analyzing the answer and query execution module performs all information retrieval queries. The architecture of the proposed system is shown in shown in Fig. 1.

Algorithm: *Documents_storing*

Input: Documents

Require: Store the documents.

1. **begin**
2. create a table named document having the field DocID, Doc Title, No of word
3. Initialize the counter variable is 1
4. While the counter variable is less than the no of total document
5. Insert the file name and counter into the table
6. Increment the counter variable
7. **End**

Fig. 2. Algorithm for storing documents into database

A. Database Initialization and Processing Module

The database initialization and processing module consists of sub-modules: store documents into database, stop word identification, synonym identification, keyword extraction. The relationships among the sub-modules are also shown in the Fig. 1. The document database is created with document ID, document title and total word into the document. Algorithm for storing documents is given in Fig. 2.

There are some words which do not make any significant change in absence of them. Those words are called stop word. Our current step is to remove those words from the documents. There are a lot of stop words in English language such as: a, about, above, across, after, afterwards, again, against, all, back, be, became, because, become, becomes, becoming, been, before, by, call, can, cannot, can't, due, during, each, eg, etc. There are also a lot of stop words in Bengali as well. A list of English stopwords and Bangla stopwords are enlisted and stored into the database, which are used in the process of stopwords elimination by the system. Algorithm for stopwords removal is given in Fig.3.

```
Algorithm: Stop_word_elimination
Input: List of words.
Require: Delete the unnecessary word.
begin
for each word do
    search the stop word list
  if word is found then
      remove the word from sentence
  else
      do nothing
  end if
end for
End
```

Fig. 3. Algorithm for stopwords elimination

```
Algorithm: Keyword_Extraction
Input: sentences and list of words.
Require: Find the keyword.
begin
for each independent word do
    initialize a 2D matrix with value=0;
end for
count=0;
for each independent word do
    if word match with the sentence's word then
        count++;
    else
        Do nothing;
    put the counted value in corresponding index;
  end if
end for
Determine the maximum value
    define the keyword;
End
```

Fig. 4. Algorithm for keywords extraction

Synonym identification sub-module performs the identification of synonyms from the documents. A words having the same meaning as another in the same language is called the synonym of that word. It is very much important to manage the synonyms efficiently. Because if the synonyms having same meaning are not treated as same words, there will be a great degradation of system's accuracy.

Keywords are used for different purposes. They are used to determine those documents which are related to the domain information. Keywords are also used to generate questions. Each keyword is stored into the database by its ID and name. Keyword extractor sub-module extracts the keywords from the documents with the help of algorithm of Fig. 4.

B. Storage Module

The storage module handles the storage of the document and important information for retrieval purposes. The stop lists are stored into the database. Synonyms are stored into the database accordingly. A bilingual dictionary is also stored for translation purposes. For further calculation keywords are necessary so keywords are also stored into the database.

C. Question and Answering module

It is the main module of our system. Here questions are generated and corresponding answers are also retrieved. There are several sub-modules: Sentence format identification, Name entity identification, Keyword and Digit based question generation and the storage of answer.

1) Sentence Format Identification: It is our first step to generate questions. Fist, we have to identify the sentence structure. If the sentence is simple then it is ready to generate question. For complex and compound sentences we convert them to simple sentences for making questions generation task easier.

2) Name Entity Selection: We use our database information to determine a name entity in the document. We use some general purpose rules to create some basic questions related to name.

3) Digit and keyword based question generation: Digits in documents play significant roles for generating questions. It is easy to generate questions by replacing the digits with a question word shown in Table I. We also consider keywords to generate the questions.

TABLE I
QUESTION TEMPLATE

English Question	Bangla Question word	Arguments
Who	কে	Person
Where	কোথায়	Place
When	কখন	Time
What	কি	Object
Which	কোনটি	Object
How	কিভাবে	Process
Why	কেন	Cause

D. Query Execution

The sub-modules are: Input query, parse query, find relevant document, user's answer, and find all possible answer. At first user input a domain name on which he/she wants to generate question. After taking the domain name as input from user our system needs to parse the domain name. Then using a clustering algorithm (such as cosine similarities) our system finds the relevant documents which are used for generating question. While answering a question our system needed to check the all possible solution for that question and match with the user's answer.

E. Documents Categorization

The similarity between domain and documents can be calculated by the cosine similarity. If the the cosine similarity -1 between the vectors of two documents means that the documents are exactly opposite, 1 means exactly same, 0 usually indicates independent documents, and in-between values indicates intermediate similarity or dissimilarity. For text matching, the attribute vectors are usually the term frequency vectors of the documents. In our situation, the cosine similarity range from 0 to 1. Based on the similarity measures, we short the documents in descending order of similarity with the query information. Then, we choose the documents those have the similarity scores grater than a defined threshold for considering question generation. Fig. 5 shows the algorithm of this approach.

```
Algorithm: Document_Categorization
Input: domain name and keyword list
Require: select the desired documents.
1.  begin
2.  for each keyword do
3.      Calculate the cosine similarity.
4.  end for
5.  if similarity_ value >= threshold do
6.      select the document for generating question
7.  else
8.      do nothing;
9.  end if
10. end for
```

Fig. 5. Algorithm for documents categorization

```
Algorithm: Duplicate_question_elimination
Input: List of generated questions.
Require: Delete the duplicate questions.
1.  begin
2.  for each question do
3.      search the question database
4.      if question is found more than one then
5.          remove the duplicate question
6.      else
7.          do nothing
8.      end if
9.  end for
```

Fig. 6. Algorithm for duplicate questions elimination

F. Duplicate Question Elimination

The system may generate same question from different documents. So, we need to remove the duplicate questions. The algorithm for duplicate questions elimination is given in Fig. 6. As our system first generates question from each document separately and store them in the database, we can easily eliminate duplicate questions by searching the database. While we insert a question into our question database, we first check whether the question is already in the database or not. If any question from our database matches with our newly generated question then the system does not insert it into our question database. Otherwise, the system inserts the question into the database.

G. Bilingual Translation

Algorithm for translation is given in Fig. 7. Generally Bangla sentence structure is different from English sentence structure. A simple Bangla sentence structure is "Subject + Object + Verb" while in English it is "Subject + Verb + Object". At first using bilingual dictionary, we have to find the translated word and feature of each word. Then by using word's feature we have to determine the sentence structure. After that we have to place those translated word in corresponding sentence structure.

H. Answer Judging

When users insert the answer for each question we have to check the answer whether it is right or wrong. There are many ways to answer a question correctly. An answer to a wh-question "How many versions of the Internet Protocol (IP)?" can be "two", "2", "2 versions" etc. The system needs to accept all these possible answers, and at the same time reject incorrect answers. Algorithm in Fig. 8 is used by our system for this purpose.

```
Algorithm: Bilingual_Translation
Input: Sentence
Require: Translated sentence.
1.  begin
2.  for each word in the sentence do
3.      search the word into the dictionary
4.      if found then
5.          Store into an array
6.      else
7.          do nothing
8.      end if
9.  end for
10. for each rule do
11.     if sentence matches with a rule do
12.         Apply translation rule to translate.
13.     else
14.         do nothing;
15.     end if
16. end for
17. End
```

Fig. 7. Algorithm for bilingual translation

```
Algorithm: Answer_Judging
Input: user's answer and answer database
Require: result.
1.  begin
2.  for each word in the answer do
3.      search the word into the database
4.      if match partially then
5.          calculate the percentage of matching
6.      else
7.          do nothing
8.      end if
9.  end for
10. set correct=0;
11. set wrong=0;
12.     if matching percentage>=70% do
13.         .increment correct value'
14.     else
15.         increment wrong value;
16.     end if
17. show the result
18. End
```

Fig. 8. Algorithm for answer judging

IV. Implementations and Experiments

In this section, we provide the implementation procedure and performance analysis of our developed system.

A. Experimental Setup

The developed Bilingual Question Answering System has been implemented on a machine having the windows 7, 2.50 Core i3-4100 processor with 4GB RAM. The system has been developed in JAVA in the front end and SQLite manager is used in the back end for storing related data to complete this project. For coding we have used NetBeans IDE.

For experimental purpose, we consider total twenty three Bangla and English documents of different domains. Table II shows the document name, domain name and number of containing words on those documents.

B. Implementation

Fig. 9 shows the generated questions with user provided answers in Bangla. Fig. 10 shows the accuracy of user's answers by comparing it with system generated answers. Here,

TABLE II

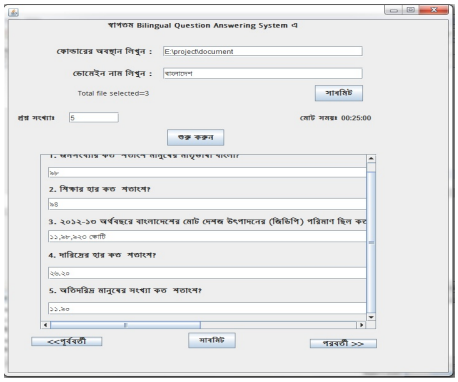

Fig. 9. Question with user's answer

for generating questions and answers for Bangladesh domain it considers eight documents out of twenty three documents.

Table III shows the number of retrieve documents considering by the system under different domains.

C. Performance Evaluation

We have evaluated the performance of our proposed system with respect to documents of Table II. For the experimental evaluation, we have generated questions and answers by our system and compared them with human generated questions and answers.

Our first experiment shows a comparison about question generation with respect to different domain information. Fig. 11 shows the result. From the graph of Fig. 11, we can find that human always generates more question than our system. This is because Human can generate a line of text in different way.

In our next experiment, we show top-10 questions generated by our system and by the human. Table IV and Table V show the results in Bangla and English, respectively. From

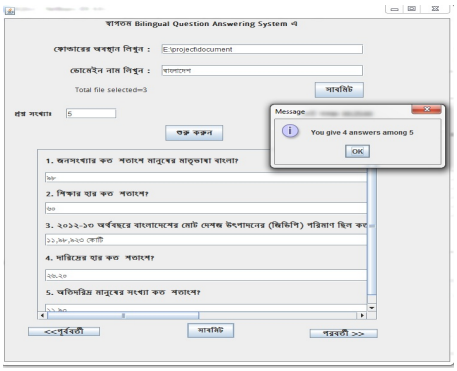

Fig. 10. User's score

TABLE III
DOMAIN SPECIFIC DOCUMENTS INFORMATION

Domain information	Total found documents	Documents
Bangladesh	8	bangladesh.doc, bangladesh_english.doc, Bangladesh_education.doc, bangladesh_government_bangla.doc, bangladesh_government2_bangla.doc, Economics.doc, bangladesh_histroy2_bangla.doc, bangladesh_histroy3_bangla.doc

the tables, we can find that our system can generate questions almost as accurate as the human. This is due to small domain size.

Our next experiment shows the accuracy in translation. The result is shown in Table VI. From Table VI we can see that our system can perform translation of the questions in the desired language upto a satisfactory level.

For each generated question our system produce answers. When user put answer for a corresponding question our system try to check produce all sorts of possibility to check the

Rank	Top 10 Questions generated by Human	Top 10 Questions generated by BQAS
1	What is the position of Bangladesh in the world in terms of area?	What is the position of Bangladesh in the world in terms of area?
2	what is the area of Bangladesh?	What percentage of population people mother tongue Bengali?
3	What percentage of population people's mother tongue is Bengali?	What percentage of literacy rate?
4	What is the total production amount of Bangladesh in 2012-2013 economic year?	
5	What is the percentage of literacy rate?	What percentage of poverty rate?
6	What is the percentage of poverty rate?	What percentage of extremely poor people number?
7	When did the constitution of Bangladesh applied?	What percentage of poverty reduction rate?
8	How many amendments brought in up to2011?	How many amendments brought in up to2011?
9	What percentage of poverty reduction rate?	How many reserved seat for women?
10	How many reserved seat for women?	How many administrative division separate in Bangladesh?

correctness. Table VII shows the result. From Table VII we can find that our system can judge the answers upto a satisfactory level.

V. CONCLUSION

In this paper, we provided a framework for bilingual question answering system. We have implemented the system with Bangla and English electronic documents. Form the experimental evaluation, we found that the developed system can generate questions and answers efficiently. Although in this paper, we have considered documents of two different languages, it can incorporate other language easily.

In this work, we considered an in-house database of documents and it is necessary to scan a document before it is considered in the system. In future, we hope to develop a system that can efficiently generate questions and answers from the documents of the Internet without scanning them in the system.
