ACKNOWLEDGEMENTS

The organizing committee acknowledges the efforts of all those who have contributed their valuable time and efforts as reviewers in ensuring high quality technical papers for the 11th International Conference on Computer and Information Technology (ICCIT 2008).

Deepest appreciation to all faculty members of the Faculty of Faculty of Electrical and Electronic Engineering, Khulna University of Engineering and Technology (KUET) for their sincere cooperation in making the conference successful. Appreciation also goes to all parties who have contributed to the success of 11th ICCIT 2008 in KUET.

Finally, the organizing committee would like to express their thanks to the followings for sponsoring this conference:

University Grants Commssion of Bangladesh
United International University (UIU), Bangladesh
Eastern University, Bangladesh
University of Liberal Arts (ULAB), Bangladesh
East West University (EWU), Bangladesh
North South University (NSU), Bangladesh
BRAC University, Bangladesh
Visual Magic Corporation(VMC) Limited, Bangladesh
Apartment design & development ltd.(ADDL), Bangladesh
Link3 Technologies Ltd.
Islamic University of Technology(IUT), Bangladesh
Meghna Cement Mills Ltd., Bangladesh
Energypac Power Generation Ltd., Bangladesh
Independent University, Bangladesh
American International University-Bangladesh (AIUB)
Military Institute of Science & Technology, Bangladesh

MESSAGES

Chairman

University Grants Commission
of Bangladesh

MESSAGE

It is heartening to note that the Faculty of Electrical & Electronic Engineering, Khulna University of Engineering & Technology (KUET), Khulna, Bangladesh is organizing the 11th International Conference on Computer and Information Technology (ICCIT 2008) during December 25-27, 2008.

Knowledge acquisition is a continuous process that involves generation of new ideas, thoughtful outlining of possibilities and consummate implementation. The attainment is fulfilled when the knowledge is shared with others. The recent rapid development in Information and Communication Technology has urged scholars, scientists, researchers, academicians, theorists, professionals, technologists, and entrepreneurs to share the improvement they are inducing. Conference like ICCIT is one of the strong and prestigious platforms for them to sustain the newer technologies they are inventing. One of the aspirations of the ICCIT 2008 is to foster co-operations among the researchers of the same and interdisciplinary fields from Bangladesh and abroad. The knowledge intakes from the conference will have a meticulous effect to broaden our views and to contemplate for inventing more relevant ideas in near future.

I hope that the research papers in different fields of ICT to be presented in the conference, discussions in the technical and Keynote sessions will benefit the scientific and engineering community of Bangladesh and around the globe. I appreciate the sincere efforts of the organizers in holding the conference on a regular basis. I wish ICCIT 2008 all success.

Nazrul Islam

(Professor Nazrul Islam)

Chief Guest

ICCIT 2008

Vice Chancellor

Khulna University of Engineering & Technology,
Khulna 9203, Bangladesh

MESSAGE

It is an honor and privilege for Khulna University of Engineering & Technology (KUET), Khulna, Bangladesh to have the opportunity to host the 11th International Conference on Computer and Information Technology (ICCIT 2008) and Workshops to be held on 24-27 December, 2008. It is my utmost pleasure to welcome participants to a congregation of researchers and scholars to share knowledge and ideas for promoting knowledge-based society.

The essence of Information and Communication Technology has been pervaded greatly over the years. ICT is now penetrating every walk of our lives- health, education, national security, economy, business, e-governance. The geographically sparse world has been commuted into a single logical demographic area amid ICT and ICCIT 2008 is the one of such exercises that made it possible. Since its commencement in 1998, ICCIT became the platform for the researchers to stand upon and to share the inwardness and pith of ICT which boosts up the spirit of intellectual growth.

KUET is committed to uphold the heritage of the conference and has indulged a new dimension for researchers, professionals, academicians, entrepreneurs, and students from diversified areas. I heartily welcome all the participants in ICCIT 2008 with ardent hope that the bonding among the researchers, faculties, and students will be strengthened through the congress.

I wish participants from home and abroad a pleasant time during the conference and workshops as Bangladesh is a land of natural beauty and heritage. I wish every success of the conference and workshops.

(Prof. Dr. Md. Nawsher Ali)
Chair, Advisory Committee
ICCIT 2008

Dean

Faculty of Electrical & Electronic Engineering
Khulna University of Engineering & Technology,
Khulna 9203, Bangladesh

MESSAGE

I am highly pleased to write few words for 11th International Conference on Computer and Information Technology (ICCIT 2008) to be held in KUET from December 24-27, 2008. For the first time the conference is being organized at Khulna, a place of about 300 kilometers from Dhaka organized by the Faculty of Electrical & Electronic Engineering, KUET. Khulna, an important divisional city of the south west region of Bangladesh, has its heritage for the Sunderbans, the Mongla port and conventional industries.

The Information and Communication Technology (ICT) aided by computers has emerged with its intensive applications for the global human life. A wide window has been opened by this technology to contribute to the society. New fields of research and areas of applications for the improvement of life style of human race and to alleviate unemployment problem are the benefits of this technology. In Bangladesh, we have a huge population and unemployment. I feel the conference will focus on this problem and deduce suggestions to overcome the problem and help advancement of the technology.

I come to know that the conference is enriched by 138 technical papers and 6 invited lectures. About 200 participants from home and abroad are going to participate in the conference. I think it will be a huge gathering of experts and fresh researchers. I hope the concluding round table discussion will find out some causes and probable solutions that will help to develop our ICT.

I feel it as a huge involvement to organize an international conference like ICCIT at Khulna. A group of teachers of the faculty have been actively working for a long period to make the conference successful. In spite there may be some unseen inconveniences and I request all the participants to overlook and forgive if any such by your generous heart.

At last, I wish grand success of the conference and pleasure stay of all participants at KUET.

(Prof. Bashudeb Chandra Ghosh)
Co-chair, Advisory Committee
ICCIT 2008

KUET

2008 11th International Conference on Computer and
Information Technology (ICCIT 2008) & Workshops

IEEE Bangladesh Section

MESSAGE

I am delighted to know that the Faculty of Electrical and Electronic Engineering, Khulna University of Engineering and Technology (KUET) is organizing 11th International Conference on Computer and Information Technology (ICCIT 2008) and Workshops. It is also pleasurable to note that ICCIT is going to be held outside Dhaka for the first time. I congratulate KUET authority and organizers for this historic event. ICCIT has prodigious reputation for being the platform of researchers and scholars from home and abroad. I hope this congregation of ICCIT will offer tangible mantle towards a fertile exchange of knowledge on the broad spectrum of ICT and will help participants in their endeavor to develop a knowledge-based society.

IEEE, the largest professional association in the world, always fosters technological innovation and excellence for the benefit of humanity. Besides supporting its members, IEEE is supporting education, training, research and socio-culture activities all over the world. KUET has a strong and active member group of IEEE and it has established student branch long back. In fact, out of 7 IEEE student branches in Bangladesh, only KUET branch is outside of Dhaka. With the technical co-sponsorship of IEEE Bangladesh Section, ICCIT 2008 is going to be the largest congress of scholars of ICT and related fields. IEEE is committed to local technical bodies to provide support to replete the global technical needs.

On behalf of IEEE Bangladesh Section, I like to welcome all the authors and participants. I would like to thank the organizers, participants, sponsors and others whose sincere efforts will constitute a fruitful communication between national and international experts in computer and IT.

I wish a grand success of ICCIT 2008.

(M. Aynal Haque)

MESSAGE

In spite of the economic signs of doom and gloom, we are faced with dramatic changes as far as computing and information science are concerned. These two fields are intertwined and are going to be impacted by the technology that is still evolving, by the science that needs to be re-interpreted, simulations that need to be designed, visualization that needs further exploration and systems that are still being re-engineered. It is in this backdrop, the 11th International Conference on Computer and Information Technology is taking place, this time being hosted by Khulna University of Engineering & Technology.

This conference is international in its scope and reach; yet of serious technical significance to Bangladesh and Bangladeshi institutions of higher learning. It continues to serve as an engine that is propelling forward a large number of energized students, researchers, and faculty members of Bangladeshi universities. It is heartening to see that each year, more professionals and institutions are joining this bandwagon. Consequently, this conference is getting continually re-energized, refocused and retooled. This year's conference received 538 submissions of which 158 were finally accepted. This amounts to an acceptance rate of 29.4%. Of the accepted papers, 42.4% came from authors from outside of Bangladesh. A team of 83 reviewers – all from outside of Bangladesh evaluated these manuscripts; 89.03% of the assignments made to the reviewers were completed. The true measure of the success of this international conference, however, will be judged by the newer ideas and techniques so disseminated through it, from the impact it will have by nurturing a technological climate in Bangladesh. Starting this year, ICCIT papers will get included in the IEEE Xplore Digital Library and of those which will be enhanced further, upon additional review and revision, may be eligible to be included in one of the five Academy Publisher journal special issues in 2009.

On behalf of the international program committee, I would like to thank each one of the participants, authors, reviewers, speakers, members of the international program and organizing committees, advisors, sponsors, session chairs, volunteers, and supporting organizations and universities for their respective contributions in making this collective effort a genuine success. Last but not the least, ICCIT 2008 owes a particular "thank you" to KUET and its leadership for hosting this international event.

(Mohammad A. Karim)

Chair, International Program Committee

2008 11th International Conference on Computer and
Information Technology (ICCIT 2008) & Workshops

Head of the Department

Dept. of Computer Science and Engineering
Khulna University of Engineering & Technology,
Khulna 9203, Bangladesh

MESSAGE

With delicate pleasance, exquisite privilege and honor, on behalf of the Organizing Committee, I am welcoming you to the 11th International Conference on Computer and Information Technology (ICCIT 2008) and Workshops. The conference is organized by the Faculty of Electrical & Electronic Engineering, Khulna University of Engineering & Technology (KUET), Khulna, Bangladesh and will be held on December 24-27, 2008.

The continuum of ICCIT since 1998 has proved the conference to be the largest and most prestigious international ICT conference in Bangladesh. ICCIT 2008 will surely indulge the intellectual community of home and abroad by presenting the newest ideas, technological advancements, thoughtful researches, and generative implementations.

We leaned on 83 prominent reviewers from 13 different countries to select the papers. The selected papers are categorized into 26 different areas. As we have pervaded the call for paper around the globe efficiently, researchers from 24 different countries have submitted their papers initially and papers from 17 different countries will be presented in the conference which adds an extra relish of diversity to the conference. The papers presented in the conference will be published in IEEEExplore of which some of them, if selected, will get the opportunity to be placed in special issue of five distinguished and well recognized journals published by Academy Publisher. Moreover, for the first time in the history of ICCIT, two workshops- Internet and Distributed Computing Systems (IDCS 2008) and Data Mining and Artificial Intelligence (DMAI 2008) organized by University of Melbourne and University of Central Queensland, respectively will be hosted by KUET in conjunction with ICCIT 2008. 14 papers will be presented in IDCS 2008 and 16 papers will be presented in DMAI 2008.

I would like to express my gratefulness to the IPC Chairman Professor Dr. Mohammad A. Karim and his team for successfully reviewing large number of papers in a short span of time. My heartfelt gratitude goes to the sponsors as without their assistance to this noble endeavor, it would be difficult for KUET to deplete the conference and the workshops successfully. Lastly, I wish my solemnest thanks to the Organizing Committee Members for their affable exertions to support and mentor the ICCIT 2008.

(Prof. Dr. M.M.A. Hashem)

Cutting a Cornered Convex Polygon Out of a Circle

Syed Ishtiaque Ahmed, Md. Ariful Islam, Masud Hasan

Department of Computer Science and Engineering
Bangladesh University of Engineering and Technology, Dhaka, 1000, Bangladesh
Email: ishtiaque@csebuat.org, arif.liton@gmail.com, masudhasan@cse.buet.ac.bd

Abstract—The problem of cutting a convex polygon P out of a piece of paper Q with minimum total cutting length is a well studied problem in computational geometry. Researchers studied several variations of the problem, such as P and Q are convex or non-convex polygons and the cuts are line cuts or rays cuts. In this paper we consider yet another variation of the problem where Q is a circle and P is convex polygon such that P is bounded by a half circle of Q and all the cuts are line cuts. We give a simple linear time $O(\log n)$ -approximation algorithm for this problem where n is the number of vertices of P .

Index Terms—Algorithm, circle, computational geometry, line cut, polygon cutting.

I. INTRODUCTION

A *cornered convex polygon* P inside a circle Q is a convex polygon which is positioned completely on one side of a diameter of Q . See Figure 1(a).

A *line cut* is a line that does not run through the polygon P and divides Q into two pieces. After a cut is made, Q is updated to the piece containing P . The *cost* of a cut is the length of the intersection of the cut with Q . A *cutting sequence* is a sequence of cuts such that after the last cut in the sequence we have $P = Q$. In this paper we consider the problem of cutting P out of Q by line cuts with total cutting cost as small as possible. See Figure 1(b).

Fig. 1. (a) A cornered convex polygon. (b) Two different cutting sequences to cut P out of Q . The cutting lengths are shown in bold. The cost of the sequence in left figure is more than that in the right figure.

A. Known results

If Q is another convex polygon with m edges, this problem has been approached in various ways by many researchers in computational geometry community [1], [2], [4], [5], [6], [7], [8], [9]. Overmars and Welzl first introduced this problem of cutting a convex polygon out of

another convex polygon optimally with line cuts [8]. If the cuts are allowed only along the edges of P , they proposed an $O(m+n^3)$ -time algorithm for this problem with optimal cutting length, where n is the number of edges of P .

The problem seems to be more difficult if the cuts are more general, i.e., they are not restricted to touch only the edges of P . In that case Bhaduri and Chandrasekaran showed that the problem has optimal solutions that lie in the algebraic extension of the input data field [1] and due to this algebraic nature of this problem, an approximation scheme is the best that one can achieve [1]. They also gave an approximation scheme [1] with pseudo-polynomial running time.

After the indication of Bhaduri and Chandrasekaran [1] on the hardness of the problem several researchers have given polynomial time approximation algorithms for this problem. Dumitrescu proposed an $O(\log n)$ -approximation algorithm with $O(mn + n \log n)$ running time [4], [5]. Then Daescu and Luo [7] gave the first constant factor approximation algorithm for this problem. Their algorithm has a running time of $O(n^3 + (n + m) \log(n + m))$. The best known constant factor approximation algorithm is due to Tan with an approximation ratio of 7.9 and running time of $O(n^3 + m)$ [9]. In the same paper [9], he also proposed an $O(\log n)$ -approximation algorithm with improved running time of $O(n + m)$. As the best known result so far, very recently, Bereg, Daescu and Jiang gave a simple $O(m + \frac{n^6}{\epsilon^{12}})$ -time $(1 + \epsilon)$ -approximation algorithm for this problem [2].

This problem has also been studied when Q is a non-convex polygon [8], P is a non-convex polygon [3], [7], [9], and/or the cuts are ray cuts [3], [7], [9].

B. Our Result

All the previous results consider Q as a polygon (either convex or non-convex). However, to our knowledge, no algorithm is known when Q is a circle. In this paper, we consider the problem where Q is a circle and P is a convex polygon such that P can be separated from the center of Q by a chord. Our algorithm has an approximation ratio of $O(\log n)$ and runs in $O(n)$ time.

When both P and Q are convex polygons, almost all the existing algorithms on line cuts use two major steps: cutting a minimal rectangle or triangle from Q that bounds

P and then cutting P out of that bounding box. Our algorithm also follows similar approach. However, we observe that the existing algorithms cannot be applied directly to solve our problem. Moreover, the running times of those algorithms are too high compared to our algorithm. For example, Tan's constant factor approximation algorithm takes $O(n^3 + m)$ time and the PTAS of Bereg et. al. takes $O(m + \frac{n^6}{\epsilon^{12}})$ time. We also observe that in those algorithms, increasing the value of m for approximating Q to a circle makes them inefficient.

C. Outline

The rest of the paper is organized as follows. We give some definitions and preliminaries in Section II. Then we present our algorithm in Section III. Finally, Section IV concludes the paper with some future works.

II. PRELIMINARIES

A line cut is a *vertex cut* through a vertex v of P if it is tangent to P at v . Similarly, a line cut is an *edge cut* through an edge e of P if it contains e .

At any time the edges of P through which an edge cut has passed are called to be *cut edges* of P and other edges of P are called to be *uncut edges* of P . To cut P out of Q all n edges of P must be cut and for that we require exactly n edge cuts. However, applying only edge cuts may not give an optimal solution and that is why we need vertex cuts as well.

In the rest of this section we give some elementary geometry that plays important role in our paper. Let c be the center of Q . An edge e of P is *visible* from c if for every point p of e the line segment cp does not intersect P in any other point. So, if e is collinear with c , then we consider e as invisible. Similarly, a vertex v of P is *visible* from c if the line segment cv does not intersect P in any other point.

In this paper we do not consider the diameter of Q as a *chord*, i.e., a chord is always smaller than a diameter. Let ll' be a chord of Q . ll' divides Q into two circular segments, one is bigger than a half circle and is called the *bigger segment* created by ll' , and the other one is called the *smaller segment* created by ll' . Let tt' be another chord intersecting ll' at x such that tx is in the smaller segment of ll' . See Figure 2(a). Then the following lemma holds.

Lemma 1: Length of xt is no bigger than length of ll' .

Following lemma is also obvious, whose illustration can be found in Figure 2(b).

Lemma 2: Let $\triangle abc$ be an obtuse triangle with $\angle bac$ being the obtuse angle. Consider any line segment connecting two points b' and c' on ab and ac , respectively, possibly one of b' and c' coinciding with b or c respectively. Then the angle $\angle bb'c'$ and $\angle cc'b'$ are obtuse.

Fig. 2. Some preliminaries.

III. ALGORITHM

Our algorithm has four phases : (1) D-separation, (2) triangle separation, (3) obtuse phase and (4) curving phase. In *D-separation phase*, we cut out a small portion of Q (less than the half of Q in size) which contains P (and looks like a “D”). Then in *triangle separation phase* we reduce the size of Q even more by two additional cuts and bound P by almost a triangle. In *obtuse phase* we assure that all the portions of Q that are not inside P are inside obtuse triangles. Finally, in *curving phase* we cut P out of Q by cutting in rounds.

Let C^* be the optimal cutting length of P from Q . Clearly $C^* \geq |P|$, where $|P|$ is the length of the perimeter of P .

A. D-Separation

A *D* of the circle Q is a circular segment of Q which is smaller than an half circle of Q . By a *D-separation* of P from Q we mean a line cut along a chord of Q that creates a *D* containing P . In general for a circle Q and a convex polygon P there may not exist any *D-separation* of P . But in our case since P is cornered, there always exists a *D-separation* of P .

We will first observe that there exists only one minimum-cost *D-separation* C_1 of P and then we will find that C_1 . (For our algorithm, however, showing the *uniqueness* of the minimum *D-separation* is not required).

Lemma 3: The minimum-cost *D-separation* C_1 for P can be found in $O(n)$ time.

Proof: Clearly C_1 must touch P . So, C_1 must be a vertex cut or an edge cut of P . Observe that any vertex cut or edge cut that is a *D-separation* must be through a visible vertex or a visible edge. Let e be a visible edge of P . Let ll' be a line cut through e . Let cp be the line segment perpendicular to ll' at p . If p is a point on e , then we call e a *critical edge* of P and ll' a *critical edge cut* of P . Observe that since P is convex, it can have at most one critical edge. Similarly, let v be a vertex of P . Let tt' be a vertex cut through v . Let cp be the line segment perpendicular to tt' at p . If tt' is such that $p = v$, then we

Fig. 3. Separating P from c by using more than one cut

call v a *critical vertex* of P and tt' a *critical vertex cut* of P . Again observe that P can have at most one critical vertex. Moreover, P has a critical edge if and only if it does not have a critical vertex. See Figure 4. Now, if P has the critical edge e , then C_1 is the corresponding critical edge cut ll' . C_1 is minimum, because any other vertex cut or edge cut of P is either closer to c (and thus bigger) or does not separate c from P . On the other hand, if P has the critical vertex v , then C_1 is the corresponding critical vertex cut tt' of P . Again, C_1 is minimum by the same reason.

Fig. 4. Critical edge and critical vertex.

For the running time note that all visible vertices and visible edges of P can be found in linear time. Then finding whether an edge of P is critical takes constant time. Over all edges finding the critical edge, if it exists, takes $O(n)$ time. Similarly, for each visible vertex v we can check in constant time whether v is critical or not by comparing the angles of cv with two adjacent edges of v , which takes constant time. Over all visible vertices, it takes linear time. ■

Lemma 4: Cost of C_1 is at most C^* .

Proof: Consider any optimal cutting sequence $\mathcal{C}$. $\mathcal{C}$ must separate P from c . However, it may do that by using a single cut or by using more than one cut. If it uses a single cut, then it is in fact doing a D-separation. By Lemma 3, it can not do better than C_1 , and therefore, cost of C_1 is at most C^* .

Now we assume that $\mathcal{C}$ separates P from c by more than one cut. There are several cases here. We will prove that

in any case the cutting cost of separating P from c is even higher than that for a single cut. Let C be the first cut in $\mathcal{C}$ that separates c from P . C can not be the very first cut of $\mathcal{C}$, otherwise, we are in the previous case considered above. It implies that C smaller than a chord of Q . See Figure 3. Let a and a' be the two end points of C . Let bb' be the chord of Q that contains aa' where b is closer to a than to a' . Now, at least one of a and a' is not incident on the boundary of Q . We first assume that a is not incident to the boundary of Q but a' is. Let $C_x = xx'$ be the cut that was applied before C and intersects C at a . Since C_x does not separate c from P , the bigger segment of C_x contains P , c and a . Now if x' is an end point of C_x , then by Lemma 1 ab is smaller than xx' . It implies that having C_x in addition to C_1 increases the cost of separating P from c (see Figure 3(a)). Similarly, if x' is not an end point of C_x , and thus another cut is involved, then by Lemma 1 the cost will be even more (see Figure 3(b)).

Now consider the case when both a and a' are not incident on Q . So at least two cuts are required to separate ab and $a'b'$ from bb' . Let those two cuts be C_x and C_y respectively. Let xx' and yy' be the two chords of Q along which C_x and C_y are applied. Now if C_x and C_y do not intersect, then by applying the above argument for each of them we can say that the cutting cost is no better than that for a single cut. But handling the case when C_x and C_y intersect is not obvious. (See Figure 3(c,d)). Let z' be their intersection point. Again there may be several subcases: x and y may or may not be end points of C_x and C_y . Assume that both x and y are end points of C_x and C_y . Remember that none of C_x and C_y separates P from c . So region bounded by $xz'y$ must contain P and c inside of it and in that case the total length of xz' and yz' is at least the diameter of Q , which is bigger than bb' (see Figure 3(c)). For the other cases, where at least one of x and y is not an end point of C_x and C_y , it can be recursively proven that the cost is even more (For example, see Figure 3(d)). ■

B. Triangle Separation

In this section we apply two more cuts C_2 and C_3 and “bound” P inside a “triangle”. From there we achieve three triangles inside which we bound the remaining uncut edges of P (in the D-separation phase, at most one edge of P becomes cut).

Let $C_1 = aa'$ be the cut applied during D-separation. We apply $C_2 = at$ such that at is tangent to P . Then we apply the third cut $C_3 = a't'$ such that $a't'$ is also tangent to P . If $a't'$ intersects at inside or on the boundary of Q , then let z be the intersection point. (See Figure 5(a)). If $a't'$ and at do not intersect, then let z be the intersection point of the lines containing at and $a't'$. (See Figure 5(b)).

We get three resulting triangles $T_a, T_{a'}, T_z$ having a, a' and z , respectively, as a vertex as follows. We describe only T_a , description of $T_{a'}, T_z$ are analogous. If C_1 is an edge cut, then let rr' be the corresponding edge such that a is closer to r than to r' . (See Figure 5(a)). If C_1 is a vertex cut, then let r be the corresponding vertex of P . Let s be the similar vertex due to C_2 . (See Figure 5(b)). Then $T_a = \triangle ars$. The polygonal chain of P bounded by this triangle is the edges from r to s that reside inside T_a .

Fig. 5. Triangle separation.

Lemma 5: Total cost of C_2 and C_3 to achieve $T_a, T_{a'}$ and T_z is at most $2C^*$. Moreover, C_2 and C_3 can be found in linear time.

Proof: Whether z is within Q or outside Q , the length of at and $a't'$ can not be more than twice the length of aa' , which, by Lemma 3, is no more than C^* . So the total cost of C_2 and C_3 is at most $2C^*$.

To find at linearly, we can simply scan the boundary of P starting from the vertex or edge where aa' touches P and check in constant time whether a tangent of P is possible through that vertex or edge. Similarly we can find $a't'$ within the same time. ■

C. Obtuse Phase

Consider the triangle T_a obtained in the previous section. We call the vertex a of T_a the *peak* of T_a and the edge rs the *base* of T_a . Let the polygonal chain of P that is bounded by T_a be H_{rs} . Observe that the angle of T_a

at a is acute. Similarly, the angle of $T_{a'}$ at its peak a' is also acute. However, the angle of T_z at its peak z may be acute or obtuse.

We obtain, by applying a cut, for each of $T_a, T_{a'}$ and T_z (if T_z is acute) one or two triangles such that the angle at their peaks are obtuse and they combinely bound the polygonal chain of the corresponding triangle. We describe the construction of the triangle(s) from T_a only, description for the triangles obtained from $T_{a'}$ and T_z are analogous.

Let P_a be the polygonal chain bounded by T_a . Length of ar and as may not be equal. W.l.o.g. assume that as is not larger than ar . Let s' be the point on ar such that length of as' equals to the length of as . Connect ss' if s' is different from r . We will find a line segment inside T_a such that it is tangent to P_a and is parallel to ss' . We have two cases: (i) ss' itself is a tangent to P_a , and (ii) ss' itself is a tangent to P_a . Case (i): If ss' itself is tangent to P_a (at s), we apply our cut along ss' . This may be a vertex cut through s . In that case we get the resulting obtuse triangle $\triangle rss'$ and the polygonal chain bounded by this triangle is same as P_a . (See Figure 6(a)). On the other hand, this may be an edge cut through the edge of P_a that is incident to s . Let u be the vertex other than s of the edge of the edge cut. Then our resulting obtuse triangle is $\triangle rus'$ and the polygonal chain bounded by this triangle is the edges from r to u . (See Figure 6(b)). Case(ii): For this case, let u, u' be two points on as and ar , respectively, such that uu' is tangent of P_a and is parallel to ss' . We apply the cut along uu' . Again this cut may be a vertex cut or an edge cut. If it is a vertex cut, let g be the vertex of the cut. Then we get two obtuse triangles $\triangle ru'g$ and $\triangle sug$ and the polygonal chains bounded by them are the sets of edges from r to g and from g to s respectively. (See Figure 6(c)). If it is an edge cut, then let gg' be the edge of the edge cut with u being closer to g than to g' . Then we get two obtuse $\triangle ru'g'$ and $\triangle sug$ and the polygonal chains bounded by them are the sets of edges from r to g' and from g to s respectively. (See Figure 6(d)).

Lemma 6: Total cost of obtaining obtuse triangles from $T_a, T_{a'}$, and T_z is at most C^* . Moreover, they can be found in $O(\log n)$ time.

Proof: Consider the construction of the obtuse triangle(s) from T_a . Length of the cut ss' or uu' is at most the length of their base ss' , which is bounded by the length of P_a . Over all three triangles $T_a, T_{a'}$ and T_z , the total cutting length is bounded by the length of the perimeter of P . Since C^* is at least the length of the perimeter of P , the first part of the lemma holds.

For running time, in T_a , we can find the tangent of P_a in $O(\log |P_a|)$ time by using a binary search. Over all three triangles $T_a, T_{a'}$ and T_z , we need a total of $O(\log n)$ time. ■

Fig. 6. Obtaining obtuse triangle(s) from T_a .

D. Curving Phase

After the obtuse phase the edges of P that are not yet cut are partitioned and bounded into polygonal chains with at most six obtuse triangles. In this section we apply the cuts in rounds until all edges of P are cut. Our cutting procedure is same for all obtuse triangles and we describe for only one.

Let $T_u = \triangle gus$ with peak u and base gs be an obtuse triangle. See Figure 7. Let the polygonal chain bounded by T_u be P_u . Let the edges of P_u be $e_1, \dots, e_k$ with $k \geq 2$. We will apply cuts in rounds and all cuts are edge cuts. In the first round we apply an edge cut C' along the edge $e_{k/2}$. Then we connect g and s with the two end points of $e_{k/2}$ to get two disjoint triangles. Since T_u is obtuse, by Lemma 2 these two new triangles are also obtuse. So, as a result we cut out one polygonal edge and get two new obtuse triangles. In the next round we work on each of these two triangles recursively, then in the next next round we work on four triangles and so on. We continue in this way until all edges of P_u are cut.

Fig. 7. Curving phase

Lemma 7: There are at most $O(\log k)$ rounds of cuts to cut all edges of P_u . Moreover, the total cost of these cuts is $|P_u| \log k$, where $|P_u|$ is the length of P_u , and the total running time is $O(|P_u|)$.

Proof: At each round the number of triangles get doubled and the number of edges that become cut also get doubled. So after $\log k$ rounds all k edges are cut.

At each round the total length of the bases plus the length of the edges that are being cut is no more than $|P_u|$. So, the total cutting cost is $|P_u| \log k$ over all rounds.

For running time, for applying an edge cut we always move to the middle edge of a polygonal chain. So, finding an edge cut takes constant time. Moreover, after each cut the corresponding edge is never considered again. So, over all rounds we can have at most $|P_u|$ cuts, which gives a running time of $O(|P_u|)$. ■

Corollary 1: The total cost of curving phase is $C^* \log n$ and the running time is $O(n)$.

Combining the results of all four phases, we get the following theorem.

Theorem 1: Given a circle Q and a cornered convex polygon P of n edges within Q , P can be cut out of Q by using line cuts in $O(n)$ time with a cutting cost of $O(\log n)$ times the optimal cutting cost.

IV. CONCLUSION

In this paper we have given a linear time $O(\log n)$ -approximation algorithm to cut out a convex polygon P out of a circle Q where P resides in one side of a diameter of Q . The general case of this problem, where P is not necessarily in one side of a diameter of Q , is still to be solved. We also think it would be interesting to see constant factor approximation algorithms or approximation schemes for these problems. One approach to achieve any improvement is to use rotating calipers around the boundary of P to cut out a bounding rectangle from Q instead of separating a D and then apply curving phase to that rectangle.

Finally, we observe that our algorithm also works if P touches the center of Q , with small modification.

ABSTRACT — In this paper, we propose an algorithm that produces the Complete Test Set (CTS) of a reversible circuit for Single Stuck-at Fault (SSF) and Multiple-Stuck-at Fault (MSF) models. Our algorithm works only for an important subclass of reversible circuits – the circuits consisting of k -CNOT gates ($k \geq 2$) though, any n -wire circuit having 0-CNOT or 1-CNOT gates can be converted to a $(n + 2)$ wire circuit having only k -CNOT gates with $k \geq 2$ with some additional hardware cost. Generated complete test set is not necessarily optimal, but minimizing the size of the complete test set is our key concern. Finally we provide some experimental results for the proposed method and compare it with existing methods to show how it outperforms almost all of the existing algorithms in terms of number of elements of CTS but is outperformed by some of the existing ones in terms of hardware cost.

I. INTRODUCTION

The more logic elements are packed in conventional computer, the more heat is dissipated. When a computational system erases a bit of information, it must dissipate $\ln 2 \times kT$ energy, where k is Boltzmann's constant and T is the temperature. In room temperature, this is about 2.9×10^{-21} joules [1, 2]. Reversible circuits dissipate very low power [3].

A test set is a set of test vectors that are applied to the circuit in question to detect faults, if any. Generating efficient test sets is hard for conventional irreversible circuits though, it is significantly simpler for the case of reversible circuits.

Research reported so far in the field of reversible circuit testing regarding the topic in question is not bountiful. Patel et al. [4] formulated the problem of constructing minimal test set as an Integer Linear Program (ILP) with binary variables. They [4] also used an algorithm that simplifies the aforementioned method for a large circuit by breaking it into smaller sub-circuits [4]. Chakraborty [5] showed that all stuck-at faults in an n -wire k -CNOT circuit $C(n)$ with $k \geq 2$ can be detected using at most n test vectors (TV), namely, n weight-1 vectors. $C(n)$ has a complete test set (CTS) of size n for multiple stuck-at faults (MSF). He [5] proved this using *fixing* property. He has also shown that if an n -wire k -CNOT circuit ($k \geq 0$) is

modified by introducing an extra wire that feeds a new control input added to every k -CNOT gate, the resulting circuit has CTS of size 3 for MSFs. Allen et al. [6] proposed an algorithm that detect and localize all Missing Gate Fault (MGF), Lock Gate Fault (LGF) and Single Stuck-at Fault (SSF). Ito et al. [7] showed that it is NP-hard to generate a minimum complete test set for stuck-at faults on a set of wires of a reversible circuit.

We propose a method which exploits *fixing property* of digital circuit, like [5], to produce CTS for a given circuit. We apply a test vector at input of the circuit and observe if the output is same as the input. If it does, then we proceed to the next test vector. If it does not, then some wire(s) of the circuit must be faulty. Our target here is to reduce the size of the complete test set as less as possible without modifying the original k -CNOT circuit with $k \geq 2$. We do not consider fault diagnosis in this paper.

II. ASSUMPTION

We follow the following assumptions throughout the whole paper if otherwise not stated:

- An n -wire reversible circuit consisting of m number of k -CNOT gates is given ($k \geq 2$ and $m \geq 0$). If we have 0-CNOT and/or 1-CNOT gates in the original circuit, then a design-for-test (DFT) of the circuit can be constructed easily by adding at most 2 extra wires (so that 1-CNOT and 0-CNOT gates becomes 2-CNOT gates having necessary extra control input(s) from the extra wire(s)), so number of wires becomes $n + 2$ and all the methods are applicable on the DFT. Thus, without losing any generality, we assume that we have only k -CNOT gates with $k \geq 2$. When we used any k -CNOT gates with $k = 0$ or 1, we specify explicitly.
- Let any test vector (TV) be $t_1 t_2 \dots t_n$ where t_i is i^{th} bit.
- In spite of altering any bit in any level of the circuit except the last, if the final output of the circuit is equal to the input, then the input vector is *fixed* by definition. But this concept leads to some extra complexity. So throughout the whole paper, when we say a vector is *fixed* by a circuit, we mean that no bit of the input vector is altered by any gate across the whole circuit.
- The whole paper is *fixing property* oriented unless otherwise stated. For example, if we say a test vector is

invalid for a circuit, it tacitly implies that this test vector is not *fixed* by that circuit and vice versa.

III. PROPOSED METHOD

A. Description of a Gate and Description Table of a k -CNOT Circuit

Let a gate g has wire indices $g_1, g_2, \dots, g_p$ as control inputs. Then we call the sequence $g_1, g_2, \dots, g_p$ the description of the gate g . If g is 0-CNOT gate, then it has no description as we are concerned here with only the control inputs. If we construct a table where the rows are descriptions of the gates of a circuit, then we call this data structure “**Description Table**” of the circuit.

Example 3.1. Fig. 3.1(b) shows the description table of the circuit shown in Fig. 3.1(a).

B. Algorithm

We will use Description table, Status table and $TV_{(temp)}$ (Temporary Test Vector). Description table is already defined. The Status table is an $n \times 2$ array. Each row holds the current test status for both SA-0 and SA-1 faults of i^{th} wire. (For example, 0 if not tested, 1 if tested) $TV_{(temp)}$ is an n element array. This is the temporary TV of which our algorithm converts some of its ‘1’ bits to 0.

Procedure 1: Process_description_table

Input: Description table of a circuit.

Output: Description table of the circuit with some sorting applied (the type of sorting is discussed later).

Step 1: Sort each row of the description table in increasing order of their elements.

Step 2: Treat a row of a description table as a single element and then sort all rows in decreasing order of their first element.

return Description table.

Procedure 2: Adjust_status_table

Input: Status table and a TV

Output: Adjusted status table.

Step 1: Adjust the status table as follows:

for all i in $\{1, 2, \dots, n\}$, **do**
 if i^{th} bit of TV is 0, then set 1st element of i^{th} row of the status table to 1.
 else set 1st element of i^{th} row of the status table to 0.

return Status table.

Procedure 3: Get_New_TV

Input: Status table.

Output: A TV that acts as the $TV_{(temp)}$ for the next iteration.

Step 1: Calculate the TV as follows:

for all i in $\{1, 2, \dots, n\}$, **do**
 if i^{th} row of status table has 0 in the second element, set t_i to 1.

else set t_i to 0.

return TV.

Algorithm 1: Efficient_Complete_Test_Set_Generator (ECTSG)

Input: The configuration of a k -CNOT ($k \geq 2$) circuit is in description table as input. Input pattern is as follows: each gate occupies 1 row in the description table. The elements of each row are the wire indices of a particular gate where this gate has control inputs. Inversion input wire index is not entered in the row. Each row is terminated with a -1 value which works as sentinel.

Output: A set CTS of TVs that constitute the CTS for the given circuit. CTS is initially empty.

Step 1: (a) Initialize $TV_{(temp)}$ with all 1 i.e. 1^n .

(b) Initialize status table by filling all n entries of its both columns with 0. First and second columns represent SA-1 and SA-0 fault respectively.

Step 2: call Process_description_table.

Step3: **for** each gate g in description table **do**

if g does not fix $TV_{(temp)}$, **then do**
 let w be the first wire index of this gate in description table i.e. first element of the row meant for this gate. Set t_w in $TV_{(temp)}$ to 0.

Step 4: Now after possible modification, $TV_{(temp)}$ is a valid TV of CTS. So include it in the set CTS.

Step 5: call Adjust_status_table with $TV_{(temp)}$ as its argument.

Step 6: Check if status table is full or not i.e. if there is any element in any row is 0 still, indicating that this wire needs further testing. If no such element found, then the algorithm halts at this point.

Step 7: If the algorithm does not halt in step 6, then it indicates that there exist some i such that i^{th} wire is not tested for SA-0 and/or SA-1 fault. So we need at least one more TV.

(a) Call Get_New_TV $_{(temp)}$. The returned TV by Get_New_TV $_{(temp)}$ is the TV $_{(temp)}$ for the next iteration.

(b) Go to step 3.

return CTS.

The following example demonstrates how ECTSG works.

Example 3.2: Consider a circuit whose description table contains the rows (4, 5), (3, 4), (2, 3), (1, 4), (1, 3) and (1,2)

Gate	Indices of Control Input	
1	3	4
2	1	4

Fig. 3.1 (a) Original circuit (b) Corresponding description table

respectively, after sorting i.e. after calling the *process_description_table* procedure.

We have shown some initial tables maintained by ECTSG in Fig. 3.2 and 3.3. The reader can verify that ECTSG generates 3 TVs as CTS for this circuit: $TV_1 = 0\ 0\ 1\ 0\ 1$, $TV_2 = 0\ 1\ 0\ 1\ 0$, $TV_3 = 1\ 0\ 0\ 0\ 0$; hence $|CTS| = 3$. $\square$

(b)

Fig. 3.3 (a) Test Vector (TV_1) after **Pass 1** (b) Adjusted status table for TV_1 's effect

If no sorting is performed on the *description_table* i.e. if *Process_description_table* is not called in step 2 of ECTSG, the correctness of the proposed method will not be hampered but possibly different CTS will be yielded. What is the rationale for sorting then? To be convinced, consider the following arguments.

In the first place, we sort each row of *description_table* in increasing order of its elements. Now we will investigate the effect if the rows of *description_table* are sorted by *description_table[i][1]*. Consider the *description_table* of Fig. 3.4(b) and Fig. 3.4(c) where the rows of *description_table* are sorted by increasing and decreasing order of the *description_table[i][1]* respectively ($1 \leq i \leq m$). Fig. 3.4(a) shows the original *description_table*.

Now we assume that ECTSG does not call *Process_description_table* in Step 2 rather works directly on the input *description_table*. Table I shows that the sorting style adopted in Fig. 3.4 (c) yields most efficient result i.e. $|CTS| = 3$ that is less than the other two.

The reason is: in both cases we choose the first control input k of a gate (i.e. first element of a row in *description_table* i.e. *description_table[i][1]*) to set t_k in $TV_{(temp)}$ to 0 if it is not already 0. In the first case of our example given above, the abovementioned first control input k may appear only in the rows where *description_table[i][1]* is the first element – possibly few because it is not natural to have all the gates connected with 1st wire.

But in the second case, the first control input k may appear throughout all subsequent rows in the *description_table* because the elements of each row are sorted in increasing order, therefore possibly reducing the total number of changes in $TV_{(temp)}$. You can recall here that ECTSG algorithm's basic target is to retain $TV_{(temp)}$ as much as possible in a pass to generate the corresponding actual TV.

We can conclude from the above discussion that ECTSG with sorting according to the discussed style *may* outperform ECTSG without sorting. We say 'may' because we are not providing any rigorous proof of our conjecture. So we are not ruling out the possibility of getting worse result after sorting according to the abovementioned style for a particular circuit. What we have shown using the above examples is based on empirical observations.

C. Evaluation of Proposed Method

i) Optimality of ECTSG

ECTSG algorithm does not necessarily return optimal result but it does in many of the cases. We mentioned earlier that it is NP-hard to generate a minimum complete test set for stuck-at faults on a set of wires of a reversible circuit [7].

ii) Time Complexity Analysis

Theorem 1: Let an n -wire circuit consisting of m number of k -CNOT ($k \geq 2$) gates is given and ${}^nC_2 + {}^nC_3 + \dots + {}^nC_{n-1} = q$; ${}^qP_1 + {}^qP_2 + \dots + {}^qP_q = p$. (C and P stands for combination and permutation respectively). Then:

(a) There are total p number of different circuits C_i where each k -CNOT gate appears at most once, and then $\max(m_1, m_2, \dots, m_p) = q = O(2^n)$; m_i is the number of gates in circuit C_i ($1 \leq i \leq p$). (It is important to note that here we treat two gates as distinct only if their control inputs differ; we do not treat two gates as distinct if they have same control inputs but different inversion input. This assumption is inline with our assumptions throughout the whole book because we said earlier that the total book is *fixing* property oriented – so we are not concerned with the inversion input of a k -CNOT gate.)

(b) If we allow more than one occurrence of a gate that have same control input wires in a circuit, then $\max(m_1, m_2, \dots, m_p) = \infty$. ■

Proof: (a) As k -CNOT gate has maximum k control inputs and the number of wires is n , so $k \leq (n-1)$. We can have nC_2 number of 2-CNOT gates, nC_3 number of 3-CNOT gates, ..., ${}^nC_{n-1}$ number of $(n-1)$ -CNOT gates in a n -wire k -CNOT circuit with $k \geq 2$. So the total number of possible gates are ${}^nC_2 + {}^nC_3 + \dots + {}^nC_{n-1} = 2^n - n - 2 = q$. Now if we build a circuit where all of the above mentioned gates are used exactly once, then $m = q$. If some of these gates are not used but the used gates have exactly one occurrence as before, then $m < q$. Now we can permute these q gates to get a circuit, so the total number of circuits comprised of these q gates is: ${}^qP_1 + {}^qP_2 + \dots + {}^qP_q = p$.

(b) If a circuit is allowed to have more than one instance of any gate, then m may be raised to ∞ because we can append as many gates as we wish to build an arbitrary circuit, but use of some of these gates may be redundant. □

Lemma 1: We can confine the size of the *description_table* of ECTSG algorithm to maximum $q = O(2^n)$ ($q \neq \infty$). ■

Proof: We impose a condition that same ordering of values of the rows of the *description_table* should be adopted while taking input – for example, if (1, 3) is entered as description of a gate then (3, 1) is considered as an old gate and vice versa as these two descriptions are in fact same from ECTSG's viewpoint. The reasoning is: if the circuit has gates having same wires as control inputs, then they will have identical rows in the *description_table* because we are not storing the index of *inversion* input wire. As we are using these rows to fix the $TV_{(temp)}$ in ECTSG algorithm, once we have checked a row, no need to check another identical row. Hence we can keep only one row in case of duplicity, which completes the proof □

From the above discussion it is clear that ECTSG may not need to check all the m gates of a circuit. As each run of the ECTSG scans all the entries of the *description_table*, so the outcome of lemma 1 may save a lot of computation. So ECTSG is computationally feasible.

IV. EXPERIMENTAL RESULT

The result after the implementation of ECTSG is depicted in Table II. The designs of the benchmark circuits are taken from [8]. It is important to note that these machine-readable versions posted on [8] have a

characteristic: all the elements (discarding the *inversion* input of a gate) of a row are sorted in increasing order. So result shown in Table II produced by ECTSG algorithm is based on this structure, but actually ECTSG algorithm not necessarily needs the rows sorted. But the result may be different if different structures are used. Table II also contains a column that shows the result of ECTSG without sorting described in Section 3.2. From this column we notice that our conjecture mentioned in Section 3.2 holds correct for all the benchmark circuits as no result is better than the result found with sorting but converse is true for many cases.

Authors of [5] and [6] also used the benchmark circuits posted in [8]. As we said earlier that [5] showed that the size of CTS can be reduced to only 3 for any circuit consisting of k -CNOT gates ($k \geq 0$) but **always** needs modification of the circuit by adding one extra wire and replacing **every** k -CNOT gate by $(k + 1)$ -CNOT gate i.e. **always** needs to construct a DFT. As there may be hundreds of thousands of gates in a real-world circuit, it may be suitable to opt for ECTSG algorithm in this regard, which **may** need to construct DFT by adding maximum two extra wires and to replace **only** the k -CNOT gates having $k = 0$ and 1 by $(k + 2)$ -CNOT and $(k + 1)$ -CNOT gates respectively

* means this case works on DFT i.e. needs same number of bits as DFT.

** means this case works on original circuit i.e. needs same number of bits as original circuit.

N/G and N/A stands for “Not Given in this paper” and “Not Applicable” respectively.

That means if $k \geq 0$ in the original circuit, then we have to add 2 extra wires and all 0-CNOT and 1-CNOT gates are replaced by 2-CNOT gates, and if $k \geq 1$ in the original circuit, then we have to add 1 extra wire and all 1-CNOT gates are replaced by 2-CNOT gates, and if $k \geq 2$ then no need to construct DFT. Obviously, the less the number of control inputs in k -CNOT gate, the cheaper the gate is [9], so replacing 0-CNOT and/or 1-CNOT gates should not cost comparatively much. Moreover, in our case $|CTS|$ may be 2 i.e. optimal, but minimum $|CTS|$ of [5] is 3 for the same circuit at hand. The other method of [5] generates n TVs, namely, n weight-1 vectors, for n -wire k -CNOT ($k \geq 2$) circuit regardless the number of gates. In Table II we show that the number of TVs of the proposed is better than the method of [5] in most of the cases which generates exactly n TVs as CTS for an n -wire k -CNOT circuit ($k \geq 2$); and in the rest of the cases it generates equal number of TVs as [5].

Some other researchers, specifically, Patel et al. [4] and Allen et al [6] did not use *fixing property*. Both the algorithms of [4] and [6] outperform ECTSG in terms of the need for modification of the original circuit (i.e. hardware cost) as none of their technique requires to construct DFT like ECTSG (possibly i.e. in case of existing 0-CNOT and/or 1-CNOT gates); but as we said earlier that cost of 2-CNOT gates, which ECTSG requires to be added in a circuit where 0-CNOT and/or 1-CNOT gates exist, are nominal [9]. Moreover, ECTSG algorithm is superior to [6] in most cases, shown in Table II in terms of $|CTS|$ and equal in rest of the cases. The computational cost of [4] and [6] is presumably larger than ECTSG. And lastly, in [6], minimum $|CTS|$ is 3 in table II but it is reduced in ECTSG to 2.

V. CONCLUSION

Utilizing fixing property, we presented an algorithm that generates complete test set for stuck-at model for reversible circuits composed of k -CNOT gates with $k \geq 2$. The limitation $k \geq 2$ can be lifted because any n -wire k -CNOT circuit with $k \geq 0$ can be converted to a $(n + 2)$ -wire k -CNOT circuit with $k \geq 2$. We also provided some experimental results and comparison between the existing methods.

Abstract — In this paper a new dictionary and memory based text compression technique is presented called a Two-Level Dictionary Based Text Compression Scheme. The original words in a text file are transformed into codewords having length 2 and 3 using a dictionary comprising 73680 frequently used words in English language. Among these words most frequently used words use 2 length codewords and the rest use 3 length codewords for better compression. The codewords are chosen in such way that the spaces between words in the original text file can be removed altogether recovering a substantial amount of space. Another unique feature of our compression scheme is that we have recovered unused bit of ASCII character representation from each character to save one byte per 8 ASCII characters. Lastly a back end existing compression algorithm is used to finally compress the file. We have achieved about 75% (compression ratio of 2.01 bits per input character) reduction in size using our new compression strategy with gzip and bzip2.

Index Terms — Text compression, Dictionary based compression, Huffman code, word transformation.

I. INTRODUCTION

Text compression is typically used to save storage and communication costs. Dictionary-based text compression is a compression technique, which provides the most significant improvement in the text compression performance [1,19]. It is based on the notion of replacing whole words with shorter codes from the real text file. Usually large volume of words with their codes is preserved in the dictionary. In the recent past, the M5 Data compression group, University of Central Florida has developed a family of reversible Star-transformations [2] which is applied to a source text along with a backend compression algorithm, achieves better compression. The drawback of these compression algorithms is that execution time performance and runtime memory expenditure is relatively high compared with the backend compression algorithm such as bzip2 and gzip.

When transmitting text or a binary executable, one must be able to reconstruct every bit perfectly—hence the need for lossless data compression. Compression is usually broken into two steps: modeling and coding. With a perfect, concise model that describes the generation of the input source which is to be compressed, one could reproduce the data without transmitting the source data. In practice, one must approximate and construct an

approximate mathematical model for the data. In English text, for example, one can model the probability of a letter occurring as a probability conditioned on letters that have already been transmitted. This probabilistic model is transmitted with a description of how the data differs from the model. In a coding step, information is mapped to compact codewords. Obviously, a codeword must decode to a unique value so there can be no doubt of the original message. Prefix codes are used so that no codeword is the prefix of any other codeword. It has been proved [3] that, for any non prefix code that may be uniquely decoded; a prefix code can be found with the same codeword lengths. Often the modeling and coding steps are tightly coupled. For instance, Lempel-Ziv [6] codes can be constructed as an input source is parsed into a “dictionary” model.

In this paper a new dictionary and memory based text compression technique is presented called a Two-Level Dictionary Based Text Compression Scheme. The original words in a text file are transformed into codewords having length 2 and 3 using a dictionary comprising 73680 frequently used words in English language. Among these words most frequently used words use 2 length codewords and the rest use 3 length codewords for better compression. The codewords are chosen in such way that the spaces between words in the original text file can be removed altogether recovering a substantial amount of space. Another unique feature of our compression scheme is that we have recovered unused bit of ASCII character representation from each character to save one byte per 8 ASCII characters. Lastly a back end existing compression algorithm is used to finally compress the file. We have achieved about 75% (compression ratio of 2.01 bits per input character) reduction in size using our new compression strategy with gzip and bzip2. Fig. 1 represents our system. We have conducted experiments on a large number of corpora and vast volume of dictionary (up to 73680 words) to evaluate the effectiveness of our approach.

The remainder of this paper is organized as follows. Section 2 introduces overview of the existing text compression algorithms. Subsequently, why transformation is needed is presented in Section 3. In Section 4, we propose the compression and decompression of our proposed method. Section 5 describes our Physical

Fig. 1. Text Transformation Architecture

Compression (PHC) technique. Experimental results are given in Section 6 to verify the feasibility and effectiveness of the proposed method. Our concluding remarks are contained in Section 7.

II. OVERVIEW OF THE EXISTING TEXT COMPRESSION ALGORITHMS

A procedure known as static *Huffman coding* [14] can be used to build an optimal code in which the most frequently occurring symbols are given the shortest codewords. Huffman codes are established by storing the symbols of the alphabet in a binary tree according to their probability. As the tree is traversed from root to leaf, the code grows in length. When visiting the right child, a 0 is appended to the code. When visiting the left child, a 1 is appended. Thus, symbols which occur frequently are stored near the root of the tree and have the shortest codes.

In Arithmetic coding optimal compression ratio for a data source is traditionally described with respect to Claude Shannon's [4] definition of source entropy [15]; a measure of the source's information and therefore the average number of bits required to represent it. Sometimes the most frequently occurring symbol can contain so little information that it would be ideal to represent it with less than 1 bit. Huffman codes are restricted to using an integral number of bits per symbol, increasing the coding overhead. Arithmetic codes have been designed to support a fractional number of bits per symbol to bring the average length of a codeword much closer to the optimal. Knowing the probability of occurrence for each symbol, a unique identifier can be established for a series of symbols in the interval (0,1). Unlikely symbols narrow this interval so that more bits are required to specify it, while highly

likely symbols add little information to a message and require the addition of fewer bits as the interval refinement is coarser. As the fraction converges, the most significant bits become fixed, so the fraction can be transmitted most-significant-bit-first as soon as it is known.

The coding techniques described above are used in the algorithm families introduced below. There are two fundamental methods for constructing Lempel – Ziv [16] codes. Introduced in the late 1970s, these methods are known by the initials of their creators and the year of introduction: LZ77 and LZ78. LZ77 [5] maintains a current pointer into the source data, a search buffer, and a look-ahead buffer [5]. The search buffer is made up of symbols encountered prior to the current symbol, and the look-ahead buffer contains symbols which appear after the current symbol. Together, the buffers comprise a "window" which specifies the section of the input source under consideration. As the current pointer advances, the algorithm searches backward for the longest match in the search buffer. Instead of transmitting the matched symbols, they can be encoded with a triple: <offset from pointer, length of match, next codeword>. The "next codeword" is the codeword corresponding to the symbol in the look-ahead buffer following the match. The LZ78 [6] scheme was introduced to account for cases in which a nearby match cannot be found. Instead of the sliding search-buffer, LZ78 uses a separate dictionary, which also serves as a codebook. As each group of symbols is encountered, the dictionary is checked. An<index, code>pair is output where *index* corresponds to the longest prefix (if any) that matches the current input, and code is the unmatched symbol which follows. The pair is then added to the dictionary. A popular improvement to LZ78 is called LZW [7]. It seeds the dictionary with letters from

the source alphabet which eliminates the need to send the second element of the pair, shortening the number of bits that must be sent for a single character.

Prediction with Partial Match (PPM) uses Markov modeling followed by arithmetic coding. The Burrows-Wheeler Transform (BWT) reversibly permutes a block of source data so that it can easily be compressed. The fact that a certain string of symbols has appeared can aid in predicting which symbol will come next. For instance, if the letters *compr* appear in this article, there is a strong probability they will be followed by an *e* (*compress*). The PPM [8,18] scheme maintains such context information to estimate the probability of the next input symbol to appear. An arithmetic coder can use this stream of probabilities to code the source efficiently. *PPMd* [9] is a recent implementation of the PPM algorithm. The BWT [16] algorithm will naturally split the data into independent blocks of a predetermined size before the data is compressed. The blocks are then processed through the BWT algorithm. Since each block is independent, it should be possible to run the BWT algorithm on multiple blocks of data simultaneously and achieve speedup on a parallel machine. The separate blocks are then concatenated back together again to form the final compressed file. The sequential version of BWT will process the blocks in order. A parallel implementation will need to keep track of block ordering and write the compressed blocks back to disk in the correct order. The newest technique among those examined, the Burrows-Wheeler Transform, converts a block S of length a into a pair consisting of a permutation of S (call it L) and an integer in the interval $(0..n-1)$.

III. WHY TRANSFORMATION IS BENEFICIAL

There are three considerations that lead us to our transform algorithm. First, we gathered data of word frequency and length of words information from our collected corpora. It is clear that almost more than 60% of the words in English text have the lengths greater than three and more than 80% of the words in English text have the lengths greater than two. There exists a list of the 1000 most frequently used words in the English language. Read Naturally passages are made up of a high percentage of these words. The English vocabulary has increased greatly in more than 1500 years of development. The most nearly complete dictionary of the language, the Oxford English Dictionary (second edition, 1989), contains more than 600,000 words, including obsolete forms and variant spellings.

The second consideration is that the transformed output should be compressible to the backend compression algorithm. In other words, the transformed intermediate output should maintain some of the original context information as well as provide some kind of “artificial” but strong context. The reason behind this is that we choose BWT and PPM algorithms as our backend compression tools. Both of them predict symbols based on context information. Finally, the transformed code words can be treated as the offset of words in the transform dictionary. Thus, in the transform decoding phase we can use a hash function to achieve $O(1)$ time complexity for searching a word in the dictionary. Based on this consideration, we use a continuously addressed dictionary in our algorithm. In contrast, the dictionary is split into 22 sub-blocks in LIPT [2]. Results show that the new transformation is better than LIPT not only in time complexity but also in compression performance.

IV. COMPRESSION AND DECOMPRESSION OF PROPOSED METHOD

The concept of replacing words with shorter codewords from a given static dictionary has at least two shortcomings. First, the dictionary must be quite large, at least tens of thousands of words and is appropriate for a single language only (our experiments described in this paper concern English text only). Second, no “higher level”, e.g., related to grammar, correlations can be implicitly taken into account. In spite of those drawbacks, such an approach to text compression turns out to be an attractive one, and has not been given as much attention as it deserves. The benefits of dictionary-based text compression schemes are the ease of producing the dictionary (assuming enough training text in a given language), clarity of ideas, high processing speed, cooperation with a wide range of existing compressors, and last but not the least competitive compression ratios.

In this section, we present our modifications to dictionary based text preprocessor, as well as a few new ideas. In any text file there are spaces between words. It holds near about 20% spaces (by calculation when average word length is 4). So it will save space if we write text file without using spaces by implementing a novel dictionary based word replacing text compression scheme. The codewords have been designed in such a way that spaces between codewords can be removed altogether without any difficulty to retrieve the original words of the target text file. The result of our modifications with bzip2 and gzip can be observed in Table II. Rules for word replacing transform are given below:

TABLE I
LETTERS AND SYMBOLS USED TO FORM CODEWORDS

Code Type	Used Symbol	Code word example	Num. of possible codewords
2 length (Started with alphabet or key board symbol except punctuation and \$#<>)	a-z = 26 nos.	aa	6,440 (70x70+70x22) (For frequent used words)
	A-Z = 26 nos.	aA	
	@ % ^ & * () _ - + = ! \ / { } [] = 18 nos.	A\$	
	0-9 : ; ' ' , . ! ? \$ # < > = 22 nos.	A# Z/ &; %"	
3 length (Started with numeric number)	a-z = 26 nos.	1aa	67,240 (82x82x10)
	A-Z = 26 nos.	1Aa	
	@ \$ # % ^ & * () _ - + = ! \ : ; ' ' , . ! ? / { } [] < > = 30 nos.	2z\$	
	0-9 = 10 nos.	3{p 5} 9:?	
Control code	EoL	Except EoL	
	< >	End of Line	
	<< >> <<< >>>	To denote non dictionary word	
	\$ #	All capital 1 st capital	
Total			73,680

- Each word is converted to a fixed length codeword.
- The codewords are two type having length 2 and 3.
- Those words that are not present in dictionary are not converted to codewords and are written between '<' and '>' symbol.
- Two length codewords start with alphabet or keyboard symbol except punctuation and \$ # < > symbols. 3 length codewords start with number.
- High frequency and long length words are converted to 2 length codewords.
- There is no codeword for punctuation. So punctuation is not converted to codeword and no codeword begins with punctuation.
- Words started with capital letter are converted to their lowercase equivalent and to denote this change the flag '\$' is put in front of the respective codeword. Additionally it is worth using another flag to mark a conversion of a full uppercase word to its lowercase form with flag '#'. If all the letters of a word are in lower case then no flag (\$ #) is present before their codeword.

The dictionary used in this experiment is prepared in advance, and is shared by both the transformation encoding module and the transformation decoding

process. Most frequently used words are listed at the beginning of the dictionary with corresponding code words. The total dictionary is divided in to 26 files according to starting alphabet of words for improving time complexity of search. The letters and symbols used to form code words are shown in Table I.

In any compression process time complexity is a very important. For a fast compression and decompression process we made 26 dictionaries according to alphabetic groups and named the dictionary by same alphabet, e.g., 'Dictionary-A' contained the most frequent words that are started by 'a' and all the words of a dictionary maintain a sequence according to their frequency to achieve better compression performance. With the ordering specified above, each word in Dictionary is assigned a corresponding codeword. The first 6440 words in Dictionary are assigned two length codewords ("aa", "ab", ..., "Za" etc.). The next 67240 words are assigned three length codewords ("1aA", "9aB", ... , "99Z" etc.). Hence, the most frequently occurring words are assigned code words of two lengths. Using this mapping mechanism, a total number of 73680 words can be included in the Dictionary.

Fig. 2. Comparative Compression Ratio

TABLE II
COMPRESSION RESULT

Name of scheme	Bit per input character (bpc)	Average size (byte)
Bzip	3.01	11264
Gzip	3.25	11264
Dictionary based	2.93	11264
bzip+StarNT [9]	2.76	11954
gzip+StarNT [9]	2.78	11954
bzip + Dictionary based	2.05	11264
gzip + Dictionary based	2.01	11264

V. PHYSICAL COMPRESSION IN PROPOSED METHOD

At one time, every manufacture had a different code for characters which led to all kinds of confusion. Eventually, industry settled on an input-output code known as the American Standard Code for Information Interchange (ASCII). This code allows manufacturers to standardize I/O hardware such as keyboards, printers, video displays and so on. The ASCII code is a 7-bit code whose format is $X_6X_5X_4X_3X_2X_1X_0$ where each X is a 0 or 1. For instance, the letter A is coded as 1000001. Any text file consists of a set of characters that are represented by ASCII codes and we also know in memory each character holds 8-bit (1 byte) space instead of 7-bits, hence we loose 1 bit for storing a character in any memory device. In this way for 8 characters, we can recover 8 bits (1byte) if we store each character in just 7 bits. Actually (7x8) 56 bits of memory space is required for storing any 8 ASCII characters, as a result we need 56 memory Cells for storing 8 symbols that is equal to 7 byte. Thus 8 characters are stored in 7 bytes releasing 1 byte for storing one additional character. By

using this approach we recover 12.5% space from any text file. Here we use 8 character cluster for such compression process and recover a byte from each cluster. If the last cluster of a file contains less number of characters the compression algorithm takes additional null values to fill the cluster.

VI. EXPERIMENTAL RESULTS

The experiments are demonstrated on the text file which is 11KB (11264 byte) in length containing 10509 characters with space and new line. We compared our results with bzip+StarNT and gzip+StarNT. The results of bzip and gzip are also included in Table II and Fig. 2.

VII. CONCLUSION

In this paper we have presented a static dictionary-based preprocessor, called word replacing transformation, intended for text compression. Our ideas are significant extensions of the mechanisms presented in former algorithms, like StarNT. We have proposed several unique

approaches with results having excellent improvement in text data compression. First we have applied our dictionary based text transformation preprocessor and the result showed that compressed file uses 2.93 bits per character. We also achieve 2.05 bit per character with bzip and 2.01 with gzip as back end text compressor. The result will be more impressive by using BOA or RK compression scheme and if we increase the dictionary volume. The second scheme we have used is physical compression by utilizing the unused bit from the ASCII representation of a character. This scheme compresses a fixed percentage (12.5%) of space for any text file or preprocessed text file.

Abstract — In this paper we develop algorithms for generating random channel specifications of channel routing problem in VLSI design. A channel is a rectangular routing region containing two sets of fixed terminals on two of its opposite sides and the other two opposite sides (of the rectangle) are open ends, may or may not contain any terminal of a net but the terminal position is not fixed before a routing solution is computed. Most of the problems in two-, three-, and multi-layer channel routing are beyond polynomial time computable. Hence for each of these problems it is unlikely to design a polynomial time deterministic algorithm. Developing heuristic algorithm might be a probable way out that hopefully provides good solutions for most of the instances occur in practice. Novelty of a heuristic algorithm is judged better if it works for a variety of large number of randomly generated instances of the problem. In fact, convergence of results of a heuristic algorithm is well established when the algorithm of a problem is executed for a huge number of randomly generated similar instances and the final result is computed making an average on all of them.

I. INTRODUCTION

In this paper we are interested in generating random channel specifications for channel routing problem. To do so we first generate channel specifications having two-terminal nets only, where none of the channel specifications contains any vertical constraint. Such channel specifications that do not have any vertical constraint, are known as *simple channel specifications* [4, 5, 6]. Then we modify our requirement for computing general channel instances with multi-terminal nets, so that we can generate channel specifications containing two- or

more than two-terminal nets; also containing vertical constraints.

We know that the two-layer channel routing problem of area minimization is polynomial time solvable for simple channel specifications [1, 7, 8], but the problem of crosstalk minimization in two-layer channel routing is NP-hard even if the channel specifications are free from any vertical constraint [4, 5, 6]. So, it is unlikely that there would exist a polynomial time algorithm for computing two-layer minimum crosstalk channel routing solutions even for the *simple instances* of channel specifications. Incidentally, such channel instances are hardly available in literature, and generally the instances that are known as *benchmark channel specifications* contain both horizontal as well as vertical constraints [7], though such channel specifications are also very few.

A *channel specification* is usually obtained in the form of two m -element vectors TOP and BOTTOM indicating the *top* and *bottom terminal lists*, respectively, of a channel. We often may use *channel specification* and *channel instance* interchangeably. A *channel* is a rectangular routing region containing two sets of fixed terminals on two of its opposite sides, say top and bottom, and the other two sides, the left and right sides of the rectangle, are open ends. The left and right sides of the rectangle may contain any terminal of a net, but the terminal position is not fixed before having a routing solution. The fixed terminals on the top and at the bottom are usually aligned vertically in *columns*. The set of terminals that need to be electrically connected together is called a *net*. A channel specification with a set of eight two-terminal nets in a channel is shown in Figure 1; the length of the channel is 18.

Figure 1. An example channel of eight nets; zeroes are non-terminals or vacant terminals, not to be connected. Intervals of the nets are placed in four different tracks. Terminals are vertically aligned along the columns of the channel. The length of the channel (i.e., the number of columns) is 18. Arrows indicate that the terminals to be connected, either on the top or at the bottom, to complete the required interconnection of all the nets present in the channel.

In order to obtain simple channel specifications, in this paper, we develop an algorithm for generating instances of such (simple) channel specification in random. There are several problems in channel routing that are hard in nature even if the channel specifications are free from any vertical constraints [4, 5, 6]; such randomly generated simple channel specifications can be used to compute desired routing solutions in executing heuristic algorithms designed for those problems [5, 6]. In the next section (Section II), we formulate the steps necessary for developing the algorithm in generating simple routing channel instances. Then we generalize the algorithm in generating general routing channel instances in Section III. We conclude the paper with a few remarks in Section IV.

II. GENERATION OF SIMPLE CHANNEL SPECIFICATIONS

A. An Overview

Let us assume, the number of nets be n in a channel that is being generated. So the channel length would be of $2n$, if no *blank column* (containing no terminal on the top as well as at the bottom) or *trivial column* (containing both the terminals of the same net) is introduced into the channel. In generating random channel specifications of simple in nature, we introduce a non-terminal (i.e., a vacant terminal) either on the top or at the bottom randomly, and the other side of the column would contain a terminal of a net. Our next task is to obtain the starting and the ending column positions of a two-terminal net, and on which side it would be (i.e., to obtain the terminal position of the net), on the top or at the bottom, randomly along the length of the channel. In this respect we like to fix up and maintain a set of criteria while generating the random channel specifications, as follows.

(a) Though it is needless to mention that the net numbers are nothing but symbols to differentiate themselves, we want to obtain the channel specifications where the net numbers would present randomly along the length of the channel, i.e., the nets are not sorted in succession based on their starting column positions from left to right or from right to left along the length of the channel, or something of that sort.

(b) Nets should be of different spans (or intervals) and they would present randomly along the length of the channel. If L_i (R_i) is the leftmost (rightmost) column position of net n_i , then $I_i = (L_i, R_i)$ is known as the *span* (or *interval*) of the net. As for example, the span of net 1 in Figure 1 is 9 and that of net 7 is 2. This criterion tells that all the smaller (or larger) nets are not accumulated on a side along the length of the channel.

(c) Generally, in practice, a channel contains smaller nets in large number and larger nets a few. Nets are defined smaller or larger based on their relative spans (or intervals) over the length of the channel. However, the number of nets with a fixed span (say, 5 nets of span 3 each, 2 nets of span 7 each, etc.) is not fixed; otherwise, the randomness of the channel to be generated may suffer.

Only we can say that, there would be a large number of smaller nets, and a few larger nets, but we do not precisely specify the exact spans of different nets or the number of nets of a fixed span. Obviously, the number of nets with some intermediate spans is neither more nor less. Actually, this criterion helps us in generating random channel instances where the number of nets gradually reduces as their spans increase along the length of the channel.

In order to generate the desired channel specifications, as guided by the criteria stated above, we now describe the channel specification generating procedure as follows. Let us assume the channel instance we want to generate is C that contains n nets, and its length is $m = 2n$ (as each of the n nets is a two-terminal net and we are not introducing any blank column or trivial column into C). We can simply generate two column numbers randomly for each net, and just place them on the top or at the bottom of the selected columns randomly. The problems that may arise in this method are that of generating the same number (as a net) more than twice (that means the net that has already been assigned) and the same column position c in C , $1 \leq c \leq m$, is accessed for assigning net j , which has already been occupied by net i , $j \neq i$, after starting the procedure (that can be considered as a *collision*). Finding out of a *free* column (where no net has yet been assigned) in some iteration might enhance the cost of the procedure (in terms of computational complexity) beyond some limit, and even if we use *linear probing technique* for such *collision resolution* (like *hashing*), it may result in some channel specification, which may not satisfy one or more criteria, mainly the third criterion described above.

So, generation of random column number for the nets is not a problem at all; even different methods for generating random numbers are easily available in literature, among which we can use any one of them. The problem gets apparent whenever a collision occurs, because we cannot predict anything about generation of random numbers. To get rid off this collision situation, we may think of the problem in a different way so that randomness remains unaffected.

B. Formulation of the Problem

In this subsection, we formulate the problem towards developing the algorithm in generating simple routing channel specifications, based on the overview of generating the same as discussed in the previous subsection. The channel specification may be thought as a linear *list* of two-tuple elements, where each element corresponds to a column in the channel (that is being generated) and the two tuples correspond to the top and the bottom terminal positions at each column. The length of the list is same as the length of the channel (say m), where n -number of nets are to be introduced when the channel is completely generated. For each list element we generate a net number; put it in one of the two tuples, i.e., either on the top or at the bottom, and the other side would contain a non-terminal.

At the very beginning, all the elements of the linear list of the two-tuple assumed above are initialized with zeros. In our algorithm, we replace $2n (= m)$ zeros in total in this two-tuple list, in order to generate a desired simple routing channel instance, where columnwise only one zero is randomly replaced by a net number. In order to generate such a channel specification, we assume another list of length m , which is same as the length of the channel specification that is being generated. Initially the list contains the natural numbers starting with zero onwards (i.e., 0 through $m-1$), i.e., each element i in the list contains the number $i-1$, $1 \leq i \leq m$.

We consider a singly linked linear list L of m nodes, and initialize the *information field* of node i ($L(i) \rightarrow info$) by $i-1$, where $1 \leq i \leq m$. In other words, the linear list L contains the column numbers 0 through $m-1$ of channel C to be generated. Initially all the columns are free, as we have not yet assigned any net to a column. If some net is assigned to column c , $0 \leq c \leq m-1$, then the node with information c is deleted from L , and keeps L as the list of free or available columns for the nets yet to be assigned. For each net i , $1 \leq i \leq n$, we randomly choose a node N from the existing list L of free nodes, retrieve its information part, which is a free column number in C , and store i in the free column. So, if N contains c in L , we replace c by i , and delete N from L . In effect, channel C would contain a terminal of net i at column c . Furthermore, in identifying the side (TOP or BOTTOM) of the channel, we choose another random number that signifies whether i is assigned on the top or at the bottom of c so that the other side of c is allotted for a non-terminal (i.e., 0). We treat this terminal as the position of the *initial terminal* of net i .

The problem of selecting a particular node in L may also arise for multiple times, if we do not delete the selected node from L . That is why we assign the current net to the column obtained by randomly selecting a node in L as stated above, and delete the node from L . In the same iteration (i.e., for net i) we generate the *final terminal* for net i too.

While generating the position of the *final terminal* of net i , $1 \leq i \leq n$, we have to keep in mind the last criterion of generating random channel specification stated above that is relating to spans of nets to be introduced in C . Here our intention is to generate many smaller nets and a few nets with larger spans. In order to obtain a random channel specification, we generate some smaller random numbers that would be added to or subtracted from column number c that is already selected randomly as the initial column position of net i . Initially we generate smaller random numbers and assign the nets with lesser spans along the length of the channel. Gradually L becomes sparse as the nets are assigned to C , and even for randomly generated smaller numbers nets with larger spans are evolved during later iterations.

As every time a new node with a new column number (as its information part) is selected, we can always be able to use the column successfully for a new net without any conflict, and in this way the problem of multiple occurrences of the same random number could be resolved.

C. The Complexity of the Algorithm

This is the way how a random channel C of n two-terminal nets is generated, where the length m of the channel specification is same as $2n$, and C contains no vertical constraint in it. One such randomly generated simple channel instance is shown in Figure 2(a). Figure 2(b) shows the horizontal constraint graph of this channel. In a *horizontal constraint graph*, n vertices are introduced corresponding to n nets belonging to a channel, and two vertices are connected by an edge if and only if the spans (or intervals) of the corresponding nets overlap in the channel [7, 10]. Table 1 shows how the nets in the channel generated are distributed over the length of the channel, as the net number increases. The table also shows the leftmost column position and the rightmost column position of each of the nets. From this table, it is clear that the spans of the nets also do not increase as the net numbers increase.

Figure 2. (a) The generated simple channel specification in this section. The channel contains 10 nets, and its length is 20. (b) The horizontal constraint graph of this generated simple channel specification. It consists of two components, as no net in this generated channel instance passes through both columns 8 as well as 9.

Net Number	Leftmost Column Position	Rightmost Column Position	Span (or Interval)
1	4	5	1
2	2	7	5
3	3	8	5
4	15	19	4
5	14	20	6
6	12	18	6
7	1	6	5
8	9	13	4
9	16	17	1
10	10	11	1

Table 1. Spans (or intervals) of different nets introduced into the randomly generated channel specification, shown in Figure 2(a).

Now we compute the computational complexities in generating such a random channel specification C as follows. In C , we have n nets in total. In addition, m is also of the order of n . Initially, we create a singly linked linear list L of order n . For each net i , $1 \leq i \leq n$, to be introduced into the channel, we randomly select a node N from the existing list L of free nodes and retrieve its information part to determine the initial terminal position of net i in a column in C . This linear search on the linked linear list L (of length $2n$) takes time $O(n)$. In the same iteration, we also determine the final terminal position of net i in a similar way, and that also takes time $O(n)$. So for each net i , $1 \leq i \leq n$, $O(n)$ time is required for finding out its terminal positions (in two different columns) in generating C . Hence for a channel of n nets to be introduced in C , the total time required is $O(n^2)$. Thus the time complexity in generating C is $O(n^2)$. Needless to mention that in generating C , we have used $O(n)$ dynamic space of computer memory. We summarize the complexity results in the following theorem.

Theorem 1. *Algorithm Simple_Random_Channel_Generator randomly generates simple channel specifications of only two-terminal nets without introducing any vertical constraint in it. The algorithm takes time $O(n^2)$, and space $O(n)$, where n is the number of nets introduced into the channel.*

III. GENERATION OF GENERAL CHANNEL SPECIFICATIONS

In the previous section we have described how to generate random channel instances, containing only two-terminal nets and there are no vertical constraints between any pair of nets. In general, (benchmark) channel specifications that are found in literature may have vertical constraints and nets may contain more than two terminals, i.e., there may be one or more than one terminals in between two end terminals of a net. So, the above-described procedure is applicable only on some special type of channel instances that are known as *simple channel specifications*. However, we can tune the procedure described above a bit, so that it becomes capable of generating channel instances having vertical constraints and nets may contain more than two terminals. In generating such general channel specifications, we

assume that there is an upper bound on the number of terminals and this number to be no more than six for a very few nets that are introduced into the channel being constructed.

Suppose we like to generate a random channel instance that consists of N nets ($N > 0$). So, the only input to be given here is the number of nets, i.e., N . Each net is assumed to be of k terminals ($2 \leq k \leq 6$). We need to place these N nets along the length of the channel. Also, there may be some non-terminals spread over the channel that should be incorporated in the specification. In order to generate a random general channel specification, first we have to estimate the length of the channel (L) in a way such that it is long enough to accommodate proposed terminals of all the nets as well as non-terminals. If k_i is the number of terminals of net i , then total number of terminals for all the nets can be computed by adding the number of terminals for each net. For example, if there are 10 nets in the channel then the total number of terminals for 10 nets is $K = k_1 + k_2 + \dots + k_{10}$. If NT is the number of non-terminals then total number of terminals is $P = K + NT$. These P terminals are evenly distributed over top and bottom positions of the channel specification along the length of the channel, in a random fashion.

Now we can calculate the estimated length of the channel as $L = \lceil P/2 \rceil$. As an illustration, say, there are 5 nets having 2 terminals each, 3 nets having 3 terminals each, and there are a 5-terminal and a 6-terminal net of a general channel specification to be generated of 10 nets. Also, say, number of non-terminals (NT) is 7. So the total number of terminals is calculated as follows:

$$P = K + NT = (2 \times 5 + 3 \times 3 + 5 \times 1 + 6 \times 1) + 7 = 30 + 7 = 37.$$

Hence, $L = \lceil P/2 \rceil = 19$.

So, the channel of length L is now capable of accommodating K terminals and NT non-terminals. In general, there are more nets having fewer terminals, and the random distribution of terminals should follow this constraint. Now, we have to locate the terminals of the nets at top / bottom positions in different columns in a random fashion. In order to place them properly, we have used three auxiliary lists, described as follows.

1. **NET_LIST**: The length of this list is also N . Initially the list is filled in with positive integers from 1 to N . An instance of the list is as follows.

NET_LIST: 1 2 3 4 5 6 7 8 9 10

This list tells that the nets to be introduced into the random general channel specification that is to be generated.

2. *TERM_COUNT*: The length of this list is N , i.e., same as the number of nets. Each location of this list is used to store the number of terminals (k) for a net. For example, if $N = 10$, then *TERM_COUNT* may be looked like as:

TERM_COUNT: 2 2 2 2 2 3 3 3 5 6

This means that, there are five nets of two terminals each, three nets of three terminals each and two nets having five and six terminals only.

3. *TERM_LIST*: The length of this list is $2L$, i.e., same as the sum of total number of top plus total number of bottom terminal positions. Initially the list is populated by positive integers started from 1 up to $2L$. For the above example, as $2L = 38$, so *TERM_LIST* must have positive integers from 1 to 38, as shown below.

TERM_LIST: 1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38

Now, it is the time to describe how channel specification C is generated with the help of these three auxiliary lists. At the very beginning of generating a desired random general channel specification, we initialize all the $2L$ top and bottom terminal positions of the channel by zeros. Then we start with generating the channel specification in N successive iterations. In each iteration, we select a net number (i) randomly and locate its terminals in different columns (c) in C , and again randomly determine the terminal position, either on the top or at the bottom at column c for net i . First we randomly select an element p from *NET_LIST* and remove the element from the list immediately; the length of *NET_LIST* is reduced accordingly. So, p is the net, whose terminals are to be assigned in different columns in C . Now, an element k from *TERM_COUNT* is selected randomly and the entry is deleted, and the size of this list is also reduced as before. So, p is considered as a k -terminal net. Say, we have selected the sixth entry from

NET_LIST and the ninth entry from *TERM_COUNT*; so $p = 6$ and $k = 5$, i.e., p is a 5-terminal net, whose terminal positions are to be determined now.

For each of these k terminals we generate a random number r and select the r -th element (which we denote by another number s) from *TERM_LIST* and delete the element as before, which results in a reduction of the length of *TERM_LIST*. The number s is now located at column $c = \lceil s/2 \rceil$; if s is odd (even), p (the net under consideration) is then placed at top (bottom) position at column c . When all the terminals of net p are assigned in different columns, we are left with *TERM_LIST* of length reduced by k , i.e., the length of *TERM_LIST* is same as $2L - k$, at the beginning of the second net / iteration under consideration.

In this way we extract elements from the three lists and using them we fill in the top and bottom positions of column c , and after N iterations we obtain a desired channel specification. Note that based on the initialization of the channel specification of length L (with all terminal positions containing only zeros), ultimately $2L - K$ terminal positions are left unassigned with some net terminals; so these terminal positions contain only non-terminals for the generated channel specification. One such randomly generated general channel instance is shown in Figure 3(a). The vertical constraint graph of this channel is shown in Figure 3(b). Vertical constraints among a set of nets determine a relative ordering over the nets along the height of the channel [7, 10]. The *vertical constraint graph* consists of n vertices for n nets present in a channel. If a column of the channel contains terminals of two different nets, say a and b , on the top and at the bottom, respectively, then in the vertical constraint graph, a directed edge is introduced from vertex a to vertex b .

Table 2 shows how the nets in the generated channel are spanned over its length, as the net number increases. Furthermore, terminal count, i.e., the number of terminals per net is also shown in the table. Data shows the randomness of the generated channel instance.

Figure 3. (a) The generated general channel specification in this section. The channel contains 10 nets, and its length is 19. (b) The vertical constraint graph of this generated general channel specification. Incidentally, it consists of two components, and does not contain any cyclic vertical constraint.

Net Number	Leftmost Column Position	Rightmost Column Position	Span (or Interval)	Terminal Count
1	4	10	6	2
2	4	11	7	3
3	8	14	6	2
4	6	10	4	3
5	1	5	4	2
6	3	13	10	5
7	12	17	5	2
8	1	2	1	2
9	12	18	6	6
10	15	19	4	3

Table 2. Spans (or intervals) of different nets introduced into the randomly generated general channel specification, shown in Figure 3(a). The number of terminals per net is also shown in this table in the rightmost column of Terminal Count.

We now analyze the computational complexities of algorithm *General_Random_Channel_Generator*. Suppose we have introduced N number of nets in total; so, N iterations are required. In each iteration, we need to search some random locations from the three auxiliary lists. Length of each of the lists *TERM_COUNT* and *NET_LIST* is same as the number of nets, i.e., N , and also the length ($2L$) of *TERM_LIST* is linearly dependent on N , i.e., L is $O(N)$. If we represent all these lists by singly linear linked lists, then the sequential search time for each list is dependent on their length. As the length of each of these (three) lists is $O(N)$, and as they are searched in a sequential manner, the total time to search the lists is $O(N)+O(N)+O(N)$, i.e., $O(N)$. So, for N iterations, as we like to introduce N nets into the channel, the total time complexity is $O(N^2)$. Also, space complexity is dependent on the length of each of all these lists, which is $O(N)$. So, space requirement is bounded by $O(N)$. We summarize the complexity results in the following theorem.

Theorem 2. *Algorithm General_Random_Channel_Generator randomly generates general channel specifications of multi-terminal nets that contain both horizontal as well as vertical constraints in it. The algorithm takes time $O(n^2)$, and space $O(n)$, where n is the number of nets introduced into the channel.*

IV. CONCLUSION

In this paper we have developed algorithms for generating random channel specifications of channel routing problem in VLSI design. We have developed two algorithms, one for generating random simple channel specifications and the other for generating random general channel specifications. Simple channel specifications contain only horizontal constraints but general channel specifications contain both horizontal as well as vertical constraints. General channel specifications may also contain cyclic vertical constraints. There are routing models, such as reserved two-layer no-dogleg Manhattan channel routing model [2, 7, 10], in which there is no feasible routing solution for general channel instances with cyclic vertical constraints. In that case an additional task of minor modification of the generated general channel specification is required in order to resolve vertical constraint violations.

In any case the algorithms developed in this paper are extremely useful when we require a large number of channel instances. As most of the problems in two-, three-, and multi-layer channel routing are computationally hard to solve [3, 4, 7, 9], for each of these problems it is unlikely to design a polynomial time deterministic algorithm. Rather, developing heuristic algorithms might be a probable way out that hopefully provides desired solutions for most of the instances occur in practice.

Dhaka, Bangladesh

Abstract—In this paper, we propose a unifying framework for efficient generation of combinatorial objects by giving recursive definition of an abstract combinatorial class. The definition can be instantiated to an array of specific combinatorial classes by specifying the framework parameters appropriately. Our framework defines a rooted spanning tree over a representative graph of that abstract combinatorial class where exhaustive generation can be done by a depth-first traversal. As an illustration, we show an instantiation for the combinatorial class of combinations as well as give a novel constant time generation algorithm for them.

Index Terms—Combinatorial Generation, Unifying Framework, Combinatorial Family, Combination, Combinatorial Algorithm

I. INTRODUCTION

The problem of generating all objects of a combinatorial class, each exactly once, so that successive objects differ in a pre-specified and usually small way, can be formulated as finding a Hamiltonian path/cycle problem in a graph; the vertices of the graph are the objects themselves. Two vertices are joined by an edge if they differ from each other in a pre-specified way. This graph is a representative graph of the corresponding combinatorial class (see Figure 1). A Hamiltonian path/cycle in this graph is called a combinatorial Gray code in the literature [1].

Fig. 1. A Hamiltonian path (indicated by the thick lines) over a representative graph of 3-digit binary number starting from 000.

Another approach that has been recently introduced in the combinatorial generation arena is genealogical tree or family tree approach. In this approach, the generation problem is formulated as finding a rooted spanning tree over a representative graph of the corresponding combinatorial class (see Figure 2). Every node of the tree, internal or external, is a combinatorial object and there is a unique child to parent relationship among the nodes. There is also a unique root object which has no parent. By traversing

this tree in a depth-first order, we can have a generation algorithm.

Fig. 2. A spanning tree (indicated by the thick lines) over a representative graph of 3-digit binary number starting from 000.

If we examine the two approaches mentioned above, we find that the goal of both approaches is to traverse every vertex of the representative graph of a particular combinatorial class exactly once. The goal is achieved by traversing a Hamiltonian path in the former and by traversing a rooted spanning tree in the later. The problem of determining whether a given graph has a Hamiltonian path or cycle is NP-complete. Moreover, it is not even guaranteed that a particular representative graph will have one. So this approach is not expected to work always. However, the best known algorithms for combinatorial generation are based on combinatorial Gray codes. On the contrary, intuitively speaking, finding a spanning tree is much easier.

In this paper, we propose a unifying framework for combinatorial generation by giving a recursive definition of an abstract combinatorial class. There are some framework parameters which are left unspecified in the definition. We can instantiate the recursive definition to define a concrete combinatorial class by specifying the framework parameters appropriately. Our unifying framework does not define any specific combinatorial class rather provides enough flexibility to define a broad range of combinatorial classes through framework parameters including n -tuple, combination as well as its variants, set partition, integer partition, binary tree and many more. Since a variety of combinatorial classes are unified under a common abstract recursive definition, we use the term 'Unifying'.

Previous attempts for combinatorial generation with minimal change using both the Gray code [2], [8] and genealogical tree approaches [5], [6], [7] are based on the intrinsic nature of each problem. This hardens the universal

adoption of a generation technique. Takaoka [4] formalizes the idea of combinatorial Gray code by a twisted lexicographic tree, and gives an iterative algorithm for efficient generation of certain combinatorial classes. In contrast, we formalize and unify the idea of genealogical tree where the formalization gives simpler constant-time generation scheme for larger classes of combinatorial family. Our idea is somewhat similar to [9]. However, we reduce the abstract reverse search procedure to instantiation of a formal framework with only two parameters depending on the specific combinatorial class.

Our framework recursively defines a rooted spanning tree over an abstract combinatorial class where the nodes of the tree are distinct objects of that class. By traversing that rooted spanning tree in a depth-first order we can visit every object. The point to focus is that we want to make a transition between two adjacent nodes in constant amount of time on average so that we can have an efficient generation scheme. We specify the parent to child relationship and child to parent relationship among the members of that class. We also present a generic algorithm for generation of every member. As an illustration of instantiation, we provide a specific example. We define the combination generation problem, instantiate our framework to the combinatorial class of combinations and prove the correctness of instantiation as well as present the specific algorithm.

The paper is organized as follows. In section 2 we present some definitions and concepts required for the rest of the paper. In section 3 we give the formal definition of our unifying framework. In section 4 we present an instantiation of our framework for the combinatorial class of combinations as well as give a novel constant time generation algorithm for them. In the conclusion we explore some future directions.

II. PRELIMINARIES

In this section, we define some terms used in this paper and follow the conventions in [3].

Fig. 3. A genealogical tree for combination of 4-element taken from a set of 6-element.

In this paper, we represent a *combinatorial object* of a combinatorial class $\mathcal{P}$ by a string $a_1 a_2 \dots a_n$ of length n such that each a_i is a value which is assigned to the i th position and taken from Σ as well as satisfies the constraint set $\mathcal{C}$ of $\mathcal{P}$. We denote the value of i th position using $v(i)$.

In the representation of a specific combinatorial object, if the value of i th position or $v(i)$ cannot be decremented due to the constraint set $\mathcal{C}$, then we call $v(i)$ the *minimal value* of the i th position of that combinatorial object. For a specific position i , this minimal value can vary from object to object. We call the minimum of all possible minimal values of the i th position as the *minimum value* of the i th position or i_{min} . In Figure 3, the minimal value of the 2nd position is 2 in 1456 but not in 2456. In 2456, minimal value of the 2nd position is 3. We cannot decrement the value of the 2nd position less than 3 with all other positions unchanged since it would violate the constraint set. However, the minimum value of the 2nd position is 2 since there are combinations that contain 2 in the 2nd position and no other combination has a value less than 2 in the 2nd position. We call a position a *minimum position* if the position contains the minimum value for that position. Otherwise we call the position a *non-minimum position*. In 1235, 1st, 2nd and 3rd positions are minimum positions and 4th position is a non-minimum position. We also define the concept of *maximal value* of the i th position, *maximum value* of the i th position or i_{max} , *maximum position* and *non-maximum position* in a similar way.

Next we give some tree-specific definitions. In the rooted spanning tree defined by our recursive definition, there is a unique root object T_r and every node $\mathcal{T}$ except the root, both internal and external, has a parent. In Figure 3, $T_r = 1234$. We denote the parent of a node $\mathcal{T}$ as $P(\mathcal{T})$ throughout the paper. Our idea of parent to child relationship is that the parent object and child object differ only in a single position r and by a single increment. The r th position is called the *change position* of $\mathcal{T}$ and a *generating position* of $P(\mathcal{T})$. According to an alternative notation, if $\mathcal{T}$ is a parent object, then $\mathcal{T}(k)$ is one of its children where k th position is a generating position in $\mathcal{T}$ and the change position in $\mathcal{T}(k)$. Note that, an object can have multiple generating positions but only a single change position. In a non-leaf object $\mathcal{T}$, the rightmost generating position is called the *start position* i and the leftmost generating position is called the *end position* j . In our framework, we assume that the generating positions are consecutive in an object. In Figure 3, 1235 is the parent of 1236. The 4th position is a generating position of 1235 as well as the change position of 1236. 1246 has a single change position namely the 3rd position but it has two generating position. The start position of 1246 is 3 and end position is 2.

III. FRAMEWORK DESCRIPTION

In this section, we give the recursive definition of our abstract combinatorial class.

A. Recursive Definition

Let $\mathcal{P}$ be the set of all objects of a combinatorial class. Let Σ be the alphabet and $\mathcal{C}$ be the constraint set defined for $\mathcal{P}$. Let $\mathcal{S}$ be the set of every object $\mathcal{T}$ that can be generated by the recursive definition given below. Let $\mathcal{T} \in \mathcal{S}$ be an object where $\mathcal{T} = a_1 a_2 \dots a_k \dots a_n$. Let $\mathcal{T}(k)$ be another object where $\mathcal{T}(k) = a_1 a_2 \dots a_k + 1 \dots a_n$. Alternatively, we can say that $\mathcal{T}(k)$ can be found by incrementing the k th position of $\mathcal{T}$ by one. We call $\mathcal{T}(k)$ the *child* of $\mathcal{T}$ and $\mathcal{T}$ the *parent* of $\mathcal{T}(k)$ if and only if $\mathcal{T}(k) \in \mathcal{S}$. We now give the formal definition of our unifying framework in definition 1.

Definition 1: The recursive definition has two steps.

Basis Step. Let $T_r \in \mathcal{S}$ be a unique object of length n , where $T_r \in \mathcal{P}$ and every position of T_r is set to the minimum. Then T_r is the unique root object.

Recursive Step. Let $\mathcal{T} \in \mathcal{S}$ be an object where $\mathcal{T} \in \mathcal{P}$. Let there be a start position i and an end position j in $\mathcal{T}$ such that $\mathcal{T}(k) \in \mathcal{P}$ for every k , where $j \leq k \leq i$. Then $\mathcal{T}(k) \in \mathcal{S}$. If there is no such pair (i, j) , then $\mathcal{T}$ is a leaf object and has no child.

Note that our recursive definition generates every object $\mathcal{T} \in \mathcal{P}$ where $\mathcal{P} = \mathcal{S}$. Specification of the root object T_r , or alternatively, specification of the *minimum value* for every position is the first parameter of our recursive definition. The choice of the root object T_r is problem specific. The start position i is specified by the parent to child relationship given below. Specification of the end position j is the second parameter of our recursive definition. The choice of the end position j is also problem specific.

B. Parent to Child Relationship

In this subsection, we define the parent to child relationship among the members of a combinatorial class that can be instantiated from our unifying framework. This relationship also serves as the child generation rule for a given object $\mathcal{T} \in \mathcal{S}$.

Definition 2: If $\mathcal{T} \in \mathcal{S}$, then $\mathcal{T}$ must have a *change position* r which is incremented in $P(\mathcal{T})$ to get $\mathcal{T}$. If $v(r)$ is not a maximal value then $i = r$. If $v(r)$ is a maximal value and r is not the leftmost position then $i = r - 1$. Otherwise, the position $r - 1$ does not exist and no start position i can be found. In that case $\mathcal{T}$ has no child. If $\mathcal{T} = T_r$ then $i = r$ where r is the rightmost position of $\mathcal{T}$.

The end position j depends on the constraint set $\mathcal{C}$ and is problem specific. By incrementing every k th position of $\mathcal{T}$ we can generate its children where $j \leq k \leq i$.

C. Child to Parent Relationship

In this subsection, we define the child to parent relationship among the objects $\mathcal{T} \in \mathcal{S}$ so that every non-root object $\mathcal{T}$ must have a parent and only one parent. In this way, each syntactically identical object is generated exactly once namely from its own parent. We need to define the constraint set $\mathcal{C}$ in such a way so that duplication never occurs. We ensure that the parent $P(\mathcal{T}) \in \mathcal{S}$ of an object $\mathcal{T} \in \mathcal{S}$ can be found by decrementing the change position of $\mathcal{T}$ so that the child to parent relationship remains the reverse of parent to child relationship. Our idea is, the parent $P(\mathcal{T})$ of an object $\mathcal{T} \in \mathcal{S}$ must be identical to $\mathcal{T}$ at every position except in its change position. We give our child to parent relationship by using the following two lemmas.

Lemma 1: For every non-root object $\mathcal{T} \in \mathcal{S}$, every position to the left of the change position r is a minimum position.

Proof: The proof is immediate from the definition 1. ■

Lemma 2: For every non-root object $\mathcal{T} \in \mathcal{S}$, the unique parent $P(\mathcal{T}) \in \mathcal{S}$ can be found by decrementing the leftmost non-minimum position.

Proof: Can be proved using Lemma 1. Detailed proof is omitted in this paper. ■

The Lemma 2 gives the definition of $P(\mathcal{T})$ and ensures that we can always find a unique parent of a non-root object $\mathcal{T}$. Next lemma ensures that there can be no duplication of objects in the tree generated by the recursive definition.

Lemma 3: For every non-root object $\mathcal{T} \in \mathcal{S}$, there is a unique sequence of decrement(s) in the leftmost non-minimum position(s) which transforms $\mathcal{T}$ into the root object T_r .

Proof: Can be proved using Lemma 2. Detailed proof is omitted in this paper. ■

Since there is a unique sequence of decrement(s) that transforms an object $\mathcal{T} \in \mathcal{S}$ into the root T_r , by reversing the decrement(s) we can generate that particular object $\mathcal{T}$, starting at the root. The path is unique, thus it will lead to a unique object.

D. Algorithm

In this subsection we give a straightforward implementation of an algorithm based on our parent to child relationship. Our algorithm generates every object in constant time on average if the determination of the end position j can be done in constant time. Thus we can have a *Constant Amortized Time* or *CAT* algorithm by carefully specifying the rule to determine end position. The algorithm is basically a depth first traversal over the rooted spanning tree defined by the recursive definition. We initialize the root object T_r and then traverse every object in a top down fashion. Here $\mathcal{T}$ is the current object

and r is the change position of $\mathcal{T}$.

Procedure Find-All-Child-Objects($\mathcal{T}, r$)
begin
 output $\mathcal{T}$;
 if ($v(r)$ is not a maximal value) **then** $i = r$;
 elseif ($r \neq 1$) **then** $i = r - 1$;
 else $\mathcal{T}$ has no generating position **return**;
 endif
 $j = \text{getEndPosition}()$; $k = i$;
 repeat
 Find-All-Child-Objects($\mathcal{T}(k), k$); $k = k - 1$;
 until ($k = j - 1$)
end;

Algorithm Find-All-Objects()
begin
 $\mathcal{T} = T_r$; $i = \text{rightmost minimum position } r$;
 Find-All-Child-Objects(T_r, i);
end;

E. Complexity Analysis

Before stating the space and time complexity we introduce some notation. Let n be the length of each object. Let $\mathcal{N}$ be the total number of objects in the combinatorial class $\mathcal{P}$. Let d_k be the difference between the maximum value and minimum value of the k th position where $1 \leq k \leq n$. Alternatively $d_k = k_{\max} - k_{\min}$. Let $d_{\max}$ be the maximum possible d_k where $1 \leq k \leq n$. We assume that the time complexity of the procedure getEndPosition is $O(\mathcal{F})$ where $\mathcal{F}$ is a placeholder for a complexity term.

Theorem 1: Algorithm **Find-All-Objects** uses $O(n * d)$ space and runs in $O(\mathcal{N} * \mathcal{F})$ time.

Proof: We give proof of space and time complexity separately.

To determine the worst case space complexity, we consider a special case. We set k th position of the root T_r to $k_{\min}$ for every k where $1 \leq k \leq n$. Let $\mathcal{T}_{\max}$ be an object with every position set to $k_{\max}$ where $1 \leq k \leq n$. In the worst case the value of $d_k = d_{\max}$ for every k where $1 \leq k \leq n$. So the path from T_r to $\mathcal{T}_{\max}$ contain a total of $n * d_{\max}$ increment and this path is the longest of all. As we traverse this tree, we must store the trace of the current path until we have reached to the leaf. So at the worst case we have the space complexity $O(n * d_{\max})$.

To determine the time complexity, we note that every transition from parent to child when we visit a child for the first time requires a single increment. In the same way every transition from child to parent when we trace back requires a single decrement. Given the change position both the increment and decrement can be done in $O(1)$. From the assumption, the complexity of selecting the end position j is $O(\mathcal{F})$. There is no need to find the end position when we are tracing back. So the traversal of

every edge of the rooted spanning tree can be done in $O(\mathcal{F})$ for forward direction and in $O(1)$ for backward direction. From the property of tree we know that a tree of $\mathcal{N}$ nodes has total $\mathcal{N} - 1$ edges. So the traversal takes $O((\mathcal{N} - 1) * \mathcal{F} + (\mathcal{N} - 1))$ which is $O(\mathcal{N} * \mathcal{F})$. We can readily see that if the end position j can be selected in $O(1)$ on average then we can have a constant amortized time or *CAT* algorithm. ■

IV. GENERATION OF COMBINATIONS

In this section we illustrate our framework with an example of the combinatorial class of combination. A *combination* of n things, taken k at a time, often called simply a k -combination of n things, is a way to select a subset of size k from a given set of size n . Set of all combinations essentially is a set of all subsets of a set of n elements or n -set with cardinality k . We use the term k -subset and combination interchangeably.

A. Framework Instantiation for Combination Generation

Let $\mathcal{P}$ be the set of all combinations. We represent a combination as $a_1 a_2 \dots a_n$ where a_i is the value of the i th position drawn from alphabet Σ . Here $\Sigma = [m]$ and $n \leq m$. Here the constraint set C has two rules. First, we do not allow same value in different positions simultaneously. Second, to avoid duplication we take the lexicographically sorted member. Combination of these two rules implies that values of the positions are kept sorted or $a_1 < a_2 < \dots < a_n$. $v(i)$ can be incremented when $v(i) + 1 < v(i + 1)$. Let $\mathcal{S}$ be the set of every combination $\mathcal{T}$ that can be generated by the instantiated recursive definition. All other definitions are as is.

To instantiate our recursive definition we follow a three-step procedure. The steps are given below:

- 1) The unique lexicographically smallest combination $\mathcal{T} \in \mathcal{P}$ of length n is defined as the root T_r where $T_r = 12 \dots n$. Every i th position of T_r is set to $i_{\min}$. Here $i_{\min}$ is the minimum value of i th position where $1 \leq i \leq n$. In this case $i_{\min} = i$. All other combinations contain an equal or a greater value at every position than T_r . Maximum value of i th position or $i_{\max}$ is $i + m - n$ where $1 \leq i \leq n$.
- 2) For root combination T_r the start position $i = n$ and end position $j = n$. For non-root combination, if the change position is r then the end position $j = r - 1$ given that $r \neq 1$. If $r = 1$ and $v(r)$ is not a maximal value then $j = r$. Otherwise, this is a leaf and has no generating position.
- 3) To prove the correctness of our instantiation we show that our parameter specifications enforce the set equality $\mathcal{P} = \mathcal{S}$ where $\mathcal{S}$ is the set of every combination $\mathcal{T}$ that can be generated by our recursive definition.

In the next few lemmas we prove several aspects of our instantiation.

Lemma 4: For every non-root combination $\mathcal{T} \in \mathcal{P}$, there is a unique combination $\mathcal{T}' \in \mathcal{P}$ where $\mathcal{T}'$ can be found by decrementing the leftmost non-minimum position.

Proof: Let r be the leftmost non-minimum position of the combination $\mathcal{T} \in \mathcal{P}$. Since $v(r) - 1 \in [m]$, the value of every position of $\mathcal{T}'$ is drawn from $[m]$. Decrementing the r th position retains the relation $v(r-1) < v(r) < v(r+1)$ in $\mathcal{T}'$. So $\mathcal{T}'$ satisfies the constraint set $\mathcal{C}$ hence $\mathcal{T}'$ is also a combination or $\mathcal{T}' \in \mathcal{P}$. ■

We call $\mathcal{T}'$ the parent of $\mathcal{T}$ or $P(\mathcal{T})$ since Lemma 4 is a restatement of the child to parent relationship in our unifying framework.

Lemma 5: For every non-root combination $\mathcal{T} \in \mathcal{P}$, there is a unique sequence of decrement(s) in the leftmost non-minimum position(s) which transforms $\mathcal{T}$ into the root combination T_r .

Proof: Can be proved using Lemma 4. Detailed proof is omitted in this paper. ■

Lemma 6: If there is a unique sequence of decrement(s) in the leftmost non-minimum position of a non-root combination $\mathcal{T} \in \mathcal{P}$ which transforms $\mathcal{T}$ into the root T_r , then $\mathcal{T} \in \mathcal{S}$.

Proof: Can be proved using Lemma 4. Detailed proof is omitted in this paper. ■

Now we state the required theorem to show that the instantiated version of our framework indeed generates every combination and no more. For this we have to show that, the set $\mathcal{S}$ of all combinations that can be generated by the recursive framework and the set $\mathcal{P}$ of all possible combinations are equal.

Theorem 2: For every combination $\mathcal{T}$, $\mathcal{T} \in \mathcal{P}$ if and only if $\mathcal{T} \in \mathcal{S}$.

Proof: *Case $n = m$.* When $\mathcal{T} = 12 \dots n$ it is the root $T_r \in \mathcal{S}$ as well as $T_r \in \mathcal{P}$. T_r is the only combination in $\mathcal{P}$. On the other hand, T_r has no generating position and the only combination in $\mathcal{S}$. So $\mathcal{P} = \mathcal{S}$.

Case $n < m$. To prove the necessary condition let $\mathcal{T} \in \mathcal{P}$ be a combination where $\mathcal{T} \in \mathcal{S}$. If $\mathcal{T} = T_r$, then the start position $i = n$ and end position $j = n$. So only the n th position of $\mathcal{T}$ is a generating position. If $\mathcal{T}$ is a non-root combination with the change position r , then $j = r - 1$ given that $r \neq 1$. If $v(r) + 1 < v(r + 1)$, then $i = r$. If $v(r) + 1 = v(r + 1)$, then $i = r - 1$. If $r = 1$ and $v(r)$ is not a maximal value, then $i = r$ and $j = r$. If $r = 1$ and $v(r)$ is a maximal value, then $\mathcal{T}$ is a leaf object. In all cases $\mathcal{T}(k) \in \mathcal{P}$, because incrementing the generating position k ensures that the value of every position of $\mathcal{T}(k)$ is drawn from $[m]$ and the relation $v(k - 1) < v(k) < v(k + 1)$ as well as the constraint set $\mathcal{C}$ is satisfied for $j \leq k \leq i$. So, if a object $\mathcal{T}$ is generated in our instantiated framework, then it is a combination or $\mathcal{T} \in \mathcal{P}$.

To prove the sufficiency condition we see that if $\mathcal{T} \in \mathcal{P}$

is a non-root combination, then using the Lemmas 5 and 6 it is immediate that $\mathcal{T} \in \mathcal{S}$. ■

B. Algorithm

In this subsection we give a straight forward implementation of our instantiated parent to child relationship. Our algorithm generates every combination in constant time on average since the determination of the end position j can be done in constant time. Thus we have a *CAT* algorithm for combination generation. We initialize the root combination T_r and then traverse every combination in a depth-first fashion. Here $\mathcal{T}$ is the current combination and r is the change position of $\mathcal{T}$.

Procedure Find-All-Child-Combinations($\mathcal{T}, r$)

```

begin
  output  $\mathcal{T}$ ;
  if( $v(r) \neq r + m - n$ ) then  $i = r$ ;
  elseif( $r \neq 1$ ) then  $i = r - 1$ ;
  else  $\mathcal{T}$  has no generating position return;
endif
 $j = r - 1$ ;  $k = i$ ;
repeat
  Find-All-Child-Combinations( $\mathcal{T}(k), k$ );  $k = k - 1$ ;
until( $k = j - 1$ )
end;
```

Algorithm Find-All-Combinations()

```

begin
   $\mathcal{T} = T_r$ ;  $i = n$ ;
  Find-All-Child-Combinations( $\mathcal{T}_r, i$ );
end;
```

Our algorithm starts with procedure *Find-All-Combinations*. This procedure set the start position i to the rightmost minimum position n . Next, algorithm calls the procedure *Find-All-Child-Combinations*. It first outputs the current combination and then checks the corresponding change position r whether $v(r)$ is a maximal value or not. If there is a room for increment, then $i = r$. If there is no room for increment and $r \neq 1$, then i is set to $r - 1$. Otherwise, this is a leaf combination and the procedure returns. If this is a non-leaf combination, then the end position $j = r - 1$. This is a *CAT* algorithm since computation of j takes constant time. Then a loop runs and increments every position from i to j and calls the procedure *Find-All-Child-Combinations* recursively. The correctness of our algorithm follows from Lemmas 5 and 6 and the complexity can be achieved from Theorem 1.

V. CONCLUSION

In this paper, we present a unifying framework for combinatorial generation. We are also working on the instantiation of other combinatorial classes. A theoretical

advancement might be capturing the core algebraic properties of the combinatorial classes those conform to this framework. Another interesting direction is to develop a random sampling scheme by making the traversal a random tree walk.

City Planning and Development Using Geographic Information Systems

Mustafa A. Kamal

Department of Computer Information Systems, University of Central Missouri
Warrensburg, MO 64093, USA

Abstract - In recent years, GIS technology is used from managing natural disasters such as landslides to habitat mapping through remote sensing. GIS system has also been used to address land use issues. Many local governments are adding GIS technology as part of their regular administrative management system. High cost of GIS system, shortage of appropriate GIS specialists, lack of understanding and policies for homogeneous integration of GIS into planning are making the system, in many public sector cases, less than successful. We worked with a city government in the middle USA and participated in evaluating their system. Although small in size (population – thirty thousand), it's location next door to a large metropolitan city made things complicated. The city incorporated a GIS system into many aspects of public sector development, offered web-based services to its community and published maps with search tools. The GIS based services gave the city government a high-tech reputation and a need-based analysis of public sector projects.

The system gave the city officials access to real and accurate data which were not previously available. This often added more policy debates on sensitive and long range issues. It added a new dimension to city development and helped to find a combination of solutions in city wide constructions, drainage system, traffic control, and other engineering applications. Overall, the GIS system improved the efficiency of the city government and their administration processes as well as improved quality of decisions made by the city planners and managers.

Index terms – GIS, planning, remote sensing, GPS

DEFINITION AND SCOPE OF GIS

A GIS (Geographic Information System) package is an organized collection of computer hardware, software, geographic data, and personnel designed to efficiently capture, store, update, manipulate, analyze, and display geographically referenced information [1-4]. The GIS database management system combines map layers and process data. Its capability of three-dimension interface can create a visual landscape or contour for infrastructure and engineering projects. For example, a GIS system can locate a traffic incident spot in a second, and call out the emergency

connections from the related database; the system can also create a 3D model of a park without physically building it. The majority of cases of desktop GIS software use are non-technical in nature. By using statistical analysis and GIS tools, practitioners can easily identify the target and build a what-if scenario. One of the most attractive point of GIS modeling is that it can quickly show the real-world results of a complex statistical manipulation [3]. However, at a local government level GIS uses is very limited to none.

CHALLENGES IN IMPLEMENTING GIS

GIS technology is not cheap. Cost come from hardware, software, infrastructure, people and training. Data acquisition and digitization also add to the cost. Integration of GIS into existing technologies, such as different operation systems, workstations, networking equipments, wireless networks, DBMS systems, management systems, are major issues. Many local governments lack funding for such implementation. With the complexity and limitation of the GIS and GPS collection, managers need to understand how to organize a GIS team. A GIS project needs GPS collectors and many specialists. For example, network specialists needed to transmit GIS data through the existing network without creating traffic overload; database specialists needed to merge and organize GIS data into database system. GIS specialist needed to process aerial photography and data digitization, store and retrieval. Website specialist may design the Internet Management System and GIS Internet tools to offer the service to the end users.

There can be impact on public policy issues too. Accurate and real time data may remove ambiguity from many public policy decisions. For example, GIS data may suggest that a planned commercial area may destroy the nature environment in that area or reduce the total area of parks in the city. Moreover, a GIS can also be a useful tool to find more ways to solve a conflict or existing problems. For example, a GIS-produced map is often used to explain zoning issues to the city council; a GIS map overlaid with different statistic data is used to solve city-wide policy issues

and conflicts. In Summit, parcel- specific maps are available on the internet for public uses and gives a common understanding of current patterns of development.

MAPPING DATA FOR POLICY MAKERS

Here are the general steps for a GIS manager to map data into a GIS project.

1. Process

- Manager needs to analyze the policy questions to identify the important features, and create different scenarios to match the basic requirement within the policy environment.
- Select visualization techniques, such as 3-dimensional GIS tools or a handy GIS software, which can appropriately emphasize the features that has been selected.
- Integrate different layers of the data and other required information, including statistical result, into a small number of displays.

2. Categorize the data

The manager decides what and how many attributes should be included in the data. For example, a street layer need parcel numbers, the name of property owners, name of the street, and

identification number etc. The manager needs to consider the future use of the data and its potential users.

3. Equal intervals

After the basic information has been built in the categories, the manager can combine it with statistical data and start to analyze the overall view of the questions. To clearly distinguish results, the data should be divided into several equal intervals and marked in different color or symbols. GIS will help the manager to create these tools and export the data to make a quick report.

4. Avoiding Visual Misperceptions

When analyzing the geographic data, visual misperception should be avoided. Misrepresentation or bias may cause mistakes in categorizing the data in analysis. For example, we may categorize houses around a lake as high income area which may not necessary be true for all units.

5. Analyze the policy questions

The analysis should involve a population large enough to allow for statistical analysis to be meaningful. Some other variables may also affect the result of analysis.

GIS Project – from planning to maintenance

Figure 1: GIS project life cycle

CASE STUDY - GIS APPLICATION IN SUMMIT CITY

Summit City routinely applies their GIS system to evaluate current and proposed activities. For example, prior to citywide events GIS system is consulted to study impact on resources such as police, fire, evacuation plan, available housing, demand on water/sewer and on public health, recycling etc are looked at. Summit City is continuously developing and updating its GIS environment and compatible database. On a regular basis, GIS applications in Summit also include review of land use, impact on tax base, water and sewer infrastructure, availability of storm and sanitary sewer and drains, etc. The local government publishes upcoming project description and estimate completion date, performance expectations and availability to public. Here is an example of upcoming projects published by Summit City. This digitized map combined several different layers from different projects.

Project Description		Estimated Completion Date
CURRENT PROJECTS	1 Pryor Rd, 4th to Chipman	November 2003
	2 Chipman Rd, Phase I, Blue Parkway to Olive	December 2003
	3 Tudor/Scruggs, 291 hwy to Blackwell	May 2004
	4 Independence/Orchard Stormwater Improvements	July 2003
	5 Bowlin Road Pump Station Renovation	September 2003
	6 Maybrook Manhole Rehabilitation - Sanitary Sewer	November 2003
	7 Eastridge Sanitary Sewer Replacement	September 2003
	8 Edgewood Trail Sanitary Sewer Replacement	August 2003
	9 SA/5B Modifications - Sanitary Sewer	August 2003
	10 Legacy Community Center	Fall 2003
	11 Longview Loop - Greenway	Fall 2003
Project Description		Estimated Start Date
UPCOMING PROJECTS	12 Chipman Road, Phase II, Olive to M-291 Hwy	Spring 2004
	13 Independence Avenue, Deerbrook to Colbern	Winter 2004
	14 Todd George, Tudor to McKee	Winter 2004
	15 Downtown Improvements - Road, Water, Storm and Sanitary Sewer	Summer 2004
	16 Blackwell and Shenandoah - Stormwater	Spring 2004
	17 West Prairie Lee Sanitary Sewer Improvements, Phase I - Stormwater	Fall 2004
	18 South Prairie Lee and Bristol Sanitary Sewer	Winter 2003
	19 Middle Big Creek Excess Flow Basin - Sanitary	Fall/Winter 2004
	20 Scruggs Road Pump Station Improvements - Sanitary	Summer/Fall 2003

Figure2: Projects at Summit City

The city government offers an active on-line city map with simplified GIS tools to search the data for personal use. The GIS department updates their services on the website and its intranet. Due to ongoing construction of roads and utilities and construction of housing and new business the GIS quickly react to the changing events and its environments. The system allows staffs at different geographical location to work, store and retrieve data from the same database on real time. The system maintains its' communication with federal, state and other local governments by transmitting digitized map data through the networks. A summary of the process of land use application and its data flow is showing in Figure 2. Applicants submit paper plan to the planning department which will check land use plan in the current and in the future as well as the environment of that land from the database and give suggestions to the applicants. After the plan is approved and receives all required signatures, the draft plan is sent to the County office for its parcel number. The final draft comes back to the city government and is added into the database. The detail information of the land can be checked on County's Web site, including the records of tax payment, name of the land lord, the location, the size and the value of that land, etc. Customers can compare value of the property, transportation layout, school district, etc.

Before a piece of land is approved for public facility, such as schools, hospitals, or shopping mall, the city evaluates whether related constructions or improvements around that land is necessary. These may include building of new roads and/or upgrade existing roads, add traffic lights and add signs. The Summit City reviews impact on school boundaries from such constructions. GIS facilitates the process by redrawing boundaries in different ways to best fit the need. School Committee members of the city select which subdivisions they want to include within the new boundary and the GIS tags them with the school's code. The GIS knows the number of elementary students within each subdivision, so it can total the number of students within the proposed boundary. They can change the boundary by changing which subdivision they select, and GIS will automatically show the results of different combinations. The same method can also be used to analyze and create legislative districts.

GIS EVALUATION: HEALTH SYSTEMS HOSPITAL IN SUMMIT CITY

Health Systems Hospitals, consisting of eight area hospitals and 14 primary care practices provide a range of primary, acute, tertiary and chronic care services. The System proposed to build a 52-bed, \$57 million hospital in the Summit City. The health system is an organization in which the physicians and hospitals, functioning as an integrated unit, assume responsibility for the delivery of comprehensive, cost-effective, quality health care for people in the metropolitan area and the surrounding region.

The state is responsible for oversight of the alarming increase in healthcare costs and control of the healthcare constructions. The Health Facilities Review Committee is responsible for issuing a certificate-of-need (CON). The program is designed to contain health care costs by stopping unnecessary spending on facilities and high-dollar equipment. There is an inherent problem in CON denial that it may hinder competitions. The Summit City was responsible to conduct its' analysis of the proposal and submit their findings to the state CON committee. The Summit City extensively used its GIS system to come up with layers of relevant data and visual images and completed its' analysis. They looked at such issues as locations of nearly hospitals, layers of emergency route, street name, current traffic on streets, population per square mile, etc. They also looked at various "what-if" scenarios.

A. EVALUATIONS - POSITIVE:

1. The planned hospital is near a grid of interstate highways with easy access.
2. The project would include a \$22 million, 70,000-square-foot health care campus, expected to open two years after start of construction. It would include a 40,000-square-foot medical office building, a 24-hour Emergency-Center and a diagnostic center. It will incorporate state-of-the-art medical technology and treatments into a patient-friendly campus setting.
3. The new hospital will increase Summit City's medical resources and the delivery of needed healthcare choices.
4. It is estimated that the new hospital will employ 150-200 healthcare employee who will reside in the City. In addition, the new hospital will have an annual payroll exceeding \$12 million and an average annual salary of \$57,000 by 2009.

B. EVALUATION - NEGATIVE:

1. According to GIS analysis, location of the new hospital is too close to the other two main hospitals in the city, Summit Hospital and St. Murray Hospital. Although the hospital is easily accessible through a grid of freeways, the majority of the population does not reside near the expressway. The emergency vehicles will end up using the main thoroughfare rather than the expressways.
2. These hospitals have almost the same target patients. The increase in number of hospital beds far exceeds the foreseeable increase in projected population growth. The other two major hospitals in the area already experience less than 80% bed occupancy. Therefore, value added will not offset the cost of constructing a new hospital.
3. The addition of a new hospital will increase the healthcare cost.

FINAL DECISION

Based on the findings the Health Facilities Review Committee decided to deny the new hospital project. "We remain convinced there's not a need for a new hospital in the area. 'There are eight facilities within the 10-mile radius and two in the most immediate area,'" the committee reported.

Health Systems Hospitals claimed that the CON law is unconstitutional, and file an appeal to ask the state Supreme Court to repeal the CON law for hospitals and other acute-care providers. They think the state should regulate health facilities based on quality criteria instead of the number of the buildings. The Health Systems Hospitals won the lawsuit and a Certificate of Need was granted.

CONCLUSION

GIS is a handy tool with wide range of applications to analyze events and decision making. The system offers decision makers multiple layers of pertinent information to select. In the event of a decision making process such as a land-use conflict illustrated here, the users can analyze various layers such as roads, housing, land owners, traffic conditions at different time of day/night, future expansion of road plans, city boundary, neighbor areas, population density, and resource locations, etc.

Various options like 'what-if' conditions - move the blocks, turn the buildings or create a virtual road across the land can be explored. Most importantly, the form of digital data can give immediate feedback and thus save valuable time and resources. However, a powerful tool is still a tool. The use of the tool depends on the user and their geopolitical environment. GIS can offer the best tools to enhance decision making process. Currently many companies are marketing handheld GPS / PDA receivers for GIS users with sub-meter accuracy in real-time.

An Application Program Interface for vBulletin

Saumen Seal Sami, Tazilur Rahman, Khondker Shajadul Hasan, Javed Siddique

Department of Computer Science & Engineering, North South University
12 Kemal Ataturk Avenue, Banani, Dhaka-1213, Bangladesh

E-mail: saumen@gmail.com, tanzilurrahman@hotmail.com, {shajadul,jsiddique}@northsouth.edu

Abstract — vBulletin Calendar API is built on calendar feature of vBulletin, a commercial internet forum software produced by Jelsoft Enterprises Ltd. It acts as a remote agent for client applications intended to be developed by third party software developers. Such applications can be Facebook application, desktop application, IRC-bot and mobile applications for instant event notification and reminder. Important notices, announcements posted from departments of educational institutions often do not reach to target people, in time, due to various reasons. In this paper, we have proposed to develop an interface through which individual client applications monitor a common source of notice service center and notify users instantly.

Index Items — API, HTML, XML, vBulletin, MySQL, PHP-BB, SMS flag, DoS, URI.

I. INTRODUCTION

Notices work as a key point for any organization or institution as media of relaying information to the respective persons and/or sectors. Especially for the large institutions or organizations, it has a vital role. Currently these notices reach to target people by means of flyers, official websites and email. But the target people have to stop by flyers or browse websites or check emails on right time. It is often not possible for all of the notices to get updated right ahead of time. The goal of this development is to make notices and announcements available to maximum internet users instantly so that an internet user does not have to sit all the time in front of computer and browse for newest announcements.

vBulletin Calendar API processes queries and performs operations remotely requested by computer and mobile applications connected to internet. Our API provides requested data in XML format.

vBulletin Calendar API is intended to build for software application developers. Our product is like an interface or remote program that provides number of functionalities which can be called to provide data and process requests.

This development carries out the motto of increasing flexibility, efficiency of the notice posting system and distribution of these notices to the target people. This

development of the calendar feature of vBulletin is designed in such a way that it easily fits to any type organization including business, educational, corporate etc.

II. PRESENT INFRASTRUCTURE

Currently different organizations follow different policies or methods to inform all of their clients and employees about the latest notifications of information. Most of the educational institutions use the group emailing system to inform the specific groups. For example: administration group, faculty group and student group. In some places, students use official/unofficial forum to notify the latest event and news. In these cases they use online full featured forum software like vBulletin, phpBB etc. In Forum system, people request/register for an account and the forum admin setup an account, provides proper user access permission. After that, the user can log in and read threads and get informed.

So, to get informed of a notice a user must have to log on to the forum or at best they can be informed through email. Still the user has to be in touch to their mailbox. In short, the present infrastructure may play an important role but surely not the quickest and most effective. Among other two's, hospital mostly informs their clients through phone. Banks and other companies mainly use paper based notices, whereas software firms, telecom companies use SMS group notification, email to post to their employees and clients.

III. PROPOSED INFRASTRUCTURE

In this manner the proposed infrastructure has been designed considering the facts that lie currently in the present infrastructure. The intention is to dynamically change the view and developing a new structure which will automatically fit into any of the present system. Our structure uses the existing technology of vBulletin Calendar system as it is one of the most popular and mostly used commercial forum software. We set our target to develop a system to work as an intermediate way between the forum database and the third party client application which can be developed in anonymous production environment by any independent software developer by following some

defined protocols. The system verifies and processes requests, collects information from the vBulletin system and passes it to the third party applications on request.

The first thing is the organizations have to maintain a vBulletin forum database of their own. The users will have the accounts to that forum as it requires to any other forums. The vBulletin has a calendar mechanism that has been customized by us to fit for the API.

Services available for client application itself are defined as follows:

1. Marked Event List (user specific)
2. Modify SMS flag (event & user specific)
3. Latest Event

Services available for client application user are available as:

1. Authentication
2. Calendar List
3. Category list (calendar specific)
4. Event List (calendar & category specific)
5. Event Description
6. Event mark/unmark
7. Latest event (user specific)

Authentication is used for user classification and as the user identified all the services are ready for him according to his access level and they are grouped as: Calendar List, Category list, Event list, Event Description, Event Mark/Unmark, latest event information.

A. Routing (URI access protocol)

Rather than using the standard "query string" approach to URLs that is synonymous with dynamic systems, vBulletin Calendar API uses a segment-based approach. For example, the authentication URL is

http://{host}/api/authenticate/{user}:{pass}/

For this, we have used Apache Module mod_rewrite URL Rewriting Engine. This module uses a rule-based rewriting engine (based on a regular-expression parser) to rewrite requested URLs on the fly. It supports an unlimited number of rules and an unlimited number of attached rule conditions for each rule to provide a really flexible and powerful URL manipulation mechanism.

As you can see, first the URL is matched against the *Pattern* of each rule. When it fails mod_rewrite immediately stops processing this rule and continues with the next rule. If the *Pattern* matches, mod_rewrite looks for corresponding rule conditions. If none are present, it just substitutes the URL with a new value

Fig. 1. Control flow through rewriting rule set structure

which is constructed from the string *Substitution* and goes on with its rule-looping. But if conditions exist, it starts an inner loop for processing them in the order that they are listed. For conditions the logic is different: we don't match a pattern against the current URL. Instead we first create a string *TestString* by expanding variables, back-references, map lookups, etc. and then we try to match *CondPattern* against it. If the pattern doesn't match, the complete set of conditions and the corresponding rule fails. If the pattern matches, then the next condition is processed until no more conditions are available. If all conditions match, processing is continued with the substitution of the URL with *Substitution*.

IV. DESIGN AND IMPLEMENTATION

The API does not come with any GUI; instead API provides XML response on request and this response is retrievable by any accessible network client application written in any programming language. No external hardware tools are required for any of the functionality. API requires vBulletin system installed and running on same web server. vBulletin works on a MySQL database consists of one hundred and sixteen (114) tables. We have added two additional tables for storing authentication tokens and event notifications. The API fetches data from this database and provides output in XML format.

Fig. 2. A simple flow diagram of the structure

Fig. 3. Data flow diagram for the proposed structure

Service request and processing are performed in following order:

- Client application sends HTTP request to API with required parameters.
- Our API then prepares and sends SQL query to vBulletin database server.

- The communication between API and client application is committed through HTTP.

A. API service description: Authentication

According to our specification, every client application keeps separate authentication token for each user. This token is required to fetch calendar list, event list, event notification etc. via API.

- Application user identifies by providing username and password to client application.
- Client application calls API using our defined URI (described in Routing section).
- API on server validates the username and password and on success returns an authentication token.
- This authentication token is assigned to a user for a time period (This time period is configurable).

On the contrary, the API returns an error code when exception occurs.

This feature offers several advantages:

1. Performance is improved because login data is validated only once per session instead of with each all other service requests.

Fig. 4. Sequence Diagram for the proposed API structure

- In response, database server returns result set to API. API converts the result set into XML format and sends XML response to client application.

2. Security is tightened by minimizing the number of times login data is transmitted per session.

B. API service description: Fetch Calendar List

Gives list of calendars to which a user has at least read access. Client application can request for list of calendars and this list is filtered on user account permission.

C. API service description: Fetch Category List

Gives list of event categories for a specific calendar to which a user has at least read access. Client application can request for list of event categories and this list is filtered on user account permission.

D. Description of Other Core Methods

Here, 3rd party sends HTTP request to API which sends SQL query to forum DB in response forum DB sends back DB result that API converts into XML format and sends XML response to 3rd party Application 3rd party gets authentication token in XML format which it uses for further data retrieve like for fetch the calendar information it sends the token with necessary parameters and in response gets the calendar information in XML format. When a mark or unmark event occurs the data is updated in forum DB as well as an output of XML format of the data saved.

V. SECURITY AND SAFETY ISSUES

Our product is strong enough to handle security issues and does not hamper vBulletin system. Any big company or institution can integrate this API without concerning security and safety issues because we have ensured these issues during our design and implementation phase.

The API is written in PHP. Therefore, the web administrator can read API source code and see what's going on inside and make changes as and if required.

Rewrite Engine defines the rules of accessing URI resources in very strict way. Therefore, our API is SQL Injection protected because of strict URI access protocol.

The API uses Cache technology. This feature stands against DoS (Denial-of-Service) attack.

VI. CONCLUSION

We feel that the model we have proposed and implemented is not only a good one but also the best solution for the moment for instant notification of any notices made by a big organizations or institutions targeting to a particular group of people that include client or employee. This is because our API makes event announcements available to various platforms

including Web browser (extensible like Firefox), Desktop application, IRC Bot, Mobile application etc.

According to the requirement of organizations, they can develop various client side applications. As our API receives HTTP request and the response is in an XML format, so the client side application can be developed and used in any environment. The one and only fact is the availability of internet connection which is not an unattainable issue in this fastest growing world with technology.

Structural Operational Semantics of Packages in Java

Abdullah Al Farook, Mohammad Shamsul Arefin and Md. Moshikul Hoque

Computer Science and Engineering Department, Chittagong University of Engineering & Technology, Bangladesh

Email(s): farookcanada@yahoo.com, sarefin_406@yahoo.com and moshikulh@yahoo.com

Abstract — A good understanding of programming language can be developed and understood in a machine independent manner called structural operational semantics. It is a mathematical model for specifying the meaning of a language by defining the effect of a running program in terms of its structure. The emphasis of this work is to present the structural operational semantics of several important aspects of packages in Java programming. With that we have showed how structural operational semantics is helpful for understanding the structure of packages.

Index Terms — Java, structural operational semantics, package, abstraction, environment.

I. INTRODUCTION

Java is unique among popular general purpose programming languages in that it provides a construct called package where classes, interfaces and sub packages defined in the source file will automatically be added to the package having the name specified by package name that are desirable in an Object Oriented Language. Package Structure helps the programmer to separate design part from coding part of the program and powerful capabilities to reuse code even outside the program.

Structural Operational Semantics (SOS) provides a framework for describing the meaning and specification of programming languages. SOS was introduced by G. D. Plotkin [1] as a logical means to defining operational semantics. The basic idea behind SOS is to define the behavior of a program in terms of the behavior of its parts, thus providing a structural, i.e., syntax oriented and inductive, view on operational semantics. An SOS specification defines the behavior of a program in terms of a set of transition relations. SOS specifications take the form of a set of inference rules, which define the valid transitions of a composite piece of syntax in terms of the transitions of its components. A growing number of programming languages from commercial to academic spheres have been given usable semantic descriptions by means of structural operational semantics. Because of its intuitive appeal and flexibility, structural operational semantics has found considerable application in the study of the semantics of concurrent processes. Moreover, it is becoming a viable alternative to denotational semantics in

the static analysis of programs and in proving compiler correctness.

Recently, structural operational semantics has been successfully applied as a formal tool to establish results that hold for classes of process description languages. This allows for the generalization of well-known results in the field of process algebra and for the development of a meta-theory for process calculi based on the realization that many of the results in this field only depend upon general semantic properties of language constructs.

A subset of Java has been taken to our work that would be termed as Mini Java [2] in the following sections of the paper. Semantics for declaration of packages have been given. The semantics is based on the environment and state. Two kinds of environment have been used – class-environment and working-environment. The semantics describes the changes in the environment and state at different steps of package execution, which is helpful for understanding the execution structure of packages.

II. LITERATURE REVIEW

Java semantics is an extensive research area. The first important research domain is the proof of the soundness of the Java type system. Drossopoulou and Eisenbach [3, 4, 5] are specifying semantics of several Java subsets in order to prove that the type soundness in these subsets (Javas, Javase, and Javar). They work on a large sequential of subset reduction theorem.

Attali et al. [6] presented a formal semantics of a large subset of Java, including inheritance, dynamic linking and multi-threading. They use a big-step semantic to describe the object-oriented features and use small-step semantics (structural operational semantics) to define the semantic of the concurrency. They are not concerned with typing. Their specification is on one side executable and on the other side it will be the basis for formal verification of Java programs.

M. S. Arefin et al. [7] showed structural operational semantics of Java interfaces. They showed how structural operational semantics is helpful for understanding the structure of Java interfaces.

P. D. Mosses [8] is working on Modular approach of Structural Operational Semantics (MSOS). They are trying to show MSOS for Java type sound.

Ryder et al. [9] conducted a study of the usage patterns of exception-handling constructs in Java programs. Their study offers an evidence to support my belief that exception-handling constructs are used frequently in Java programs and more accurate exception flow information is necessary. There are several research directions for exception constructs. The one is enabling a developer to make better use of exception mechanism, which includes analysis of uncaught exceptions, analysis of exception flow to facilitate understanding of the exception behavior. In Java, the JDK compiler ensures, by an interprocedural analysis, that clients of a method either handle the exceptions declared by that method, or explicitly redeclare them. Robillard and Murphy [10] have developed Jex: a tool for analyzing exception flows in Java. They describe a tool that extracts the flow of exceptions in a Java program, and generates views of the exception structure.

B. Chang et al. [11] proposed inter procedural exception analysis that estimates uncaught exceptions independently of programmer's declared exceptions. They compared their analysis with JDK-style analysis by experiments on large realistic Java programs, and have shown that their analysis is able to detect uncaught exceptions, unnecessary catch and throws clauses effectively.

In this paper the structural operational semantics of Packages in Mini Java is defined. In comparing with other semantics (denotational, axiomatic) the structural operational semantics seem to be simpler to understand. It may even be argued that the denotational one is a great deal more complex, because it requires an understanding of fixed points.

III. MINI JAVA

Mini Java is a subset of Java that contains some important properties of Java. Below we have provided the abstract syntax [2] of Mini Java on which we will work. Nonterminals appear in italics, identifiers with the suffix Id (e.g. ClassId) indicate the identifiers of newly declared entities whereas identifiers with the suffix Name (e.g. ClassName) are entities that have been previously declared. The keyword appears in bold.

```

n          ::= an integer
Class      ::= class ClassId [extends ClassName]
              {ClassVarDec (MethodDec)*}
MethodDec  ::= AccessMode ReturnTyp MethID
              (Para) {MethodBody}
MethodBody ::= VarDec Command ; return
              [Expr]

```

```

ClassVarDec ::= ε
              | ClassVarDec; ClassVarDec
              | AccessMode int VarId
              | AccessMode boolean VarId
              | AccessMode ClassName VarId
VarDec      ::= ε
              | VarDec; VarDec
              | int VarId
              | boolean VarId
              | ClassName VarId
AccessMode  ::= public | private | protected
ReType     ::= int | boolean | void |
              ClassName
Para        ::= ε
              | para, para
              | int VarId
              | boolean VarId
              | ClassName VarId
Commands    ::= ε

```

IV. ENVIRONMENT AND STATES

The environment of a program contains all mapping from identifier to denotable value known to the phrase at an instant. The state (σ) of a program contains all mapping from location to some value, which is storable or undefined. It is a snapshot of the contents of the program memory of the abstract machine. Thus, the state provides the means of storing temporarily the values that needed to be manipulated

IV. HOW JAVA PROGRAM ELABORATED AND INTERPRETED

The environment can be classified into two parts, class environment (η) and working environment (ρ). Here is how the Java program deals with them.

Step 1: Before the execution of the main method, class declarations are elaborated. The result is a class environment (η). Class environment of a program contains all mapping from identifier to class abstraction. Class abstraction of a class will contain all needed information (field attributes, method abstraction and super class name) of that class. It can be defined as follows:

```
ClassAbn ::= { { SuperClassName FieldAttr*
MethodAbn* } }
FieldAttr ::= (AccessMode Type FieldName)
MethAbn ::= (AccessMode MethodName ArgumentType
ReturnType MethodBody)
Type ::= int | boolean | ClassName
AccessMode ::= private | public
ArgumentType ::= () | (T1f1, ..., Tzfz)
Where z ≥ 0 and fi is a name of a formal parameter
(i ≤ z) And Ti is a Type (i ≤ z)
ReturnType ::= void | Type
```

Step 2: The execution of the main method starts and working-environment (ρ) will be created by declarations in the main method.

IV. DEVELOPING SEMANTIC FUNCTION FOR PACKAGE DECLARATION

In this section, we have provided the detail developing procedure of SOS of packages in Java. For this purpose, we have provided the required grammar and an example based on which we have developed the semantic function.

A. Package Declaration

A package declaration introduces a new technique where each class and interface defined in the source file will automatically be added to the package having the name specified by package name. A Package consists of a number classes, interfaces and sub packages. General form of package declaration is given below.

```
PackageDeclaration ::= SystemPackageopt package
PackageName Nestedopt PackageBody
SystemPackageopt ::= import System package name
Nestedopt ::= import NestedpackageName
packageBody ::= packageMember Declarations
packageMember Declaration ::= ( InterfaceDeclaration*,
ClassDeclaration * )
IfaceDeclaration ::= IfaceModifieropt interface IfaceName
ExtendsIFacesopt IfaceBody
```

```
IfaceModifier ::= public
ExtendsIFacesopt ::= extends SuperInterfaceName+
IfaceBody ::= { IfaceMemberDeclaration }
IfaceMemberDeclaration ::= MethodDeclaration*
ConstDeclaration*
MethodDeclaration ::= AccessModeopt ReturnType
MethodName (para)
ConstDeclaration ::= AccessModeopt Type Final-
varName= value
AccessMode ::= public
ClassDeclaration ::= ClassModifieropt class Class Name
superopt Interfaceopt ClassBody
Superopt ::= extends SuperClassName
Interfaceopt ::= implements InterfaceName1,
.....,InterfaceNameN
ClassBody ::= { ClassMemberDeclaration }
```

Below we have provided our own package definition, which will be used for developing semantic functions in later section. In the following example keywords are written in bold.

```
import java.util.* //System Package
package pack_01 //User Defined Package
import pack_01.nested1.* //Nested Package
public class class_01
{
    private int a ; float b ;
    protected int c;
    public void display() {MethodBodyOfdisplay} ;
    public void getdata() {MethodBodyOfgetdata} ;
}
public interface IFace_1
{
    void meth1 ();
    int meth2 (int i);
    int Y=1; int N =0; }
public interface IFace_2
{ void meth3 (); }
public interface IFace_3 extends IFace_1, IFace_2
{ void meth4 (); }
public class class_02 extends class_01
{
    double z;
    public int display1() {MethodBodyOfdisplay1}; }
public class class_03 implements IFace_1, IFace_2
{ int p ; private float q;
    public void meth1() {meth1Body};
    public int meth2 (int i) {meth2Body};
    void nonIfaceMethod () {nonIfaceMethodBody}
}
package pack_01.nested1
public class class_05
```

```
{
  int m; float n;
  public void display2( ){MethodBodyOfdisplay2};
}
```

B. Package Abstraction

Package abstraction of a package will contain all needed information of that package. When a package declaration is found in a Java Program, the information about that package will be kept as a package abstraction.

```
Package Abn ::= { SystemPackage PackageName
NestedPackage InterfaceAbn ClassAbn }
InterfaceAbn ::= {SuperIFaceName MethodAbn*
ConstAttr* }
MethodAbn ::= (AccessMode MethodName
ArgumentType ReturnType Body )
ConstAttr ::= ( Access Type VarDeclarator ConstValue)
ClassAbn ::= (SuperClassName FieldAttr* MethodAbn*)
FieldAttr ::= (AccessModes Type FieldName )
MethodAbn ::= (AccessMode MethodName ArgumentType
ReturnType Body )
```

C. Semantic Functions

Several semantic functions are necessary to define in order to process and keep important information about packages.

CreateFieldAttr is a semantic function that will take variable declaration in a class declaration as an argument. It will return field attribute as a result. Several variable declarations will be processed one by one.

CreateMethodAbn is a semantic function that will take method declarations in a class declaration as an argument. It will return method abstraction as a result.

CreateClassAbn, *CreateExtendClassAbn* are semantic functions that will take class declarations in a package declaration as an argument. As every class is an extension of class object, so first function will return object as super class name, which is called class abstraction. The second function will take super class name, variable declarations and method declarations as argument.

v range over variable declaration in a class
m range over method declaration in a class
s range over super class name
I range over interface names

$$\frac{\text{CreateFieldAttr}(v) = \text{VarAttr}^* \quad \text{CreateMethodAbn}(m) = \text{MethodAbn}^*}{\text{CreateClassAbn}(v, m) = \text{ClassAbn}}$$

$$\frac{\text{CreateFieldAttr}(v) = \text{VarAttr}^* \quad \text{CreateMethodAbn}(m) = \text{MethodAbn}^*}{\text{CreateExtendClassAbn}(s, v, m) = \text{ExtendClassAbn}}$$

CreateInterfaceAbn and *CreateExtendsInterfaceAbn* are semantic functions that keep necessary information about Interfaces declared in a package declaration.

w range over constant declarations in an interface
n range over method declaration in an interface
declaration

$$\frac{\text{CreateConstAttr}(w) = \text{ConstAttr}^* \quad \text{CreateMethodAbn}(n) = \text{MethodAbn}^*}{\text{CreateInterfaceAbn}(w, n) = \{ \{ _, \text{ConstAttr}^* \} \text{MethodAbn}^* \}}$$

I range over super interface names

$$\frac{\text{CreateConstAttr}(w) = \text{ConstAttr}^* \quad \text{CreateMethodAbn}(n) = \text{MethodAbn}^*}{\text{CreateExtendIfaceAbn}([I_k]_1^n, w, n) = \{ \{ [I_k]_1^n \text{ConstAttr}^* \text{MethodAbn}^* \} \}}$$

IsSameSignature is a semantic function that takes method declaration in the interface definition and method declarations in the class declaration. If all the methods declared in the interface exist exactly in the class declaration (fulfilling all the requirements mentioned above), and then it returns **true**, otherwise it returns **false**.

IsSameSignature(methDeclarationsInIface,
methDeclarationsInClass) = **true** | **false**

CreateClassAbnImplement is a semantic function, which takes interface names (the interfaces that are implemented by that class), variable declarations and method declarations of the class as its arguments. It will return *ClassAbn* as a result.

CreatePackageAbn and *CreateNestedPackageAbn* are semantic functions that will take class declarations and interface declarations as arguments. These functions will return package abstractions as a result. The first function imports extra argument the system package name. The creation of package abstraction is explained with the help of example 1 and example 2.

Example 1: Creation of package abstraction of package pack_01.

```
importSystemPackageName    import Java .util.*
importNestedPackag        import pack_01.Nested1
```

CreateClassAbn

$$\left\{ \begin{array}{l} \text{(private int a) (float b)} \\ \text{(protected int c)} \\ \text{public void display ()} \\ \quad \{MethodBodyOfdisplay\} \\ \text{public void getdata ()} \\ \quad \{MethodBodyOfgetdata\} \end{array} \right\}$$

=

$$\left\{ \begin{array}{l} \text{Object (private int a)} \\ \text{(_float b)(protected int c)} \\ \text{public display () void} \\ \quad \{MethodBodyOfdisplay\} \\ \text{public getdata () void} \\ \quad \{MethodBodyOfgetdata\} \end{array} \right\}$$

CreateExtendClassAbn

$$\left\{ \begin{array}{l} \text{class_01, _ double z,} \\ \text{public void display1 ()} \\ \quad \{MethodBodyOfdisplay1\} \end{array} \right\}$$

=

$$\left\{ \begin{array}{l} \text{class_01, _ double z} \\ \text{(public display1() void)} \\ \quad \{MethodBodyOfdisplay1\} \end{array} \right\}$$

CreateInterfaceAbn

$$\left\{ \begin{array}{l} \text{(void meth1 (); int meth2} \\ \text{(int i); int Y =1; int N = 0;)} \end{array} \right\}$$

=

$$\left\{ \begin{array}{l} \text{_, ConstAttrOfIface_1,} \\ \text{MethodAbnOfIface_1} \end{array} \right\}$$

CreateExtendIfaceAbn

$$\left\{ \begin{array}{l} \text{([IFace_1, IFace_2]} \\ \text{(void meth4 ())} \end{array} \right\}$$

=

$$\left\{ \left\{ \begin{array}{l} \text{[IFace_1, IFace_2] (public} \\ \text{meth4 () void) } \end{array} \right\} \right\}$$

CreateClassAbnImplement

$$\left\{ \begin{array}{l} \text{IFace_1,} \\ \text{int p; private float q;} \\ \text{public void meth1()} \\ \quad \{meth1Body\} \\ \text{public int meth2 (int i)} \\ \quad \{meth2Body\} \\ \text{void nonIfaceMethod ()} \\ \quad \{nonIfaceMethodBody\} \end{array} \right\}$$

=

$$\left\{ \begin{array}{l} \text{Object (public int Y 1) (public} \\ \text{int N 0) (_ int p) (private float q)} \\ \quad \text{MethodAbnOf_meth1} \\ \quad \text{MethodAbnOf_meth2} \\ \quad \text{MethodAbnOf_nonIfaceMethod} \end{array} \right\}$$

CreatePackageAbn

$$\left\{ \begin{array}{l} \text{import Java .util.*,} \\ \text{import Pack_01.Nested1,} \\ \\ \left\{ \begin{array}{l} \text{(private int a) (float b)} \\ \text{(protected int c)} \\ \text{public void display ()} \\ \quad \{MethodBodyOfdisplay\} \\ \text{public void getdata ()} \\ \quad \{MethodBodyOfgetdata\} \end{array} \right\} \\ \\ \left\{ \begin{array}{l} \text{class_01, _ double z,} \\ \text{public void display1 ()} \\ \quad \{MethodBodyOfdisplay1\} \end{array} \right\} \\ \\ \text{(void meth1 (); int meth2} \\ \text{(int i); int Y =1; int N = 0;)} \\ \\ \left\{ \begin{array}{l} \text{([IFace_1, IFace_2]} \\ \text{(void meth4 ())} \end{array} \right\} \\ \\ \left\{ \begin{array}{l} \text{IFace_1,} \\ \text{int p; private float q;} \\ \text{public void meth1()} \\ \quad \{meth1Body\} \\ \text{public int meth2 (int i)} \\ \quad \{meth2Body\} \\ \text{void nonIfaceMethod ()} \\ \quad \{nonIfaceMethodBody\} \end{array} \right\} \end{array} \right\}$$

$$\left\{ \left\{ \begin{array}{l} \text{Java, _util, pack01.nested1} \\ \text{Object (private int a)} \\ \text{(_float b)(protected int c)} \\ \text{public display () void} \\ \quad \{MethodBodyOfdisplay\} \\ \text{public getdata () void} \\ \quad \{MethodBodyOfgetdata\} \end{array} \right\} \right\}$$

$$\left\{ \begin{array}{l} \left\{ \begin{array}{l} \text{class_01, _ double z} \\ \text{(public display1() void)} \\ \quad \{MethodBodyOfdisplay1\} \end{array} \right\} \\ \\ \left\{ \begin{array}{l} \text{_, ConstAttrOfIface_1,} \\ \text{MethodAbnOfIface_1} \end{array} \right\} \\ \\ \left\{ \left\{ \begin{array}{l} \text{[IFace_1, IFace_2] (public} \\ \text{meth4 () void) } \end{array} \right\} \right\} \end{array} \right\}$$

$$\left\{ \begin{array}{l} \text{Object (public int Y 1) (public} \\ \text{int N 0) (_ int p) (private float q)} \\ \quad \text{MethodAbnOf_meth1} \\ \quad \text{MethodAbnOf_meth2} \\ \quad \text{MethodAbnOf_nonIfaceMethod} \end{array} \right\}$$

```

ConstAttrOffface_1 = (public int Y 1) (public int N 0)
MethodAbnOffface_1 = (public meth1 ( ) void) (public
                    meth2 (int i) int)
MethodAbnOf_meth1   = (public meth1 ( ) void
                    meth1Body)
MethodAbnOf_meth2   = (public meth2 (int i) int
                    meth2Body)
MethodAbnOf_nonIfaceMethod = ( _ nonIfaceMethod ( )
                    void nonIfaceMethodBody)

```

$$\text{CreateClassAbn} = \left\{ \begin{array}{l} \text{int m; float n;} \\ \text{public void display2(} \\ \quad \{ \textit{MethodBodyOf display2} \}; \end{array} \right\}$$
$$\begin{aligned} \text{CreateNestedPackageAbn} & \left[\begin{array}{l} \text{int m; float n;} \\ \text{public void display2()} \\ \quad \{ \textit{MethodBodyOfdisplay2} \}; \end{array} \right] \\ = & \left\{ \begin{array}{l} \text{pack_01, object, (_int m)} \\ \quad \quad \quad (_ \text{float n}) \\ \text{public display2 () void)} \\ \quad \{ \textit{Method body of display2} \} \end{array} \right\} \end{aligned}$$

Package abstraction that we have got by using the functions *CreatePackageAbn* and *CreateNestedPackageAbn* will be added to the package environment.

$$\frac{\text{CreatePackageAbn}(t, u, x, y, z) = p}{\langle \text{package } d, t, u, x, y, z, \eta, \rho, \sigma \rangle \Rightarrow_d \langle _, \eta', \rho, \sigma \rangle}$$

Here, $\eta' = \eta[p/d]$

We have given a formal description of structural operational semantics for a solid subset of Java called Mini Java. Structural operational semantics of several important aspects of packages in Java programming were clearly written down. With that we have showed how structural operational semantics is helpful for understanding the structure of packages. It can also be concluded that SOS of this important property of Java can serve as a basis of understanding and reasoning how programs behave. Moreover, these semantics can be used for various kinds of analysis and verification. These semantics may be provided for reference –potentially even for standardization.

Abstract - Land management is an important issue for Bangladesh, where the land registration process is a major barrier to the economic growth of the country. Technology and IT can greatly facilitate the creation of a proper land management system. This paper focuses on various issues and problems related to the current system of land management. It offers an alternative management system using IT features and shows a comparison between the existing system and the proposed system. It is shown that a digitized land management system in Bangladesh can bring positive outcomes in the entire process by minimizing hassle, expenditure, time, and staff dishonesty.

Index Terms - Land, Records, Bangladesh, Automated

I. INTRODUCTION

Land dominates the life of almost every person in Bangladesh, particularly in rural areas. A proper recording of land rights, along with the need for a sound land management system is important for a largely agrarian economy under heavy population pressure. The existing land management system is very ineffective and cumbersome at best. The governmental system of land trading is very time consuming and problematic. Taking the advantage of this intricate system, a section of personnel are grabbing the properties of the weak. As a result, the number of lawsuits, illegal possessions, strife, scuffles, and other crimes are increasing day by day. The present superannuated land management system is responsible to a great extent for the deteriorating law and order situation of the country.

II. PRESENT SYSTEM

The directorate of Land Records and Surveys (DLRS) is entrusted with the responsibility of carrying out cadastral surveys and preparation and maintenance of Record Of Rights (ROR) in respect of every parcel of land in the country. With the passage of time, the organizational structure of the Directorate changed considerably to meet new requirements.

There are two parts in the preparation of the record of rights. The first part is to draw a revised mouza map showing changes in location, area and characteristics of land. The second part is to prepare the Khatian (cadastre)

including the ownership, area and character of land. These two parts together are called record of rights. The phases followed in the survey and preparation of record of rights are traverse survey, plot to plot survey, Kistwar (demarcation of boundary), Khanapuri (preliminary record writing), Bujharat (local explanation), attestation, draft publication, hearing of objections, appeal, final Junch (checking), printing and publication of Khatian.

A. Land Sale Registration

One fundamental aspect of land registration in Bangladesh is that it is merely the record of an isolated transaction. It only shows that a particular transaction took place but it does not establish whether the parties are legally entitled to enter into such a transaction. In other words registration takes place without any critical examination of relevant records. This kind of registration of deeds in Bangladesh has been in force since the Registration Act of 1908.

The amount of tax levied on the immovable property transferred is 10 percent of the total value of the property. When the buyer and the seller of a parcel of land come to an agreement on the transfer of land, a deed is prepared on the stamp of required value with the help of a deed writer, and then it is presented before the Sub-Registrar for registering it and for putting the official seal on it. Both the buyer and the seller have to appear before the Sub-Registrar who takes cognizance of the land transfer and puts his signature with the official seal. The registered deed is copied in the relevant volume. It takes about 9-12 months to get the registered deed. The deed prepared by the deed writer contains a lot of unnecessary words and sentence, which could be avoided. At present the land records kept in the Tehsil office are not checked to find out whether the seller is the real owner of the land or not, or if any other persons have got any interest in the plot of land in question. There are instances of false registration in both urban and rural areas. The incidence of false registration is much higher in urban areas. A plot of land may be sold to different people leading to decades- long litigation.

A. Detailed Mapping

Information on the area and location of land can be collected through four different approaches:

- Ground Survey,
- Aerial/Satellite Photography,
- GPS based data collection system and
- Existing information of lands in the land offices.

Bangladesh is well suited for cadastral mapping by vertical air photographic techniques. Its primary advantage is its flatness and air visibility of plot boundaries. A scale of 1:12,000 will be sufficient enough in most areas. The main steps in aerial survey will consist of:

- i) taking of photographs,
- ii) rectification (1:12,000 scale),
- iii) correction in site,
- iv) providing a survey number,
- v) area calculation,
- vi) preparation of draft Khasra,
- vii) preparation of map with internal details,
- viii) public review of draft Khasra and map
- ix) and the final publication.

Using aerial photography methods will have three main advantages:

First, contrary to the prevailing notions it will be less costly and will have less man-management problems to deal with. Second, it will cut down the time taken for conventional cadastral settlement operations of about ten years by at least three years. And finally it will yield much more accurate results. However, this method will require substantial initial investment in terms of purchase of equipment and aircraft and training of officials.

B. Creating Effective Database

In the existing procedure, the land records stored in the Tehsil office are not checked to find out whether the seller is the real owner of the land or not. Retrieval of any information is very difficult which raises a question to the purpose the volumes of registers will serve. Computerization of registration records would therefore make the job much simpler and facilitate easy retrieval of registration records. The new system will handle all the manual activities of land records and tax using computerized database system. It will have database with a simpler format with the necessary information for the conveyance of the property. The database will contain information such as names and occupations of both buyer and seller, with their present and permanent addresses, the particulars of the land (lot number, JL number, name of mouza), the mode by which the seller became the owner

of the plot (i.e. purchase, inheritance, etc.), the classification of land, area of land, boundary demarcating, the value at which the land is being transferred, tax etc. In case of property inheritance the buyer field will be replaced by present owner and the seller field will be replaced by previous owner.

The effectiveness objectiveness of the database will include:

- Ensuring that the stored data can be used for a variety of applications like: record keeping, land registration, mutation, property tax and capital gain collection and resolving dispute.
- Maintaining data that are both accurate and consistent and avoiding data redundancy.
- Ensuring purposeful information retrieval system so that all the data required for current and future applications will be readily available.
- Ensuring efficient upgrading system etc.

C. Database Organization (Logical and Physical Views)

The database is to be shared by many users. Users at different levels will have different user schema. Examining the required views an overall logical model of the database will be developed. Finally the logical model of the database will be transformed into a corresponding physical database design. The physical design will involve fundamental information on how data will be stored and related as well as how they will be accessed. The figure below shows how the user reports and user schema will be related to the logical model and physical design.

D. Features of the Proposed System

The Land Information Management Systems software will be an integrated system wherein the user will be provided with the facility to navigate and perform all operations from Data Entry to Data Validation to Records Display through one single Interface. The main modules available in the LIMS will be as follows:

Data Entry Module: The Data Entry Module will have interfaces to enter data of the registers that are maintained for revenue purposes. Facility to view and take prints for each and every register will be provided along with the option to view and list the contents of the registers.

Security Module

Considering the confidential and sensitive nature of the land records, the issue of security is to be given the highest priority while designing the software. The important features of the Security Setup will be:

Restricted user access to records wherein only authorized land functionaries have permission to edit records in the database.

* Digital signature for authentication; All relevant employees will have the option to encrypt their digital signatures in the document that they will handle.

* A separate module for tracking each and every transaction that takes place in the database along with the name of the user responsible for such action.

* Backup facility to help in regeneration of past records in case of accidental or deliberate deletion.

The security of the software along with the entire system will be maintained at three separate levels:

Logical Level:

The system will permit the user with correct passwords or authorization codes to enter the system or a particular part of the database. There will be at least three different level of security access:

1) Level 1: Employed personnel at the supreme level will be allowed to view all the stored land records. They will be allowed to add delete and edit land records related to buying, selling and mutation of land. They will also be allowed to view the taxation records on a certain piece of land.

2) Level 2: Employees at the second level will be allowed to view, add and edit the existing data, i.e. they will be able to store land sell and mutation records. However, to delete any land record from the database, they will require special permissions or they will have to hand over the word to the level 1 user.

3) Level 3: The database will have a limited portion of the each entry as “read only to all”. Any one interested to view the buying and selling records on any piece of land will be able to do so by paying certain government fees.

Graphical Module

This module will be developed using VC++ and Active X components and will have a linkage with the GIS software. This is primarily the map display module of the system. It will provide all the tools that are available in any of the Graphic Viewer Software of international repute. The noteworthy features of the graphical module will be:

- 1) Map Display
- 2) Display the maps within a predefined window area.
- 3) Zoom In, Zoom Out, Pan View, Fit View, Refresh View, and Window Zoom facilities.
- 4) Facility to view legends like schools, masjids, graves etc.
- 5) Edge-matched maps within the villages so that one village will correspond to one map in the digital environment. However, in the real world, a village map may well be distributed over multiple sheets.
- 6) The spatial database (maps) generated on a true scale thus keeping the dimensions accurate.

Query Capabilities

The system will provide facility to query on the owner name, Khatian number in addition to random selection of parcels from the map and querying on them. Since the spatial and the textual data will be integrated, all queries have spatial components, which will give the user the flexibility to pinpoint locations on the map. In addition, a number of Reports will be designed keeping the daily requirements of the district administration in view. The reports to be available at proposed system will include:

- 1) List of Government owned lands
- 2) List of revenue assigned land's
- 3) Status of mutation transactions
- 4) Mutation types.

Solution Architecture to the Proposed System

The Solution provided for proposed network system will have a decentralized structure. A computer at the District level will act as the local server whereas all the other machines installed in the Thana Headquarters and other focal points will be designated as clients. Connectivity between the clients and the local server will be established by means of an appropriate method like Wi-Max. The local servers at the District levels can be connected to the main server via the optical fiber backbone of Bangladesh Railway.

The software will be designed following the client/server architecture in order to improve the usability, flexibility, interoperability and scalability of the solution as compared to a centralized system. Here, a client will be defined as a requester of services and a server as the provider of services.

Strategic Approach to the Proposed System

Ascertaining the overall feasibility of the IT implemented land management system relates to clarifying the objectives of the new system and determining if the system moves towards its objectives in some way. The objectives of the proposed system include:

- * Developing a digital archive and retrieval system,
- * Automating manual procedures to improve in various ways like reducing errors, increasing speed and accuracy and cutting down employee time required,
- * Smoothing the land purchase and sale registration process,
- * Reducing law suits related directly or indirectly to land,
- * Introduce transparency in the government thereby reducing corruption.

Technical Feasibility: The proposed system requires around 534 computers and 138 printers that are to be distributed to all the corners of the country.

Number of computers:

Client computers at the Thana levels : $460 \times 1 = 460$
 Local servers at the District levels : $64 \times 01 = 64$
 Main server and backups at the Capital : $5 + 5 = 10$
 Total : 534 computers

Number of Printers:

Printers with local servers : $64 \times 2 = 128$
 Printers with Main servers : 05
 Additional printers : 10
 Total : 138 printers

Fig. 2 Architecture of the Proposed System

V. DIFFICULTIES OF CHANGE:

There will be several obstacles to moving forward from the present land management system to the proposed system. Some of the difficulties the new system has to overcome are:

- * The Directorate of Land Records and Survey has earned notoriety for corruption and inefficiency.
- * The low level stuffs are temporary and they try to make as much as they can through corrupt practices.

* Powerful land owners try to induce officers to do undue favors.

* Corruption exits at the stage of attestation and objection hearing.

If the new system is implemented, not only will the corrupt system come down, the previous records of the employees will be exposed to the public. Strong opposition from existing employees is to be expected.

TABLE 1
COMPARISON OF PRESENT AND PROPOSED SYSTEMS

Function	Process	Present System	Proposed System
Land Record System	Updating	Highly time consuming. About 46 years will be needed for total updating	Updating will be done immediately after the change. So no extra time will be needed.
	Intricacy	High intricacy	No intricacy
	Objection/Appeal	Takes several months to years for completion	A few days will be needed
	Manpower	DLRS has a total of 9098 stuffs for survey on payroll	Not more than one thousand people will be needed for the job
	Printing time	At least 28 years are required for printing all Khatians with current setup	It may take a few days for a whole Thana & the job can be done at several Thanass simultaneously
	Printing Cost	About 400/- per Khatian	About 2-3/- per Khatian
Land Sale Registration	Backlog	High backlog	No backlog
	Amount of Printing	10 copies per Khatian	As much as needed, whenever needed.
	Integrity	No linkage between DLRS & Collectorate setup	A linkage will be developed through computerized networked
	Information Dissemination	No information dissemination. The record is kept in the office where the transaction occurred	Information will be disseminated through computer network
	Immoral Behavior of Land Buyers	Tendency of understating actual land value for paying less stump duty	Due to stored up-to-date price no opportunity of understating.
	Deed Registration	Takes 9-12 months	1-7 days will be required

IV. COMPARISON BETWEEN PRESENT AND PROPOSED SYSTEM

The proposed Land Information Management System will help to improve efficiency and processing and. It can be an effective database, providing accurate information to both officials and the public. It will give a secure access of data and also check unauthorized manipulation. The system will speed up the present system significantly, introducing transparency in the government, and reducing corruption. Having a Relation Database LIMS can be integrated to other e-Governance Applications.

V. CONCLUSION

The present process of land registration process is a barrier to the economic growth of our country, and creates financial overheads on the trading of land. The problems occur mainly due to the backdated land record and storing system. The proposed system will greatly simplify the tasks, and become an effective replacement to the existing system.

Abstract— A real-time operating system (RTOS) is software which ensures that time critical events are processed as efficiently as possible. In this paper, an attempt has been taken to develop a real time operating system, named Preemptive Real Time Operating System (pRTOS), in which all of the important issues regarding to a real time application have been considered. In this pRTOS, strictly preemptive scheduling algorithm has been used. This scheduling policy makes sure that important tasks are handled first and the less important later. The Bitmap technique has been used to find out the highest priority task from the unsorted ready list. The complexity of this technique for selecting the highest priority task is $O(1)$, which is much faster than the linear search technique having complexity of $O(n)$. This pRTOS can support 64 priority levels ranges from 0 to 63. In addition with this, it is a highly configurable RTOS. Moreover, it can be adopted in a board range of hardware platform, say, Intel x86, MIPS, Hitachi SH, Power PC and Strong ARM processors. This RTOS has been tested on Intel x86 and from the obtained result, it has been found that our developed pRTOS can be used for various application, say, for automated industrial systems, control-systems, high-tech electronics/electrical products and home applications.

Index Terms — RTOS, Scheduling, Context Switching, Priority Resolution, Task Synchronization, Preemptive Real Time Operating System (pRTOS)

I. INTRODUCTION

Real-time computing is where system correctness not only depends on the correctness of logical result but also on the result delivery time. So the operating system should have features to support this critical requirement to render it to be termed a Real-time operating System (RTOS). The RTOS should have predictable behavior to unpredictable external events. "A good RTOS is one that has a bounded (predictable) behavior under all system load scenario i.e. even under simultaneous interrupts and thread execution [1]." A true RTOS will be deterministic under all conditions. These operating systems occupy little space from 10 KB to 100KB as compared to the General Operating systems which take hundreds of megabytes [2]. Many commercial embedded operating systems (RTOSs) are available on the market [3, 4, 5] and most of these

RTOSs have primitive real-time capabilities that are adequate for only very simple real-time applications. On the other hand, some real-time systems often require sophisticated scheduling capabilities to handle applications with high performance requirements.

With this background, in this paper, an attempt has been taken to develop a real time operating system, named Preemptive Real Time Operating System (pRTOS), in which all of the important issues regarding to a real time application have been considered. This operating system (pRTOS) has been developed to provide the optimized approach to handle the critical issues of scheduling and synchronization, response-time constraints, task priorities, latencies and deadlines, and inter-task communications. It also provides some additional services, say management of the resources, memory, tasks, and time.

II. BASIC REQUIREMENTS OF RTOS

The following are the basic requirements of an RTOS.

- Multitasking and Preemptability
- Task Priority Level
- Task Synchronization & Inter-task Communication
- Predefined latencies
 - Task switching latency
 - Interrupt latency
- Portability and Modularity
- Scalable
- Scheduling Policy

III. ARCHITECTURE OF THE DEVELOPED pRTOS

Fig. 1. illustrates the architecture of the developed RTOS. The aim of this work is to design a Real Time Operating System mainly with the following characteristics

1. Low overheads in terms of time, code size.
2. Ease of portability to other CPU architectures.

Fig. 1. Architecture of the pRTOS

From the point of view of portability, since it is very important to have a modular design, in which the hardware (CPU/board) dependent code must be clearly isolated from the hardware independent code, as a result, in developing this pRTOS, the design phase has been divided into two parts, these are,

- Processor independent part
- Processor dependent part

In this RTOS, the processor independent part has been written in C language. The processor dependent part has been written in assembly language. The necessities of processor dependent part is that the operations, such as, context switching involves of storing of the CPU register contents of the currently running process and loading of the parameters of new task into the CPU registers.

A. Scheduling Policy

The heart and soul of any operating system is its scheduler [6, 7]. We have used strictly preemptive scheduling algorithm in our developed pRTOS. In this policy, at any instance of time, only the highest priority task that is ready to run executes. If a task T_i runs, it means that all tasks T_j with priorities lesser than T_i are blocked. This scheduling policy makes sure that important tasks are handled first and the less important later. For example, in an aircraft cruise control system, the fight controller task

will have more priority than a task that controls the air-conditioning system.

Algorithm: Preemptive Scheduling

1. Task T_i with priority i is running.
 2. If (task T_i has finished){
 - a) Select the next highest priority task is ready to run.
- ```

}
Else{
 if (a task T_j ($j > i$) is in the ready list){
 a) Select the task T_j which is ready to run.
 }
 Else{
 Go to step 1.
 }
}

```

#### B. Priority Resolution Technique

Priority based task switching may kill considerable amount of time when searching of highest priority task is a great challenge. From this view point, a robust technique, called Bitmap technique, has been used in this RTOS which ensures single time find out the highest priority task [8, 9]. The complexity of this technique for selecting the highest priority task is  $O(1)$ . This is more faster than the linear search technique to find the highest priority task from the ready list whose complexity is  $O(n)$ .

### C. Context Switching and Interrupt Handling

Context switching means saving the context of the interrupted routine or task and retrieves or load the new context of the called routine or task. It becomes the responsibility of the RTOS to service this context switching. An interrupt is a signal that the hardware can send when it wants the processor's attention. It also becomes the responsibility of the RTOS to service these interrupt as immediately as it can at a "safe" time.

Two types of context switching method are developed in this RTOS.

**Task level context switch:** To perform task level context switch the following functions are developed:

- void pOSStartHighRdy(void);
- void OS\_FAR pOSCtxSw(void);

**Interrupt level context switch:** To perform interrupt level context switch the following function are developed:

- void pOSIntCtxSw(void);

### D. Task Synchronization & Inter-Task Communication

Semaphores have been used to achieve synchronization of tasks and resources. When semaphore is created, it is associated with a specific of tokens. Once a semaphore is created, tasks can request a specific number of tokens from the semaphore. When the requested number of token are available, the number of tokens in the semaphore is decremented, and given to the task. If the number of tokens exceed the number of available tokens, the tasks blocks. We have developed semaphore management API. Mailbox is an inter-task communication mechanism. A task posts a message in the mailbox and another task will read the message. This pRTOS has mailbox functions.

We have developed a structure (Semaphore or Mailbox Control Block) to maintain the Semaphore and Mailbox functionality.

Semaphore or Mailbox Control Block:

```
typedef struct sema_mailbox {
 UBYTE Wait_Group;
 UBYTE Wait_Table[8];
 UWORD SemaCnt;
 void *Pointer;
} OS_SEMA_MAILBOX;
```

**Wait\_Group:** Group corresponding to the tasks waiting for an event (Semaphore or Mailbox) to occur

**Wait\_Table[8]:** List of tasks waiting for event (Semaphore or Mailbox) to occur

**SemaCnt:** It is used to count when this structure is used in Semaphore

**Pointer:** It is used to point to a message in the mailbox and also used to make chain of SemaMailbox Control block.

## IV. EVALUATION OF INVOLVED FEATURES IN THE DEVELOPED pRTOS

The features which we have included and developed are listed below

1. To support multiple tasks in real-time applications, the pRTOS is multi-tasked and preemptible.
2. pRTOS supports 64 tasks out of which one are system Idle Task. pRTOS is a pre-emptive priority base scheduler with 64 priority levels within 0 to 63 assigned during task creation.
3. pRTOS is a portable operating system. Its code can be ported on many processors that are commonly used in the designing of real time application.
4. pRTOS has task synchronization and inter-task communication functions. It uses Semaphore, Message Mailbox for task synchronization and inter-task communication. pRTOS has semaphore functions, which are usable like event flags, resource acquiring keys or counting semaphores.
5. pRTOS handles multiple levels of interrupts i.e., the pRTOS is preemptible at task level and at the interrupt level as well.
6. pRTOS is extremely modular. It has a clear set of functions defined for doing jobs like task, semaphore, scheduling management and context switching.
7. pRTOS is scalable. The functions which are needed in our application can be predefined in a configuration file included in the application codes.
8. pRTOS uses strictly pre-emptive scheduling. This scheduling policy makes sure that important tasks are handled first and the less important later.

## V. TEST METRICS AND MEASUREMENT RESULTS

RTOS has strict timing constraints and it should respond, under all possible load condition, in a very

predictable way. Real time operating systems are required to be very deterministic. This means different latencies of the systems should be predictable. Best operating system should have minimum latency and least amount of standard deviation.

#### A. Context Switching Time

The operation of context switching has been developed in assembly language. The context switching time can be optimized by only using proper coding and it has been done in this work. It is included in the processor dependent part of the pRTOS. It can be recalled that context switching involves storing the CPU register contents of the currently running process and loading the new task parameters in the CPU registers. We have calculated the required bus cycle in executing the assembly code for context switching which is shown in Table I.

TABLE I  
MEASUREMENT RESULTS

| Test Metrics                   | CPU cycles |
|--------------------------------|------------|
| Task Level Context Switch      | 225        |
| Interrupt Level Context Switch | 177        |

#### B. Scheduling Complexity

The scheduling complexity characterizes the time required by the RTOS to select a ready task. This duration depends not only on the scheduling algorithm, but also on the number of ready tasks when the algorithm runs. The scheduling algorithm of pRTOS uses Bitmap technique to find the highest priority task from the unsorted ready list. The complexity of this technique for selecting the highest priority task is  $O(1)$ . This is more faster than the linear search technique to find the highest priority task from the ready list whose complexity is  $O(n)$ .

#### C. Space Complexity

A true RTOS should occupy little space from 10 KB to 100KB as compared to the General Operating systems which take hundreds of megabytes. RTOS should be scalable. Only the OS functions that are necessary part of

the applications codes, thus having reduced memory requirements. The functions needed for task servicing, inter-process communications, etc. must be predefined in a configuration file included in the user codes. This pRTOS is highly scalable. It occupies only 25 KB memory if we consider all of its functionality and its kernel.

## VI. CONCLUSION

There is a need of real-time operating system (RTOS), which can provide the solution of the complex issues of real time-time system and can provides some services of different functionalities. Our developed pRTOS can be used for various applications, say, for automated industrial systems, control-systems, high-tech electronics/electrical products and home applications.

**Abstract**—Traditional legacy HTML based web sites/ page can be thought of as *web services* because the dynamic web pages can take user input argument via web forms and response to user query. The ability of agents and services to automatically locate and interact with unknown partners is a goal for Web based Data Integration system. This "serendipitous interoperability" is hindered by the lack of an explicit means of describing what web pages are able to do and in order to do it what input it takes and what output it produces, that is what is their *capabilities* [1]. The tremendous success of the WWW is countervailed by the efforts needed to search and find relevant information. For tabular structures embedded in HTML documents, typical keyword or link-analysis based search fails. The next phase envisioned for the WWW is automatic ad-hoc interaction between intelligent agents, web services, databases and semantic web enabled applications. A large amount of information available on the Web is formatted in HTML tables, which are mainly presentation oriented and are not suited for database applications. As a result, how to capture information in HTML tables semantically and integrate relevant information is a challenge. We are envisioning another layer of web abstraction where user can query intra web document table like structure. Our prototype application is based on *WebFusion* and an ad hoc query language *BioFlow* [2], [3], [4], [5], [6] a software agent that can simulate a person interacting with web search forms and extracting information from the resulting pages by means of an API. We need to develop a framework which is able to query search web forms and the web page tables in a SQL way. In this context we also report a Java based implementation for integrating Flybase and AlignACE site.

**Index Terms**—Table structure, Table modeling, Web mining, Ontology generation, Semantic Web, Intelligent Wrapper, Web Information Extraction, HTML forms, Web Data Integration, extraction ontology, Hidden Web, Web Automation.

## I. INTRODUCTION

Turning the current Web into a Semantic Web requires automatic approaches for annotation of existing data since manual annotation approaches will not scale in general. By "capability" we mean an operation offered by the provider of a data source to a user to extract data from the services

data store and structure it for transfer to the customer [7]. By Web resource we mean any information, data structure, representation which can be queried by some language. Example of web resource are: URLs, links, Web Forms which can be filled for query, outgoing URLs, Keyword, attribute which can be found inside Meta Tag (this conforms to key string matching problem) or anywhere in web page; Repeated structure found in web page (e.g Table, list). Information extraction from the Web is the process of extracting data from a set of Web pages in order to fill a given database schema. Web information extraction presents two particular features: (a) the input documents are semi-structured: they are neither raw data (full text) nor strictly typed (relational tables), but a structure is provided (typically by HTML tags) (b) the information sources are heterogeneous, i.e. the same kind of information is often presented in different formats. A Web IE system receives two kinds of input: a DB schema that represents the information the user wants to retrieve; a set of IS (Web sites) containing the data to be extracted.

Such a system aims at populating the database with data extracted from the sources and must provide mechanisms for dealing with semi-structured documents and for accessing heterogeneous information sources. The presence of heterogeneous information sources, whose models are not known a priori, makes scalability one of the main features for these systems. In other words, the system must be easily programmed for dealing with a large number of different information sources. An important design element for these systems is the representation techniques used for modelling the database schema and the information sources. Indeed, this issue permits a classification of approaches to Web Information Extraction, which are as follows: *Manual extraction*, *Procedural extraction*, *Declarative extraction* and *Automatic extraction*.

### A. Motivating Example

**Example 1.** Suppose a user want to do the following series of activities on a site:

- Go to [www.amazon.com](http://www.amazon.com).
- Type "Ruby" into the search text field.
- To narrow down the results, click "Books",
- then for further narrowing click "Computers & Internet" in the left sidebar.

By fetching the web page from the URL and parsing and analyzing the links and auto form filling, the above tasks can be automated by our system. We call it *Web User Activity Automation*. Web task automation can be done by two different ways: *Recorded Macro* and *Programmable API*. We will go for the second one.

**Example 2.** Suppose a client want to search for Book from two sites [www.amazon.com](http://www.amazon.com) and [www.bn.com](http://www.bn.com) at once and see the combined result. Both the site offer advanced search web form. Traditionally the client has to visit both the sites iteratively filling the form and gather data manually. If a Web Data Ingetration System as envisioned by ours is present, the client has to submit the query once and the system will do the rest automatically on the fly.

**Example 3.** Let us consider the following SQL query for book search from amazon site.

```
SELECT Title, Rating
FROM amazon.com
WHERE Title like "Discrete Mathematics"
AND Rating=5;
```

By analyzing the advanced search option of amazon, we see that *Title* attribute can be mapped to Interface Schema, whereas *Rating* attribute can be mapped to Result Schema. For the above example with the Interface that are available in amazon site, user query can be satisfied only for the *Title* attribute, not for *Rating* attribute. Consequently, user will see a lot of tuples containing all the *Rating* returned in response to query, whereas he/she is only interested to see record corresponds to Rating 5. Our system can solve these types of user query by efficiently mapping user query to site.

**Technical Challenges:** The web forms of the two sites look the same but how to automatically fill the form is much more difficult as will be clear from the following discussion. The client will have a GUI, the query will be submitted from there. The query need to be rewritten as per the mappings of the respective site. Our proposed web resource capability description/ discovery method will take care of the mappings. Each site's capability (*form information*) will be captured and stored in resource description repository. The envisioned overall architecture is shown in the following figure 1. In response to the form, we will have tabular data. Semantic enrichment of the tabular data will be made semi-automatically and through ontology and human knowledge. Tabular schema will also be stored

Fig. 1. Resource Description /Discovery Mechanism

in the resource description repository. Thus our *resource capability description* will be focused toward handling web form and representing table schema, i.e column name identification and label assignment. The rest of the paper deals with based on the above two ideas. The current research is our ongoing work where we proposed and identified a model for web data integration. The current focus of our research is to describe a web page so that some body else can later use to query source. We have developed prototypes for bioinformatics web data integration. To the end, our system can solve Web Data Intergration problem in an ad hoc manner as follows:

```

Define function RegulatoryRegion
Extract 800bp sequence
Using wrapper FlyBaseToACE in ontology GeneMapping
From URL Flybase
Submit FBgnNum string;

Define function motif
Extract 6..8bp sequence
Using wrapper FlyBaseToACE in ontology GeneMapping
From URL AlignACE
Submit 800bp string;
```

### B. Related Work

Turning the current web into a semantic web requires automatic approaches for annotation of existing data since manual approaches will not scale in general. [8] presented a method for automatically filling in forms to retrieve the associated dynamically generated pages. They consider the task of duplicate record elimination and uses a stratified sampling approach to decide when a particular source has been fully extracted. Using their approach automated agents can begin to systematically access portions of the "Hidden Web". The Hidden Web Exposer (HiWE) project at Stanford proposed a way to extend crawlers beyond

the Publicly Indexable Web (PIW) by giving them the *capability* to fill out Web forms automatically. The related work references are the following: [9], [8], [10], [11], [12],[13], [14]. [15] presented **DeLa**, which reconstructs (part of ) a "hidden" back-end database. It does this by sending queries through HTML forms, automatically generating regular expression wrappers to extract data objects from the result pages and restoring the retrieved data into an annotated (labelled) table. The present research work is our ongoing work where we have identified and proposed ontology based and declarative workflow query language for ad hoc web data integration on the fly [16], [17]. Our experimentation on Bioinformatics Web Data and Service Integration has also been reported in another work [18].

## II. DEEP WEB QUERY MODEL

Structured Web databases can be queried via query forms or through Web service interfaces. We uniformly refer to both access methods as "query interfaces". Through query interfaces, data consumers (e.g end users) are able to express their information needs by imposing selection conditions on certain attributes of interest. Our system views a Web database as a single relational table  $DB$  with a set of queriable attributes  $A_q = \{attr_{q1}, attr_{q2}, \dots, attr_{qn}\}$  (interface schema) and a set of result attributes  $A_r = \{attr_{r1}, attr_{r2}, \dots, attr_{rm}\}$  (result schema). Each  $attr_{qi} \in A_q$  represents the queriable attribute through the query interface, while the result attribute  $attr_{rj} \in A_r$  corresponds to the attributes displayed in the result pages. Each query operation can be modelled using SQL syntax as:

```
SELECT {attrr1, attrr2, ..., attrrm}
FROM DB
```

```
WHERE attrq1 = valq1, attrq1 = valq1, ..., attrqn = valqn
```

where  $val_{qi}$  is the corresponding attribute value filled into the query form.

We model the web site as  $S \subseteq Q \times R$ , where  $Q$  is the query interface schema and can be represented as  $Q \subseteq F \times P$  and  $R$  is the result schema, can be represented as  $R \subseteq L \times V$ . The semantics of the above definition is as follows: we have a set of form label  $F$  and a set of corresponding parameter  $P$ . In response to the web form, we will have tabular data, which have a set of values  $V$ . The label  $L$  of the values  $V$  may or may not be in the web page. One of the major fundamental research problem is how to find  $L$ , given  $F, P, V$ . This is a separate research topic and we address the problem somewhere else.

## III. ONTOLOGY DEFINITION

Ontologies are a convenient way to describe relationships among the terms in the universe being modeled for the purpose of heterogeneous information integration on the web. It is also a convenient way to describe extraction

rules for web resources in the form of wrappers. So, in BioFlow, we allow schema mapping relationships and data extraction rules for web sites be included for the use by the query engine. An ontology mainly captures three types of relationship: *synonym*, *isa* and *partof* [19]. The general structure of ontology definition is shown below - for a given ontology  $o$ , its definition contains a set of schema mapping statements and a set of wrapper statements. The syntax of the mapping statements and wrapper statements are shown next.

define ontology  $o$

schema mapping statements/wrapper statements;

end ontology  $o$ ;

mapping  $m : URL\ u \rightarrow a_1 : b_1, \dots, a_k : b_k$

$c_1 \# d_1, \dots, c_m \# d_m, e_1 @ f_1, \dots, e_n @ f_n$ ;

wrapper  $w : URL\ u \rightarrow a_1 :: r_1, \dots, a_k :: r_k$ ;

where  $a_i, b_j, c_k, d_l, e_m, f_n$  are terms (including nested terms), and  $r_p$  are regular expressions corresponding to XPath expression of the table in an HTML page, and where  $a : b$  means  $a$  is a synonym of  $b$  (and vice versa),  $c \# d$  means  $c$  is a homonym of  $d$  (and vice versa),  $e @ f$  means  $e$  is an antonym of  $f$  (and vice versa), and finally  $a :: r$  means  $a$  is an attribute located at  $r$ .

As a simple example of ontology, we present here a table pertaining to Flybase site. We call the table ontology *GeneMapping*. The above ontology shows mapping between

TABLE I  
GENEMAPPING

a CG number to a corresponding FBgn Number gene, its direction, forward or reverse as well as its corresponding range in the *chromosome arm*. We went further in *geneontology* site to see synonymous name for the *EjTum* gene. The following three names showed up: CG6050 ; l(3)L4569 and mtEF-Tu. We also get the Flybase Database entry field as FBgn0024556. We report in the above table last row only one mapping (CG6050, FBgn0024556), whereas user can pose query using any one of the set  $\{CG6050, l(3)L4569, mtEF - Tu, FBgn0024556\}$ . A system is required which can rewrite user query variable to the site. We need to use a most Generalized Term as query variable to be submitted into the site. For the Flybase site, the Generalized Term happens to be the FBgn number. We store all the synonymous relationship in relational table

as multivalued dependency [20] as follows: GO ontology

TABLE II  
SYNONYM GENE MAPPING

| Generalized Term | Synonym Term                               |
|------------------|--------------------------------------------|

which is a more a nomenclature and taxonomy, than a formal ontology, is highly successful and extensively used. Although GO is technically a nomenclature rather than an ontology it has been successfully used to annotate large volumes of data and consequently support interoperability and integration from heterogeneous data sets. *Applied to Bioinformatics, an ontology is a "controlled vocabulary for the description of the molecular functions, biological process and cellular components of gene products"*. Current data integration approaches should be enhanced by ontological knowledge and ISA relationships in ontologies should be explored. [21]

#### IV. WEB FORM FILLING

Information transmitted to the server in a CGI request is fundamentally just a list of (name, value) pairs with appropriate URL encoding string. Thus we can characterize a form with  $n$  controls as a tuple  $F = \langle U, (N_1, V_1), (N_2, V_2), \dots, (N_n, V_n) \rangle$ , where  $U$  is the URL to which the encoded CGI request is sent, and the  $(N_i, V_i)$  are (name, value) pairs to be sent. [10] described 5 heuristics to deal with the from filling problem. There are two ways to submit a form for CGI processing. HTTP POST method submit the form in the body of the request. HTTP GET method submit the form as part of the URL. A question mark (?) separates the base URL and action path from the encoded names and values. This query is then sent directly to the Web site of interest. It has the same effect as that of a user clicking the Go button without selecting or typing anything on the Web form. For our experiment with *Flybase* and *AlignACE* site form filling, the following Java code snippet captures those functionality:

```
System.out.println("Enter Flybase ID ");
try {
 inputStr = mystdin.readLine();
} catch (IOException e) {
 System.out.println("IOException: " + e);
}
url1String.append("http://www.flybase.org/reports/");
url1String.append(inputStr);
url1String.append(".html");
```

```
url1 = url1String.toString();
FlyBaseToACE fetcher1 = new FlyBaseToACE(url1);
if (HEADER.equalsIgnoreCase(option)) {
 pageHeader1 = fetcher1.getPageHeader();
}
else if (CONTENT.equalsIgnoreCase(option)) {
 pageContent1 = fetcher1.getPageContent();
 rangeIndex = pageContent1.indexOf("Sequence location");
 if (rangeIndex != -1) {
 ourRange = pageContent1.substring(rangeIndex+26,
 rangeIndex+51);
 checkForwardReverse = pageContent1.substring
 (rangeIndex, rangeIndex+60);
 }
 computedRange = deleteComma(ourRange);
 url2String.append("http://www.flybase.org/cgi-bin
 /getseq.html?range=");
 url2String.append(computedRange);
 url2String.append("&source=dmel&format=
 DecoratedFasta&adrange=");

 if (checkForwardReverse.indexOf("+") != -1)
 url2String.append("-2000"); // the gene is forward
 else
 url2String.append("+2000"); // the gene is reverse

 url2 = url2String.toString();
 FlyBaseToACE fetcher2 = new FlyBaseToACE(url2);

 if (checkForwardReverse.indexOf("+") != -1) {
 System.out.println("THE GENE IS FORWARD,
 add 2K upstream");
 pageContent2 = fetcher2.getPageContent();
 output800bp = process2Kup(pageContent2);
 }
 else {
 System.out.println("THE GENE IS REVERSE COMPLEMENTED,
 add 2K downstream");
 pageContent2 = fetcher2.getPageContent();
 output800bp = process2Kdown(pageContent2);
 }
 url3 = "http://atlas.med.harvard.edu/cgi-bin/alignace.pl?
 name='Drosophila'&nc=10&xp=10&gc=0.38&seq=";
 url3 = url3 + output800bp;
 FlyBaseToACE fetcher3 = new FlyBaseToACE(url3);
 pageContent3 = fetcher3.getPageContent();
 log (pageContent3);
}
```

#### A. Need to consider Web Form DOM

In spite of having a tag in the HTML specification called **label** for the declaration of a label, it is almost not used. Form labels refers to which is visually adjacent to the left or on the top of a form field. Labels in Web Form always appear in HTML page, but DOM do not catch it, programmers have to parse the page and extract label. Based on the above discussion, we propose to take care of the web form label. DOM for a typical web form look like:

document.form.name.element.value (*Existing*)  
document.form.**label**.name.value (*our proposal*)

#### B. HTML tables - location and extraction problems

Data on the Web in HTML tables is mostly structured, but we usually do not know the structure in advance. Thus we cannot directly query for data of interest. [9] proposed a solution based on document-independent extraction ontologies. DeLA uses four heuristics to assign label for the tabular data. As for their second heuristics, when data

is represented in voluntary labels in table headers such as  $\langle TH \rangle$ ,  $\langle THEAD \rangle$ , then the label assignment is trivial. We take whatever we find inside the heading. We experimented with the following site: [http://www.mrc-lmb.cam.ac.uk/genomes/FlyTF/quite\\_sure\\_TFs.html](http://www.mrc-lmb.cam.ac.uk/genomes/FlyTF/quite_sure_TFs.html) to test the functionality and materialize the web response in MySQL relational DB. We use MySQL as it outperform other relational DB for Data Intensive Web Application (DIWA) [22]. On the fly materialization of web page table need to take care of the following delimiter characters and clean those, otherwise they will conflict with the DB system's DDL and DML.

String delims = " ' ! @ # % & \* ( ) - \_ = + ] [ | ' ; : / ? . > , < " ;

More heuristics for column label assignment are as follows: Inner Label Assignment (extract repeating prefix as label of column); Inter Label Assignment (consider consecutive two columns, first one is the label, second one is the data); Column Splitting (first portion is the column label, second portion is the data)

We wish to add more heuristics such as any consecutive four character in the set "ACGT" will not be anything other than a sequence (of course exception is there like TATA, which is a company name as well as a gene sequence) We also wish to add that only *syntactic labeling* is not enough. Suppose we get X as the repeating prefix character in a column of all the data. Then according to our heuristics it will be labeled as X. But X can be *chromosome* as well as *geometric coordinate*. In order to mitigate the confusion, we plan to use web knowledge source such as Wikipedia, Google etc to resolve the concept extraction, thereby enabling *semantic labeling*.

## V. INTEGRATING FLYBASE TO ALIGNACE SITE

In this section, we briefly discuss our experience with implementation of a Bioinformatics Web Data Integration system. Flybase is a site about a database for drosophila genetics and molecular biology. We search the site for gene, say *sin3*. In response to the quick search, a *overview page* shows the attribute name and values e.g sequence location, gene direction etc. We extract those from the *overview page*. Then we get the genome region, the result is given in *detail page* as *Decorated Fasta* format. The Flybase site has limited query processing capability such as it can take 2K - 5K sequence to update region display. But in our program, we allow user to add arbitrary region, then also allow to add arbitrary up and down sequences. Our target is to extract say 800 bp from start sequence from *sin3* gene. The whole process is automated as a sequence of *web access as scientific workflow*. Then the extracted sequence is automatically submitted in the AlignACE site to extract sequence motif, say 6 to 8 bp. We have plan to extend the functionality to integrate from AlignACE to TRANSFAC as well.

## VI. IMPLEMENTATION ARCHITECTURE

The high level architecture of the system has been shown in Figure 1. Here we implement the systems as a layered architecture consist of four layers as depicted in the following Figure 2. The *first layer* is the entire

Fig. 2. Overall System Architecture

world-wide web on the Internet. Because HTML documents are not only generated automatically by specific application programs such as *FrontPage*, *DreamWeaver*, but also written by human manually, it is common that some documents have syntactic errors. Tools like *JTidy* can be used to fix the HTML tag errors. The *second layer* is the Intelligent Wrapper that will implement our proposed Label Assignment method. It accesses the world-wide web through the Internet (Java URL and URLConnection class), fetches HTML documents and converts them into web objects as nested table. In order to speed-up query processing, the Intelligent Wrapper will also cache web objects in the local *resource description repository* and builds proper indexes on these web objects. It will allow the user to adjust web objects by adding, adjusting or deleting attributes or objects and it can also learn the pattern from the user's interaction and then process similar HTML documents accordingly. *Not only the proposed Wrapper will extract tabular data from web, but also it will map the data into attribute-value construct so that the system can later query as ordinary relational database.* That is why it is called the Intelligent Wrapper. The *third layer* of the system is the Search and Inference Processor that will implement *BioFlow*. It is mainly in charge of query processing. It obtains queries to be processed from the user interface layer and checks whether or not web objects involved are in the local resource description repository. If web objects involved are not in the local resource description repository, then it invokes

the Intelligent Wrapper to fetch them. The *last layer* is the Intelligent User Interface. Two kinds of interfaces will be provided: textual interface and browser interface (*we have already implemented using Java JEditorPane*). They will provide different kinds of environment for the user to issue commands and express queries, perform syntactical analysis, and pass valid commands in internal format to the Search and Inference Processor. They also display query results generated by the Search and Inference Processor to the user in different format, the web objects generated by the Intelligent Wrapper, and original web document like Internet Explorer.

## VII. CONCLUSION AND FUTURE WORK

In this paper we presented an implementation of a procedural and logical approach to web resource capability description/ discovery. By capability we mean what a web site can do for us and in order to perform its tasks what input it needs and what output it produces. In this connection we have identified web form to be the gateway. In response to web form, we assume a tabular output. By our *Intelligent Wrapper*, we convert the repeated structure into relational model, we can identify attributes and values in the table by our label assignment heuristics, then we can apply normal DB SQL like queries on it.

The main contribution of this paper is that we have presented a new top-down approach how to query HTML pages declaratively, which even Google search engine is missing i.e *Google can NOT search within a table of HTML document*. We have proposed a novel architecture consisted of four layers which can modularize the activities. We have proposed to take care of the Web Form DOM as it will enable greater web information integration as discussed in our paper. Our Java based implementation used the classes URL, URLConnection, JEditorPane, HTML Swing Parser etc. To the best of our knowledge, such a integrated solution is not available anywhere although some other systems can only extract/export region of interest web data. Ours is an integrated solution, which we plan to extend further by the concepts as discussed in the paper.

## ACKNOWLEDGMENT

<sup>\*\*</sup>Ferdowsi university of Mashad, Mashhad, Iran, *shk@ieee.org*

**Abstract-** In this paper an estimation technique for the data hiding capacity in biometric images is presented. We consider the QSWT algorithm for data hiding in biometric images and investigate the effect of message strength in increasing capacity in the presence of different types of attacks.

**Index terms-** data hiding, image watermarking, DWT, QSWT, channel capacity.

## I- Introduction

Data hiding refers to embedding information within a host data such as text, audio, image or video. In watermarking applications, the hidden data represents authorship information, a time stamp or copyright information [1]. Data hiding in biometric images has been proposed to make the biometric systems secure and resilient to deliberate manipulations and attacks.

Data hiding capacity is a measure of the amount of information that can be hidden in a digital image while satisfying requirements such as robustness and invisibility. Estimating the capacity can set an upper-bound to the amount of data that can be hidden in an image, therefore it can help in the design of efficient data hiding algorithms. There has been ongoing research in data hiding capacity estimation in recent years. In [2], each pixel is considered as an independent channel and the capacity is calculated based on the theory of parallel Gaussian channels. Reference [3] presents an information theoretic model for data hiding and studies the capacity problem under several types of attacks. In [4], zero-error information hiding capacity in JPEG-compressed domain is presented. Reference [5], presents an analysis of watermarking capacity based on the content of wavelet sub-bands and uses the concept of wavelet quantization matrix and Noise Visibility Function.

The factors determining data hiding capacity include (1) the statistical model used for the host image, (2) the distortion constraints placed on the data hider and the attacker, and (3) the information available to the data hider, attacker and decoder. In fact, the content of an image has great influence on its data hiding capacity.

Data hiding capacity can also be influenced by the watermark strength, but high strength does not necessarily imply high capacity, as will be shown in simulation results. In previous works [2-5], capacity is estimated for data hiding in wavelet domain. In those works, the watermark strength is constrained based on the content of wavelet sub-bands.

In this paper, a framework for estimating the capacity of data hiding in biometric images based on QSWT algorithm is presented. Automated biometrics can provide accurate and reliable user authentication method. Watermarking biometric images can guarantee secure transmission of acquired images from intelligence agencies to a central image data base [6]. We assume that these watermarked biometric images are used for automatic user recognition and authentication. Since authentication will be done automatically, considerations of Human Visual System in watermarking can be ignored to some extent. In other words, in this proposed scheme, watermark (message) strength can be distributed equally among different wavelet sub-bands, regardless of their frequency contents.

Also in this paper, we compare the data hiding capacity in the presence of different attacks and discuss the effect of increased watermark strength on the capacity.

This paper is organized as follows. In section II, a mathematical model used for image watermarking is presented. Section III describes the QSWT approach for data hiding. Section IV gives capacity results for Gaussian channels. In section V, simulation results for biometric images are presented.

## II- Mathematical Model for Data Hiding

In data hiding schemes, a host image is considered as a communication channel for transmitting messages. Therefore, watermarking capacity can be estimated using traditional information theory. Fig. 1 shows a common model for watermarking in transform domain. In this model, the forward transform block decomposes the image into its coefficients of L bands. This forward transform can be either discrete cosine transform (DCT)

Fig 1. watermarking model

or discrete wavelet transform (DWT). Then, a watermark (message) is added to each band. The watermarked image is reconstructed using an inverse transform block. This image undergoes some certain type of processing (such as compression, addition of noise, median filtering) to yield the image. At the receiving end, watermark is extracted by decomposing this image into its  $L$  bands (using the same forward transform block) and the hidden message is extracted from each band. In this paper, we aim to estimate the capacity of such communication channel which is used to hide messages in biometric images such as fingerprint and iris images. In [9] a model for data hiding channel is presented, as shown in Fig.2 where,  $S$  is a watermark (message) to be transmitted through the channel. The channel noise is modeled as a combination of two sources:  $I$  the noise due to the host image and  $P$ , the noise due to processing. In this paper, we estimate the capacity for the case that image undergoes median filtering, JPEG compression, Gaussian filtering, sharpening and addition of Gaussian noise.

Fig 2. Data hiding channel [9]

### III- Channel Specification

In the above model for data hiding, we assume that the data hiding channel is a combination of  $L$  parallel sub-channels. The decomposition of the image is performed by applying a forward DWT transform. DWT transform is identical to a hierarchical sub-band system where the sub-bands are logarithmically spaced in frequency domain. The image is first decomposed into 4 parts of high, middle and low frequencies ( $LL1$ ,  $HL1$ ,  $LH1$ ,  $HH1$ ). The sub-bands  $LH1$ ,  $HL1$  and  $HH1$  are the finest scale wavelet coefficients. Sub-band  $LL1$  is further decomposed and this process is repeated several times. In some data hiding schemes, the watermark message is hidden in these sub-bands according to the magnitude of their coefficients. So each sub-band of the wavelet decomposition can be

considered as one of the sub-channels defined in our model.

In some schemes, the coefficient selection method is based on the Qualified Significant Wavelet Tree (QSWT) [7]. This method takes the relationships of DWT coefficients and spatial information into consideration and thus achieves more robustness. The principles of QSWT are as follows:

A parent-child relationship can be defined between wavelet coefficients at different scales corresponding to the same location. Excluding the highest frequency sub-bands, every coefficient at a given scale can be related to a set of coefficients at the next finer scale of similar orientation. The coefficient at the coarse scale is called the *parent*, and all coefficients corresponding to the same spatial location at the finer scales are called *children*. In other words, a family tree is constructed by grouping  $n$  levels of wavelet coefficients in the same spatial direction. The parent is a wavelet coefficient in one of the three highest frequency sub-bands  $HL_n$ ,  $LH_n$  or  $HH_n$  and its children are the ones located along the same spatial location in the next higher scales [8]. For a given parent, the set of all coefficients of all finer scales corresponding to the same orientation are called *descendants*. In Fig. 3 a wavelet tree consisting of all descendants of one coefficient in  $LH3$  is shown.

Fig. 3. DWT decomposition and all descendants of one coefficient in  $LH3$ .

Choosing an appropriate coefficient as a parent for data hiding is done based on some amplitude thresholds.

If a wavelet coefficient  $x_n(i, j) \in D$ , where  $D$  is a sub-band labeled  $HL_n, LH_n, HH_n$ , at the coarsest scale is a parent of  $x_{n-1}(p, q)$ , satisfying  $|x_n(i, j)| > T_1$ ,  $|x_{n-1}(p, q)| > T_2$  and,  $p = 2i - 1, \dots, 2i$ ,  $q = 2j - 1, \dots, 2j$ ,  $n, i, j > 1$ , for a given threshold  $T_1$  and  $T_2$ , then  $x_n(i, j)$  and its children are called a QSWT [7].

So in this case the elements of each sub-channel are the coefficients of the QSWT.

In this paper, we will show the effect of appropriate data hiding schemes in increasing the data hiding capacity. As will be shown in section V, we have estimated the data hiding capacity for two cases and compared estimated capacities.

#### IV- Channel Capacity

The capacity of an AWGN channel can be calculated according to

$$C = W \log_2(1 + \sigma_x^2 / \sigma_n^2)$$

in which  $W$  is the channel bandwidth,  $\sigma_x^2$  is the variance of the message signal to be transmitted and  $\sigma_n^2$  denotes the noise variance. In this work we assume that message is transmitted through  $L$  bands of transformed (DWT) image. So in an  $M \times N$  pixel image, we have  $(M \times N) / L$  coefficients. According to the Nyquist sampling theory, sampling points should be  $2W$ , so the bandwidth of an image will be  $M \times N / 2$  [5].

The decomposition of an image into  $L$  sub-bands results in  $L$  parallel sub channels with two noise sources in each sub-channel. Since we have no knowledge about the distribution of these noises, we assume the worst Gaussian distribution [10]; we assume that these two noises are Gaussian and independent. So the channel noise can be replaced by one noise with variance  $\sigma_i^2 + \sigma_p^2$  where  $\sigma_i^2$  is the variance of image noise and  $\sigma_p^2$  is the variance of processing noise. Thus the total capacity of  $L$  parallel channels is given by [9]:

$$C = \frac{MN}{2L} \sum_{j=1}^L \log_2 \left( 1 + \frac{\sigma_{x_j}^2}{\sigma_{i_j}^2 + \sigma_{p_j}^2} \right) \quad (1)$$

In most watermarking applications,  $\sigma_x^2$  is calculated according to perceptibility requirements. For instance in [9]  $\sigma_{x_j}^2$  is replaced by the visual threshold of band  $j$ . In other words,  $\sigma_{x_j}^2$  is the maximum message signal energy permitted in band  $j$  based on its perceptual quality effects. This parameter also depends on the magnitude of the particular coefficient. Due to the properties of human visual system, a coefficient with larger magnitude can be altered to a larger extent than a coefficient with smaller magnitude. Our goal is to have an estimate of the average energy that can be added to a particular band. Since the human visual system is more

sensitive to lower frequency bands than higher ones, and lower frequency bands have higher variance, a reasonable model for the visual threshold can be [9]

$$\sigma_{x_j}^2 = k \sigma_{i_j}^{2\alpha} \quad (2)$$

where  $0 \leq \alpha \leq 1$ , and  $k \ll \sigma_{i_j}^2$ , and  $\sigma_{i_j}^2$  is the variance of the coefficients in band  $j$ .

In some scenarios such as automatic biometric user authentication, where recognition is done automatically, human perception will be of less importance. In these cases, the energy of message signal can be distributed equally among different bands regardless of their variances. In this paper, we set  $\alpha = 0$  and calculate the capacity for different values of  $k$ .

Channel noise is the sum of two noise sources, image noise with variance  $\sigma_i^2$  and processing noise with variance  $\sigma_p^2$ . In order to model the image noise, we assume that  $f_{i_j}(i_j)$  is the distribution of the  $j^{\text{th}}$  sub-band of the host image. The image noise is split into its components in  $L$  sub-bands which are modeled as random variables with variance  $\sigma_{i_j}^2$ . The next step is to obtain their entropy equivalent Gaussian variances (or the Gaussian random variable that has the same entropy as these random variables). This is achieved by plotting a histogram of the coefficients of each band and calculating the entropy. If  $\Delta x$  is the width of  $n$  bins of the histogram  $g_i(m), m = 1, 2, \dots, n$  and  $p$  is the total number of coefficients in band  $j$ , the entropy and the equivalent Gaussian variance  $\sigma_{i_j}^2$  are obtained as

$$H_j = - \sum_{i=1}^n \frac{g_j(i)}{p \Delta x} \log_2 \left( \frac{g_j(i)}{p \Delta x} \right) \Delta x \quad (3)$$

$$\sigma_{i_j}^2 = 2^{2H_j / \ln 2} / 2\pi e$$

Thus the image noise in sub-band  $j$  can be replaced by a Gaussian noise of variance  $\sigma_{i_j}^2$  [9]. Note that this noise source can be omitted in non-blind approaches, since the image noise can be subtracted from the received image. Therefore, we expect such schemes to have higher capacity than blind watermarking approaches.

The processing noise is estimated as the variance of an equivalent additive noise which substitutes the actual (nonlinear) processing noise sources [9], such as JPEG compression and gamma correction. We define processing noise as the equivalent additive noise which accounts for the reduction in correlation between the transform coefficients of the original image and the transform coefficients of the image obtained after processing. We assume the processing noise in each sub-band as  $\sigma_{p_j}^2, j = 1, \dots, L$ . In order to obtain this variance, we apply the processing to  $n_i$  test images and decompose both the original and processed images into  $L$  sub-bands. Thus we will obtain  $MNn_i / L$  samples for each sub-band. Let  $c_{j_k}, k = 1, \dots, (MNn_i) / L$  be the coefficients of band  $j$  of test images and

$\tilde{c}_{j_k}, k=1, \dots, (MNn_i)/L$  be the corresponding coefficients of the images subjected to processing. The variance of processing noise is obtained as follows:

$$\frac{\langle c_j, \tilde{c}_j \rangle}{|c_j| |\tilde{c}_j|} = \frac{\langle c_j, (c_j + n_j) \rangle}{|c_j| |c_j + n_j|} = \rho_j \quad (4)$$

$$\sigma_{p_j}^2 = \left( \frac{1}{\rho_j^2} - 1 \right) |c_j|^2$$

In the next section, image noise and processing noise are estimated for fingerprint and iris images based on the above equations by means of simulations.

## V- Experimental Results

We estimate data hiding capacity for two databases of fingerprint images (364×328 pixels) and iris images (576×768 pixels). The images were decomposed into  $L=10$  sub-bands by applying two dimensional wavelet transform. We used 4-tap Daubechies filters for wavelet decomposition of images. We have assumed that the watermarked image may be subjected to different types of attacks including median filtering, JPEG compression, Gaussian filtering, sharpening and addition of Gaussian noise. We estimated the noise due to these attacks and figured out that in order for the images to resist these attacks how many bits can be hidden in them. In other words, acceptable capacities for these images were estimated in order to be robust against different attacks. Since we have focused on data hiding for automatic user authentication schemes, we are able to eliminate the effect of human visual system on designing watermarking algorithms. Thus we choose  $\alpha = 0$  in Equation (2) so that message energy is distributed equally among different sub-bands. The constant  $k$  is chosen to be smaller than the variance of the coefficients of each sub-band.

Also since we are targeting user authentication applications, we use non-blind data-hiding, as a result we have omitted the variance of image noise  $\sigma_i^2$ . The variance of processing noise  $\sigma_p^2$  is estimated according to Equaion (4). So the capacity of data hiding channel is given by

$$C = \frac{MN}{2L} \sum_{j=1}^L \log_2 \left( 1 + \frac{k}{\sigma_{p_j}^2} \right) \quad (5)$$

The estimated capacity for different values of  $k$  in the presence of different kind of attacks is shown in Fig.4 and Fig.5 for the following two cases:

- Case A: We have assumed that all coefficients of each sub-band can be used for data hiding.
- Case B: We have assumed only the coefficients of QSWT are considered as data hiding channels.

Fig 4. Capacity estimates (case A) a) fingerprint images, b) iris images

It is shown that in the first case, fingerprint images provide more capacity for data hiding in comparison with iris images. In our simulations, constant  $k$  indicates the energy of the message to be hidden. It is shown that increasing  $k$  has no effect in increasing capacity in the presence of sharpening attacks. In other words, increasing message energy is not appropriate for achieving higher capacity in these cases. This is true because sharpening is a kind of high pass filtering and we assumed that the data is hidden in mid and high frequency bands. Also by using QSWT algorithm, the total capacity will increase. This is more obvious for iris images.

## VI- Conclusion

We have presented a technique for estimating the data hiding capacity of biometric images for user authentication applications. Since human perception is of less importance in such scenarios, the message energy can be distributed equally among different sub-bands of wavelet transform. Our experimental results show that increasing message energy will increase data hiding capacity, although other properties such as visual

perception may decrease. Also it was shown that the QSWT algorithm will increase the capacity.

Fig. 5. Capacity estimates (case B) for a) fingerprint image b) iris image

Also increasing message energy in the presence of compression and Gaussian noise will cause a significant increase in the capacity but in the case of sharpening and filtering message energy does not have any significant effect on data hiding capacity.

**Abstract** — “Learning methods” play a key role in the fields of statistics, data mining, and artificial intelligence, intersecting with areas of engineering and other disciplines. These methods for analyzing and modeling data come in two flavors: supervised and unsupervised learning. Regression analysis and classification are two well known supervised learning techniques. To get an effective model from regression analysis it is necessary to check and preprocess the data set in astronomy, bio-informatics, image analysis, computer vision etc, especially when the data sets are large and high dimensional. In these industries large or fat data appear with unusual observations (outliers) very naturally. Checking raw data for outliers in regression is regression diagnostics. Most of the popular diagnostic methods are not good enough for large and high dimensional data. The aim of this paper is to provide a new measure for identifying influential observations in linear regression for large high dimensional data.

**Index Terms** — Data mining, high dimensional data, influential observation, outlier, regression diagnostics, supervised learning.

## I. INTRODUCTION

Data and knowledge mining/discovery is learning from data. Learning means extraction of the regularity from the data. Learning methods for analyzing and modeling data are divided into two: “supervised learning” and “unsupervised learning” to the pattern recognition and machine learning community. Classification, decision trees, neural networks, and regression analysis are well known supervised learning methods. In recent years regression analysis has drawn much attention for its wide range of applicability to the user of learning community. Regression can be performed using many different types of techniques, including classification, genetic algorithms, neural networks and optical flow estimation.

Supervised learning requires input data that has both predictor (independent) variables and target (dependent/response) variable, whose value is to be estimated. By various means, the process “learns” how to model (predict) the value of the target variable based on the predictor variables. Regression analysis is one of the most important supervised learning methods that have the

objective to specify a relationship between the target and explanatory (independent) variables. Supervised learning requires that the target variable is well defined and that a sufficient number of its values are given. Data contamination is a practical problem, introduced either due to unreliable data sources or during data transmission. Noise (data contamination) can greatly impair data learning. It is often more severe problem in the context of streams (large and high dimensions) because it interfaces with change adaptation. Regression analysis is not an exception to this kind of problem and regression diagnostics is a remedy. Problem is that most of the identification techniques are performed well only for small and few dimensional data.

In this paper we have a brief introduction of outliers in large and high-dimensional data in Section II, Section III focused on regression diagnostics. We propose a new diagnostic measure for identifying multiple influential observations for high dimensional large data set in Section IV. Numerical demonstrations are thereafter followed by conclusion in Section VI.

## II. OUTLIERS DETECTION IN LARGE AND HIGH DIMENSIONAL DATA

Outlier detection has been suggested for numerous applications, such as credit and fraud detection, clinical trials, voting irregularity analysis, network intrusion, severe weather prediction, geographic information system, and other data mining tasks [1], [2]. Outlying observations do not inevitably ‘perplex’ or ‘mislead’; they are not necessarily ‘bad’ or ‘erroneous’, and the experimenter may be tempted in some situations not to reject an outlier but to welcome it as an indication of new and important findings.

Outlier detection methods can be divided into two, univariate and multivariate methods. Another fundamental taxonomy of outlier detection methods is between parametric and nonparametric methods that are model-free (e.g., [3]). Statistical parametric methods either assume a known underlying distribution of the

observations or, at least, they are based on statistical estimates of unknown distribution parameters. These methods flag as outliers those observations that deviate from the model assumptions. They are often unsuitable for high-dimensional data sets and for arbitrary data sets without prior knowledge of the underlying data distribution [4]. Within the class of non-parametric methods one can set apart the data mining methods, also called distance-based methods. These methods are usually based on local distance measures and are capable of handling large databases (*e.g.*, [3], [5], [6]). Another class of outlier detection methods is founded on clustering techniques, where a cluster of small sizes can be considered as clustered outliers [7], [8].

### III. REGRESSION DIAGNOSTICS

The purpose of regression (model function) is to map a data item to a real valued function prediction variable, classical model is

$$Y = X\beta + \varepsilon. \quad (1)$$

We predict the output  $Y$  with least squares method via the model,

$$\hat{Y} = X\hat{\beta} \text{ (in vector-matrix form);} \quad (2)$$

where  $\hat{\beta} = (X^T X)^{-1} X^T Y$  and the corresponding

residual vector,  $r = Y - \hat{Y} = (I - H)\varepsilon$ ; in scalar form,

$$r_i = \varepsilon_i - \sum_{j=1}^n h_{ij} \varepsilon_j; \quad i = 1, 2, \dots, n$$

where  $H = X(X^T X)^{-1} X^T$  is the leverage matrix and its  $j$ th diagonal element is  $h_{jj}$ . Usually  $r_i$  and  $h_{ij}$  along with their different transformed versions are used for the diagnosis of outliers and leverage points respectively.

In regression, outliers can deviate into three ways (i) the change in the direction of response ( $Y$ ) variable (ii) the deviation in the space of explanatory variable(s), deviated points in  $X$ -direction called leverage points, and (iii) the other is change in both the directions. It is known that as with outliers, high leverage points need not be influential, and influential observations are not necessarily high-leverage points. According to Belsley *et al.* [9], influential observation is one which either individual or together with several other observations has a demonstrably larger impact on the calculated values of various estimates than is the case for most of the other observations. Robust regression and regression diagnostics are two complementary approaches to study with unusual observations. Robust regression first wants to fit a regression to the majority of the data and then to discover outliers. On the contrary, field diagnostics is a combination of graphical and numerical tools. It is

designed to detect and delete (if necessary recheck/correct) and then fit the good data by classical methods. It tries to iteratively detect possibly wrong data and reject/refit them through analysis of globally fitted model.

A large body of literature is now available (see [9-12]) for the identification of outliers and influential observations. Among them Cook's distance [13], DFFITS and DFBETAS [9] become very popular with the practitioners for identifying influential observations. These are based on single case deletion and unable to cope with multiple unusual observations. There are some group deletion measures (see [14]) but they are failed in case of high dimensional large data sets.

High dimensional data introduces several problems to traditional statistical analysis. Computation time increases more rapidly with number of explanatory variable than the number of observations. Another problem for group deletion diagnostics is to find group of outlying observation  $d$ , the deletion of which produces the largest reduction to the residual sum of squares.

### IV. NEW DIAGNOSTIC MEASURE

We introduce a two-step diagnostic measure originated from Pena's [15] idea attaching with formal and/or informal group deletion methods (see [14]). Group deletion helps us to reduce the maximum disturbance by deleting the suspect group of influential cases at a time and 'the deletion of which produces the largest reduction in the residual sum of squares. It helps to make the data more homogeneous. We look how every point in a sample is influenced by the specific ( $i$ th) observation. In our method, after deleting the suspect group at a time we again delete specific sample point from each of the observations one after another and measure the difference between the forecast with and without the specific one. Group deletion attaching with Pena's [15] idea improves the measure and show nice results in presence of masking and/or swamping phenomena. Graphical displays like index plot and character plot of explanatory and response variables could give us some ideas about the influential observations, but these plots are not useful for higher dimension of regressors. There are some suggestions in the literature for using robust regression techniques like LMS, LTS, reweighted least squares (RLS) (see [10]) for finding the group of suspect influential observations. We consider one of the two proposed procedures of Hadi and Simonoff [14], where they suggested dividing the data set in two initial subsets: a 'basic' subset that contains the first  $k+1$  clean observations and a 'nonbasic' subset that contains the remaining observations.

At the first step we find out all suspect influential (unusual) cases. We suggest using graphical display and/or regression diagnostic measures and/or robust regression methods

whatever can helps to find the suspect group with maximum number of influential cases.

In the second step, we assume that  $d$  observations among a set of  $n$  observations are suspected as influential observations and to be deleted. Let us denote a set of cases 'remaining' in the analysis by  $R$  and a set of cases 'deleted' by  $D$ . Hence without loss of generality, assume that these observations are the last  $d$  rows of  $X$  and  $Y$  so that

$$X = \begin{bmatrix} X_R \\ X_D \end{bmatrix} \quad Y = \begin{bmatrix} Y_R \\ Y_D \end{bmatrix}.$$

After formation of the deletion set indexed by  $D$ , we would compute the fitted values  $\hat{Y}^{(-D)}$ . Let  $\hat{\beta}^{(-D)}$  be the corresponding vector of estimated coefficients when a group of observations indexed by  $D$  is omitted. We define the vector of difference between  $\hat{y}_j^{(-D)}$  and  $\hat{y}_{j(i)}^{(-D)}$  as

$$t_{(i)}^{(-D)} = (\hat{y}_1^{(-D)} - \hat{y}_{1(i)}^{(-D)}, \dots, \hat{y}_n^{(-D)} - \hat{y}_{n(i)}^{(-D)})^T \quad (3)$$

$$= (t_{1(i)}^{(-D)}, \dots, t_{n(i)}^{(-D)})^T \quad (4)$$

and

$$t_{j(i)}^{(-D)} = \hat{y}_j^{(-D)} - \hat{y}_{j(i)}^{(-D)} = \frac{h_{ji} \hat{\epsilon}_i^{(-D)}}{1 - h_{ii}}, j=1, 2, \dots, n \quad (5)$$

where

$$h_{ji} = x_j^T (X^T X)^{-1} x_i \text{ and } \hat{\epsilon}_i^{(-D)} = y_i - \hat{y}_i^{(-D)}.$$

Finally, we introduce our new measure as squared standardized norm,

$$M_i = \frac{t_{(i)}^{(-D)T} t_{(i)}^{(-D)}}{kV(\hat{y}_i^{(-D)})}, \quad (6)$$

where

$$V(\hat{y}_i^{(-D)}) = s^2 h_{ii} \quad \text{and} \quad s^2 = \frac{\hat{\epsilon}^{(-D)T} \hat{\epsilon}^{(-D)}}{n - k}.$$

Using (3) to (6), we obtain

$$M_i = \frac{1}{ks^2 h_{ii}} \sum_{j=1}^n h_{ji}^2 \frac{\hat{\epsilon}_i^{(-D)2}}{(1 - h_{ii})^2}. \quad (7)$$

We use a confidence bound type cut-off value for it, and consider the  $i$ th observation to be influential if it satisfies the rule

$$|M_i| > \text{median}(M_i) + 4.5 \text{MAD}(M_i), \quad (8)$$

where

$$\text{MAD}(M_i) = \text{median}\{|M_i - \text{median}(M_i)|\} / 0.6745.$$

## V. NUMERICAL EXAMPLES

We consider here two artificial large data sets, one is multi-structural clustered (step) and the other is high-dimensional, for the identification of influential observations. Such data sets are frequently used in classification, cluster analysis and optical flow estimation. We want to show the performance of our new measure and compare with the existing popular diagnostic methods.

### A. Multi Structural Step Data

Our first example uses an artificial data set that is taken from (see [16]) a paper of optical flow estimation (computer vision). In this experiment, we investigate how a multistructural clustered data is analyzed which is contaminated by number of outliers (noise). We generate the step data set, since every line is corrupted by Gaussian noise with zero mean and different variances. The  $i$ th line has  $n_i$  samples,  $n_0$  data points are randomly distributed in the range of (0,100). The data points are defined as follows.

Steps are:  $X = (0, 55)$ ,  $Y = 30$ ,  $n_1 = 120$ ,  $\sigma = 1.5$  ('+');

$X = (20, 100)$ ,  $Y = 60$ ,  $n_2 = 50$ ,  $\sigma = 2$  ('-');  $n_0 = 50$  ('o').

First we plot the points with LS and robust (LMS and LTS) line, it is clearly shown that data sets are clustered on two lines and some observations do not hold any pattern. As the common definition, observations those are assigned 'o' and '-' in Fig.1 can be treated as outliers (apart from the bulk of the data). Judging from the LMS line it is worth mentioning that last 100s are outliers. Now we apply our newly proposed diagnostic technique and form the deletion set  $D$  by the hundreds. Index plots (Fig. 2. (b) and (d)) of residuals and leverage points do not show any indication of heterogeneity.

Fig.1. Scatter plot of multi structural step data.

Fig. 2. Regression diagnostics for multistructural step data; (a) Plot of residual versus fitted value (b) Index plot of residuals (c) Histogram of residuals (d) Index plot of leverage,  $h_i$  values (e) Index plot of deleted residuals (f) Histogram of deleted residuals (g) Deleted residual versus deleted fit (h) Index plot of Cook's distance (i) Histogram of Cook's distance (j) Index plot of DFFITS (k) Histogram of DFFITS (l) Index plot of  $S_i$  (Pena) (m) Histogram of  $S_i$  (n) Index plot of  $M_i$  and (o) Histogram of  $M_i$ .

We compute the diagnostic measures Cook's distance and DFFITS along with Pena's measure ( $S_i$ ) and  $M_i$  (new measure) and use them to draw index (dot) plot and histogram. Without  $M_i$ , rest 3 are failed to indicate

influential cases properly. Index plot of  $M_i$ , Fig. 2 (n) shows that last 100 observations are influential with a

few masking observations. Histogram of  $M_i$ , Fig. 2 (o) clearly indicates the presence of three different patterns of observations.

### B. Large and High Dimensional Data

We consider an artificial data set that is generated in a similar fashion described by Pena [15]. The data set shows the presence

of heterogeneous variances in the sample points and a mixture of continuous and categorical variables, generated by the model

$$Y = \beta_0 + \beta_1 X_1 + \dots + \beta_{20} X_{20} + \beta_{21} Z + \varepsilon. \quad (9)$$

We generate 500 observations, where  $X$ 's have 20 dimensions and they are independent random drawings from uniform distributions. The first 400 observations for each of the  $X$  variables are generated from Uniform (0, 10)

and last 100 observations (401-500) from Uniform (9, 10) that makes the presence of heterogeneous variance in the data set. For the categorical explanatory variable  $Z$ , the first 400 observations are set at  $z = 0$  and the last 100 observations are set at  $z = 1$ . For the null model we generate errors from Normal (0, 1). The parameter values have been chosen as

$\beta_0 = \beta_1 = \dots = \beta_{20} = 1$ , and  $\beta_{21} = -100$  so that the standard diagnostics do not show any evidence of heterogeneity.

Fig. 3. Influence analysis of the large and high dimensional data; (a) Plot of residual versus fitted value (b) Index plot of residuals (c) Histogram of the residuals (d) Plot of deleted residual versus deleted fitted value (e) Index plot of deleted residuals (f) Histogram of the deleted residuals (g) Index plot of Cook's distance (h) Index plot of DFFITS (i) Index plot of  $Si$  (j) Histogram of  $Si$  (k) Index plot of  $Mi$ , and (l) Histogram of  $Mi$ .

Results that we obtain from this artificial data are shown in Fig. 3. The residual versus fitted value plot, Fig. 3 (a)

shows no indication of heterogeneity. When the last 100 observations are deleted, the deleted residual versus deleted fitted value plot and histogram of deleted residual ( Fig. 3. (d), (f) ) show clear indications of the presence of heterogeneity. We consider above mentioned three measures to identify the 100 influential cases but their index plots (Fig. 3. (g), (h), and (i)) show they are totally failed to identify the influential cases. In index plot, Fig. 3. (k) we see that proposed  $M_i$  can successfully identify all influential cases. Fig. 3. (l), histogram of  $M_i$  also shows the heterogeneous variances in the data set that is absent in histogram of  $S_i$ .

## VI. CONCLUSION

In this article, we propose a group deletion diagnostic measure for identifying influential observations (outliers) in linear regression that performs well for large and high dimensional data. The technique also gives some clear indications of presence of influential cases in a multidimensional step (cluster) data when the existing popular diagnostic methods are not well enough. To get real data involving thousands of cases and hundreds of dimensions is not easy and also expensive. Time and space constrains do not permit us to perform the tasks this time; we shall try to do it as a further work.

## ACKNOWLEDGEMENT

The authors are thankful to the anonymous reviewers for their valuable suggestions and to the organizing and publication committee of the conference.

**Abstract** — In this paper, the main target is to compare the system lifetimes in diverse scenarios based on our new energy dissipation model in the body sensor network as well as maximize the system lifetime of sensor nodes when they will make communication among body sensors and personal communication unit. Nowadays, the ultra low energy consumption is the very much important challenge for medical applications. The best compression technique like LPC is selected for energy saving based on some calculations. This research work studies and analyzes the transceiver energy consumption for different compression algorithms and select the best technique like LPC for energy saving. Formulation of a linear programming problem is also the important part of this research work, where is to maximize the system lifetime which is equivalent to the time until the first node runs out of battery. Maximum system lifetimes are calculated by MATLAB optimization technique using and without using efficient compression algorithm like LPC in various environments. Results show that maximum system lifetimes calculated in different scenarios using efficient compression technique like LPC is better than without using compression technique.

**Index Terms** — WBSN, transmitting energy and receiving energy, linear prediction coding (LPC), maximum system lifetime, linear problem, low energy consumption.

## I. INTRODUCTION

Consider a wireless body sensor network of static nodes as depicted in Fig.1, where each node operates on limited battery energy. Assume that each node generate constant bit rate and send or receive information to or from neighbors with and without compression technique. Also assume that the patient's body sensor (one sensor node for every patient to detect heart beat signal) is fixed and its distribution is shown in the Fig.1. In this paper, we select the best compression algorithm like LPC and calculate the transmitting and receiving energy according to the new energy dissipation model shown in Fig.4. Then we formulate the linear programming problem where

objective is to maximize the system lifetime. Finally compare the results with the help of optimization technique and show that maximum system lifetimes calculated in various scenarios using efficient compression technique like LPC is better than without using compression technique. Most of the previous works deal with low energy consumption for WSN but they did not maximize the system lifetime with the help of optimization technique using energy efficient LPC algorithm. In [1], the authors described the application of WSN just to monitor the battle field. In [2], the authors described the WBAN architecture for broader telemedical system using energy efficient local communication protocols such as ZigBee, Wi-Fi.

Fig.1. Application scenario for maximum system lifetime

The authors in [3] explained the energy aware network layer protocols like LEACH, CICADA, and S-MAC for

maximize the battery lifetime. The work in [4] considered multi destination case instead of single destination case for maximizing the system lifetime. In [5], instead of minimizing the total consumed energy, they tried to maximize the network lifetime till first node dies.

## II. OBJECTIVES OF THE RESEARCH

The objectives of the research work are written in below:

- To study the energy consumption parameters in the sensor networks.
- To analyze the different compression techniques to select the best one for energy consumption in the sensor nodes
- To formulate the problem as a linear programming problem where the objective is to maximize the minimum system lifetime of sensor nodes
- To create an application scenario and calculate the energy consumption parameters for various environments
- To calculate and compare the maximum system lifetime using the best energy efficient algorithm like LPC and without using compression algorithm with the help of optimization technique for a fixed bit rate

## III. MAXIMUM SYSTEM LIFETIME

Maximum system lifetime which is equivalent to the time until the first node runs out of battery for a particular network.

### A. Formulation of linear problem

The formulation of maximum system lifetime routing problem is described by the author for the case where information generation rates are fixed [4], [6]. Since  $T_{sys}$  in equation (1) is not a linear function of flow variables,  $x_{ij}^k$ , to formulate as a linear programming problem, the author defined  $T_{sys}^{-1}$  as an inverse system lifetime shown in equation (6) [6]. Linear programming problem is formulated considering some parameters described below:

### B. Given information for the network

The parameters that are considered to formulate the problem for the network as follow [6]:

- $\mathcal{V}$  : set of nodes (including node 0 which is central node)
- $\mathcal{V}'$  : set of nodes (excluding node 0)
- $\mathcal{V}_i$  : set of nodes that can be reached by node  $i$
- $t^k$  : traffic rate from sensor node  $k$  to central node
- $E_i$  : initial battery energy of sensor node  $i$

- $\alpha_{ij}^t$  : energy consumed by sensor node  $i$  to transmit a packet (total bits) to node  $j$
- $\alpha_i^r$  : energy consumed by sensor node  $i$  to receive a packet (total bits)

So, the *Lifetime* of node  $i$  is written by

$$T_i = \frac{E_i}{\sum_{k \in \mathcal{V}'} \sum_{j \in \mathcal{V}_i} \alpha_{ij}^t x_{ij}^k + \sum_{k \in \mathcal{V}'} \sum_{j \in \mathcal{V}_i} \alpha_i^r x_{ji}^k} \quad (1)$$

### C. Decision variables, system lifetime and their relations

- $x_{ij}^k$  : traffic flow in bps from node  $i$  to node  $j$  for data of sensor node  $k$ .

The *Lifetime* of node  $i$ , denoted by  $T_i$  can be computed as in (1) follows [5], [6]. But, our target is to maximize the system *lifetime*, called MLR (Maximum Lifetime Routing), denoted by  $T_{sys}$ . The system lifetime under the flow  $x_{ij}^k$  can be defined as the length of time until the first node dies among all nodes in the network, which is the same as the minimum lifetime over all nodes, shown in equation (2).

$$T_{sys} = \min_{i \in \mathcal{V}} T_i \quad (2)$$

So, maximizing  $T_{sys} = \min_{i \in \mathcal{V}} T_i$  can be rewritten by

$$\text{Minimizing } T_{sys}^{-1} = \max_{i \in \mathcal{V}} T_i^{-1} \quad (3)$$

To maximize the system lifetime, the author needs to find the flow under flow conservation condition and satisfaction of traffic demands as follows [6]:

Flow conservation and satisfaction of traffic demands:

$$\forall i \in \mathcal{V}, k \in \mathcal{V}', \sum_{j \in \mathcal{V}_i} x_{ji}^k - \sum_{j \in \mathcal{V}_i} x_{ij}^k = \begin{cases} -t^k, & i = k \\ t^k, & i = 0 \\ 0, & \text{otherwise} \end{cases} \quad (4)$$

$$\forall k \in \mathcal{V}', i \in \mathcal{V}, j \in \mathcal{V}_i, x_{ij}^k \geq 0 \quad (5)$$

### E. Overall optimization problem

The overall problem is to minimize the cost function mentioned in equation (2) subject to the above set of constraints. From equation (1), it is obvious that the cost function is not yet a linear function of decision variables but it should be linear as considered as linear programming problem. So, the overall linear optimization problem is as follows [5], [6]:

$$\text{minimize } T_{sys}^{-1} \quad (6)$$

subject to

$$\sum_{k \in \mathcal{V}'} \sum_{j \in \mathcal{V}_i} \alpha_{ij}^t x_{ij}^k + \sum_{k \in \mathcal{V}'} \sum_{j \in \mathcal{V}_i} \alpha_i^r x_{ji}^k - T_{sys}^{-1} E_i \leq 0 \quad (7)$$

$$\forall i \in v, k \in v', \sum_{j \in v_i} x_{ji}^k - \sum_{j \in v_i} x_{ij}^k = \begin{cases} -t^k, i = k \\ t^k, i = 0 \\ 0, \text{otherwise} \end{cases} \quad (8)$$

$$\forall k \in v', i \in v, j \in v_i, x_{ij}^k \geq 0 \quad (9)$$

#### IV. SELECTION OF AN EFFICIENT ALGORITHM

The energy consumption of the transceiver depends on the both system and circuit level design. If the CMOS circuits for designing the sensor nodes increase, total energy consumption must be increased. It is given that 20k and 10k CMOS gate circuits are needed for compression and decompression respectively [7], [8]. Every 1k gate needs 24  $\mu$ W powers for compression and decompression. So, computation power depends on the hardware of the sensor nodes. Another one is the transmission power and it is related to data rate minimization, distance and frequency. This data rate minimization can be achieved by local processing at the sensor node like data compression algorithms. We compare the different data compression algorithms by the following equation (10), [7], [8] and select **LPC** as the best algorithm for our purpose based on some calculations.

$$E_{tot} = P_{TX} \times (T_{ON-TX} + T_{START-TX}) + P_{RX} \times (T_{ON-RX} + T_{START-RX}) + P_{OFF} \times T_{OFF} \quad (10)$$

$P_{TX/RX}$  = compression and decompression power consumption of the transceiver

$T_{ON-TX/RX}$  = transmitter/receiver on-time

$T_{START-TX/RX}$  = start up time of the transceiver

$P_{OFF}$  = power consumption of the transceiver in the standby/off state

$T_{OFF}$  = transceiver off-time =  $1 - [T_{ON-TX} + T_{START-TX} + d \times (T_{ON-RX} + T_{START-RX})]$

$d$  = ratio of received packets to transmitted packets

##### A. Energy consumption in different methods varying transceiver ON time and Data Rate

We calculate the energy consumptions in different methods varying ON time of the transceiver with help of equation (10) and finally compare to select the best algorithm like LPC that are shown in the following Fig.2 and Fig.3.

Fig.2. Energy consumption in different methods varying transceiver ON time

Fig.3. Energy consumption in different methods varying transceiver data rate

#### V. NEW ENERGY DISSIPATION MODEL

We used our new energy dissipation model for calculating the transmitting and receiving energy consumption of the transceiver which is shown in the following Fig.4 [9].

Fig.4. New energy dissipation model for calculating the energy consumption parameters

### Case I: Without compression algorithm

We calculate transmit and receive energy consumption according to proposed radio energy dissipation model for our work as follows [9]:

Transmit energy consumption,  

$$\alpha_{ij}^t = E_{total} + P_{out} \times T_{on} + P_{off} T_{off} + E_{amp} \times d_{ij}^n \quad (11)$$

Where,  $E_{total}$  = total electronic circuit energy consumption (i.e ADC, filtering etc),  $P_{out} \times T_{on}$  = required transmission energy consumption,  $P_{off} T_{off}$  = transmitter off energy consumption,  $E_{amp}$  = amplifier energy consumption

$d_{ij}^n$  = distance between node i and j where n is the path loss exponent

Received energy consumption,  

$$\alpha_i^r = E_{total} + P_{rec} \times T_{on} + P_{off} T_{off} \quad (12)$$

Where,  $E_{total}$  = total electronic circuit energy consumption (i.e ADC, filtering etc),  $P_{rec} \times T_{on}$  = required received energy consumption,  $P_{off} T_{off}$  = receiver off energy consumption

### Case II: Using compression algorithm

We also calculate transmit and receive energy consumption according to proposed radio energy dissipation model for our work as follows [9]:

Transmit energy consumption,  

$$\alpha_{ij}^t = E_{total} + P_{TX} \times (T_{ON-TX} + T_{START-TX}) + P_{off} T_{off} + E_{amp} \times d_{ij}^n \quad (13)$$

Where,  $E_{total}$  = total electronic circuit energy consumption (i.e ADC, filtering etc),  $P_{TX} \times (T_{ON-TX} + T_{START-TX})$  = compression circuit energy with start-up time of compressor,  $P_{out} \times T_{on}$  = required transmission energy consumption,  $P_{off} T_{off}$  = transmitter off energy consumption,  $E_{amp}$  = amplifier energy consumption

$d_{ij}^n$  = distance between node i and j where n is the path loss exponent

Received energy consumption,  

$$\alpha_i^r = E_{total} + P_{RX} \times (T_{ON-RX} + T_{START-RX}) + P_{rec} \times T_{on} + P_{off} T_{off} \quad (14)$$

Where,  $E_{total}$  = total electronic circuit energy (i.e ADC, filtering etc),  $P_{RX} \times (T_{ON-RX} + T_{START-RX})$  = decompression circuit energy consumption with start-up time of decompressor,  $P_{rec} \times T_{on}$  = required received energy consumption,  $P_{off} T_{off}$  = receiver off energy consumption.

## VI. COMPARISONS OF THE SYTEM SYSTEM LIFETIME

We compare the system lifetime of our system by the following ways:

### Case I: For free space model (When n = 2)

TABLE I

## VII. CONCLUSION

In wireless body sensor networks, the nodes operate on limited battery energy. Our major target to support uninterrupted operation by enhancing the battery lifetime of the body sensor nodes for diagnosis the heart beat signal. Therefore, the main objective of this paper is to study and analyze the different algorithms for selecting the best one for low energy consumption in the body sensor nodes and then apply this efficient technique to maximize the system lifetime for a particular application scenario. In this paper, a new energy dissipation model is proposed and applied this best technique for this improved model to calculate the energy consumption parameters like transmitting and receiving energy consumption with respect to a particular application environment. MATLAB optimization technique is used to find out the system lifetimes with respect to our application scenario where we assumed our problem as a linear programming problem. Finally, we compared our results (system

lifetimes) using and without using compression technique in two different environments like free space model where  $n = 2$  and multipath model where  $n = 4$ . Results show that the maximum system lifetime using compression technique is definitely better in both cases.

# Cluster Analysis of Microarray data of *Shewanella oneidensis*

Sharmin Nilufar and Mst. Jannatul Ferdousi Ara

Department of Computing Science, University of Alberta, Edmonton, Canada T6G 2E8  
Department of Computer Science and Engineering, Dhaka City College, Dhaka, Bangladesh

**Abstract**— This paper presents a comprehensive analysis of a novel temporal dataset of *Shewanella oneidensis*. Here we propose to cluster the temporal gene expression data of *Shewanella oneidensis* to define its molecular response at different time intervals following acidic pH and basic pH exposure and to find a relation of these temporal data at different environmental conditions. A mapping between those clusters is also defined to describe the interaction and reaction of those genes in different time in two separate conditions. Several conceptually variant clustering algorithms are applied to find the actual structure within data and the results of clustering algorithms are evaluated by several robust internal indices.

**Index Terms**— Clustering, temporal data, *Shewanella oneidensis*, validation techniques.

## I. INTRODUCTION

Recent advents of technologies in the area of bioinformatics allow us to study thousands of genes by analyzing microarray gene expression data qualitatively. The cluster analysis of gene expression data facilitates to identify and group those genes with similar expression pattern. Clustering can be considered as the important initial steps of categorization and investigation of genes in most of the microarray data analysis research. Preliminary validation of the data quality can also be achieved by the visualization of the clustering results. Clustering also helps to explain the inter-correlation structure and expression changes across the samples.

In this paper we propose to analysis a novel temporal dataset of *Shewanella oneidensis*. *Shewanella oneidensis* is a metal-reducing bacterium. It has diverse respiratory capability [16]. It is very challenging and imperative task to define the genetic basis and regulatory mechanisms underlying the ability of *S. oneidensis* to survive and adapt to various environmentally relevant stresses. Gao *et al* [19] examines temporal gene expression profiles in cells subjected to heat stress by using whole-genome DNA microarrays for *S. oneidensis* to define this organism's molecular response to elevated growth temperatures. The molecular response of *Shewanella oneidensis* MR-1 to variations in extracellular pH was investigated by Leaphart *et al* [24] based on genomewide gene expression profiling. They discovered that cells elicited both general and specific transcriptome responses when challenged with environmental acid (pH 4) or base (pH10) conditions over a 60-min period.

This paper endeavors to analysis the microarray data of *Shewanella oneidensis*. There is not enough insight

information on the underlying molecular mechanisms and interaction enabling this bacterium to cope with extracellular acid and alkaline environments is available at present. To define this *Shewanella oneidensis*'s molecular response at different time intervals following acidic pH and basic pH exposure and to find a relation of these temporal data at different environmental conditions we propose to cluster the temporal gene expression data of *Shewanella oneidensis* and find a mapping between those clusters to describe the interaction and reaction of those genes in different time in two separate conditions. Since the actual number of clusters in this dataset is unknown we propose to use a number of conceptually variant clustering algorithms to find the actual structure within data. The result of clustering algorithm can be evaluated by several internal indices. The rest of the paper is organized as follows. Different aspects of gene clustering are described in section 2. A number of challenges of clustering methods including validation of the clustering results and estimation of the proper number classes are discussed in section 3 and section 4 respectively. Section 5 gives a brief idea about the dataset used in this research and section 6 discusses experimental setup and results. Finally concluding remarks are given in section 7.

## II. CLUSTERING

Current experiments on microarray data contain  $10^3$  to  $10^4$  genes. It is actually important and meaningful to cluster both gene and samples (also called features). Gene based clustering aims to group co-expressed genes together by considering genes as objects and samples as features. On the other hand sample based clustering cluster samples by treating gene as sample where each sample based group may represents some macroscopic phenotype, such as clinical syndromes or subtypes of disease [1] [2]. Another very powerful approach known as bi-clustering or subspace clustering designed to cluster subset genes that have similar expression pattern only in a subset of samples or time periods [13]. The results of these clustering techniques provide a good initial investigation in most of the microarray data before actually examining into specific pathways or genetic mechanisms. In the literature, there are a large number of statistical and computational approaches proposed and applied for gene clustering. The most popular clustering algorithm for gene expression data analysis are hierarchical clustering [11], K-means [6], partitioning around medoids [1], self-organizing maps (SOM)

[9], Self-Organizing Tree Algorithm (SOTA) [7] [8], fuzzy c-means, finite mixture models. These clustering algorithms are relatively equivalent in the sense that one method does not dominate all others and their performance depends on the structure and quality of the data.

K-means is probably the most widely used general clustering algorithm. This algorithm starts by assigning the input data points into  $k$  initial sets, either at random or using some heuristic data. The centroid of each set is then calculated. It reassigns each data point to the cluster with the closest centroid. The cluster centers are recalculated for the new clusters, and algorithm iterate these two steps until convergence. This algorithm is very popular because of its quick convergence. Different kinds of distance measures are used in kmeans and centroid of clusters are calculated differently for the different supported distance measures. Widely used distance measures are squared Euclidean distance where each centroid is the mean of the points in that cluster, cosine distance where data points are treated as vectors, correlation distance where objects are considered as sequences of values and hamming distance which calculates percentage of bits that differ is actually suitable for binary data

Hierarchical algorithms find successive clusters using previously established clusters. Hierarchical algorithms can be agglomerative or divisive. Agglomerative algorithms begin with each element as a separate cluster and merge them into successively larger clusters. Divisive algorithms begin with the whole set and proceed to divide it into successively smaller clusters. Single linkage, complete linkage and average linkage based methods are applied to calculate distances between new cluster and each of old clusters. Single-linkage considers the distance between one cluster and another cluster to be equal to the shortest distance from any member of one cluster to any member of the other cluster. Complete-linkage computes the distance between one cluster and another cluster to be equal to the greatest distance from any member of one cluster to any member of the other cluster. Average-linkage calculates the distance between one cluster and another cluster to be equal to the average distance from any member of one cluster to any member of the other cluster. Although the standard hierarchical clustering performs well for gene expression data, it is comparatively slow and not very robust when analyzing thousands of gene expression profiles [6] [4].

Self-Organising Maps (SOM) is based on the unsupervised neural networks and offer a more robust framework when clustering huge amounts of noisy microarray data [7] [8] [9]. The process can be summarized in two phases. In the first phase called training phase a map is built, the neural network organizes itself, using a competitive process. A large number of input vectors are given to the network. During the next phase the mapping phase a new input vector may quickly be given a location on the map, it is automatically classified or categorized. There will be one

single *winning* neuron: the neuron whose weight vector lies closest to the input vector. However, the SOM has some inherent problems. Firstly, since SOM is a topology-preserving, the number of clusters has to be fixed at the beginning of the method. Secondly, the clusters obtained in this technique are not proportional since training of the network depends on the number of items in each cluster.

In fuzzy clustering which is based on fuzzy subset, each point has a degree of belonging to clusters, rather than belonging completely to crisp cluster. The concept of fuzzy c-means clustering is very similar to k-means clustering where the number of clusters should be fixed before starting the clustering process. Main challenge of apply fuzzy clustering or microarray data is the choice of the fuzziness parameter [20]. Some new approaches for example model-based clustering and tight clustering have been proposed to handle scattered genes which contains noisy gene [1] [12]. Good reviews of various gene clustering methods and their advantages and limitations are discussed in [1] and [4].

### III. CLUSTER VALIDATION MEASURE

Since microarray data are very high dimensional and usually contain high levels of noises and many missing values, it is very challenging to detect the appropriate clusters. Moreover clustering approaches are biased towards particular clustering results which match with their own clustering properties. Most of the clustering techniques produce some kind of clusters even in the absence of natural clusters. To detect these limitations, cluster validation techniques are essential tools to verify the clustering result. Cluster-validation techniques provide a logical and systematic evaluation of the amount and type of structure captured by a clustering and should therefore be an important measurement in the analysis of clustering results [3].

A number of different validation techniques proposed by several researchers. Validation techniques are mainly divided into two board categories, external and internal validation measures. External validation measures are applied to obtain an entirely objective evaluation when the prior knowledge of the correct class levels is available. On the other hand internal validation measures do not use any prior information of the correct class level and are appropriate for the clustering result evaluation of new dataset where the actual class levels are not known. This kind of measures assesses the quality of the clustering result by employing information intrinsic to the data [3] [4] [22].

Popular external indices are rand index and Jaccard coefficient which used contingency table to assess the consensus between a partitioning and ground truth [22]. The rand Index determines the similarity between two clusters as a function of positive and negative agreements in pairwise

cluster assignments while in Jaccard coefficient only positive agreements are rewarded. *Internal validation measures* can be categorized into several groups based on the properties they considered for validation for example compactness, connectedness and separation. Most of the popular internal validation indices employ a linear or nonlinear combination of several properties for example Dunn Index, the Davies–Bouldin Index or the Silhouette Width [21] assess both intra-cluster homogeneity and inter-cluster separation, and compute a ultimate score as the linear or non-linear combination of these measures. Some other external indices are also proposed which are based on the stability of the clustering results and compliance between partitioning and distance information of the original data. An extensive review of the different validation techniques can be found in [3].

#### IV. ESTIMATING OF NUMBER OF CLUSTERS

Estimating the actual number of clusters is very difficult in the real microarray data, since the underlying genetic interactions in an organism are so complex that the definition of gene clusters and the exact number of clusters are vague. Many methods for estimating the number of clusters have been proposed in the literature. One of the popular and vigorous techniques is to perform a comprehensive comparison of internal validation measures with different number of clusters and pick the cluster number which has the maximum performance under internal measure [3] [22]. This type of use in class number selection has been the most common application of internal validation measures in bioinformatics. Most of the internal measures can be used to estimate the number of clusters in a dataset. A robust method is to compute clustering results for a range of different numbers of clusters and plot of the performance under the internal measure as a function of the number of clusters. The best number of clusters can often be identified as a ‘knee’ in the resulting performance curve.

#### V. DATASET

The dataset we used in this project are obtained from Leaphart et al [24]. Datasets contains gene expressions of 4692 genes after espousing them to pH 4(acid) and pH10 (base) environment for 60 min time. Expressions are recorded after 30 min and 60 min. We apply filtering technique to eliminate all genes with missing values and obtain 3560 genes which have value in all time points in both conditions. We divide the data sets as acid dataset which contains the expression values of genes in 30 min and 60min time point in acidic condition and base dataset which contains the gene expressions in 30 and 60 min after exposing them in base environment.

### VI. EXPERIMENTS AND RESULTS

#### A. Experimental Setup

Most of the experiments are performed in MATLAB 7. Several special matlab toolboxes are used to perform cluster analysis and validation for example self organizing map toolbox and fuzzy clustering toolbox.

#### B. Clustering and cluster validation

When clustering a novel biological dataset, cluster validation plays a very different role. Although a completely objective validation of cluster quality is truly not possible, the application of cluster validation at different steps during the clustering process can help us to improve the quality of results, and enhance the confidence in the obtained final result. Several conceptually distinct clustering algorithms are applied to *Shewanella oneidensis* dataset. We have applied five different clustering algorithms namely kmeans, self organizing map (SOM), single linkage, average linkage and complete linkage hierarchical methods to find the actual structure of the dataset. The clustering results are obtained for different number of clusters. The performances of the clustering methods are evaluated by computing the silhouette width which is one of the effective internal measures. Figure 4 shows the plot of the performance of clustering techniques for different number of clusters. The clustering results on the acid datasets are given here. From the figure 1 we can see that most of the algorithms generate highly similar partitions. Since several conceptually different algorithms generate highly similar partitions we can say that the actual structure of the data has been discovered.

From the graph in Figure (1) we can see that kmeans outperforms all other clustering method for almost all of the cases. The complete and average linkage algorithms also obtained similar results. The worst performance is obtained from single linkage hierarchical algorithm especially for cluster size 2 to 8. Single linkage which employs the concept of connectedness is not appropriate for the structure of our dataset.

#### C. Kmeans with different distance measures

We have applied different types of distance measure in kmeans to find clusters which match with the meaningful biological clusters. Figure 2 shows the clusters retrieved with kmeans for different types of distance measures. From the visualization of clustering results and their silhouette widths we can see that cosine distance is performed best and able to find the well defined clusters which are also biologically meaningful. The correlation distance gives the worst performance.

Figure 1: Performance of several clustering algorithms

Figure 2: Clusters with kmeans using (a) Euclidian distance (Silhouette width= 0.6327), (b) Correlation distance (Silhouette width= -0.0386) and (c) Cosine distance (Silhouette width= 0.766322)

#### D. Number of Clusters

To select optimum number of clusters ( $k$ ) we compute several internal indices. Plot in figure 3 shows the performance curves of several internal indices for various values of  $k$ .

Most of internal indices agreed that cluster number 4 and cluster number 8 give good results comparing to other values of  $k$ . When considering the two most robust internal measures: Davis Bouldin index, silhouette width we can easily see that 4 and 8 are promising numbers of clusters as Davis Bouldin index achieve minimum values and silhouette width get maximum values in those cases. As a result, we have selected cluster number 4 and 8 for further experiments. From the several internal measures we can conclude that 4 is the best number of clusters for two datasets. We perform kmeans with four clusters. The clustering results we obtained from kmeans for 4 clusters using cosine distance can be defined

biologically. We define each cluster based on the nature of most gene expression in two time points of that clusters. For example figure 4 shows four clusters namely induced-induced, repressed-induced, repressed-repressed, induced-repressed. Most of the genes or in some cases all of the genes in those clusters have the same properties as their cluster names. For example, all of the genes in the cluster induced-induced are induced in both time points (i.e. at T1 and T1).

Figure 3: Clustering result with 8 clusters in Base condition

Figure 4: Visual examples for four clusters for (a) Acid dataset and (b) Base dataset

The sizes of similar clusters in two conditions are very close. For example, the size of cluster induced-induced in acidic condition is 1391 and in base condition is 1244. Although the number of genes shared in these two conditions are only 446. Also the number of genes that are induced in both time points in acid condition and repressed in both time points in base condition is 530. Thus we can say that many of the genes behave very differently in two different conditions

Table 1  
CLUSTER BEHAVIOUR IN (a) ACID AND (b) BASE CONDITION

| Acid (pH4)  | T1        | T2        | Number of genes |                                                                                   |
|-------------|-----------|-----------|-----------------|-----------------------------------------------------------------------------------|
| Cluster1    | induced   | induced   | 1391            |  |
| Cluster2    | repressed | induced   | 441             |                                                                                   |
| Cluster3    | repressed | repressed | 1456            |                                                                                   |
| Cluster4    | induced   | repressed | 302             |                                                                                   |

| Cluster1    | induced   | induced   | 1244            |  |
| Cluster2    | repressed | induced   | 536             |                                                                                   |
| Cluster3    | repressed | repressed | 1363            |                                                                                   |
| Cluster4    | induced   | repressed | 417             |                                                                                   |
| (b)         |           |           |                 |                                                                                   |

Considering the plot of internal indices in figure 3 we can also find a pick when the number of clusters is 8. Figure 5 shows the clustering results for two conditions using 8 clusters. From the clustering results for acid condition we see that the two big clusters induced-induced and repressed-repressed, each of them are divided into 3 different clusters based on the difference of the inducement and repression in two time points. For example the clusters1 we obtained are sub clusters of i-i(L-H) which are slightly induced in first time point and largely induced in the second time points. On the other hand i-i(simi) is induced similarly in both time points and cluster 4 i-i(H-L) are induced highly in first time point and decrease inducement in second time point. When considering the base condition we see that the cluster induced-induced are divided into two clusters: i-i(simi) and i-i(H-L). Similarly the cluster repressed-induced are divided into two clusters: r-i(simi) and r-i(L-H). On the other hand the cluster repressed-repressed in divided into 3 different clusters. To compare the reaction of genes in two different environments we calculate the intersection between classes. There are only 5 genes sharing the cluster 7 (i-r) in acid condition and cluster 5 (r-i) in base condition. On the other hand maximum number of genes are found in the intersection of cluster 3 (i-i(simi)) in acid condition and cluster 6 (i-i(simi)) in base condition.

## VII. CONCLUSION

In this paper, we employ several clustering methods and validations techniques to detect the actual structure of a novel dataset of *Shewanella oneidensis*. It is in fact not easy to provide an unbiased and experimental comparison of different

Figure 5: Visualization of Clustering result with 8 clusters in (a) Acid and (b) Base conditions respectively

clustering approaches. The original true clustering assignment in a novel dataset is generally unknown and the concept of a cluster is not mathematically well-defined in unsupervised learning. After explaining several validation indices we found that kmeans with cosine distance perform best for this dataset. The cluster number 4 and 8 able to find biologically meaningful clusters. Genes of *Shewanella oneidensis* have strong response to acid condition than base condition. More genes are induced and repressed in both time points in acidic condition than the base condition. In both conditions more genes are repressed than induced. Although the results shows similar distribution of the genes in four classes, the intersection between similar clusters in two different conditions contain small number of genes which imply many of the genes behave completely different in two conditions. Clustering result obtained with 8 clusters give more meaningful small clusters than 4 clusters. Detail study of dataset using different number of clusters and draw a complete mapping between clusters in two different conditions are left for our future work.

**Abstract** — An analytical model has been developed to improve the performance of a wireless mobile communication network with voice and data integrated traffic system. To reduce the probability of no channel available, which is an important quantity for performance evaluation, delays to the last data end user is introduced to the system. It has been found that by applying a very small delay to the last data end user, the probability of no channel available can be drastically reduced compared to the usual erlang case.

**Index Terms** — Last data end user, performance evaluation, probability of no channel available, voice/data integration.

## I. INTRODUCTION

As the wireless communications industry moves toward 3G and 4G networks, one of the important objectives is the use of a single wireless system for multimedia applications to support a variety of communications services, including voice, data, and voice in various forms and combinations [1]. A key technical problem in such integrated systems is that of multi-user access. As we know that an access method that efficiently supports one category of service may be unsuitable for another category of service. In the 1G and 2G networks, the wireless industry evolved around two separate paths for voice- and data-oriented applications [2]. If a data service can be efficiently integrated with a voice service, transmission resources that are otherwise wasted (because there is no voice transmission) can be used for data, which typically do not have stringent delay requirements. First, the voice-oriented networks evolved into supporting data. More recently with the popularity of voice over IP over the Internet and PSTN, supporting voice in data-oriented WLANs has become attractive as well [3].

In a packet communication environment, voice and data have different requirements. Voice packets can tolerate errors and even packet losses of 1 to 2 percent of voice packets has insignificant effect on the perceived quality of reconstructed voice [3], whereas data packets are sensitive to loss and errors but can generally tolerate delays. Also, the rate at which information is transmitted is constant in the case of voice, thereby making circuit-switching a viable and

efficient approach, whereas information generated for data transmission is very bursty. As a result, voice- and data-oriented networks use different multiple access methods. In a wireless environment, the simplest approach is to assign different frequency bands to isochronous (voice) and asynchronous (data) packets. However, integration in one frequency band will result in a more efficient use of the bandwidth, a simpler radio interface, and an environment that provides a better control for synchronizing voice and video [3].

Let us consider a mixed service environment with data and voice. For bandwidth detection, such a mixed service can further classified into the forms of circuit switching, burst or packet switching and hybrid switching which support both circuit and packet switching [4]. To support the maximum number of voice users, the best case would be that all available channels are shared between voice users. However, in cases where voice users occupy all available channels any data presented to the system is buffered and the mean delay for the data becomes high. This situation is defined to be the scalar quantity ‘bursty queue length’. It is clear that in this worse data case the buffer occupancy quickly becomes elevated and queuing time rapidly increase. Conversely, a better data case would be that all channels are available for data at any time. In this case the earlang capacity of voice user becomes low as voice users are less able to occupy channels. Trivially, it is clear that improvement in traffic for data could be made if bursty queue lengths could be ameliorated [5].

We organize the paper as follows. Section II describes the traffic model for the derivation of the stationary probability distribution of the network states. Expressions for the probability of no channel available and blocking probability have been obtained in this section. Section III describes the results of the investigation by showing the variation of the above mentioned two important quantities with respect to the offered traffic of both voice and data and also with respect to the delay of data end user. Finally, Section IV concludes the paper.

## II. TRAFFIC MODEL

We consider a hybrid traffic system with voice and data traffic. We assume that the voice has a high priority and that data has low priority.

For a queuing system with  $n$  servers and an infinite number of users consisting of both voice and data traffic according to Poisson process with the same arrival rate  $\lambda$  and service rate  $\mu$ , then the system can be denoted by  $M/M/n/n$ , and is known as  $n$ -server loss system [6]. The servers can be considered as channels. The steady state distributions of the probability states can then be written as

$$P_x = \frac{a^x}{x!} P_0; \quad x = 0, 1, 2, \dots, n \quad (1)$$

where  $a \equiv \lambda / \mu$  is known as the offered traffic and  $P_0$  can be obtained from the normalization that the sum of all the stationary probability states is unity. This is the usual Erlang theory [6]. The quantity  $P_n$  is an important quantity, called the probability of no channel available. It is the fraction of the time that the system is full, or the fraction of the time that customers are lost in the long run. It is implied that the system is saturated with the users and the mean duration is given by  $m_n = (n\mu)^{-1}$ . In general,  $m_n$  is in the order of many seconds and consequently bursty length of queue occurs. Now if we consider that the state of the system be at  $n-1$ , the next user is given the last available channel. A new protocol called delay of voice end user (DOVE) has been proposed in [5]. When the  $n$ -th user presents, this call is delayed for an arbitrary time. We redefine that the state space to be  $\{0, 1, 2, \dots, n-1, D, n\}$ . Fig. 1 shows the queuing model of DOVE.

Fig. 1. Model of exchange with DOVE.

Implementation of DOVE is straightforward for mobile networks and would be triggered by a last user success condition [5]. Let  $d$  be the duration of time that the new call experiences in delay before being allowed a channel. In this

situation we can either have that  $d$  expires. In which case the delayed voice user is given permission to occupy the channel, or a channel becomes available before the expiration of the  $d$  and the voice user is given permission to this other channel. By delaying the  $n$ -th user, the duration for which all of the channels are occupied is reduced and the system stays in the state  $n-1$  for a greater proportion of time. Detail analysis is described in [5].

Since voice traffic should have higher priority than the data traffic, instead of DOVE we intend to study the delay of data end user (DODE) in this paper. Further, we do not assume the same arrival rate of the voice and data traffic. Instead, we assume that voice traffic and data traffic have different arrival rates and these are respectively as  $\lambda_v$  and  $\lambda_d$ . The corresponding Markov chain is shown in Fig. 2.

Fig. 2. Markov chain for the delay of data end user.

The steady state probability distributions are obtained from the following systems of equations:

$$(\lambda_v + \lambda_d)P_0 = \mu P_1, \quad (2)$$

$$(\lambda_v + \lambda_d + \mu)P_1 = (\lambda_v + \lambda_d)P_0 + 2\mu P_2, \quad (3)$$

$$(\lambda_v + \lambda_d + 2\mu)P_2 = (\lambda_v + \lambda_d)P_1 + 3\mu P_3, \quad (4)$$

$$\vdots$$

$$\begin{aligned} \{\lambda_v + \lambda_d + (n-1)\mu\}P_{n-1} \\ = (\lambda_v + \lambda_d)P_{n-2} + (n-1)\mu P_{n-1,D} + n\mu P_n, \end{aligned} \quad (5)$$

$$\{\delta + (n-1)\mu\}P_{n-1,D} = \lambda_d P_{n-1}, \quad (6)$$

$$n\mu P_n = \delta P_{n-1,D} + \lambda_v P_{n-1}. \quad (7)$$

The stationary probability distributions up to state  $n-1$  are still given by (1) with  $a \equiv (\lambda_v + \lambda_d) / \mu$  and the remaining  $P_{n-1,D}$  and  $P_n$  are obtained as

$$P_{n-1,D} = \left( \frac{\lambda_d}{\delta + (n-1)\mu} \right) \frac{a^{n-1}}{(n-1)!} P_0, \quad (8)$$

and

$$P_n = \left( \frac{a\delta + (n-1)\lambda_v}{\delta + (n-1)\mu} \right) \frac{a^{n-1}}{n!} P_0, \quad (9)$$

where

$$P_0 = \left( \sum_{x=0}^{n-1} \frac{a^x}{x!} + \left( \frac{a\delta + n\lambda_d + (n-1)\lambda_v}{\delta + (n-1)\mu} \right) \frac{a^{n-1}}{n!} \right)^{-1}. \quad (10)$$

The probability of no channel available and the blocking probability are obtained as

$$P_N = P_n = \left( \frac{a\delta + (n-1)\lambda_v}{\delta + (n-1)\mu} \right) \frac{a^{n-1}}{n!} P_0, \quad (11)$$

and

$$\begin{aligned} P_B &= P_N + P_{n-1,D} \\ &= \left( \frac{a\delta + n\lambda_d + (n-1)\lambda_v}{\delta + (n-1)\mu} \right) \frac{a^{n-1}}{n!} P_0, \end{aligned} \quad (12)$$

where the constant  $P_0$  is given by (10).

### III. RESULTS AND DISCUSSIONS

For the numerical appreciation of our results, we have displayed in the forms of graphs, the variation of the probability of no channel available and the blocking probability as functions of the arrival rates of the voice and data traffic as well as with respect to the delay of the data end user. Figs. 3 and 4 are displayed for the probability of no channel available with respect to the arrival rates of voice and data traffic respectively taking the delay  $d$  of the data end user as a parameter; whereas in Figs. 5 and 6 we show the variation of the probability of no channel available and the blocking probability respectively with respect to the delay  $d$  taking the service rate  $\mu$  as a parameter [7].

From Figs. 3 and 4 we notice that the behavior of the probability of no channel available is almost same, particularly for the lower values of the arrival rates of the voice and data traffic, whereas for the higher values of the arrival rates, the two cases differ markedly if we increase the delay  $d$ . We also observe that as we increase the delay  $d$ , the probability of no channel available drops noticeably. Since delay is applied to data traffic, slope of  $P_N$  against  $\lambda_d$  changes with respect to  $d$  but it does not have impact on slope of  $P_N$  versus  $\lambda_v$  curve (Figs. 3 and 4).

Fig. 5 shows the variation of the probability of no channel available with respect to the delay  $d$  of the data end user. It is interesting to note from this figure that we need only to give a very small value of the delay  $d$  to reduce  $P_N$  up to 67% from the Erlang value (with no delay to the data or voice end user). This is a remarkable result of the paper.

Fig. 3. The probability of no channel available as a function of the arrival rate of the voice traffic  $\lambda_v$  under different delay  $d = 1/\delta$  ( $n=7$ ,  $\mu = 1.5$ ,  $\lambda_d = 4$ ).

Fig. 4. The probability of no channel available as a function of the arrival rate of the data traffic  $\lambda_d$  under different delay  $d = 1/\delta$  ( $n=7$ ,  $\mu = 1.5$ ,  $\lambda_d = 4$ ).

Fig. 5. The probability of no channel available as a function of the delay  $d = 1/\delta$  for different  $\mu$  ( $n=7$ ,  $\lambda_v = 4$ ,  $\lambda_d = 4$ ).

Fig. 6. The blocking probability as a function of the delay  $d = 1/\delta$  for different  $\mu$  ( $n=7$ ,  $\lambda_v = 4$ ,  $\lambda_d = 4$ ).

Fig. 6 shows the variation of the blocking probability  $P_B$  with respect to the delay  $d$  for different values of  $\mu$ . We observe that the blocking probability is somewhat increased (negligibly) when we include the delay of data end user for the data traffic in the system for small values of  $\mu$ . From the user's point of view, as to handle a voice request is more important than the blocking of data traffic, this negligible increase in the blocking probability for small value of  $\mu$  has no effect on the Erlang capacity for the users of the voice

calls. However, it is interesting to observe that as we increase  $\mu$ , the blocking probability decreases from the Erlang case. Furthermore, for large holding time (small  $\mu$ ) of call, the impact of delay is very small as is visualized from Fig. 6.

## VII. CONCLUSION

An analytical model has been developed to improve the probability of no channel available, which is a very important quantity for performance evaluation of a wireless mobile communication system. Delay of data end user has been introduced instead of delay of voice end user as the voice traffic is impatient traffic (customer retry until getting free channel) should have higher priority than the data traffic. It has been found that by applying a small delay to the data end user, the probability of no channel available can be drastically reduced. We have in this analysis incorporated different arrival rates of the voice and data traffic but same service termination rate.

# A New Weighted Centroid Localization Algorithm in Wireless Sensor Networks

Yahya Forghani

Toos Institute of Higher Education, Mashad, IRAN

**Abstract** — Nodes in a sensor network are often randomly distributed. To assign measurements to locations, each node has to determine its own position. Algorithms for positioning in wireless sensor networks are classified into two groups: approximate and exact. In this paper, we propose a range-based approximate positioning approach which is almost the combination of WCL and EBTB. Then, compare it with two other approximate positioning approaches (WCL with time complexity of  $O(n)$  and EBTB with time complexity of  $O(n^2)$  and an exact positioning approach (QR Factorization with time complexity of  $O(n^3)$ ). Finally, it will be shown that EWCL (with time complexity of  $O(n)$ ) is the best localization algorithm with respect to the three other localization algorithms when the noise is high and its accuracy is close to the accuracy of QR when the noise is medium.

**Index Terms** — range-based; approximate; positioning; wireless sensor networks; noisy.

## I. INTRODUCTION

The increasing miniaturization of electronic components and advances in modern communication technologies lead to the development of extreme small, cheap, and smart sensor nodes [1]. These nodes consist of sensors, actuators, a low power processor, small memory, and a communication module. Nodes measure conditions of the environment, precalculate, aggregate, and transmit data to a base station. Thousands of these nodes form a large wireless sensor network to monitor huge inaccessible terrains.

Processor performance and available energy of each sensor node are highly limited by its physical size. Therefore, intensive communication and computation tasks are not feasible. Thereby, algorithms in sensor networks are subject to strict requirements covering reduced memory consumption, communication, and processing time.

As a result of the stochastic distribution of all nodes in the deployment phase, a determination of the node's position is required. Then, every measurement can be assigned to its physical position. Basically, a global position can be approximately determined with state-of-the-art positioning systems such as the Global Positioning System (GPS) or the Global System for Mobile Communication (GSM) [2], [3]. These systems are not suitable for tiny sensor nodes because of their physical size and costs as well as their high power consumption

resulting from the communication overhead [4]. A better approach is to equip only few nodes with a global positioning system. Then, these nodes determine their own position very precisely and provide this position to other nodes in the sensor network. Based on this approach, we present a new approximate positioning approach for localization in wireless sensor networks.

This paper is structured as follows. In Section II, we give a basic overview of the approaches for positioning in the wireless sensor networks and in Section III, BTB algorithm is described. Next, In Section IV, we describe our new positioning approach. Then, in Section V, we describe our simulation environment and its parameters. After discussing our simulation results in Section VI, finally we conclude the paper in Section VII.

## II. RELATED WORK

For the above-mentioned reasons, existing positioning techniques (e.g. GPS) cannot be integrated on all sensor nodes. The number of nodes with known position has to be limited. These nodes are referred to here as beacons, with the remaining nodes classed as sensor nodes. For the positioning of the sensor nodes we distinguish between approximate and exact approaches [5].

### A. Approximate Positioning

Many approximate approaches for the determination of sensor nodes exist in literature. These approaches are often resource-efficient but also result in higher positioning errors than exact positioning approaches, especially when the input parameters have low deviation of their true value. Examples of such approaches are the hybrid approaches [6], the Coarse Grained Localization (CGL) [7], the Approximate Point in Triangulation-algorithm (APIT) [8], the Weighted Centroid Localization (WCL) [9], the EBTB algorithm [10] and the Binary algorithm [11].

WCL is simple, has low complexity, requires a few resources, has rather good accuracy (especially in high noise situations) and is range-based. APIT has more complexity, requires more resources and has lower accuracy than WCL. But, it is range-free. The resource requirement of EBTB is more than WCL and less than APIT and its accuracy is often better than WCL and APIT

but it is range-based. CGL is range-free and requires fewer resources than the two previous approaches, but has low accuracy. The resource requirement of Binary is more than EBTB and less than APIT; its accuracy is often better than them and is range-free.

### B. Exact Positioning

In contrast to approximate approaches, exact approaches use the known beacon-positions and the distances to the sensor nodes in order to calculate their coordinates through the solution of non-linear equations. Using a minimum of three beacons (in two dimensions), the coordinates of the sensor nodes may be determined by their intersection. The use of more than three beacons gives more information in the system and allows the refinement of the position and the detection and removal of outlying observations. The least squares method (LSM) is used for the solution of the simultaneous equations. The LSM produces accurate results, however it is complex and resource-intensive and therefore it is not feasible on resource-limited sensor nodes. So, this approach is implemented distributed with some communication efforts [12]–[17].

In this paper, we introduce a new Weighted Centroid Localization algorithm called Extended WCL. Then, we compare it with QR Factorization [17] (which is a LSM) and WCL and EBTB (which are approximate positioning approaches).

## III. ESTIMATING THE POSITION OF A NODE USING TWO BEACONS (BTB ALGORITHM)

When  $C$  is a sensor node on the connecting line segment of the beacons  $A$  and  $B$ , and the range between the beacon  $A$  and the sensor node  $C$  is  $AC$  and the range between the beacon  $B$  and the sensor node  $C$  is  $BC$ , we have

$$AB = AC + BC. \quad (1)$$

Also, we know that parametric equation of the line segment  $AB$  is

$$\begin{aligned} x(u) &= x_A + u\Delta x \\ y(u) &= y_A + u\Delta y. \end{aligned} \quad (2)$$

where

$$\begin{aligned} \Delta x &= x_B - x_A \\ \Delta y &= y_B - y_A. \end{aligned}$$

So, with replacing  $u = \frac{AC}{AB}$  in (2), the coordinate of the point  $C$  is obtained.

If the sensor node  $C$  is not on the line segment  $AB$ , but is near to it, then

$$AB = AC + BC - \epsilon. \quad (3)$$

Whatever the sensor node  $C$  is nearer to the line segment  $AB$ ,  $|\epsilon|$  becomes less and when the sensor node  $C$  is on the line segment,  $\epsilon$  becomes equal to zero. As it is seen in Fig. 1, if the coordinates of the beacons  $A$  and  $B$  and the ranges between them and the sensor node  $C$  is determinate, the position of the sensor node  $C$  will be the point  $C_1$  or  $C_2$ . But, if  $|\epsilon|$  is small, the intersection of the line segment  $AB$  and the line segment  $C_1C_2$  (which is the point  $F$ ), will be a good approximation of the position of the sensor node  $C$ .

The point  $F$  (the approximate position of the sensor node  $C$ ) is approximately in middle of the two points  $E$  and  $D$ , where the coordinate of the point  $D$  (the intersection of a circle with the radius  $AC$  and the line segment  $AB$ ) and the coordinate of the point  $E$  (the intersection of a circle with the radius  $BC$  and the line segment  $AB$ ) are obtained easily from the parametric equation of the line segment  $AB$  (see [10]).

Fig. 1. Positioning in a sensor network

As it was said, if  $|\epsilon|$  is small, the point  $F$  will be a good approximation of the position of the sensor node  $C$ . So, we can select two beacons with minimum  $|\epsilon|$  and then estimate the position of the node  $C$  using the selected two beacons (BTB algorithm).

## IV. NEW APPROACH

### A. First Improvement of BTB

Almost like EBTB, in a noisy environment we should select two beacons with minimum  $|\mu|$ , where

$$\mu = \epsilon \cdot (aC + Cb), \quad (4)$$

because the accuracy of estimated range between the node  $C$  and the beacons “a” and “b” has inverse relation with the true range. In the other word, when the true range between the node  $C$  and the beacon “a” becomes more, the estimated range “aC” probably has more bias from the true range. So, in a noisy environment, we should select two beacons “a” and “b” that their  $\epsilon$  with respect to the node  $C$  is relatively minimum and these two beacons should be relatively the nearest beacons in the range of the node  $C$ .

So, instead of selecting two beacons with minimum  $|\epsilon|$ , we select two beacons with minimum  $|\mu|$ .

### B. Second Improvement

In BTB and EBTB algorithm and the prior subsection, we used only some couples of beacons which the vertical line from the node C on the connecting line of those couples of beacons was positioned on the connecting line segment of those couples of beacons (Fig. 1). But we can extend the algorithm to use the other couples of beacons. The Fig. 2 shows such a couple of beacons. As it is seen in this figure, the vertical line from the node C on the connecting line of the couple of beacons doesn't position on the connecting line segment of the couple of beacons.

Fig.2. Positioning in a sensor network

### C. Third Improvement

Unfortunately, even with the prior improvements the described algorithm doesn't have a good accuracy in a noisy situation because the node C estimates its position using only two beacons with minimum  $|\mu|$ , while we can use the other couples of beacons to obtain a better estimation of the position of node C. In the other word, we can obtain an estimation of the position of the node C using each couples of beacons and then combine the estimated positions with different weights using the following equation to obtain a better estimation of the position of the node C (like WCL algorithm)

$$(x_N, y_N) = \frac{\sum_{i=1}^n \sum_{j=1, j \neq i}^n w_{ij} \cdot (x_{ij}, y_{ij})}{\sum_{i=1}^n \sum_{j=1, j \neq i}^n w_{ij}}, \quad (5)$$

where  $i$  and  $j$  are two beacons,  $n$  is the number of beacons,  $(x_{ij}, y_{ij})$  is the obtained estimation of the position of the node C using  $i$  and  $j$ ,  $(x_N, y_N)$  is the final estimation of the position of the node C. With regard to (4), if  $\epsilon_{ij}$  of two beacons  $i$  and  $j$  become close to zero,  $\mu_{ij}$  of them becomes close to zero, too. So, two problems occur.

First problem: In this case or in general when

$$\frac{\epsilon_{ij}}{iC + Cj} \quad (6)$$

become close to zero, the distance from the node C to the each of the beacons  $i$  and  $j$  will not affects much on  $\mu_{ij}$  which is not desirable and we want in this situation that the node C has positioned close to the connecting line of the couple of beacons,  $\mu_{ij}$  become close to zero only if the sum of the distances from the node C to each of the beacons  $i$  and  $j$  is a small value. In the other words, if the sum of the distances from the node C (which is close to the connecting line of the couple of beacon) to each of the beacons  $i$  and  $j$  is a big value, we should not rely much on the estimated position of the node C using this couple of beacons. But unfortunately in this case,  $\mu_{ij}$  become close to zero, so the described algorithm relies much on estimated position of the node C using this couple of beacons.

Second Problem: when  $\mu_{ij}$  of two beacons  $i$  and  $j$  become close to zero,  $w_{ij}$  of them become so big that  $(x_N, y_N)$  become close to a  $(x_{ij}, y_{ij})$  (the estimated position of the node C using this two beacons) and the effect of the other estimated positions of the node on  $(x_N, y_N)$  become too low which is not desirable (see (5)).

So, we should skip the couples of beacons which their  $\epsilon_{ij}$  is close to zero. In the other words, if

$$\frac{\epsilon_{ij}}{iC + Cj} < \delta, \quad (7)$$

We should skip the estimated position of the node C using the couple of beacons  $i$  and  $j$ .

## V. SIMULATION

To study the accuracy of EWCL and to compare it with WCL, EBTB and QR, we did many simulations in different situations in a square area with sides of 100 m. At the start of each simulation, some beacons (between 10 to 100 beacons, as an input parameter of simulation) and 10,000 nodes were randomly placed with a uniform distribution within the area. Then, the range between connected nodes was blurred by drawing a random value from a normal distribution having a normalized standard deviation with respect to the true range and having the true range as the mean. Maximum transmission range of each beacon was assumed between 20 m to 100 m.

Then, with a given input parameters, the position of each node was estimated using EWCL, EBTB, WCL and QR. Then, the number of the sensor nodes which could not estimate their position and the average of positioning error of sensor nodes (excluding the sensor nodes which

can not estimate their positions) and many other output parameters were registered. To account for the randomness in generating topologies and range errors we repeated each experiment 50 times with a different seeds, and report the averaged results.

Meanwhile, in the simulation, we found that 0.02 is a good value for  $\delta$  in (7). So, we present only the results of simulations which were done by this value of  $\delta$  and maximum transmission range of 50 m.

## VI. RESULTS

Fig. 3,4,5 show the accuracy of the proposed algorithm with respect to the three other algorithms, in three situation: when there is not any noise, when the noise is medium and when the noise is high. As it is seen in Fig. 3, in a noiseless situation, EWCL doesn't have a good accuracy. But in a real situation, when there is some noise in the environment, it has rather good accuracy and when AH becomes more than about 40, it becomes the best algorithm with the aspect of accuracy (Fig. 4). In high noise situation (Fig. 5), EWCL has the best accuracy with respect to the three other positioning algorithms.

Fig. 6,7,8,9 shows the sensitivity of each of the four localization algorithm to the noise. As it is seen, EWCL and WCL have low sensitivity to the noise, while QR and EBTB have high sensitivity to the noise.

## VII. CONCLUSION

As it was said, that WCL is with time complexity of  $O(n)$ , EWCL and BTB are with the time complexity of  $O(n^2)$  and QR is with time complexity of  $O(n^3)$ . So, EWCL is in the middle of the three other localization algorithms with respect to the resource requirement. But as it was seen, EWCL is the best localization algorithm when the noise is high and its accuracy is close to the accuracy of QR when the noise is medium.

**Abstract** — In this paper, we study the effect of various concatenated Forward Error Correction (FEC) codes on the performance of a wireless Orthogonal Frequency Division Multiplexing (OFDM) system. In FEC concatenated channel code, the OFDM system incorporates Reed-Solomon (RS) encoder of (255,239,8), Cyclic Encoder of (15,11), Bose-Chadhuri-Hocquenghem (BCH) encoder of (127,64) with Convolution encoder of  $\frac{3}{4}$  and  $\frac{1}{2}$ -rated codes under different combinations of digital modulation (QPSK, 8PSK, 32-QAM and 64-QAM). The simulation study is made with the development of a computer program written in MATLAB source code on the processing of recorded audio signal under additive white Gaussian noise (AWGN) channel. The simulation results of estimated Bit error rate (BER) show that the implementation of concatenated RS(255,239,8) code with  $\frac{3}{4}$ -rated Convolutional code under QPSK modulation technique is highly effective to combat inherent interference in the communication system. Due to constraint in data handling capability of the MATLAB Editor, a segment of the recorded audio signal is used for analysis. The transmitted audio message is found to have retrieved effectively under noisy situation.

**Index Terms** — Orthogonal Frequency Division Multiplexing, Cyclic encoding, Reed-Solomon encoding, Convolution encoding (CC), Bose-Chadhuri-Hocquenghem (BCH) Bit error rate (BER) and Additive White Gaussian Noise (AWGN).

## I. INTRODUCTION

Orthogonal frequency division multiplexing (OFDM) is a multi carrier modulation technique well suited to overcome adverse effects in hostile transmission environment. This technique provides a reliable reception of signals affected by multipath propagation and selective fading and has been used in broadcast media such as European terrestrial digital video broadcasting (DVB-T) and digital audio broadcasting (DAB) and in the IEEE 802.11a(local area network, LAN) and the IEEE

802.16a(metropolitan area network, MAN) standards. OFDM is also being pursued for dedicated short-range communications (DSRC) for roadside to vehicle communications. With the advent of next generation (4G) broadband wireless communications, the combination of multiple-input multiple-output (MIMO) wireless technology with orthogonal frequency division multiplexing (OFDM) has been recognized as one of the most promising techniques to achieve high data rate and provide more reliable reception compared with the traditional single antenna system [1, 2]. However, in the present study, an effort has been made merely to concatenate the various channel encoding codes to improve the reliable reception performance of an OFDM wireless communication system under different digital modulation schemes such as QPSK, 8PSK, 32-QAM, 64-QAM. In OFDM, generally, the transmitted bit stream is divided into many different sub streams and sent over many different sub channels. Typically the sub channels are orthogonal under ideal propagation conditions. The data rate on each of the sub-channels is much less than the total data rate, and the corresponding sub-channel bandwidth is much less than the total system bandwidth. The number of sub streams is chosen to insure that each sub channel has a bandwidth less than the coherence bandwidth of the channel, so the sub channels experience relatively flat fading with insignificant amount of ISI effect. In almost all applications of multi-carrier modulation, satisfactory performance cannot be achieved without the addition of some form of channel coding. In wireless systems subjected to fading, extremely high signal-to-noise ratios are required to achieve reasonable error probability. In addition, interference from other wireless channels is frequently severe. On wire-line systems, large constellation sizes are commonly employed to achieve high bit rates. Coding in this case is essential

for achieving the highest possible rates in the presence of crosstalk and impulsive and other interference. Channel coding in OFDM systems can be implemented in time and frequency domain such that both dimensions are utilized to achieve better immunity against frequency and time selective fading. A concatenated coding scheme constituted from a combination of two 8-bit channel codes (block and convolution) along with proper time/frequency interleaving has been used in the present study. [3,4].

## II. TRANSMISSION SIMULATION MODEL

Fig. 1. A block diagram of an OFDM communication system with interleaved concatenated channel coding.

The block diagram of the simulated system model is shown in Figure 1. The input binary data stream obtained from a segment of recorded audio signal is ensured against transmission errors with Forward Error Correction codes (FECs) and interleaved. A block Reed Solomon (255, 239,8) code based on the Galois field GF (28) with a symbol size of 8 bits is chosen that processes a block of 239 symbols and can correct up to 8 symbol errors calculating 16 redundant correction symbols. The block formatted (Reed Solomon encoded) data stream is passed through a convolution interleaver of depth 12. A convolution code (CC) is applied to the interleaved symbols. Its rate  $R = m/n$ , where  $m$  is the number of input bits and  $n$  is the number of output bits- is equal to  $\frac{1}{2}$  and  $\frac{3}{4}$  and the constraint length,  $K$  of 5 and 7. The convolutionally encoded bits are interleaved further prior to converted into each of the either four complex modulation symbols in QPSK 8PSK, 32-QAM and 64-QAM modulation and fed to an OFDM modulator for transmission. The simulated coding and modulation schemes used in the present study are shown in Table 1.

TABLE I  
SIMULATED CONCATENATED CODING AND MODULATION SCHEMES

| FEC # | Modulation | RS code     | CC code rate  | BCH code    | Cyclic Code |
|-------|------------|-------------|---------------|-------------|-------------|
| 1     | QPSK       | (255,239,8) | $\frac{2}{3}$ |             |             |
| 2     | 8PSK       | (255,239,8) | $\frac{2}{3}$ |             |             |
| 3     | 32QAM      | (255,239,8) | $\frac{2}{3}$ |             |             |
| 4     | 64QAM      | (255,239,8) | $\frac{2}{3}$ |             |             |
| 5     | QPSK       | (255,239,8) | $\frac{3}{4}$ |             |             |
| 6     | 8PSK       | (255,239,8) | $\frac{3}{4}$ |             |             |
| 7     | 32QAM      | (255,239,8) | $\frac{3}{4}$ |             |             |
| 8     | 64QAM      | (255,239,8) | $\frac{3}{4}$ |             |             |
| 9     | QPSK       |             | $\frac{2}{3}$ | BCH(127,64) |             |
| 10    | 8PSK       |             | $\frac{2}{3}$ | BCH(127,64) |             |
| 11    | 32QAM      |             | $\frac{2}{3}$ | BCH(127,64) |             |
| 12    | 64-QAM     |             | $\frac{2}{3}$ | BCH(127,64) |             |
| 13    | QPSK       |             | $\frac{3}{4}$ | BCH(127,64) |             |
| 14    | 8PSK       |             | $\frac{3}{4}$ | BCH(127,64) |             |
| 15    | 32-QAM     |             | $\frac{3}{4}$ | BCH(127,64) |             |
| 16    | 64-QAM     |             | $\frac{3}{4}$ | BCH(127,64) |             |
| 17    | QPSK       |             | $\frac{2}{3}$ |             | CC(15,11)   |
| 18    | 8PSK       |             | $\frac{2}{3}$ |             | CC(15,11)   |
| 19    | 32QAM      |             | $\frac{2}{3}$ |             | CC(15,11)   |
| 20    | 64QAM      |             | $\frac{2}{3}$ |             | CC(15,11)   |
| 21    | QPSK       |             | $\frac{3}{4}$ |             | CC(15,11)   |
| 22    | 8PSK       |             | $\frac{3}{4}$ |             | CC(15,11)   |
| 23    | 32QAM      |             | $\frac{3}{4}$ |             | CC(15,11)   |
| 24    | 64QAM      |             | $\frac{3}{4}$ |             | CC(15,11)   |

In OFDM modulator, the digitally modulated information symbols are transmitted in parallel on sub carriers through

implementation as an inverse discrete Fourier transform (IDFT) on a block of information symbols followed by an analog-to-digital converter (ADC). To mitigate the effects of intersymbol interference (ISI) caused by channel time spread, each block of IDFT coefficients is typically preceded by a cyclic prefix [5,6]. At the receiver side, the received signal is OFDM demodulated, de-mapped, de-interleaved and then de-decoded in order to recover the data transmitted.

### III. SIMULATION RESULTS

BER performance of the wireless OFDM system under three concatenated FEC channel coding and different modulation schemes listed in the Table 1 have been evaluated. We first investigate the use of interleaved concatenated RS (255,239,8) and CC codes with code rates of  $\frac{1}{2}$  and  $\frac{3}{4}$  under QPSK, 8PSK, 32-QAM, and 64-QAM modulations. The BER performance is investigated and results are shown in Fig. 2.

Fig. 2. System performance under different modulation schemes for RS (255,239,8) concatenated with CC (code rate of 2/3, 3/4)

The use of concatenated RS ((255,239,8) and CC with code rate  $\frac{1}{2}$  in 64-QAM modulation degrades the performance of the system. Next, we compare the BER performance of the OFDM system when channel coding is BCH and CC. The results are given in Fig. 3.

Fig. 3. System performance under different modulation schemes for BCH (127,64) concatenated with CC (code rate of  $\frac{1}{2}$  and  $\frac{3}{4}$ )

Finally; we compare the BER performance of the OFDM system when channel coding is Cyclic and CC. The results are given in Fig. 4. The simulation study gives an insight into ways of concatenating 8-bit Reed Solomon Code with  $\frac{2}{3}$  and  $\frac{3}{4}$  -rated Convolution code in 64-QAM modulations perform better than other concatenated codes and modulations. Fig. 2 through Fig. 4 show the bit error rate (BER) for different values of energy per bit to noise ratio ( $E_b/N$ ). Simulation results in Figure 2 show the advantage of considering a low ( $\frac{2}{3}$  and  $\frac{3}{4}$ ) convolution-coding rate for each of the four considered digital modulation schemes (QPSK, 8PSK, 32-QAM and 64-QAM). The performance of transmitted audio message is

found to have retrieved effectively under noisy situation that is shown in Fig. 5.

Fig. 4. System performance under different modulation schemes for Cyclic (15,11) concatenated with CC (code rate of  $\frac{1}{2}$  and  $\frac{3}{4}$ )

## VII. CONCLUSION

In this contribution, we have studied the performance of a wireless Orthogonal Frequency Division Multiplexing (OFDM) system adopting various concatenated FEC channel coding schemes and digital modulations. A range of system performance results highlights the impact of both digital modulation and concatenated channel coding schemes. In the context of system performance, it is observed that the implementation of interleaved Reed Solomon code with  $\frac{3}{4}$ -rated Convolution code under QPSK modulation technique provides satisfactory result among the three concatenated FEC channel coding schemes.

**Abstract** — In the literature there are several location based routing schemes available for MANET. The effective management of location information has the maximum impact on the performance of this type of routing protocols. In this paper first we have made a study of the different categories of existing location services. Then we have proposed a new location management scheme which effectively implements the major location management functions; namely location update and location query. In this scheme we have incorporated the multi-granular location information strategy. This is particularly aimed at reducing the orthogonal costs associated with location update and location query which we have clearly shown in the analysis part of this paper.

**Index Terms** — Location Query Cost, Location Service, Location Update Cost, Mobile Ad-Hoc Networks, Multi-Granular Location Information, Position Based Routing Protocols.

## I. INTRODUCTION

Position based routing protocols (such as GLS [1], SLURP [2], SLALoM [3], DLM [4]) use information about the physical position of the participating nodes, hence eliminating some of the limitations of topology based routing algorithms. Commonly, each node determines its own position through the use of GPS. The routing decision at each node is then based on destination's position and the position of forwarding node's neighbors.

In position based routing, the nodes have neither to store routing tables nor to transmit messages to keep the routing table up to date. The overhead is also reduced, since the establishment or maintenance of routes is not required in a protocol that uses location information for routing. Another advantage is scalability. And lastly it uses localized algorithm.

## II. REVIEW OF LOCATION SERVICES

### A. Flooding-based Location Services

Location services can be broadly divided into flooding-based and quorum-based approaches. Flooding-based protocols follow two different approaches: proactive and reactive. In case of proactive approach, each (destination)

node periodically floods its location information to other nodes in the network, which maintain location tables to keep track of this information. DLS is an example of proactive flooding-based location services.

### DREAM Location Service (DLS)

In the DREAM Location Service (DLS) [5] each location packet (LP) contains the coordinates of the source node based on some reference system, the speed of the source node and the last transmission time of the LP. Each mobile node in the ad hoc network transmits an LP to other nodes. The rate of transmission to nearby nodes is higher than to faraway nodes. The faraway nodes *appear* to move more slowly than nearby mobile nodes, and, therefore, it is not necessary for a mobile node to maintain up-to-date location information on faraway nodes. The overhead of location packets is limited by differentiating between nearby and faraway nodes. In DLS, the accuracy of the location information in the network is controlled via the frequency with which the LPs are transmitted and how far the LP is allowed to travel.

In case of reactive (on-demand) flooding-based approaches (e.g. RLS [5]), if a sender node cannot find a recent location of a destination, it floods a scoped query in the network in order to search the destination.

### B. Quorum-Based Location Services

In case of quorum-based protocols, all the nodes in the network agree, implicitly or explicitly, upon a mapping that associates each node's unique identifier to one or more other nodes in the network. The mapped-to nodes act as the location servers for that node. The location servers will store periodical location updates. Location queries will be routed to and looked up at these servers. As long as the lookup reaches one of the servers that was updated about the location corresponding to a given identifier, the correct location information will be found. In other words, the quorum of location servers updated on each location change needs to intersect the quorum of location servers consulted with in a lookup.

### C. Explicit Quorum-based Location Services

In the explicit quorum-based approach, each location update of a node is sent to an explicitly defined subset of available nodes. This subset forms the *update quorum*. On the other hand, a location query for that node is sent to a potentially different subset known as the *query quorum*. The two subsets are designed such that their intersection is non-empty, and thus the query will be satisfied by some node in the update quorum.

### D. Flat Quorum-based Location Services

In case of flat quorum-based location services, the operation is based on the notion of quorums. However, in these approaches, all quorum servers are symmetric in their roles. In particular, no hierarchical structure exists in such quorums. The Column-row quorum-based protocol [6] is an example of flat geographical quorum-based location service.

### E. Hierarchical Geographical Quorum-based Location Services

In case of hierarchical explicit geographical quorum-based location services a hierarchical structure of the quorum nodes is deployed. LLS [7] is an example of hierarchical explicit geographical quorum-based location service.

#### The Locality aware Location Service (LLS) [7]

The Locality aware Location Service (LLS) [7] uses hierarchical spiral structure in order to guarantee the *locality aware* properties of the lookup/publish algorithms. A location service has a *locality aware lookup* algorithm if the cost of locating destination  $t$  from source  $s$  is proportional to the cost of the minimal cost path between  $s$  and  $t$ . A location service has a *locality aware publish* algorithm if the cost of updating the location service due to the movement of a node from  $x$  to  $y$  is proportional to the distance between  $x$  and  $y$ .

Fig. 1. Basic structure of LLS

Fig. 1 shows the basic structure of LLS. The issue of mobility is addressed in LLS by using virtual coordinates within the squares for storing information on  $t$  rather than searching for certain pre-designated nodes.

LLS achieves worst case lookup cost of  $O(d^2)$  and an average case linear cost of  $O(d)$ , where  $d$  is the minimal path length between source and destination. Additionally,

when a node moves distance  $d$ , the average cost of publishing its new location is  $O(d \log d)$ . The inherent locality of LLS makes it fault tolerant both to nodes failures and to network partitions.

### F. Implicit (Hashing-based) Quorum-based Location Services

In case of implicit quorum-based protocols, location servers are chosen via a hashing function, either in the node identifier space or in the location space.

### G. Flat Hashing-based Location Services

In flat hashing-based protocols (for example, SLALoM [3]), a well-known hash function is applied to map each node's identifier to a *home region* consisting of one or more nodes within a fixed location in the network area. All nodes in the home region act as location servers. They maintain the location information for the node and can reply to queries for that node. Typically, the number of location servers in the home region is independent of the total number of nodes in the network, and thus effectively each node's location is disseminated to  $O(1)$  location servers.

#### SLALoM [3]

SLALoM combines the strengths of SLURP [2] and GLS [1]. In this scheme each node is assigned multiple home regions distributed uniformly over the area in which the nodes move about. (The nodes in these home regions act as location servers for the node.) It is assumed that the nodes move about in a square region of area  $A$ . According to SLALoM the square is divided into  $G$  unit regions called *order-1 squares*. It then combines  $K^2$  of the order-1 squares to form *order-2 squares*. A node's home region will consist of an order-1 square. With some exceptions, every node has a home region in each order-2 square. Hence, every node has  $O(A/K^2)$  home regions.

Fig. 2. Network hierarchy of SLALoM

### H. Hierarchical Hashing-based Location Services

In the hierarchical hashing-based protocols, the area in which nodes reside is recursively divided into a hierarchy of smaller grids. For each node, one or more nodes in each grid

at each level of the hierarchy are selected as its location servers. Location updates and queries traverse up and down the hierarchy. A major advantage of maintaining a hierarchy is that when the source and destination nodes are nearby, the query traversal is limited to the lower levels of the hierarchy.

The hierarchical grid structure is very efficient in distributing the load evenly across the network and in achieving efficiency and scalability of the location service. Since the height of the hierarchy is usually  $O(\log(N))$ , effectively each node's location is disseminated to  $O(\log(N))$  location servers.

The examples of hierarchical hashing-based protocols are Grid Location Service (GLS) [1], Distributed Location Management (DLM) [4].

#### GLS [1]

Grid Location Service (GLS) divides an area containing the ad hoc network into a hierarchical grid of squares. The largest square is called the level-H square. The level-H square is then recursively divided into four level-(H-1) squares until level-0 squares are reached, forming a so-called quad-tree. In each level- $i$  square (for  $i > 0$ ), node A selects three location servers, one in each level-( $i-1$ ) square that A is not in. The structure of GLS is shown in Fig. 3.

Fig. 3. Network structure of GLS

GLS selects the location servers based on the node ID in each server's service area (i.e., a quadrant). For a node C to be node A's location server, C has the smallest ID that is larger than A's ID in that quadrant, i.e.,  $C = \min \{x | \text{node } x \text{ is in the quadrant, } ID(x) > ID(A)\}$

Each node updates its location servers with its *exact* location after it moves a threshold distance  $\delta$ . To query for a particular node A, a node B sends the query to the node that is closest to A for which B has location information, and so on. Eventually the query would reach one of A's location servers.

### III. PROPOSED SCHEME

In our proposed scheme we have assumed that each node is equipped with GPS enabled devices through which the node can acquire location information about its current

geographic position. We also assume that each node has a transmission range of  $r_t$ .

Fig. 4. Complete network structure of our proposed scheme

In our scheme we have divided the entire network area into  $N$  level of square regions. The arrangement is such that each level  $k$  square region encapsulates the level  $(k-1)$  square region and is encapsulated by level  $(k+1)$  square region. Each square region has a side length of  $2.2^l s$ , where  $l$  denotes the level number and  $s$  depends on the node density. The innermost region is the level-1 square region and the outermost region is the level- $N$  square region.

An implicit characteristic of MANET is the high mobility of nodes and frequent changes in network topology. As a result, the cost for location update becomes a major burden. If we keep track of only the fully qualified location information of the nodes, then there is a possibility of this information becoming stale quickly and thus requiring to invoke expensive location update routines. This increases the location update cost tremendously. In order to reduce this cost, in our scheme, we apply the concept of multi-granular location information strategy. We have assumed that the location information can be of two types – fully qualified location information and relative location information.

The fully qualified location information of a node includes the following parts.

|                    |
|--------------------|
| Node -id           |
| x-coordinate       |
| y-coordinate       |
| Location server-id |

Fig. 5. Fully qualified location information

On the other hand relative location information has two components.

|                    |
|--------------------|
| Location server id |
| Node id            |

Fig. 6. Relative location information

The location servers within a location server region are responsible for keeping track of the fully qualified location information of only those nodes that are currently within its assigned sub-region. On the other hand the location servers within a particular location server region also keep track of the relative location information of all the nodes that are currently within other sub-regions of the same level  $i$  square region. Therefore, when a node moves within a particular sub-region it needs to notify only the single location server region- that is currently in charge of that sub-region, regarding the change in its fully qualified location information, thereby reducing the location update cost.

#### A. Location Update

Location update has three components.

I. Location update for node movement within sub-region:

When a node A moves within the sub-region in which it is currently residing it needs to notify only the location servers currently in charge of that particular sub-region.

II. Location update for node movement between sub-regions:

On reaching its new sub-region the node A probes its neighbors to get information about its new location server region. Once it collects this information, it sends its current  $x$  and  $y$  coordinate positions and the node id to the new location server region. Now the node A is under the direct supervision of this new location server region. Therefore, this new location server region needs to update the location information regarding node A from relative to fully qualified. This new location server region then sends the new relative location information of the node to other location server regions within the same level  $i$  square region. Each of these other location server regions need to modify the location information about the node.

III. Location update for node movement between square regions at different levels:

After reaching its new sub-region within its new square region, node A probes its neighbors to get information about its new location server region. Once it gets this information, it sends its previous fully qualified address and the current  $x$  and  $y$  coordinate positions to this new location server region. The new Location server region can know the

previous level no. of node A from its previous fully qualified address. This new location server region then sends the new relative address of the node, (i.e., current location server id and node id) to the location server region in the previous level. This information is then relayed to all the other location server regions in the previous level. These location server regions after analyzing the current relative address of the node, delete the entry corresponding to node A from their database to reflect the fact that the node A is no longer at this level.

As the new location server region is in a square region which is at a level that is different than the level of its previous square region, therefore, it must make a new entry in its location information database about the new fully qualified location information of node A. This new location server region then needs to send the relative location information of node A to other location server regions within the new square region. These other location servers being in a square region at a level which is different than the previous square region, had no location information about node A and therefore, they will need to make new entries about the new relative location information of node A.

#### B. Location Query

Suppose a source node A wants to send a data packet to a destination node B but node A does not know the location information of node B. Under this scenario three situations can evolve.

Fig. 7. Destination B is within same sub-region at same level as of source A

I. Destination B is within same sub-region at same level as of source A:

In this case the location server region that is in-charge of the sub-region contains the fully qualified address of node B. The source node A sends the data packet to the location server region. The location server region extracts the current  $x$  and  $y$  coordinate position of node B from its fully qualified address and sends the data packet to node B at that position.

II. Destination B is within other sub-region at the same level as of source A:

In this case the source node A sends the data packet to the assigned location server region of its sub-region. But the destination B is within a different sub-region. Therefore, the location server region of node A contains only the relative location information about destination B. From this information, the location server region of node A can find which location server region is currently containing the fully qualified address of node B. The location server region of node A then sends the data packet forwarded by node A to that particular location server region. This new location server region ultimately sends the data packet to the destination node B.

Fig. 8. Destination B is within other sub-region at the same level as of source A

III. Destination B is within other square region at different level than that of source A:

Fig. 9. Destination B is within other square region at different level than that of source A

The location server region now sends the data packet to the location server region of the square region that is encompassing the current level square region. It also forwards the packet to the location server region of the square region that is contained by the current level square region. The location server regions at other levels now follow the previously mentioned steps for location query. This process is continued until the destination node B is

found or the network boundary is reached. Thus, if the destination node falls within the network boundary, the data packet is propagated from the source node S to the destination node B through the intermediate location server regions.

#### IV. ANALYSIS OF LOCATION MANAGEMENT COSTS

Basically there are two types of costs, which are important for any location management scheme. They are - cost for location update and cost for location query. In the following sections we analyze these two types of costs.

##### A. Location Updation Cost [ $Cost_{update}$ ]

The cost for location update can be divided into three parts - i>Cost for location update for node moving within sub-region ( $Cost_{update-intra-subregion}$ ) ii>Cost for location update for node moving between sub-regions ( $Cost_{update-inter-subregion}$ ) iii>Cost for location update for node moving between square regions at different levels( $Cost_{update-inter-level}$ ).

Thus we can write,

$$Cost_{update} = Cost_{update-intra-subregion} + Cost_{update-inter-subregion} + Cost_{update-inter-level}$$

The cost for location update depends upon the amount of forwarding load. Thus the forwarding load, and as a result the cost will be higher for a packet traveling a greater distance. Cost for location update for node moving within sub-region ( $Cost_{update-intra-subregion}$ ) is basically the product of updation frequency and the cost of updation of one location server region. The cost of updation of one location server region is proportional to the average number of hops an update packet takes to reach the assigned location server region. We denote this cost by  $Cost(1)$ . We can approximate this cost by considering the distance  $D=\sqrt{2}.2^l.s$ ; where  $l$  denotes level number.

Let us denote  $z$  as the average progress for each forwarding hop where  $z$  is a function of the radio transmission range  $r_t$  and the node density ( $\gamma$ ) [8]. We assume both  $r_t$  and  $\gamma$  are constants. Therefore,  $z$  is also a constant. It is possible to derive the average number of hops an update packet takes by  $D/z$ . If we consider the average velocity of a node as  $v$ , and the transmission range of a node as  $r_t$ , then the updation frequency is  $v/r_t$ . Thus,

$$Cost_{update-intra-subregion} = v/r_t \cdot Cost(1)$$

$$\begin{aligned} \text{and } Cost(1) &\propto \sum_{l=0}^N \sqrt{2}.2^l.s/z \\ &\approx \sqrt{2}.s.N/z. \end{aligned}$$

If we assume  $S$  as the side length of the square region at the maximum level, i.e.  $N^{\text{th}}$  level square region,

then,  $S \propto 2^N$ . Thus,  $N \propto \log S$ . Since,  $S \propto \sqrt{M}$ , ( $M$ =Total Number of nodes in the network), we have  $N \propto \log \sqrt{M}$ .

$$\text{Thus, Cost}_{\text{update-intra-subregion}} = O(v \cdot \log \sqrt{M}). \quad (1)$$

Cost for location update for node moving between sub-regions ( $\text{Cost}_{\text{update-inter-subregion}}$ ) is the product of the boundary crossing rate ( $\Omega$ ) and the cost for updating the four location server regions ( $\text{Cost}(4)$ ).

$$\text{So, Cost}_{\text{update-inter-subregion}} = \Omega \cdot \text{Cost}(4).$$

The boundary-crossing rate is proved [9] to be proportional to  $v$ . The cost of updating four location server regions can be approximated by  $4(D_1)/z$ . Thus

$$\begin{aligned} \text{Cost}(4) &\propto \sum_{l=0}^N 4 \cdot \sqrt{2} \cdot 2^l \cdot s/z \\ &\approx 4\sqrt{2} \cdot s \cdot N/z. \end{aligned}$$

$$\text{Therefore, Cost}_{\text{update-inter-subregion}} = O(v \cdot \log \sqrt{M}). \quad (2)$$

Similarly we can formulate  $\text{Cost}_{\text{update-inter-level}}$  as

$$\text{Cost}_{\text{update-inter-level}} = \Omega \cdot \text{Cost}(8).$$

We can approximate the cost of updating eight location server regions by  $4(D_1 + D_{l-1})/z$ . Thus

$$\begin{aligned} \text{Cost}(8) &\propto \sum_{l=0}^N 6 \cdot \sqrt{2} \cdot 2^l \cdot s/z \\ &\approx 6\sqrt{2} \cdot s \cdot N/z. \end{aligned}$$

$$\text{Therefore, Cost}_{\text{update-inter-level}} = O(v \cdot \log \sqrt{M}). \quad (3)$$

Thus from “(1)”, “(2)” and “(3)” we have

$$\begin{aligned} \text{Cost}_{\text{update}} &= \text{Cost}_{\text{update-intra-subregion}} + \text{Cost}_{\text{update-inter-subregion}} + \\ &\quad \text{Cost}_{\text{update-inter-level}} = O(v \cdot \log \sqrt{M}). \end{aligned}$$

### B. Location Query Cost [ $\text{Cost}_{\text{query}}$ ]

If a source node has some data to send to a destination node, the source node must first query a location server region to get the current location information of the destination node. The cost for this activity of querying the location information is known as location query cost ( $\text{Cost}_{\text{query}}$ ). In order to calculate  $\text{Cost}_{\text{query}}$ , we have to measure the expected number of forwarding hops traveled by a query packet from the source node to its assigned location server region, which can be approximated by  $D/z$ . Therefore, the expected query cost is,

$$\begin{aligned} \text{Cost}_{\text{query}} &= \sum_{l=0}^N \sqrt{2} \cdot 2^l \cdot s/z \\ &\propto H \\ &= O(\log \sqrt{M}). \end{aligned}$$

## V. CONCLUSION

In this paper, we have discussed some of the existing location service schemes and have proposed a new scheme for location based routing among the nodes in mobile ad hoc network. The use of geo-location information allows us to avoid network wide flooding of data and control packets and reduces the total normalized overhead. This reduction is significant as it saves a lot of time as well as energy which are serious constraint issues one needs to keep in mind while designing the network ensuring its smooth functioning so that an optimum performance is tenable. In our scheme by dividing the entire network area into  $N$  level of square regions and using multi-granular location information, we have been able to provide a unique way to reduce the cost associated with both location update and location query. Further investigation on performance analysis of this scheme in different network scenarios can be taken as extended work.

# QoS based Fair Load-Balancing: Paradigm to IANRA Routing Algorithm for Wireless Networks (WNs)

Ayyoub Akbari Moghanjoughi <sup>\*,1</sup>, Sabira Khatun<sup>\*</sup>, Borhanuddin M. Ali<sup>\*</sup>, Raja S. A. R. Abdullah<sup>\*</sup>

**Abstract** — In this paper, a new algorithm, Intelligent agent AntNet based Routing Algorithm (IANRA) is proposed to enhance load balancing strategy in Wireless Networks (WNs). IANRA is based on Ants behaviour with some important factors such as: the specific self-organizing behaviour of ant colonies, the shortest path discovery and the related framework of Ant Colony Optimization (ACO). The main focus in IANRA is to find optimum and near optimum route by means of Genetic Algorithm (GA) using breeding capability of ants. Here, ants can produce a number of generations with the target to discover an optimized route. Hence IANRA is able to prevent of the difficulties which exist in existing routing algorithms, such as Ad hoc On-Demand Distance Vector (AODV), AntNet etc. The obtained results show that the efficiency of IANRA algorithm is better than AODV and AntNet or any other related algorithm. In addition, the proposed algorithm (IANRA) is able to reduce the end-to-end delay and increase the packet delivery ratio significantly.

## I. INTRODUCTION

In the past few years, a lot of research interest has been seen for routing in Wireless Networks (WNs). As mobile hosts and wireless network equipments have become widely available, an entirely new class of wireless application has been created, which wired network infrastructure can not support. With the rapid growth and evolution of wireless computer networks, not only their topologies are changing and progressing in continuous form, but also manner and type of utilization are permanently changing for various goals. Present routing algorithms, used in wireless computer networks are not suitable to coordinate with the instant growth. Hence, new algorithms for routing and load balancing are needed [1, 2, 3].

New mobile Ad-hoc networks (MANETs) are networks in which all nodes are mobile and communicate with each other via wireless connections. Nodes can join or leave a specific network domain at any time. There is no fixed infrastructure, all nodes are equal and there is no centralized control. There are no designated routers; any

node can serve as router for others, and data packets are forwarded from node to node in a multi-hop fashion [1]. In other hand WNs consist of static wireless routers and gateways, which are directly connected to the wired infrastructure. User stations are connected to the wired infrastructure via wireless link.

The main goal of routing algorithm is to maintain the Quality of Service (QoS) and to prevent the traffic overload in some parts of the networks [2, 3, 4]. First Dorigo and Di Caro proposed AntNet algorithm by considering only the delay in their routing tables [4, 5, 6]. It has been observed that, ants in a colony can focus on moving over the shortest path among various paths connecting their nest to source of food [7, 8]. The main catalyst of this colony-level shortest path behaviour and discovery is the use of a volatile chemical substance called pheromone. Usually shorter paths are discovered quickly and more frequently by the ants, and therefore can be marked with higher pheromone intensity [9].

The Asymmetrical Route Synchronization (ARS) algorithm is based on agents, and supports QoS routing, resource reservation, and admission control functions using ant-like agents [2, 6]. It works under two conditions: (i) every node in a network supports the weighted fair queuing algorithm and (ii) network users require two service class deliveries: datagram and real-time flow. The ARS efficiently allocates network resources according to user requests. Details of the algorithms and their performance comparison can be found in “Ant-Routing vs. Q-Routing in Telecommunication Networks” by Pacut et al., 2006 [10].

In this paper, a new algorithm is proposed by considering the QoS, the issue of load balancing and optimum routing for Wireless Networks. The algorithm is based on a specific self-organizing behaviour of ant colonies, the shortest path discovery, and on the related framework of ant colony optimization [7].

This paper is organised as follows. Section II, describes related routing algorithms based on ants colonies behaviour. Section III, describes the IANRA algorithm. Section IV, presents performance evaluation for IANRA,

<sup>1</sup> A. A. Moghanjoughi (✉), E-mail: ayyoub@ieee.org

followed by the simulation results in Section V and finally conclusion in Section VI.

## II. ROUTING ALGORITHMS BASED ON ACO BEHAVIOUR

One of particularly brilliant experiment was designed and run by Denebourg and colleagues [11]. They ran experiments varying the ratio,  $r = l_l / l_s$ , between the length of two branches of a double bridge, where  $l_l$  was the length of the longer branch and  $l_s$  the length of the shortest one. In their first experiment (shows in Figure 1.a), the bridge had two branches of equal length ( $l_s = l_l = 1 \Rightarrow r = 1$ ). At the beginning, ant's based agents were left free to move between the N (Nest) and F (Food) and the percentage of ants that chose one or the other of the two branches were observed over time. Then used the other bridge with two different length of branches which are depicted in Figure 1.b ( $l_s = 1$  and  $l_l = 2 \Rightarrow l_s \neq l_l$ ). In Figure 1.a the probability of path/branch selection was same depending to the pheromone congestion on each of paths. In second experiment (Figure 1.b), the length ratio between the two paths was set to  $r = 2$ , so that the longer path was twice as long as short one [11].

Figure 1.a. Branches with equal length ( $l_s = l_l = 1 \Rightarrow r = 1$ ).

Figure 1.b. Branches with unequal length ( $l_s = 1$  and  $l_l = 2 \Rightarrow r = 2$ ).

If,  $\rho_{i\gamma}(t)$  is the probability of the ant arriving at decision spot  $i \in \{1, 2\}$  (see Figure 1.b) and selects paths  $\gamma \in \{s, l\}$ , also  $\phi_{i\gamma}(t)$  denote the total amount of pheromone on the path. For example, the probability of discovering the shorter path is given by Equation (1).

$$\rho_{is}(t) = \frac{(t_s + \phi_{is}(t))^\alpha}{(t_s + \phi_{is}(t))^\alpha + (t_s + \phi_{il}(t))^\alpha}, \quad \alpha = 2 \quad (1)$$

Where,  $\alpha$  is two and  $\rho_{il}(t) + \rho_{is}(t) = 1$ . Now suppose  $\psi$  be the number of ants cross the path per second in one direction at constant speeding of  $v$  cm/s that depositing one unit pheromone on the way. So, an ant will choose the short path traverse it  $t_s = l_s / v$  seconds. This time for longer path will be  $r \times t_s$  seconds, where  $r = l_l / l_s$ . To describe the evolution of the stochastic systems, the differential equations are as follows.

$$d\phi_{is} / dt = \psi \rho_{js}(t - t_s) + \psi \rho_{is}(t), \quad (i = 1, j = 2; i = 2, j = 1) \quad (2)$$

$$d\phi_{il} / dt = \psi \rho_{jl}(t - r \cdot t_s) + \psi \rho_{il}(t), \quad (i = 1, j = 2; i = 2, j = 1) \quad (3)$$

In the basic ACO algorithm the base idea for routing [8, 12] is the possession of routing information through the sampling of paths using small control packets, which are called ants. The ants are generated concurrently and independently at the nodes, with the task, to test a path, from Source (S) to Destination (D). Ants always sample complete paths, so that routing information can be updated in a pure Monte Carlo way, without relying on bootstrapping information from one node to the next [13]. The routing table for each destination contain a vector of real-valued entries. One entry indicates source to destination route for each known neighbour node. They are termed pheromone variables, and are continually updated according to path quality values calculated by the ants. The repeated and concurrent generation of path-sampling ants results, the availability of a bundle of paths, each with an estimated measure of quality, at each node. In turn, the ants use the routing tables to define the path they may sample.

The pheromone information is used for routing data packets, more or less in the same way as for routing ants. Packets are routed stochastically, giving higher probability to links with higher pheromone values. Usually, data for the same destination are spread over multiple paths (but with more packets travel over the best paths), resulting balanced load in the network. This mechanism is usually adopted to avoid low quality paths, while to make the ants more explorative, so that the good paths can be maintained and less good paths can be avoided. The path exploration is kept separate from the ongoing paths. Enough ants are sent to different destinations to make sure nodes have up-to-date information about the best paths and can automatically adapt their data load accordingly.

In computer networks, probability of using routing tables, in all nodes in networks for routing, can act as pheromone. This probability is calculated with ant's traffic or packages [4, 6]. Dorigo and Di Caro show a method, named Basic AntNet(B-AntNet) where the information that comes from Ant's appear in each node

like a routing table and a data structure (LTS) that involve information about local traffic and delay quantities[5, 6].

To accomplish this task, they are using ants to gather information about the traffic load in the network. Pheromone matrix is an isomorphic local data-base that helps router to decide where to forward data packets or not. It contains the information which specifies the next (neighbour) node to travel by a data packet to go to any possible destination in the network. Each routing table is organized as a set of all the possible destinations (all the nodes in the network) and the probabilities to reach these destinations through each of the neighbours of the node which is located in next hop.

The routing tables are organized like vector distance algorithms. The local model (LTS) shows structure of local traffic plays the role of a local adaptive model for the expected delay toward each possible destination. In AntNet, two different kinds of ants were used: Forward Ant (FA) and Backward Ant (BA) [4, 5, 6].

The quantity of  $\rho_{j,i}$  in the pheromone matrix (routing table) is calculated as follows: if only one ant arrive (from node  $i$ ) to node  $j$ , the probability of choosing that route will be increased base on Equation (4). In addition, probability of connective routes to other nodes will be decreased base on Equation (5), because the probability table must be normal. Finally, equation (6) is correct for all columns in the probability table in Fig 2 [4, 7].

$$\rho_{j,i} = \frac{(\rho_{j,i})' + \Delta\rho}{1 + \Delta\rho}, \quad (\rho_{j,i})' = \rho_{j,i} \text{ (OLD)} \quad (4)$$

$$\rho_{j',i} = \frac{(\rho_{j,i})'}{1 + \Delta\rho}, \quad j' \in \text{Neighbour} \Rightarrow j' \neq j \quad (5)$$

$$\sum_{j \in L_n} \rho_{j,i} = 1, \quad j \in [1, N], \quad L_n = \{\text{Neighbour}(n)\} \quad (6)$$

$$\Delta\rho = \eta + 0.005, \quad \eta = 0.08 / \lceil \xi \rceil \quad (7)$$

$\Delta\rho$  in Equation (7) shows the effect of ant movement at the entrance of probability table and it is created from delay reverse or ant age ( $\xi$ ), plus one fix number. If, in a route, ant age and delay are low, the probability of use of that route is high and then inclination of other Ant's to follow that route will be increased.

One of the most important problems that exist in this routing algorithms with ant's colonies is statistic route and not adaptive as per need in the network [14, 15, 16]. Statistic means that after Ants choose the  $\mathcal{R}_{OP}$  route as optimum route, the inclination of other ant's to choosing this route is usually increased. This causes traffic congestion due to increased traffic and at the same time the probability of use of other routes will be decreased. Choosing  $\mathcal{R}_{OP}$  route as the only optimized route in the network caused undesired result and problems like no optimization of  $\mathcal{R}_{OP}$ .

To solve this statistic nature route problem, Multiple Ant Colony Optimization (MACO) [14] use different ants with their special "pheromone" instead of using one kind of ant. In MACO, each kind of ant can find the separate optimum route and this increase route adaptation and solve the statistic route problem.

In addition, Bonabeaul has showed that success of ants when they act as gregarious to find the shortest route is proportional. If a group of ants choose non-optimum route,  $\mathcal{R}_{N-op}$ , by chance, the other ants will choose and follow the same  $\mathcal{R}_{N-op}$  at the end. The concentration of 'pheromone' will be increased and the non optimized route  $\mathcal{R}_{N-op}$  will be used as optimum route. Therefore, non-efficient routing can be created [15, 16].

In this paper, the proposed IANRA attempts to decrease the probability of choosing not optimized route instead of optimized one by more searches among possible routes. Also, instead of using one optimizing route, use of several optimized (or sub-optimized) routes can solve the congestion problems caused by a single optimizing route.

### III. THE PROPOSED INTELLIGENT ANTNET BASED ROUTING ALGORITHM

In this Algorithm, the used ants are able to produce new generation using *GA* concept. In the routing process when an ant from a particular family arrives to a junction node with  $m$  different connective routes, the ants regenerate  $m$  successive ants and then send them one per each connective route accordingly based on the same considered criterion. These new generations of ants inherit identifier of their family, the generation numbers and the routing information from their parents that includes route delay, bandwidth and identification of visited nodes. IANRA uses various kinds of ant for routing while one type of ant is applied in MACO. In addition, each kind of ant is used for one specific type of services for different QoS needs. To achieve a complete optimum routing table, several kinds of ants with different quality of services are used for each node.

The AntNet method converted to prepare QoS, required bandwidth and stage or Hop Count (*HC*) [3] by forcing the *FA* to use all available connective routes. Whenever a *FA* passes more than a certain number of stages,  $H_{max}$  it dies and the routing algorithm of AntNet is updated based on number of stage [16].

In IANRA, minimum bandwidth (*BW*) and maximum stage ( $H_{max}$ ) are considered as QoS parameters. As usual, here also, if *FA* passes the stage more than  $H_{max}$  it die and an ant produces  $m$  new ants when it arrives to a node with  $m$  connective routes in it to cover all possible routes. While ants move towards destination, like AntNet method, store the identification of visited nodes and

quantity of QoS routes in their stack. When an ant arrives to a new node, it first checks whether any co-family ant has already pass this node or not. If passed, it means an ant passes this node in a shorter route than the present ant, so the present route is not optimum and this ant will die there. Otherwise the ant regenerates like its parent and send new generation of ants towards the route that can prepare QoS conditions. This process continues until ants of that family arrive to destination. When the primary ant arrives to destination it finds out, first: whether the route that it has passed becomes the shortest route or not, second: the QoS condition. Therefore, the primary ant produces *BA* ant and transfer the information that has been gathered during route optimization period and then die there. Here *BA* has duty to use existing information stack transferred by *FA*, follow backward the same route created by *FA* and update the existing routing tables.

For example, in Figure 2, an ant in the *a* family at time *t* is going to search optimum route from *S* to *D*. First, this ant generates four new ants as there are total four routes from *S* to next neighbouring node. These four new ants are considered as 1st generation  $\delta I$  and will follow the routes *SA*, *SB*, *SC* and *SE*. In each stage, when an ant moves forward from one node to next, the generation number will be increased accordingly (depicted in Figure 2). But no ant will generate on *A* node for discovering *AD* route due to longest distance and weak signal in coverage area (i.e., Lack of QoS). Let  $\theta$  be a node number which are discovered by *FA*, and  $\tau$  denoted service time per node on supposed network, then the value of  $\xi$  for each of ant which is arrived to *D* from *S* is;

$$\xi = \sum_{k=1}^n \xi_{\delta k} + \sum_{l=1}^m \tau_{\theta} \quad (8)$$

Number of generation *s*,  $k = \{1, 2, 3, \dots, n\}$   
Number of nodes on  $\mathcal{R}_{op} \Rightarrow l = \{1, 2, 3, \dots, m\}$

Figure 2. Distribution intelligent ant based agent's generations on sample network.

When ant  $\delta II$  arrives from node *F* to *G* and see that a co-family ant  $\delta II$  with smaller generation already passed

it, then the route, *SCFG* will not be optimized and ant  $\delta II$  dies there. Same thing happens for route *SEGF*.

At destination *D* three co-family ants  $\delta II$ ,  $\delta III$  have reached there from three different routes *SBD*, *SCFD* and *SEGD* respectively. It is considered that  $\delta II$  ant passes the shortest route compared the other Ants and finally the routing table will be updated with *SBD* as optimum route for *SD* connection. The similar process is used for all possible *S-D* pair for optimum and sub optimum (near-optimum or next possible optimum route) to balance the overall network load.

The second phase of IANRA algorithm is called route maintenance that is responsible for preservation of the paths during the communication. In IANRA algorithm no need to generate special packets for route maintenance, because while *FA* and *BA* construct pheromone tables for each node located on the path from source to destination, at the same time they are used for preservation of routes regularly. When *FA* arrives to a node between source and destination, the pheromone matrix is updated as in Biological System when, *S* relays a data packet to *D* via neighbours, it increases pheromone on the used path. It can be described as: suppose *FA* travels from node  $N_i$  to node  $N_d$  through neighbour nodes  $N_j$ , it increases the pheromone entry value  $(N_d, N_j, \rho)$ , by  $\Delta\rho$  according to equations (4) and (5). For each of next hops on  $\mathcal{R}_{OP}$ , the increased is  $\Delta\rho$  strength by arrived *FA*. The same procedure is followed by *BA* for backward paths.

The final stage of IANRA is to handle the link failure. This problem usually occurs due to movement of nodes in an optimized route (physical layer problem) and weak signals in coverage area. Since IANRA considers IEEE 802.11 both physical and the MAC layer, it's able to recognize a link failure through a missing acknowledgment message in the MAC layer. On the other hand in IANRA, each node maintains an updated view of its immediate neighbours at each instant. Hence it is easy to discover link failures as rapidly as possible, before they can lead to transmission errors and packet loss.

If a node receives *Link failure Notification* message for a settled path, it first removes this path from routing table by change pheromone value to zero (0) for failed link. Subsequently, the mentioned node starts to search selected new alternative path for data transmission. For discovering alternative path, a node updates its pheromone matrix. If there is another available route to destination which supports QoS, it will be used to send data packets instantly. Otherwise, the node sends *FA* to inform neighbours for updating its pheromone matrix and discovers a valid optimum route. In this process, if a *FA* can not travel a link to the next hop (due to link failure), it is backtracked to pervious hop to proceed further.

#### IV. IANRA PERFORMANCE EVALUATION

For performance evaluation of IANRA the OMNeT++ [17] simulation software is used, and then the obtained results are compared with AntNet and AODV. The considered performance evaluation parameters are average end-to-end delay per packet, packet delivery ratio and packet overhead. These 37 wireless nodes are placed randomly in an area of  $1400 \times 250 m^2$ . NED and C++ are applied for developing source code to make scenario of IANRA. Definitely, some headers and objects are created for these source codes. The arrival rates and the distribution of packets in each session follow a Poisson distribution. The data packet size is exponentially distributed. Size of  $BA$  is calculable by number of Visited Nodes ( $VNs$ ),  $FA$  and size of each  $FA$ . The  $BA$  calculation is as follows:

$$BA_S = NV + FA_S, NV = \delta + 1, FA_{Size} = \sum_{i=1}^m (FA_{Size})_{\delta_i} \quad (9)$$

To avoid increasing load in network, the number of generated ants in each node is two and the process of generation continues until the final generation. Data traffic flows contain 15 Constant Bit Rate (CBR) sources each transmitting 64 byte packet per second. Transmission time for each node follows stochastic process between 0 and 80 second after the start of the simulation. The bandwidth of each of all connective routes is 2.0 Mbits/s. IANRA designed buffer model for each of nodes that placed on network topology. Also the maximum speed in MANET scenario considered 20 m/s. In this section the considered buffers model at the node in IANRA algorithm are discussed. Each connected node has three kinds of buffers; (i) Input Buffer, (ii) Output buffer with high- and low-priority queues for every neighbour and (iii) Wireless Networks (WNs) buffer with one queue for each destination in the network. In order to make coverage of all aims for the proposed Algorithm, we implemented an extra buffer. A buffer called WNs buffer.

#### V. SIMULATION RESULTS

Experiment results show that the average end-to-end delay is decreased and the packet delivery ratio is increased in IANRA compared to two other algorithms AntNet and AODV Routing algorithm. Figure 3, shows that the average end-to-end packets delay is increased with increasing number of packets in the network. For example, when numbers of packets approach to 3300, the average end-to-end packet delays are around 0.17, 0.19 and 0.28 seconds for IANRA, B-AntNet and AODV respectively. This shows that for WMNs, the average end-to-end packet delay of IANRA algorithm is about 10.2 % and 7.21% lower than AODV and B-AntNet algorithms

respectively. Also, for Ad-hoc networks the average end-to-end packet delay is about 0.24 seconds which is lower than AODV and B-AntNet. Figure 4 shows the packet delivery ratio versus frequency of packet generation per second. It is seen that, with 20 packet/sec, IANRA gives higher packet delivery ratio about 92 % and 87% for WMNs and Ad-hoc networks respectively.

Figure 3. Average end-to-end delay with increasing number of data packets in the network.

Figure 4. Packet delivery ratio with changing packet generation frequency.

In Figure 5 the average end-to-end packets delay versus number of network nodes with low data load shown. Low data load is considered as five packets per node per second approximately in the network.

Results show that, the average end-to-end packet delay is 10.75% and 5.65% lower than AODV and B-AntNet algorithms respectively. Also it reveals the related results of average end-to-end packet delay with high data load in the network. High data load is considered as 20 packets per node per second. The obtained result shows that, with 37 nodes, IANRA gives lower average end-to-end packet

delay about less than 0.12 seconds, where as it is for B-AntNet and AODV more than 0.13 and 0.14 seconds respectively. On the other hand, experiment result for packet overhead is depicted on Figure 6. Overhead results show that with increasing packet generation rate in the starting point, packet overhead is reduced. Also in this graph exponential behaviour of three algorithms are shown as well.

Figure 5. Average end-to-end packets delay with low (5 p/sec) and high (20 p/sec) data load on network.

Figure 6. Packet overhead with changing packet generation frequency.

## VI. CONCLUSION

In this paper IANRA algorithm for load balancing with QoS has been introduced based on Ant Colonies Optimization. Three current problems in Ant colony Algorithms are (i) routing table freezes due to selecting same path, (ii) Statistic network and (iii) choosing a non-optimized route, have been eliminated by considering ant's and their successive generations, which shows the better load distribution among network nodes. Finally, IANRA is able to solve the routing, load-balancing and QoS problem in any wireless and mobile networks; including Ad-hoc, WSN etc.

# An Artificial Ant Based Novel and Efficient Approach of Regular Geometric Shape Detection from Digital Image

Ayan Acharya, Kaushik Chattopadhyay, Deepyaman Maiti, and Amit Konar

Department of Electronics and Telecommunication Engineering, Jadavpur University, Kolkata:  
700032, India

**Abstract-** The paper presents a novel and efficient method of regular geometric shape detection from gray scale images. Artificial ant based methods have not been used much in the field of image processing. This paper demonstrates how artificial ants can be used effectively to extract regular geometric shapes from images. We propose here Ant Regeneration and Recombination System (ARRS), an entirely new approach developed by ourselves. Our scheme of detection of shapes comprises of three steps. Firstly, MATLAB edge detection operator converts a gray scale image into a binary one. Ant Regeneration and Recombination System algorithm is then applied on this binary image to detect closed loops. Finally, these closed loops are tested for different geometric shapes like circle, ellipse, rectangle and square. The most important aspect of the scheme is it can detect both intersecting as well as non intersecting regular shapes from images consisting of different open and closed loop configurations. It is the incredible time and memory efficiency of the scheme that makes it useful in real time applications where decisions have to be taken within a very small time interval by observing an image.

**Index terms**— Edge Detection, Loop detection, Shape detection, Ant Regeneration and Recombination System.

## I. INTRODUCTION

Detection of regular geometric features like circles, ellipses, rectangles and polygons in digital images is an important exercise in image analysis and computer vision applications such as automatic inspection and assembly. Various methods for regular geometric shape detection have been researched till date. The Hough Transform (HT) technique, one of the most popular one, has been used extensively to extract analytic features, such as straight lines, circles, and ellipses ([2],[3],[5],[6]) because of its robustness against noise, clutter, object defect, shape distortion etc. A serious drawback of this technique is its huge time and space complexity. In HT technique, edge detected image is first mapped into a parameter space. For detection of circles, each edge point in the edge image is mapped to a region in the parameter space or accumulator as one count (or vote) for each point in the appropriate region. The parameter space for a circle is a 3-dimensional space where the center coordinates and the radii of

probable circle in the image are specified. Detection of ellipse requires a 4-dimensional or a 5-dimensional parameter space, depending on whether the ellipse has been rotated about its center. The time complexity grows exponentially with the number of parameters used to characterize the shape. For circles this gives rise to a complexity of  $O(n^3)$ . For ellipse, the complexity, in general, is of  $O(n^5)$ . Consequently, in many simple real time applications this method often turns out to be far from practical.

In this paper, we propose a completely new approach to detect regular shapes efficiently from images using Ant Regeneration and Recombination System (ARRS), an entirely novel algorithm. The ant colony system **ARRS** developed by ourselves is inspired by the ant system algorithm ([11],[12],[13],[14]) and its numerous variants but conceptually **ARRS** is widely different from these existing algorithms. Moreover, as far as our knowledge goes, we are not aware of any work related to the extraction of both intersecting and non-intersecting shapes from images efficiently, accurately and quickly. These points specify the main contribution of our paper.

The paper has been subdivided into eight sections. We introduce our scheme Ant Regeneration and Recombination System in section II. Sections III and IV deal with the implementation and pseudo code of the scheme. A modified approach of closed loop detection based on the graph explored by the scheme is presented in section V. Algorithms for detection of various geometric shapes are provided in section VI. Simulation results are provided in section VII. The paper ends at section VIII with conclusion and scope of future work.

## II. ANT REGENERATION AND RECOMBINATION SYSTEM (ARRS)

In an edge detected image, a string of edge pixels stand for the boundary of an object present in the image. When we are talking about intersecting shapes, it is clear that such boundaries will cross each other. We can say, a **graph** (in not too technical a sense) is formed. A string of edge pixels, where each pixel is connected to only two adjacent pixels, is called a **branch**. Where more than two branches meet, we call that pixel a **node**. A branch is completely described by the pixel co-ordinates of that branch, taken in order. A node is completely specified if we have its co-ordinates along with the information that,

to which other nodes it is connected and by which branches. This connectivity information is gathered in a matrix form which we call the **incidence matrix**.

Ants are basically one-pixel agents that explore the graph. Each ant has its own co-ordinates which indicate on which pixel it is, and those co-ordinates are continuously updated as the ant moves. Before making a move an ant finds the number of directions available to move, by counting the number of edge pixels around the pixel it is resting upon, excluding the pixel it has just come from (this pixel is not to be covered again, i.e. the ant cannot move back).

If an ant moves into a pixel on a branch, then it updates its own co-ordinates and stores the co-ordinates of the previous pixel in an array of its own called the **path[ ]** array. If an ant discovers a node, the co-ordinates of the node are recorded. The ant also realizes that the node it has come from and the newly discovered node are connected to each other by the branch it has traversed through. At this point, this ant becomes inactive (i.e. it stops travelling, its co-ordinates are never updated again) but reproduces new ants and place them on the starting pixels of each of the new branches originating from that particular node. The '**child**' ant now continues further exploration of the **graph**. We call this process as **regeneration** of ants. It can easily be perceived that this process allows complete exploration of the **graph** no matter how complex it is.

In fact, the process of searching starts with placing of an ant (we call it the 'mother' ant) at a randomly selected edge pixel. The mother ant moves up to a node (this is the first discovered node) and generates new ants which travel along branches originating from this node and create newer ants upon discovering new nodes. In this way a whole system of ants builds up. Thus far we observe three properties of the ants:

**Property I:** All ants move at the same speed, i.e. one pixel at one step.

**Property II:** Ants are generated at nodes.

**Property III:** Ant remembers the node it has originated from

The above listed properties of ants have an interesting consequence. Suppose, between two nodes A and B, there is a shorter path S and a longer path L. The ants are generated at A and move towards B. The one along S will reach B sooner and place a new ant on the pixel that connects L to B, oblivious of the fact that there is already one coming towards B along L. The new ant will move towards A along L. Thus the two ants on L move toward each other and after some time their co-ordinates will become the same. We then say that the two ants **recombine**. Whenever two ants recombine, we take advantage of that as follows: (i) Each of them has partially discovered the same branch. They recorded pixel co-ordinates of the branch from two sides in their **path[ ]** arrays. If we join the **path[ ]** arrays of these two ants back

to back, we get an array which has all the pixel co-ordinates of the branch, in order. (ii) Since each ant remembers from which node it had originated, when they meet, the connection between those two nodes is discovered. We use this information to build up the **incidence matrix** (how this is done is described in the next section).

After meeting each other, both the ants are made inactive. This keeps one ant from going through the same pixels that has already been visited by some other ant, which guarantees that each edge pixel is visited only once and by only one ant.

The ant can stop moving even when it finds a dead end. Thus we get another property:

**Property IV:** An ant must end up either reaching a dead end or a node or meeting another ant, and thereby becoming inactive.

### III. IMPLEMENTATION OF ARRS

We here explain the data structures modeled for our algorithm and provide the pseudo code to make the entire aspect of the algorithm comprehensible.

**Ants:** Each ant is represented as a structure having the following fields.

- i) **(x, y)** : its current co-ordinates ,
- ii) **(x<sub>n</sub>, y<sub>n</sub>)**: co-ordinates of the node it came from
- iii) **path[ ]**: this array stores the pixel co-ordinates of the branch it is moving along

Several ants are represented as blocks of a linked list. Each block corresponds to a single ant. As new ants are generated, new blocks are added to the list. When an ant becomes inactive, the block corresponding to that particular ant is deleted from the list.

**Branches:** Each branch is represented as a structure which has the following fields:

- i) **index**: if index is **n**, we call that branch the **n**th branch or branch **n**
- ii) **branch\_arr[ ]**: this array contains the co-ordinates of the pixels on the branch

Each branch is a block of a linked list. When a new branch is discovered, a block is added to the list. When an ant travels from one node to the other, it discovers a branch completely. Its **path[ ]** array becomes the **branch\_arr[ ]** of the newly discovered branch. When two ants move toward each other from the terminal nodes of a branch and eventually meet, each has a part of the branch stored in their **path[ ]** arrays. As explained earlier, we join these two **path[ ]** arrays back to back (to keep the order of the pixels right) and this becomes the **branch\_arr[ ]** of this newly discovered branch. There is one variable called **B**. This is initially set to zero, is incremented each time a branch is discovered and becomes the **index** of the newly discovered branch. After the ants finish their exploration, all the branches would have been discovered and the

variable  $B$  will be the total number of branches. Also  $B$  will be the highest branch index.

**Nodes:** Each node is also represented as a structure with the following fields:

i) **index:** if the index is  $n$ , we call it the  $n$ th node or node  $n$ , ii)  $(x, y)$ : co-ordinates of the node, iii) **connectivity** [ ].

The array connectivity [ ] has some special importance. If an ant coming from the  $i$ th node reaches the  $j$ th node or meets another ant coming from  $j$ th node, through the  $k$ th branch (i.e. branch with index  $k$ ), then we do the following operations: node  $p$ .connectivity[ $k$ ] = 1 for  $p=i, j$  : node  $p$ .connectivity[ $k$ ] = 0 otherwise.

Since branch indices are array positions of the connectivity[ ] arrays, after exploration is complete, these arrays will have length that corresponds to the maximum branch index, i.e.  $B$ . Let the total number of nodes be  $N$ . Now we stack the connectivity[ ] arrays of the nodes one below the other, starting with node 1 at the top, node 2 below that, then node 3 and so on. Then it is clear that the  $N \times B$  matrix so formed will be the **incidence matrix** of the **graph**. If somehow  $i=j$ , i.e. both the ants come from the same node then existence of a branch is detected which is itself a closed loop and consists the node the ants came from. In that case we join the path[ ] arrays of the ants to get the pixel co-ordinates of this 'loop-branch' and then test it. We do not include such branches which are connected to one node only in the incidence matrix for ease of computation.

#### IV. PSEUDO CODE FOR ARRS

First an ant, i.e. the mother ant is placed at any randomly selected edge pixel. As it moves along the edge pixels, if it comes back to the starting pixel without encountering any node, then it has discovered a closed loop. The path[ ] array of this ant stores the co-ordinates of the pixels forming this loop. This array is tested for specified shapes. But, if the mother ant reaches a node, it places new ants at the starting pixels that originate from this node, the node is recorded as the first node discovered, and this ant itself becomes inactive. The pseudo code describing the movement of the ants from this point onwards is given.

Let the total number of active ants be  $M$  and the number of branches discovered be  $B$ , at any time. Searching ends when  $M$  becomes zero, i.e. no active ants are left. The algorithm described above is presented below in a more compact form.

```

while $M > 0$
 $i = 1$;
 while $i \leq M$
 find d , the number of edge pixels around the pixel
 occupied by the i th ant ;
 if $d > 1$
 add a block to the list of nodes and record this
 pixel as a node;

```

```

 $B = B + 1$;
 add a block to the list of branches and make
 the path[] array of this ant the branch_arr[] of
 the new branch; the index of this branch is B ;
 if the ant was coming from node p and has
 reached node q
 then node p .connectivity[B] = 1;
 node q .connectivity[B] = 1;
 end
 delete the block of this i th ant from the list of
 ants; place $d-1$ new ants at the starting pixels of
 the $d-1$ new branches originating from this
 node by adding $d-1$ new blocks to the list of
 ants;
 $M = M - d + 2$;
 else if $d = 1$
 if the only pixel available to move into is
 occupied by some other ant let one ant be
 from node p and the other from node q
 then delete the block of the two ants from the
 list of ants;
 $M = M - 2$;
 if $p \neq q$
 then $B = B + 1$;
 add a new block to the list of branches;
 join the path[] arrays of the ants back to
 back and make this the branch_arr[] of
 the new branch ;
 the index of the branch is B ;
 node p .connectivity[B] = 1;
 node q .connectivity[B] = 1;
 connectivity[B] = 0 for all other nodes;
 else
 join the path[] arrays of the two ants
 and test for circle;
 end
 else update the co-ordinates of the i th ant
 according to the adjacent pixel it moves into;
 record the co-ordinates of this pixel in the
 path[] array of the i th ant;
 end
 end
 $i = i + 1$;
end
end

```

#### V. MODIFIED ALGORITHM FOR FINDING CLOSED LOOPS

Suppose a set of  $k$  branches are selected from the set of all  $B$  number of branches. Two points are to be noticed here:

I. Each branch is associated with the two nodes it connects. Let, for branch  $b_i$  the terminal nodes are  $n_{i_1}$  and  $n_{i_2}$ . If  $b_i$  is a part of a closed loop then the loop must pass

through  $n_{i_1}$  and  $n_{i_2}$ . Then it is clear that if the selected branches form a closed loop, the loop must pass through all the nodes that belong to the set of nodes  $N_k = \{(n_{i_1}, n_{i_2}) \cap (n_{j_1}, n_{j_2}) \cap \dots \cap (n_{k_1}, n_{k_2})\}$  i.e. the set of all nodes that these selected branches are associated to. On a closed loop, the number of branches forming the loop and the number of nodes lying on the loop must be equal, i.e. the cardinality of  $N_k$  must be equal to  $k$ .

**II.** Each node in the set  $N_k$  must be connected to exactly two of the branches in  $B_k$ .

The above mentioned conditions I & II together are necessary and sufficient for any selected set of branches to form a closed loop. However they do not suggest the order in which they form a loop.

Let the columns of the incidence matrix that correspond to the selected branches be augmented to form a new  $M \times k$  matrix, let us call it  $I_k$ .  $I_k$  has only 1 and 0 entries since it is formed from the incidence matrix. Since a branch can be connected between only two nodes, there are exactly two 1's in a column. Each row of  $I_k$  corresponds to a node and the number of 1's in a row gives the number of branches connected to the node. If branches in  $B_k$  form a loop then in  $I_k$  the rows corresponding to nodes belonging to  $N_k$  must have two non-zero entries each (condition II) and all other rows (i.e. rows not belonging to set  $N_k$ ) should have 0 entries, i.e. if a row has a 1 then it should have exactly two such 1's otherwise all its entries are 0's.

We start at a cell  $(r, c)$  of  $I_k$  which contains a 1 and where  $r$  is the row number and  $c$  is the column number. Now an entry in row  $r$  is 1, therefore there should be exactly another 1 in  $r$  (otherwise the branches in set  $B_k$  would not form a closed loop and then we reject  $B_k$  and look for another such set). We update the row number  $r$  and go to the other non-zero cell in  $c$ . This is equivalent to moving from one end of the branch to its other end. This new row has also a 1 (this cell), so we check for the other 1 (if that is not present then we reject  $B_k$ ) and update the column number  $c$  accordingly to move into that cell. Modifying  $c$  implies that we are on the other branch that is connected to the same node and we shall go to the other end of this branch (modifying  $r$ ) and then to the other branch connected to that end (modifying  $c$ ) and so on, each time checking for condition II for each node. A variable  $p$ , initially set to zero is maintained. Each time we modify  $r$ , we cover one branch (we move from one node to the other) and increment  $p$ . When  $p$  becomes  $k$ , i.e. all branches are covered, we check whether we have come back to the starting node (the row in we had started with); if yes, then condition I is satisfied (condition II is already satisfied because we came up to this point checking condition II for each node in  $N_k$ ) therefore a closed loop is formed, otherwise not. If we come back to the starting

node then we check whether  $p$  has become equal to  $k$ . If it happens, then branches in  $B_k$  form a closed loop, else not. We also record the column numbers in an array in order each time we modify  $c$ . Then it is obvious that this array will contain the branches of  $B_k$  in the order in which the form loop. So, this algorithm accomplishes two tasks at the same time, checks whether a set of branches forms a loop or not and finds their order if they do form a loop. Since non-zero entries mean only 1, if there are two non-zero entries in a row the sum of all entries in the row must be two.

Now, in a special case, where we are required to detect only circles from images, we can simplify calculations further by reducing some complexity. Now, only a single circle can be drawn using a branch if at all. This is because if two or more circles have a common branch then they have to intersect at more than two points (a branch by definition consists of three or more points) which is practically impossible. So, if a set of branches indeed form a circle, we can delete all these branches from the graph without affecting the possibility of finding other circles from the graph. Therefore, once it is found that some  $k$  number of branches form a closed loop which is a circle, we delete the blocks corresponding to those branches from the list of branches and reduce number of branches  $B$  by  $k$ . This reduces the time complexity by leaps and makes the overall process faster.

## VI. ALGORITHM FOR DETECTION OF VARIOUS SHAPES

**Algorithm for circle detection:** The algorithm used for circle detection from closed loop follows from the geometric property that a unique circle can be drawn through three non collinear points. The steps are described here: **1.** Choose three equidistant points on a closed loop randomly and find equation of the unique circle that passes through these three points. **2.** Compare distances between every other point in the loop and the centre of the circle with the radius of the circle. **3.** If deviation error  $\delta > \epsilon$  (threshold value, which is a function of the radius of the circle), the loop is not considered as a circle. **4.** Even if condition 3 is false, if more than one fourth of the points on the loop result in deviations greater than half of the threshold value, then discard the loop from being a circle. **5.** A close loop that has passed through all the above four conditions is considered to be a circle. The threshold value  $\epsilon$  is taken as a function of the radius of the probable circle as for a larger circle we can afford greater deviation. We have chosen  $\delta$  proportional to the radius. The proportionality constant, called Deviation Constant  $\lambda$ , is determined from experiments in such a way that more or less all visible circles fall within this range. It should be noted that due to discrete points in the graph each detected circle will produce some deviation even if it perfectly looks like a circle.

**Algorithm for ellipse detection:** Detection of ellipse is a multistage process which is described as follows: 1. Find  $x_{max}$ ,  $x_{min}$ ,  $y_{max}$ ,  $y_{min}$  from the entire array containing the pixels that form the closed loop. Now the centre of prospective ellipse would be given by  $x_c = (x_{max} + x_{min})/2$  and  $y_c = (y_{max} + y_{min})/2$ . 2. Find the point  $(x_1, y_1)$  farthest from the centre from one half of the loop and the other such point  $(x_2, y_2)$  from the other half. If  $|x_c - (x_1 + x_2)/2| < \epsilon_x$  and  $|y_c - (y_1 + y_2)/2| < \epsilon_y$  then the line joining these two points is the major axis otherwise the loop cannot be an ellipse and no further steps are needed. Let,  $a_1 = \sqrt{(x_c - x_1)^2 + (y_c - y_1)^2}$ ,  $a_2 = \sqrt{(x_c - x_2)^2 + (y_c - y_2)^2}$ . The semi major axis of the ellipse is taken as  $a = (a_1 + a_2)/2$ . And the inclination of the major axis is given by  $\alpha = \tan^{-1}((y_2 - y_1)/(x_2 - x_1))$ . 3. From one half of the loop find the point  $(x_3, y_3)$  which when joined to  $(x_c, y_c)$  makes an angle with the major axis closer to  $90^\circ$  and within as compared to other points. Find the other such point  $(x_4, y_4)$  from the other half of the loop. Now, if  $|x_c - (x_3 + x_4)/2| < \delta_x$  and also  $|y_c - (y_3 + y_4)/2| < \delta_y$ , then the line joining these two points forms the minor axis of the supposed ellipse else we discard the loop and make no further tests.

Let,  $b_1 = \sqrt{(x_c - x_3)^2 + (y_c - y_3)^2}$ ,  $b_2 = \sqrt{(x_c - x_4)^2 + (y_c - y_4)^2}$ . The semi minor axis of the ellipse is taken as  $b = (b_1 + b_2)/2$ . The eccentricity of the ellipse is  $e = \sqrt{1 - (b/a)^2}$ . The co-ordinates of the foci can be found to be  $(x_c + a \cos \alpha, y_c + a \sin \alpha)$  and  $(x_c - a \cos \alpha, y_c - a \sin \alpha)$ . For an ideal ellipse the sum of focal distances of each point on the ellipse is  $2a$ . Here we test the following condition for each pixel on the closed loop:  $|2a - \text{sum of focal distance}| < \Delta l$  where  $\Delta l$  had to be considered for the error due to digitization. If all the pixels of the loop satisfy the above condition then the loop is an ellipse with parameters  $x_c$ ,  $y_c$ ,  $\alpha$ ,  $a$  and  $b$ . The procedure is advantageous because it makes use of various parameters like  $\epsilon_x$ ,  $\epsilon_y$ ,  $\delta_x$ ,  $\delta_y$ ,  $\delta$ ,  $\Delta l$  which can be set to desired values as per requirement to suit different levels of accuracy and to allow different kinds of distortions in the shape of an ellipse in the image. This method also uses intermediate check-points where a loop can be discarded without any need for further computation.

**Algorithm for detection of rectangles and squares:** This algorithm can be presented as follows: 1. While moving from one pixel to the next note the gradient difference  $\frac{\Delta y}{\Delta x}$ .

Define  $\theta = \tan^{-1}[\frac{\Delta y}{\Delta x}]$ . If  $\theta$  is nearly equal to  $90^\circ$  degrees, mark any of the pixels as a possible corner of a rectangle or square. If not, we consider the two pixels as part of the same straight line. 2. Four such abrupt gradient differences indicate that the closed loop is either a rectangle or a square. A measurement of sides distinguishes further between a rectangle and a square.

## VII. SIMULATION RESULTS

We test our algorithm on four different sets of images. A comparative study of the system performance under gradually increasing complexity is provided in tabular form for the first set of images. Complexity increases from fig 1(a) to 1(d).

Fig : 1(a), 1(b), 1(c), 1(d) and 1(d.I) to 1(d.V)

|                                     | (129,125)::53, 28,0.85,0.03     | {(216,140)(216,181 |
|                                     | (161.5,179.5)::54.5,24.5,0.9,88 | )(171,181)         |
|                                     | .28                             | (171,140)}         |
|                                     |                                 | {(122,120)(122,177 |
|                                     |                                 | )(36,177)(36,120)} |

Time efficiency of our scheme is obvious from above results. But the scheme is memory efficient too. Memory is used to store (i) the two dimensional matrix corresponding to the intensity information of the image pixels (ii) the co-ordinates of the pixel corresponding to each discovered branch (iii) the incidence matrix storing the connectivity information..

#### VIII. CONCLUSIONS AND SCOPE OF FUTURE WORK

The algorithm and ant system **ARRS** are entirely novel concept and have been proved to be efficient and applicable in real life situation. But the time complexity and memory requirement of our scheme have not been compared with other existing methods such as Hough Transform or GA based method ([1]). We are trying to compare our algorithm with those mentioned on the basis

# Codebook Design Method for Speaker Identification based on Genetic Algorithm

**Abstract** — In this paper, a novel method of designing a codebook for speaker identification purpose utilizing Genetic Algorithm has been proposed. Speech features have been extracted using standard speech parameterization method such as LPC, LPCC, RCC, MFCC,  $\Delta$ MFCC and  $\Delta\Delta$ MFCC. For each of these techniques, the performance of the proposed system has been compared. In this codebook design method, Genetic Algorithm has the capability of getting global optimal result and hence improves the quality of the codebook. Experimental results show the superiority (i.e. 92% accuracy has been achieved) of this proposed codebook design method.

**Index Terms** — Automatic speaker identification, codebook design, genetic algorithm, speech pre-processing, speech parameterization.

## I. INTRODUCTION

Person recognition can be based on both the separate or combined use of several biometric features (voice, face, fingerprints, iris, etc...). A usual approach, to cope with the speaker recognition problem, involves in classifying acoustic parameters derived from the input speech signal by short time spectral analysis. These parameters contain both phonetic information, related to the uttered text, and individual information, related to the speaker [1]. According to the application area, speaker recognition systems can be divided into speaker identification systems and speaker verification systems [2].

Speaker Identification is the task of finding the identity of an unknown speaker among a stored database of speakers. To implement the speaker identification system in real time environment, codebook design is essential. The LBG algorithm is most popular to design the codebook due to its simplicity. But the limitations of the LBG algorithm are the local optimal problem and its low speed. It is slow because for each iteration, determination of each cluster requires that each input vector be compared with all the codewords in the codebook. This paper deals the efficient approach for implementing the codebook design method for real time close-set text-dependent speaker identification system.

## II. SYSTEM OVERVIEW

The proposed codebook designed method can be divided into two operations. One is the encoder and another is the decoder. The encoder takes the input speech utterance and outputs the index of the codeword with considering the minimum distortion. To find out the minimum distortion, different types of genetic algorithm operations have been used. In decoding phase, when the decoder receives the index then it translates the index to its associate speaker utterance. Fig. 1 show the block diagram of this proposed codebook designed method.

## III. SPEECH SIGNAL PREPROCESSING

### A. Speech start-end points detection and silence parts removal

To capture the speech signal (Fig. 2) high quality microphone has been used according to the parameter set (Sampling frequency 8000 Hz, resolution 16-bits/sample and recorded file format = \*.wav). After taking the speech signal, start and end point detection algorithm [3] has been used. Speech endpoints detection is used to detect the presence of speech and to remove the silences in background noises [4]. Fig. 3 shows the signal status after start and end point detection algorithm. Short-time energy is implemented to remove the silence parts by using the following equation.

$$E_i = \sum_{t=n_i}^{n_i+N-1} S^2(t) \quad (1)$$

Where  $s(t)$  is the data sample,  $i$  is the frame number,  $E_i$  is the frame energy,  $N$  corresponds to the frame length and  $n_i$  is the index of first data sample in the frame. This results show in Fig. 4.

Fig. 1. Paradigm of the proposed codebook (both encoding and decoding) design method for automatic speaker identification system.

### B. Pre-emphasizing Filtering

The Pre-emphasizing filter has been used here as a noise reduction system to increase the amplitude of the input signal at frequencies where signal-to-noise ratio (SNR) is low. Pre-emphasis has been used to balance the spectrum of voiced sounds that have a steep roll-off in the high frequency region [5]. Fig. 5 displays the output after applying the pre-emphasizing filtering technique by using the following equation.

$$H(z) = (1 - az^{-1}) \quad (2)$$

Fig. 2. Sample form of recorded speech signal.

Fig. 3. Speech after start and end points detection algorithm.

Fig. 4. Removing the silence parts from the speech.

Fig. 5. Speech after Pre-emphasis filtering.

Fig. 6. Processes of segmented speech.

### C. Speech Segmentation Or Frame Blocking

After pre-emphasizing, speech signal has been blocked into frames of  $N$  samples, with adjacent frames being separated by  $M$  ( $M < N$ ). The purpose of the overlapping analysis is that each speech sound of the input sequence would be approximately centered at some frame [6], [7]. 10-30 milliseconds frame length and around 25% to 75% frame overlap has been considered for frame blocking. Fig. 6 shows the process of frame blocking.

### D. Windowing

Among various types of windowing techniques (i.e. hamming window, blackman window, hanning window etc.) hamming window has been used. The purpose of using windowing is to reduce the effect of the spectral artifacts that results from the framing process [8]. The hamming window has been implemented by the equation:

$$w[k+1] = 0.54 - 0.46 \cos(2\pi \frac{k}{n-1}), k=0, 1, \dots, n-1 \quad (3)$$

## IV. SPEECH PARAMETERIZATION

To extract the features from the speech some effective and standard speech parameterization methods such as RCC, MFCC, MFCC, MFCC, LPC, LPCC have been applied [9], [10] because the quality of the speaker modeling and pattern matching strongly depends on the quality of the feature extraction methods. Fig. 7 shows the features after applying different types of feature extraction methods.

(a) LPC features of 12th order.

(b) LPCC features of 12th order.

(c) RCC features with 15 coefficients.

(d) MFCC features with 15 coefficients.

(e) MFCC features with 15 coefficients.

(f) MFCC features with 15 coefficients.

Fig. 7. Feature extraction form of speech.

## V. GENERATE SEARCH ENGINE ON GENETIC ALGORITHM

Genetic Algorithm has been applied in two ways for the encoding and decoding purposes. On encoding every speaker utterance is compared with an environmental noise utterance and made some groups. In each group one utterance is selected which is defined as the codeword of that group. As a result on encoding, some groups have been

defined and one speaker utterance will lead one group. On decoding side, when unknown speaker utterance will come then it is matched with a leading utterance. The unknown utterance will then find out within that group.

In GA processing selection, crossover and mutation operators have been used here. The fitness function is expressed as follows:

$$fitness = (unknown\ speech\ features \times each\ stored\ speech\ features)$$

In the recognition phase, for each unknown group and speaker within the group to be recognized, the processing shown in Fig. 8 has been carried out.

Fig. 8. Recognition model on Genetic Algorithm for the automatic speaker identification system.

## VI. EXPERIMENTAL RESULTS AND PERFORMANCE ANALYSIS

### A. Experiments on the Crossover Rate

The identification rate has been measured according to the various crossover rates. Fig. 9 shows the comparison among results of different crossover rates. It is shown that the highest identification rate was achieved at crossover rate 5.

### B. Experiments on the No. of Generations

The number of generations has also been varied to measure the best performance of this codebook design

method. According to the number of generation 5, 10 and 20 (with crossover rate 5), a comparative identification rate was found which is shown in Fig. 10. When the comparison is continued up to 5th generation, highest speaker identification rate is achieved.

Fig. 9. Performance comparison among different crossover rate.

Fig 10. Performance comparison among various numbers of generations.

## VII. CONCLUSION AND OBSERVATION

The experimental results reveal that the performance of the proposed codebook design method yields about 92% identification rate that is seemingly higher than the previous technique that utilized LBG clustering method. However, a benchmark comparison is needed to establish the superiority of this proposed method and which is underway. In the speaker identification technique, noise is a common factor that influences the performance of this technique significantly. In this sense, the conventional techniques are not very efficient and are not flawless. So, GA based codebook design method is capable to protect the system from noise distortion. The performance of this system may be improved by using some noise removing techniques and some advanced signal pre-processing methods.

# Emotion-Driven Learning Agent for Setting Rich Presence in Mobile Telephony

Sumanta Saha\* and Rumana Quazi

\*The Royal Institute of Technology (KTH), Sweden and University of Dhaka, Bangladesh  
sumanta@kth.se, rquazi@hotmail.com

**Abstract**—Presence or personal status information is going to be an integral part of human life in the near future. With the possibility of personalizing user preferences in a fine grained way, mobile presence will appeal to most users. Among all the advantages, one of the most annoying problems is to set the presence status manually each time. This paper discusses the development of an intelligent agent based presence client that will learn and make decisions on behalf of the user about his or her presence status. The decision is emotion driven and the learning depends on real world experience. The proposed system utilizes a neural network (NN) based emotion-driven agent to learn user preferences. As a NN learning algorithm, two approaches based on Differential Evolution and Reinforcement have been proposed, of which either one can be used. Rich presence status is set using a scripting language named Call Processing Language; and SIP is used for publishing the presence to others.

**Index Terms** — Presence; neural network; ANN; CPL; context aware; learning agent; SIP; DE; reinforcement

## I. INTRODUCTION

For a long time emotion has been kept out of the computing world. And then slowly, but surely it started to gain attention to the computing field. Scientists started to build systems with human like behavior that can respond to human emotion, and can modify their own behavior accordingly. Unfortunately the intrusion of emotion into computing has largely been in the fixed systems, rather than in mobile computing. Knowing that mobile computing is going to be a major part of a human's life in the coming days, it is hard to keep human feelings out of it.

In the present situation, mobile devices cannot understand how irritated the user gets when he or she receives a call while in a meeting or while driving on a busy road. The user may prefer that the call be diverted to voice mail, rather than ringing in the user's jacket pocket. With mobile devices, the best one can do is to set his own preferences explicitly as he or she changes context. Mobile services have been developed which are context aware and enable the user to set preferences according to their context, such as, divert my calls while I am at the office or keep my mobile device in silent mode while I am in meeting room. But still, these

preferences have to be set explicitly by the user prior to the event.

If mobile devices can be smart enough to sense the emotion of human users and act accordingly, thus irritation and many embarrassing situations can be avoided permanently. We have performed a survey in Stockholm, Sweden and received a very healthy response in favor of an intelligent presence agent. In this paper, we have focused on making the mobile device a learning agent that will learn human feelings and try to mimic the act of a human in a certain situation. To determine the context the user is in, location awareness has been used. A neural network (NN) based system has been proposed that will learn in an emotion based reinforced environment. The network will make a decision depending on two inputs: the location of the device and the decision that the user took previously in that location. To make the decision more realistic and avoid false positives, the agent will memorize a decision only when it has a specific frequency more than a threshold. The learnt presence statuses can be transcribed to Call Processing Language (CPL) script by the agent and published to subscribers with Session Initiation Protocol (SIP).

The rest of the paper is organized into a discussion about related works and a motivation behind our work in section two and three. An introduction to presence, location awareness, and the learning agent have been presented in sections four, five, and six respectively. Section seven presents the proposed algorithm and its analysis and section eight compares two approaches of performing the solution. The paper ends following a discussion of possible future works in section nine.

## II. RELATED WORK

With the introduction of the highly popular Instant Messenger (IM) ICQ (I Seek You), people understand the power of presence information. Since then, there has been much work on presence to make it configurable and customizable. In [1], the authors propose a personalized service where a user can configure his own preferences about presence using a simple scripting language called "Call Processing Language" (CPL). In some papers, such as [2], presence information has been used as a means of efficiently manage other tasks, for example, session setup of Push-to-

Talk over Cellular (PoC). Little work has really been done as of today to build intelligence into the presence system, to make it a learning agent which responds to human emotion which acts thereby. To learn more about learning agents and context aware preference learning please refer to [3] and [4].

### III. PROBLEM SPECIFICATION AND MOTIVATION

#### A. Problem specification

According to Ashworth [5], social interaction among humans depends on the functions of perception, motivation, and behavior. Humans perceive their environment, feel the context, and behave with other fellow human beings according to their perception and emotion. When it comes to mobile communication, much depends on the context of the receiver. The attitude towards the incoming call varies according to the environment. Based on our day to day experience, we can infer that the outcome of human emotion mostly depends on context and location in the case of mobile communication.

A learning agent or intelligent agent [6] is a software or hardware agent which observes the environment and acts accordingly to be as close as possible to the performance goal set by the user. In our paper, we propose a context-aware intelligent agent based system to enable rich presence information on mobile devices. The system utilizes the context of the mobile device and the behavior of its owner in that particular context and tries to correlate the context with the user's device setting. If we specify the decision taken by the agent as  $d$  and the reward factor as  $R$ , then  $R$  can be modeled as a function of the user's satisfaction with  $d$ , where:

$$R = f(d) \quad (1)$$

The human contributes by modifying the reward factor  $R$ , which he or she does by changing the mode of presence set by the agent. Based on the discussions, a simplified version of human-agent interaction is shown in figure 1.

#### B. Motivation

Presently, there are many services such as instant messaging applications which provide us with presence information but most of them are very limited and have to be set by the user. However, when it comes to mobile devices, presence information brings a lot of new possibilities. Inclusion of CPL ensures that the user has very fine grained control over the presence information and the way he wants to publish it. Still the problem remains, often the user forgets to set their status or presence information causing embarrassing situations. It could be avoided altogether, if the mobile could decide itself about its status.

While [1] describes how to extend presence information by extending CPL to provide rich information, our proposed

presence system is not limited to user input, but rather introduces an intelligent agent who acts on behalf of the user.

### IV. PRESENCE

*Presence* is a popular way to convey to your friends or contacts your willingness to communicate and the means of communication. This has been widely used in Instant Messengers (IM) for quite a long time. Most popular "Presence" statuses have been "Busy", "Away", or "Stepped out". The application of presence is not only limited to IM but can be very successfully applied in cellular communications. Knowing where a friend will eliminate the requirement of calling many times when the sole reason of calling is to know where he or she is. Additionally, it will help to determine the best way to communicate with a friend if necessary. When the reason to call is just for social interaction, it is better not to call if the person is busy or her mood is sad.

'Presence' has been called "The best thing that ever happened to voice" by Jonathan Rosenberg [7], by one of the authors of SIP RFC and inventor of SIP SIMPLE protocol. He declared the extinction of caller ID; presence will be the way to convey who I am, where I am, and what kind of communication I am willing to receive.

'Presence' could be much more diverse in cellular world than it is in IM world. Probable scenarios include:

- You want to call one of your friends, but find that he is now driving in downtown, and as it was a social call, you decide to leave a voice message instead.
- When you are in a meeting the calls would be automatically redirected to voice mail.
- You expressed your interest in real estate before and when you are wondering in near an available property a descriptive message is automatically delivered.
- The location of your best friends nearby can be detected and the phone can inform you with an integrated map with directions.

The Internet Engineering Task Force (IETF) RFC 2778 [8]

Figure 1: Human-Agent Interaction

defined a model to describe presence information. A SIP implementation of this RFC has been defined in [9]. In [9], the presence information of a user is published as an event to the interested parties defined as *watchers*. While several technologies can be used to enable a presence service, SIP is well suited for this purpose because of its simplicity, focus on the Internet, compact format, and simplicity.

#### A. Session Initiation Protocol (SIP)

In the contemporary world, two signaling protocols are dominant for session setup and teardown, namely: IETF's SIP from and ITU-T's H.323 [10]. Although both are quite successful and have similar features, SIP is the predominant protocol today due to its simplicity. In our paper, we have used SIP for signaling and session setup, although our concept applies equally to both. SIP is an application layer protocol for establishing, maintaining, and terminating multimedia sessions or calls. Two SIP extension messages for presence have been defined by IETF, namely: SIP SUBSCRIBE and SIP NOTIFY. These messages are defined and discussed in [9, 11]. Later an event state publication method SIP PUBLISH [12] was proposed. This message can be used for presence event publication in a presence system.

With the advent of many customized services, it has become critical to control and manage them. The Call Processing Language (CPL) is a solution built on top of SIP to let the end users specify and control services.

#### B. Call Processing Language (CPL)

CPL [13] is a simple markup language to specify and control Internet telephony services. It is based on XML syntax and made to be easily used by non-professional users to control their services. According to [13], "It is meant to be simple, extensible, easily edited by graphical clients, and independent of operating system or signaling protocol. It is suitable for running on a server where users may not be allowed to execute arbitrary programs, as it has no variables, loops, or ability to run external programs." For examples of CPL scripts please refer to [1].

A CPL script is usually associated with a user and only activated when a SIP INVITE message for that particular user arrives. So, the scripts can be on the user device as well as in a proxy server (freeing the mobile device from the load of processing) while providing the necessary privacy and personalization.

### V. LOCATION AWARENESS

Location awareness enables a device to be geographically located, while presence allows a user to know the status of another user. These two services act as a complement to each other. The application of location-awareness along with presence is so promising that people in telecommunication industry (as well as statistical research organizations) are

predicting that location aware services will increase exponentially every year. One reason behind such high expectations is a 1996 mandate requiring that by December 2005 all mobile carriers in the US be able to locate a subscriber making an emergency 911 call to within an accuracy of 50 to 100 meters 60% of the time.

A mix of technologies is used today for location awareness. The most accurate one is Global Positioning System (GPS) which can pinpoint a device with the highest accuracy and another is Cell triangulation [14]. In triangulation, using the signal strength of the cellular towers a triangle is formed and thus the location of a device is discovered. Another technology is ultra wideband [15], which is even more accurate than GPS but is still under active research.

### VI. LEARNING AGENT

A learning agent is a programmable software or hardware agent that helps human beings by acting on their behalf. The intelligence in a learning agent can be implemented in various ways. For example: an Artificial Neural Network (ANN), Bayesian network, Markov random fields, and so on. The learning process can be supervised, unsupervised, reinforced, semi-supervised, transduction, and learning to learn.

In our proposal we have used ANN with both Reinforced learning and Unsupervised learning with a Learning to learn technique. ANN uses adjustable weights attached to each input of the layers to vary the influence they have on the output [16]. A model of the neural network used in this paper is presented in figure 2.

#### A. Reinforced Learning

In many situations, while learning, it is hard to find any feedback. There may not be any benchmark set of data available to compare the output with and it becomes pretty impossible to evaluate whether the agent is providing the proper output. Sometimes, there is only a little information available after a long sequence of input to indicate whether the output is right or wrong. Reinforced learning is

Figure 2: Artificial Neural Network

Figure 3: High level architecture of the system

developed to deal with these kinds of situations. It is a kind of supervised learning where the only feedback available is from the environment. Moreover, the information is evaluated rather than instructive. So, reinforced learning is often called “Learning with a critic” rather than “Learning with a teacher”.

### B. Unsupervised learning with Learning to Learn

In unsupervised learning there is no teacher at all. The ideal outcome is completely unknown. The agent has to evolve over the course of time to learn how to react to the inputs to provide the best output which fits the environment. It adjusts through direct confrontation with new experiences. With Learning to learn technique the bias of its weights are also changed automatically.

## VII. METHOD

In this section, we describe the architecture of the proposed presence system while detailing the context identification and the strategy for learning user preferences based on location and emotion. The total system can be divided into high level blocks where each level does its work based upon input from the previous level. The architecture of system looks like figure 3. The context identification part of the architecture helps the ANN by providing a scratchy model output set.

### A. Context identification

The context identification method of our system works on location data available from any location-provider services in the phone. Day by day, services like GPS are getting popular and so our system presumes that such a system is available either in users’ devices or in the cellular infrastructure. The system allocates a node represented by a binary number to each location that is relevant for the system. To evaluate relevancy, it takes the following approach:

1. Detect the location information when the user changes the status of her device
2. Store the information in a temporary buffer and initialize a counter with respect to the (location, status) combination
3. The next time the user comes to this location:
  - a. Check the status information she set
  - b. If it is same as the previous status then increase the counter  
else if the status set is different than that in buffer do

- i. start multiplicative decrease of the counter value
  - c. else if the user sets no status then do nothing
- If the value of the counter reaches a threshold then in a separate process goto step 4.
4. Make the location value permanent and feed it as input to the Neural Network
5. Store the value of status as a model outcome of user preference to use with the Neural Network

The location data is fed to the learning process if and only if the system finds that the user is repetitively setting the same status for that location.

### B. Learning process

The learning process of the agent is done online. Whenever a location node is added to the systems input, the system starts learning the users’ decision in that location. The learning process is done by a Neural Network with one hidden layer. The process is similar to an environmental learning process such as face detection, which does not depend on any explicit equation rather on environmental feedback on a particular decision.

### C. Construction of the network

The Artificial Neural Network (ANN) has a very simple design of an input layer, one hidden layer, and one output layer. The design need not to be complex because the decision to be taken does not depend on many variables. Rather the agent only learns what is trivial for the user to save the effort and disturbance from the users’ part. The input layer takes the location information as input from the previous block of the system, the context identification block. The location is encoded as a 6 bit binary value in our system based on the assumption that a single user will not go to more than  $2^6$  places regularly. It is possible to change this number of bits if necessary. The hidden layer consists of 3 neurons and the output layer consists of 4 neurons. The decision about the output layer is taken under the assumption that a user normally does not have more than  $2^4$  presence statuses. As before, these values are changeable if necessary.

### D. Learning algorithm

We designed the solution with two different learning algorithms where both are equally capable of solving the problem having their own advantages and disadvantages. Both algorithms are specially suited to this kind of situation

where the correct output is not known beforehand, but in the course of learning, environmental feedback is available.

**Differential Evolution:** Differential evolution [17] is an effective, efficient, and robust optimization technique based on an evolutionary strategy. It can be considered as a stochastic search algorithm to determine the best solution in the complex solution space. DE exploits a population of potential solutions, individuals, to probe the search space. New set of solutions are generated by combination and evolution of randomly chosen solutions. To be more specific, for each individual solution  $X_i$  of current generation, where  $i = 1, 2, \dots, N$  and  $N$ =number of random initial solution, a new individual solution  $Y_i$  is generated according to the following equation [18]:

$$Y_i = X_{i1} + F(X_{i2} - X_{i3}) \quad (2)$$

where,  $X_{i1}$ ,  $X_{i2}$ , and  $X_{i3}$  are randomly chosen individual from the current generation to produce offspring  $Y_i$  and  $X_{i1} \neq X_{i2} \neq X_{i3}$ .  $F$  is called the scaling factor or amplification factor. This operation is similar to what is commonly known as mutation in evolutionary biology. The final offspring  $X_{i+1}$  of the next generation are produced from mutation of  $X_{i1}$  and  $Y_i$ . The parameter which regulates how many consecutive genes of the mutated individual on average are copied to the offspring is called crossover rate CR. Finally the offspring  $X_{i+1}$  is evaluated and replaces its parents  $X_{i1}$  in next generation if and only if its fitness is better than that of its parent. This is called the selection process.

The fitness function is the central part of the algorithm where the new generation is evaluated against the parent for fitness. If it is better suited to the ultimate performance goal, then the new breed replaces the parent otherwise the parent is kept. In our algorithm, the fitness function depends on the proximity to the user preferred value of presence status in response to the input location value. A model result is taken from the database as created at the context identification step of the system. If the model result vector is  $Y_i$ , the new generation of weight is  $W_i$  and the input vector is  $X_i$ ; then the fitness function becomes:

$$Y_i \approx \text{ANN}_{W_i}(X_i), \text{ with threshold } t \quad (3)$$

where ANN is the neural network. The less the difference between the model  $Y$  and the derived  $Y$  the more fit is the generation. The approach followed for the ANN in our system in this case is as follows:

1. Take location input from the context identifier
2. Initialize the parameters( $F$ , CR, Population Size) of DE
3. Randomly Initialize the first (initial) population
4. for  $i=1$  to PopSize do
  - a. for  $j=0$  to Number of Input Nodes do Create random candidate weights  $w[i][j]$
  - b. Calculate fitness value of the individual using ANN fitness function

5. While iteration < max iteration (or termination criteria not satisfied)
  - for Each Individual of Current Population
    - i. Select three random and mutually exclusive individuals
    - ii. Create new breed with DE operators and Crossover from the original three random parents
    - iii. Calculate fitness value of the newly generated offspring
    - iv. If (offspring fitness value > original parent fitness value) then promote the offspring to next generation
    - Else promote the original parent to next generation
  - v. End If
6. Report the best fitness value and the offspring as a weighted combination for the input nodes of the ANN.
7. Adjust the weights of ANN according to the output of DE.
8. In case of the user contradictions with any of the decisions made by ANN, multiplicative decrease of the fitness score of that offspring and start the learning process again.

**Reinforced Learning:** In reinforced learning, the weight matrix  $W$  has the size of  $n$  by  $m$  where  $n$  is the number of possible inputs and  $m$  is the number of possible outputs. The value at  $w_{ji}$  denotes the possibility of taking action  $i$  while in state  $j$ . If  $s$  is a new state reached by taking action  $i$  at state  $j$ , we can compute the reward of this move as:

$$R^k = R(i|j) = R_s \quad (4)$$

Let  $l$  be the change of reward score between two moves:

$$l^k = R^k - R^{k-1} = R_s - R_j \quad (5)$$

Equation (5) represents the human attitude towards the decision made. Depending upon that, the rule of updating the weights can be as simple as:

if  $l_k \geq 0$ :

$$w_{ji}^{k+1} = w_{ji}^k + a(1 - w_{ji}^k),$$

$$w_{jh}^{k+1} = (1 - a)w_{jh}^k \quad \text{for } h \neq i \quad (6)$$

if  $l_k < 0$ :

$$w_{ji}^{k+1} = (1 - a)w_{ji}^k,$$

$$w_{jh}^{k+1} = \frac{a}{m-1} + (1 - a)w_{jh}^k \quad \text{for } h \neq i \quad (7)$$

Where  $a$  is the learning rate [19].

The rules encourage the decisions that have better score. If the decision is supported by a better score, such as  $l^k \geq 0$ , it is rewarded by (6). Otherwise it will be penalized by (7). In this case of mobile presence decision making, no feedback from user indicates that the user is happy with the decision made by the agent. So if there is no change in the reward score, we can safely assume that the decision was correct and it can be rewarded. But if the user changes the decision, then the decision made by the agent will be penalized. A more detailed mathematical analysis of reinforced learning can be found at [20].

### E. Realization of Presence status change

In the system, the user is able to create his own presence statuses using a simple web-based client where he can specify every single detail of his preferences. The statuses are translated to a CPL script and stored as output nodes in the system. According to the output from the ANN, a particular node is selected and a SIP PUBLISH method is used to publish the presence status to the subscribers. CPL also sets the status of various mobile device properties such as vibration, ringer, etc.

## VIII. COMPARISON

The main advantage of using differential evolution as a weight adjusting algorithm is that it is unsupervised and it learns the learning rate itself by driving the learning rate through the evolution process. We do not have to provide anything other than the initial fitness function. According to the user's emotion, which is realized by changing an agent decision, the fitness value is adjusted. When using differential evolution, we do not have any problem similar to the typical back propagation where we can be trapped in local minima, and which scales exponentially with the complexity of the problem. On the other hand, reinforcement algorithms such as the one stated above has the property of being extremely fast to learn and adapt. It quickly finds the slope to the reward function and modifies itself by propagating the findings towards the other layers of neuron. The only limitation is that sometimes reinforcement algorithms are trapped in local minima. A good evaluation of differential algorithm and the back propagation approach is given at [21].

## IX. CONCLUSION

An approach to make the mobile devices intelligent for making decisions about the user's presence status in accordance to their location and previous decisions is presented in this paper. Presence status will be an inevitable part of the mobile technology in the near future where everyone can learn about the current status of their contact to make knowledgeable decision about contacting them. Life of most of the people in the world is limited to a certain boundary and in most cases they seem to be occupied in the same kind of work at a certain place. This makes an intelligent agent perfectly capable of predicting or deciding what their status should be if they are in a particular place depending upon what the user did before for the same position. With the plethora of location data providing systems, this approach of human-computer interaction seems to be inevitable. Two algorithms for decision making using artificially intelligent agent along with a market research about the approach have been presented in this paper.

# An HPSG Analysis of Arabic Passive

Md. Shariful Islam Bhuyan and Reaz Ahmed

Department of Computer Science and Engineering,  
Bangladesh University of Engineering and Technology,  
Dhaka, Bangladesh

**Abstract**—In spite of being a successful syntactic theory in many respects, Head-driven Phrase Structure Grammar (HPSG) has inadequate coverage for morphological constructions, especially for nonconcatenative morphology, which is prominent in the Semitic languages such as Arabic, Hebrew etc. Among various syntactic and semantic phenomenon, passive constructions draws attention of many researchers in theoretical linguistics due to their diversity. Arabic exhibits lexical passives with nonconcatenative morphology. In this paper, we extend the HPSG framework to support the nonconcatenative construction of Arabic passives along with the necessary lexical rules and type hierarchy.

**Index Terms**—Passive Construction, Arabic Morphology, Nonconcatenative Morphology, Head-driven Phrase Structure Grammar, Constraint-based Grammar

## I. INTRODUCTION

Broad-coverage precision grammar [1], [2] and computational lexicon development for deep linguistic processing is a research-intensive area with several potential applications [4]. Amidst the vast literature on formal linguistic theory [5], Head-driven Phrase Structure Grammar (HPSG) [6] has a unique position since it combines the best features of the contemporary approaches as well as establishes an integrated framework for cross-layer representation comprising phonology, morphology, syntax, semantics, pragmatics and discourse. Although, HPSG successfully describes numerous syntactic and semantic phenomena, it lacks rigorous analyses for morphological phenomena, especially for non-concatenative morphology [7]. Nonconcatenative morphology illustrates an interesting paradigm of morphological operations, which is prominent in the Semitic languages such as Arabic, Hebrew etc [9].

From the inception of mathematical formalism in theoretical linguistics, passive construction draws attention of many researchers. HPSG is used in successful analysis of passive for several languages [8], [9]. However, there is no HPSG analysis for Arabic passives. Among the living languages, Arabic demonstrates the best instance of nonconcatenative morphology. Arabic verb system exhibit both concatenative and nonconcatenative morphology, capable of lexically expressing diverse syntactic and semantic phenomena including passive. In this paper, we extend the HPSG framework to support Arabic passive along with its nonconcatenative morphology.

## II. PASSIVES IN ARABIC

Arabic word formation is an excellent example of root-pattern morphology [8], [9]. A combination of root letters are plugged in a variety of morphological pattern with priory fixed letters and particular vowel melody that gives rise to corresponding syntactic and semantic phenomena.

An Arabic word can encode a complete sentence. For example, *sayaktubuhu* – *He will write it*. We can break the word in the following component.

- 1) Prefix: *sa* – the particle indicating future.
- 2) Suffix: *hu* – the object pronoun attached as a clitic
- 3) Root: *k, t, b* – the root letters bearing the concept of writing
- 4) Measure: *ya\_\_u\_\_u* – bearing the syntactic and semantic information of the event

It may be possible to concatenate multiple prefixes and suffixes. However, there must be a single measure and single set of root letters, where the measure packages syntactic and semantic features and root supplies the core concept. Here the measure indicates that – the actor is in 3rd person, singular number, masculine gender; the verb is in indicative case, active voice and derived form I; it also indicates that the event has not yet been completed. If we plug in another set of root letters, for example, *n, S, r* – which bears the concept of helping, we get *sayanSuruhu* – *He will help him*.

Arabic passives are constructed using measures. There are dedicated measures for expressing passives. For example, the passive of *yaktubu* is *yuktabu*. The passive measure is *yu\_\_a\_\_u*. Several syntactic and semantic information has been modified in this measure. First, the straight forward change is stem alternation. The measure *ya\_\_u\_\_u* has been changed to *yu\_\_a\_\_u*. Next, its subcategorization feature has been changed. In general, only the transitive verbs can exhibit passive sense. In active form, these verbs expects syntactic object(s). In passives, these objects are promoted to the position of syntactic subject. Subject in active forms are realized by obligatory prepositional phrase in languages like English. However, Arabic passives do not expect this subject in active forms to be its syntactic argument. Rather, they remain unexpressed. The object in the active form becomes the subject in passive. Another important concept is hidden

Fig. 1. (a) An HPSG sign (b) An HPSG construction (c) A standard HPSG type hierarchy

pronoun. The semantic actor of Arabic verbs may not be syntactically realized. In that case, a hidden pronoun is introduced which plays the role of semantic actor. In passive, this hidden pronoun plays the role of semantic undergoer. In the next sections, we present the necessary formalisms to capture Arabic passives under HPSG framework.

### III. AN HPSG PRIMER

Natural languages generally consist of two components. First, the utterances that can be used by human. Second, the linguistic rules that license those utterances. For example, in English, "He writes books", "writes books", "writes" - all are valid utterances. However, "Writes he books", "writes he", "rwrite" are not valid, since the rules do not license them. HPSG is a mathematical theory for natural languages that formally captures these two core linguistic components. Utterances are modeled using a mathematical object *Sign* (a formal representation of words, phrases as well as sentences) and rules are captured using another mathematical object *Construct* (a formal representation of grammar rules or schema which are used to license signs). Both sign and construct are described using feature structure - a collection of features of corresponding linguistic objects along with their values. These features and their values constitute a very detailed type hierarchy (see figure 1(c)).

An utterance can have linguistic feature spanning multiple layers, e.g. phonological morphological, syntactic, semantic, pragmatic and others. To capture these features, the description of a typical HPSG sign looks like figure 1(a). To capture grammatical rules, the feature structure of a construct has a *mother* (MTR) feature and a *daughters* (DTRS) feature. The value of the MTR is a sign and the value of the DTRS is a nonempty list of signs. The description of a typical HPSG construct looks like figure 1(b). The licensing of signs follows *The Sign Principle* which states that "Every sign must be lexically or constructionally licensed, where, lexically licensed only if it satisfies some lexical entry, and constructionally licensed only if it is the mother of some construct" [6].

From the type hierarchy of figure 1(c), we can see that there are two types of feature structure. Functions are those feature structures which are described using an attribute value matrix (AVM). They map features to feature structures. Atoms are atomic types that can be used as the value of features. Notable functions are sign, cxt (construction), lexeme, phrase and others. To model a linguistic phenomenon we first need to identify the involved signs with their hierarchy. Next, we need to design functional feature structures for them with linguistically motivated features. Then we also need to define the necessary constructs as well as the atomic type hierarchy. In the next section, we

Fig. 2. HPSG Sign for *kataba*

build these ingredients for Arabic passives.

#### IV. HPSG ANALYSIS OF ARABIC PASSIVE

Here we give the attribute value matrix (AVM) for an Arabic verb *kataba* – *He wrote* in active form and its corresponding passive form *kutiba* – *It was written*, using our analysis.

In the figure 2, we have three features associated with morphology. First, the feature TYPE, which denotes the associated root class. Arabic roots are classified into several root class according to their derivational and inflectional paradigm. This feature affects both root and measure. So, it has been taken out to a first level morphological feature. In this case, its value is *sound*. Next, the feature ROOT, which has a list of root letters as well as the CONTENT feature, which gives the semantic contribution made by root letters. In this case, its value is structure-shared with the *write-fr* in the FRAMES feature. Next, the feature MEASURE, which contains the morphological, syntactic and semantic information contributed by measure. First,

Fig. 3. HPSG Sign for *kutiba*

the feature FORM, which denotes the semantic paradigm. *kataba* - is a form-I derivative. Next, the feature PATTERN which captures the stem along with the root letters using structure sharing. Then, the feature CAT, which contains the syntactic category for this measure. Its value is structure-shared with the syntactic feature CAT. Finally, the feature PNG, which captures the PERSON, NUMBER and GENDER information of our semantic actor in the case where it is not syntactically realized.

We present the syntactic and semantic information using the SYN and SEM feature, for the word - *kataba*. First, the CAT features identifies the syntactic category of - *kataba*. It contains the VFORM and VOICE feature of Arabic, which governs the derivational paradigm of verb lexeme. In this case their values are *perfect* and *active* respectively. Next, the VAL feature, which captures the subcategorization of verbs. VAL is a list of signs, which are required by the syntactic head. In this case, the verb - *kataba*, requires an object. The verb - *write* is a transitive verb that takes an object. We should note that the hidden pronoun. *he* is encoded by the inflectional morphology, when no explicit subject is used. The semantic actor is not realized syntactically. So, the verb only subcategorizes for

Fig. 4. Lexical rule for passive construction

syntactic object. We can also see the constraints imposed over the object. In this version, its syntactic head should be a noun phrase with the value of its CASE feature set to *accusative*. The negative value of the OPT feature indicates that this object is not optional, rather required to be syntactically correct.

Next, we need to consider some semantic features. Here, we use a type feature version of predicate logic to capture semantics of natural language. First, we consider the INDEX feature, which is a reference to a discourse entity. Then, the PNG feature, which capture the semantics of PERSON, NUMBER and GENDER. Next, the FRAMES feature, which serves as a bag for elementary predicates to describe the situation at hand. For example, in the case of *kataba*, the event of writing is expressed. The event is completed in the past and there is a discourse referent to the actor. To capture the core event, write-predicate is introduced. To capture the temporal constraint, we use the perfect-predicate. Finally, to express the actor of the event, the hidden pronoun, we introduce a discourse referent with corresponding PNG feature.

Predicates have their respective arguments. write-predicate has a situation hook, expressed by the feature SIT. There are two semantic role associated with this predicate. First, we consider the role of writer, who plays a doer role, expressed by the feature ACTOR. Second, we consider the role of written, who plays an undergoer role, expressed by the feature UNDGR. The perfect-predicate

Fig. 5. Type hierarchy for lexical construction

Fig. 6. Lexical type hierarchy

takes a situation hook as an argument, which is expressed as the feature ARG. We use the technique of co-indexing for sharing semantic objects. The discourse referent predicate is actually the actor of the write-predicate. To denote this constraint, the INDEX value of hidden pronoun and the ACTOR value of the write-predicate are co-indexed, both are given the value *i*. This is an example of reference co-indexing. We also use event co-indexing. The event hook SIT of write-predicate, situation hook of the entire scenario and argument ARG of the perfect-predicate, all are co-indexed and expressed using the value *s*. Another important issue of HPSG representation is the syntax-semantics interface. In this example, this is done by co-indexing the INDEX value of the syntactic object and the UNDGR value of the write-predicate with a value *j*. This indicates that the syntactic object is our semantic undergoer whereas from our previous discussion we can note that the semantic actor is not syntactically realized.

In the figure 3, we show the HPSG representation of the passive - *kutiba*. We identify the associated changes for this conversion. The PATTERN feature is changed to capture the derivational morphological operation. Next change can be found obviously in the feature VOICE, changing

its value to passive. Unlike English, which can have a prepositional complement in passives, Arabic passives do not subcategorize for a subject or any other argument. For this reason, the VAL list is empty. Moreover, the discourse referent in the feature FRAMES is now co-indexed with the UNDGR feature of the write-predicate, expressed by the value *j*. Semantic actor now completely unknown by not having any syntactic or semantic reference, which is a distinctive property of Arabic passive. These changes can be succinctly captured by the lexical construct in figure 4. We also give the type hierarchy for active and passive verb lexeme and lexical construction for passive. They are given in the figure 5 and figure 6.

## V. CONCLUSION

In this paper, we give the proposal how to capture Arabic passives along with their nonconcatenative morphology within the framework of HPSG. There are lots of syntactic and semantic phenomena that needs to be captured for the development of a full-fledged computational grammar for Arabic. Results will be immensely helpful for the construction of resource grammar for languages with rich nonconcatenative morphology.

# WalkSAT Approach in Solving The Staff Transfer Problem

Sriyankar Acharyya

Department of Computer Science & Engineering, West Bengal University of Technology, Kolkata,  
West Bengal, email: srikalpa8@yahoo.co.in, India

**Abstract** — Staff Transfer is an important issue in Human Resource Management. It is concerned with the assignment of transfer postings to employees in large organizations. A large organization has offices and worksites at multiple locations and it is customary to transfer a subset of employees at periodic intervals. The Staff Transfer Problem (STP) can be viewed as a Constraint Satisfaction Problem(CSP). The deterministic methods were proved to be inferior to local search methods in solving this problem. In earlier investigation GSAT(L) easily outperformed the Simulated Annealing (SA) which was the then best among all approaches. In this work computer experiments indicate that WalkSAT(L,p) easily outperforms GSAT(L) in most of the instances.

**Index Terms** — Constraint Satisfaction, Local search, Satisfiability, Tabu Search, Staff Transfer

## I. INTRODUCTION

A transfer is a lateral movement of an employee in an organization not involving a change in rank. In many large organizations that maintain offices and work-sites at multiple locations, it is customary to transfer a subset of employees at periodic intervals from one office or work site to another. Examples of such organizations are the armed forces, government departments, commercial banks, and construction firms. Transfers play a major role in human resource flow in organizations, and the satisfactory assignment of transfer postings to employees is an important issue in Human Resource Management [4,5].

The *Staff Transfer Problem* (STP) [1] is described and formulated as a Constraint Satisfaction Problem(CSP). The variables take values that correspond to transfer postings of employees. A typical constraint enforces the requirement that the total number of employees assigned to a transfer posting should not exceed the specified number of vacancies. The objective is to find transfer postings for a given subset of employees that satisfy all the constraints. Fig. 1 represents a diagram showing the basic structure of the problem

The constraints here are not binary but involve a number of variables. The constraints are of two types, *strict* and *desirable*. A strict constraint must be satisfied; for example, an employee can only be transferred to a location where there is a vacancy for a job the employee can perform. A solution that satisfies all strict constraints is a feasible solution. A desirable constraint should be

satisfied if possible. For example, it is desirable that senior employees get priority over their juniors in the assignment of transfer postings. The quality of a feasible solution is determined by the degree to which desirable constraints are satisfied. The objective is to find feasible solutions of high quality.

The transfer policy that is adopted in an organization must be both fair and systematic to be acceptable to employees. When the transfers involve a large number of employees, it is typically quite difficult to find suitable alternative positions for everyone. Some preliminary results are reported in [2]. More detailed results comparing some CSP techniques and showing the superiority of Simulated Annealing over other methods are reported in [3]. But when the Staff Transfer Problem(STP) was converted to Satisfiability (SAT) and GSAT with tabu list was applied, the Simulated Annealing was outperformed by GAST(L) significantly[13]. In this paper we have shown that WalkSAT(L,p) approach is significantly better than GSAT(L) in performance.

In this paper the sections are arranged as follows. Section 2 describes the Staff Transfer Problem (STP) in detail. Section3 presents solution methods applied to this problem. Experimental results are provided in Section 4. Section 5 summarizes the paper and discusses some unsolved issues.

## II. PROBLEM DESCRIPTION

There is a set of  $E$  employees who are to be transferred. The organization has other employees who are not being transferred. At any office or work site, the number of vacancies is the difference between the number of sanctioned positions and the number of employees who are not being transferred. An employee can perform only certain types of jobs. An employee has a seniority level, which is determined by factors such as the level of the current position in the organizational hierarchy, the date of joining the current position, and the date of birth. There is a set  $LOC$  of locations participating in this process. A location corresponds to an office or a work site. There is a set  $J$  of job categories. Typical job categories are electrician, typist and manager. For each pair  $(loc, j)$ ,  $loc$  in  $LOC$  and  $j$  in  $J$ , the number of vacancies  $vacancy(loc, j)$  is known. This number includes the chain vacancies that

arise as a result of the E transfers. It can be zero, indicating that job type j does not exist at location loc or that there is currently no vacancy for job type j at location loc. Fig. 1 shows a schematic representation of the Staff Transfer Problem.

Fig.1. A schematic diagram of the Staff Transfer Problem where no of locations = k, no of job types in location 2 = m, no of employees in bucket (loc<sub>2</sub>, job<sub>2</sub>) = n

An employee who is due for transfer submits options for  $T \geq 2$  destinations, each represented by a (loc,j) pair. The job types in the transfer options correspond to jobs that the employee can perform. The parameter T has a typical value of 3. The options are arranged by preference, the first option having the highest preference for the employee, the second the next highest, and so on.

For convenience, we assume that the employees to be transferred are numbered 1 through E in decreasing order of (rank, seniority). Thus employee 1 has the highest rank and is seniormost, and employee E has the lowest rank and is juniormost. Let *vac* be the total number of vacancies. Then  $vac = E \cdot (1 + extra)$ , where *extra* gives the total number of positions lying vacant prior to the transfers, expressed as a fraction of E. It is possible that *extra* = 0, in which case the chain vacancies are the only vacancies. To avoid problems in implementation arising out of the chain vacancies, we assume that all E transfers take effect at the same instant of time. Let us call each (loc,j) pair a *bucket*. The buckets are numbered 1 through B. The number of vacancies in bucket  $k = (loc,j)$  is  $M_k = vacancy(loc,j)$ .

As already mentioned, constraints are either strict or desirable. There are three strict constraints:

SC1: Each of the N employees must be assigned a new posting. A new posting is a (loc,j) pair that differs from the original (loc,j) pair in at least one position.

SC2: An employee can only be transferred to one of the T options specified by the employee.

SC3: For each (loc,j) pair, the total number of persons transferred to (loc,j) must not exceed vacancy(loc,j).

The problem can be formulated mathematically as follows. An ExTxB matrix  $A = [a_{ijk}]$  is given, where  $a_{ijk} = 1$  if transfer option j of employee i is bucket k, and 0 otherwise. We have to determine the ExT solution matrix  $X = [x_{ij}]$ , where  $x_{ij} = 1$  if employee i is assigned transfer option j, and 0 otherwise. An employee is assigned exactly one new transfer option. The solution is *feasible* if the number of employees transferred to any bucket k does not exceed the number of vacancies  $M_k$ . This condition can be expressed as follows:

$$\sum_i x_{ij} a_{ijk} \leq M_k \text{ for } 1 \leq k \leq B$$

where the summations are over  $1 \leq i \leq E$ ,  $1 \leq j \leq T$ . A feasible solution satisfies all the three strict constraints mentioned above.

There are two desirable constraints:

DC1: Among the T options, an employee should be assigned an option of as high a preference as possible.

DC2: When two employees contend for the same transfer posting, the employee who is senior should get priority over the employee who is junior.

DC1 can be expressed by the condition

$$\sum_i x_{ij} \geq \sum_i x_{ij+1} \text{ for } 1 \leq j < T,$$

where the summation is over  $1 \leq i \leq E$ . This says that more employees should be assigned an option of preference j than an option of preference j+1.

DC2 is satisfied if *seniority violations* can be avoided. Such a violation occurs if there exist employees  $k_1$  and  $k_2$ , where  $k_1 < k_2$  and integers r, s and t,  $1 \leq r, s < t \leq T$ , such that:

- i) the junior employee  $k_2$  is assigned a transfer option (loc,j) that has preference r for  $k_2$ ;
- ii) the senior employee  $k_1$  is assigned an option of preference  $t > r$ ;
- iii)  $k_1$  has specified the same (loc,j) pair assigned to  $k_2$  as an option with preference  $s < t$ .

The condition for no seniority violation, of an employee i assigned option j, by a junior employee q assigned option r is

$$\sum_i \sum_j \sum_k \sum_l \sum_p \sum_q x_{ij} a_{ipk} x_{qr} a_{qrk} = 0$$

where the summations are over  $1 \leq i < q \leq E$ ,  $1 \leq p, r < j \leq T$ , and  $1 \leq k \leq B$ . In explanation, we note that: i) the juniormost employee cannot suffer a seniority violation; ii) it must be the case that  $j > 1$ , for if employee i gets the first transfer option then no seniority violation can occur; and, iii) q must get an option  $r < j$  to violate the seniority of i. Stated in this form, the Staff Transfer Problem is just a CSP and not an optimization problem, since there is no objective function to optimize.

We can view the Staff Transfer Problem, with seniority violations ignored, as a problem in which a complete matching of maximum weight must be found in a weighted bipartite graph [7]. Let an instance of the Staff Transfer Problem be given in which all bucket sizes are

unity. We construct a bipartite graph  $G = (V_1 \cup V_2, E')$ , where  $V_1$  is the set of vertices on the north side,  $V_2$  the set of vertices on the south side, and  $E'$  is the set of edges.  $V_1$  and  $V_2$  are assumed to be disjoint. In our case,  $V_1$  represents the set of employees and  $V_2$  the set of buckets. An edge from a vertex  $v_1$  of  $V_1$  to a vertex  $v_2$  of  $V_2$  indicates that  $v_2$  is a transfer option of employee  $v_1$ . We assign to each edge a positive integer weight that depends on the employee, the bucket, and the preference of the transfer option. This weight reflects the value of this particular option to the organization and to the employee. A transfer option that is a first preference has a higher weight than one that is a second preference, and so on. Since the buckets have unit size, our objective here is to find a matching that is complete for  $V_1$  and maximizes the sum of weights of the selected edges. This problem can be solved in time that is polynomial in the size of the input. Now, suppose there is a bucket that has a size  $k > 1$ . In  $V_2$  we split this big bucket into  $k$  smaller buckets each of unit size. If the big bucket happens to be a transfer option with weight  $w$  for employee  $v_1$ , we join  $v_1$  to each of the  $k$  smaller buckets with edges of weight  $w$ . As a result we are again left with a complete matching problem. Since bucket sizes are constant integers supplied as input, the solution can still be obtained in time that is polynomial in the size of the input.

When seniority violations must be resolved, it becomes much harder to assign transfer options to employees in a satisfactory manner. It is not yet known whether the Staff Transfer Problem becomes NP-complete in this case.

The Staff Transfer Problem models an idealized situation. In practice, an organization might want to impose additional conditions on the transfer options of employees or change some of the assumptions. For example, the number  $T$  of transfer options need not be the same for all employees. The organization could decide how many transfer options an employee would be entitled to submit. Assuming an employee is allowed to submit options freely, it is advantageous to submit as few options as possible, since this means the employee is more likely to get a desired posting. If the organization wants to impose some degree of control over the transfers, it could itself supply one of the transfer options, perhaps the one of highest preference, and the employee could be requested to submit the remaining options. There are many other possibilities.

### III. SOLUTION METHODS

A satisfactory analytical solution procedure for the problem, even in its idealized form, has not yet been found. We are thus forced to use heuristic methods. In our earlier work[2,3,13] it was shown that GSAT(L)

outperformed other heuristic and deterministic methods. Here, we have tried to solve randomly generated problem instances using WalkSAT(L,p). The implementations given below consider only the basic version of the problem consisting of: i) the strict constraints and ii) desirable constraint DC2.

Here, the STP is viewed as a SAT. One way to express the Staff Transfer Problem in terms of logical satisfiability is as follows. Let the  $T$  transfer options of employee  $k$  be  $(loc_{1,j_1}), (loc_{2,j_2}), \dots, (loc_{T,j_T})$ . Then employee  $k$  must be assigned a transfer posting at one of these  $T$  destinations. This can be mathematically expressed by the logical proposition

$$X(k, loc_{1,j_1}) \cup X(k, loc_{2,j_2}) \cup \dots \cup X(k, loc_{T,j_T})$$

where  $X(k, loc_{i,j_i})$ ,  $1 \leq i \leq T$ , are logical variables that correspond to positive literals. The literal  $X(k, loc_{i,j_i})$  is *true* if  $k$  is assigned bucket  $(loc_{i,j_i})$ , and is *false* otherwise. There are as many such propositions as there are employees. We refer to this set of clauses as the first set.

Another set of clauses arise out of the size restrictions on the  $(loc_{i,j_i})$  buckets. Suppose  $m'$  employees  $k_1, k_2, \dots, k_{m'}$ , have all given bucket  $(loc_{i,j_i})$  as the transfer option. If  $m' > M = \text{vacancy}(loc_{i,j_i})$ , bucket  $(loc_{i,j_i})$  could become overfull. To prevent the bucket from becoming overfull, for *every* subset  $\{k'_1, \dots, k'_M, k'_{M+1}\}$  of size  $M+1$  of the set  $\{k_1, k_2, \dots, k_{m'}\}$ , we generate a clause of the form

$$\sim X(k'_1, loc_{i,j_i}) \cup \sim X(k'_2, loc_{i,j_i}) \cup \dots \cup \sim X(k'_{M+1}, loc_{i,j_i})$$

We refer to this set of clauses as the second set. The number of such clauses for this particular bucket is  $C(m', M+1)$ , the number of combinations of  $m'$  objects taken  $(M+1)$  at a time.

Seniority violations can be incorporated in our scheme as follows. Suppose a seniority violation has occurred between employees  $k_1$  and  $k_2$ , where  $k_1 < k_2$ . Then, as stated before, there exist integers  $r, s$  and  $t$ ,  $1 \leq s, r < t \leq T$ , such that: i) the junior employee  $k_2$  is assigned a transfer option  $(loc_{i,j_i})$  which has preference  $r$  for  $k_2$ ; ii) the senior employee  $k_1$  has specified the same  $(loc_{i,j_i})$  pair as an option with preference  $s$ ; iii)  $k_1$  is assigned an option of preference  $t > r$ . We can express this constraint as a clause

$$\sim X(k_1, loc_{i,j_i}) \cup \sim X(k_2, loc_{2,j_2})$$

where option  $t$  corresponds to  $(loc_{i,j_i})$  and option  $r$  corresponds to  $(loc_{2,j_2})$ . To generate all such clause, the transfer options of all the  $E$  employees must be examined and potential seniority violations identified. We refer to this set of clauses as the third set. Many such clauses would be generated in a typical problem instance.

The satisfaction of the first set of clauses ensures that each employee is assigned a new posting. This means that strict constraints SC1 and SC2 are satisfied. The satisfaction of the second set of clauses ensures that there is no overfull bucket, so the strict constraint SC3 is satisfied. The satisfaction of the third set of clauses

ensures that there are no seniority violations, so desirable constraint DC2 is satisfied. No effort was made to satisfy desirable constraint DC1, because this constraint is difficult to state in terms of clauses.

#### A. GSAT(L)

The greedy local search procedure GSAT assigns truth values to variables in an effort to satisfy all the clauses in a given set [11,12]. GSAT looks for the variable with the property that its truth-value when flipped causes the *largest net decrease* in the number of unsatisfied clauses. It flips the truth-value of this variable, and again looks for such a variable. Ties are resolved arbitrarily. This is repeated until a satisfying assignment is found. If no satisfying assignment is found within a specified number of flips (*maxflips*), the procedure is restarted with a new initial truth assignment. This cycle is repeated a specified number of times (*maxtries*).

The performance of GSAT can be significantly improved in another way, namely by incorporating a *tabu search* strategy to ensure that the same variable is not flipped again and again [10]. The tabu list is initially empty and is implemented as a FIFO queue. A variable that has just been flipped is inserted into the list. The variable to be flipped next is selected randomly [6] from among those variables *not* in the tabu list that cause the largest decrease in the number of unsatisfied clauses. As new variables get flipped and enter the tabu list, older entries fall out of the list at the other end. Thus some variables are prevented from being flipped for a limited period of time, determined by the length of the tabu list. In some applications this length plays a critical role in the performance of GSAT. We represent GSAT with a tabu list of length L as GSAT(L). In Procedure GSAT(L), the values of *maxflips* and *maxtries* are selected by trial and error so that good solutions are obtained in reasonable time. GSAT outputs feasible solutions that are *completely free* of seniority violations. Thus the solutions obtained by GSAT(L) are superior to those obtained by SA.

#### B. WalkSAT(L,p)

The algorithm with a tabu list of length L and random walk probability p is denoted by WalkSAT(L,p). The WalkSAT algorithm [11] also starts from a randomly chosen variable assignment but the variable selection method differs from the ones used in GSAT. Here the variable is always selected from a randomly chosen unsatisfied clause. If in the chosen clause, variables can be flipped without unsatisfying other clauses, one of these is randomly chosen. Otherwise, with a given probability p a variable is randomly chosen from the clause, and with probability 1-p a variable is picked that minimizes the number of clauses that are currently satisfied but would

become unsatisfied when the variable is flipped. A tabu list can also be used with WalkSAT

```
Procedure WalkSAT(L,p){
 for (try = 1; try ≤ maxtries; try++) {
 X = TA; /* TA is random truth assignment */
 for (flip = 1; flip ≤ maxflips; flip++) {
 if (X satisfies all clauses) return X;
 }
 else {
 randomly select an unsatisfied clause; determine
 the set of variables in the selected clause, not
 present in the tabu list, flipping any of which
 does not unsatisfy a satisfied clause;
 if (the set is non-empty)
 arbitrarily select a variable from this set;
 else {
 with probability p, pick a variable randomly
 from the selected clause; with probability 1-p,
 pick a variable from the selected clause, not in
 the tabu list, flipping which unsatisfies the
 minimum number of satisfied clauses;
 }
 }
 flip the selected variable and insert into the list;
 }
 announce failure;
}
```

## IV. EXPERIMENTAL OBSERVATIONS

We now summarize our experimental observations on the Staff Transfer Problem. The methods were programmed in C in Linux Environment, and run on Pentium-IV, 1.8 GHz, 1024MB RAM Machine. Identical problem instances were run for the two methods. We have not run other methods because they have been proved to be inferior as compared to the Simulated Annealing [3]. We wanted to create random instances of the STP that were realistic and indicative of real life situations. So we kept the number E of employees to be transferred between 500 and 2000. Specialists in Human Resource Management informed us that more than 2000 employees are rarely transferred by any organization in one lot. For all runs we took T = 3. Initially, the E employees to be transferred were randomly assigned to buckets. This information was used for computing chain vacancies. The value of parameter *extra* was chosen to lie between 0% and 40% of E; it was felt that a higher vacancy rate would be unrealistic. The parameter *extra* is calculated as  $extra = MPOST * loc * j * 0.5 * 100 / E$ , where MPOST is an integer for generating extra vacancies randomly. Additional vacant positions were created for each value of *extra* and randomly assigned to buckets. For each employee, T

transfer options were also randomly created. Transfer options to buckets having no vacancies were not permitted. No restrictions were imposed on which jobs an employee could perform, it being felt that such restrictions were unlikely to affect the runtime. 100 problems were generated for each set. We determined the number of problems solved in a set and the average runtime in seconds. We also computed, per problem instance, the average numbers of employees who were assigned their first, second and third transfer options. The averages were taken over solved instances. The methods were compared on the basis of three criteria: i) the number of problems solved in each set of 100; ii) the runtime averaged over solved problems, iii) the quality of the solution obtained, quality being determined by the extent to which desirable constraints were satisfied.

Our observations on the experiments are as follows:

The Staff Transfer Problem is a difficult problem. The run times are high when E is large. In the earlier implementations [2,3,13], the GSAT(L) was the best method. But, in this paper, we have shown that WalkSAT(L,p) has outperformed the GSAT (L) significantly. In Table 1, the comparative performance of WalkSAT(L,p) and GSAT(L) is shown. We see that in most of the cases WalkSAT(L,p) performs better in solving the more number of instances as well as in runtime. Of course, not every randomly generated problem instance has a feasible solution. When *extra* = 0, it is quite possible that the problems may not have feasible solutions. From our experimental results it appears that this is very likely the case. The problem instances were all generated randomly. If the transfer scheme described in this paper is used in real life, the transfer options submitted by employees could exhibit bias in favor of certain postings and against some other postings. This

TABLE I  
COMPARISON OF THE PERFORMANCE BETWEEN GSAT AND WALKSAT

| E    | loc,j | T | Extra (%) | Method  | Prob | Solved | 1 <sup>st</sup> opt | 2 <sup>nd</sup> opt | 3 <sup>rd</sup> opt | Time (s) |

|      |       |   |           | WalkSAT |      | 49     | 469                 | 418                 | 313                 | 50.25    |
| 1250 | 40,10 | 3 | 16        | GSAT    | 100  | 23     | 520                 | 427                 | 303                 | 112.97   |
|      |       |   |           | WalkSAT |      | 47     | 487                 | 434                 | 329                 | 133.28   |
| 1500 | 40,10 | 3 | 13.3      | GSAT    | 100  | 19     | 624                 | 507                 | 369                 | 298      |
|      |       |   |           | WalkSAT |      | 32     | 590                 | 517                 | 393                 | 123.11   |

would make the data less random, and the problems could become harder to solve using randomized CSP techniques. One way to resolve this difficulty might be the following. The organization could generate an extra transfer option for each employee, and this could be the option of least preference. If this last option is allocated properly among employees, an acceptable solution would always be found.

## V. CONCLUSION

In this paper, the Staff Transfer Problem is viewed as a CSP. It is converted to a SAT and the experiments indicate that WalkSAT(L,p) has solved this problem very efficiently. In most of the instances it has easily outperformed GSAT(L) which was the best among earlier implementations. But SAT techniques have a limitation with the size of the problem. The number of clauses increases with the increase in size of the problem. In the present machine with 1 GB RAM we could not run instances having more than 1500 employees.

Some interesting issues remain open. The first concerns the formulation of an analytic solution procedure for the STP. If the problem can be suitably expressed in the language of Mathematical Programming, we can compare the runtime and the quality of solution obtained by an analytical procedure with that obtained by WalkSAT(L,p). The second relates to the NP-completeness of the Staff Transfer Problem when seniority violations are taken into account. The difficulty level of the problem suggests that it is NP-complete, but this has not yet been proved formally.

# Simulation and Bit Error Rate Performance Analysis of 4G OFDM Systems

Md. Sadek Ali, Md. Mahbubur Rahman, Md. Delowar Hossain, Md. Shariful Islam, Md. Moinul Islam

Communication Research Laboratory, Dept. of Information & Communication Engineering, Islamic University, Kushtia-7003, Bangladesh. E-mail: (sadek\_ice, drmahbub\_07, shohelictiu2005, s\_ice\_iu, mmislam\_ice@yahoo.com)

**Abstract** — In this paper a simulation based system developed for analysis and Bit Error Rate (BER) performance measurement of Orthogonal Frequency Division Multiplexing (OFDM) systems. This paper involves the basics of OFDM system. In this paper bit error rate is calculated and measured with respect to Signal to Noise Ratio (SNR), Doppler Effect, and guard interval. BPSK, QPSK and 16PSK are used as modulation techniques. Additive White Gaussian Noise (AWGN) is used as a communication channel. The effect of SNR, Doppler Effect, and guard intervals on OFDM signals improves the system performance.

**Index Terms** — AWGN, Bit Error Rate (BER), Doppler Effect, Guard interval, OFDM, Signal-to-Noise Ratio (SNR).

## I. INTRODUCTION

The goal for the next generation of mobile communications system is to seamlessly integrate a wide variety of communication services such as high speed data, video and multimedia traffic as well as voice signals. The technology needed to tackle the challenges to make these services available is popularly known as the Fourth Generation (4G) OFDM System. Although the principles of Orthogonal Frequency Division Multiplexing (OFDM) modulation [1] [2] have been in existence since 1960, in the last few years OFDM modulation is emerged as a key modulation technique of commercial high speed communication systems. The principal reason of this increasing interest is due to its capability to provide high-speed data rate transmissions with low complexity and to counteract the intersymbol interference (ISI) introduced by dispersive channels. For this reason OFDM modulation has been adopted by several digital wireline and wireless communication standards, such as the European digital audio and video broadcasting standards, as well as local area networks.

The rest of the paper is organized as follows. In section II shows the literature review. Section III describes the mathematical tools and techniques for OFDM systems. Section IV describes OFDM system design. Simulation results are described in section V. Finally, section VI concludes the paper.

The main idea behind OFDM is the so-called Multi-Carrier Modulation (MCM) transmission technique. MCM is the principle of transmitting data by dividing the input bit stream into several parallel bit streams, each of them having a much lower bit rate, and by using these sub-streams to modulate several carriers. The first systems using MCM were military high frequency radio links in the late 1950s and early 1960s, like Kineplex, Andeft and Kathryn. OFDM is a special form of MCM with densely spaced sub-carriers and overlapping spectra, whose main idea was patented by Chang, from the Bell Labs, in 1966. OFDM abandoned the use of steep bandpass filters that completely separated the spectrum of individual sub-carriers, as it was common practice in older analogue FDMA systems. Instead, OFDM time domain waveforms are chosen such that mutual orthogonality is ensured even though carrier spectra may overlap. Orthogonality is achieved by performing a Fourier Transform (or equivalently a Fast Fourier Transform) on the input stream.

Implementation aspects have delayed the introduction of OFDM into real systems. For instance, the complexity of a real-time FFT requires powerful digital signal processors, which were not available at the time when OFDM was invented. Furthermore, in order to keep the orthogonality between the different subcarriers, highly stable oscillators are required in the transmitter and receiver, as well as linear power amplifiers. Now a days many of the implementation problems appear solvable and OFDM has gained a big interest since the beginning of the 1990s [3]. This interest is mainly motivated by the advantages OFDM offers when transmitting through a fading channel.

## II. MATHEMATICAL TOOLS AND TECHNIQUES FOR OFDM SYSTEMS

OFDM is a special case of multicarrier transmission, where a single data stream is transmitted over a number of lower rate subcarriers. OFDM is a combination of modulation and multiplexing. Multiplexing generally refers to independent signals, those produced by different sources. In OFDM, multiplexing is applied to independent signals but these independent signals are a sub-set of the one main signal. The signal itself is first split into independent

channels, modulated by data and then re-multiplexed to create the OFDM carrier.

In a 1971 paper [4], Weinstein and Ebert suggested that the multicarrier modulated signal is effectively the Fourier transform of the serial data stream and the bank of coherent demodulators the inverse Fourier transform. In this paper the following is the mathematical derivation used to show the validity of the argument:

Consider a data sequence  $(d_0, d_1, \dots, d_{N-1})$ , where each  $d_n$  is a complex number  $d_n = a_n + jb_n$ . The result of a DFT operation on the vector  $\{2d_n\}_{n=0}^{N-1}$  is then the vector  $S = (S_0, S_1, \dots, S_{N-1})$  of  $N$  complex numbers, with

$$S_m = \sum_{n=0}^{N-1} 2d_n e^{-j(2\pi mn/N)} = 2 \sum_{n=0}^{N-1} d_n e^{-j2\pi f_n t_m}, m = 0, 1, \dots, N-1 \quad (1)$$

Where

$$f_n \triangleq \frac{n}{N\Delta t} \quad (2)$$

$$t_m \triangleq m\Delta t \quad (3)$$

and  $\Delta t$  is an arbitrarily chosen interval. The real part of  $S$  has components:

$$Y_m = 2 \sum_{n=0}^{N-1} (a_n \cos 2\pi f_n t_m + b_n \sin 2\pi f_n t_m), m = 0, 1, \dots, N-1 \quad (4)$$

If these components are applied to a low pass filter at time intervals  $\Delta t$ , a signal is obtained that closely approximates the frequency division multiplexed signal as

$$y(t) = 2 \sum_{n=0}^{N-1} (a_n \cos 2\pi f_n t + b_n \sin 2\pi f_n t), 0 \leq t \leq N\Delta t \quad (5)$$

In order to recover the modulated data, a DFT with twice the sampling rate is employed. This is necessary since only the real part of the modulated signal is transmitted. Therefore, the DFT operates on the  $2N$  samples

$$Y_k = y\left(k \frac{\Delta t}{2}\right) = 2 \sum_{n=0}^{N-1} \left( a_n \cos \frac{2\pi nk}{2N} + b_n \sin \frac{2\pi nk}{2N} \right), k = 0, 1, \dots, 2N-1 \quad (6)$$

The result of the DFT operation is then

$$z_l = \frac{1}{2N} \sum_{k=0}^{2N-1} Y_k e^{-j(2\pi lk/2N)} = \begin{cases} 2a_0, & l=0 \\ a_l - jb_l, & l=1, 2, \dots, N-1 \\ \text{irrelevant}, & l > N-1 \end{cases} \quad (7)$$

The original data  $a_l$  and  $b_l$  can then be extracted as the real and imaginary parts of  $z_l$  (except at  $l=0$ ) [5]. Since the sinusoidal components of the parallel input are time limited,

they have a  $\left[\frac{\sin f}{f}\right]^2$  - shaped power spectrum. This special shape ensures that as long as the components are samples at the right instance, the neighboring components have zero contribution. This orthogonal nature of the OFDM symbols helps prevent ICI.

In this paper, we also proposed some simple equalization schemes and studied the effect of linear channel distortions.

### III. OFDM SYSTEM DESIGN

For performing the simulations, the chain shown in Figure 1 was developed under MATLAB environment. This paper is mainly dependent on this system model. This model has implemented the basic characteristics of OFDM systems. MATLAB environment has assisted to implement that purposes.

Fig. 1. Block diagram of the system implemented.

#### A. Algorithm

The following is a general overview on the operation of the system.

1. Generate a binary message with a length divisible by the number of subcarriers
2. Modulate the signal using BPSK. This is done quite easily by the following operation  $\text{out} = \text{msg} \cdot 2 - 1$
3. Perform Serial-to-Parallel (S/P) conversion using the MATLAB function `reshapes`
4. Perform the Inverse FFT

5. Add a cyclic extension to each symbol. The length of the extension to add in us is defined by the input parameter guard length
6. Perform Parallel-to-Serial (P/S) conversion to make the signal ready for transmission
7. Pass it through the Rayleigh fading multipath channel with Additive White Gaussian Noise. An estimate of the channel at a rate defined by estRate is also performed simultaneously
8. Perform S/P conversion
9. Remove the guard cyclic prefix
10. Using the channel estimate obtained, perform equalization of the received signal
11. Perform the FFT to recover the signal
12. Perform P/S conversion
13. Demodulate the BPSK symbols using a decision boundary of 0: demod = double (real (RXmsg) >= 0)
14. Calculate the bit error rate of the system

#### IV. SIMULATION RESULTS

The effect of SNR, Doppler Effect, and guard intervals on OFDM signals are simulated in this paper. The simulation results are given below:

##### A. Simulation Results of BER Performance vs. SNR

At first we generate a random signal using a random bit generator. The signal is modulated using different modulation techniques such as BPSK, QPSK and 16PSK. Then the signal is passed away through AWGN channel. The signal is demodulated and checked the errors. The simulation is dependent on signal to noise ratio (SNR). Here SNR used as average symbol-energy-to-noise ratio. Different values of BER are obtained from the simulation graph with respect to different values of SNR. The simulations are performed using sub carriers 100 and bit rate 100bps.

Fig. 2. BER vs. Channel SNR for BPSK.

Fig. 3. BER vs. Channel SNR for QPSK.

Fig. 4. BER vs. Channel SNR for 16PSK.

Fig. 5. BER vs. Channel SNR for 16PSK, QPSK and BPSK.

From the simulation results we can show that the transmission can tolerate a SNR > 28 dB using 16PSK. QPSK transmission can tolerate a SNR of > 15-17 dB. BPSK transmission can tolerate a SNR of > 7-10 dB. Among these modulation techniques 16 PSK can tolerate highly than BPSK and QPSK. Bit error performance can be calculated and measured approximately using 16PSK modulation techniques.

##### B. Simulation Results of Guard Length on the BER Performance

In order to analysis the effect of a cyclic prefix, the maximum expected channel delay spread was fixed at 5μs and the length of the guard prefix was varied as 1μs, 4μs, and 20μs. The multipath simulation was carried out with 2

different paths and the maximum Doppler spread used was fixed at 1 kHz. A plot of the relative performance of the different lengths is shown in following figures.

Fig. 6. Effect of guard length on the BER performance for 1 micro seconds for BPSK.

Fig. 7. Effect of guard length on the BER performance for 4 micro seconds for BPSK.

Fig. 8. Effect of guard length on the BER performance for 20 micro seconds for BPSK.

Fig. 9. Effect of guard length on the BER performance for 1, 4 and 20 micro seconds for BPSK.

Fig. 10. Effect of guard length on the BER performance for 1 micro seconds for QPSK.

Fig. 11. Effect of guard length on the BER performance for 4 micro seconds for QPSK.

Fig. 12. Effect of guard length on the BER performance for 20 micro seconds for QPSK.

Fig. 13. Effect of guard length on the BER performance for 1, 4 and 20 micro seconds for QPSK.

As expected when the length of the cyclic guard prefix is less than the expected  $5\mu\text{s}$  of the channel, the OFDM symbols undergo ISI and the bit error rate of the system goes up. The trend in the plot is also clear; as long as the guard length is greater than or equal to  $5\mu\text{s}$ , the bit error rate is low. When the guard is made a little shorter than needed, i.e.  $4\mu\text{s}$ , the bit error rate increases. When it is further reduced to just  $1\mu\text{s}$ , there is severe ISI and hence the bit error rate is much higher.

Finally, it can be seen that for both BPSK and QPSK modulation techniques, if guard length is reducing the bit error rate is gradually increasing and vice-versa.

### C. Simulation Results of Maximum Doppler Effect on the BER Performance

In this case of simulation we consider various channel estimation rates such as  $3^{\text{rd}}$ ,  $5^{\text{th}}$  and  $10^{\text{th}}$ . Here 2 kHz is the maximum Doppler spread. Once again the channel is simulated considering only two different paths to the receiver. A cyclic prefix of  $5\mu\text{s}$  is used to keep ISI from affecting the results. The plots obtained are shown in the following figures.

Fig. 14. Effect of estimation rates on the BER performance for 3 symbols.

Fig. 15. Effect of estimation rates on the BER performance for 5 symbols Using BPSK

Fig. 16. Effect of estimation rates on the BER performance for 10 symbols Using BPSK.

Fig. 17. Effect of estimation rates on the BER performance for 3, 5, and 10 symbols Using BPSK.

Fig. 18. Effect of estimation rates on the BER performance for 3 symbols using QPSK.

Fig. 19. Effect of estimation rates on the BER performance for 5 symbols using QPSK.

Fig. 20. Effect of estimation rates on the BER performance for 10 symbols using QPSK.

Fig. 21. Effect of estimation rates on the BER performance for 3,5,10 symbols using QPSK.

Here we have used two modulation techniques such as BPSK and QPSK. From this particular simulation, it is possible to determine a requirement on the minimum estimation rate for a given maximum Doppler spread. Comparing the three symbol plots, it can be seen that if symbols are increasing, bit error rate is gradually increasing and vice-versa. It is clear for both modulation techniques.

## V. CONCLUSION

Inter Symbol Interference (ISI) and Inter Carrier Interference (ICI) are dominant problems in OFDM systems. These problems are solved with the help of guard period/cyclic prefix. In the case of BER vs. SNR when we are increasing signal to noise ratio (SNR), bit error rate (BER) is decreasing in the same way. At that time bit error rate is zero. We use three modulation techniques such as BPSK, QPSK and 16PSK. BER depends on sub-carriers and symbol time. The minimum signal to noise ratio (SNR) required for BPSK is 7dB, 12dB for QPSK and 26dB for 16PSK. In case of Guard length on the BER performance when we are increasing guard length, bit error rate is reducing in the same way. At that time bit error rate is zero. In case of Doppler Effect on the BER performance when we are increasing number of symbols, bit error rate is increasing in the same way.

Finally, from the analysis of the system simulations, it is concluded that a cyclic prefix at least as long as the maximum multipath delay spread is required for complete protection against ISI effects. Also during low velocity and hence Doppler spread conditions it is possible to have lower channel estimation rate for improved data throughput efficiency.

## ACKNOWLEDGEMENT

I am most grateful to my all assistant. Special thanks should go to IEEE Bangladesh section and organizing committee of ICCIT-2008 for sending necessary information.

**Abstract** — Stackable ROADMs (S-ROADMs) have been proposed for use in regional IP-over-CWDM networks. The S-ROADM can be constructed by connecting modules with different wavelengths required in the node. The experimental results clarified that the S-ROADM could mux and demux the wavelengths successfully, and gave no limit to the passing-through wavelengths, making the network be wavelength transparent. Contrary to the S-ROADM, the existing fixed ROADMs were not wavelength transparent. The bidirectional S-ROADMs have also been proposed, and lightpaths could be reconfigured successfully in an IP-over-CWDM network with the bidirectional S-ROADMs.

**Index Terms** – CWDM, Stackable ROADM, Wavelength Transparency, Lightpath Reconfiguration

## I. INTRODUCTION

Optical networks have been introduced commonly to satisfy the rapid increase of traffic demands. Optical networks are also expected to provide effective broadband communication in optical LAN (Local Area Network) for business use, campus networks, and factory networks to meet different application requirements. The CWDM (Coarse Wavelength-Division Multiplexing) technologies are effective for such applications, because no wavelength control is necessary and the devices are low cost. Such networks have to be operated and maintained by the network administrators. One of the important tasks by the administrators is lightpath reconfigurations [1,2] to avoid traffic congestion, depending on the demand changes.

For the reconfiguration purpose, reconfigurable optical add/drop Multiplexers (ROADMs) were proposed [1] and investigated. Lightpaths are reconfigured by ROADMs consisting of WDM devices and wavelength-tunable transceivers (SWs) [1]. The ROADMs with SWs are simple and made of low-cost devices, leading to a promising candidate for such applications as optical LAN and campus networks. We investigated the ROADMs with SWs, and it was clarified that the ROADMs could reconfigure lightpaths successfully in IP (Internet Protocol) networks. However, the ROADMs have some problems: i.e. the ROADMs are not wavelength transparent, restricting network scalability and flexibility. We propose stackable ROADMs to solve the problems, which are described in this paper together with the performance evaluated by experiments.

## II. PROPOSAL OF STACKABLE ROADM

Figure 1 shows a basic structure of the ROADM developed to reconfigure 4 wavelengths  $\lambda_1 - \lambda_4$  in our experiment. The ROADM could reconfigure lightpaths successfully in CWDM networks [4]. The ROADMs were controlled by receiving control packets via the network interface. However, the ROADM had some problems. One of the problems is that the coupler/splitter should mux/demux more wavelengths than the 4 wavelengths  $\lambda_1 - \lambda_4$  of the ROADM, if other wavelengths are used in the network: e.g. the coupler/splitter should mux/demux 8 wavelengths, if wavelengths  $\lambda_5 - \lambda_8$  are used in other ROADMs. The 4 wavelengths  $\lambda_1 - \lambda_4$  can be reconfigured in this ROADM, and wavelengths  $\lambda_5 - \lambda_8$  pass through this ROADM. The second problem is the limited wavelengths in the network: i.e. the 4 wavelengths  $\lambda_1 - \lambda_4$  can be reconfigured by the ROADM, and other 4 wavelengths can be used in other ROADMs. But no other wavelengths can be used, if one more wavelength, e.g.  $\lambda_9$  is required in the network. The coupler/splitter must be replaced. Therefore, we call this type of ROADM fixed ROADM (F-ROADM). To distinguish the type of the wavelengths, we call the 8 wavelengths  $\lambda_1 - \lambda_8$  working wavelengths (W- $\lambda$ s) in the network, and call such 4 wavelengths as  $\lambda_1 - \lambda_4$  reconfigurable wavelengths (R- $\lambda$ s) of the ROADM in Fig.1. And we call such 4 wavelengths as  $\lambda_5 - \lambda_8$  passing-through wavelengths (PT- $\lambda$ s) of the ROADM. It is possible to have some wavelengths of the PT- $\lambda$ s to be R- $\lambda$ s in the ROADM, if the ROADM has reserve SWs, and

Fig.1 Structure of F-ROADM

the fibers connecting the coupler and splitter are re-connected so as to connect the coupler or splitter and the SWs. Two SWs are reserved in Fig.1, and therefore, 2 of the PT- $\lambda$ s, e.g.  $\lambda_5$  and  $\lambda_6$  can be used as R- $\lambda$ s in this F-ROADM. We call such wavelengths as  $\lambda_5$  and  $\lambda_6$  reserve wavelengths (RV- $\lambda$ s). As a result, the W- $\lambda$ s are  $\lambda_1 - \lambda_8$  in the network, where the F-ROADM shown in Fig.1 is used, but no other wavelength, e.g.  $\lambda_9$  can be used in the network. Thus, the F-ROADMs restrict the wavelength transparency of the network, giving the limitation to the network scalability. The R- $\lambda$ s of the F-ROADM are  $\lambda_1 - \lambda_6$ , including 2 RV- $\lambda$ s, but no other wavelengths can be reconfigured by this F-ROADM. Thus, the F-ROADMs restrict the lightpath reconfigurability in the node.

To remove all the problems of the F-ROADMs, we propose a stackable ROADM (S-ROADM), shown in Fig.2. The S-ROADM can be constructed by connecting stackable modules with different wavelengths. The stackable module consists of an OADM connected by a 2x2 optical SW. The SW has 2 states C1 and C0, and works in the same way as in the F-ROADM. When muxed lightwaves are input to a common input (Cin) port of the S-ROADM, only  $\lambda_1$  passes the OADM1 in the first module, and other wavelengths are reflected. When SW1 state is C1, the passed  $\lambda_1$  is dropped, and received by a  $\lambda_1$  optical transceiver ( $\lambda_1$ -OTR). The  $\lambda_1$  lightwave from the  $\lambda_1$ -OTR is added by SW1, muxed by OADM1, sent to the following modules, reflected by the modules, and sent to the network. When SW1 state is C0 in the first module,  $\lambda_1$  is sent back to the network: i.e.  $\lambda_1$  passes through this S-ROADM. Thus, one module has the reconfigurable function for the specified wavelength. The reflected lightwaves other than  $\lambda_1$  at the first module are input to the second module, and  $\lambda_2$  is added/dropped (A/D) or passes through (PT) the module, depending on the state of SW2.

Fig.2 Proposed S-ROADM

Thus, each wavelength can be set to be A/D or PT at the module independently, and gives no influence on the other wavelengths. Therefore, S-ROADM can be constructed in a stackable way by connecting the modules with as many different wavelengths as required.

### III. PERFORMANCE OF STACKABLE ROADM

The loss properties of S-ROADM and F-ROADM were investigated and compared. Firstly, loss estimation equations were derived as follows. Three kinds of loss affect the transmission between nodes: i.e. the add, drop and PT losses denoted by  $L_{ad}$ ,  $L_{dp}$  and  $L_{PT}$ , respectively. The losses depend on the position of the module. When a module is located in the  $n$ -th position from the Cin port in the S-ROADM, as shown in Fig.2, the losses are given by

$$L_{ad}(n) = (N-n)L_r + L_p + L_{SW} \quad (1-1)$$

$$L_{dp}(n) = (n-1)L_r + L_p + L_{SW} \quad (1-2)$$

$$L_{PT}(N) = NL_r, \quad (1-3)$$

where  $L_r$  and  $L_p$  are the reflection and passing losses at/through the OADM, respectively, and  $N$  is the total module number connected in the S-ROADM. The loss of the SW is denoted by  $L_{SW}$ , assuming that the losses are the same value for the C1 and C0 states. In the equations the losses are assumed to be independent of wavelength. The losses of the F-ROADM can be estimated by the similar equations, because the coupler and the splitter have optical bandpass filters which can mux or demux one wavelength at each filter in a similar way as the connected OADM in the S-ROADM. Therefore, the estimation equations for the F-ROADM are given by

$$L_{ad}'(n) = (W-n)L_r' + L_p' + L_{SW} \quad (2-1)$$

$$L_{dp}'(n) = (n-1)L_r' + L_p' + L_{SW} \quad (2-2)$$

$$L_{PT}'(W) = (W-1)L_r' + 2L_p' \quad (2-3)$$

Here,  $W$  denotes the W- $\lambda$  number in the network, and primes denote the values of the coupler/splitter.

The values of  $L_r$  and  $L_p$  were measured for 4 sets of the OADMs used in the S-ROADM, and the values were obtained by averaging the 4 values at each  $\lambda$  of the 8 wavelengths from 1470 nm to 1610 nm. The wavelength dependence of the averaged values is found to be small. Therefore,  $L_r = 0.451\text{dB}$ , and  $L_p = 0.38\text{dB}$  were obtained by averaging all the values. The loss  $L_{SW} = 0.684\text{dB}$  was obtained by averaging measured losses of the SWs. In the same way,  $L_r' = 0.202\text{dB}$ , and  $L_p' = 0.38\text{dB}$  were obtained for the 3 sets of coupler and splitter in the F-ROADM.

Figure 3 shows optical loss properties of the S- and F-ROADMs, when the numbers of R- $\lambda$ s and W- $\lambda$ s are 4 and 8, respectively. The 4 R- $\lambda$ s are the standard values from  $\lambda_1=1470\text{nm}$  to  $\lambda_4=1530\text{nm}$ . The number  $m$  in Fig.3 denotes  $\lambda_m$ . The S-ROADM was constructed by connecting the 4 modules as shown in Fig.2, and the add and drop losses were measured. The results are plotted in

Fig.3. The calculated losses  $L_{ad}(m)$  and  $L_{dp}(m)$  by Eqs.(1-1) and (1-2) are also shown in Fig.3. In the same way, the F-ROADM was constructed as shown in Fig.1, and the add and drop losses were measured. The measured values are plotted in Fig.3, together with the calculated lines by Eqs.(2-1) and (2-2). It is found that the measured and calculated values are consistent with each other for S- and F-ROADMs, respectively, and the maximum losses are comparable between S- and F-ROADMs. The add losses of F-ROADM are higher than those of S-ROADM, whereas the drop losses of F-ROADM are lower than those of S-ROADM. The coupler/splitter of the F-ROADM must mux/demux 8 wavelengths, because the number of  $W\text{-}\lambda$ s is required to be 8. Therefore,  $W=8$  in Eq.(2-1) gives higher add loss. On the other hand, the angle of inclination for S-ROADM loss lines is steeper than that of F-ROADM loss lines, due to the large reflection loss  $L_r$  of OADM in S-ROADM. This is because the reflection loss  $L_r$  of S-ROADM contains the reflection loss at the OADM and the connection loss between modules. The connection loss by connectors in the S-ROADM is higher than the loss connecting adjacent bandpass filters in the waveguide structure of the coupler/splitter for the F-ROADM. As a result, the maximum losses are comparable between S- and F-ROADMs in the present case, but the maximum loss of S-ROADM shall be higher than that of F-ROADM, if numbers of  $R\text{-}\lambda$ s and  $W\text{-}\lambda$ s are 8.

As the next experiment, 2 sets of the S-ROADM were constructed by connecting 4 modules with wavelengths from  $\lambda_2=1490$  to  $\lambda_5=1550$ nm, respectively. The states of the 4 SWs were set to be C1, and the optical mux properties were evaluated. Four OTRs with wavelengths  $\lambda_2 - \lambda_5$  were connected to the add ports, respectively, and the wavelength dependence of the output optical power was measured. The result is shown in Fig.4. It is seen clearly that the 4 wavelengths could be multiplexed by the S-ROADM. The optical powers increase with increasing the wavelength number, consistent with the loss decreasing property of the S-ROADM, as expected by Eq.(1-1).

The passing-through (PT) properties of the S-ROADM were evaluated. Figure 5 (a) shows the measured loss between Cin and Cout ports of the first S-ROADM, when all the SW states were set to be C1. It is found that the losses at the 4  $R\text{-}\lambda$ s were around 22 dB, showing that the 4 wavelengths were dropped. It is also found that smaller PT loss ranges were obtained at wavelengths below  $\lambda_1=1470$ nm, and over  $\lambda_6=1570$ nm. The PT losses were almost constant, being about 1.9 – 2.3 dB. The values agree with the estimated value  $L_{PT}(4) = 4L_r = 1.8\text{dB}$ , given by Eq.(1-3). Thus, the S-ROADM gives no restrictions to the transmissions of the lightwaves with other wavelengths

Fig.3 Optical loss of S-ROADM and F-ROADM

Fig.4 Measured multiplexing properties of S-ROADM

(a) S-ROADM

(b) F-ROADM

Fig.5 Measured passing-through losses

than the 4 R- $\lambda$ s of the S-ROADM, showing that PT transmissions are  $\lambda$  transparent.

The same PT properties were measured for the F-ROADM with 8 W- $\lambda$ s from  $\lambda_1$  to  $\lambda_8$ . The 4 SWs and the coupler/splitter were connected such that 4 wavelengths from  $\lambda_2=1490$  to  $\lambda_5=1550\text{nm}$  were R- $\lambda$ s, and other 4 wavelengths were PT- $\lambda$ s. The PT losses were measured for the F-ROADM with the 4 SWs set to be C1 state. The measured losses are shown in Fig.5 (b). It is found that the losses at wavelengths from  $\lambda_2$  to  $\lambda_5$  were around 22 dB, showing that the 4 wavelengths were dropped. And the PT losses at the 4 PT- $\lambda$ s were as small as about 2.3dB, which agrees with a value of  $L_{PT}(8)=2.17\text{dB}$  calculated by Eq.(2-3). Fig.5 (b) also shows that the PT losses are higher than 20dB at smaller wavelengths than  $\lambda_1$ . This property of the F-ROADM restricts the transmissions of other wavelengths than the W- $\lambda$ s: i.e. the F-ROADM is not  $\lambda$  transparent at other wavelengths than W- $\lambda$ s.

#### IV. PROPOSAL OF BIDIRECTIONAL S-ROADM

The packet transmissions may be uni- or bi-directional in the network with the S-ROADMs. We propose bidirectional S-ROADM (BS-ROADM) structure shown in Fig.6 so as to cover possible lightpath reconfigurations in more general way. The BS-ROADM has 2 sets of input and output ports, and the sets are used for clockwise (CW) and counter clockwise (CCW) transmissions, respectively. Two OTRs per one wavelength can be connected to the BS-ROADM, and are used for CW and CCW transmissions, respectively. In the BS-ROADM, 3 types of configuration are proposed, depending on the SW number and the fiber connections. Each wavelength can be given one of the types independently in the BS-ROADM.

Three SWs are used in Type-1 configuration: the connections for  $\lambda_1$  are the example for Type 1 shown in Fig.6. The CW  $\lambda_1$  lightwave from the left node is demuxed by OADM11 and the direction is determined by C1 or C0 state of SW11. When SW11 state is C1, the demuxed lightwave is dropped and received by a  $\lambda_1$ -OTR1. The lightwave from the  $\lambda_1$ -OTR1 is added, and is sent to the CCW or CW direction, according to C1 or C0 state of SW13, respectively. On the other hand, the lightwave demuxed by OADM11 passes through SW11, when SW11 state is C0, and is sent to the CCW or CW direction, according to SW13 state. The CCW  $\lambda_1$  lightwave from the right node is demuxed by OADM12 and specified to be dropped or PT by SW12. When the lightwave passes through the module, it is sent to the CCW or CW direction by SW13 in the same way as for the CW  $\lambda_1$  lightwave.

Table 1 summarizes possible transmissions by Type-1 configuration for one wavelength, showing the lightpath connections among OTRs installed in the left and right

nodes and the 2 OTRs in this node where the BS-ROADM is working. Since there are 3 SWs in Type-1, 8 states are possible. When #1 state, i.e. the states of all the 3 SWs are C1, CW lightwave from the left node is received by OTR 1 in this node, and the lightwave from OTR1 is sent back to the left node. This is the point-to-point (P2P) transmission, connecting this and the left nodes. The CCW lightwave gives also P2P transmission, connecting this and the right nodes. When #2 state (SW1 and SW2  $\rightarrow$  C1, and SW3  $\rightarrow$  C0), CW lightwave is received in this node, and the lightwave from this node is sent to the right node. This is the one-by-one (O-O) transmission [5], connecting nodes one-by-one with one wavelength. The CCW lightwave also gives O-O transmission in the #2 state. When #3 state (SW1 and SW3  $\rightarrow$  C1, and SW2  $\rightarrow$  C0), CW lightwave gives P2P transmission, because the 2 SW states are the same as #1. The CCW lightwave passes through SW1 and is sent back to the right node by SW3. This is a loop back transmission, which cannot be used for signal transmission, but may be used for the hardware test consisting of the loop back route, i.e. fibers and the optical components in the ROADMs. The OTR 2 is waiting for use in the #3 state. When #5 state (SW1 and SW3  $\rightarrow$  C0 and SW2  $\rightarrow$  C1), the CW lightwave passes through the 2 SWs, and is sent to the right node i.e. the lightwave passes through this node.

Fig.6 Bidirectional S-ROADM

Table 1 Possible transmissions by Type-1

| # | SW |    |    | Optical Transceiver |         |         |
|---|----|----|----|---------------------|---------|---------|
|   | 1  | 2  | 3  | Left Node           | OTR 1   | OTR 2   |
| 1 | C1 | C1 | C1 | P2P                 |         | P2P     |
| 2 | C1 | C1 | C0 | O-O/CW              |         | O-O/CCW |
| 3 | C1 | C0 | C1 | P2P                 |         | Waiting |
| 4 | C0 | C1 | C1 | Loop Back           | Waiting | P2P     |
| 5 | C0 | C1 | C0 | PT/CW               | Waiting | O-O/CCW |
| 6 | C1 | C0 | C0 | O-O/CW              |         | Waiting |
| 7 | C0 | C0 | C1 | Loop Back           | Waiting | Waiting |
| 8 | C0 | C0 | C0 | PT/CW               | Waiting | Waiting |

Therefore, OTR 1 in this node is not used, waiting for use. The other states i.e. #4 and #6-8 states have the same combinations of the 3 SWs, and therefore, the lightpath connections can be given by Table 1. It is possible to make such tables for Type-2 and Type-3, respectively.

To examine the lightpath reconfiguration performance, an experimental network was designed so as to connect 5 nodes with bi-directional dual fibers. The network configuration is shown in Fig.7. Three sets of the BS-ROADMs were prepared, and installed in Nodes 1, 2 and 3. The BS-ROADM configurations are shown by symbols schematically in Fig.7: e.g. when  $\lambda_1$  is configured by Type-1, it is denoted as  $\lambda_1/T1$  symbolically, and no precise SW configurations are shown. Each BS-ROADM was designed such that it has three Type-1 configurations. In Nodes 4 and 5, bidirectional fixed ROADMs (BF-ROADM) with 2 sets of coupler and splitter were installed. The SW configurations were adopted Type-1 for different 3 wavelengths. As a result, each node has 3 sets of OTRs with different wavelengths. By this configuration, the 5 nodes with BS-ROADM or BF-ROADM are connected by more lightpaths than the full-mesh connections. The 3 wavelengths  $\lambda_1 - \lambda_4$  of 1530, 1550, 1570 and 1590 nm were adopted, respectively. To control the BS-ROADMs, a control system (CS) was connected to the L3SW in Node 1. A LAN analyzer (LA) was also connected to the L3SW in Node 1 to monitor packets, when lightpaths are reconfigured. A personal computer (PC) is connected in each node as shown in Fig.7 to send and receive packets between nodes.

Firstly, the lightpath reconfiguration performance was examined by adding 6 lightpaths to the star connections shown in Fig.8 (a) to obtain the full-mesh connections shown in Fig.8 (b). While ICMP (Internet Control Message Protocol) echo requests were sent continuously from PC1 to PC2, PC3, PC4 and PC5, the CS sent control signals to the BS-ROADMs and BF-ROADM so as to change the SW states. In the reconfiguration processes, the packets were monitored by the LAN analyzer (LA), and the monitored results are shown in Fig.9. The observed packets were classified, depending on the packet types, and were plotted at the observed time in Fig.9. The echo request and reply packets were observed between Node 1 and other 4 nodes, respectively, via Node 5, before the control signals were observed. It is found that the ICMP echo request and reply packets via Node 5 disappeared in 7.62 s, after the TCP packets for the control were observed. Just after this, it was observed that the echo request and reply packets were sent by the direct lightpaths between Node 1 and other 4 nodes, respectively, as shown in Fig.9. This is because the 6 lightpaths were added by the BS-ROADM and BF-ROADM, OSPF (Open Shortest Path

First) found the new direct connections, and OSPF re-calculate the routing table dynamically. After this, the packets were transmitted by the new direct paths, leading to the observed packet changes. It is understood that it took 7.62 s to reconfigure the lightpaths, including the routing table re-calculation time by OSPF. The hello and dead intervals were 1s and 4s, respectively.

Fig.7 Experimental network configuration

Fig.8 Lightpath connections made by BS-ROADMs in the experimental network

Fig.9 Monitored packets in lightpath reconfiguration from the star to full-mesh connections

As the next experiment, the lightpaths were reconfigured from the full-mesh to a ring connections, as shown in Figs.8 (b) and (c). To evaluate the performance, ICMP echo requests were sent continuously from PC1 to other 4 PCs in the same way as before in the full-mesh network (b), and the packets were monitored. The results are shown in Fig.10. The request and reply packets were observed by the direct paths between Node 1 and other 4 nodes, before the reconfiguration. After control signals were detected, the request and reply packets disappeared between Node 1 and Nodes 3 and 4, respectively, and the packets reappeared in 5.8s between Nodes 1 and 3 via Node 2, and between Nodes 1 and 4 via Node 5. This is because OSPF detected that the 2 direct connections between Node 1 and Nodes 3 and 4 disappeared, tried to find other routing paths, and found the possible route from Nodes 1 to 3 via Node 2, and from Nodes 1 to 4 via Node 5, taking 5.8s to complete the processes on the packet detection base. It is found that no changes were observed for the ICMP packet transmission between Node 1 and Nodes 2 and 5, respectively. This is because no lightpaths were changed between the nodes, proving that the reconfigurations for Node 1 and Nodes 3 and 4 gave no influence on the packet transmissions by other lightpaths.

## V. CONCLUSION

A S-ROADM structure has been proposed for use in campus networks, large-scale LANs and other local networks. The wavelength types were classified as W- $\lambda$ s, R- $\lambda$ s, PT- $\lambda$ s and RV- $\lambda$ s so as to determine what wavelength ranges are  $\lambda$  transparent and what wavelengths can be used for reconfiguration between particular nodes, when applying ROADMs to such networks. The S-ROADMs and F-ROADMs were manufactured for the case that the numbers of W- $\lambda$ s and R- $\lambda$ s are 8 and 4,

respectively, and the performance was evaluated. The equations to estimate the add, drop and PT losses were derived and the 3 types of losses were measured for the S- and F-ROADMs. The measured and calculated results are consistent with each other, showing that the maximum losses were identical for the 2 types of ROADMs. It has been clarified that the S-ROADM could mux the 4 R- $\lambda$ s successfully. It has been shown that the losses at the other wavelengths than the R- $\lambda$ s were as small as 1.9 – 2.3dB for the S-ROADM, clarifying that the S-ROADM provides  $\lambda$  transparent networks. Contrary to the S-ROADM, the losses at other wavelengths than the W- $\lambda$ s were as large as over 20 dB for the F-ROADM, showing that the network by F-ROADMs is not  $\lambda$  transparent. As a result, the S-ROADMs provide more flexible CWDM networks in terms of scalability and reconfigurability.

Three types of SW connection configurations have been proposed for bidirectional S-ROADM structures, enabling us to reconfigure lightpaths such that P2P and O-O links can be made and/or changed between/among nodes. Thus, the BS-ROADMs provide lightpath reconfiguration functions in more general way. To examine the BS-ROADM performance, 3 BS-ROADMs and 2 BF-ROADMs were manufactured, and an experimental network was constructed by connecting the ROADMs. A control system could send control signals to the ROADMs in the network, and it was found that the lightpaths could be reconfigured successfully from star to full-mesh lightpath connections, and full-mesh to ring lightpath connections. The SB-ROADMs together with the reconfiguration functions of the control system provide network administrators with easy management for the network in a skill-less and centralized way.

**Abstract** — Mobility of user devices connecting to the Internet is of major interest in today's research in networking. For users as well as for applications, network mobility should be transparent. Reliable transport protocols like TCP has served well the wired Internet where the packet losses are mainly due to congestion, but is not ready for Mobile IP wired-cum-wireless environments where the significant packet losses are due to bit errors and handoffs. In this paper, we have investigated the performance of TCP among the various TCP variants. We have observed both TCP senders (Newreno & Vegas) and TCP receivers (Base & Delayed-Ack). Using ns-2, we have evaluated the TCP throughput and packet delay over a single TCP connection. The simulation results suggest that a particular combination (one TCP sender with one TCP receiver) of TCP shows the best result in such Mobile IP networks.

**Index Terms** — Wired-cum-Wireless Networks, TCP, Mobility, Mobile IP, Handoff.

## I. INTRODUCTION

TCP was basically developed assuming that it would run on wired networks. Wired networks usually have less bit error rates and hence less packet loss. Also, since mobility was not considered, there are no packet losses and delays caused by mobility. Hence, TCP was designed to assume that any segment loss is caused by the network congestion and on seeing any segment loss; TCP invokes its congestion control measures.

In various circumstances wired and wireless networks are connected together to take the advantages of both. Usually, the wireless links have high bit error rates. Also, temporary disconnections occur because of the factors like channel fading, and handoffs when a mobile node is in motion. The handoff period depends on both the link level handoff protocol being used as well as the IP level handoff protocol being used, if any. The standard TCP implementations assume the cause of any packet loss to be the network congestion. Then, they reduce the congestion size to a minimum. Also, TCP invokes the slow-start mechanism. If the network links are slow, it takes long time to grow the congestion window. Thus, reduction in the size of the congestion window reduces the transmission rate and hence degrades the performance. Also, TCP undergoes a binary exponential backoff, causing long pauses of communication. Because of this, some time may be unused even after the mobile node recovers from the temporary disconnection. It has been observed that even a single wireless link can reduce the TCP performance considerably. In theory we can use existing transport protocols like TCP on a wireless host to

communicate with a fixed network. Though this keeps the transport layer transparent to mobility, disconnection and other features of wireless and mobile hosts reduce the performance.

Thus TCP proved not so efficient in Mobile IP wired-cum-wireless environments and suffers from performance degradation introduced by the conditions that exist in those environments. Hence, an optimized reliable transport protocol is very important for the development of the wireless Internet.

This paper provides a realistic comparison of the performances of the various TCP variants over Mobile IP wired-cum-wireless network. The TCP variants include both TCP senders (TCP Newreno and TCP Vegas) and TCP receivers (Base TCP Sink and Delayed-Ack TCP Sink).

The reminder of this paper is organized as follows: Section II depicts the related works; mobile IP and TCP variants are described in Section III. We define the simulation model in Section IV and present the results and discussions in Section V. The conclusion and future work follow in Section VI.

## II. RELATED WORKS

TCP/IP is the standard networking protocol stack for Internet. So it is expected to be deployed over wireless networks to allow seamless integration with the Internet. However, earlier research suggested that TCP performs poorly over cellular (single-hop) wireless networks [1]. A good amount of research has been done in the past to improve the performance of TCP in the conditions that prevail in mobile and wireless environments.

Split connection approach is one of them. It separates TCP connection, one for the wireless network and the other for the wired network between a sender and a receiver. The motivation behind the use of separate connections is the fact that the characteristics of a wireless network are different from the characteristics of a wired network, hence a separate connection that is optimized to the kind of network it operates on, can be used. I-TCP [2], ELN [3] can be classified in this group.

Enhanced link layer approach is another solution. Since the basic factor that causes degradation in wireless environments is the nature of the transmission medium, an improvement in the link technology that operates over the physical layer can improve the overall performance. This was the idea behind enhanced link layer solutions.

Mechanisms like ARQ, FEC [4] were suggested to improve the performance at the lower layers which, in turn, can reduce the chances of TCP getting timed out and does not invoke its congestion control measures.

Most of the above-mentioned solutions require special support from the network infrastructure in some form or the other. Some other approaches were suggested that do not require any special support from the intermediate infrastructure and changes are confined to the end nodes. Path Prediction [5] and ACK Regulator [6] come under this category. These solutions are not bound by the problem of encrypted traffic, and they do not assume any special support from the network infrastructure.

As suggested earlier, most related work focuses on to improve the TCP performance in wireless network. Also most of the earlier solutions (except ELN) try to optimize the mobile host acting as a TCP receiver but do not consider the case of a mobile TCP sender, which can also be a common case in the future. Also a few of the earlier work measured TCP performance with combining both the TCP senders and the TCP receivers.

This paper provides a realistic comparison of performance of the various TCP variants over Mobile IP wired-cum-wireless network. The TCP variants include both TCP senders (TCP Newreno and TCP Vegas) and TCP receivers (Base TCP Sink and Delayed-Ack TCP Sink).

### III. MOBILE IP AND TCP VARIANTS

In order to achieve the mobility function, the Internet Protocol (IP) has extended to become the Mobile Internet Protocol (Mobile IP or MIP). Mobile IP provides hosts with the ability to change their point of attachment to the network without compromising their ability to communicate. The mobility support provided by Mobile IP is transparent to the other protocol layers so as not to affect the operation of applications which do not have the mobile capability.

Among various IP mobility proposals, Mobile IPv4 [7, 8] is the oldest and probably the most widely known mobility management proposal with IP. MIPv4 introduces three new entities required to support the protocol: the Home Agent (HA), the Foreign Agent (FA) and the Mobile Host (MH). Home and foreign agents are introduced for mobility management. Each time a mobile host connects to a network at a new location, it will obtain a temporary address, called Care-of Address (COA) from a foreign agent in the local network. Then the mobile host must inform its home agent of the new address by a registration procedure, which begins when the mobile host, possibly with the assistance of the foreign agent, sends a registration request with the COA. When the home agent receives this request, it may typically add the necessary information to its routing table, approve the request, and send a registration reply back to the mobile host.

A basic function of TCP is to provide reliable communication over an unreliable network layer. TCP ensures that the data is delivered from the sending process to the receiving process correctly and in order. TCP controls the traffic flow and network congestion by maintaining window (buffer to store data packets); and various TCP variants are classified according to the mechanism for maintaining this window.

#### A. TCP New-Reno

A modification to Reno TCP called New-Reno TCP [9]. Since most TCP sessions last only for a short period of time, the initial slow start period is significant for the overall performance. A method is proposed to estimate an optimum slow start threshold (ssthresh) value by calculating the byte equivalent of bandwidth delay product of the network when a new connection is made. TCP New-Reno also deals with multiple packet losses from a single window. If two or more segments have been lost from the transmitted data (window), the Fast Retransmission and Fast Recovery algorithms will not be able to recover the losses without waiting for retransmission time out. New-Reno overcomes this problem by introducing the concept of a Fast Retransmission Phase, which starts on detection of a packet loss (receiving 3 duplicate ACKs) and ends when the receiver acknowledges reception of all data transmitted at the start of the Fast Retransmission phase.

The transmitter assumes reception of a partial ACK during the Fast Retransmission phase as an indication that another packet has been lost within the window and retransmits that packet immediately to prevent expiry of the retransmission timer. New Reno sets the congestion window (cwnd) to one segment on reception of 3 duplicate ACKs (i.e. when entering the Fast Retransmission Phase) and unacknowledged data are retransmitted using the Slow Start algorithm. The transmitter is also allowed to transmit a new data packet on receiving 2 duplicate ACKs. While the transmitter is in the Fast Retransmission Phase, it continues to retransmit packets using Slow Start until all packets have been recovered (without starting a new retransmission phase for partial ACKs). Although this modification may cause unnecessary retransmissions, it reduces transmitter timeouts and efficiently recovers multiple packet loss using partial ACKs.

#### B. TCP Vegas

TCP Vegas [10] does not involve any changes to the TCP specification; it is merely an alternative implementation that is able to interoperate with any other valid implementation of TCP. In fact, all the changes are confined to the sending side. There are some techniques that Vegas employs to increase throughput and decrease losses.

It calculates the RTT more accurately. Using an accurate RTT estimate serves two purposes. First, it leads to a more accurate timeout calculation. Second, it is used

in conjunction with the mechanism described next to decide to retransmit a dropped segment in a more timely fashion. It includes the new mechanism for deciding to retransmit Vegas treats the receipt of certain ACKs as a trigger to check if a timeout should happen. Moreover, Vegas only decreases the congestion window if the retransmitted segment was previously sent after the last decrease. Any losses that happened before the last window decrease do not imply that the network is congested for the current congestion window size, and therefore do not imply that it should be decreased again. Another most important feature of TCP Vegas is that the detection of congestion. Vegas calculates the expected throughput by:

$$Expected = WindowSize / BaseRTT$$

where *WindowSize* is the size of the current congestion window and *BaseRTT* is the RTT of a segment when the connection is not congested. It then calculates the current *Actual* throughput of the network. Then, Vegas compares *Actual* to *Expected*, and adjusts the window accordingly.

### C. Base TCP Sink

The base TCP sink object is responsible for returning ACKs to a peer TCP source object. It generates one ACK per packet received. The size of the ACKs may be configured. The creation and configuration of the TCP sink object is generally performed automatically by a library call.

### D. Delayed-Ack TCP Sink

A Delayed-Ack sink object is available for simulating a TCP receiver that ACKs less than once per packet received. This object contains a bound variable, which gives the number of seconds to wait between ACKs. The Delayed-Ack sink implements an aggressive ACK policy whereby only ACKs for in-order packets are delayed. Out-of-order packets cause immediate ACK generation. It is possible to configure the bound variable (interval) of the Delayed-Ack TCP Sink.

## IV. SIMULATION MODEL AND DESIGN

To design the Mobile IP wired-cum-wireless network topology we have considered various simulation parameters, which are supported by the network simulator-2 (NS-2) [11]. We have done simulation for two different topologies and call them topology 'A' and topology 'B' respectively.

There is a roaming mobile node called Mobile Host (MH) that moves between its home agent and foreign agent in a certain velocity. Data will be exchanged between the roaming mobile node (MH) and the wired node W(0) via the two base-station nodes (HA or FA). Base station nodes are like gateways between wireless and wired domains and allow packets to be exchanged between the two different types of nodes. The initial positions, (x,y), of the nodes MH, HA and FA are

(50,100), (200,300) and (500,300) respectively in the 700mX800m topology. In this network, the mobile node MH starts moving from position (50,100) at 10 sec towards destination (650,100) at fixed speeds (0, 5, 10, 15, 20, 25, or 30) m/s. After reaching the destination position (650,100), MH will stay there 1sec (pause time) and then again moves back to its initial starting position (50,100) at the same velocity. In this way, the mobile node MH changes its home agent (HA) and foreign agent (FA) several times depending upon its speed. We have used DSDV ad hoc routing protocol. FTP begins transferring packets of size 1000 bytes after 10 second. Each wireless node has a buffer size of 50 packets. Each simulation ends at 150 seconds.

Fig. 1. Topology 'A' for Mobile IP wired-cum-wireless simulation

There are fewer changes in Topology 'B'. We have used three base-station nodes in topology 'B' and call them Home Agent (HA), Foreign Agent-1 (FA1) and Foreign Agent-2 (FA2) respectively. The initial positions, (x,y), of the nodes MH, HA, FA1 and FA2 are (50,100), (200,300), (500,300) and (800,300) respectively in the 1000mX800m topology. In this case, simulation starts at 10 sec and ends at 190 sec. Here the mobile node MH starts moving from position (50,100) at 10 sec towards destination position (950,100) at a fixed speed of (0, 5, 10, 15, 20, 25, or 30) m/s while nodes HA, FA1 and FA2 serve as base station (gateway) nodes. As before, the pause time is 1 sec, that is, the mobile node MH will stay 1 sec at position (950,100) and then moves back to its initial position (50, 100) at the same velocity. Staying there 1 sec, it moves again towards the destination position.

## V. PERFORMANCE ANALYSIS AND DISCUSSION

This section describes a realistic analysis comparing the performance of the various TCP variants over multi-hop Mobile IP wired-cum-wireless networks. We have

combined the TCP senders (New-Reno & Vegas) with the TCP receivers (Base & Delayed-Ack). We have considered the mobile node as a TCP sender.

#### A. Throughput Analysis

We have evaluated the throughput for topology 'A' obtained with the TCP variants in terms of the total number of packets received at the destination node per unit time over intervals of 7 seconds for mobility 0 meter/sec, 15 meter/sec and 30 meter/sec and the results are plotted in figures.

From figure 2, we observe that after the initial connection establishment, all the variants achieve almost fixed throughput to the whole simulation time. It is common that if the window size increases, the throughput will also increase. Among the four variants, Vegas to Delayed-Ack shows the best throughput.

Fig. 2. Throughput (kbps) versus Simulation Time for topology 'A' for mobility 0 (meter/sec)

From figure 3 (a), it is seen that the throughput of each of the TCP variant decreases drastically. By comparing this figure to figure 2, it is observed that the throughput performance is worse in this case. From the start of the simulation to 35 seconds, throughput is the same (almost 700 kbps) as before (figure 2). But after 35 seconds it shows different result. The mobility of the mobile host is the cause of this degradation. In the case of figure 2, the mobile host remains stationary. But in this case the mobile host changes its base station for a number of times during simulation time. When changing base station a mobile host requires a handoff. The mobile host changes base station three times; so require three handoffs. And at the time of each handoff packets are dropped and throughput decreases.

Figure 3(b) shows the similar type of result except the throughput is reduced more times than that of figure 3(a). Since in this case, the mobility is 30 meter/sec, more handoff is required and at the time of each handoff throughput is reduced.

One interesting feature which is observed from figures 3(a) and 3(b) is that during first handoff throughput performance decreases drastically but during the second,

third and successive handoffs throughput decreases slightly. But in such an environment Vegas to Delayed-Ack performs well among the TCP variants. Its throughput reduces less than that of the others.

Fig. 3(a). Mobility 15 (m/s)

Fig.3(b). Mobility 30 (m/s)

Fig. 3. Throughput (kbps) versus Simulation Time for topology 'A'

Concentrating on the receiver portion in figure 2, 3(a) and 3(b), we see that the performance of the Base TCP receivers is lower than that of the Delayed-Ack TCP receivers; no matter whether the TCP sender is New-Reno or Vegas.

Since all the terminals in Mobile IP network share the same radio channel to send and receive packets, the collision of data packets and acknowledgement (ACK) packets in the radio channel can severely reduce TCP throughput. But Delayed-Ack receiver employs less ACK packets. So, for transferring TCP data packets, TCP sender can utilize the channel more. Hence throughput of any TCP sender synchronized with Delayed-Ack receiver is better than that of TCP sender with Base receiver.

Now with fixed Delayed-Ack receiver, we are going to observe the performance of New-Reno and Vegas sender. By evaluating the throughput from three different mobility scenarios it is seen that TCP Vegas sender performs well. As stated earlier, TCP Vegas estimates the network status to adjust its window value. This property

enriches its performance in such a heterogeneous environment.

Fig. 4. Throughput vs Mobility for topology 'A'

Fig. 5. Throughput vs Mobility for topology 'B'

We also average the throughput over the simulation duration and plot the average throughput obtained with the TCP variants as a function of node mobility for both topology 'A' and 'B' in figure 4 and figure 5 respectively.

According to figure 4 and 5, when the source node is stationary (node mobility 0 meter/sec), all the TCP variants achieve their own highest throughputs in both topology 'A' and topology 'B', because of occurring no handoffs in this situation.

The throughputs achieved with New-Reno to Base TCP and Vegas to Base TCP are lower than those achieved with New-Reno to Delayed-Ack TCP and Vegas to Delayed-Ack TCP in both topology 'A' and topology 'B'. It is due to the fact that ACKs and TCP packets share the same channel; so decreasing the ACKs by using the Delayed-Ack receiver instead of Base receiver it is possible to improve the throughput of TCP.

#### B. Average Delay Analysis

From figure 6 and figure 7, it is seen that the average delay of New-Reno sender (receiver may be Base or Delayed-Ack) is high as compared to Vegas sender in both topologies. Vegas reads and records the system clock

each time a segment is sent. When an ACK arrives, Vegas reads the clock again and does the round trip time (RTT) calculation using this time and a timestamp recorded for the relevant segment. Using an accurate RTT estimates, Vegas leads to a more accurate timeout calculation. This is why Vegas shows very low delay as compared to New-Reno.

The average delay of New-Reno to Delayed-Ack is the worst among all the variants. This is why it has given the lowest packet delivery ratio. The average delay of New-Reno to Base is better than that of New-Reno to Delayed-Ack but worse than Vegas to Base and Vegas to Delayed-Ack. The same thing has happened in case of packet delivery ratio, that is, the packet delivery ratio of New-Reno to Base is better than New-Reno to Delayed-Ack but worse than the Vegas to Base and Vegas to Delayed-Ack.

Fig. 6. Average delay vs Mobility for topology A

Fig. 7. Average delay vs Mobility for topology B

The delay performance of Vegas to Delayed-Ack TCP and Vegas to Base TCP is relatively similar and they show low delay in all the mobility so they show relatively similar and high packet delivery ratio in both the topologies. Since the average delay of Vegas to Delayed-Ack TCP is low it has given a very good throughput in the simulation time in both topologies.

## VI. CONCLUSION

While TCP is needed for a Mobile IP network, the current variants of TCP are not adequate for the task. To

achieve good TCP performance in Mobile IP wired-cum-wireless networks a variety of solutions have been proposed and in most of the solutions the mobile node acts as a TCP receiver. However, little attention has been paid to study the performance of TCP traffic over combining both TCP senders and receivers. We have investigated the performance of TCP over combining both TCP senders (Newreno & Vegas) and TCP receivers (Base & Delayed-Ack) using simulations in ns-2 for a range of node mobility with a single traffic source. The performance metrics that we have considered include TCP throughput and packet delay.

On throughput performance, Vegas TCP to Delayed-Ack gains the best performance. On the sender side, the effective congestion control technique of Vegas makes it optimal in such a heterogeneous environment. And in the receiver side, the Delayed-Ack receiver makes the proper use of channel by sending fewer ACK packets.

We have also evaluated throughput with respect to node mobility. The result shows that throughput of each TCP variant varies similarly with respect to each other against mobility of node. But Vegas to Delayed-Ack shows the best result as compared with other variants.

Delay performance of each variant shows the confidential result. TCP Vegas has the lowest delay no matter whether the receiver is Base or Delayed-Ack. New-Reno has large delay. But among them New-Reno to Delayed-Ack has the highest delay. After observing packet delivery ratio and delay, it is seen that the variant that gains highest packet delivery ratio has lowest delay.

Though all the variants of TCP suffer in Mobile IP wired-cum-wireless networks, it is clear from the various results that if we use Vegas TCP as a source (sender) and Delayed-Ack as a sink (receiver), then this combination shows the best result among the all TCP variants. Next, we plan to investigate the performance of all the TCP variants with multiple traffic sources in more complex heterogeneous networks and also consider some link layer and network layer feedbacks to improve their performance.

# A System for Locating Users of WLAN using Dynamic Mapping in Indoor and Outdoor Environment-LOIDS

Karamtot. Krishna Naik and M.N. Giri Prasad

Sree Visvesvaraya institute of Technology & Science, Mahabubnagar, India  
JNTU College of Engineering, Pulivendula, India

**Abstract** — The development of portable, light weight, hand held computing devices and high speed wireless local area networks enable user to remain connected while moving in indoor and outdoor environment. Wireless local area network has a wide range of utilization in moving from one location to another location. When a user is moving from one location to another, how the other user knows about the required station inside WLAN, for that we designed and implemented a system to locate a mobile user inside the wireless local area network based on RSSI. We designed four different architectures and used dynamic radio mapping of indoor and outdoor locations. These architectures are based on dynamic configuration of radio map in indoor and outdoor environment with the help of Sniffer, a specially designed application to locate a station at that time. We found a better location of a mobile user in WLAN with the help of Pamvotis a WLAN simulator. We tested this work in indoor and outdoor environment with different locations practically.

## I. INTRODUCTION

These days wireless local area network has become very popular, when the initial IEEE802.11 is the standard for providing wireless connectivity to automatic machinery, equipment and stations that require rapid deployment, which may be portable, handheld or which may be mounted on moving vehicles within a local area. IEEE802.11 Wireless local area network is a shared-medium communication network that transmits information over wireless links for all IEEE802.11 stations in its transmission range to receive [3][4][5][10]. The main characteristic of the IEEE802.11 WLAN's is its simplicity, scalability & robustness against failures due to its distributed nature. IEEE802.11 wireless networks can be configured into two different modes: Ad-hoc & infrastructure modes. In Ad-hoc mode, all wireless stations within the communication range can communicate directly with each other, whereas in infrastructure mode, an Access Point is needed to connect all stations to a distribution system, each station can communicate with one another through the Access point.

IEEE802.11 provides the data rates upto 2 Mbps at 2.4 GHz ISM band. Later, IEEE802.11 working group published its enhanced version named IEEE802.11b that extends the data rate upto 11Mbps at this ISM band. Its high-speed version at 5 GHz UNII band (IEEE802.11a) was also defined. IEEE802.11a standard can achieve data rate of upto 54Mbps

by using OFDM (Orthogonal Frequency Division Multiplexing) modulation technique at physical layer. The fundamental building block of the IEEE 802.11 architecture has the Basic Service Set (BSS). A BSS can be defined as a group of stations that are located in the same geographical area. The area covered by the BSS is also known as basic service area (BSA). Any station can establish a direct communication session with any other station in the BSS, without the requirement of channeling all traffic through a centralized AP.

Fig. 1. An Extended Service Set

Infrastructure network is built to provide wireless users with specific services and range extensions. In the context of IEEE 802.11, infrastructure network is established using APs. AP supports geographical range extension by providing the integration points necessary for network connectivity among multiple BSSs to form an Extended Service Set (ESS). The ESS consists of multiple BSSs which are integrated together using a common distributed system as shown in the Figure-1 above. Based on this infrastructure network with location of every station in the network to provide better services must be known to the service provider. That is possible only with the help of creating a map i.e. radio map. This map is based on the geographical area of our institute. We divided this area into few blocks and placed an individual access point which covers the entire area to make the complete network. These access points form a dynamic mapping whenever the user tries to locate the required station, where it/that is.

Here we mainly focus on the signal propagation which can generally attribute to reflection, diffraction and scattering mechanisms. The changes in furniture placement, surrounding structures and occupancy conditions seriously affect signal propagation condition in normal WLAN environment. Large scale fading and small scale fading are the two methods, which are used to explain RSSI (Received Signal Strength Indication) fluctuations. The large scale fading occurs due to the distance

separation between AP (Transmitter) and wireless Sniffer (Receiver), where RSSI decreases as the distance increases. The small scale fading is given by the rapid fluctuations of the RSSI over very short distances or short time durations caused by multipath in the radio environment.

## II. WLAN LOCATION ARCHITECTURE

In the existing WLAN infrastructure without using any additional hardware we can increase efficiency of the network by using suitable network location architecture. With that aspect we are developing a system architecture which estimates the accurate location of the user. Here we are proposing four types of location architectures. One is Source- Destination, another one is Client-Server, third one is Sniffer based and final one is Access Point (AP) based architectures[6][8].

*Source-Destination Architecture:* Source station in one area can search for any other required (destination) station in same or different network. Here a source station sends request to the nearby station that may be the destination or may be connected with the destination. The concerned station which is helping to find the location of the destination records the received signal strength indication from the destination. Based on that RSSI we can identify the location of the destination with help of radio map. The architecture of this is shown in the Figure 2.A.

*Client-Server Architecture:* This architecture has two phases of location estimation, the first one is offline phase and second one is real-time phase. In offline phase infrastructure mode of WLAN access point (AP) provides services to all clients in that area as an ESS. The ESS may have many APs, Client in one AP can receive signal from other or many other APs. But only one AP has to serve the client. That selection of the AP by client is based on the RSSI from other APs. In real-time phase service provided to the clients based on the request made by the respective client with the help of the location based services i.e. as client needed for service made available with that AP. The architecture of this is shown in the Figure 2.B.

*Sniffer Based Architecture:* It has great advantages over all other architectures because it is the application based architecture. In this architecture all stations are preinstalled specially designed application which can identify the location of the system. The application software that monitors all the stations will capture all the traffic in the network. This application software is considered as a Sniffer in the network. For reading the RSSI information from WLAN we will try to connect over the network by using a WNIC (here we are using DWL and NetGare). The WNICs work like passive entities, try to send packets in the wireless medium and capable of capturing all frames transmitted in the same channel. Basically to detect and monitor the wireless medium, Sniffer has to execute two functions continuously. Firstly detecting the wireless clients and recording the available RSSI values of it and second one is measuring RSSI from one or more reference

devices in order to construct the location model in the map. The architecture of this is shown in the Figure 2.C.

*Access point Based Architecture:* As we all are aware of WLAN that, it has two modes of operation one is Ad-Hoc mode and another is Infrastructure mode, these

Fig. 2. Architectures for location determination

two modes will be used to form BSS and ESS. Here we are considering ESS to construct a specialized architecture for WLAN location determination system. In ESS basically we use an access point to connect available stations in the coverage area. Suppose any client wants to connect any remote station a client need to contact parent AP to find the location of destination station. The destination station may be available with any other AP or the same AP. In this connection to remember all the stations in the network we are placing a RADIUS server with every AP. RADIUS is a server which will keep information about all stations available with that AP if any AP sends a request asking information about any station, then that AP [1] RADIUS server sends reply to the originated AP with the available information. The architecture of this is shown in the Figure 2.D.

### III. LOIDS- LOCATION OF OUTDOOR AND INDOOR DETERMINATION SYSTEM

Our aim is to discuss and differentiate the Indoor and outdoor locations of WLAN enabled stations and providing the best services to every station in the network. This system (LOIDS) helps to find the required station in the network. A lot of efforts in preparing LOIDS include building of Radio map. There are two methods to consider one is empirical and mathematical methods. In empirical method the radio map created by involving a mobile user in different places and recording physical coordinate at each position for different APs with in the range. In mathematical method the radio map is generated by using the RSSI of RF propagation.

While describing the LOIDS in the indoor and outdoor environment let us assume the physical dimensional space  $L$  where a device is situated, a AP with Sniffer loaded at  $l$ , RSSI measured by  $K$  Sniffer given a tx device located at  $l$  for each position  $l \in L$ . Here we assume  $L$  discrete and also define a signal space  $S$  with  $K$  dimensions where element of this space is a vector of dimension  $K$  in which its positions represent RSSI readings from the  $K$  different Sniffers[6][7][9]. Samples from the signal space  $S$  are denoted by  $s$ , the given RSSI vector  $s=(s_1, s_2, \dots, s_k)$  we are determining the position of the station by  $l \in L$ , this maximizes the probability  $p(l/s)$  of a tx device to be located at  $l$  with a captured RSSI vector measured by  $K$  Sniffers. The required information is then molded into the database where the location server creates the radio propagation map (RPM), where the grid position  $l=(x,y)$  is associated to probability distribution  $p(s/l)$ . The location server builds a RPM for each Sniffer  $I$ , i.e. for  $K$  Sniffers a total of  $K$  RPM  $s$  will be formed at the server. To measure the signal strength  $S_i$  from a tx situated at  $l$  is given by  $p(s/l)$  according to Gaussian distribution:

$$P(s/l) = \frac{1}{\sigma(l)\sqrt{2\pi}} \exp\left(-\frac{s - \mu(l)^2}{2\sigma^2(l)}\right) \quad (1)$$

Here  $\mu(l)$  is RSSI expected values of all stations in the network at a Sniffer loaded station and  $\sigma(l)$  is the distribution standard deviation (SD).  $\mu(l)$  Can be estimated by large scale propagation model,

$$\mu_{(l)}(d) = \mu_0(d_0) - 10_{n0} \log\left(\frac{d}{d_0}\right) - \alpha \quad (2)$$

In this equation  $\alpha$  is attenuation caused by interferences and  $d$  distance between transmitter, receiver and Sniffer placed station. To calculate the distance  $d$  between transmitter, receiver and Sniffer placed station is

$$d = \sqrt{(|x_{\text{SNIFFER}} - x|)^2 + (|y_{\text{SNIFFER}} - y|)^2}$$

in above equation  $x$  and  $y$  are coordinates at location  $l$ . RPM can be constructed when the significant changes in RSSI occur. RSSI measurements are used between the pairs Sniffers and APs to sense whether the WLAN propagation environment has changed and when to rebuilt RPM. If RSSI follows Gaussian distribution where mean and standard deviation between the pair of Sniffers and APs the RPM can be estimated by real-time measurements between the pair of Sniffers and APs. After measuring many times the above said measurements for  $M$  consecutive RSSIs may fall outside the interval( mean and standard deviation), with that a new RPM should be formed. Another method to reconstruct the RPM is for every  $T$  seconds. If found any changes in mean and standard deviation that may not affect the RPM because, it is a pre-defined map. Here any number of users may enter into the scenario and may leave the scenario. The calculated RSSI with Sniffer  $s$  and APs may not show much difference. In radio environment no user would stay at a specific point or location, for that the dynamic formation of the RPM is more comfortable than statistical formation of RPM.

As we discussed above the statistical and dynamic location of RPM the RSSI vector  $s = (s_1, s_2, \dots, s_k)$  we found a position  $l \in L$  which maximizes the probability  $p(l/s)$ . As per Bayes theorem to find position of a user in the location  $l$  is by using this formula

$$P(l/s) = \frac{P(s/l)P(l)}{P(s)} = \frac{P(s/l)P(l)}{\sum_{l' \in L} P(s/l')P(l')} \quad (3)$$

This is for  $l \in L$  ie all possible positions in the RPM grid the sum goes through.  $P(s/l)$  indicates the probability to receive  $s$  from tx position at  $l$   $P(l)$  is the probability a priority of finding a tx in the position  $l$ . Let a wireless transmitter situated at  $l$  and  $k$  Sniffer will calculate a vector  $s = (s_1, s_2, \dots, s_k)$  and for each Sniffer  $P(l/s)$  is determined.

### IV. EXPERIMENTAL EVALUATION

As we discussed in the above sections, we prepared a setup of all four types of WLAN location determination architectures (A, B, C & D architectures) in our laboratory. We used DWL and NetGear network interface card which supports IEEE802.11a/b/g standards. In the institute premises we prepared a radio map in area of 1KM range. Two modes of WLAN Ad-Hoc and Infrastructures are prepared by using DWL and NetGear NICs and APs. In this section we are discussing and showing the differences between Indoor and outdoor locations and determining the location of the user with different positions.

Here we discussed indoor and outdoor location determination of a user in the wireless local area network, with IEEE802.11a/b/g by using DWL and NetGear NICs. The differences between a/b/g are tabulated in the table below in

the table-1. A dynamic mapping of RPM is somewhat difficult than statistical mapping. In dynamic mapping Sniffer has to search and scan the channel all the time in the form of “Refresh Always” method, without which it is not possible to see who is entering the network and who is leaving the network.

TABLE-1

Differences between IEEE802.11a/b and IEEE802.11g

| Properties  | 802.11a/b                                           | 802.11g                                                               |
|-------------|-----------------------------------------------------|-----------------------------------------------------------------------|
| Frequency   | 2.4Ghz / 5Ghz                                       | 2.4 GHz                                                               |
| Modulation  | Direct sequence spread spectrum (CCK, DQPSK, DBPSK) | Orthogonal frequency division multiplexing (64QAM, 16QAM, QPSK, BPSK) |
| Data rate   | 1,2,5.5,11Mbps                                      | 1,2,5.5,6,9, 11,12,18,18, 24,36, 48,54Mbps                            |
| Os platform | Windows Vista                                       | Windows XP                                                            |

Here Figure-3 is a Sniffer application which shows how many users are coming into the network and working in the network by Green indication as shown below, and whoever leaving the network by a Red Cross mark indication. The traffic can also be monitored by a statistics graph.

Fig. 3. Sniffer indications

After taking many iterations practically in Indoor and Outdoor locations by using IEEE802.11 a/b/g by connecting DWL and NetGear NICs at client side and server side, readings were recorded in the form of signal strength (RSSI). In indoor we found the location of the user somewhat slow when compared to the outdoor location and it is shown with the graphical notation below. One thing we can say and understand

that, we cannot carry and move AP dynamically from one place to another. For that reason we are proposing a statistical radio map location by equal division area spaces as shown below. We considered all four architectures and verified by taking RSSI indications at client and server sides in both indoor and outdoor environment. Figure-4 and Figure-5 show that the performances of indoor and outdoor environment and performance of Ad-hoc and infrastructure modes differences respectively in different positions i.e. 50mts, 75mts, 100mts, 125mts, 150mts and so on with RSSI indications Excellent, Very good, Good and Poor.

We have clearly seen location of a user in indoor and outdoor environment with Ad-hoc and Infrastructure modes. An infrastructure mode shows better results than Ad-hoc mode in both environments.

Fig. 4. Performance at Indoor and Outdoor environment

Fig. 5. Performance of Ad-hoc and Infrastructure modes

## V. RELATED AND FUTURE WORK

In this work we basically concentrated to determine location of a user in the environment of indoor and outdoor with dynamic location mapping. We found some difficulty in finding location of a user in statistical method, because of how to locate a position to an access point. Here we are using automatically connect and detect method to connect a system to the network. At the same time we are also focusing to form a radio map with equally divided area in indoor and outdoor locations. Finding an accurate position of a user we used the dynamic method by using Bayes theorem and tried to find the

correct position of the user in both the indoor and outdoor environment. In future we try to design a system, based on Bayes theorem in statistical environment. We are trying to test our work by using some other NIC's and with multiple locations. We also working on continuation of this work with cluster based calibration-free dynamic mapping of signal strength of a user in indoor and outdoor environment.

## VI. CONCLUSION

In this paper we discussed the system LOIDS which helps to locate and finds a user in Indoor and Outdoor environment with the help of dynamic location mapping. Here we developed four architectures and enabled WLAN strategies in those architectures in testbed. We tested all four architectures with different places in indoor and outdoor environment. In source destination architecture, it is somewhat difficult to continue the communication path while searching the location of a user, because of if any node in the sequence or Ad-hoc network is not having next node or station, this system may not work properly. In client server based, Sniffer based and Access point based architectures we found the considerable results shown in the graphical representations in indoor and outdoor environment with Ad-hoc and Infrastructure modes of operation.

**Abstract** — In many communication systems, two or more traffic links are merged together to form a common trunk line. Usually, a Markovian technique is used to determine the different traffic parameters of aforementioned combined trunk line. But the technique does not hold good and also the Markov chain takes a complex shape for a network where offered traffics are more than two different types. In this paper, we propose a tabular method instead of a Markovian technique for calculating various traffic parameters of a network with multimedia traffic, applicable in mobile cellular networks. It is found in this work that the proposed tabular method overcomes the complexities of the Markovian approach and yields similar results.

**Keywords** — Call blocking, combined trunk, Markov chain, M/M/n traffic model, multimedia traffic.

## I. INTRODUCTION

Penetration of wireless mobile cellular networks has been tremendous in the last decade, and this will continue in the coming years as well. To remain in harmony with this ever increasing user demand, wireless mobile cellular networks have already been shaped to provide multiple services ranging from normal voice calls to image and video transmission. The intermittent handoff in mobile cellular networks has added another dimension to it. As a result, in recent days, for analyzing the quality of service (QoS) issues for mobile cellular networks, a three-dimensional (3D) traffic scenario is being thought to be the appropriate way to cover all incoming traffics to the network. Generally, probability state transition or Markovian chain is used to design limited and unlimited source traffic of various dimensions. To solve such a chain, cut or node equations are widely used [1]-[3].

In this paper, a model is proposed and analyzed further to realize the same in a normalized tabulated form. For an  $m$ -dimensional traffic ( $m \geq 3$ ), state transition diagram takes a complex shape and also, the large number of

equations for the chain causes additional complexity to gain detail information pertaining to the process. We suggest an alternative way here for the special case of 3D offered traffic system to avoid the complex calculations of state transition or the Markovian chain method. Here in the system, we assume that the offered traffic follows an exponential arrival and service time distribution in a limited server link, i.e. M/M/n traffic. The concept of tabular solution of two-dimensional (2D) Poisson's or Erlang's distribution is adopted here, and normalization of table is done after eliminating unreachable state of combined traffic link, based on the method discussed in [4]-[6]. Though this paper reveals a tabular solution of a three input traffic system, it would become a lengthy work for more than three input trunks or servers. However, it is worth to mention here that the proposed model can be extended for any number of offered traffic cases.

The plan of the paper is as follows. The proposed tabular method is explained in Section II. Section III of the paper deals with the methodology of solution of a 3D offered traffic of a trunk line along with results of the model. In this section, blocking probability of trunk is also represented graphically against offered traffic. Finally, Section IV concludes the paper.

## II. THE PROPOSED MODEL

In this section we describe our model to determine the normalized probability states or QoS of a mobile cellular network in a direct form. One of the convenient ways of presenting a 2D traffic case is in triangular matrix form, where each element of the matrix is obtained by multiplication of specific terms from two series of two-offered traffics.

Fig. 1. Synthesis of Three Offered Traffic

Let us first consider that two out of three links are selected to achieve the generalized tabular solution of a 2D traffic situation. Here  $A_1$  and  $A_2$  are selected first and shown in Table 1 after analyzing them based on the method described in [6], [7]. The entries of Table 2 is then multiplied by 1,  $A_3$  and  $A_3^2/2!$ , and at the same time the number of servers is reduced by 0, 1 and 2, respectively. The resulting tables are shown as Tables 3a, 3b, and 3c. The entries of the tables are then normalized in combined forms which are shown as Tables 4a, 4b, and 4c. Call blocking is the sum of dark cells according to the concept given in [6]-[8].

Probability states and blocking probability for individual Tables 4a, 4b and 4c can be evaluated mathematically by applying equations (1)-(4) easily according to [7], [9]-[10]. However, it is not convenient to evaluate ultimate traffic parameters from the combination of the above mentioned three tables based on equations (1) and (2). Hence our tabular solution is preferable for multidimensional traffic, especially, for dimension more than 2.

For example, let us solve the case where  $A_1 = 2$  Erlangs,  $A_2 = 1$  Erlang, and  $A_3 = 5$  Erlangs for  $n_1 = 5$  trunks,  $n_2 = 3$  trunks,  $n_3 = 2$  trunks, and  $n = 6$  trunks. After solving the network, blocking probability comes out to be  $B = 0.18385$ . The numerical value of carried and lost traffic from equations (5) and (6) is evaluated as 6.52916 Erlangs and 1.47084 Erlangs respectively. Blocking probability is also depicted graphically in Fig. 2 against offered traffic  $A_1$  and  $A_3$ .

Fig. 2. Variation of call blocking probability against (a) offered traffic  $A_1$ , (b) offered traffic  $A_3$ .

It is noticed from the graphs of Fig. 2 that the blocking probability against  $A_1$  is greater than the blocking probability against  $A_3$ . The traffic  $A_3$  is offered to a link of only two trunks (Fig. 1). Hence, very little carried traffic will reach to the combined trunk line. On

the contrary,  $A_1$  traffic is offered to a link of five trunks. So, less traffic will be lost and almost all of the offered traffic will reach to the combined trunk link  $n$ . Hence, offered traffic  $A_1$  will dominate on call blocking of the combined trunk link compared to  $A_3$ . These are also clearly visualized from the graphs shown in Fig. 2.

#### IV. CONCLUSION

An approach of tabular method is described in this paper for analyzing a multidimensional traffic system of calculating various traffic parameters of a network with multimedia traffic, applicable particularly in the mobile cellular systems. It is found that the tabular method described here overcomes the complexities of the Markovian approach particularly for more than 2D traffic cases. In this paper, the analysis is done for three different offered traffic of similar bandwidth. However, some networks, for example, 3G mobile systems of voice/data integrated services, where voice and data traffic have different bandwidth, the analysis can easily be carried out based on our proposed model described in this paper by using the bandwidth sharing scheme (viz. Eq. (5)).

Dhaka, Bangladesh

**Abstract** — This paper describes in detail the analysis results of the Bangla Dental consonants /ত/ [t], /থ/ [th], /দ/ [d] and /ধ/ [dh] analyzed through the spectral estimation techniques in four long vowel contexts /আ/ [a], /ই/ [i], /ও/ [o], and /উ/ [u] for an accurate description of their acoustic characteristics and features and the differences between the corresponding cognate sounds. Various parameters like duration of closure/voice bar, duration of burst, voice onset time, duration of aspiration, rate of second formant transition and burst frequencies and amplitudes have been studied in details. For the synthesis of dental sounds, the source and vocal tract parameters of the synthesizer configuration were selected very carefully along with formant frequencies and their relative amplitudes besides the burst amplitude. The quality of synthetic speech was evaluated through subjective listening along with matching the spectra of synthetic speech with original speech.

**Index Terms** — Speech Processing, Synthesis, LPC, Phoneme.

## I. INTRODUCTION

Bangla is an Indo-Aryan language of more than 300 million people in the world concentrating in the eastern region of Indian subcontinent i.e. Bangladesh, Indian states of West Bengal, Tripura, Assam and around. The history of Bangla begins in the late centuries and before that there was only a family of dialects commonly known as Prakrit [1].

Every language has its own set of basic sounds, which constitute the language. Bangla speech contains a set of eleven vowels with eight being the cardinal vowels and 39 consonants, of which about 30 consonants are of frequent usage. The vowels can be pronounced independently, but the consonants need the support of vowels to be pronounced. These consonants can be conveniently classified according to the manner and place of articulation [1].

The Bangla consonants possess certain special features, which are not so common to other European languages and American English. The major discrepancy results from a difference in the number of places at which the stops can be formed by the tip of the tongue making contact with the front portion of the top of the mouth. Consonants differ from vowels in that they had more

energy in the high frequency region compared to the low frequency region. Bangla linguistics classify consonants on the basis of their place of articulation. In fact in Bangla, there are five ways distinction in the place of articulation for the stops sounds, compared to English where there is only four way contrast [2].

Dental sounds involve the upper teeth as the passive articulator. The active articulator may be either the tongue tip or tongue blade and generally diacritic symbols are used to represent the class of dental sounds. In Bangla, the dental sounds are classified in two categories: dental and the labio-dental. In case of dental sounds /ত/ [taa], /থ/ [tha], /দ/ [daa], /ধ/ [dha] – the tip of the tongue is against the back of the upper teeth, or even further forward. In labio-dental sounds /ফ/ [fa], /ব/ [va] – the sound requires the participation of one or both lips and dental ridge. The constriction is formed between lips and dental ridge to generate labio-dental sounds [1-3].

In this work, we investigated spectral properties of Bangla dental sounds from 1800 speech corpora containing vowel-consonant-vowel (VCV) and consonant-vowel-consonant (CVC) syllables produced by male and female speakers of different age groups. The revealed spectral properties of the dental sounds along with the burst amplitude and duration is used in the synthesis of dental sounds. The synthetic sound and spectra was evaluated. The rest of the paper is organized as follows: Section II discusses the analysis procedure and Section III discusses the synthesis procedure with experimental results and discussion in Section IV.

## II. ANALYSIS PROCEDURE

All the consonants were recorded in the form of CVC and VCV syllables spoken by male and female native Bangla speakers in all four vowel contexts /আ/ [a], /ই/ [i], /ও/ [o], and /উ/ [u] at the sampling rate of 16 kHz. These CVC and VCV syllables were then broken into CV and VC syllables for the entire analysis through spectral techniques. The starting and ending times of the vocalic nuclei was measured by hand from high-resolution digital spectrograms. Only the first 10 ms of the release burst or the whole burst was considered.

The spectral analysis of these syllables were carried out using digital spectrograms and other techniques like short time FFT and LPC spectra [4], pitch, formants, waveforms and envelope displayed together. Using the spectrogram most of the important acoustical events were studied in time as well as frequency domain. Duration and sequences of events in each sound/syllable was noted down using time scale of the spectrogram. Unlike other sounds, which can be described largely in terms of steady-state spectra, stops are transient phonemes and thus are acoustically complex. Bangla consonant-vowel (CV) and vowel-consonant (VC) syllables of the type stop plus vowel consist of at least four phonetic segments, viz. the closure or voicebar, burst, voice onset time (VOT), aspiration and a voiced interval for vowel [5, 6].

The burst frequency is the frequency at which the maximum amplitude in the frequency spectrum occurred. The burst frequency was estimated from the frequency spectrum of the release burst. Burst frequency measurements were made using a 20-pole LPC spectrum.

### III. SYNTHESIS PROCEDURE

Bangla dental sound segments were synthesized on the basis of extracted spectral parameters achieved through analysis. Based on the analyzed data, synthetic CV tokens were created from a number of source and tract parameters that were adjusted iteratively in order to achieve a close imitation to natural syllables. These include the source parameters such as amplitude of voicing, frication and aspiration (AV, AF, and AH respectively), Open Quotient (OQ) and vocal tract parameters like formant frequencies, amplitudes, and their respective bandwidths which was fed into the Klatt formant synthesizer [7, 8].

Same formant frequencies of burst (and transitions) were used for consonants belonging to same place of articulation. For example same values of first four formants were used for all four consonants /ত/ [t], /থ/ [th], /দ/ [d] and /ধ/ [dh] in the dental group for a given vowel context.

Figure 1: Analysis of Bangla speech segment /আত/ [aat] from the Bangla corpus  
আতা [ata] produced by a male speaker

A half-Hamming window of 20 ms was used that is (only the latter half of the Hamming window was multiplied with the 10 ms of the release burst samples). The LPC spectrum was obtained using a 512-point FFT. The frequency of the maximum amplitude of spectral peak was extracted from LPC spectrum using a global peak picking algorithm. Once this acoustic analysis was done for the clean consonants, the frequencies at which the peaks for the consonants occurred were computed and plotted [6].

### IV. EXPERIMENTAL RESULTS AND DISCUSSION

The spectrogram of Bangla speech corpus আতা [ata] produced by male speaker is shown in the Figure 1 along with the consonant segment of speech corpus আত [aat] in the time domain with other spectral measurements. As can be seen from the spectrogram, at the beginning of the phonation আ [aa], a small voice bar is visible and then followed by a set of formants during the production of the phonation আ [aa]. During the transition phase from the

vowel segment to the consonant segment for ত [ta] and from consonant to vowel segment v [diacritics] a burst frequency range is visible without any noticeable formant frequencies.

As can be seen from the Figure 1, the speech segment /আত/ [aat] is displayed on the top frame and the segment length is about 65msec. The FFT and LPC smoothed spectrum is captured in another frame whereas frame wise formant contour and log Mel power spectrum of the same speech segment is captured in another two frames.

The formant contour clearly demonstrates the transition of formant frequency due to consonant segment /ত/ [ta]. The first formant F1 tend to increase due to the closure of the oral tract. The FFT and LPC smoothed portion of the spectrum shown is the last frame of the speech segment under analysis.

TABLE I  
COMPARISONS OF BURST FREQUENCIES OF DENTAL  
SOUNDS

(a) /আ/ [a] context

| Formant | /ত/ [t] | /থ/ [th] | /দ/ [d] | /ধ/ [dh] |
|---------|---------|----------|---------|----------|
| F1 (Hz) | 600     | 950      | 380     | 750      |
| F2 (Hz) | 1450    | 2000     | 1700    | 1900     |
| F3 (Hz) | 2700    | 2900     | 2700    | 3000     |
| F4 (Hz) | 3400    | 3900     | 3350    | 3850     |

(b) /ই/ [i] context

| Formant | /ত/ [t] | /থ/ [th] | /দ/ [d] | /ধ/ [dh] |
|---------|---------|----------|---------|----------|
| F1 (Hz) | 400     | 450      | 350     | 450      |
| F2 (Hz) | 2150    | 1850     | 2150    | 2150     |
| F3 (Hz) | 2550    | 2950     | 2900    | 2800     |
| F4 (Hz) | 3800    | 4150     | 3250    | 3750     |

(c) /উ/ [u] context

| Formant | /ত/ [t] | /থ/ [th] | /দ/ [d] | /ধ/ [dh] |
|---------|---------|----------|---------|----------|
| F1 (Hz) | 550     | 450      | 375     | 350      |
| F2 (Hz) | 1600    | 1750     | 1650    | 1600     |
| F3 (Hz) | 2750    | 3150     | 2750    | 3000     |
| F4 (Hz) | 3850    | 3550     | 3450    | 3950     |

(d) /ও/ [o] context

| Formant | /ত/ [t] | /থ/ [th] | /দ/ [d] | /ধ/ [dh] |
|---------|---------|----------|---------|----------|
| F1 (Hz) | 550     | 500      | 250     | 450      |
| F2 (Hz) | 1500    | 1900     | 1725    | 1450     |
| F3 (Hz) | 2850    | 2550     | 2550    | 2850     |
| F4 (Hz) | 3550    | 3950     | 3950    | 3900     |

In English, in the production of /t/ and /d/ sounds, the tip of the tongue comes in contact with the alveolar ridge while in Bangla, there is a mixed alveolar sounds and it has either dental consonants or retroflex. These sounds are produced by the tip of the tongue in interaction with the back part of the alveolar ridge.

As can be seen from the Table 1, the place of articulation and the vowel context determine the burst frequencies of dental sounds. The burst and formant transition of the target vowel varies across the stop consonants. The same stop consonant shows variation in the formant frequency transition in different vowel context.

The vowel context /ই/ [i] shows significant difference in formant transition between first formant F1 and second formant F2 for all the retroflex sounds of Bangla. The formant transition between the second and third formant frequency F2 and F3 is consistent throughout different dental sounds. Besides, the context /উ/ [u] and /ও/ [o] shows persistent formant transitions for different retroflex sounds as can be seen from the Table 1.

The relative burst amplitudes of various dental sounds of Bangla in different vowel contexts were measured and all the measurements were recorded in the Table 2 below.

Table 2 postulate the relative burst amplitude of dental sounds in different vowel contexts. As can be seen from the Table 2, the consonant /ত/ [t] in the vowel context /আ/ [aa] shows relatively higher burst amplitude for second formant frequency compared to higher formant frequencies. While the consonant /ত/ [t] in the vowel context /ই/ [i], /উ/ [u] and /ও/ [o] shows relatively higher amplitude for the burst for higher formant frequency compared to lower formant frequencies. The consonants /থ/ [th], /দ/ [d], and /ধ/ [dh] shows higher relative burst amplitude in the vowel context /আ/ [aa] and /ই/ [i].

The formant frequency transition of various dental sounds of Bangla in different vowel contexts were measured through the formant contour observation and all the measurements were recorded in Table 3 as shown below.

As can be seen from the Table 3, for all the dental sounds of Bangla, the first formant frequency F1 transits from high to low during the movement towards the vowel segment and to high during the retraction from the vowel segment. In case of dental sounds, the second formant frequency is steady during the transition but the third formant frequency transits from low to high and the fourth formant frequency transits from high to low while the segment moves to and from the vowel. In case of dental sounds as can be seen from the Table 3, the fourth formant frequency is steady during the transition but the second formant frequency transits from low to high and the third formant frequency from high to low during movement towards the vowel and to high while the segment moves away from the vowel.

TABLE II  
RELATIVE BURST AMPLITUDES OF RETROFLEX SOUNDS IN VOWEL CONTEXTS  
(WITH RELATIVE LEVEL DIFFERENCE; A2F: F2 AMPLITUDE; A3F: F3 AMPLITUDE; A4F: F4 AMPLITUDE)

| Consonant | /আ/ [aa]    | /ই/ [i]     | /উ/ [u]     | /ও/ [o]     |
|-----------|-------------|-------------|-------------|-------------|
| /ত/ [t]   | A2F>A3F>A4F | A4F>A3F>A2F | A4F>A2F>A3F | A4F>A2F>A3F |
| /থ/ [th]  | A4F>A2F>A3F | A4F>A2F>A3F | A2F>A3F>A4F | A3F>A4F>A2F |
| /দ/ [d]   | A4F>A2F>A3F | A3F>A4F>A2F | A2F>A3F>A4F | A4F>A3F=A2F |
| /ধ/ [dh]  | A4F>A2F>A3F | A3F>A4F>A2F | A2F>A3F>A4F | A2F>A3F>A4F |

TABLE III  
FORMANT TRANSITION OF DENTAL SOUNDS TO AND FROM THE VOWEL SEGMENT

| Consonant | F1                | F2     | F3       | F4       |
|-----------|-------------------|--------|----------|----------|
| /ত/ [t]   | High – low – high | Steady | low-high | high-low |
| /থ/ [th]  | High – low – high | Steady | low-high | high-low |
| /দ/ [d]   | High – low – high | Steady | low-high | high-low |
| /ধ/ [dh]  | High – low – high | Steady | low-high | high-low |

Figure 2: Formant contour of original and synthetic Bangla speech segment আত [aat] of the Bangla word আতা /ata/ produced by a male speaker

The original speech segment of speech corpora /আত/ [aat] is shown with the synthesis counterpart is Figure 2 along with spectral measurements. As can be seen in the Figure 2, the original speech segment /আত/ [aat] containing Bangla consonant /ত/ [t] in the word /আত/ [ata] has duration of about 85 msec. The formant contour is shown on the upper right frame. The formant contour shows the formant transition. The synthesized speech segment is shown on the lower left frame of the display which has almost the same spectral characteristics as well as the duration of the segment. The synthesized segment shows the formant contour same as the original segment with identical formant transition characteristics.

TABLE IV  
FORMANT FREQUENCIES OF SYNTHESIZED BANGLA  
DENTAL SOUNDS IN /আ/ [a] CONTEXT

| Formant | /ত/ [t] | /থ/[th] | /দ/ [d] | /ধ/ [dh] |
|---------|---------|---------|---------|----------|
| F1 (Hz) | 580     | 850     | 400     | 820      |
| F2 (Hz) | 1460    | 1900    | 1580    | 1780     |
| F3 (Hz) | 2690    | 2890    | 2550    | 3150     |
| F4 (Hz) | 3400    | 3490    | 3450    | 3980     |

As can be seen from the Table 4, the formant frequencies of synthesized dental speech segment in vowel context /আ/ [a] follows identical variation compared to the original speech segment.

## V. CONCLUSION

Bangla dental consonants are analyzed for spectral representations and the results are postulated in Table 1 through Table 3 and some of the results are shown in Figure 1 and Figure 2. It has been observed at the burst position that third and the fourth formant contains most of the energy in case of dental sounds while formants four contained most of the energy. Also there is general lowering of the third and fourth formants in case of dentals.

It has also been observed that the bandwidths of the formants are narrower (i.e. the formant peaks are better

defined) in the case of voiced aspirated sounds /দ/ [d], /ধ/ [dh], /ড/ [d], and /ঢ/ [dh] as compared to unvoiced aspirated sounds /ত/ [t], /থ/ [th], /ট/ [t], and /ঠ/ [th]. The formant transitions from burst frequency to the target vowel frequency are part of the aspiration segment. Aspiration duration is about 90-110 ms in case of retroflex sounds, while the duration is 80-100 ms for dental sounds.

Burst frequencies depend on the place of articulation of the stop as well as the vowel context. The spectral difference among the dental consonants across the places of articulation is primarily reflected in the spectra of the burst and formant transitions of the target vowel. The burst frequencies of the same consonants do show slight variation in different vowel contexts. In a very good quality of synthetic sounds, burst frequencies and relative amplitudes along with overall burst intensity plays a major role as the burst frequencies of synthesized retroflex and dental sounds in Bangla vowel context /আ/ [a] is shown in Table 4.

# AN APPROACH TO RECOGNIZE HANDWRITTEN BENGALI NUMERALS FOR POSTAL AUTOMATION

Md. Saidur Rahman, G. M. Atiqur Rahaman, Asif Ahmed and G. M. Salahuddin

Computer Science and Engineering Discipline, Khulna University, Khulna-9208, Bangladesh

E-mail: msrku@yahoo.com, atiq@ku.ac.bd, asif\_cseku@yahoo.com, gms\_far@yahoo.com

**Abstract** — A recognition approach for handwritten Bengali numerals and its application for Bangladesh Postal system are presented in this paper. The approach consists of preprocessing, feature extraction and recognition. Using the canny edge detector the top left corner of the post-code box has been detected and the four handwritten numeral images have been segmented. Each image then goes through the steps of normalization, filtering and thinning. Kirsch mask has been used to get the edges through the horizontal, vertical, right and left diagonal. Principal component analysis (PCA) has been used for dimension reduction as the final feature vector consists of the four directional feature vector along with the normalized image. Then the output of the PCA is passed to a trained Support Vector Machine (SVM) to determine which class the input belongs to. Experiments demonstrate that the average recognition rate, error rate and reliability achieved by the proposed system are 92.5%, 7.5% and 92.5% respectively.

## I. INTRODUCTION

Bengali is the second most popular language in South Asia. But unfortunately we have not yet got the appropriate application towards handwritten Bengali numeral character recognition system as most of the research works have been on retrieving content of printed document [1]-[3]. But for our postal automation a system is really necessary that can recognize Bengali numerals from the envelope. Most of the countries in the world already have been developed the system for their postal automation. Postal automation is a topic of research interest for last two decades and many pieces of published article are available towards postal automation of non-Bengali languages documents [4]-[7]. Several systems are also available for postal automation in USA, UK, France, Canada and Australia. But very few works have been done towards the automation of Bangladeshi postal system [8].

Handwritten character recognition is highly subjective as different people have different art of writing the same numeral character. That is why to get the actual numerals from handwriting is difficult in real time. So the main objective of our work is to recognize handwritten Bengali numerals from the envelope of Bangladesh Postal system to

get the post code with high recognition rate, less error rate, high reliability and comparatively less response time.

## II. LITERATURE SURVEY

Various approaches have been proposed by the researchers for numeral recognition [9] but most of them are used for non-Indian numeral recognition. One of the most widely used approaches is based on neural networks [10]. Here the network architecture is trained by a set of training data and then the input is classified by the trained networks. In structural approach each pattern class is defined by structural description and the recognition is performed according to structural similarities [11]. Statistical approach is also applied to numeral recognition. It is relatively insensitive to pattern noise and distortion but modeling of statistical information is a tedious task [9]. Among others, Hidden Markov Models, Fourier and Wavelet Descriptors [12], Fuzzy rules [13], tolerant rough set [14], are reported in the literature.

Feature extraction plays a vital role for a recognition system. Principal component analysis is a well-known method for feature extraction. By calculating the eigenvectors of the covariance matrix of the original inputs, PCA linearly transforms a high-dimensional input vector into a low-dimensional one whose components are uncorrelated [15]-[17]. Recently, support vector machine (SVM) has become a popular tool for numeral recognition due to its remarkable characteristics such as good generalization performance, the absence of local minima. SVM implements the structural risk minimization principle which seeks to minimize an upper bound of the generalization error rather than minimizing the training error [18].

In this paper, we present a recognition system for handwritten Bengali numerals. The system consists of three main parts: preprocessing, feature extraction and recognition. The input of the system is the image of an envelope and the output is the recognized Bengali numerals of the post-code written upon the envelope. Here we propose a recognition approach based on the direction feature combined with PCA and SVM. The experimental

results show that the recognition performance of the proposed approach is superior to other conventional recognition approaches.

### III. MATERIALS AND METHODS

The overall system is represented in Fig.1. Here the preprocessing phase consists of post-code box detection, segmentation, normalization, filtering, thinning and dilation. In the dimension reduction phase Kirsch mask and the PCA method are applied. Then the SVM is trained up. And in the recognition phase the numeral characters are recognized.

Fig. 1. Block diagram of the proposed system

#### A. Preprocessing

The goal of this part is to extract numeral images of postcode from an envelope image for the subsequent recognition. In Bangladeshi postal documents there are pre-printed boxes to write post-code. We call these boxes as post-code boxes. People generally write the destination post-code of four digits inside these boxes.

**Detection of Post-code Box and Segmentation:** Getting an image of envelope as input, the first task is to locate the post-code box in the envelope. To serve the purpose at first the true color image has been transformed into a binary image and then the edge detection procedure has been applied on it. For edge detection the canny method [19] has been used. The Canny method finds edges by looking for local maxima of the gradient of binary image. The gradient is calculated using the derivative of a Gaussian filter. The

method uses two thresholds, to detect strong and weak edges, and includes the weak edges in the output only if they are connected to strong edges. This method is therefore less likely than the others to be "fooled" by noise, and more likely to detect true weak edges. The Fig.2 shows an example of the effect of applying Canny Method.

Fig. 2. (a) The input image (b) After applying 'Canny' method for edge detection.

We have started searching for the post-code box from a pre-specified location which is nearby the searching location. During the search for an edge, whenever we have found the top horizontal edge of the post-code box, we also get the left most point. We have noticed that for a 72 dpi image of the envelope, each box is of size 18x20 pixels. So after getting the left-top point of the post-code box, we can easily crop the required 4 images of handwritten Bengali numerals.

**Normalization, Filtering, Thinning and Dilation:** Size normalization is implemented on each character image that has been collected from previous stage. The size is normalized to be 16x16 pixels. Then, we employ the Gaussian filter to remove the noise and then transform the image into binary image. We notice that the thickness of the stroke is varying because different people use different writing tools. Since the thickness of the stroke influences the recognition result, we use the thinning and dilation algorithm to process the normalized numerals and get the same thickness of the stroke.

#### B. Dimension Reduction

**Use of Kirsch Mask on the Normalized Image:** The normalized image can pass through the SVM as input but there will be lot of relevant information missing in that case. That is why, in this experiment, we first obtain four directional feature maps of a numeral image by the Kirsch Mask. The size of each map is 16x16 pixels. The original image is considered as the fifth feature map. Then we arrange the five images to get the feature vectors ( $5 \times 16 \times 16 = 1280$  dimensions). But this is huge dimension to be given as input to the SVM. To solve this problem we have used PCA to decrease the dimension and extract more significant features. In this way, recognition time and training time can be reduced. Fig.3 illustrates this step.

Fig. 3. Applying kirsch mask on the normalized image.

### C. Training of SVM

We have collected hand written Bengali numerals of a number of people. A sample has been shown in Fig.4.

Following the same preprocessing procedure of an input image, we have collected the 10 Bengali numerals of different handwriting. After using Kirsch mask and PCA on these images, we have stored it in a .mat (a MATLAB file extension) file which is used to classify the SVM.

After getting input from PCA for each numeral image, the SVM tries to find the class where the input numeral image should belong.

Fig. 4. Samples of handwritten Bengali numeral images (০-৯)

### D. Recognition

Based on PCA and SVM, we propose the recognition approach based on Kirsch mask combined PCA and SVM. Generally, Kirsch edge detector, Prewitt edge detector, Sobel edge detector and so on are the representative edge detectors. Among them the Kirsch edge detector has been known to detect four directional edges more accurately than others because the Kirsch edge detector considers all eight

neighbors. Kirsch defined a nonlinear edge enhancement algorithm as follows [20]:

$$G(i, j) = \max_{k=0}^7 \{1, \max[5S_k - 3T_k]\} \quad (1), \text{ where}$$

$$S_k = A_k + A_{k+1} + A_{k+2} \quad (2)$$

$$T_k = A_{k+3} + A_{k+4} + A_{k+5} + A_{k+6} + A_{k+7} \quad (3)$$

In Equations (1), (2) and (3)  $G(i, j)$  is the gradient of pixel  $(i, j)$ ,  $A_k$  ( $k = 0, 1, \dots, 7$ ) is eight neighbors of pixel  $(i, j)$  as defined in Fig.5.

|       |          |       |
|-------|----------|-------|
| $A_0$ | $A_1$    | $A_2$ |
| $A_7$ | $(i, j)$ | $A_3$ |
| $A_6$ | $A_5$    | $A_4$ |

Fig. 5. Definition of eight neighbors of pixel  $(i, j)$

In this paper, we calculate directional feature vectors for horizontal (H), vertical (V), right-diagonal (R), and left-diagonal (L) directions as follows:

$$G_H(i, j) = \max(|5S_0 - 3T_0|, |5S_4 - 3T_4|) \quad (4)$$

$$G_V(i, j) = \max(|5S_2 - 3T_2|, |5S_6 - 3T_6|) \quad (5)$$

$$G_R(i, j) = \max(|5S_1 - 3T_1|, |5S_5 - 3T_5|) \quad (6)$$

$$G_L(i, j) = \max(|5S_3 - 3T_3|, |5S_7 - 3T_7|) \quad (7)$$

The Fig.6 shows the Kirsch masks used for calculating directional feature vectors. The normalized image is processed by the pairs of Kirsch masks ( $3 \times 3$  pixels), resulting in four graded feature maps, coding for the presence of horizontal, vertical or diagonal edges. In this way, we get four directional feature maps. We also take the original image as the fifth map in order to compensate the disadvantages of four directional feature maps. The final data representation corresponds to  $5 \times 16 \times 16 (=1280)$  dimensional inputs. The 1280-dimension is too much for input of a classifier so we employ PCA to extract feature and decrease the dimension. Finally, we obtain the new feature presentation as the input of SVM.

Fig. 6. Kirsch masks, (a) horizontal, (b) vertical, (c) right-diagonal and (d) left-diagonal

#### IV. EXPERIMENTAL RESULTS

##### A. Data Collection

To meet the requirements of a practical usage of the letter sorting machine for Bangladesh Postal System, we should consider not only the recognition rate and the error rate but also the response time. There are various writing styles. For our experiments, 1600 numerals were obtained from the real letters written by Bangladeshis. We randomly select 900 numerals as the training set and the rest as the test set.

For this paper, our experiments were tested on Windows XP, Pentium T(R) D CPU 2.8G and 760 RAM. We employ MATLAB to realize the program.

##### B. Time Performance:

To evaluate the performance of our proposed approach, we have implemented both the proposed method as well as an existing method which takes normalized image as the input of SVM classifier. Table I shows the training and recognition time of our proposed system and the existing system.

TABLE I  
THE RECOGNITION AND TRAINING TIME OF TWO APPROACHES

| Approach               | Recognition time (ms) | Training time (s) |
|------------------------|-----------------------|-------------------|
| Normalized image + SVM | 21.44                 | 67.94             |
| Our Proposed System    | 31.24                 | 146.47            |

##### C. Recognition Performance

The proposed method demonstrates a very high recognition rate. The experimental result shows that close similarity in geometric shape of some numerals led to the chance of false recognition. The Table II represents the recognition rate for different numerals with respect to all numerals.

To evaluate the recognition results, the following measures are employed: recognition rate (Recog.), error rate (Err.), rejection rate (Reject.), and reliability (Reliab.). They are defined as follows:

TABLE II  
THE RATE OF RECOGNITION OF EACH NUMERAL WITH RESPECT TO ALL THE 10 NUMERALS

| Input | Recognition Rate (%)  |      |      |     |     |     |     |     |     |      |
|-------|-----------------------|------|------|-----|-----|-----|-----|-----|-----|------|
|       | Numeral recognized as |      |      |     |     |     |     |     |     |      |
|       | 0                     | 1    | 2    | 3   | 4   | 5   | 6   | 7   | 8   | 9    |
| 0     | 91.7                  | 0    | 0    | 8.3 | 0   | 0   | 0   | 0   | 0   | 0    |
| 1     | 0                     | 91.7 | 8.3  | 0   | 0   | 0   | 0   | 0   | 0   | 0    |
| 2     | 0                     | 16.7 | 83.3 | 0   | 0   | 0   | 0   | 0   | 0   | 0    |
| 3     | 16.7                  | 0    | 0    | 75  | 0   | 0   | 8.3 | 0   | 0   | 0    |
| 4     | 0                     | 0    | 0    | 0   | 100 | 0   | 0   | 0   | 0   | 0    |
| 5     | 0                     | 0    | 0    | 0   | 0   | 100 | 0   | 0   | 0   | 0    |
| 6     | 0                     | 0    | 0    | 0   | 0   | 0   | 100 | 0   | 0   | 0    |
| 7     | 0                     | 0    | 0    | 0   | 0   | 0   | 0   | 100 | 0   | 0    |
| 8     | 0                     | 0    | 0    | 0   | 0   | 0   | 0   | 0   | 100 | 0    |
| 9     | 0                     | 16.7 | 0    | 0   | 0   | 0   | 0   | 0   | 0   | 83.3 |

TABLE V  
COMPARISON OF AVERAGE RECOGNITION RATE WITH OTHER EXISTING APPROACHES

|                              | Proposed System | Normalized Image to SVM | Neural Network Based method |                         |
|------------------------------|-----------------|-------------------------|-----------------------------|-------------------------|
|                              |                 |                         | With momentum factor        | Without momentum factor |
| Avg. rate of recognition (%) | 92.5            | 79.1                    | 60.75                       | 89.75                   |

$$\text{Recog.} = \frac{N1 \text{ (correctly recognized)}}{N4 \text{ (tested)}} \times 100\% \quad (8)$$

$$\text{Err.} = \frac{N2 \text{ (error recognized)}}{N4 \text{ (tested)}} \times 100\% \quad (9)$$

$$\text{Reject.} = \frac{N3 \text{ (rejected)}}{N4 \text{ (tested)}} \times 100\% \quad (10)$$

$$\text{Reliab.} = \frac{\text{Recog.}}{100\% - \text{Reject.}} \times 100\% \quad (11)$$

where N1 (correctly recognized) is defined as the number of numerals correctly classified, N2 (error recognized) is defined as the number of numerals falsely classified, N3 (rejected) is defined as the number of numerals rejected by the classifier, and N4 (tested) is the number of input numerals for test.

Table III shows the recognition rate, the error rate and the reliability of different numerals for the proposed system. Finally, we get the average recognition rate; the average error rate and the average reliability are 92.5%, 7.5% and 92.5%, respectively. Experimental results

demonstrate that our presented system performs very well. It meets the response time with the accuracy requirements.

## V. PERFORMANCE COMPARISONS AND DISCUSSIONS

To compare the results of our proposed method we have implemented existing method applying normalized image to SVM and neural network based system using back-propagation algorithm [21]. Table IV presents the recognition results of our proposed approach and other existing method.

The Table V represents the average recognition rate of Bangla numerals. The third method which is based on neural network using back propagation algorithm [21] is tested during the training period with iteration number from 4000 to 7000 with momentum and without momentum.

The experimental results of Table IV and Table V show that the recognition rate of our method is better than other existing system. But from Table I it is found that the time performance of our proposed approach is not better than the other. But it is remarkable that the recognition rate of our method is much higher than the two other existing methods.

From Table II it has been found that the highest reliability is 100% obtained by Bengali numeral “৪”, “৫”, “৬”, “৭”, “৮”. The false recognition or rejection

is due to variability of handwritings as well as bad writing. From the experiments we note that the most confusing numeral pair is “০” and “০” as shown in Fig.7(a). Second confusing pair is “১” and “১” as shown in Fig.7(b). Third confusing pair is “১” and “১” as shown in Fig.7(c). Therefore, error rate or rejection rate for these numerals is higher.

Fig. 7. Examples of some confused handwritten Bengali numeral pairs: (a) “০” and “০” (b) “১” and “১” (c) “১” and “১”.

## VI. CONCLUSIONS

In a recognition system the single most important issue is to ensure a good recognition rate. We have used PCA and SVM to enhance the recognition rate. In order to maximize the performance of numeral recognition, our proposed approach extracts four directional local feature vectors with the Kirsch masks and one global feature vector from a normalized input image. Hence, the important features are retained and the non-important pixels are minimized. The recognition result of our proposed approach outperforms the others. However, our proposed approach has extracted more significant features than the method applies normalized image to SVM. So it needs more time to estimate than that specific approach. But our method also works better with respect to recognition performance than the method for numeral recognition by neural network using back-propagation algorithm with and without momentum factor. As far as the recognition rate is concerned, it is experimentally shown that the recognition approach that we have proposed in this paper is superior to other conventional approaches.

**Abstract** — Script segmentation is an essential and preprocessing task for any OCR system. Bangla is one of the most popular scripts in the world. Since segmentation effects the recognition process, accurate and proper segmentation is necessary to implement Bangla OCR. Many works have been done for both handwritten and printed Bangla text. This paper presents the segmentation process of different bangla modifiers from printed bangla words.

**Index Terms** — Segmentation, Optical Character Recognition, Bangla Modifier.

## I. INTRODUCTION

The structure of bangla language is quite different than any other European language. It consists of 50 basic characters including 11 vowel and 39 consonant characters. Again, there are vowel and consonant modifiers, touching and compound characters which are formed by touching the adjacent characters and by combining 2 or more characters in the word accordingly. So when they are used to form words, we find that thousands of various combinations (both simple and complex) are formed. Segmentation of these complex parts are extremely difficult task. As a result, printed Bangla OCR still remains researchable.

Generally Bangla texts are divided into three zones namely upper zone, middle zone and lower zone [1], [2], [4], [6], [7]. Upper zone contains , , . Middle zone contains the basic character symbols and the lower zone contains the lower modifiers such as , , , etc. Detection of text line, matra line and base line [1], [2], [4], [6], [7] lead towards the character segmentation process. If one of the above three is ignored, it will generate many errors. So it is necessary to detect them accurately.

It is observed that Bangla words have different kinds of complexities like , , , , , , , , , , etc. Some works have been done to solve a few of above the problems such as , , , , , , [1], [2], [4], [6]-[8]. A, font size independent, more efficient technique is proposed in this paper, which can perfectly segment , , , , , , , , , .

## II. LITERATURE REVIEW

Segmentation of a Bangla document into lines, words and words into individual characters is an important and preprocessing task for Bangla OCR. The line segmentation of a document is solved by finding white pixels between two consecutive headlines [1], [2], [4]-[7]. Matra zone detection has been done with the approach that matra line will be that row which contains maximum no of black pixels than any other portion of the text [4], [6], [7] and considering multiple rows that defines matra zone [1], [3]. Baseline is detected by selecting that row which contains highest lowermost points of the components [1,3].

Word segmentation is done by finding some couple of 0 consecutive columns (white pixels) as a word delimiter [5], [6], or n (taken experimentally) consecutive 0 columns [3], or first two 0 consecutive columns [4] or the midpoint of a run of at least k consecutive 0 columns [1], [7].

The most difficult and important part is to segment the characters individually from the words. At first, the adjacent characters are separated by finding the 0 columns between them [1]-[5], [7]. But this process is not sufficient at all due to the problems of overlapping (multiple characters which do not touch each other but enter into the zone of each other like  (   )), touching and compound situations. Even the situation becomes more complex due to many peculiar patterns of the bangla characters and their placement in the word. Sometimes a character (  ) gets divided into sub portions in the character segmentation process and the problem is overcome by joining them to each other [1]. As there are many modifier, , ,  are segmented as matra upper portion character like , ,  [1], [4], [7] and , ,  are segmented after the detection of base line [1], [2], [4], [7] or considering the height, which exceeds the average size of the segmented characters [6],  is picked up as it makes a regular angle with the matra line [2] and  is picked up as it is not touching the matra line [2]. A piecewise linear scanning [1], [3], DFS (Depth First Search) [7], a combination of flood fill and boundary fill algorithm [4] were proposed when the characters overlap with other characters. In paper [2], they detect  when they find that the present

TABLE I

character size is greater than the regular size and apply the segmentation process.

### III. SEGMENTATION PROCESS

This is the most vital and important portion for designing an efficient Bangla OCR because character recognition process depends on this phase to make the recognition process successful. In this paper, the following steps are considered to do the segmentation with the existing techniques along with our approach. The steps are:

- A. Line Segmentation Process
- B. Baseline Detection Process
- C. Word Segmentation Process
- D. Character Segmentation Process
  - Words with only basic character
  - Words with modifier ি ি ি
    - . Segmentation of মি, টি, ঠি
    - . Segmentation of জী, চী, ঠী
    - . Segmentation of কী, ঠী, ঠী
  - Words With lower Modifier ৲, ৳, ৴

#### A. Line Segmentation Process

The lines of a text block are segmented by finding white pixels between two consecutive matra zone [1], [2], [4]-[7]. Fig: 1 shows the result.

(a)

(b)

Fig. 1. Text line detection process (a) full image, (b) result of text line detection

#### B. Baseline Detection Process

Base line is the row where the middle zone ends and lower modifier zone starts i.e. a separator between middle and lower zone. This is the row where an abrupt change occurs between the previous and next row [7]. Detection of base line is very important.

Fig. 2. Process of baseline detection

We proceed with the idea, shown in fig: 2, that there are small no of black pixels at the end portion of the middle zone and from there lower modified zone starts with increasing black pixels. So at first we detect L th row which denotes the lower position of the middle zone. Then we scan from L to end row to find where the black pixels start to increase. That row will be denoted here as the base line.

The difference between the end row and the base line is the lower modified zone. With this technique, sometimes the lower portion of the middle zone may enter into this zone. We can ignore them since they do not touch end row. Lower modifiers always touch end row. Table I compiles the various line detection capability of different works.

### C. Word Segmentation Process

Fig. 3. Process of word segmentation

There are always some white spaces between two words in a text line shown in fig: 3. Vertical scan is done ignoring the matra zone.

Fig. 4. Word with three 0 consecutive columns between two characters inside it

Sometimes it is also seen that some 0 consecutive columns are formed between two characters in a word shown in fig. 4. Most of the time it occurs when the matra less character is used in a word. If there is a white vertical column then it is treated as a gap between two characters in a word [2]. But this gap is not fixed and can increase with the increase of font size. So these issues require care during word segmentation. We try to solve it with the following technique.

During word segmentation, we start scanning vertically from start row to end row and keep the record of the width

of 0 consecutive columns for each line. Then we take the average of the total widths. If any width is less than half of average, then it is considered as a gap between two characters and easily ignored. Table II shows the capability of different papers considering the above problems.

TABLE II  
SUMMARY OF WORD SEGMENTATION

| Type              | Papers |   |   |   |   |   |               |
|-------------------|--------|---|---|---|---|---|---------------|
|                   | 1      | 2 | 3 | 4 | 5 | 6 | 7 Our process |
| Word segmentation | Y      |   | Y | Y | Y | Y | Y             |

### D. Character Segmentation Process

It is the most difficult and challenging part for building printed Bangla OCR. Many works have been done in order to segment the bangla characters from the words. Different problems are discussed below and some algorithms are made to solve them.

Fig. 5. Character segmentation

### Words with only basic character

The basic idea is that, under the lower boundary of the matra zone, the first black pixel column is fetched and is treated as a starting boundary and then a column of white pixel is searched. When it is found, it is treated as a separator from the next character [1]-[5], [7]. It is shown in fig: 5. The works that use this technique for character separation as well as ours are mentioned in Table III.

TABLE III  
SUMMARY OF WORDS WITH SINGLE CHARACTERS

| Simple | Papers |   |   |   |   |   |             |
|--------|--------|---|---|---|---|---|-------------|
|        | 1      | 2 | 3 | 4 | 5 | 7 | Our process |
| কলম    | Y      | Y | Y | Y | Y | Y | Y           |
| ঐষধ    | Y      | Y | Y | Y | Y | Y | Y           |

Some times this technique fails to segment the characters properly [1]-[7]. Extra care is needed to solve those problems. They are discussed below.

Words with modifier ি, ি, ি

Most of the previous works considered the segmentation of these modifiers as matra upper portion character. In our system মি, জী, টি, ঠি, টী, ঠী, কাঁ, টাঁ, ঠাঁ are segmented properly and efficiently keeping their original shape. The technique is given below.

1) In order to decide whether the current portion contains basic character or character with ি, ি, ি, the system finds first discontinuity point i, e. first white column. Then it searches in the top of the matra zone to get whether the same column contains black pixel or not. If it gets that column of black pixel, then it goes right to end and searches a column of white pixel in the matra upper zone. If gets that column, it searches for the same column contains white pixel under the matra zone. If it gets that column then it will be a basic character. Otherwise, along with not getting the column of white pixels in the matra upper zone, it will be the character with above modifiers.

2) Then the thickness of the characters x and y is determined shown in fig: 6.

Fig: 6. Determination of the thickness of each character in the syllable

3) If  $x < y$  then there exists ি. For ি, we will get the following situations. They are like মি, টি/ঠি etc. From the immediate upper row of the matra upper boundary we go right to fetch black pixel. After finding that we again go right to find white pixel. After getting that we continue to go to the same direction. During that time if there exist all 0 in that row, the system can understand that the character, which is under the matra zone, has no upper

part. If it is not, then the system can understand that the character has upper part.

a) For the first case, to separate ি it is picked up by removing the adjacent character and that adjacent character is picked up by removing ি. The result is shown below:

$$\text{মি} = \text{মি} + \text{মি}$$

(b) For later case, to separate ি, it is needed to detect whether it is টি or ঠি.

Fig: 7. Segmentation process of টি

At first, first black pixel is searched in the immediate upper row of the matra upper boundary from the end column to left. If it is found, then from the same column of the immediate lower row of the matra lower boundary, next searching is occurred, which lasts at the end column, for finding black pixels. If it is found then there is ঠ otherwise there will be টি[2]. Fig. 7 shows the following process.

i) Segmentation of টি: Form the start row we scan right to get the first black pixel and after getting that we start to pick up those. When we get the first white pixel i, e. 0, we pick up the rest of the image as 0. In this way we pick up the matra upper portion. Matra zone remains identical. Under the matra zone, the first character is picked up by removing the adjacent character. Then the remaining character is picked up from the upper part of matra zone by making the black pixels to white, which was unchanged during the previous one and the rest of the pixels remain unchanged. Under the matra zone, the second character is picked up by removing the previous character. Here, removing means making the 1(black pixel) to 0 (white pixel). But this is not actually done. The result is shown below.

$$\text{টি} = \text{মি} + \text{টি}$$

ii) Segmentation of ঠি: At first the thickness of upper portion of ঠি and a gap are calculated. The system counts the black pixels where the gap becomes zero. Then ঠি is separated by starting to find the start position where summation of the black pixels is greater than the thickness and removing the adjacent portions from the upper zone and as well as from the middle zone. ঠি is separated by picking up the thickness portion and the middle zone portion,

removing rest of the pixels. The result is shown below:

$$\text{ঐ} = \text{ি} + \text{ঔ}$$

4) If  $x > y$  then there exists ঐ or ঔ. For ঐ or ঔ we will get the following situations. They are like ঐ, ঔ, ঐ, ঔ etc. From the startrow if we find that the sum of the black pixels is greater than 3 then there will be ঐ and if not Then ঔ remains there. For the above technique, for ঐ, ঐ is detected as ঐ. We solve this problem later. In the case of জী, টী- From the startrow to half of the upper zone we calculate the maximum gap (no of sequence of 0s between two 1s) between the black pixels.

a) *Segmentation of জী* - If only one gap is found then the system can understand that, the basic character does not have upper part. Then to separate ঐ, it is picked up by removing the adjacent character and that adjacent character is picked up by removing ঐ. The result is shown below.

$$\text{জী} = \text{জ} + \text{ঐ}$$

b) *Segmentation of টী* - From the start row to the matra upper boundary the area is divided into two halves. In the upper half, the system starts from left to right to find the cutting point (the white column after getting the first black pixel). After getting that the rest of the pixels will be removed. This process will continue for this half. In the lower half the system stats from right to left to find the cutting point. The left pixels from the cutting point will remain same by removing others. In this way the upper portion of ট is detected and picked up with the matra zone and middle portion by removing the adjacent one. ঐ is segmented by keeping unchanged the right portion of the cutting point removing the left portion. This will continue to 1<sup>st</sup> half. The second half will remain identical. In this way the upper potion of ঐ is picked up with the matra zone and by removing adjacent characters of the middle portion. The result is shown below

$$\text{টী} = \text{ট} + \text{ঐ}$$

In the case of গী, কী, ণী, ঙী -- গী is isolated from by finding the gaps. There are 2 gaps in the immediate upper row of the matra upper boundary for গী where the others hold one.

c) *Segmentation of গী* - the thickness of the upper portion of ঙ is calculated. From start row, the system scans horizontally to search for black pixels. When the first one is found then the thickness is added with that black pixel's column position called thicknessColumn. Now the system goes left to right and keep the pixels same until it reaches to thicknessColumn making the rest of the pixels 0. In this way the upper potion of ঙ is picked up with the

matra zone and by removing adjacent characters of the middle portion. For ঐ, the system starts from left to right and if the gap is less than or equal to 1, the pixels will remain unchanged. Else the pixels will be zero to thicknessColumn. Then the rest of the pixels will remain unchanged. In this way the upper potion of ঐ is picked up with the matra zone and by removing adjacent characters of the middle portion. The result is shown below.

$$\text{গী} = \text{ঙ} + \text{ঐ}$$

d) *Segmentation of কী, ঙী* - This segmentation process is similar to the segmentation process of মি. The only difference is the process starts from the right side. The result is shown below.

$$\text{কী} = \text{ক} + \text{ঐ}, \text{ঙী} = \text{ঙ} + \text{ঐ}$$

e) *ণী* - the system starts from right to left and continue until the system get white pixel after getting the first black one i.e. cutting point making the rest of the left pixels 0. During this time if the cutting point less than the previous one the current point will be replaced by the previous one.

TABLE IV

SUMMARY OF ঐ, ঐ, ঐ SEGMENTATION

| Complex | Papers |   |   |   |   | Our process |
|---------|--------|---|---|---|---|-------------|
|         | 1      | 2 | 4 | 5 | 7 |             |
| আমি     |        | Y |   |   |   | Y           |
| ঢিয়া   |        | Y |   |   |   | Y           |
| জীব     |        | Y |   |   |   | Y           |
| টাকা    |        | Y |   |   |   | Y           |
| জেঠী    |        | Y |   |   |   | Y           |
| কোটা    |        |   |   |   |   | Y           |
| টা      |        |   |   |   |   | Y           |
| গী      |        |   |   |   |   | Y           |

In this way the upper portion of ট is detected and picked up with the matra zone and by removing adjacent characters of the middle portion. ঐ is picked up by going right to left to the cutting point removing the rest of the left pixels. In this way the upper potion of ঐ is picked up with the matra zone and by removing adjacent characters of the middle portion. The result is shown below.

$$\text{টী} = \text{ট} + \text{ঐ}$$

Table IV shows the result for different papers as well as ours.

Words With Lower Modifier ঐ, ঐ, ঐ

As they occur under the middle zone, they can be segmented properly after the successful detection of base

line [1], [2], [4], [7]. If the base line is not equal to end row of the text then the system can understand that there are lower modifiers. Then the system segments them by finding white pixels after finding first black pixels. Table V shows the use of this technique in different papers as well as ours.

TABLE V  
SUMMARY OF  SEGMENTATION

| Complex | Papers |   |   |   |   |   |             |
|---------|--------|---|---|---|---|---|-------------|

| সুখ     | Y      | Y | Y | Y |   | Y | Y           |
| কুল     | Y      | Y | Y | Y |   | Y | Y           |
| কুড়া   |        |   |   |   |   |   | Y           |
| গুন     | Y      | Y | Y | Y |   | Y | Y           |
| রুই/রুই |        |   |   |   |   |   | Y           |
| তুন     | Y      | Y | Y | Y |   | Y | Y           |

#### IV. CONCLUSION

This paper presents an approach to detect Baseline and a new algorithm to segment  in an intact shape i.e. by not separating the upper portions of them like . This algorithm is font size independent and matches best with Sutonny, karnaphuli, Rinkiy fonts etc. We didn't consider any noise in the textual image. We are working to develop segmentation algorithm to separate the overlapping, touching and compound characters.

# An Empirical Framework for Translating of Phrasal Verbs of English Sentence into Bangla

Mohammed Moshikul Hoque, Md Mokaddem Ahamad, Mohammad Shamsul Arefin, Md. Monjur-Ul-Hasan and Md. Gahangir Hossain

Dept. of Computer Science & Engineering, Chittagong University of Engineering & Technology (CUET), Chittagong-4349, Bangladesh

**Abstract:** Generally Phrasal verbs comprise a verb followed by a preposition that is commonly occurring feature in English. Each of the phrasal verbs acquires absolutely different meanings in different contexts. Having highly context dependent meanings, phrasal verbs may be disambiguated only by devising a technique involving utilization of semantic information pertaining to the context. This paper presented a framework for translating the Phrasal verbs in English sentence into its equivalent Bangla. Semantics is necessary in the field of natural language processing to detect the meaning of the individual words in the sentence. This paper also describes different types of semantic features that perform semantic based disambiguation of phrasal verbs. A translation engine works to find out the exact Bangla meaning of the Phrasal verb from different English sentences. We have tested our model for different type of English sentences containing phrasal verbs that are taken from the English newspaper and English textbook. We got successful results for most of the test cases.

**Index Terms:** Phrasal Verb, Semantic Features, Parse Tree, Example Base, Translation Engine.

## I. INTRODUCTION

Natural language is the most versatile communication medium of mankind. They contain infinite number of different words. Phrasal verbs are then a commonly occurring feature in English and comprise a verb followed by a preposition. Hence, translation of Phrasal verbs requires lexical analysis and syntactic analysis. There must be some semantic features included in the knowledge base for different types of Bangla words. Machine Translation (MT) of English text in terms of occurrence of phrasal verbs poses a great challenge and in case of English of Bangla, it becomes more challenging as not so many remarkable works have been done or seen in this field. The same phrasal verb acquires absolutely different meanings in different contexts. Moreover, no existence of phrasal verb is observed in the Bangla sentences and the Bangla meanings of these phrasal verbs are simply as verbs. Hence, it utmost important to separate the verbs and phrase in machine translation of English sentences to Bangla sentences. In the same way, the special semantics delivered by those phrasal verbs in different sentences should also be analyzed. For this reasons, machine translation of phrasal verbs from

English to Bangla claims importance in the field of natural language processing (NLP). Very few research activities have been done on the Bangla Language Processing and hence translation of Phrasal verbs from English to Bangla has not been done yet. An approach to classify the Phrasal verbs in the Danish language is used in SIMPLE system [1]. Disambiguation of Phrasal Verb form English to Hindi Machine Translation has been described in [2]. The transfer techniques for Bangla to English machine translation system through the transfer component the source language structures are translated into target language structures are focused [3]. An Example based Machine Translation System for translating News Headlines from English to Bengali is also developed [4]. Matrix representation of semantic features of Bangla words with redundancy rules is described in [5]. In Bangla, for semantic analysis we may use Bangla case analysis that is proposed to develop a smart conversation processor [6]. In this paper, we proposed a framework for translating of the occurrences Phrasal verbs in English sentences into its Bangla equivalent. We also find the semantic features of each word that constitutes the given input sentence and specify the exact Bangla meaning delivered by the phrasal verb used in the given sentence.

## II. SEMANTIC FEATURES OF THE ENGLISH WORDS

The features or characteristics that help to recognize a part of speech are known as semantic features [5]. In semantic analysis, many semantic features should be collected to easily identify the tokens.

### A. Noun

Noun is generally used as subject in simple assertive sentence. However, Noun acts both the role of the subject as well as the object in the sentence. Every verb is dependent fully on this subject [7]. To find out semantic features first we have to consider the physical appearance that can help us to easily recognize a noun or pronoun. As for example, “The Cow (গরু)” is noun, which has four legs, two ears, two horns, a tail. It has no wings, no hands and no intelligence [8]. So, “The Cow” comes as the subject of an English sentence, and then it must not read/write or fly in the sky. But as “The Bird (পাখি)” has wings it can fly in the sky. We know that bulb is inanimate and flammable, but inhuman and not

wearable. So, its semantic feature would be: *Bulb Inanimate (1), Flammable (1), Human (0), Wearable (0)*. Again, Noun and Pronoun is also used as the object in the sentence. The correct meaning of a phrasal verb in a sentence depends principally on the semantic feature of the object and the relation between the subject and object of that sentence. For instance, “the Bulb (বাতি)” is a noun of which job is to emit light (জ্বালা). Hence, being used in the sentence “I put on the light” as an object “the light” is going to be “switched on (জ্বালানো)”. Generally, noun in English sentence contains the following semantic features:

[Subject, Object, Animal, Human, Flammable, Wearable, Inanimate]

Although the above features are not completed for all kinds of noun but these are the most common features that can be used in semantic analysis. For some sentences, few features become more dominant than the other; symbolized by one (1) and the inapplicable features are symbolized by zero (0). Semantic features for some noun are shown in the Table I.

TABLE I:  
SEMANTIC FEATURES OF NOUN

| Word  | Semantic Features |        |           |          |         |           |
|-------|-------------------|--------|-----------|----------|---------|-----------|
|       | Human             | Animal | Inanimate | Wearable | Revolve | Flammable |
| Cow   | 0                 | 1      | 0         | 0        | 0       | 0         |
| Shirt | 0                 | 0      | 1         | 1        | 0       | 0         |
| Light | 0                 | 0      | 1         | 0        | 0       | 1         |
| Bulb  | 0                 | 0      | 1         | 0        | 0       | 0         |
| Rahim | 1                 | 0      | 0         | 0        | 0       | 0         |
| Boy   | 1                 | 0      | 0         | 0        | 0       | 0         |
| Fan   | 0                 | 0      | 1         | 0        | 1       | 0         |

#### B. Pronoun

In English sentences, pronoun is also used instead of noun in many situations. Actually, pronoun is the identifier of that noun. Pronoun comes as subject in the sentences generally. So it play vital role in semantic analysis. Generally, semantic features of pronoun are similar to that of noun. But there are also some extra features should be included for identifying pronoun [9]. Semantic features of some pronoun are given in the Table II.

TABLE II  
SEMANTIC FEATURES OF PRONOUN

| Word | Semantic Features |        |           |          |         |
|------|-------------------|--------|-----------|----------|---------|
|      | Human             | Animal | Inanimate | Imitable | Subject |
| I    | 1                 | 0      | 0         | 1        | 1       |
| You  | 1                 | 0      | 0         | 1        | 1       |
| He   | 1                 | 0      | 0         | 1        | 1       |
| They | 1                 | 0      | 0         | 1        | 1       |
| It   | 1                 | 1      | 1         | 0        | 1       |

#### C. Phrasal Verb

When a verb attached with a preposition or adverb, is used as an idiomatic sense, then it is called a Phrasal Verb [10]. The preposition attached with the verb is called as its particle. For example, many verbs take idiomatic senses by connected with their next prepositions. Such as, “I shall call on him” means “আমি তার সাথে দেখা করবো”. Here, “call on” means “দেখা করা”, which is a special meaning where as “call” & “on” individually has separate meanings. In this way, Example of commonly used phrasal verbs are call at, call on, come across, come by, put on, put off etc. The absolute meanings of these phrasal verbs depend on the category of the subject and the object of the sentence in which they are used. Some Phrasal verbs of English are presented in table III with their different possible meanings and Bangla equivalent respectively.

### III. PROPOSED TRANSLATION FRAMEWORK

The overall translating process can be depicted as in Fig. 1. This module can be able to translate the Phrasal verbs from English sentence to Bangla. Lexical analyzer will produce tokens of English words from the input sentence. The Tokens produced by the lexical analyzer are passed as input to the syntax analyzer. Syntax analyzer produces parse tree according to given grammatical rules and this parse tree acts as an input to the semantic analyzer. Semantic analyzer

TABLE III  
DIFFERENT BANGLA MEANINGS OF PHRASAL VERBS

| Phrasal Verb | English Meaning                                    | Equivalent Bangla Meaning                                                                                         |
|--------------|----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| Put on       | 1. Wear<br>2. Enkindle<br>3. Show<br>4. Switch on  | 1.Poridhan_kora (পরিধান করা)<br>2.Jaalaano (জ্বালানো)<br>3.Prodarshan_kora (প্রদর্শন করা)<br>4.Chaalaano (চালানো) |
| Run over     | 1. Occurring accident<br>2. Be overflow<br>3. Read | 1.Chaapaa_deya (চাপা দেয়া)<br>2.Upche_pora (উপচে পড়া)<br>3.Pora (পড়া)                                          |
| Take off     | 1. Put off<br>2. Take flight<br>3. Mock at         | 1.Khule_fela (খুলে ফেলা)<br>2.Uddoyon_kora (উড্ডয়ন করা)<br>3.Upohaash_kora (উপহাস করা)                           |
| Put off      | 1. Take off<br>2. extinguish                       | 1.Khule_fela (খুলে ফেলা)<br>2.Neevaano (নিভানো)                                                                   |
| Look up      | 1. Visit<br>2. Find out<br>3. Improvement          | 1.Dekha_kora (দেখা করা)<br>2.Khonja(উড্ডয়ন করা)<br>3.Unnoti_hoya(উনডুবতি হওয়া)                                  |
| Hold up      | 1. Keep up<br>2. Exposition<br>3. Stopped          | 1.Jaagiye_rakha (জাগিয়ে রাখা)<br>2.Jaahir_kora (জাহির করা)<br>3.Thamiye_rakha (থামিয়ে রাখা)                     |

produces annotated parse tree for analyzing the English sentences semantically. The example base contains the semantic information of English word with their possible Bangla meaning. Finally, the translation engine compares with the output of each node of the semantic analyzer with the example base. If translation engine find a match with semantic features of subject and object then gives the output of the equivalent meaning in Bangla. As for example, a sentence “*I put on cap*” is considered as input.

Fig 1: Translation process for translating Phrasal verbs.

#### A. Lexical Analysis

In this analysis, the stream of characters making up the sentence is read from left to right and grouped into token. A set of characters that have a collective meaning is called token. Actually, lexical analyzer separates each meaningful word in the sentence. Unfortunately, many words have several meanings and it may not be possible to choose the correct one just by looking at the word itself. To find out the correct meaning whole sentence should be looked up. And this reflects the semantic feature of machine translation. For example, the output of the lexical analyzer for the input sentence, “*I put on cap*”, is represented as: “*I*”, “*put*”, “*on*”, “*cap*”.

#### B. Syntactic Analysis

Syntactic analysis is the process of taking an input string of expressions and producing representation of kind. In Syntactic analysis, characters or tokens are grouped hierarchically into nested collections with collective meaning. It involves grouping of the tokens into grammatical phrases that are used as the input of semantic analyzer. Usually, a parse tree represents grammatical phrases of the sentence. A parse tree is a graphical representation of a sentence, which shows how the start symbol of a grammar derives the tokens or words in the sentence. Actually syntactic analysis is the process of determining if a string of tokens can be generated by a set of grammatical rules [11]. For the input sentence, “*I put on cap*”, the parse tree is shown as in Fig. 2.

Fig. 2. Parse tree for the sentence, “*I put on cap*”.

#### C. Semantic Analyzer

Semantics is concerned with the meaning of words and a word with semantic features is corresponding to their sense component. The job of the semantic analyzer is to collect the semantic features of the tokens generated by the Lexical analyzer or of the nodes of the parse tree generated by the syntactic analyzer. It also generates the semantic tree i.e. the annotated parse tree. It is a parse tree with semantic features and attributes. The annotated parse tree with semantic features of the input sentence, “*I put on cap*” is shown in Fig. 3. In the Fig. 3, the annotated parse tree of

Fig. 3. Annotated parse tree for the sentence, “*I put on cap*”.

the input sentence “*I put on cap*” have been described for detection of phrasal verbs and execution of the semantic features of subject and object. Semantic features of the nouns and pronouns used here are represented as follows:

*I*: [Human(1), Subject(1), Pronoun(1)] *Cap*: [Inanimate(1), Wearable(1), Object(1), Noun(1)]

From the Fig .3. it can easily be noticed that subject “*I*” is a human and object “*cap*” is an inanimate and wearable thing. And there remains a phrasal verb “*put on*”.

#### D. Example-Base

Example-base contains the semantic information of different types of English word. The example base entries incorporate information about context, form and semantics. All possible meaning in different context is stored in the example base. Example base also contains the different possible meanings of Phrasal verb in different context with their equivalent Bangla. Table IV shows the different Bangla meanings of the phrasal verb “*put on*” for four different semantic features of subject and object in the input sentences.

TABLE IV  
DIFFERENT BANGLA MEANING OF PHRASAL VERB, **PUT ON** WITH DIFFERENT SUBJECT AND OBJECT.

| Input Sentence                 | Semantic feature of Subject    | Semantic feature of Object                  | Equivalent Bangla Meaning      |
|--------------------------------|--------------------------------|---------------------------------------------|--------------------------------|
| I <b>put on</b> cap            | I: [Human, Subject, Pronoun]   | Cap: [Inanimate, Object, Noun, Wearable]    | Poridhan_kora (পরিধান করা)     |
| You <b>put on</b> the light    | You: [Human, Subject, Pronoun] | Light: [Inanimate, Object, Noun, Flammable] | Jaalaano (জ্বালানো)            |
| The boys <b>put on</b> a drama | Boy: [Human, Subject, Noun]    | Drama : [Inanimate, Object, Noun, Showable] | Prodorshon_kora (প্রদর্শন করা) |
| He <b>put on</b> the fan       | He: [Human, Subject, Pronoun]  | Fan: [Inanimate, Object, Noun, Revolvable]  | Chaalaaano (চালানো)            |

#### E. Translation Engine

After generating the parse tree and annotated parse tree with semantic features of the input sentence, the translation engine translates the Phrasal verb from English to Bangla. The translation process may be describes as follows:

1. The semantic analyzer gives the annotated parse tree with semantic information of each node including subject and object of the input sentence.
2. The example base contains the several possible meanings of phrasal verbs with semantic features. Example base also contains the semantic features of the subject and object of the input sentence respectively.
3. Identify the Phrasal verb of the input sentence. Generally, a verb followed by a preposition is assigned to a Phrasal verb.
4. The machine compares the semantic features of subject and object of the input sentence with the example base.
5. Search the possible meaning of the Phrasal verb. If the semantic information of each node is matched.
6. With the example base then the equivalent Bangla meaning of that Phrasal verb is found.
7. Else machine shows 'No meaning'.

#### IV. EXPERIMENTAL RESULTS AND DISCUSSION

We have tested our proposed engine for about 1000 sentences with different word length. The length of the sentences generally varies from three to seven words. All the sentences contained the different Phrasal verbs in different contexts. Most of the examples have been taken from the English newspapers, journal and text books. Translation snapshot of the English phrasal verb “put on” that have different meanings in different context have been represented in Table V as an example. From the Table, we have seen that the proposed module can be able to translate the phrasal verbs of English sentence into its Bangla equivalent successfully. The proposed system may be extended and hence the overall performance of the system will be improved by incorporating with more constituent parts to the existing system.

#### A. Performance Evaluation

The module is able to translate the phrasal verbs with good accuracy. Table VI shows the number of successful and unsuccessful translation of sample sentences as well as the translation rate and error.

TABLE VI  
SUCCESS RATE OF THE PROPOSED TRANSLATION MODULE

| Length of Sentence (No. of words) | No. of Sentences | Successful Translation | Unsuccessful Translation | Translation Rate (%) | Translation Error (%) |
|-----------------------------------|------------------|------------------------|--------------------------|----------------------|-----------------------|
| 3                                 | 150              | 120                    | 30                       | 80%                  | 20%                   |
| 4                                 | 300              | 280                    | 20                       | 93.33%               | 6.67%                 |
| 5                                 | 250              | 240                    | 10                       | 96%                  | 4%                    |
| 6                                 | 200              | 120                    | 80                       | 60%                  | 40%                   |
| 7                                 | 100              | 20                     | 80                       | 20%                  | 80%                   |
| <b>Total</b>                      | <b>1000</b>      | <b>780</b>             | <b>220</b>               | <b>79%</b>           | <b>21%</b>            |

From the Table VI it is observed that translation rate is very high for the sentences having four and five words individually. For three-word sentences, the rate is satisfactory i.e. eighty percent. Fig. 4 represents the translation accuracy and error rate versus word lengths of the system. From three to five words, translation accuracy increase moderately while accuracy starts decreasing with the increase of the length of the sentences from five words and even for seven-word sentences it is only twenty percent. On the other hand, there is a gradual rise in error rates with the number of word lengths.

Fig. 4. Word Vs Translation Rate & Translation Error Rate

**TABLE V**  
**EXAMPLE TRANSLATION FOR THE PHRASAL VERB, “PUT ON”**

|                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                                                                                                                                                                                                                                                                                                     |

## V. FUTURE POSSIBILITIES

There are lots of research scopes of this paper on the field of Bangla NLP. The possible future improvements are mentioned in the following:

- The disambiguation module can be incorporated into the front-end of an existing MT system.
- The example base may be extended incorporating more semantic features for long sentences.
- Translation of Phrasal verbs in English complex and compound sentences may be carried on.
- Another component pertaining to prepositional phrases can be incorporated in the example base.
- Compositional semantics features may be used to identify the English words.
- For disambiguated meaning the concept of neural networks may be employed.

## VI. CONCLUSION

Phrasal verbs have highly context-dependent meanings and may be disambiguated only by devising a technique involving utilization of semantic information pertaining to the context. The machine translation of Phrasal verbs of English into Bangla becomes more difficult and challenging tasks because English and Bangla are widely different in structure and style. The semantic interpretation is the most difficult stage of transformation process. For unambiguous analysis or generation, semantic properties of each word of a sentence must be taken into account for actual translation. For accurate machine translation from Bangla to English or vice versa, semantic features of Bangla words should be structured. Their interpretation may require the use of heuristics, syntactic and semantic constraints, inference, and other forms of object analysis within the discourse content. The proposed framework gives the very high accuracy with the simple assertive sentence for three to five word lengths but the accuracy is degraded for a sentence of long phrase structure with Phrasal verb. If more semantic features are employed with the existing features then the performance of the system will be improved.

**Abstract** — In this paper, a Bangla mobile keypad layout is proposed based on ergonomics. The finger movement across the keypad is analyzed and an optimal keypad layout is proposed for right handed one thumb operation. To minimize the effort of the user's thumb movement, the characters are organized in such a way that the most frequently used characters are positioned in the most comfortable zone of the keypad. A couple of equations are derived to calculate the required time to insert a character in different existing layouts. The performance is analyzed by comparing time which reveals that the proposed layout outperforms the other layouts.

**Index Terms** — Bangla Characters, Bangla, Ergonomics, Mobile keypad, Mobile phone.

## I. INTRODUCTION

Minimizing the time to insert Bangla text in a mobile handset is a challenge to researchers because in Bangla script there are huge number of characters and joint characters. It is even more difficult to accommodate all the characters in a mobile keypad of only 12 buttons. Mobile phone manufacturer used the concept of English sequential keypad layout to introduce Bangla in mobile phones [1], [2], [3] which is not feasible. A frequency based multi-tap keypad layout is also proposed in [4]. Another keypad layout is proposed based on phonetics [5]. All of the designs require more keystrokes and effort to insert Bangla character. To reduce time to write Bangla using mobile keypad one has to consider human factor, Bangla joint character formation and Bangla character frequency. In this paper an innovative approach is considered to propose a Bangla keypad layout where character frequency and user comfort is taken into account and this fulfills all of the above criteria.

## II. ANALYSIS OF MOBILE KEYPAD

The main difficulty to introduce Bangla characters to mobile keypad is that it has to accommodate a large number of characters onto a keypad consisting only 12

keys. To perform this task a number of keypad layouts have been proposed.

### A. The English Keypad

The English keypad is designed using sequential ordering of English characters. So user can easily memorize the position of the characters. To position the characters sequentially the character frequency is not considered.

### B. The common Bangla keypad based on character sequence

The most common Bangla keypad is designed based on the alphabet ordering (Like English). The layout of a typical Bangla keypad used by the mobile phone manufacturer [1]-[3] is given in Table I.

TABLE I  
COMMON BANGLA LAYOUT

|                      |                       |                           |
|----------------------|-----------------------|---------------------------|
| 1<br>Punctuation key | 2<br>ক খ গ ঘ ঙ ১      | 3<br>চ ছ জ ঝ ঞ ২          |
| 4<br>ট ঠ ড ঢ ণ ৩     | 5<br>ত থ দ ধ ন ৪      | 6<br>প ফ ব ভ ম ৫          |
| 7<br>য র ও ল শ ষ স ৬ | 8<br>হ ড় ফ় র় ৭ ৪ ৭ | 9<br>অ ই দ্বি উ ঊ ঋ ঌ ঐ ৮ |
| *<br>† ৿ ৺ ৻ ৼ ৽ ৾ ৿ | 0<br>special symbol   | #<br>joint character      |

It is a very simple layout and there is no complicated using procedure. So the user may feel comfort with this layout. In this layout, many keystrokes are needed for vowels and short vowels because one key is used to represent each group. Each key is used to represent up to eleven characters which is very inefficient. There is no mode change key or any shift key which can easily decrease the key-tapping. Joint characters also consume more time in this design. The keypad is not based on ergonomics.

option of doing the same thing by pressing the special symbol key (# key). It reduces user's burden from memorizing difficult formation of joint characters. As it is an alternative feature, it placed in the least comfortable zone.

6) Other characters are placed following the sequence of Bangla alphabet.

7) The Mobile keypad is too small to draw many characters on it. Using sequential character positioning, several characters are shown using only two characters. For example, the characters ক, খ, গ, ঘ, ঙ can be shown as ক - ঙ .

#### B. Bangla typing procedure

The Bangla typing procedure in the proposed layout is explained with some examples. To write 'ক্ষা', the joint consonant ক্ষ (ক্ষ = ক + খ) can be entered using two ways. Firstly, user has to press key-2 once then press 'Mode' key to change mode from normal to extended, then press key-9 five times. The 'Mode' key automatically switches to normal mode after inserting the joint character. Secondly, user can also insert the joint consonant using 'Special' key (# key) several times. To insert 'খ' user has to press key-8 five times. To insert 'ব' he has to press 'Mode' key once to switch to extended mode and has to press key-4 once. The 'Mode' key automatically switches to normal mode after inserting short vowel. Another example, to insert 'বুক্ষ' one has to press key-9 once, 'Mode' key once, key-4 four times, then key-2 once, 'Mode' key once and finally key-6 once.

#### IV. PERFORMANCE ANALYSIS

In this paper, a couple of equations are derived to calculate the time required to enter a character in mobile

phone. The performance of the proposed layout is analyzed by comparing the time. In the following equations  $T_s$ ,  $T_p$ , and  $T_e$  represent total time to insert character in sequential, phonetic and ergonomic layout respectively.

$$T_s = t_a + c * (t_i * n_r) \quad (1)$$

$$T_p = (t_a + t_i) * s + (t_a + c * (t_i * n_r)) + (t_a + t_i) * l \quad (2)$$

$$T_e = (t_a + t_i) * m + (t_a + c * (t_i * n_r)) \quad (3)$$

In (1), (2) and (3), the following notations are adopted:

|       |                                                                                  |
|-------|----------------------------------------------------------------------------------|
| $t_a$ | average time required to bring the finger to desired key                         |
| $t_i$ | time interval between consecutive keystrokes to search a character in a same key |
| $n_r$ | number of key repressing                                                         |
| $c$   | Comfort factor                                                                   |
| $m$   | mode variable                                                                    |
| $l$   | link variable                                                                    |
| $s$   | shift variable                                                                   |

The value of  $m$ ,  $l$  and  $s$  is equal to 1 when these keys are pressed and otherwise 0. The value of  $c$  depends on the comfort zones. The different values of  $c$  are as follows,

|                        |            |
|------------------------|------------|
| Most comfort zone      | $c = 0.75$ |
| Medium comfort zone    | $c = 0.90$ |
| Least comfortable zone | $c = 1.00$ |

TABLE III  
REQUIRED TIME TO INSERT VOWELS AND SHORT VOWELS

| Character | Phonetics | Sequence | Ergonomics | Character | Phonetics | Sequence | Ergonomics |
|-----------|-----------|----------|------------|-----------|-----------|----------|------------|
| অ         | 1.525     | 0.8      | 0.725      | ই         | 0.725     | 0.725    | 1.525      |
| আ         | 0.725     | 1.525    | 0.95       | ঈ         | 0.95      | 0.95     | 1.75       |
| ই         | 1.175     | 1.1      | 1.175      | ঊ         | 1.175     | 1.175    | 1.975      |
| ঈ         | 1.875     | 1.4      | 1.4        | ঋ         | 1.4       | 1.4      | 2.2        |
| উ         | 1.04      | 1.7      | 1.615      | ঌ         | 1.615     | 1.615    | 2.425      |
| ঊ         | 1.84      | 2.0      | 1.85       | ঍         | 1.85      | 2.525    | 1.525      |
| ঋ         | 1.875     | 2.3      | 0.725      | ঔ         | 2.075     | 1.85     | 1.75       |
| এ         | 1.04      | 2.6      | 0.95       | ও         | 2.3       | 2.075    | 1.975      |
| ঐ         | 1.84      | 2.9      | 1.175      | ঔ         | 2.525     | 2.3      | 2.2        |
| ও         | 1.31      | 3.2      | 1.4        |           |           |          |            |
| ঔ         | 2.11      | 3.5      | 1.615      |           |           |          |            |

If  $t_a = 0.5$  sec and  $t_i = 0.3$  sec, then the time required to insert vowels and short vowels are listed in Table III. These are arbitrary value. As we are only interested to compare between layouts, any arbitrary value according to finger movement is suitable for it.

Fig. 3 illustrates a performance comparison between phonetics, sequential and ergonomics based Bangla keypad layout. Among the 11 vowels, 7 of them need less time in comparison with phonetics and sequential layout. And among 9 short vowels, inserting 4 short vowels need less time than other keypad layouts. As vowels and short vowels are most frequently used characters [6], [7], ergonomics based keypad shows better performance than others. 20 out of 39 consonants require less time than other keypads. Table IV shows the time required to insert consonants in different

layouts. Table V shows some joint characters where ergonomic keypad performs the best.

Fig. 3. Required time comparison between different layout

| খ         | 4.31     |                                                                  | 4.23      |
| গ         | 2.495    |                                                                  | 2.295     |
| ঘ         | 3.62     |                                                                  | 3.05      |
| ঙ         | 3.61     |                                                                  | 2.6       |
| চ         | 3.2      |                                                                  | 2.25      |
| ছ         | 3.6      |                                                                  | 3.025     |
| জ         | 4.17     |                                                                  | 4.65      |

Table VI shows a number of examples which clearly states that the proposed ergonomics based layout outperforms the other two layouts.

TABLE VI  
PERFORMANCE COMPARISON WITH DIFFERENT WORDS

| Words    | Phonetics | Sequence | Ergonomics |
|----------|-----------|----------|------------|
| বাংলাদেশ | 10.935    | 9.655    | 9.91       |
| ঐশ্বর্য  | 5.79      | 6.525    | 5.015      |
| ঋণ       | 23.715    | 3.925    | 2.35       |
| ঈদ       | 3.185     | 2.525    | 2.525      |
| এখন      | 3.83      | 5.175    | 3.525      |

#### IV. CONCLUSION

Efficiency of the keypad can be increased by reordering Bangla vowels and short vowels according to character frequency and comfortable zone. The performance analysis and examples prove that the ergonomics based keypad layout significantly outperforms the phonetics and sequential layouts. In ergonomics layout, 7 out of 11 vowels, 4 out of 9 short vowels and 20 out of 39 consonants require less time than other two layouts because of the placements of the most frequently used characters in the most comfortable zone. The proposed layout performs better than the existing layouts and represents a good solution for Bangla typing in mobile phone.

**Abstract**—This paper presents an approach to detect an abnormal situation in a crowd scene. The proposed approach estimates sudden changes and abnormal motion variations in a set of interest points. The number of tracked points of interest is reduced by using a mask that corresponds to the hot areas of the built motion heat map. Optical flow technique tracks the points of interest. There are sufficient variations in the optical flow patterns in a crowd scene when there are cases those showing abnormal situations. Statistical treatment of optical flow information has been thresholded. To demonstrate the interest of this approach, we present the results based on the detection of collapsing events in real videos of airport escalator exits.

**Index Terms**—Points of interest, Motion heat map, Optical flow, Entropy, Breakdown situation, Escalator exits.

## I. INTRODUCTION

Escalators, are often installed in pairs, are the mechanized moving stairways, can frequently be seen in airports, shopping malls, cinema halls, museums, hospitals, hotels, multi-story parking garages, train stations, subway stations, or other public and private places. Escalator-related injuries occur infrequently but may result in significant trauma. To evaluate the effect of the safety rules and passenger education, authors in [1] studied escalator-related injury patterns occurring at Taipei Metro Rapid Transit (MRT) stations. In 2000, the accident rate for escalator riding was about 0.815 accidents per million passenger trips through MRT heavy capacity stations. However, their study reported that the majority of escalator injuries were caused by passengers trying to perform other tasks while riding, loss of balance, not holding the handrail, or riders who were struck by other passengers. Automatic video surveillance systems would benefit from a system capable of observing people as well as other moving and interacting objects in a given environment (e.g., escalator in airport, supermarket, subway, etc.) for patterns of normal or abnormal activities, interesting events, and other domain-specific goals.

We will demonstrate an approach which is characterized by optical flow patterns of human behaviours followed by some statistical treatments to detect abnormalities in crowd scenes. We set out by performing a calculation of a motion heat map during a period of time to extract the main regions of motion activity. The use of heat map image improves the quality of the results and reduces processing time which is a great consequence for real-time applications. Points of interest are extracted in the hot regions of the scene. Optical flow is computed on these points of interest, marked off the boundaries by the hot areas of the scene. The optical flow information from video presents

the crowd multi-modal behaviors as optical flow patterns make different in time. There is sufficient agitation in the optical flow pattern in the crowd in case of abnormal and/or emergencies situations (see Fig. 3 (c)). Variations of motions are estimated to make a distinction in favor of potential abnormal events. We consider that we are in a crowd environment with no restrictions of the number of people. To analyze the optical flow patterns of human crowds scenes, we have concentrated on escalator videos to use in our applications. One practical application of our approach is in the detection of real-time collapsing events, which could lead to potentially full of danger or risk situations in exit escalators. The videos used are from camera installed at an airport to monitor the situation of escalator exits. The impression of the application is to have exit escalators continuously perceived to respond rapidly in the event of any collapsing (breakdown). With this aim, cameras are installed in front of the exit locations to view and dispatch the video signal to a control room. In the control room consecrated employees can oversee, take control, and react favorably to a breakdown under the circumstances of an anomalous and/or emergency.

In the remaining parts of the paper, we will start by presenting some related works in Section 2. In Section 3, we will confer our proposed approach. In Section 4, we will discuss the experimental results. Finally, Section 5 presents the conclusion with few clues for further investigation.

## II. RELATED WORKS

We classify the related works into two groups namely *estimation of crowd density* and *aberrant episode detection*.

*Estimation of crowd density*: The methods applied [2], [3], [4], [5] are based on textures and motion area ratio and make an interesting static analysis for crowd surveillance, otherwise than detect abnormal situations.

*Aberrant episode detection*: These works detect irregular events in crowd flows. The general approach consists of modeling normal behaviours, and then estimating the deviant behaviour or attitudes between the normal behaviour model and the observed behaviours. Those deviations are labeled as abnormal. The determining characteristic of the general approach is to exploit the fact that data of standard behaviours are generally available, and data of abnormal behaviours are reasonably less available. For this reason, the divergences from examples of standard behaviours are used to distinguish as the characteristic of abnormality. In this category, authors in [6] encoded optical flow features with Hidden Markov Models (HMM). They used a local modelling

approach to increase the detection sensitivity. The same authors in their another approach [7], where they also used HMM, characterised crowd behaviour by observing the crowd optical flow and used unsupervised feature extraction to encode normal crowd behaviour. The unsupervised feature extraction applied spectral clustering to find the optimal number of models to represent normal motion patterns. The aim of both of their methods is to detect emergency or abnormal events in the crowd. The methods were experimented with simulated data. Authors in [8] proposed a mathematical method based on Lagrangian particle dynamics for crowd flow segmentation and flow instability detection. The method is efficient for segmentation of high density crowd flows (marathons, political events, etc.). Authors in [9] formulated the problem of detecting regularities and irregularities as the problem of composing (explaining) the new observed visual data using spatiotemporal patches extracted from previous visual examples. In the same category, but for low crowded scenes, authors in [10] proposed a visual monitoring system that passively observes moving objects in a site and learns patterns activity from those observations, detect of unusual events in the site that do not fit common patterns using a hierarchical classification.

Our approach contributes to the second category of related works, with succeeding specificities: (i) it considers simultaneously density (motion area ratio) and direction, whereas the previous works methods these factors do not take into account together; (ii) without imposing a restriction of the number of people in the crowd, it detects all events where the variations are important as compared to previous events; (iii) it uses a mask to define a region of interest. This mask is obtained from the hot areas of the motion heat map image. Consequently, useless to analyze the whole scene particularly where there are few motion intensities or no motions. So, it is arousing the attention for real-time applications.

### III. PROPOSED APPROACH

This section shows a flow diagram (see Fig. 1) of the intended approach followed by blow-by-blow implementation procedures.

Fig. 1. Block diagram of the proposed framework

#### A. Motion heat map

A heat map is a graphical representation of data where the values taken by a variable in a two-dimensional (2D) map are represented as colours. Motion heat map is a 2D histogram expressing briefly the most important regions of motion activity.

This histogram is built from the accumulation of binary blobs of moving objects, which were extracted following background subtraction method [11]. Assume symbols  $H$  and  $I$  indicate *heat map* and *intensity* respectively. The  $H$  is defined as:

$$H_n(i, j) = H_{n-1}(i, j) + I_n(i, j) \quad (1)$$

$$H_0 = I_0(i, j) \quad (2)$$

where  $n$  is the frame number ( $n \geq 1$ ), and  $i$  &  $j$  are the coordinates (line and column) of the pixel  $(i, j)$  of a frame. The obtained map is used as a mask to define the *region of interest* for the next step of the method. Figure 2 makes noticeable an occurrence of the obtained heat map from an escalator camera view. The use of heat map ameliorates the quality of the results and reduces processing time which is an important factor for real-time applications. The results are more significant when the video duration is long. In practice, even for the same place, the properties of abnormal events may vary depending on the context (day-night, indoor-outdoor, normal-peak time, occasion, vacation, etc.). We build a motion heat map for each set of conditions.

### B. Points of interest extraction

Moravec's corner detector [12] is a relatively simple algorithm that was used by Moravec and others, but is now commonly considered out-of-date. It is not rotationally invariant (a property prevalent even in more modern corner detectors) as the response is anisotropic (not invariant with respect to direction), is considered to have a noise response, and is susceptible to reporting false corners along edges and at isolated pixels so is sensitive to noise. Nevertheless, it is computationally efficient which was critical for Moravec as he was interested in a real-time application and had minimal computational power at his disposal. The other way around the Harris corner detector [13] is computationally demanding, but directly addresses many of the limitations of the Moravec corner detector. In our approach, we consider Harris corner as a point of interest. The Harris corner detector is a famous point of interest detector due to its strong invariance to rotation, scale, illumination variation, and image noise [14]. It is based on the local auto-correlation function of a signal, where the local auto-correlation function measures the local changes of the signal with patches shifted by a small amount in different directions. Assume a point  $(x, y)$  and a shift  $(\Delta x, \Delta y)$ , then the local auto-correlation function is defined as:

$$c(x, y) = \Sigma_w [I(x_i, y_i) - I(x_i + \Delta x, y_i + \Delta y)]^2 \quad (3)$$

where  $I(\cdot, \cdot)$  denotes the image function and  $(x_i, y_i)$  are the points in the smooth circular window  $w$  centered on  $(x, y)$ . The shifted image is approximated by a Taylor expansion truncated to the first order terms as:

$$I(x_i + \Delta x, y_i + \Delta y) \approx I(x_i, y_i) + [I_x(x_i, y_i)I_y(x_i, y_i)] \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix} \quad (4)$$

where  $I_x(\cdot, \cdot)$  and  $I_y(\cdot, \cdot)$  denote the partial derivatives in  $x$  and  $y$ , respectively. Substituting the right hand site of Eq. 4 into Eq. 3 yields:

$$c(x, y) = \Sigma_w ( [I(x_i, y_i)I_y(x_i, y_i)] \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix} )^2 \quad (5)$$

$$= [\Delta x \Delta y] M(x, y) \begin{bmatrix} \Delta x \\ \Delta y \end{bmatrix} \quad (6)$$

where  $M(x, y) =$

$$\begin{pmatrix} \Sigma_w (I_x(x_i, y_i))^2 & \Sigma_w I_x(x_i, y_i)I_y(x_i, y_i) \\ \Sigma_w I_x(x_i, y_i)I_y(x_i, y_i) & \Sigma_w (I_y(x_i, y_i))^2 \end{pmatrix}. \quad (7)$$

The  $2 \times 2$  symmetric matrix  $M(x, y)$  captures the intensity structure of the local neighborhood. Let  $\lambda_1$  and  $\lambda_2$  are the eigenvalues of matrix  $M(x, y)$ . The eigenvalues form a rotationally invariant description. There are three cases to be considered [13]:

- **No point of interest is found:** If both  $\lambda_1$  &  $\lambda_2$  are small, so that the local auto-correlation function is flat, i.e., little change in  $c(x, y)$  in any direction, then the windowed image region is of approximately constant intensity.
- **An edge is found:** If one eigenvalue is high and the other is low, so the local auto-correlation function is rigid shaped, then only shifts along the ridge (i.e., along the edge) cause little change in  $c(x, y)$  and significant change in the orthogonal direction.

- **A point of interest is found:** If both  $\lambda_1$  &  $\lambda_2$  are high, so the local auto-correlation function is sharply peaked, then shifts in any direction results in a significant increase in  $c(x, y)$ .

Figure 3 (a) discloses an example of Harris corner detector. We consider that in video surveillance scenes, camera positions, and lighting conditions allow to get a large number of corner features that can be easily captured and tracked.

### C. Optical flow computation

Optical flow techniques are based on the idea that for most points in the image, neighboring points have approximately the same brightness. To calculate the optical flow between successive video frames the well known combination of feature selection as introduced by Shi and Tomasi [15] and the algorithm of Lucas and Kanade for feature tracking [16] is used. Feature selection finds image blocks which are believed to allow the exact estimation of optical flow translation vector. The Shi-Tomasi algorithm makes use of the smallest eigenvalues of an image block as criterion to ensure the selection of features which can be tracked reliably by the Lucas-Kanade tracking algorithm. This algorithm matches the selected image blocks with blocks in the next frame using an efficient gradient descent technique. A pyramidal implementation of this algorithm is used to deal with larger feature displacements by avoiding local minima in a coarse to fine approach [17]. This combination has proven to allow fast and reliable computation of optical flow information [18], [19]. Once we define the points of interest, we track those points over the next frames using the combination feature tracker. Upon matching points of interest (features) between frames, the result is a set of vectors:

$$V = \{V_1 \dots V_N | V_i = (X_i, Y_i, D_i, \theta_i)\}$$

where  $X_i \mapsto X$  coordinate of the feature  $i$ ,  $Y_i \mapsto Y$  coordinate of the feature  $i$ ,  $D_i \mapsto$  distance between the feature  $i$  in the frame  $f$  and its matched feature in frame  $f + 1$ ,  $\theta_i \mapsto$  direction of motion of the feature  $i$ . Images in figure 3 (b) and (c) give evidence of the set of vectors obtained by optical flow features tracking in two different situations. The image in 3 (b) divulges an orderly vector flow. The image in 3 (c) substantiates a littered vector flow due to the breakdown situation.

*a) Calculation of  $D_i$ :* Figure 4 illustrates the feature  $i$  in the frame  $f$  with its coordinate  $P(X_i, Y_i)$  and its matched in the frame  $f + 1$  with coordinate  $Q(X_i, Y_i)$ . We can easily calculate the Euclidean distance between  $P(X_i, Y_i)$  and  $Q(X_i, Y_i)$  using Euclidean metric as:

$$D_i = \sqrt{(Q_{X_i} - P_{X_i})^2 + (Q_{Y_i} - P_{Y_i})^2}. \quad (8)$$

*b) Calculation of  $\theta_i$ :* The direction of motion ( $\theta_m$ ) of the feature  $i$  can be calculated using the following trigonometric function:

$$\theta_m = \text{atan}\left(\frac{y_i}{x_i}\right) \quad (9)$$

where  $x_i = Q_{X_i} - P_{X_i}$  and  $y_i = Q_{Y_i} - P_{Y_i}$ . But there are several potential problems if we have a desire to calculate motion direction using Eq. 9, e.g., out of phase, generation

(a)

(b)

(c)

Fig. 3. White points in (a) portray Harris point of interest. Red arrows are optical vector flows: (b) and (c) limn standard and aberrant situations in precisely the given order.

Fig. 4. Cardinal point of the state of change of any feature  $i$ .

of exceptions, etc. To avoid these problems, we apply the  $atan2(y_i, x_i)$  function which takes both  $x_i$  and  $y_i$  as arguments. Henceforth, the accurate direction of motion ( $\theta_i$ ) of the feature  $i$  can be calculated as:

$$\theta_i = atan2(y_i, x_i) = \begin{cases} \phi \cdot \text{sign}(y_i) & \text{if } x_i > 0, y_i \neq 0 \\ 0 & \text{if } x_i > 0, y_i = 0 \\ \frac{\pi}{2} \cdot \text{sign}(y_i) & \text{if } x_i = 0, y_i \neq 0 \\ \text{undefined} & \text{if } x_i = 0, y_i = 0 \\ (\pi - \phi) \cdot \text{sign}(y_i) & \text{if } x_i < 0, y_i \neq 0 \\ \pi & \text{if } x_i < 0, y_i = 0 \end{cases}$$

where  $\phi$  is the angle in  $[0, \pi/2]$  such that  $\phi = atan(|\frac{y_i}{x_i}|)$ . The sign function  $\text{sign}(y_i)$  can be defined as:

$$\text{sign}(y_i) = \begin{cases} -1 & \text{if } y_i < 0 \\ 0 & \text{if } y_i = 0 \\ 1 & \text{if } y_i > 0 \end{cases}$$

As a consequence the function  $atan2(y, x)$  gracefully handles infinite slope, and places the angle in the correct quadrant [for instances:  $atan2(0, 3) = 0$ ,  $atan2(0, -3) = \pi$ ,  $atan2(3, 3) = \pi/4$ ,  $atan2(-3, -3) = -3\pi/4$ , and so forth].

#### D. Statistical treatment of optical flow information

1) *Motion Area Ratio*: In each video frame, the motion area ratio ( $M_R$ ) estimates the ratio between the number of blocks containing motion and the total number of defined blocks. In crowded scenes the area covered by the moving blobs is important as compared to uncrowded scenes. We can use this measure as a density estimator. To estimate  $M_R$ , we divide each video frame into  $N \times M$  blocks, where  $N$  and  $M$  are number of columns and rows respectively. For any block  $(i, j)$ , we define the moving block by means of:

$$\text{movingblock}(i, j) = \begin{cases} 1; & \text{if movement exists} \\ 0; & \text{otherwise} \end{cases}$$

If there are several movements exist in one block, then that block will be enumerated as one moving block. We count out the total number of moving blocks to define  $M_R$  as:

$$M_R = \frac{\sum_{i=1}^N \sum_{j=1}^M \text{movingblock}(i, j)}{N \times M}. \quad (10)$$

2) *Direction Variance-Mean Ratio*: To estimate direction variance ( $\theta_V$ ), it is important to estimate the mean direction  $\bar{\theta}$  of the optical flow vectors in each video frame. The  $\bar{\theta}$  is determined by:

$$\bar{\theta} = \frac{1}{n} \sum_{i=1}^n \theta_i \quad (11)$$

where  $n$  is cardinality of the optical flow vectors in the frame and  $360^\circ \geq \theta_i > 0^\circ$ . Having firsthand knowledge of  $\bar{\theta}$ , we calculate the  $\theta_V$  of those vectors as:

$$\theta_V = \frac{1}{n-1} \sum_{i=1}^n (\theta_i - \bar{\theta})^2 = \frac{1}{n-1} \sum_{i=1}^n \theta_i^2 - \frac{n}{n-1} \bar{\theta}^2. \quad (12)$$

The direction variance-to-mean ratio (coefficient of direction variation) is defined as the ratio of the variance to the mean:

$$\theta_R = \frac{\theta_V}{\bar{\theta}}. \quad (13)$$

3) *Direction Histogram*: The direction histogram ( $\theta_H$ ) gives directions to the direction tendencies and the number of peaks. In the histogram each column puts an address on the number of vectors in a given angle. The  $\theta_H$ , is affiliated to the frame, can be clearly characterized by the way of:

$$\theta_H = \{\theta_H(\theta_i), i = 1 \dots s\} \quad (14)$$

$$\theta_H(\theta_i) = \frac{\sum_{i=1}^n \text{angle}(i)}{s} \quad (15)$$

$$\text{angle}(i) = \begin{cases} 1, & \text{if } \text{angle}(i) = \theta_i \\ 0, & \text{otherwise} \end{cases}$$

where  $\theta_H(\theta_i)$  is the normalized frequency of optical flow vectors those have the same angle  $\theta_i$ . The  $\theta_H$  is a vector of size  $s$  where  $s$  is the total number of angles considering the angle range between  $-\pi$  and  $+\pi$ .

4) *Distance Variance-Mean Ratio*: Observation shows that Distance variance ( $D_V$ ) increases in abnormal situations. With one or many people walking even in different directions, they tend to have the same speed, which means a small value of the motion distance variance. But in case of abnormal observable activities (e.g., collapsing situations, a sudden overwhelming fear, escape circumstances, etc.) that often gives rise to a big value for the  $D_V$ . The mean of distance variance  $\bar{D}$  is clearly delimited by:

$$\bar{D} = \frac{1}{n} \sum_{i=1}^n D_i \quad (16)$$

where  $n$  is the number of optical flow vectors in the frame. Having  $\bar{D}$  it is easy to ascertain  $D_V$  by:

$$D_V = \frac{1}{n-1} \sum_{i=1}^n (D_i - \bar{D})^2 = \frac{1}{n-1} \sum_{i=1}^n D_i^2 - \frac{n}{n-1} \bar{D}^2. \quad (17)$$

The distance variance-to-mean ratio (coefficient of distance variation) is defined as the ratio of the variance to the mean:

$$D_R = \frac{D_V}{\bar{D}}, \quad \text{where } \bar{D} > 0. \quad (18)$$

5) *Entropy Estimation*: We enumerate a function called *Entropy* that depends on motion area ratio, coefficient of direction variation, coefficient of distance variation, and direction histogram characteristics at any frame  $f$ , as:

$$\{Entropy\}_f = P(E_f) \log \frac{1}{P(E_f)} = -P(E_f) \log P(E_f) \quad (19)$$

where  $0 \leq P(E_f) \leq 1$ . In case of  $P(E_f) = 0$ , the  $P(E_f) \log P(E_f)$  will be considered as 0. The  $E_f$  is defined as:

$$E_f = M_R \times \theta_R \times \theta_H \times D_R. \quad (20)$$

To calculate  $P(E_f)$  we use cumulative distribution function (*cdf*) which has strict lower and upper bounds between 0 and 1. Deeming  $\Omega_{\mu,\sigma}(E_f)$  denotes the *cdf* of  $E_f$ . Then  $\Omega_{\mu,\sigma}(E_f)$  can be expressed in terms of a special function called the *error function* (*erf*) or *Gauss error function*, as:

$$\Omega_{\mu,\sigma}(E_f) = \frac{1}{2} [1 + \text{erf} \{ \frac{E_f - \mu}{\sigma \sqrt{2}} \}] \quad (21)$$

where  $\sigma > 0$  is the standard deviation and the real parameter  $\mu$  is the expected value. The *erf* can be defined as a *Maclaurin* series:

$$\text{erf}(E_f) = \frac{2}{\sqrt{\pi}} \sum_{n=0}^{\infty} \frac{(-1)^n \{E_f\}^{2n+1}}{n! (2n+1)} \quad (22)$$

$$= \frac{2}{\sqrt{\pi}} \{E_f - \frac{E_f^3}{3} + \frac{E_f^5}{10} - \frac{E_f^7}{42} + \frac{E_f^9}{216} - \dots\}. \quad (23)$$

Since  $E_f$  is skewed to the right (positive-definite) and variances also large, we can use Log-normal distribution. The structure of log-normal distribution of the Eq. 21 yields:

$$P(E_f) = \frac{1}{2} [1 + \text{erf} \{ \frac{\log(E_f) - \mu}{\sigma \sqrt{2}} \}]. \quad (24)$$

By means of Eq. 24 & 23, and having extensive information of the values of  $\mu$  and  $\sigma$  (say  $\mu = 0$ ,  $\sigma = 10$ ) we can expressly estimate the value of  $P(E_f)$  between 0 and 1.

#### E. Decision of Normal or Abnormal events

We examine and note the similarities or differences of each calculated value of *Entropy* with a beforehand defined entropy threshold  $T_E$ , i.e., a deviant frame can be detected if and only if  $Entropy < T_E$ , otherwise standard frame. The hypothetical outlook of reckoning  $T_E$  is that we pay attention to the minimum number of entropies in large videos that keep under control snobbishly standard events:

$$T_E = \min_{k=1 \dots n} \{Entropy\}_k \quad (25)$$

$n$  is the number of frames of the video database. The  $T_E$  (also *Entropy*) depends on the controlled environment (video stream), specifically the aloofness of the camera to the scene, the orientation of the camera, the type and the position of the camera, lighting system, density of the crowd (e.g., motion area ratio, direction & distance variance-mean ratios, etc.), etc. The more is the remoteness between camera and the scene, the less is the considerable amount of optical flows and blobs. In case of escalator,  $T_E$  also places trust on the escalator type and position. Taking into account of these facts, we think carefully that we have at least one threshold by a video stream. If we have  $N$  video streams, then we put forward at least  $N$  thresholds. If the video stream leaves for another, then the threshold should be made over.

#### IV. EXPERIMENTAL RESULTS

The approach is tested on a set of real videos taken from cameras installed in an airport to monitor the situation of escalator exits. The videos were used to provide informative data for the security team who may need to take prompt actions in the event of a critical situation such as collapsing or complete failure or breakdown. The data sets are videos from a video surveillance system on escalator exits. Data sets are 10 different length video streams taken in different duration of different time and seasons. Each video stream consists of standard and abnormal events. The standard situations correspond to crowd flows without breakdown in the escalator exits. Generally, in the videos we have two escalators corresponding to two-way-traffic of opposite directions. Abnormal situations correspond to videos that contain collapsing/breakdown events chiefly in escalator exits. The original video frame size is  $640 \times 480$  pixels. For the features detection and tracking we extract about 1500 features per frame.

Figure 5<sup>1</sup> describes an example of a breakdown situation in an escalator exit point in a video stream. Two persons were standing on the moving escalator, suddenly a trolley rushed out toward them. One person escaped by running (and was not descended under the force of trolley) while other did not. In the scene that followed the non-escapee was rundown by the run-away trolley, and subsequently fell down at the exit point of the moving escalator. The situation was successfully detected by the proposed algorithm. Different video frames in normal and fortuitous circumstances have been differentiated by a threshold label (horizontal red line in FIG. 5). The detection result has been compared with ground truth. Ground truth is the process of manually marking what an algorithm is looked forward to the probable output. The exhaustive evaluation of the proposed algorithm for the provided data-set has been listed in Table I. The algorithm does not put into effective operation of one of the video streams (the 5th video stream listed on the Table I). Syntactically, the anomalous event of that video stream has taken place significantly far distance from the camera, and hence the considerable amount of optical flow vectors is not sufficient to analyze abnormal frames. In Table I *root mean squared error* ( $\Psi$ ) has been also appraised. The symbol  $\infty$  shows deliberately that we could not straightforwardly determine the *squared error* by mathematical calculation in respective cases, because of end of video files. However, it is more important to detect the commencement of the atypical state of affairs than that of termination. The assessed  $\Psi$  performs appointively for many computer vision applications together with escalators.

#### V. CONCLUSION

We came up with an approach that appraises the aberration of a populace flow in escalator exit points. The approach assesses sudden shift and strange locomotion discrepancy of a set of interest points. Optical flow information is computed from those points of interest from the specific parts of the escalator using motion heat map, which primarily helps to make faster the calculation process by providing regions of interest. Statistical

Fig. 5. Person falling situation on the exit point of an escalator. The blue coloured curve is the output of the algorithm.

scrutiny of the optical flow information has been thresholded. The achievement of the algorithm has been assessed by a set of escalator videos obtained by a single camera. The results reveal the efficacy of the proposed procedure for recognizing exceptional events on the escalator exits. It is worth mentioning that, as a short coming of the approach, it is vulnerable to the selection of the appropriate  $T_E$  and region of interest with a view to getting outstanding output.

Future work will take into account the dedication of multiple-camera so that video could be conclusively broken down into its essential features properly in all parts of an elongated escalator (commencement, halfway point, outlet) to proclaim the eccentric event if there will exist any. Future work will also carry on the algorithm (if something indispensable) to bring about the circumstances where crowds are milling like in retail or a surveillance video of a famous public/private space, etc.

**Abstract**— Human motion self-occlusion due to motion overlapping in the same region is a daunting task to solve. Various motion-recognition methods either bypass this problem or solve this problem in complex manner. Appearance-based template matching paradigms are simpler and hence faster approaches for activity analysis. In this paper, we concentrate on motion self-occlusion problem due to motion overlapping in various complex activities for recognition. This paper illustrates the directional motion history image concept and compares this motion representation approach with multi-level motion history representation and hierarchical motion history histogram representation to solve the self-occlusion problem of basic motion history image representation. We employ some complex aerobics and find the robustness of our method compared to other methods for this self-occlusion problem. We employ seven higher order Hu moments to compute the feature vector for each activity. Afterwards, k-nearest neighbor method is utilized for classification with leave-one-out paradigm. The comparative results clearly demonstrate the superiority of our method than other recent approaches.

**Keywords**— MHI, DMHI, MMHI, HMHI, motion recognition, complex activity, template matching.

## I. INTRODUCTION

Human motion and behavior analysis is very important area in computer vision. There are many approaches to deal with action or activity recognition and analysis. We concentrated the MHI method [1] as it is an appearance-based template-matching motion recognition approach. It has been widely employed and modified a bit based on the requirements. Various interactive systems have been successfully constructed using motion history template as a primary sensing mechanism. For example, using the MHI method, Davis et al. [19] has developed a virtual aerobics trainer that watches and responds to the user as he/she performs the workout. An interactive art demonstration can be constructed from the motion templates [20]. An interactive and narrative play space for children, called KidsRoom was developed using MHI method successfully. Yau et al. [21] has developed a method for visual speech recognition employing the MHI method. The video data of the speaker's mouth is represented using grayscale images named as motion history image. Automatically localizing and tracking moving person or vehicle for an automatic visual surveillance system was demonstrated in [22-23] by employing MHI method before

employing an extended mean shift approach in [23]. Son et al. [24] calculated MHI and then combined with background model to detect the candidate road image.

Gait history image and gait energy image are created for gait analysis based on the concept of MHI [25-26]. Ref. [27] proposed threat assessment method for automated visual surveillance with the aid of MHI. A PDA-based recognition system based on MHI method is developed by [28]. Petras et al. [29] has devised a flexible test-bed for unusual behavior detection and automatic event analysis using MHI. A recent method by Kellokumpu et al. [12] proposed a recognition method at the top of the MHI method using texture-based description of the movements by employing local binary pattern (LBP) operator. They used HMM later for recognition. Usually, the MHI-based methods consider global image in the scene, rather body parts. However, they split the MHI image into four regional parts to compute histograms of those areas.

Refs. [2-5] cover some dominant methods for activity analysis and recognition. We see that most of the approaches consider simple or one-directional actions (e.g., sitting on a chair, standing from a chair, raise a hand, etc.) for recognition. However, usual activities are complex in nature and not simple in dimension. By complex action or activity, it is meant the action comprises more than one action primitives or basic action elements. Hence, a sit-stand action is a complex action, as it has 'sitting motion' and 'standing motion' in two directions (down and up direction consecutively). Real-life activities are complex in nature. In this paper, we discussed the motion recognition problem of complex action that has motion overwriting problem. Motion overwriting can be defined using the sit-down action as once sitting and then standing will erase or passes the prior motion information due to the sitting down action. In this paper, we started with the Motion History Image (MHI) method [1] as it is found to be robust in recognition and simple in computation. However, this method can not solve the overwriting or motion self-occlusion problem [7,10,14].

Section II covers the basic MHI method and the concept of overwriting problem. Then we present three template-based representations including our method to solve the self-occlusion problem in Section III. The recognition methods based on these motion representations are outlined in Section IV. Section V presents that comparative results and analysis using recognition rates and confusion matrices for various aerobics sequences. Finally, Section VI concludes the paper with some future guidelines.

## II. MOTION HISTORY IMAGE TEMPLATE

The MHI is a scalar-valued image where more recently moving pixels are brighter, and vice versa [1]. The MHI expresses the motion flow or sequence by using the intensity of every pixel in temporal manner. To describe the motion-shape and spatial distribution of motion, [1] proposed Motion Energy Image (MEI) or binary motion region. One of the advantages of MHI representations is that a range of times from frame to frame to several seconds may be encoded in a single frame, and in this way, MHIs span the time scale of human gestures. The MHI  $H_t(x, y, t)$  can be computed from update function  $\Psi(x, y, t)$ :

$$H_t(x, y, t) = \begin{cases} \tau & \text{if } \Psi(x, y, t) = 1 \\ \max(0, H_t(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \quad (1)$$

Here,  $x, y$  and  $t$  show the position and time;  $\Psi(x, y, t)$  signals object presence (or motion) in the current video image;  $\tau$  decides the temporal duration of MHI (in terms of frames); and  $\delta$  is the decay parameter. This update function is called for every new video frame analyzed in the sequence. Some possible image processing techniques for defining this update function are background subtraction, image differencing, optical flow, etc. The MHI is generated from a binarized image, obtained from frame subtraction, using a threshold  $th$ :

$$D(x, y, t) = |I(x, y, t) - I(x, y, t \pm \Delta)| \quad (2)$$

where,  $D(x, y, t)$  with difference distance  $\Delta$  is:

$$B(x, y, t) = \begin{cases} 1 & \text{if } D(x, y, t) \geq th \\ 0 & \text{otherwise} \end{cases} \quad (3)$$

$I(x, y, t)$  is the intensity value of pixel location with coordinate  $(x, y)$  at the  $t^{th}$  frame of the image sequence. MEI is cumulative binary motion images. We generate the MEI by thresholding the MHI above zero,

$$E_t(x, y, t) = \begin{cases} 1 & \text{if } H_t(x, y, t) \geq 1 \\ 0 & \text{otherwise} \end{cases} \quad (4)$$

For details, we refer to Ref. [1]. However, the MHI can not solve self-occlusion or overwrite problem, since previous motion is deleted or overwritten by the later motion information, if the motion has opposite directions in action (e.g., if a person sits down, and then stands up, the final MHI image should contain brighter pixels in the upper part of the image to represent the stand-up motion). This *self-occlusion* of the moving object or person overwrites the prior information [7]. Hence, for complex actions or activities, the basic MHI method can not recognize properly due to its inherent nature of motion history calculation. We developed a robust method considering four compass directions (namely, up, down, left and right directions) of an action and thereby can simply separate the action into its directional elements. This method is called Directional Motion History Image (DMHI) method. This is based on the computation of optical flow. In this paper, we show that the DMHI method outperforms the basic MHI method. We extend the evaluation with other representation methods that claim to be a solution for such motion

overwriting problem. We evaluate recent methods, called the Hierarchical Motion History Histogram (HMHH) representation [14-16] and the Multi-level Motion History Image (MMHI) method [10-11].

## III. TEMPLATE-BASED REPRESENTATIONS TO SOLVE MOTION SELF-OCCLUSION PROBLEM

### A. Multi-level Motion History Image (MMHI) Representation

The Multiple-level MHI (MMHI) aims at overcoming the problem of motion self-occlusion by recording motion history at multiple time intervals (i.e., multi-level MHIs) [10-11]. It creates all MHIs to have a fixed number of history levels  $n$ . So, each image sequence is sampled to  $(n+1)$  frames. The modified MHI is:

$$H_t(x, y, t) = \begin{cases} s * t & \text{if } \Psi(x, y, t) = 1 \\ H_t(x, y, t-1) & \text{otherwise} \end{cases} \quad (5)$$

where  $s = (255/n)$  is the intensity step between two history levels.  $H_t(x, y, t) = 0$  for  $t \leq 0$ . The final MHI is found by iteratively computing Eq. (5) for  $t = 1, \dots, n+1$ . It focused on automatic detection of facial actions units that compose expressions. It requires sophisticated registration system, because all utilized image sequences must have the faces at the same position and on the same scale. The result does not clearly demonstrate the superiority of MMHI with respect to basic MHI in their experiment on facial action unit detection [11]. However, it is reported that self-occlusion due to motion overwriting problem might be solved using this MMHI [11]. We implemented this method for this proof.

### B. Hierarchical Motion History Histogram (HMHH) Representation

A motion representation and recognition system called Hierarchical Motion History Histogram (HMHH) is proposed to similar overwrite problem [14]. In [15-16], few related other methods are compared [1,6,9] with this HMHH representations for some actions. In basic MHI, at any frame  $k$ ,  $D(x, y, k)$  might have combinations of 1s and 0s (e.g., 00011001000111100010...). Due to the formation of MHI, it keeps the later information of the presence of 1 (i.e., motion) in a specific pixel when there are some earlier movement in the same pixel. For example, for a pixel, the last '1' in the sequence are retained in the MHI at that pixel. It is clear that previous '1' in the sequence, when some action occurred, are not represented, and usually almost every pixel have more than one '1' in their sequence. It can be mentioned as overwriting problem in different form.

To solve this problem, we can define some patterns  $P_i$  in  $D(x, y, :)$  sequences based on the number of connected '1' (e.g.,  $P_1 = 010$ ,  $P_2 = 0110$ ,  $P_3 = 01110$ , ...  $P_M = 01...10$  (M 1s)) [14]. Now define a subsequence  $C_i = b_{n1}, b_{n2}, \dots, b_{ni}$  and denote the set of all sub-sequences of  $D(x, y, :)$  as  $\Omega\{D(x, y, :)\}$ . Then for each pixel  $(x, y)$ , count the number of occurrences of each specific pattern  $P_i$  in the sequence of  $D(x, y, :)$  as shown,

Fig. 1. Six activities in sequential order. Activities are complex.

$$HMHH(x, y, P_i) = \sum_j \mathbf{1}_{\{C_j = P_i | C_j \in \Omega\{D(x, y, :)\}\}} \quad (6)$$

Here,  $\mathbf{1}$  is the indicator function. Hence, from each pattern  $P_i$ , we construct one gray-scale image (called Motion History Histogram (MHH)), and in aggregation, we call all MHH images as Hierarchical MHH (HMHH)). Similar to the concept of the MEI, we can threshold each MHH to compute the corresponding binary energy image. They used these final feature images for classification and then recognition.

### C. Directional Motion History Image (DMHI) Representation

The above-mentioned approaches can not solve the overwriting problem as smartly as our optical flow-based

Directional Motion History Image (DMHI) method [7]. In this approach, instead of background or frame subtraction, gradient-based optical flow is calculated between consecutive two frames and split it into four channels, based on the concept of motion descriptors based on smoothed and aggregated optical flow measurements in four channels [17]. In this way, we get four-directional motion templates for left, right, up and down directions. We calculate the corresponding four history and energy images based on the Eqs. 7 and 8.

$$\begin{aligned} H_{\tau}^{-x}(x, y, t) &= \begin{cases} \tau & \text{if } \Psi_{\tau}^{-x}(x, y, t) > th_p \\ \max(0, H_{\tau}^{-x}(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \\ H_{\tau}^{+x}(x, y, t) &= \begin{cases} \tau & \text{if } \Psi_{\tau}^{+x}(x, y, t) > th_p \\ \max(0, H_{\tau}^{+x}(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \\ H_{\tau}^{-y}(x, y, t) &= \begin{cases} \tau & \text{if } \Psi_{\tau}^{-y}(x, y, t) > th_p \\ \max(0, H_{\tau}^{-y}(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \\ H_{\tau}^{+y}(x, y, t) &= \begin{cases} \tau & \text{if } \Psi_{\tau}^{+y}(x, y, t) > th_p \\ \max(0, H_{\tau}^{+y}(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \end{aligned} \quad (7)$$

$$\begin{aligned} E_{\tau}^{-x}(x, y, t) &= \begin{cases} 1 & \text{if } H_{\tau}^{-x}(x, y, t) > 0 \\ 0 & \text{otherwise} \end{cases} \\ E_{\tau}^{+x}(x, y, t) &= \begin{cases} 1 & \text{if } H_{\tau}^{+x}(x, y, t) > 0 \\ 0 & \text{otherwise} \end{cases} \\ E_{\tau}^{-y}(x, y, t) &= \begin{cases} 1 & \text{if } H_{\tau}^{-y}(x, y, t) > 0 \\ 0 & \text{otherwise} \end{cases} \\ E_{\tau}^{+y}(x, y, t) &= \begin{cases} 1 & \text{if } H_{\tau}^{+y}(x, y, t) > 0 \\ 0 & \text{otherwise} \end{cases} \end{aligned} \quad (8)$$

## IV. RECOGNITION METHODOLOGY

From the final template images, the corresponding feature vectors are computed by employing the seven Hu moments [8]. For the MHI method, for each action, seven higher order Hu moments are calculated for history and energy images and therefore, a 14-D feature vector is created for each activity. In the same way, for the MMHI representation, we computed a 14-D feature vector. In this experiment, we implemented the HMHH representation with four patterns because patterns more than the first four have almost no information to employ further for calculating feature vectors.

Therefore, for these four patterns, using the HMHH representation, we computed a 28-D feature vector (for each pattern, we compute seven higher order moments). In another experiment, we also computed the binarized energy images of the four patterns of the history images. But we have not achieved any difference to consider the energy versions for calculating feature vectors. However, for the four directional history and energy components, we need to compute seven Hu moments for each of the eight components. Moreover, to cover the overwriting issue significantly, we also computed the normalized 0<sup>th</sup> order Hu moments. E.g., for  $H_{\tau}^{+x}$  for an image  $f(x, y)$ , the 0<sup>th</sup> order moment is:

$$m_{00}(H_{\tau}^{+x}) = \sum_x \sum_y f(x, y) \quad (9)$$

Then we get normalized 0<sup>th</sup> order moment for  $H_{\tau}^{+x}$  by employing the following equation:

$$\overline{m_{00}(H_{\tau}^{+x})} = \frac{m_{00}(H_{\tau}^{+x})}{m_{00}(H_{\tau}^{+x}) + m_{00}(H_{\tau}^{-x}) + m_{00}(H_{\tau}^{+y}) + m_{00}(H_{\tau}^{-y})} \quad (10)$$

The 0<sup>th</sup> order moments provide the total object area or mass, and hence provide important cues for motion region. Finally, for DMHI, We estimate eight normalized 0<sup>th</sup> order moments for the eight templates (DMHIs and DMEIs) to get a 64-dimensional feature vector (7 Hu moments for each template in addition to normalized 0<sup>th</sup> order moments).

In this experiment, we consider some aerobics which are complex in nature [18]. Fig. 1 shows six activities that are taken from a frontal-view camera without any calibration process or special markers. The actors performed the exercises indoor with almost the same illumination level, without any special arrangements and therefore, the frame numbers are varied for the same activity by various persons. Also the dress, height, etc. of the persons were different.

For classification, we used the nearest neighbor classifier [13]. For partitioning scheme, we employ leave-one-out cross-validation scheme. This means that out of  $N$  samples from each of the  $c$  classes per database,  $N - 1$  of them are used to train (design) the classifier and the remaining one to test it [13]. This process is repeated  $N$  times, each time leaving a different sample out. Therefore, all of the samples are ultimately used for testing. This process is repeated and the resultant recognition rate is averaged.

Fig. 2. Energy images of six activities using MMHI representation.

## V. RESULTS AND ANALYSIS

In this paper, we presented the MHI, MMHI, HMHH and DMHI representations for recognizing aerobics dataset. Fig. 2 illustrates the final energy images employing MMHI method for the six activities of Fig. 1. Fig. 3 depicts the four patterns for HMHH representation for six activities. We can note that Pattern-4 of Fig. 3 has almost no information and hence we did not consider pattern-5 or more for this experiment.

Fig. 4 shows the MEIs and MHIs for six activities. Fig. 5 presents the directional history images for four different directions – namely, up, down, left and right for each activity.

Fig. 3. Four patterns for activities (images in each row represent activity 1 through 6) employing HMHH representation.

Fig. 4. MEIs and MHIs for six activities sequentially.

Table I. Comparative recognition rates for various aerobic datasets. All results are presented in %.

|    | MHI  |      | MMHI |      | HMHH |      | DMHI |      |
|----|------|------|------|------|------|------|------|------|
|    | K=1  | K=1  | K=1  | K=3  | K=3  | K=3  | K=1  | K=3  |
| A1 | 50.0 | 50.0 | 83.4 | 83.4 | 66.7 | 66.7 | 100  | 100  |
| A2 | 16.7 | 16.7 | 50.0 | 33.4 | 83.4 | 83.4 | 100  | 83.4 |
| A3 | 66.7 | 66.7 | 16.7 | 33.4 | 50.0 | 50.0 | 83.4 | 83.4 |
| A4 | 33.4 | 16.7 | 16.7 | 16.7 | 33.4 | 33.4 | 100  | 100  |
| A5 | 83.4 | 83.4 | 33.4 | 50.0 | 100  | 100  | 83.4 | 83.4 |

| RR | 55.6 | 52.8 | 41.7 | 44.5 | 66.7 | 66.7 | 94.4 | 91.7 |

Fig. 5. Directional motion history images for six activities.

Table I shows the comparative recognition results for the four methods for  $k$ 's value as 1 and 3 in the nearest-neighbor classifier. For every activity (in the Tables, these six activities are represented as A1 to A6), the recognition results with our DMHI representation are very satisfactory. With  $k$ 's value as 1, for the DMHI method, we have achieved more than 94% recognition result. This is very good result considering the complexity of the activities. Though the HMHH representation achieved better results than the MHI and MMHI representations, the performance of the former is unacceptable as it achieved about 67% recognition rate.

## VI. CONCLUSION

This paper presents various template-based solutions to the motion self-occlusion problem in action analysis and recognition. The basic MHI method is very simple to calculate and hence many researchers employed this method or its variants for various action/gesture recognition, motion analysis, etc., with different datasets.

The motion self-occlusion problem is addressed and solved with satisfactory recognition rate with our DMHI method. We compared the DMHI representation with the MHI, the multi-level motion history image (MMHI) method and the hierarchical motion history histogram (HMHH) approaches. The latter two approaches claim to be better in overwriting problem. However, these representations failed to perform well compared to our method.

Though the performance of the DMHI representations and the employed feature vectors for recognition are satisfactory, we find that this method can not perform well or faces difficulties in some cases. When two or more than two persons are in-view, this method (along with other presented methods in this paper) can not recognize properly, especially when all of them are moving in different directions. Also, like the MHI, it can not recognize properly if the person is walking towards the camera's optical axis or if it moves something like diagonal directions. For these types of actions, we need to consider a bit different feature vector sets. For walking towards or off the camera, if we can exclude the energy images, the history image can separate and recognize the actions properly. These problems will remain for future research so that the method can be made a robust one for different types of motions or activities. Another important pair of activities are running and walking across the optical axis and to recognize these is very crucial for video surveillance. These are difficult to recognize in a simple manner. Currently, we are working by considering time measurement to

differentiate both actions, so that these could be recognized separately. Note that using the DMHI, it is far easier to understand the motion flow, i.e., the direction of the motion – running or walking easily. This information is very useful for behavior understanding and analyzing.

E-mail: {ashik, etheltan, ishikawa}@ss10.cntl.kyutech.ac.jp

**Abstract** — In this paper, our proposed structured human motion database is adopted for different motion representations. The motions are first represented as a sequence of frames of 2D images, which were compressed using three recognized motion representation techniques: Exclusive-OR, MEI (Motion Energy Image), and MHI (Motion History Images). The representation is a 2D feature image. The feature image is compressed by characterizing the eigenvectors. A complete vector space called an Eigenspace is constructed that represents the image feature vectors for the feature image. The motions are indexed using the projections onto the eigenspace. For the purpose of efficient searching within the database, our proposed B-Tree Motion Database is created and maintained. The comparative performance evaluations for the aforesaid representations were investigated and satisfactory performances (about 90% recognition rate and smaller searching time) were realized for all of the cases using our proposed motion database structure.

**Index Terms** — Motion database, motion representation, motion compression, eigenspace, indexing, B-Tree.

## I. INTRODUCTION

A motion is, in a concise sense, any kind of activity performed by any subject. The activity might include any task, or simply any movement of the object. Human motion signifies the actions or movements performed by any human being. The researches involved in the recognition of human motion are considered to be a highly challenging task in computer- and robot-vision areas. With the development of computer vision system, the task of human motion/ activity recognition is getting huge significance in recent times. The motivation behind this kind of researches is the variety of applications in surveillance, discovering persons' physical problems in a medical system, aerobics, video conferencing, motion understanding, man-machine interfaces like robotics, biomechanics, virtual/ mixed reality, and in many other real-life applications[1][2]. There are a wide variety of human motion analysis techniques which are beyond this context. Aggarwal and Cai highlighted various forms of human motion representation and recognition [2]. Analyzing the techniques mentioned in [2], the field of motion representation and recognition can be briefly classified into two classes of methods: model-based and appearance-based methods [3]. Model-based methods

basically deal with the development of human 3D model for the task of representation. 3D human models are generally represented in terms of generalized cones, elliptical cylinders, and spheres [4]. For these geometric modeling a number of parameters is needed to be computed. For the complexity of computation, model-based methods are less preferable than appearance-based methods because of the simple modeling involved in appearance-based method. It deals with the 2D representation of motion rather than 3D. The motions are supposed to be composed of postures (appearances) that are somehow transformed into a suitable form or model for representation and recognition. Some recognized representations include Hidden Markov Model [5], Eigenspace [6], Body parts-based modeling [7], Motion Energy Images and Motion History Images [8], Exclusive-OR Technique [14], Directional MHI [9], and many others. The representation of eigenspace technique is much compact, as well as, suitable and applicable representation. It is identified as an image compression or coding technique. It is based on Principle Component Analysis (PCA), deviation of Karhunen-Loeve Transform [10]-[11]. Until now this technique was adopted successfully in many posture, gait, and motion recognition researches [3][6][12]. Different researchers have adopted different concepts of representation and recognition. For the reliable and real-life application of these representations and recognition strategies, the efficiency of those strategies in terms of recognition rate, as well as, searching complexity is a major issue. Recognition rate is simply the rate of recognized motions, whereas searching complexity is considered as the time that is employed for searching similar motions within the motion database.

However, the motion recognition strategies adopted earlier used to maintain a simple database capable of linear searching within that. But such searching is a brute-force searching approach that takes much time for searching in case of enormous motion data registered in the database. At this point, it is recommended to deduce some technique to reduce the searching by structurizing the searching technique. But in order to structurize the searching, construction of structured database is mandatory. Emphasizing on this point, a structured database is also proposed recently with human poses and motions [13]-

[14]. But the registration of huge amount of data, and high-speed searching with excellent performances is not yet been analyzed fruitfully. In [15]-[16], the balanced tree structure called a B-Tree was proposed as the structured database structure. Moreover, the B-Tree structure was successfully employed in many other researches, e.g., [15]-[16]. The reason behind the employment of B-Tree structure is its data arrangement. However, other database structure was also adopted in the motion analysis researches [17]-[18]; most of those were computationally complex to handle the database management.

In this research, successful analysis of motion database is accomplished by proposing a database capable of handling huge data with the ability of high recognition performance. The performance of the proposed technique is evaluated suitably and lucratively. Various representations are used to validate the performances and flexibility of our proposed method. The database development flowchart of the system is shown in Fig. 1.

Fig.1. Database Development Flowchart.

## II. MOTION REPRESENTATION

Motion representation is a form of characterizing a motion for the computer to understand and to use the motion for recognition. In this sense it is a very crucial task. However, among many motion representations we have chosen three standard representations: Exclusive-OR, Motion Energy Image (MEI), and Motion History Image (MHI). The overview of these representations will be discussed in this section.

### A. Exclusive-OR (XOR) Representation

Rather taking all the motion frames into account, the Exclusive-OR (XOR) operations are performed between consecutive frames and the cumulative XORed form of the frames are referred to as XOR Image [14]. This is simple, effective, and fast generating motion representation method. Considering  $m$ ,  $h$ ,  $c$  representing motion, persons, camera-directions, and  $f$ ,  $U$  denoting original motion frame and XOR frame, then (1) presents the complete XOR operation on the motion frames.

$$\begin{aligned}
 U_c^{m,h}(2) &= f_c^{m,h}(1) \text{ XOR } f_c^{m,h}(2), \\
 U_c^{m,h}(r) &= U_c^{m,h}(r-1) \text{ XOR } f_c^{m,h}(r), \\
 U_c^{m,h} &\equiv U_c^{m,h}(R).
 \end{aligned} \quad (1)$$

### B. Motion Energy Image (MEI)

Bobbic and Davis [8] represented *Motion Energy Image* (MEI) as the region where there is motion. This information can be used to identify the motion occurrence and viewing condition. It is defined as the cumulative binary image of the motion regions extracted between the consecutive motion frames. Let,  $I(x, y, t)$  be an image sequence and  $D(x, y, t)$  be a binary difference image. Then binary MEI  $E(x, y, t)$  is defined by (2).

$$E_t = \bigcup_{i=0}^{t-1} D(x, y, t-i) \quad (2)$$

Here,  $t$  is the temporal extent which is critical to define. But for the flexibility of the value of  $t$ , it can be taken as the maximum gray level pixel value 255 [9].

### C. Motion History Image (MHI)

Bobbic and Davis [8], like MEI, also represented *Motion History Image* (MHI) as a frame-based temporal template for human motions. As the name implies, this form of motion representation keeps track of the motion history, i.e. representing how the motion is moving along a certain period of time. Let  $H$  be the pixel intensity function of the temporal history of motion at a particular point. The function is represented in a simple way in (3).

$$H_t(x, y, t) = \begin{cases} \tau & \text{if } D(x, y, t) = 1 \\ \max(0, H(x, y, t-1) - 1) & \text{Otherwise} \end{cases} \quad (3)$$

The function returns a scalar value, and according to the function, in the generated image the more recently moving pixels are brighter than past moving pixels. However, both the MEIs and MHIs are represented as vector-images (where and how motion is moving) that can be matched against stored representations of known movements.

In this research, we employed the aforesaid three representations for our proposed technique. However, the motion that is represented as a sequence of 2D frames is transformed into a suitable form to signify the region of interest as well as to eliminate unnecessary and unwanted noise elements. Therefore, the motionless or static region of the motion frames is excluded from each frame. Static region may include motionless part, noise, uneven edge pixels, etc. This portion can be treated as ignorable portion; so it is primarily removed from each motion frames using (4).

$$I_h(n) = \begin{cases} I_h(n) & \text{if } \exists k I_h(n) \neq I_k(n), h \neq k \\ 0 & \text{Otherwise} \end{cases} \quad (4)$$

Here,  $I_h(n)$  and  $I_k(n)$  are the  $n$ -th pixel value of  $h$ -th and  $k$ -th frame, respectively;  $n \in N$  and  $k \in F$ , where  $N$  is the total number of pixels and  $F$  is the total number of motion frames.

Fig. 2. Generation of different motion Representations.

After the elimination of static portion, the images are filtered using maximum filter to take significant regions into account. Then motion representations are adopted and the resultant motion images are generated step-by-step (Fig. 2). Next, the motion images generated from the input motion frames are *compressed* by projecting the motion images onto the *eigenspaces*.

### III. MOTION COMPRESSION

Motion compression is an important step in the human motion recognition system. It refers to either motion coding, or compressed data that are extracted from the motion. For example, extracting the features and parameter values from the motion are forms of motion compression. The parametric eigenspace representation is considered as an excellent motion compression technique. An *Eigenspace* is a hyperspace or a parametric feature space representing an image as a point on the hyperspace. It is a modified form of Karhunen-Loeve Transform which is basically used to derive relationship among different random variables. It has been used as a standard compression technique for its simplicity of use. In practice, a large set of learning motions is needed to be projected onto the parametric eigenspace by finding featuring eigenvectors. For each *motion image* (*XOR image*, *MEI*, or *MHI*)  $I_m$  ( $m = 1, 2, \dots, M$ ), an image matrix  $\hat{x}_m = (x_1, x_2, \dots, x_N)$  is defined and normalized as  $\|x_m\| = 1$ . A data matrix  $X$  is obtained by subtracting the average image  $c$  from each motion image set as follows,

$$X = (x_1 - c, x_2 - c, \dots, x_M - c) \quad (5)$$

The average image  $c$  is defined by,

$$c = \frac{1}{M} \sum_{m=1}^M x_m \quad (6)$$

The image matrix  $X$  is  $N \times M$ , where  $M$  is the total number of motion images, and  $N$  is the total number of pixels in each image. To compute eigenvectors of the image set (motion set), the *covariance matrix*  $Q$  is defined as (7).

$$Q = XX^T \quad (7)$$

$$\kappa = \frac{\sum_{i=1}^k \lambda_i}{\sum_{i=1}^N \lambda_i} \quad (8)$$

The eigenvalues and corresponding eigenvectors are calculated from the  $N \times N$  covariance matrix  $Q$  by solving the eigenvalue problem. However, Principal Component Analysis (PCA) strategy can be used here to reduce the dimensions of the eigenspace. Among  $N$  eigenvectors,  $k$  most prominent eigenvectors ( $e_1, e_2, \dots, e_k$ ) are chosen to create an eigenspace  $ES$  consisting of the learning motions using the metric expressed in (8). In (8), the value of  $\kappa$  is taken to be greater than or equal to 0.80. The eigenvectors for which the variances are more, those are chosen as the prominent eigenvectors. Each learning motion is projected onto the eigenspace  $ES$  as a point  $g_m$  by,

$$g_m = (e_1, e_2, \dots, e_k)^T x_m \quad (9)$$

For each camera direction, separate eigenspaces are created by projecting corresponding directional motions onto the eigenspace using (9). However, a *global eigenspace* is also constructed with all the learning motions. It confirms the decision about the most similar motions.

#### IV. MOTION INDEXING

Indexing is the processing denoting data in a suitable form so that it can be easily allocated into the database for further query. However, in this context, indexing involves the task of generating index from the points inside the eigenspace corresponding to each motion. The indexes are stored within the database afterwards. For the task of indexing the dimensions of the eigenspaces is taken as an important cue. The eigenspaces are uniformly divided into several subdivisions. Each eigen-axis  $e_k$  ( $k = 1, 2, \dots, K$ ) is separated into  $S$  sections each having equal length  $L$ . A hypercube with length  $L$  along each eigen-axis of an eigenspace is referred to as a *bin*. Each bin is assigned a number from 0 to  $S-1$ . Along each eigen-axis, each motion point is assigned a number between 0 and  $S-1$ . Thus each motion point in the eigenspace is represented as  $K$ -digit  $S$ -nary number which is termed as an *index* (Fig. 3). With large number of motions, if the number of bins is small, there is higher possibility that more motion points will have an identical index and need much time to search similar motions. Conversely, if the number of bins is large, less motion points will be sought. The reason behind it is: each bin covers less number of motion points at the time of higher number of bins.

|                  |       |                  |                  |                  |
|------------------|-------|------------------|------------------|------------------|
| Digit-( $N-1$ )  | ..... | Digit-2          | Digit-1          | Digit-0          |
| ( $0 \sim K-1$ ) | ..... | ( $0 \sim K-1$ ) | ( $0 \sim K-1$ ) | ( $0 \sim K-1$ ) |

Fig. 3. Index of  $N$ -digit  $K$ -ary number.

#### V. CONSTRUCTION OF STRUCTURED DATABASE

In this paper, a database is constructed capable of structured organization and fast query. As the large motion-database structure, B-Tree [19] data structure is employed in our proposed method. A B-Tree is a balanced tree that is capable of fast external memory searching. The B-Tree consisting of  $m$  descendents with height  $h$  is defined by  $\tau(m, h)$  and each page can hold up to  $m$  keys. It has the following properties:

- (a) Each path from the root to leaf has the same length  $h$ .
- (b) Root is a leaf or has 2 to  $m$  descendents.
- (c) Each node has  $\lfloor m/2 \rfloor$  to  $m$  descendents, except the root and leaves.

Within each page of the B-Tree, there are two kinds of data: a pointer and a key (Fig. 4). Pointer points to another page within the B-Tree, whereas the key stores the main information, i.e., the index. Considering the above properties, a B-Tree is constructed with the indexes. The generated index is stored in the B-Tree systematically. Those indexes are used for recognizing unknown motions in the recognition phase.

So far discussed database construction steps can be summarized as follows: First, for each camera direction, separate eigenspaces are created, then indexes are generated, and those are stored in a corresponding B-tree. The *global eigenspace* consisting of all the motions is used at the recognition stage. Separate eigenspaces arrange the motion data in an organized way and store much data within each B-Tree, at the same time we can still keep our searching faster. The structure of the page of B-Tree is shown in Fig. 5.

Fig. 4. A B-Tree structure in  $(4, 3)$ .

|       |       |       |       |       |       |              |
|-------|-------|-------|-------|-------|-------|--------------|
| $p_0$ | $x_i$ | $p_i$ | $x_2$ | $p_2$ | ..... | Unused Space |
|-------|-------|-------|-------|-------|-------|--------------|

Fig. 5. Organization of a page of a B-Tree.

#### VI. SEARCHING STRATEGY

The most significant part for developing a recognition system is the searching strategy. Both excellent and faster recognition is the concern here. As the B-Tree is a well-structured database structure, the searching is simpler and less time-consuming. The following conditions [19] maintained by the B-Tree structure guarantees efficient searching within the database:

$$\begin{aligned}
 &(\forall y \in \text{Keys}(p_0))(y < x_1), \\
 &(\forall y \in \text{Keys}(p_i))(x_i < y < x_{i+1}); \quad i = 1, 2, \dots, l-1, \quad (10) \\
 &(\forall y \in \text{Keys}(p_l))(x_l < y).
 \end{aligned}$$

Here, the B-Tree assumes  $l$  keys and  $l+1$  pointers within the page.

With the above structural arrangement, an index is searched within the B-Tree. If the query index resides within the database, it is found by simple *retrieval algorithm*. But for the case of the index not residing within the database, the most similar index corresponding to the most similar motion within the database is found. The pseudo code for finding the most similar index within the B-Tree after using the retrieval algorithm is as follows:

**STEP-1:** If query index  $y > x_i$  and  $Keys(p_i) = \text{NULL}$  and  $Keys(p_{i+1}) = \text{NULL}$ , calculate  $\text{MinDist}(x_{i+1}, y)$  and  $\text{MinDist}(x_i, y)$ . Then return the minimum distance index.

**STEP-2:** If query index  $y > x_i$  and  $Keys(p_i) = \text{NULL}$  and  $Keys(p_{i+1}) \neq \text{NULL}$ , select the last index from  $Keys(p_{i+1})$ . Then calculate  $\text{MinDist}(x_{i+1}, y)$  and  $\text{MinDist}(x_{p_{i+1,l}}, y)$ , and return the minimum distance index.

Besides the above, no other condition holds. The above algorithm finds the most similar index from the B-Tree.

## VII. RECOGNITION

The recognition strategy is also simple, but effective. An unknown motion is tested for recognition. When an unknown motion comes, it is first represented as a sequence of image frames. Then *XOR image*, *MEI*, or *MHI* is obtained from the motion frames, and then projected onto each camera-directional eigenspace. An index is generated from the unknown motion for each eigenspace representing motion identity within the directional database. For each camera direction, the number of similar motions is obtained by searching the corresponding B-Tree by calculating Euclidian distances among the indexes. Thus we get several *candidate* motions. Those candidate motions are then projected onto the global eigenspace as  $g_m (r=1,2,\dots,D)$ , where  $D$  is the number of directions. The unknown is projected as  $g_m$ . The most similar motion is calculated within the large motion database using (11):

$$d_m = \min_r \|g_{m_r} - g_m\| \quad (11)$$

Finally, the global eigenspace is used for finding the most similar motion.

## VIII. PERFORMANCE ANALYSIS

The performance of our proposed structure was analyzed with three different motion representations: Exclusive-OR, MEI, and MHI. The leave-one-out cross-validation method was used with a set of 60 motions, including 4 persons, 5 motions (*Pick-up*, *Carry*, *Walking*, *Headache*, and *Stomachache*) and 3 camera-directions

(*Left*, *Right*, *front*). The concept of bins is introduced here to reduce the amount of searching within the database. It can be assumed that the more the number of bins, the less the amount of searching. Different number of bins along each eigen-axis was taken into account for performance evaluation.

Fig. 6. Motion representations (frontal view) (a) Original motion frames, (b) XOR Image, (c) MEI, (d) MHI.

Fig. 7. Performance analysis using recognition rate.

Fig. 8. Performance analysis using searching time.

For each motion representations, 60 motion images were generated with original size 160X107 pixels (Fig. 6) and were scale normalized to 32X32 pixels. Then the eigenspace was created for each camera direction by calculating eigenvalues and eigenvectors using SVD (Singular Value Decomposition) method. The performance was evaluated for each representation. The motions used for learning and testing were quite noisy; even for a single bin the recognition rate is not 100%. Still our proposed method shows excellent result with increased number of bins (Fig. 7). At bin length 0.14, 90% recognition rate was achieved. However, if the database searching time is considered, we see that at bin length 0.14 or less, the searching time is near about 22ms that is surely better than the brute-force search within a single bin (Fig. 8). The average recognition rate and searching time for Exclusive-OR, MEI and MHI are 84.5%, 87%, 81%, and 21.8ms, 23.2ms, 21.2ms, respectively. MEI shows the best recognition rate whereas MHI shows the least searching time with our experimental motions. The experiment was performed by taking the B-Tree parameter values  $m=4$ ,  $h=2$  operated on the PENTIUM IV, 2.8 GHz processor, 384 MB RAM Computer.

## IX. CONCLUSIONS

The main contribution of this research is the achievement of an excellent recognition rate with large number of motions in the motion database keeping searching time shorter. The flexibility of our database structure is also considered by employing different motion representations. For simple motions MEI can show satisfactory results, whereas incorporating MEI and MHI together, the performance will truly be improved [8]. Other representation and compression methods can be fruitfully employed by creating index, and storing into the B-Tree database for recognition by fast searching with accommodating huge number of motions. The proposed method has, indeed, much potential to be applicable in the real-time human motion recognition applications.

## ACKNOWLEDGEMENT

This work was partly supported by KAKENHI under grant 19700175, which is greatly acknowledged.

**Abstract**— Usually, various motion recognition approaches can not perform well on actions that have variable speeds, or part of the dataset is speedy and vice versa. In this paper, we present the timing issue of our Directional Motion History Image method. This method can solve overwriting or motion self-occlusion problem significantly and thereby it performs well for complex and repetitive activities. However, it is important to analyze the method with activities having various speeds to show its robustness. The experimental results demonstrate that it can perform well with variable paces of the actions though the recognition rate is compromised a bit compared to the dataset having usual speed. We also improve the classification method with the incorporation of motion duration in the final feature vector so that for similar type of activities having different pace, it can show better result. Experiments on another dataset show better performance with the timing incorporation. The achieved recognition rates are very encouraging for further research and implementation is some intelligent systems for surveillance and related applications.

**Keywords**— DMHI, appearance-based model, action recognition, feature vector, moment.

## I. INTRODUCTION

Human action recognition with various speeds is very important for real-life video surveillance, aged care home, video annotation and indexing, security, image understanding, sports and video analysis, etc. to name a few [1-6]. Real-life activities vary from person to person, shape, etc. The same action (e.g., walking) may have different nature, speed, shapes based on the person's body structure (height, cloths, etc.) and therefore, it is important to have a global-based motion representation system that can be computed easily and without much computational cost. Most of the existent activity analysis methods concern and consider simple activities [2]. There are various gait analysis methods considering the length of foot-steps, angle, etc. However, gait analysis gives local information of the motion. For gesture or overall motion information of the human activity, we need to consider either human body parts analysis or template-based approaches considering the global human motion [1]. Ref. [23] points out that non-facial gestures must involve the rest of the body to appear natural and convincing. In this paper, we present our directional motion history image (DMHI) method for human motion recognition and activity analysis. However, earlier researches have considered regular pace of the actions. In this paper, to show DMHI method's robustness, we implement actions having various speeds and test with normal speed dataset and faster dataset. We show the robustness of the

DMHI method with actions having various speeds for the same action.

The paper is organized as follows: Section II presents some related works. In Section III, we present the temporal motion descriptors which are employed in this paper. Section IV explains the recognition methodology and timing issues related to feature vector calculations. Based on these concepts, Section V demonstrates some experimental results with two different datasets. Finally, Section VI concludes the paper with some directions on future work based on the present results.

## II. RELATED WORK

Vitaladevuni et al. [7] propose a method for temporally segmenting videos into atomic movements. At the same time, they use the approach on gesture recognition in rapid succession and at high speeds. Other approaches for temporal segmentation methods are available to understand complex actions [19-22]. For example, inspired by the natural language processing, Wang et al. [22] presented an approach for automatically segmenting sequences of natural activities into atomic sections and clustering them. Like words are extracted from long sentences, they extracted primitive gestures from sequences of human motion and clustered using HMM. Vili et al. [8] extract spatially enhanced local binary pattern (LBP) histograms from MHI and MEI temporal templates and model their temporal behavior with HMMs. They choose a fixed frame numbers in order to give a short term motion representation and the MHI is divided into four sub-regions. All the MHI and MEI LBP features are concatenated into one histogram and normalized so that the sum of the histogram equals one.

An adaptive model is constructed automatically by detecting human activity in MHIs using an iterative candidacy-classification-reduction process [12]. Singh et al. [13] used MHI and MEI and developed a Motion Color Image (MCI) by combining of motion and color cues. MCI is constructed by bit-wise OR of the MEI for four previous levels and color localization data. They dynamically controlled the frame differencing. Later they divide the MCI into 9 boxes and compute motion pixels count of motion data in MHI in each of the 9 boxes. Feature vectors are calculated as the sum of motion pixels in each box for classification.

Gorelick et al. [9] analyze actions by considering a video sequence as a space-time volume (XYT). They utilize properties of the solution to the Poisson equation to extract space-time features such as local space-time saliency, action

dynamics, shape structure and orientation. However, this method requires that the background is known ahead. They use the database that contains walk, run and some other motions. Another complex motion patterns' recognition approach considers local spatio-temporal interest points (local features) and integrates such representations with SVM classification schemes [10]. They recognize walking, running, jogging and other three activities. On the contrary to this approach, the MHI and the DMHI approaches consider global motion on the scene or global image measurements. In their experiment, confusion between walking and jogging as well as between jogging and running have high similarities of these classes (running of some people may appear very similar to the jogging of the others). However, this approach shows its robustness with both indoor and outdoor environments.

### III. TEMPORAL MOTION DESCRIPTORS

In this paper, we employ our directional motion history image (DMHI) approach for recognizing some activities with various speeds for complex activities of some aerobics motions. This section briefly presents the MHI and the DMHI representation. To recap what is the MHI method, we can state that the motion *history* image (MHI) can describe *how* the motion is moving in the image sequence [14]. Another representation called motion *energy* image (MEI) can demonstrate the presence of any motion or a spatial pattern in the image sequence. Both MHI and MEI templates comprise the motion history image (MHI) template-matching method. The MHI  $H_\tau(x, y, t)$  can be computed from update function  $\Psi(x, y, t)$ :

$$H_\tau(x, y, t) = \begin{cases} \tau & \text{if } \Psi(x, y, t) = 1 \\ \max(0, H_\tau(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \quad (1)$$

Here,  $x, y$  and  $t$  show the position and time;  $\Psi(x, y, t)$  signals object presence (or motion) in the current video image;  $\tau$  decides the temporal duration of MHI (in terms of frames); and  $\delta$  is the decay parameter. The MHI is a scalar-valued image where more recently moving pixels are brighter, and vice versa, whereas, MEI is a binary image that can be generated by thresholding the MHI above zero:

$$E_\tau(x, y, t) = \begin{cases} 1 & \text{if } H_\tau(x, y, t) \geq 1 \\ 0 & \text{otherwise} \end{cases} \quad (2)$$

We develop the directional-MHI (DMHI) to solve the overwriting or self-occlusion problem of complex motions. A natural real-life motion has more than one atomic movements or basic actions. Using the basic MHI method, we can not solve the overwriting problem (e.g., motions like – sit-down and then stand-up motion; raise hand and then down motion; running both ways motion, etc.) because the former part of the motion (e.g., sit-down) is overwritten by the latter motion elements (e.g., then stand-up) [11, 15-16]. To solve this problem, four directional motion representations are proposed by splitting the optical flow [17] into four different channels and thereby, by creating four motion templates or images [18]. This DMHI approach can solve the motion overwriting problem significantly, and hence performs well for repetitive

or complex activities. Eq. 3 shows four motion history templates for this method based on four-directional optical flow components.

$$\begin{aligned} H_\tau^{-x}(x, y, t) &= \begin{cases} \tau & \text{if } \Psi_x^-(x, y, t) > th_p \\ \max(0, H_\tau^{-x}(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \\ H_\tau^{+x}(x, y, t) &= \begin{cases} \tau & \text{if } \Psi_x^+(x, y, t) > th_p \\ \max(0, H_\tau^{+x}(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \\ H_\tau^{-y}(x, y, t) &= \begin{cases} \tau & \text{if } \Psi_y^-(x, y, t) > th_p \\ \max(0, H_\tau^{-y}(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \\ H_\tau^{+y}(x, y, t) &= \begin{cases} \tau & \text{if } \Psi_y^+(x, y, t) > th_p \\ \max(0, H_\tau^{+y}(x, y, t-1) - \delta) & \text{otherwise} \end{cases} \end{aligned} \quad (3)$$

We also compute four motion energy images (DMEI) after thresholding the motion history templates above zero:

$$\begin{aligned} E_\tau^{-x}(x, y, t) &= \begin{cases} 1 & \text{if } H_\tau^{-x}(x, y, t) > 0 \\ 0 & \text{otherwise} \end{cases} \\ E_\tau^{+x}(x, y, t) &= \begin{cases} 1 & \text{if } H_\tau^{+x}(x, y, t) > 0 \\ 0 & \text{otherwise} \end{cases} \\ E_\tau^{-y}(x, y, t) &= \begin{cases} 1 & \text{if } H_\tau^{-y}(x, y, t) > 0 \\ 0 & \text{otherwise} \end{cases} \\ E_\tau^{+y}(x, y, t) &= \begin{cases} 1 & \text{if } H_\tau^{+y}(x, y, t) > 0 \\ 0 & \text{otherwise} \end{cases} \end{aligned} \quad (4)$$

These eight motion templates are required for further motion representations. Using only history images or energy images for motion representation are not worthy. It has been proved both theoretically and experimentally that both templates are required for better motion representations. Though some researchers employ the history images only for their research, they employ or implement some other features along with the history image to represent the motion sequence in a robust way. However, to use only energy image for representation makes no real sense due to the fact that energy image gives the total motion region in the full video sequence. To make it clear, let's consider the stand up and sit-down motion sequence. In both reverse directions, we will get the same energy image (for sit and then stand sequence; or stand and then sit sequence) and hence energy image only can not give good cue unless the motions or actions are very much different among each other. E.g., actions like walk, jump on a place, raise hands, sleep on the floor, etc., have different dimensions and will give different energy images to separate these. Therefore, to accommodate various activities, as the MHI [14], energy and history templates are utilized [11].

### IV. FEATURE VECTORS COMPUTATION

This paper presents view-based template matching approach. An example of template matching comparisons is the use of distance measurements between the current data record (feature vectors) and each of the data records in the posture set recognizing the posture with the lowest distance measurement [5]. Template matching is the simplest of the hand posture and gesture recognition techniques, and for a

small set of postures, it is appropriate and can be quite accurate [5]. Traditionally, shape descriptors based on moments, which are invariant relatively to rotations, translations and scale, are utilized for feature vector calculation. Shape representation by statistical moments is a classical technique in the literature [25]. We employ Hu moments [24] to develop feature vectors for the MHI and the DMHI representations for each activity. To define the 2D  $(p+q)^{\text{th}}$  order moments of a density distribution function  $\rho(x,y)$  we can write,

$$m_{pq} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} x^p y^q \rho(x,y) dx dy \quad p, q = 0, 1, 2, \dots \quad (5)$$

The central moment  $\mu_{pq}$  can be defined as,

$$\mu_{pq} = \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} (x - \bar{x})^p (y - \bar{y})^q \rho(x,y) d(x - \bar{x}) d(y - \bar{y}). \quad (6)$$

Here,  $\bar{x} = m_{10} / m_{00}$ ,  $\bar{y} = m_{01} / m_{00}$ . The first four orders (i.e.,  $(p+q)$  is from 0 to 3) are defined as,

$$\begin{aligned} \mu_{00} &= m_{00} \equiv \mu, \\ \mu_{10} &= \mu_{01} = 0, \\ \mu_{20} &= m_{20} - \mu \bar{x}^2, \\ \mu_{11} &= m_{11} - \mu \bar{x} \bar{y}, \\ \mu_{02} &= m_{02} - \mu \bar{y}^2, \\ \mu_{30} &= m_{30} - 3m_{20}\bar{x} + 2\mu \bar{x}^3, \\ \mu_{21} &= m_{21} - m_{20}\bar{y} - 2m_{11}\bar{x} + 2\mu \bar{x}^2 \bar{y}, \\ \mu_{12} &= m_{12} - m_{02}\bar{x} - 2m_{11}\bar{y} + 2\mu \bar{x} \bar{y}^2, \\ \mu_{03} &= m_{03} - 3m_{02}\bar{y} + 2\mu \bar{y}^3. \end{aligned} \quad (7)$$

For the second and third order moments, following seven orthogonal invariants (Eqs. 8) are achieved [24] to calculate feature vectors and we employ these invariants as feature vector:

$$\begin{aligned} I_1 &= \mu_{20} + \mu_{02}, \\ I_2 &= (\mu_{20} - \mu_{02})^2 + 4\mu_{11}^2, \\ I_3 &= (\mu_{30} - 3\mu_{12})^2 + (3\mu_{21} - \mu_{03})^2, \\ I_4 &= (\mu_{30} + \mu_{12})^2 + (\mu_{21} + \mu_{03})^2, \\ I_5 &= (\mu_{30} - 3\mu_{12})(\mu_{30} + \mu_{12})[(\mu_{30} + \mu_{12})^2 - 3(\mu_{21} + \mu_{03})^2] + \\ &\quad (3\mu_{21} - \mu_{03})(\mu_{21} + \mu_{03})[3(\mu_{30} + \mu_{12})^2 - (\mu_{21} + \mu_{03})^2], \\ I_6 &= (\mu_{20} - \mu_{02})[(\mu_{30} + \mu_{12})^2 - (\mu_{21} + \mu_{03})^2] + 4\mu_{11}(\mu_{30} + \mu_{12})(\mu_{21} + \mu_{03}), \\ I_7 &= (3\mu_{21} - \mu_{03})(\mu_{30} + \mu_{12})[(\mu_{30} + \mu_{12})^2 - 3(\mu_{21} + \mu_{03})^2] - \\ &\quad (\mu_{30} - 3\mu_{12})(\mu_{21} + \mu_{03})[3(\mu_{30} + \mu_{12})^2 - (\mu_{21} + \mu_{03})^2]. \end{aligned} \quad (8)$$

Based on these seven invariants, the MHI method calculates the 14-D feature vector (7 for MHI and 7 for MEI). In the DMHI method, we have eight history and energy components. Considering seven invariants for each along with eight normalized 0<sup>th</sup> order moment invariants ( $\overline{m_{00}^\sigma}$  where  $\sigma \in \{up, down, left, right\}$ ), we compute a 64-D feature vector ( $FV_{dmhi}$ ). These normalized 0<sup>th</sup> order invariants confer

the relative mass of the motion area in the scene. We can define  $FV_{dmhi}$  as:

$$FV_{dmhi} = (\forall h)(I_{1 \rightarrow 7}) \cup (\forall e)(I_{1 \rightarrow 7}) \cup (\forall h)(\overline{m_{00}^\sigma}) \cup (\forall e)(\overline{m_{00}^\sigma}). \quad (9)$$

where,  $h$  denotes the motion *history* image components, and  $e$  stands for energy components of the DMHI method.

Fig. 1. Walk-type Database: some consecutive frames. Numbers 1 to 6 denotes the actions as – 1 for Walk, 2 for run, 3 for crouch, 4 for pick, 5 for walk as searching and 6 for sideway walk.

In this paper, another feature vector set is proposed considering the timing issue in mind, especially for actions having similarity in the templates but speed variations (Fig. 1). For example, to cover a specific distance by walking and running take different timing and hence, the timing incorporation can significantly improve the recognition rates. We can refer to this feature vector set as *timed-DMHI* ( $\tau$ -DMHI) feature vector,  $FV_{\tau \cup dmhi}$  and achieve a 65-D feature vector set:

$$FV_{\tau \cup dmhi} = (\forall h)(I_{1 \rightarrow 7}) \cup (\forall e)(I_{1 \rightarrow 7}) \cup (\forall h)(\overline{m_{00}^\sigma}) \cup (\forall e)(\overline{m_{00}^\sigma}) \cup (\tau). \quad (10)$$

## V. EXPERIMENTAL RESULTS AND ANALYSIS

For recognition process, we employ nearest-neighbor method for classification. For partitioning scheme, we consider leave-one-out cross-validation partitioning scheme. Two different datasets are employed here to establish the robustness of the DMHI method with various speeds. The achieved recognition results are satisfactory.

### A. Experiment I: Aerobics Datasets

Several aerobics datasets are considered in this experiment. The entire dataset has 10 activities done by 8 subjects. Table I shows the recognition results for various combinations of datasets. With the PA\_66 dataset (six persons' six activities) and 15 fps, we achieve lower recognition result for Activity-6. Without the presence of activity-6, the recognition rate is

better (96.7% for 15 fps). Similarly, with 10 activities for 8 persons (i.e., PA\_810 dataset), activity-6 and activity-7 show poor recognition results comparing to other activities. Due to this factor, the overall recognition rate is not as good as with the dataset of 30 fps.

Table I. Recognition rates (in %) of aerobic datasets with various speeds and combination. Note that the last row is only with the MHI; others are with the DMHI method.

| Dataset  | Testing Condition                                 | Rec. rate |
|----------|---------------------------------------------------|-----------|
| PA_810   | 30 fps                                            | 93.8      |
|          | 15 fps                                            | 78.8      |
| PA_66    | 30 fps                                            | 94.4      |
|          | 15 fps                                            | 86.2      |
| PA_86    | 30 fps                                            | 95.9      |
|          | Training 30 fps; Testing: 20% less data for a1~a4 | 83.4      |
| PA_810   | Training 30 fps; Testing: 20% less data for p1~p4 | 82.5      |
|          | Training and Testing: 20% less data for p1~p4     | 82.5      |
| With MHI | 30 fps                                            | 55.6      |
|          | 15 fps                                            | 38.9      |

We also implement the basic MHI method with 15 fps (thereby, speed is changing by 50%), and the recognition results are dropped than earlier (with 15 fps, the average recognition rate is achieved 38.9% only, whereas with normal speed of 30 fps, the average recognition rate was a bit better and 55.6%). These activities are not slow and the exercise sequences were taken with various subjects without considering any specific pace of the actions. Hence, by considering 15 fps, i.e., taking half of the frames compared to 30 fps for a period, we have lost some important correlations among the pixels. This is a reason to have a bit lower recognition rates with 15 fps. Fig. 2 shows some templates of energy images for 30 fps and 15 fps. For 15 fps, some missing information are visible (as black spots in the bottom row).

Fig. 2. Motion energy components for two actions with 30 fps and faster 15 fps.

In another experiment, we reduced the frames for activity-1 to activity-4 and rests of the activities are remained with usual speed (means, 30 fps). We reduced it about 20% and we consider training dataset having normal speed with 30 fps, but

for testing, we take reduced dataset. Hence, it is evident that the recognition will be a bit difficult as the speed is changing by one-fifth (<20%) for part of the dataset. In this case, we achieve 83.4% recognition results.

Fig. 3. For six actions (for Walk-type database), two rows represents DMHIs (top row) and the DMEIs (bottom row) respectively.

### B. Experiment II: Walk-type Datasets

Later, we implemented this DMHI method (and few other template-matching methods – not presented here as their performances were poor) for another dataset (we will refer to

it as ‘Walk-type Dataset’), consisting of different six actions (see Fig. 1), namely: normal-walk, run, walk-crouch-walk; walk-pick-walk, walk as if searching, sideways-walk. These actions have variable speeds. It is clear from the action-names that all the actions are very similar (starting from one corner in the scene and finishing the other side with variable pace and style) and to recognize this kind of datasets is quite difficult. There are some complex methods to recognize this kind of actions, but we upgraded the DMHI method with timing incorporation in the feature vectors. This is a simple approach.

Using 64-D feature vectors ( $FV_{dmhi}$ ) of the usual DMHI method for this kind of actions are not suitable as these actions have similarity in the final templates (Fig. 3 shows the final motion history and energy templates for the six actions) but the timing is different.

Table II. Recognition results with two different feature vectors ( $FV_{dmhi}$  and  $FV_{\tau \cup dmhi}$ )

| Action name                    | $FV_{dmhi}$ | $FV_{\tau \cup dmhi}$ |
|--------------------------------|-------------|-----------------------|
| 1. Walk                        | 66.7        | 100                   |
| 2. Run                         | 33.4        | 66.7                  |
| 3. Crouch (with walk)          | 66.7        | 100                   |
| 4. Pick from floor (with walk) | 66.7        | 100                   |
| 5. Search walk                 | 66.7        | 100                   |
| 6. Sideways walk               | 66.7        | 100                   |
| Average Rec. Rate              | 61.2        | 94.5                  |

Table II shows the recognition rates of various Walk-type activities. With the  $\tau$ -DMHI feature vector set ( $FV_{\tau \cup dmhi}$ ), we achieve much better recognition rate. However, to show its robustness, we have to consider various other datasets, which consist of this type of activities. An important pair of activities are running and walking across the optical axis and to recognize these is very crucial for video surveillance. As evident from Table II, the usual DMHI shows a bit similar results for both cases. By considering time measurement, these could be recognized separately.

## VI. CONCLUSIONS AND FUTURE WORKS

Human motion analyses in robust ways are still its infancy. Through various methods we can achieve good results; however most of the cases, these are dataset-specific or environment-specific with various constraints. We demonstrated the robustness of the DMHI method having various speeds and complexity of the actions. We achieved satisfactory recognition results. For Walk-type dataset and with the  $\tau$ -DMHI feature vector set ( $FV_{\tau \cup dmhi}$ ), we achieve much better recognition rate.

However, to show its robustness, we have to consider various other datasets, which consist of this type of activities. The system considers single frontal-view camera and not view-invariant. Moreover, all the experiments are accomplished indoor with almost constant illumination. In future, we need to consider outdoor recognition process as

well as with the presence of more than one person in the view. Currently, we are developing a robust temporal motion segmentation method based on this directional method.

# Intelligent Video Surveillance for Monitoring Fall Detection of Elderly in Home Environments

Homa Foroughi<sup>1</sup>, Baharak Shakeri Aski<sup>2</sup>, and Hamidreza Pourreza<sup>1</sup>

<sup>1</sup>Department of Computer Engineering, Ferdowsi University of Mashhad, Mashhad, Khorasan, Iran

<sup>2</sup>Islamic Azad University of Ramsar, Ramsar, Mazandaran, Iran

**Abstract** — Video Surveillance is an omnipresent topic when it comes to enhancing security and safety in the intelligent home environments. In this paper we propose a novel method to detect various posture-based events in a typical elderly monitoring application in a home surveillance scenario. These events include normal daily life activities, abnormal behaviors and unusual events. Due to the fact that falling and its physical-psychological consequences in the elderly are a major health hazard, we monitor human activities with a particular interest to the problem of fall detection. Combination of best-fit approximated ellipse around the human body, projection histograms of the segmented silhouette and temporal changes of head position, would provide a useful cue for detection of different behaviors. Extracted feature vectors are fed to a MLP Neural Network for precise classification of motions and determination of fall event. Reliable recognition rate of experimental results underlines satisfactory performance of our system.

**Index Terms** — Elderly Monitoring, Fall Detection, Home Surveillance, Human Shape, MLP Neural Network, Posture Recognition.

## I. INTRODUCTION

Intelligent video surveillance systems are receiving a great deal of interest especially in the fields of personal security and assistance. These systems are built in order to accomplish several tasks from detection of human presence to recognition of their activities. In the past few decades, vision-based surveillance has been extensively applied on industrial inspection, traffic control, security systems, and medical and scientific research.

One of the application areas of video surveillance is monitoring the safety of elderly in home environments. In the case of elderly people living on their own, there is a particular need for monitoring their behavior, such as a fall, or a long period of inactivity. Fall in the elderly is a major public health problem and may lead to injury, restricted activities, fear or death. A fall incident not also causes many disabling fractures but also has dramatic psychological consequences that reduce the independence of the person. It is shown in [12] that 28-34% elderly people in the community experience at least one fall every year, and 40-60% of the falls lead to injury.

Human society is experiencing tremendous demographic changes in aging since the turn of the 20th

century. Thus with the population growing older and increasing number of people living alone, supportive home environments able to automatically monitor human activities are likely to widespread due to their promising ability of helping elderly people.

Nowadays, the usual solution to detect falls is wearable sensors [1], [3]. These autonomous sensors are usually attached under the armpit, around the wrist, behind the ear's lobe or at the waist. These devices integrate accelerometer and/or inclinometer sensors and can monitor velocity and acceleration, vertical posture toward lying posture. However the problem of such detectors is that older people often forget to wear them, indeed their efficiency relies on the person's ability and willingness to wear them. Moreover in the case of noncontact sensors, they often provide fairly crude data that's difficult to interpret. Although, computer vision systems try to extract some considerable features from video sequences of movement patterns to detect falls. The data provided by cameras are semantically richer and more accurate than standard sensors.

In this paper we present a novel video analysis based approach for monitoring human activities with a particular interest to the problem of fall detection. The reminder of the paper is organized as follows: in section II we briefly review some existing vision-based fall detection systems, in section III our proposed system is introduced and then more technical details are described in section IV. Experimental results are represented in section V and finally we conclude in section VI.

## II. RELATED WORK

Recently some research has been done to detect falls using image processing techniques. A simple method was used in [5], [6] based on analyzing aspect ratio of the moving object's bounding box. This method could be inaccurate, depending on the relative position of the person, camera, and perhaps occluding objects. The works in [2], [7] used the normalized vertical and horizontal projection of segmented object as feature vectors. To overcome occluding objects problem, some researchers have mounted the camera on the ceiling: Lee [8] detected a fall by analyzing the shape and 2D velocity of the

person. Nait-Charif [9] tracked the person using an ellipse and inferring falling incident when target person is detected as inactive outside normal zones of inactivity like chairs or sofas. Rougier [4] used wall-mounted cameras to cover large areas and falls were detected using motion history image and human shape variation. Other systems used the audio information or using 3D trajectory and speed of head to infer events [11]. These mechanisms tend to be more complex and need more additional cost. Despite the considerable achievements that has accomplished on this field in the recent years, there are still some clear challenges to overcome:

- Visual fall detection is inherently prone to high levels of false positive as what appears to be a fall might not be a fall, but a deliberate movement towards the ground. In other words, most of current systems [6], [7], [9], [10] are unable to discriminate between real fall incident and an event when person is lying or sitting down abruptly.
- Existent fall detection systems tend to deal with restricted movement patterns and fall incidents are usually detected in contrast with limited normal scenarios like walking; however in real home environments various normal /abnormal motions occur.

### III. PROPOSED SYSTEM OVERVIEW

This paper proposes a novel method for monitoring human posture-based events in a home environment with focus on detecting three types of fall. We tried to simulate real life situations; to this aim, we considered comprehensive movement scenarios consisting normal daily life activities such as walking, running, bending down, sitting down and lying down, some abnormal behaviors like limping or stumbling, and also unusual events like falling. Furthermore several scenarios of falling have been regarded. These ten different postures are described in section V.A in more details.

Since we are interested in analyzing the motion occurring in a given window of time, firstly we need to obtain the segmentation of moving objects. Therefore, a background estimation procedure is performed to separate motion from background. After the silhouettes are acquired, the next step involves extracting features. Since changes in the human shape can discriminate if the detected motion is normal (e.g. the person walks or sits) or abnormal (e.g. the person falls), we analyze the shape changes of the extracted silhouettes in the video sequence. It seems that combination of approximated ellipse around the human body, horizontal and vertical projection histograms and temporal changes of human head position; would provide a useful cue for detecting different behaviors. By using the motion feature, the key motion

information can be encoded without any accurate visual tracking. The extracted features will then be fed to the MLP neural network with back propagation learning scheme for precise classification of motions.

## IV. TECHNICAL DETAILS

### A. Foreground Segmentation

Background subtraction is a particularly popular method for motion segmentation and attempts to detect moving regions in an image by differencing between current image and a reference background image in a pixel-by-pixel fashion. In order to human segmentation and extracting the moving objects; here we use a background subtraction method described in [15], which is fairly robust and gives appropriate results on image sequences with shadows, highlights and high image compression.

### B. Feature Extraction

One of the issues of major importance in a recognition system is feature extraction, i.e., the transition from the initial data space to a feature space that will make the recognition problem more tractable. So we analyze the shape changes of the extracted silhouettes in the video sequence. To this aim, three main features that retain the motion information of the actions and can be easily obtained are selected to form a feature vector.

#### • *Approximated Ellipse*

When a motion is detected, an analysis on the moving object is performed to detect a change in the human shape, more precisely in orientation and proportion. The person is then approximated by an ellipse using moments [4]. An ellipse is defined in a 5D parameter space by its center  $(\bar{x}, \bar{y})$ , its orientation and the length  $a$  and  $b$  of its major and minor semi-axes [13]. The authors believe that this representation of a person is rich enough to support recognition of different events. For a continuous image  $f(x, y)$ , the moments are given by:

$$m_{pq} = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} x^p y^q f(x, y) dx dy \quad \text{for } p, q = 0, 1, 2, \dots \quad (1)$$

The center of the ellipse  $(\bar{x}, \bar{y})$  is used to compute the central moment as follows:

$$\mu_{pq} = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} (x - \bar{x})^p (y - \bar{y})^q f(x, y) d(x - \bar{x}) d(y - \bar{y}) \quad (2)$$

Fig. 1. Approximated Ellipses of Different Human Postures

The angle between the major axis of the person and the horizontal axis  $x$  gives the orientation of the ellipse and can be computed as follows:

$$\theta = \frac{1}{2} \arctan\left(\frac{2\mu_{11}}{\mu_{20} - \mu_{02}}\right) \quad (3)$$

$I_{\min}, I_{\max}$  - the least and greatest moments of inertia-are computed by evaluating the eigenvalues of the matrix:

$$J = \begin{bmatrix} \mu_{20} & \mu_{11} \\ \mu_{11} & \mu_{02} \end{bmatrix} \quad (4)$$

Then, the major semi-axis  $a$  and the minor semi-axis  $b$  of the best fitting ellipse are given by:

$$a = \left(\frac{4}{\pi}\right)^{1/4} \left[\frac{I_{\max}^3}{I_{\min}}\right]^{1/8} \quad b = \left(\frac{4}{\pi}\right)^{1/4} \left[\frac{I_{\min}^3}{I_{\max}}\right]^{1/8} \quad (5)$$

With  $a$  and  $b$ , we can also defined the ratio of the ellipse  $= a/b$  (related to its eccentricity). In order to detecting changes in the human shape discriminate an abnormal behavior from other normal activities, two values are computed:

- **The orientation standard deviation of the ellipse:** If a person falls perpendicularly to the camera optical axis, then the orientation will change significantly and  $\sigma_\theta$  will be high. If the person just walks,  $\sigma_\theta$  will be low.
- **The ratio standard deviation of the ellipse:** If a person falls parallelly to the camera optical axis, then the ratio will change significantly and  $\sigma_p$  will be high. If the person just walks,  $\sigma_p$  will be low.

Note that  $\sigma_\theta$  and  $\sigma_p$  are computed for a 2 second duration. As Fig. 1 demonstrates,  $\sigma_\theta$  and  $\sigma_p$  are completely distinctive for different postures.

#### • Projection Histograms

The shape of a 2D binary silhouette can be represented by its projection histogram [13]. The horizontal and vertical projection histogram of foreground is obtained by calculating the number of foreground pixels row wise and column wise. Since projection histograms vary according to location of object in the scene, it's necessary to perform normalization step first. The widely used approach for normalization is rescaling the detected silhouette to a fixed length  $M$  [2]. However, the normalization parameter is usually obtained by trial and error and also it is posture dependant and strongly sensitive to different postures. To overcome these drawbacks, we propose exploiting *Discrete Fourier Transform* method for normalization.. Let us denote the image size as  $N \times M$ , so we can consider the foreground  $F$  as cloud of  $(x_p, y_p)$  points. Then the horizontal and vertical projection histograms of foreground  $F$  can be defined as follows:

$$Hz(y) = \left| (x_p, y_p) \in F, y_p = y \right| \quad (6)$$

$$Vt(x) = \left| (x_p, y_p) \in F, x_p = x \right|$$

Applying DFT on  $H_z(y)$  and  $V_t(x)$  results in:

$$DFT_{Hz(h)} = \frac{1}{N} \sum_{i=1}^N H_z(i) e^{-2j\pi \frac{hi}{N}} \quad h = 0, \dots, N-1 \quad (7)$$

$$DFT_{Vt(v)} = \frac{1}{M} \sum_{i=1}^M V_t(i) e^{-2j\pi \frac{vi}{M}} \quad v = 0, \dots, M-1$$

Fig. 2. Projection Histograms

Magnitudes of these DFT coefficients tend to decay for large values of  $h$  and  $v$ . Besides, different postures magnitudes differ mostly in the first few term.

Thus we extract first fifty significant DFT coefficients i.e.  $DFT_{Hz(1)} \dots DFT_{Hz(50)}$  and  $DFT_{Vt(1)} \dots DFT_{Vt(50)}$  are selected and normalized by:

$$NDFT_{Hz(h)} = \frac{|DFT_{Hz(h)}|}{|DFT_{Hz(1)}|} \quad h = 2, \dots, 50 \quad (8)$$

$$NDFT_{Vt(v)} = \frac{|DFT_{Vt(v)}|}{|DFT_{Vt(1)}|} \quad v = 2, \dots, 50$$

Normalized magnitudes of fifty significant DFT coefficients of different postures are shown in Fig. 2.

#### • Temporal Changes of Head Position

Head position is a potentially powerful and intuitive pointing cue if it can be obtained accurately and noninvasively. We choose to track the head because it is usually visible in the scene (no occlusion problems), and has a large movement during a fall. Our proposed method tries to estimate a person's head position in every frame of a video sequence and further infer his attentive behavior. To localize the head of the person, firstly silhouette is enclosed by minimum bounding rectangle and then the topmost detected point of the bounding box is marked in each frame [14]. Then the absolute difference values in successive frames are obtained. The difference in topmost point of the head over successive frames forms this part of our feature vector, and applying appropriate threshold on the vertical displacement of topmost point, results in proper differentiation of various behaviors. The curves obtained from sequence of successive head positions are shown in Fig. 3. Notice that the movement of head is computed for a 3 second duration.

#### C. Posture Classification

Neural Network is an interesting approach for analyzing time-varying data. Here, for each activity which has to be recognized a solitary neural network has been used. So for recognition of  $n$  activities,  $n$  neural networks exist. In this study we use a four-layered MLP network with backpropagation learning schema. MLP is a supervised neural network that can have multiple inputs and outputs and multiple hidden layers with arbitrary number of neurons. The activation function is  $a_j = f(\sum w_{ji} a_i)$ , where the  $w_{ji}$  is the weight of  $j$ th node in current layer to  $i$ th node in previous layer and  $a_i$  is the output of  $i$ th node in previous layer.  $f(x)$  is sigmoid function. All available data are random divided into two subsets, for training and testing respectively.

### V. EXPERIMENTAL RESULTS AND DISCUSSION

#### A. Experimental Setup

In order to evaluate the overall system performance, we apply the proposed approach to a set of videos recorded in our lab. Here we consider indoor environment settings with single fixed camera monitoring static scene. Distance of person to the camera is approximately 4-5 meters. We could expect three different kinds of behavior: Normal, Unusual and Abnormal.

- a) **Normal Daily Activity:** Five different normal daily activities are considered: Walking, Running, Bending down for catching something and rising up, Sitting down on the floor and standing up and Lying down.
- b) **Unusual -Fall-:** As most falls occur during intentional movements initiated by the person, they happen mainly in forward or backward: stumbling on an obstacle during walking, backward slip on wet ground.

Fig. 3. Vertical Movement of Person's Head

But in some cases the fall occurs sideways, either during a badly controlled sit to stand transfer. In this case, the person frequently tries to grip the wall [1].

#### c) Abnormal

**Stumble:** Subjects were asked to walk in an unusual way, e.g. as if they were suffering a balance deficiency such as dizziness. In these situations person is unable to keep his balance or symmetry and synchrony of his movement. Body movements suggest the person is in a dubious condition.

**Limp:** Limping may be caused by unequal leg lengths, experiencing pain when walking, muscle weakness, disorders of proprioception, or stiffness of joints.

50 subjects with different height, weight and genders whose ages ranged from 20 to 30 were asked to participate in the project. We repeated 10 kinds of activities by 5 times in the experimental space.

#### B. Evaluation of the Proposed Method

TABLE I  
RECOGNITION RATE FOR VARIOUS EVENTS

| Events        | $N_a$ | $N_c$ | $N_f$ | $R$   |
|---------------|-------|-------|-------|-------|
| Walk          | 125   | 114   | 11    | 91.20 |
| Run           | 125   | 112   | 13    | 89.60 |
| Stumble       | 125   | 112   | 13    | 89.60 |
| Limp          | 125   | 110   | 15    | 88.00 |
| Forward Fall  | 125   | 116   | 9     | 92.80 |
| Backward Fall | 125   | 118   | 7     | 94.40 |
| Sideway Fall  | 125   | 114   | 11    | 91.20 |
| Bend down     | 125   | 113   | 12    | 90.40 |
| Sit down      | 125   | 112   | 13    | 89.60 |
| Lie down      | 125   | 118   | 7     | 94.40 |

The experimental results show that the proposed system is able to achieve promising results under most test conditions. Table I represents robust recognition rate of experimental results.  $N_a$  refers to number of actions,  $N_c$

is number of correctly detected events,  $N_f$  is number of falsely detected events and  $R$  is the recognition rate.

To evaluate performance of the proposed system, we use two famous criteria that are widely used in fall detection systems. Sensitivity is the capacity to detect a fall and Specificity is the capacity to detect only a fall:

$$Sensitivity = \frac{TP}{TP + FN}, \quad Specificity = \frac{TN}{TN + FP}$$

The definitions of TP, FP, FN and TN are as follows:

| Fall Incident \ System Recognition | Occurs | Does Not Occur |
|------------------------------------|--------|----------------|
| Positive                           | TP     | FP             |
| Negative                           | FN     | TN             |

According to section V.A dataset of our experiments is composed of video sequences representing 875 normal/abnormal activities and 375 simulated falls. Table II itemizes all the results obtained with our dataset. According to above information, Sensitivity and Specificity of the proposed system would be 92.80 and 97.60 respectively.

TABLE II  
EVALUATION OF RECOGNITION RESULTS

| Fall Incident \ System Recognition | Occurs | Does Not Occur |
|------------------------------------|--------|----------------|
| Positive                           | 348    | 21             |
| Negative                           | 27     | 854            |

#### VI. CONCLUSIONS

In this paper we developed a novel real-time video surveillance system principally dedicated to fall detection. We claim that the proposed system is not just an ordinary

Fig.4. Example of Each Motion

human fall detection system; it has many applicable properties and can be employed in different surveillance systems. Moreover while existing fall detection systems are only able to detect occurrence of fall behavior, the proposed system is able to detect type of fall incident (forward, backward or sideway). Since temporal changes of the human shape give crucial information on human activities, we used combination of approximated ellipse around the human body, horizontal and vertical projection histograms and temporal changes of human head position as feature vectors. Also, our experiments indicate that MLP Neural Network is totally a suitable classifier for human motion recognition. Reliable average recognition

rate of experimental results (91.12%) underlines satisfactory performance and efficiency of our system.

# An Improved Keyword Extraction Method Using Graph Based Random Walk Model

Md. Rafiqul Islam and Md. Rakibul Islam

Computer Science and Engineering Discipline, Khulna University, Khulna-9208, Bangladesh

**Abstract** — Keywords can be considered as condensed versions of documents, which can play important role in some text processing tasks such as text indexing, summarization and categorization. However, there are many digital documents especially on the Internet that do not have a list of assigned keywords. Assigning keywords to these documents manually is a difficult task and requires appropriate knowledge of the topic. Automatic keyword extraction process can solve this problem. In this paper, we introduce a new improved method for keyword extraction using random walk model by considering position of terms within the document and information gain of terms corresponds to the whole set of documents. We also incorporate mutual information (*MI*) of terms with random walk model to extract keywords from documents. The experiments on standard test collections show that our method outperforms the previously proposed methods.

**Index Terms** — Keyword extraction, random walk model, mutual information, term position, information gain.

## I. INTRODUCTION

Keywords can be considered as brief summaries of a text. Therefore, it is possible to think of them as a set of phrases semantically covering most of the text. Although a summary of a text is capable of providing more information about the text than keywords of the text, the summary may not be suitable for some applications due to the complex structure of sentences. Keywords can not be replaced for summarization but these are alternative summary representations that could be consumed by other applications more easily.

Keywords enable readers to decide whether a document is relevant for them or not. They can also be used as low cost measures of similarity between documents. Unfortunately, a great portion of existing documents available today does not have keywords available for them [8]. Considering the fact that it is a hard and time consuming task to assign keywords to documents, it is desirable to automate this task by natural language processing (NLP) techniques.

The random walk ranking algorithm on a graph proposed by Brin and Page in [10], has been used in citation analysis, social networks and analysis of the link structure of the web [1]. A graph-based ranking algorithm is a way of deciding on the importance of a vertex within a graph, by taking into account global information, recursively computed from the entire graph, rather than

relying only on local vertex-specific information. The basic idea implemented by a random walk algorithm is that, when one vertex links to another one, it is basically casting a vote for other vertex [2]. The higher the number of votes that are cast for a vertex, the higher the importance of the vertex. On the other hand, mutual information is used to identify relatedness of two or more terms [7].

Term weighting is one of the most important considerations for keyword extraction. The purpose of a term weighting method is to classify the terms by assigning them weights corresponding to how well they improve both recall and precision. Mihalcea and Tarau propose a modified random walk model to weight terms for keyword extraction which provides better result than state-of-the-art systems developed in these areas [3]. They consider term dependencies with edge weights in their approach. However, they do not take into account terms importance within total corpus and terms positions in a single document to calculate the weight of terms. In our approach to weight a term, we exploit the relationship of local information of a vertex (term position) as well as global information (*MI*) and term dependency. Moreover, taking into account mutual information (*MI*) of co-occurrence terms, we introduce a new formula to weight terms for extracting keywords. Experimental results show the improvement of our graph based random walk-model, providing better result than the work of Mihalcea and Tarau [3] and Jinghua *et al.* [4].

The rest of this paper is organized as follows: In section II we describe the basic random walk model, related works and their problems are discussed in section III. Section IV presents our improved keyword extraction method. The experimental results are discussed in section V. Finally, we present conclusion in section VI.

## II. RANDOM WALK MODEL – TEXTTRANK

The basic idea implemented by a random-walk algorithm is that of *voting* or *recommendation* [2]. When one vertex links to another one, it is basically casting a vote for that other vertex. The higher the number of votes that are cast for a vertex, the higher the importance of the vertex [2]. Moreover, the importance of the vertex casting a vote determines how important the vote itself is, and this

information is also taken into account by the ranking algorithm. There are several random-walk algorithms that have been proposed in the past and between these algorithms, TextRank is previously found successful in a number of applications, including web link analysis, social networks, citation analysis, and more recently in several text processing applications [2].

Given a graph  $G = (V, E)$ , let  $In(V_a)$  be the set of vertices that point to vertex  $V_a$  (predecessors), and  $Out(V_a)$  be the set of vertices that vertex  $V_a$  points to (successors). The TextRank score associated with the vertex  $V_a$  is defined using the equation 1.

$$s(v_a) = (1 - d) + d \times \sum_{b \in In(v_a)} \frac{s(v_b)}{|Out(v_b)|} \quad (1)$$

Where  $s(v_a)$  = score of vertex  $v_a$ ,  $s(v_b)$  = score of vertex  $v_b$ ,  $In(v_a)$  = indegree of vertex  $v_a$ ,  $|Out(v_b)|$  = outdegree of vertex and  $d$  is a parameter that is set between 0 and 1 [2].

The score of each vertex is recalculated upon each iteration based on the new weights that the neighboring vertices have accumulated. Neighbors of a vertex are determined by window size  $N$ . If  $N$  is 3 then consecutive forward and backward three vertices are neighbor. The algorithm terminates when the convergence point is reached for all the vertices, meaning that the error rate for each vertex falls below a pre-defined threshold. This vertex scoring scheme is based on a random-walk model, where a walker takes random steps on the graph, with the walk being modeled as a Markov process [2]. Under certain conditions, the model is guaranteed to converge to a stationary distribution of probabilities associated with the vertices in the graph. Intuitively, the stationary probability associated with a vertex represents the probability of finding the walker at that vertex during the random-walk, and thus it represents the importance of the vertex within the graph [2].

### III. RELATED WORKS

The state-of-the-art in this area is currently represented by supervised learning methods, where a system is trained to recognize keywords in a text, based on lexical and syntactic features. This approach is first suggested in [5], where parameterized heuristic rules are combined with a genetic algorithm into a system for keyphrase extraction that automatically identifies keywords in a document [3].

In Frank *et al.* method where a Naive Bayes learning scheme is applied on the document collection [6], with

improved results observed on the same data set as used in [5].

In [3], it is stated that neither Turney nor Frank report on the recall of their systems, but only on precision: a 29.0% precision is achieved with GenEx for five keyphrases extracted per document, and 18.3% precision achieved with Kea for fifteen keyphrases per document.

In [8], Hulth applies a supervised learning approach that integrates part of speech information into the learning process to keyword extraction from abstracts, using a combination of lexical and syntactic features and proves the improvement significantly over previously proposed methods. Hulth states that, keyword extraction from abstracts is more widely applicable than from full texts, since many documents on the Internet are not available as full-texts, but only as abstracts [3]. Her experiment shows that the accuracy of the system is almost doubled by adding linguistic knowledge to the term representation [3].

In [4], a new algorithm is presented that represents the text as a semantic graph with synset from WordNet, disambiguates the words, and finally extracts keywords from the text based on UW-PageRank. It needs no corpus, moreover it has the ability to disambiguate all the words in the text, and extracts keywords by analyzing the semantic structure of the whole text. The experiment result shows that their algorithm is effective and practical.

The work described in [4], is a corpus independent method. Generally it is accepted that corpus independent method does not yield better method than corpus dependent method [12].

Mihalcea and Tarau introduce the TextRank graph-based ranking model for keyword and sentence extraction from natural language texts [3]. Here, a new formula is introduced for graph-based ranking that takes into account edge weights while computing the score associated with a vertex in the graph [3].

$$WS(v_i) = (1 - d) + d \times \sum_{v_j \in In(v_i)} \frac{w_{ji}}{\sum_{v_k \in Out(v_j)} w_{jk}} WS(v_j) \quad (2)$$

Where  $WS(v_i)$  is the weighting score of vertex  $v_i$ ,  $d$  denotes the damping factor and  $w_{ji}$  is the edge weight of the vertex  $v_i$  and  $v_j$ .

We describe another work of Hassan *et al.* [2] used for text classification, as our approach has similarity with this work. Hassan *et al.* introduce a system that models the weighting problem as a “random-walk” rather than “random choice” [2]. They assume an imaginary reader who steps through the text on a term by term basis. In this setting, the importance of the term is determined by the probability of the random-walker to encounter the target term in the text during the walk. In this paper, the various best random-walk based term weighting models are

summarized such as  $rw_e \cdot idf$ ,  $rw_{e.oc}$  etc. Here we describe the following model:

$rw_e \cdot idf$ : This model represents an undirected graph approach that uses the weighted edge version of PageRank with a variable damping factor. The weight of an edge is calculated by the equation 3.

$$E_{v_1, v_2} = tf \cdot idfv_1 \times tf \cdot idfv_2 \quad (3)$$

Where  $E_{v_1, v_2}$  is the edge connecting  $v_1$  to  $v_2$  and  $tf \cdot idfv_1$ ,  $tf \cdot idfv_2$  represent the term frequency multiplied by the inverse document frequency respect to vertices  $v_1$  and  $v_2$ . The damping factor is expressed as a function of the 'incoming edges' weight, calculated as follows:

$$d_{E_{v_1, v_2}} = E_{v_1, v_2} / E_{\max} \quad (4)$$

where  $d_{E_{v_1, v_2}}$  is the damping factor and  $E_{\max}$  represents the highest weight for an edge in the graph. Thus the score of a vertex can be calculated by the formula in [2] is as follows:

$$s'(v_1) = \frac{(1-d)}{|N|} + \sum_{v_2 \in \ln(v_1)} C \times \frac{d_{E_{v_1, v_2}} \times s(v_2)}{|Ou(v_2)|} \quad (5)$$

where  $s'(v_1)$  = score of vertex  $v_1$ ,  $N$  = total number of nodes,  $C$  = scaling constant [2].

Here the new measure of term weighting integrates both the locality of a term and its relation to the surrounding context. Though Hassan *et al.* use the work for text classification, we describe it here as it is related to our work.

#### IV. KEYWORD EXTRACTION METHOD USING GRAPH BASED RANDOM WALK MODEL

This section describes the method we use to extract keywords from documents. To do our work we use two phases - preprocessing phase and post processing phase, in our method. We determine the weight of each vertex in a graph in preprocessing phase. In post processing phase we construct multiword keywords (key phrases) if needed. Description of our method is given bellow:

1) To identify the text units (terms), the document is tokenized using text operations - stopword removals, stemming and each token is annotated with part of speech tags. We use the list of stop words enlisted in the Smart System [11] to remove stop word from graph. Considering only single words as candidates for addition to the graph, we avoid excessive growth of the graph size by adding all

possible combinations of sequences consisting of more than one lexical unit.

2) For each term in the processed documents, we calculate  $tf \times idf$  and random-walk weights ( $rw$ ). To calculate the  $tf \times idf$  of each vertex, we use the method described by Yue-Heng Sun *et al.* in [9], state that terms in the title should have higher importance than those in the abstract. Similarly the terms in the abstract should have higher importance than those in the text, and so on. Therefore in [9], computing method of  $tf_{ij}$  uses some factors to reflect the importance of term position, shown in the equation 6.

$$tf_{ij} = \alpha tf_{ij1} + \beta tf_{ij2} + \gamma tf_{ij3} \quad (6)$$

Where,  $tf_{ijk}$  is the frequency of a term in the  $k^{th}$  area and  $\alpha, \beta, \gamma$  are the factors that can be adjustable according to pre-experiments. Here  $\alpha > \beta > \gamma \geq 1$ .

Moreover, to give more importance to a term that has discriminating power to identify a document, Yue-Heng Sun *et al.* introduce *information gain* ( $IG_j$ ) for a term  $j$  [9]. We calculate  $tf \times idf$  according to the equation 7 given in [9].

$$tf_{ij} \times idf_j = \frac{tf_{ij} \times \log\left(\frac{N}{n_j} + 0.01\right) \times IG_j}{\sqrt{\sum_{i \in d} \left[tf_{ij} \times \log\left(\frac{N}{n_j} + 0.01\right) \times IG_j\right]^2}} \quad (7)$$

Where  $tf_{ij}$  = frequency of term  $j$  within document  $i$ ,  $idf_j$  = inverse document frequency of term  $j$ ,  $n_j$  = number of documents holding term  $j$ ,  $N$  = total number of documents in the corpus. The  $tf_{ij} \times idf_j$  value of each selected term reflects their importance within the document and corresponds to whole documents corpus.

After that, mutual information  $MI_{v_1, v_2}$  of an edge of vertex  $v_1$  and  $v_2$  is determined that express the relatedness of two co-occurrence terms as described in [7] Weight of an edge is calculated using equation 3. Weight of each edge is required to determine the damping factor  $d_{E_{v_1, v_2}}$  in equation 4. The value of damping factor  $d_{E_{v_1, v_2}}$  varies in equation 5 to reflect importance of term. The more the value of damping factor, the term is more important to retrieve the related information. With all of these, our equation will be as follows

$$s'(v_1) = \frac{(1-d)}{|N|} + \sum_{v_2 \in \ln(v_1)} C \times \frac{d_{E_{v_1, v_2}} \times MI_{v_1, v_2} \times s(v_2)}{|Out(v_2)|} \quad (8)$$

All the terms in the document are added as vertices in a graph to represent the document. Identifying relations that connect such terms, we draw edges between vertices in graph. All the terms that fall in the window size of a given term are considered dependent term. This is represented by a set of edges that connect the terms to all other terms in a fixed window size ( $N$ ). After constructing the graph we iterate the random walk algorithm until convergence.

3) Vertices are sorted on their final score. For ranking decision, we use the scores associated with each vertex. Once a final score is obtained for each vertex in the graph, vertices are sorted in reversed order of their score, and the top vertices in the ranking are retained for post-processing. While may be set to any fixed value, usually ranging from 5 to 15 keywords.

Our post-processing phase is similar to work of Mihalcea and Tarau described in [3]. Here all lexical units selected as potential keywords by the graph based ranking algorithm are marked in the text, and sequences of adjacent keywords are collapsed into a multi-word keyword. For instance, in the text *Integrating Logical Operators In Query Expansion*, if *Integrating*, *Logical* and *Operators* are selected as potential keywords by our algorithm, since they are adjacent, they are collapsed into one single keyword *Integrating Logical Operators*.

## V. EXPERIMENTAL RESULT AND DISCUSSION

The data set used in the experiments is a collection of 500 abstracts from the *Inspec* database, and the corresponding manually assigned keywords. This is the same test data set as used in the keyword extraction experiments reported in [3]. The *Inspec* abstracts are from journal papers from Computer Science and Information Technology. Each abstract comes with two sets of keywords assigned by professional indexers: controlled keywords, restricted to a given thesaurus, and uncontrolled keywords, freely assigned by the indexers [3]. We use the uncontrolled set of keywords to compare with the result in [3]. We divided each document in two sections - *title* and *abstract*. The terms in *title* have higher value than the terms in *abstract*.

The result of Mihalcea and Tarau in [3] evaluated using precision, recall, and F-measure is better than the result in [8]. On the other hand, recent corpus independent work of Jinghua *et al.* uses coverage and precision to evaluate their method and achieves better result than  $tf \cdot idf$  method

[4]. So we compare our method with the methods described in [3] and [4].

In [3], experiments are performed with various syntactic filters, including all open class words, nouns and adjectives, and nouns only, and the best performance are achieved with the filter that selects nouns and adjectives only. It is also experimented with a setting in [3], where no part of speech information is added to the text, and all words except a predefined list of stopword are added to the graph. We do our experiments in the similar way. For each method, the Table I list the total number of keywords assigned automatically by each method, the mean number of keywords per abstract, the total number of correct keywords and the mean number of correct keywords. The correctness of keywords is determined against the keywords assigned by professional indexers.

Table II shows comparison between our method and Jinghua *et al.* method. Here coverage is the result of the number of correct keyword divided by the number of keywords the indexers have assigned. Our method achieves better coverage and precision than Jinghua *et al.* method.

We can see from the Table I that we achieve highest precision 39.1 for window size 2 which is greater than the highest precision value 31.2 of Mihalcea and Tarau method. Data of Table II shows that, both coverage and precision values of our method are better than values of Jinghua *et al.* So we can say that our proposed method performs reasonably well than other previous methods.

## VI. CONCLUSION

Automatic keyword extraction is the task of automatically selecting a small set of terms describing the content of a single document. That a keyword is extracted means that it is present verbatim in the document to which it is assigned [8]. In this paper, we describe a new improved way for keyword extraction using random walk model by considering position of terms within the document and information gain of terms corresponds to the whole set of documents. We also incorporate mutual information (*MI*) of terms with random walk model to extract keywords from documents. Using *Inspec* benchmark we test our method to compare with the work of Jinghua *et al.* and Mihalcea and Tarau. The experimental results show that our approach achieves better result than their works. Moreover, our method is language knowledge resources or any manually constructed training data independent.

**Abstract** — Question answering systems use information retrieval (IR) and information extraction (IE) methods to retrieve documents containing a valid answer. Question classification plays an important role in the question answer frame to reduce the gap between question and answer. This paper presents our research work on automatic question classification through machine learning approaches. We have experimented with machine learning algorithms Support Vector Machines (SVM) using kernel methods. An effective way to integrate syntactic structures for question classification in machine learning algorithms is the use of tree kernel (TK) functions. Here we use SubSet Tree kernel with Bag of words. Trade-off between training error and margin, Cost-factor and the decay factor has significant impact when we use SVM for the mentioned kernel type. The experiments determined the individual impact for Trade-off between training error and margin, Cost-factor and the decay factor and later the combined effect for Trade-off between training error and margin, Cost-factor. Depending on these result we also figure out some hyperplanes which can maximize the performance. Based on some standard data set outcomes of our experiment for question classification is promising.

**Index Terms** — Precision, Recall, SVM, kernel, SST, Question Classification, Question Answering.

## I. INTRODUCTION

The World Wide Web continues to grow at an amazing speed. So, there are also a quickly growing number of text and hypertext documents. Due to the huge size, high dynamics, and large diversity of the web, it has become a very challenging task to find the truly relevant content for some user or purpose. The Open-domain Question Answering system (QA) has been attached great attention for its capacity of providing compact and precise results for users.

The study of Question Classification (QC), as a new field, corresponds with the research of QA. At present the studies on QC are mainly based on the text classification. Though QC is similar to text classification in some aspects, they are clearly distinct in that: Question is usually shorter, and contains less lexicon-based information than text, which brings great trouble to QC. Therefore to obtain higher classifying accuracy, QC has to make further analysis of sentences, namely QC has to

extend interrogative sentence with syntactic and semantic knowledge, replacing or extending the vocabulary of the question with the semantic meaning of every word.

In QC, many systems apply machine-learning approaches [1-3]. The classification is made according to the lexical, syntactic features and parts of speech. Machine learning approach is of great adaptability, and 90.0% of classifying accuracy is obtained with SVM method and tree Kernel as features. However, there is still the problem that the classifying result is affected by the accuracy of syntactic analyzer, which need manually to determine the weights of different classifying features. Some other systems adopting manual-rule [4].

This paper presents our approaches at Question Classification to improve the f1-measure [6] of question categorization. Our experiment tried to determine the optimum value for trade-off between training error and margin, cost-factor by which training errors on positive examples outweighs errors on negative examples. It is used to adjust the rate between Precision and Recall on the development set [5-6] and the decay factor which has the role to penalize larger tree structures by giving them less weight in the overall summation [7]. To represent questions, the paper uses the standard Li and Roth [8] question classification dataset.

After this overview, question classifying method, a brief description about the used algorithm and the kernel methods are introduced, and then impact of different parameters and parameters combination methods has been investigated. The comparisons are testified in experiments based on precision, recall and f1-measure. The last part of the paper is about the conclusion of the present research and about the introduction of the further work could be done on this issue.

## II. QUESTION CLASSIFICATION

Question Classification means putting the questions into several semantic categories. Approaches to question classification can be divided in two broad classes, namely, rule-based and machine learning methods. Most recent studies have been based on machine learning approaches. Li and Roth [8] proposed 6 coarse classes and 50 fine classes for TREC factoid question answering. The UIUC

QC dataset, which they developed, contains 5,500 training questions and 500 test questions, and it is now the standard dataset for question classification [9].

In Table I Each coarse grained category contains a non-overlapping set of fine grained categories. Most question answering systems use a coarse grained category definition. Usually the number of question categories is less than 20. However, it is obvious that a fine grained category definition is more beneficial in locating and verifying the plausible answers.

TABLE 1: THE COARSE AND FINE GRAINED QUESTION CATEGORIES.

| Coarse | Fine                                                                                                                                                                                           |
|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ABBR   | Abbreviation, expansion                                                                                                                                                                        |
| DESC   | description, definition, manner, reason                                                                                                                                                        |
| ENTY   | body, color, event, food, creation, currency, animal, disease/medical, instrument, language, letter, other, plant, product, religion, sport, substance, symbol, technique, term, vehicle, word |
| HUM    | description, group, individual, title                                                                                                                                                          |
| LOC    | city, country, mountain, other, state                                                                                                                                                          |
| NUM    | code, count, date, distance, money, order, other, percent, period, speed, temperature, size, weight                                                                                            |

### III. SUPPORT VECTOR MACHINE (SVM)

Support vector machine are based on the Structural Risk Minimization principle from statistical learning theory [10]. The idea of structural risk minimization is to find a hypothesis  $h$  for which we can guarantee the lowest true error. The bounds are connected on the true error with the margin of separating hyperplanes. In their basic form support vector machines find the hyperplane that separates the training data with maximum margin. Since we will be dealing with very unbalanced numbers of positive and negative examples in the following, we use cost factors  $C_+$  and  $C_-$  to be able to adjust the cost of false positives vs. false negatives as [11]. Finding this hyperplane can be translated into the following optimization problem:

$$\text{Minimize: } \frac{1}{2} \|\vec{w}\|^2 + C_+ \sum_{i: y_i=1} \xi_i + C_- \sum_{i: y_i=-1} \xi_i$$

$$\text{Subjected to: } \forall k : y_k [\vec{w} \cdot \vec{x}_k + b \geq 1 - \xi_k]$$

Here  $x_i$  is the feature vector of example  $i$ .  $y_i$  equals +1 or -1, if example  $i$  is in class '+' or '-' respectively.

Using support vector machine we tried to determine the optimal value of trade-off between training error and

margin (c), cost-factor (j) by which training errors on positive examples outweighs errors on negative examples. It is used to adjust the rate between Precision and Recall on the development set [11]. Here Lambda ( $\lambda$ ) the decay factor which has the role to penalize larger tree structures by giving them less weight in the overall summation.

### IV. KERNEL METHODS

One of the most difficult tasks on applying machine learning for question classification is the feature design. Feature should represent data in a way that allows learning algorithm to separate positive from negative examples. In SVMs, features are used to build the vector representation of data examples and the scalar product between example pairs quantifiers how much they are similar. Instead of encoding data in the features vectors, kernel functions can be designed that provide such similarity between example pairs without using an explicit feature representation [6].

The kernel we considered in this paper represents trees in terms of their substructure. Such fragments define the feature space which, in turn, is mapped into a vector space. The kernel function measures the similarity between trees by counting the number of common fragments. These functions have to recognize if a common tree subpart belongs to the feature space that we intended to generate. Here we considered SubSet Trees (SSTs). A SubTree is defined as any node of a tree along with all its descendants. A SubSet Tree is more general structure which not necessarily includes all the descendants. The only restriction is that an SST must be generated by applying the same generated the original tree [12].

The main idea of the tree kernel is to compute the number of the common substructures between two trees  $T_1$  and  $T_2$  without explicitly considering the whole fragment space. From [6] given a tree fragment space  $\{f_1, f_2, \dots\} = F$ , here we denote the indicator function  $I_i(n)$  which is equal 1 if the target  $f_i$  is rooted at the node  $n$  and 0 otherwise. It followed that-

$$K(T_1, T_2) = \sum_{n_1 \in N_{T_1}} \sum_{n_2 \in N_{T_2}} \Delta(n_1, n_2) \dots (1)$$

where  $N_{T_1}$  and  $N_{T_2}$  are the sets of the  $T_1$ 's and  $T_2$ 's

nodes, respectively and  $\Delta(n_1, n_2) = \sum_{i=1}^F I_i(n_1) I_i(n_2)$ .

This letter is equal to the number of common fragments rooted at the  $n_1$  and  $n_2$  nodes. We can compute  $\Delta$  as follows-

1. if the production at  $n_1$  and  $n_2$  are different the  $\Delta(n_1, n_2) = 0$ ;

2. if the production at  $n_1$  and  $n_2$  are the same, and  $n_1$  and  $n_2$  have only leaf children (pre-terminal symbols) then  $\Delta(n_1, n_2) = 1$  ;
3. if the production at  $n_1$  and  $n_2$  are the same, and  $n_1$  and  $n_2$  are not pre-terminals then

$$\Delta(n_1, n_2) = \prod_{j=1}^{nc(n_1)} (\sigma + \Delta(c_{n_1}^j, c_{n_2}^j))$$

where  $\sigma \in \{0,1\}$ ,  $nc(n_1)$  is the number of the children of  $n_1$  and  $c_n^j$  is the  $j$ -th child of the node  $n$ . As the production is same  $nc(n_1) = nc(n_2)$ .

When  $\sigma = 0$ ,  $\Delta(n_1, n_2)$  is equal 1 only if  $\forall j \Delta(c_{n_1}^j, c_{n_2}^j) = 1$ , i.e. all the productions associated with the children are identical. By recursively applying the property, it follows the SubTrees in  $n_1$  and  $n_2$  are identical. Thus Eq. 1 evaluate the SubSet Tree kernel .When  $\sigma = 1$ ,  $\Delta(n_1, n_2)$  evaluates the number of SSTs common to  $n_1$  and  $n_2$  as proved in [12].

To include the leaves as fragments it is enough to add, to the recursive rule set for the  $\Delta$  evaluation, the condition is- if  $n_1$  and  $n_2$  are leaves and their associated symbols are equal then  $\Delta(n_1, n_2) = 1$ . By [6] such extended kernel can be referred as SST+bow (*bag-of-words*). Here the decay factor ( $\lambda$ ) is defined as  $\Delta(n_x, n_z) = \lambda$

$$\text{and } \Delta(n_x, n_z) = \lambda \prod_{j=1}^{nc(n_x)} (\sigma + \Delta(c_{n_1}^j, c_{n_2}^j)).$$

## V. RESULTS AND ANALYSIS

We evaluate the performance of Question Classification using SVM with SubSet Tree kernel with Bag of words (SST+BOW). First we investigate the optimum value of trade-off between training error and margin ( $c$ ) keeping cost-factor ( $j$ ) and the decay factor ( $\lambda$ ) constant. Then we investigate the impact of cost factor ( $j$ ) for constant trade-off between training error and margin ( $c$ ) and decay factor ( $\lambda$ ). Then for constant factor ( $\lambda$ ) we determine the hyper plane for trade-off between training error and margin ( $c$ ) and cost-factor ( $j$ ) which have the maximum f1-measure. Finally we determined the impact of decay factor ( $\lambda$ ) for a constant trade-off between training error and margin ( $c$ ) and cost-factor ( $j$ ).

Fig. 1 (a-d). shows the Trade of between Training error and Margin ( $c$ ) versus performance (measured by f1-measure) curve for different types of QC data set using different Cost Factor ( $j$ ) and fixed Decay factor ( $\lambda=0.01$ ). Here it is notable for same set of parameters different data

types have different performance level. For different cost factor highest f1-measure can be achieved by setting the trade-off between training error and margin ( $c$ ) around 2, Afterwards its performance becomes almost constant.

Fig. 1 (a). Training error and Margin Vs F1 Measure for  $j = 0.5$ .

Fig. 1 (b). Training error and Margin Vs F1 Measure for  $j = 1.5$ .

Fig. 1 (c). Training error and Margin Vs F1 Measure for  $j = 3.5$ .

Fig. 1 (d). Training error and Margin Vs F1 Measure for  $j = 6.0$ .

Fig. 2 (c). Cost factor Vs F1 measure for  $C=1.5$ .

Fig. 2. (a-d) shows the cost factor ( $j$ ) versus performance (measured by f1-measure) curve for different types of question classification data set using different of Trade of between Training error and Margin ( $c$ ) and fixed Decay factor ( $\lambda=0.01$ ).

Fig. 2. (a) Cost factor Vs F1 measure for  $C=0.5$ .

Fig. 2 (b). Cost factor Vs F1 measure for  $C=1$ .

For a constant trade-off between training error and margin different types of questions have highest f1-measure. For different value of  $c$  highest f1-measure can be achieved by setting the cost factor ( $j$ ) less than 2.

Fig. 2 (d). Cost factor Vs F1 measure for  $C=3.5$ .

If the value of cost factor is increased then the f1-measure is decreased a certain amount and after a stage it becomes almost constant.

Fig. 3. Impact of Decay Factor.

Fig. 3. shows the Decay factor ( $\lambda$ ) versus f1-measure curve for a constant values of Trade off between Training error and Margin ( $c=1.5$ ) and cost factor ( $j=1.5$ ). To get a very high f1 measure decay factor should have very small. Starting after 0, up to 0.5 its performance is almost steady but if we increase the decay factor more the performance decreased drastically.

Fig. 4(a). Hyperplane for ABBR data type.

Fig. 4(d). Hyperplane for LOC data type.

Fig. 4(b). Hyperplane for HUM data type.

Fig. 4(e). Hyperplane for ENTJ data type.

Fig. 4(c). Hyperplane for DESC data type.

Fig. 4(f). Hyperplane for NUM data type.

Fig. 4(a-f). Shows the hyper plane by which maximum f1-measure can be achieved. For a constant Decay factor ( $\lambda$ ) a set of values of Trade of between Training error and margin (c) and cost factor (j) can provide the highest f1-measure.

Among the six type of data set 'LOC' type of question have to classified by some fixed combination of Trade of between Training error and Margin (c) and cost factor (j) because there is no hyper plane but some peaks.

TABLE 2: MAXIMUM F1- MEASURE OBTAINED USING SUBSET TREE KERNEL-BAG OF WORDS (SST+BOW) FOR  $\lambda=0.01$ .

| Coarse | F1    | P(%) | R(%)  | A(%)  | j   | c   |
|--------|-------|------|-------|-------|-----|-----|
| ABBR   | 88.89 | 99.6 | 88.89 | 88.89 | 6   | 1   |
| DESC   | 96.77 | 98.2 | 95.74 | 97.83 | 1   | 2.5 |
| ENTY   | 82.87 | 93.8 | 86.21 | 79.79 | 6   | 2   |
| HUM    | 95.24 | 98.8 | 98.36 | 92.31 | 4   | 3.5 |
| LOC    | 87.8  | 96   | 86.75 | 88.89 | 5.5 | 0.5 |
| NUM    | 94.01 | 97.4 | 98.08 | 90.27 | 5   | 1   |

Table 2 shows the maximum F1- measure (F1) obtained using SubSet tree Kernel-Bag of words (SST+BOW) for  $\lambda=0.01$  and the corresponding precision (P), recall (R), accuracy (A) for specific cost factor (j) and trade-off between training error and margin (c).

## VI. CONCLUSION

Question classification is one importance role in the QA frame to reduce the gap between question and answer. It can conduct answer choosing and selection. Our question classification method based on the use of linguistic knowledge and machine learning approaches and it exploit different classification features and combination method, also. Though among all the experiments one or two data set didn't provide distinguishable hyperplane in every cases thereafter the outcome of experiments done using the tool SVM\_light on Li and Roth question classification data sets demonstrate some optimal set of values. In the future we aim to investigate the impact of different parameters on constituent trees using different types of kernel.

# On the Design of an Effective Corpus for Evaluation of Bengali Text Compression Schemes

Md. Rafiqul Islam, and S. A. Ahsan Rajon

Computer Science and Engineering Discipline, Khulna University, Khulna-9208, Bangladesh.

**Abstract** — In this paper, we propose an effective platform for evaluation of Bengali Text Compression Schemes. We perform a methodical study on the formulation-approaches of text corpus for data compression and present an effective corpus named *Ekushe-Khul* for evaluating the Bengali text compression schemes, which is the first initiative in the context of Bengali Text Compression. To design the Bengali text compression corpus, we consider Type to Token Ratio as the selection criteria with a number of secondary considerations. This paper also presents a mathematical analysis on data compression performance with structural aspects of corpora. The proposed corpus is effective for evaluating compression efficiency of small and middle sized text files.

**Index Terms** — Corpus, Bengali Text, Bengali Text Compression, Dictionary Coding, Data Management, Evaluation Platform, Compression Efficiency, Type to Token Ratio (TTR).

## I. INTRODUCTION

With a number of languages in the world, Bengali is the only language, which has been established at a cost of lives. However, in the establishment of Bengali as a glittering candidate in the field of research the number of steps or achievements is not so mention-worthy. Enhancing Data Management techniques for Bengali text has not yet got any robust base. Text Compression, which is one of the important aspects of elementary data management and text manipulation schemes, is still now mostly based on generalized universal compression techniques. The remaining sophisticated Bengali text compression schemes also suffer from unavailability of standard evaluation platform, *i.e.* unavailability of text compression corpus. This paper proposes a text compression corpus for evaluating Bengali text compression.

The construction of a data compression corpus is now a demand-of-time. The state-of-the-earth technologies of data management have already equipped the benchmarks and standard collection of experimental data sets for performance evaluation. In Bengali, though a highly impressive step has been initiated in [1] for constructing a linguistic corpus having CIIL corpus [2] as a pioneer, still now any mentionable sophisticated data compression

corpus is not available with text compression benchmarks. This paper focuses on designing a Bengali text compression corpus based on *Type to Token Ratio (TTR)* and provides the mathematical framework for various aspects of choosing the corpus with compression benchmarks.

The paper is organized into eight sections. Section II provides elementary concepts on corpus and text compression schemes. The key-points for constructing a corpus is presented in section III. Section IV is devoted with the literature review presenting various aspects of the existing corpora (Corpuses). Section V describes the proposed approach for formulating the corpus. A brief description on the files comprising the proposed text compression corpus is presented in section VI. Analysis of the proposed corpus depicted in section VII. The paper ends with section VIII providing recommendations and directions for future work.

## II. OVERVIEW OF CORPUS AND DATA COMPRESSION

Text Compression is an elementary aspect of data compression. Compression is the process of reducing the size of a file or data by identifying and removing redundancy in its structure [3],[4]. Data Compression offers an effective approach of reducing communication costs by using available bandwidth effectively. Data Compression technique is generally divided into two categories; namely, Lossless Data Compression and Lossy Data Compression. For Lossless schemes, the recovery of data should be exact. Lossless compression algorithms are to some extent essential for all kinds of text processing, scientific and statistical databases applications, medical and biological image processing, DNA and other biological data management and so on. However, a lossy data compression technique does not ensure the exact recovery of data. For image compression and multimedia data compression, there is a great use of lossy data compression. From the early 1990, certain specific platforms of evaluating English text compression are adapted for standard researches, which are better known as data compression corpus.

In general sense, a corpus is simply a collection of texts. From the point of view of data compression, compression-corpus is a standard collection of texts or data for analyzing and evaluating effectiveness and efficiency *i.e.* performance of compression schemes. The mostly used data compression corpora for evaluating data compression are namely Calgary Corpus, Canterbury Corpus and Project Gutenberg. Though the corpora for English were introduced in the early 1990, still now, for analyzing and evaluating Bengali text compression performance, no such complete and standard corpus is available. In this paper, we present a new Corpus for evaluation of Bengali text compression approaches.

### III. CHARACTERISTICS OF A DATA COMPRESSION CORPUS

The characteristics of a corpus is defined by the purpose of creating the corpus and the evaluation arena for which the corpus is designed for. This criteria give rise to the necessity to field-specific corpora like data compression corpus, information retrieval corpus, corpus for data mining research etc. According to Arnold *et al.* [5], there are six criteria for choosing a corpus.

The mentioned criteria [5] for choosing corpus have successfully established *Canterbury Corpus* as one of the extensively adapted corpus for data compression. However, due to the rapid growth of technology, additional criteria have been evolved in constructing the corpus. Firstly, the criteria were specified for evaluating the compression of middle-sized files. But, with the advancement of embedded devices with lower processing devices and small memory (like mobile-phones) it has become extremely important to provide a new test-bed for evaluation of small text compression schemes. Frequent uses of mobile phones, short text messages and emails have already made a transformation on the use of texts, and hence necessity of field and size specific corpus formation has been evolved. Taking these limitations into concern, we provide specific files regarding the issues with consideration of other traditional characteristics. Moreover, the file structure *i.e.* sentence structure was not considered as any important criteria for choosing corpora. But, compression ratio gradually varies with variations of sentence construction and file structure. Besides these, probability of occurrences of texts-components and frequency of those are important criteria, which fluctuates the text compression performance.

### IV. LITERATURE REVIEW

The history of mostly adapted data compression corpus started a long ago. *Calgary Corpus*, which was collected in 1987 and was published in 1990 is considered as the

pioneer of Data Compression Corpus. The next initiative and the mostly adapted one is *Canterbury Corpus*. It was developed by Arnold *et al.* [5]

The files are solely English text compression evaluation corpus and hence not effective or at all applicable for evaluating Bengali text compression. The most recent and extremely organized analysis on Bengali News Corpus is provided by Majumder *et al.* [1]. This paper proposes a new Corpus on the basis of the well circulated newspaper *prothom-alo* [6] and provides exhaustive analysis regarding *TTR* (Type-to-Token-Ratio), Function Word and other morphological and linguistic analysis. For analysis of data compression efficiency, this corpus requires some specific modification in the sense that, data compression involves the additional criteria of heterogeneity and text-size. Moreover, the news corpus proposed in [1] is extensively tested for linguistic analysis only. In order to use this for data compression, further text-compression related analysis is a must. According to their methodology, they collect html news files from *prothom-alo* websites and converting it to Unicode, they categorize the total collection into twenty seven distinct groups, which are also available in a single file of size three hundred and eighteen mega bytes. For most practical applications and researches on middle-sized or small text compression, it is rarely necessary to have larger files, rather it is essential to have standard small and medium sized corpus.

The first corpus in Bengali developed by Central Institute of Indian Languages (CIIL) in the years 1991-1995 possess a collection of three million Bengali words, which provides valuable linguistic data for research on Bengali language analysis [2]. In evaluating compression efficiency, this impressive corpus also suffers from the limitation of heterogeneity and lack of embedded and small device supportability.

### V. PROPOSED CORPUS FOR EVALUATION OF BENGALI TEXT COMPRESSION SCHEMES

We propose a new Corpus for evaluation of Bengali text Compression Schemes namely *Ekushe-Khul Corpus*. This corpus is intended for evaluating only short and middle-sized text compression schemes rather than evaluation for large text compression. One of the worth-mentionable points is, this corpus is selected by applying a new approach, which takes both *TTR* and *Compression Ratio (CR)* into account. We have adapted the two concepts because; we do not have any standard and sophisticated Bengali text compression corpus available with which we may incorporate and compare the performance and thus perform the selection from candidate files as done for other existing data compression corpora.

To form the corpus we have considered ten groups- Articles, Poems, Advertisements, Speeches, News, SMS, Emails, Particulars, Stories and Reports. The files are of sized 4KB to 1800KB. The files of the proposed Ekushe-Khul Corpus is shown in Table I. The steps of constructing the proposed corpus is depicted in Fig 1.

Fig. 1: Steps for constructing the Proposed Bengali text compression corpus.

TABLE I

FILES CONSTITUTING THE PROPOSED *EKUSHEY-KHUL* CORPUS.

| File Name        |                  | Type                         |
|------------------|------------------|------------------------------|
| Article1.txt     | Article2.txt     | <i>Articles in Bengali</i>   |
| Poem1.txt        | Poem2.txt        | <i>Bengali Classic Poems</i> |
| Advertise1.txt   | Advertise2.txt   | <i>Advertisements</i>        |
| Speech1.txt      | Speech2.txt      | <i>Various Speeches</i>      |
| News1.txt        | News2.txt        | <i>News from Newspaper</i>   |
| SMS1.txt         | SMS2.txt         | <i>Short Bengali Message</i> |
| Email1.txt       | Email2.txt       | <i>Emails in Bengali</i>     |
| Particulars1.txt | Particulars2.txt | <i>Particulars</i>           |
| Story1.txt       | Story2.txt       | <i>Bengali Stories</i>       |
| Report1.txt      | Report2.txt      | <i>Academic Reports</i>      |

Collecting the files, the first step was to remove redundancies and other components (e.g. html tags, letters and words from other languages, formatting etc.) and convert them into Unicode as several documents were non-standard encoded and saved as Unicode text files. These files are then forwarded for further analysis.

For each category of files, all the files are passed to a *TTR Calculator* and then *Compression Ratio Evaluator* for selection of final documents. In case of *Canterbury Corpus*, which is the pioneer for data compression corpus was formed by comparing each file with the standard of

the *Calgary Corpus* of same group or category, and the file demonstrating the closest match in terms of compression performance was selected. But, as no such standard exists for Bengali, we are to take account of both the criteria and hence selected two with the maximum and minimum consistence.

*TTR* or *Type to Token Ratio* is a measurement of how many times a previously encountered words repeat themselves before a new word makes its appearance in the text [1]. It is note worthy that though this measure is essential for language engineering, its application in data compression is not mandatory. For calculative approaches, *TTR* is calculated by dividing the total number of word tokens by the total number of distinct words. Texts with a large number of distinct words results into lower *TTR*. For this case, the task of forming a data compression dictionary appears to be more accurate. Conversely, for texts with greater *TTR* i.e. with greater number of frequent words (resulting lower number of distinct words) provides a suitable arena for constructing and evaluating dictionary-based and repetition-analysis oriented text compression schemes. This is the reason, which inspires us to provide peer-files for each category. The files with suffix '2' indicates the file with lower *TTR* (suitable for text compression fluctuation evaluation) and files with suffix '1' indicates greater *TTR* (suitable for dictionary-based text compression scheme evaluation) for the respective group.

The next step involves analyzing the files in terms of compression ratio [7] to establish logical and implementational validity of choosing *TTR* as a benchmark for constructing the corpus. Though a number of approaches exist for compression of English texts, (like Burrows-wheeler Transform [2], Arithmetic Coding, Huffman Coding etc.) it is a sad tale that, still now a little research has been dedicated for Bengali text compression schemes. The uses of non-sophisticated text compression schemes do not provide optimal performance for Bengali text compression purposes. For providing a benchmark of the proposed corpus, we adapt the dictionary based compression scheme in [3] and demonstrate the inter-relation of *TTR* with *Compression Ratio*.

## VI. ASPECTS OF CORPUS SELECTION CRITERIA AND TEXT COMPRESSION PERFORMANCE

Let  $n$  be the total number categories of collections of texts. The categories are representative of texts bearing distinct themes with differences in sentence construction, sentence wording and sentence structure.

Let the categories are  $c_1, c_2, c_3, \dots, c_n$  respectively. For category  $c_1$  the files are

$f_{1,1}, f_{1,2}, f_{1,3}, \dots, f_{1,n}$  with length  $l_{1,1}, l_{1,2}, l_{1,3}, \dots, l_{1,n}$  where, the length indicates total number of characters (including blank spaces, tabs, new lines and other punctuation marks).

If there are total of  $w_{1,1}, w_{1,2}, w_{1,3}, \dots, w_{1,n}$   $p$  words in  $f_{1,1}, f_{1,2}, f_{1,3}, \dots, f_{1,n}$  respectively with number of distinct words be  $d_{1,1}, d_{1,2}, d_{1,3}, \dots, d_{1,n}$  for the same.

Here, for any file  $f_{i,j}$ , where  $i$  denotes *Category Index* and  $j$  denotes *File Index*, and  $w_{i,j} \geq d_{i,j}$ . Assume  $T_{i,j}$  be the Type to Token Ratio (*TTR*) for file  $f_{i,j}$ .

That is,  $T_{i,j} = w_{i,j}/d_{i,j}$ .

For any two files  $p, q$  in category  $i$ , with *TTR*  $T_{i,p}$  and  $T_{i,q}$ , if  $T_{i,p} \geq T_{i,q}$  indicates that,  $T_{i,p}$  contains larger number of distinct words than that of  $T_{i,q}$ .

Applying this rule, we count the *TTR* for the files. Then the file with maximum and minimum *TTR*s are selected. For the file with maximum *TTR*, if the elements comprise the set  $S_d$  and  $S_t$  for distinct words and total words respectively, then for ideal case, set  $S_d - S_t$  would tend towards  $\Phi$  (empty or null) set.

Though *Type to Token Ratio* has been considered as a means of forming linguistic Corpora and Natural Language Processing Corpora including Information Retrieval Corpora, taking it into concern, it is possible to design Data Compression Corpus too. Here, we provide an analysis on the effectiveness of using *TTR* as a criteria of constructing Corpora.

The basic relation between *TTR* and word-distribution is:

- If *TTR* is larger (greater) then the number (frequency) of matching word is also greater; consequently, number of distinct words is smaller.
- If *TTR* is smaller (lower) then, the number (frequency) of matching word is smaller; consequently, number of distinct word is larger.

For designing dictionary based data compression approaches, *TTR* plays a great role. For constructing the dictionary, the prime concern is to analyze the probability of occurrence of each character or syllable or substring or words (or any combination of the mentioned units). The frequencies in which they occur are an important aspect of figuring the probability. As the total number of distinct words are greater in files with lower *TTR* value, the detection of the probability of syllables may be easier as the word distribution is approximately flat in those files. For building word-based dictionaries for data compression, files with higher *TTR* values are more effective as the recurring words may be very easily pointed out. The fluctuation may be easily identified by comparing the performance of the compression scheme using the peer files.

Let us consider a tertiary dictionary based text compression approach *DCA*, which uses a dictionary of  $n$  items. The total  $n$  items consist of  $c$  characters,  $s$  syllables and  $w$  substrings, which save (in average)  $sc$ ,  $ss$ , and  $sw$  bits each. Traditionally,  $sw \geq ss \geq sc$  as words or substrings are generally considered as a collection of syllable and/or symbols and syllables are considered as a collection of characters, but the indices or pointers in most designs require consecutive values spanning against a threshold value.

For a file with greater *TTR* (i.e. Greater number of frequent words and lower number of distinct words), the probability of encoding using word-based coding is high. Consequently, the bit-savings will also be high as the saving weightage is greater for words in compassion with other units. Let the replacement of number of distinct words be  $rw$ . Here,  $rw$  theoretically tends towards the total occurrence in average.

Therefore, the total savings in this phase is  $S_1 = \sum_{y=1}^{rw} (sw_y \times fw_y)$  where  $fw$  is the frequency of corresponding distinct word. That is,  $fw$  indicates the frequency of occurrence of distinct word-indexed at  $y$  and ideally,  $fw \rightarrow tw$ .

The number of distinct syllable  $rs$  in a collection of highly distinct words should be lower. If the weightage is considered as double as distinct words, the total savings would be  $S_2 = \sum_{y=1}^{rs} (ss_y \times fs_y)$  where  $fs$  is the frequency of the syllable.

The rest of the characters should be encoded separately resulting a savings  $S_3 = \sum_{y=1}^{rc} (sc_y \times fc_y)$

If we encode a total of  $p$  characters separately, which saves  $sp$  bits for each characters and if we encode  $q$  words separately with an average of  $d$  characters per word, whenever even  $d = p$ , the savings will be much more greater for word based bit-savings, since the indexing of the constructed code base will be approximately sequential and hence, each single character and each single word based encoding will occupy about same length. Thus, the total saving is  $S = S_1 + S_2 + S_3$

$$S = \sum_{y=1}^{rw} (sw_y \times fw_y) + \sum_{y=1}^{rs} (ss_y \times fs_y) + \sum_{y=1}^{rc} (sc_y \times fc_y) \quad (1)$$

For a file with lower *TTR*, (i.e. greater number of distinct words and lower number of frequent words) there will have non-frequent occurrence of matching words and syllables. This will result extensive application and usage of character based encoding, as the primary unit of encoding is character. That is,  $rw' < rw$  and  $fw' \rightarrow 1$ .

Similarly,  $rs' < rs$  and Therefore, if there are total of  $tw$  words in the file, then,  $fs' \rightarrow l$ . But, because of remaining large number of character units,  $rc' \rightarrow tc'$ .

If there a total of  $tw'$  words in the file with lower  $TTR$  values, then,  $S'_l = \sum_{y=1}^{rw'} (sw_y \times fw'_y)$  and  $fw' \rightarrow tw'$

As low frequent words will be encountered, as much frequent syllables will be faced. However, a minor portion of the syllables may be coded in form of words. That is, we will have a larger number of character units and syllable units ( $ts'$  and  $tc'$ ) left to be coded. For syllable

based coding,  $S'_2 = \sum_{y=1}^{rs'} (ss_y \times fs'_y)$

After the two steps, we will have a greater number of characters left to be coded with distinct characters. Typically this value  $tc'$  may be  $tc' < ts'$  and for usual cases,  $tc' < tw'$ . Let this steps saves,

$$S'_3 = \sum_{y=1}^{rc'} (sc_y \times fc'_y)$$

Again,  $S' = S'_1 + S'_2 + S'_3$

$$S' = \sum_{y=1}^{rw'} (sw_y \times fw'_y) + \sum_{y=1}^{rs'} (ss_y \times fs'_y) + \sum_{y=1}^{rc'} (sc_y \times fc'_y) \quad (2)$$

It has been stated that, the ratio of bit-saving for word based, syllable based and character based encoding is 4:2:1 (i.e. for the ratios  $a : b : c$  we may write,  $a > b > c$ ). The ratio is taken as standard because, for character based dictionary oriented encoding, single character or symbol is considered as the primary unit. Consequently, substrings and syllables ranges from two to any higher value. The number of characters that comprise any word may ideally be considered in the range of greater than four whereas short length words may be thought of as the subgroup of substrings. Hence, we may easily remark that, for the above consequences,

(i)  $S_1 \geq S'_1$ ; since the number of word-matching is greater in  $S_l$  and the difference is a multiplier of four.

(ii)  $S_2 \geq S'_2$ ; since the number of syllable-matching is greater in  $S_2$  and the difference is a multiplier of two.

(iii)  $S_3 \leq S'_3$ ; since the number of matching-character is greater in  $S_2$  and the difference is an unit multiplier.

From the above three consequences, we may easily point that, though  $S'_3 \geq S_3$ , it is nit an average case that,  $S'_3$  will cross the saturation point or threshold value comprising of  $(4 + 2 = 6)$  times higher amplitude. Consequently, we may easily conclude:  $S > S'$ .

We may also prove the same as follows:

From the third clause we may write,  $S_3 + \alpha = S'_3$ , where  $\alpha$  is a constant bit-factor. From clause (i) and (ii), we can write  $S_1 + S_2 \geq S'_1 + S'_2$ .

From (i), (ii), we may deduce that (by adding the same value  $S'_3$  in both sides),

$$S_1 + S_2 + S'_3 \geq S'_1 + S'_2 + S'_3 \quad (3)$$

Being a constant factor  $\alpha = 1, 2, 3, \dots, \text{etc (number of bits)}$ , we may write (3) as,

$$S_1 + S_2 + S_3 + \alpha \geq S'_1 + S'_2 + S'_3 \quad (4)$$

It has been presented that,

$$S = S_1 + S_2 + S_3 \text{ and } S' = S'_1 + S'_2 + S'_3.$$

Hence, from (4),  $S + \alpha \geq S'$ .

Recall from earlier explanation that,  $S$  and  $S'$  are the aggregation of bit savings for matching characters, syllables and words. Again, as the ratio of bit saving for word-based, syllable based and character based encoding is considered 4:2:1, consideration of linear transformation factor  $l$  indicates that,  $S$  will rush towards  $6l$  where  $\alpha$  tends words  $l$  for the average cases.

In better cases, as all the characters are likely to be pre-coded with either syllable based coding or word based coding section. After coding with word based and syllable based coding there will be little portion of source text left for character based coding. That is, the total saving is probable to be derived from word based saving.

Consequently,  $S_1 + S_2 \rightarrow S$ , whereas, character based saving will tend towards zero.  $S_3 \rightarrow 0$ . Again, being  $S_3 + \alpha = S'_3$ ;  $\alpha$  too will tend towards zero. That is,  $\alpha \rightarrow 0$ .

$$\text{Again, from clause (i), we get, } S_1 = S'_1 + \alpha_1 \quad (5)$$

$$\text{Similarly, from clause (ii), } S_2 = S'_2 + \alpha_2 \quad (6)$$

$$\text{We get from (iii), } S_3 = S'_3 - \alpha_3 \quad (7)$$

Where  $\alpha_1, \alpha_2, \alpha_3$  are non negative integer values because they all are equalizing factors in terms of bits.

It has already been stated that,  $S_3 \rightarrow 0$ .

Consequently,  $S'_3 - \alpha_3$  will only tends towards zero if and only if,  $\alpha_3 \rightarrow 0$ . That is, we may clearly deduce that,  $\alpha_1 + \alpha_2 - \alpha_3 = c \geq 0$ .

As a result, we may write,  $\alpha_1 + \alpha_2 - \alpha_3 \geq 0$ .

It has been previously stated that,  $\alpha_3 \rightarrow 0$ .

$$\text{Consequently, } \Rightarrow \alpha_1 + \alpha_2 \geq \alpha_3 \quad (8)$$

Now, (5) + (6) + (7) results-

$$S_1 + S_2 + S_3 = S'_1 + \alpha_1 + S'_2 + \alpha_2 + S'_3 - \alpha_3$$

$$\Rightarrow S_1 + S_2 + S_3 = S'_1 + S'_2 + S'_3 + \alpha_1 + \alpha_2 - \alpha_3$$

$$\begin{aligned} \Rightarrow S_1 + S_2 + S_3 &= S'_1 + S'_2 + S'_3 + c \text{ [Using (8)]} \\ \Rightarrow S_1 + S_2 + S_3 &\geq S'_1 + S'_2 + S'_3 \\ \Rightarrow S &\geq S' \text{ [Since } c \text{ is non-negative]} \end{aligned}$$

That is, the performance of dictionary based data compression would be better for files with larger *TTR* Values and the result will deteriorate for lower *TTR* valued files. This is the aspect, which motivates us to provide peer files of each category to recognize the fluctuation of performance for dictionary based data compression.

## VII. ANALYSIS OF THE PROPOSED CORPUS

In this section, we present statistics regarding *TTR* and *Compression ratio* of the files of each groups. The experimental results demonstrate that, not only in expressing the effectiveness of any corpus, *TTR* may also be employed as a criteria for constructing data compressing corpus with the great scope of presenting the performance fluctuation of dictionary based (*i.e.* repetition analysis oriented) text compression scheme for best case and worse case analysis.

We also analyze the compression ratio for the files using the dictionary-based approach for Bengali text compression provided in [3] and find the following statistics-

Fig. 2: Relation between Type to Token Ratio and Compression Ratio.

In Fig 2, we have presented a comparative analysis on Compression Ratio with Type to Token Ratio in terms of

applicability of dictionary based data compression techniques. *Compression Ratio (CR)* is a metric of data compression efficiency. Compression Ratio indicates the number of bits required to describe one byte in compressed form. The lower the compression ratio, the better is the compression. In order to evaluate the performance fluctuation of dictionary based Bengali text compression schemes, we propose to use the peer files with assumption that, the best case would be obtained from the files with greater *TTR* values and the worse case will occur for lower *TTR* files. The construction of the dictionary may really be facilitated from the files with larger *TTR*.

## VIII. CONCLUSION

We have proposed a new Corpus for evaluation of Bengali text compression schemes named *Ekushey-Khul*. The methodology is also robust to some extent that, it takes both linguistic and compression-ratio into account. It is also a contribution that, we specify new criteria for choosing text compression corpus, which includes consideration of expected device and the changed attitude of text varying with communication framework for which the compression is intended. Though it is an inaugurating step towards forming a Bengali text compression evaluation corpus, further improvement may be achieved by integrating other types and modes of document like technical documents, Bengali dictionary, and Bengali spreadsheets etc. with consideration of more training files.

# A Corpus-based Evaluation of Lexical Components of a Domain-specific Text to Knowledge Mapping Prototype

Rushdi Shams<sup>1</sup> and Adel Elsayed<sup>2</sup>

Department of Computer Science and Engineering, Khulna University of Engineering & Technology (KUET), Bangladesh<sup>1</sup>

M3C Research Lab, the University of Bolton, United Kingdom<sup>2</sup>

**Abstract** — The aim of this paper is to evaluate the lexical components of a Text to Knowledge Mapping (TKM) prototype. The prototype is domain-specific, the purpose of which is to map instructional text onto a knowledge domain. The context of the knowledge domain of the prototype is physics, specifically DC electrical circuits. During development, the prototype has been tested with a limited data set from the domain. The prototype now reached a stage where it needs to be evaluated with a representative linguistic data set called corpus. A corpus is a collection of text drawn from typical sources which can be used as a test data set to evaluate NLP systems. As there is no available corpus for the domain, we developed a representative corpus and annotated it with linguistic information. The evaluation of the prototype considers one of its two main components- lexical knowledge base. With the corpus, the evaluation enriches the lexical knowledge resources like vocabulary and grammar structure. This leads the prototype to parse a reasonable amount of sentences in the corpus.

**Index Terms** — Corpus, NLP Systems, Knowledge Mapping, Lexicon, Morphology.

## I. INTRODUCTION

Text to Knowledge Mapping (TKM) Prototype [1] is a domain-specific NLP system, the purpose of which is to parse instructional text and to model it with its pre-defined ontology. During development, the prototype has been tested with a limited data set from the domain Physics instructional text on DC electrical circuit. The prototype now reached a stage where its lexical components need to be evaluated with a representative linguistic data set, a corpus- a collection of text drawn from typical sources. Information retrieved during parsing contributes to map and model domain-specific text on its knowledge domain. Therefore, the usability of the TKM prototype as a specialized knowledge representation tool for the domain depends on the evaluation of its lexical components.

An important precondition to evaluate NLP systems is the availability of a suitable set of language data called corpus as test and reference material [2]. With an extensive web-based search, we did not find any corpus for the domain DC electrical circuit. Therefore, we need to develop a representative corpus to evaluate the lexical components of the prototype because a representative

corpus reflects the way language is used in the domain [3]. A usable corpus requires various annotations according to the scope and type of evaluation. As we intend to evaluate the lexical components of the TKM prototype, the corpus should be annotated with linguistic information like Parts of Speech (POS) tagging, phrasal structure annotations, and stem word tagging. These annotations can lead us to adjust the lexical components of the prototype according to the qualitative and quantitative layers [1] [4] of its knowledge model.

In this paper, we proposed a stochastic development procedure of a domain-specific representative corpus that is used to evaluate the lexical components of the TKM prototype. We also represented detail procedure of corpus-based evaluation of an NLP system- that includes enriching the lexicon and morphological database, testing the parsing ability of the prototype, and the adjustment of the lexical components according to the linguistic information in the corpus.

The remainder of this paper is organized as follows. In Section II, corpus-based evaluations of various NLP systems have been discussed. Section III describes the proposed procedure of representative corpus development and annotations. Section IV describes the evaluation of lexical components of the TKM prototype such as the vocabulary and grammar structure. Section V concludes the paper.

## II. RELATED WORK

A text based domain-specific NLP system can be evaluated according to the type, context or discourse of text from the domain although no established agreement has been developed on test sets and training sets [5]. Corpus is not restricted today only for researches on linguistics [6]; it is now becoming the principal resource to evaluate such domain-specific NLP systems. Many NLP systems like Saarbrucker Message Extraction System (SMES) [8] have been tested with a corpus as proper evaluation depends on a representative test set of data like corpus [7]. Corpus contains structured and variable but representative text. A corpus is said representative if the

findings from it can be generalized to language or a particular aspect of language as a whole [3]. Corpus-based evaluations like MORPHIX [13] and MORPHIX++ [7] showed that the evaluation with a representative corpus results in proper adjustments. MORPHIX++ was tested with a corpus and systematic inspection revealed some necessary adjustments like missing lexical entries, discrepant morphology incomplete or erroneous single words.

Now-a-days, many web corpora are present and researchers successfully utilize web data including machine translation [9], prepositional phrase attachment [10] and other anaphora resolution [11] to evaluate NLP systems. One problem in evaluating domain-specific NLP systems with a web corpus is the discrepancy between the domain of the corpus and the domain of the system [14]. Having the ease of access [15], the web corpora development tools like BootCaT [16] and WebBootCaT [17] are used world wide to develop corpus using web data.

NLP systems use either pre-defined or customized grammar rules. For instance, the lexical components of the TKM prototype use Combinatory Categorical Grammar (CCG) [12]. The prototype follows some specific clausal and phrasal structures according to CCG. As it follows a particular grammar, we need to adjust the grammar and phrasal structures according to the structures of text from the domain. For example, TKM prototype, on its early test, was able to parse simple sentences only. This becomes a drawback if majority of text in the domain is written in compound and complex sentences. Therefore, necessary adjustment on CCG can let the prototype parse compound and complex sentences as well. In addition, NLP systems may recognize specific clausal and phrasal structure which maybe absent in domain-specific text. For example, if an NLP system uses grammars that handle one subject and one object, both parsing and knowledge extraction from domain-specific text becomes difficult if majority of the text contains more than one subject and one object. These linguistic properties of domain-specific text bring in the issue of adjustment. The lexicographical resources of such systems can be increased by analyzing linguistic patterns in domain-specific corpus. Statistical data like frequency of words, number of simple, complex or compound sentences, number of subject and object present in the sentences assist to adjust the lexical components of the systems. The grammar structure MORPHIX++ supported was not efficient in its early days. It was adjusted and extended according to the corpus used as its test suite.

### III. CORPUS DEVELOPMENT

In this section, we will discuss regarding the development approach of a domain-specific corpus, proof or its representativeness, and its annotation procedure.

#### A. Development Approach

As we did not find any corpus for the domain DC electrical circuit with extensive web searches, we initiated WebBootCaT to develop a representative corpus. We developed five corpora using the WebBootCaT and analyzed them by comparing the number of distinct domain-specific terms and number of distinct words present. The significant difference between these two numbers and inconsistency on the size of the corpus in Fig. 1 state that web-based tools are not usable to develop domain-specific corpora, but maybe useful for developing domain independent corpora.

Fig. 1. Inconsistency of WebBootCaT to develop a domain-specific corpus

WebBootCaT works on the basis of searching the web according to user defined keywords called seeds. Researches like [15] showed that search engines like Google provide 67 search results for Speculator and about 82,000 search results for Speculator? which vividly shows the reason behind inconsistent nature of web-based corpus developing tools. Therefore we decided to develop the corpus manually and collected text from 141 web resources containing 1,029 sentences and 18,834 words. During the development, we left the non textual information (e.g., equations and diagrams) as the TKM prototype operates only on text.

#### B. Representativeness of the Corpus

The representativeness of the corpus can be justified with a notion of saturation or closure described by [18]. At the lexical level, saturation can be tested by dividing the corpus into equal sections in terms of number of words or any other parameters. If another section of the identical size is added, the number of new items in the new section

should be approximately the same as in other sections [19].

To find out the representativeness for the corpus, it has been segmented into 15 samples. Each sample is comprised of 1,267 words on average. We plotted the cumulative frequency of the most frequent technical terms in the samples.

Fig. 2. Representativeness of the corpus with domain-specific technical terms

Fig. 2 depicts that the presence of the domain-specific technical terms becomes stationary after a few samples. This is one of the criteria showing the representativeness of the corpus. After a certain point, no matter how much text we add to the corpus, the frequencies of the terms are becoming stationary.

Similarly, we counted the frequency of non-technical words in the corpus and grouped them according to their parts of speech. Statistics on verbs, prepositions and coordinators in Fig. 3 (a), 3 (b) and 3 (c) respectively show that the corpus has been saturated after sample 11.

(a)

(b)

(c)

Fig. 3. Representativeness of the corpus with (a) verbs, (b) prepositions and (c) coordinators

We also counted the frequency of types of sentences in the corpus. As the domain contains instructional text and most of which are simple sentences, it needs to be reflected on the corpus as well. Fig. 4 shows that majority of the text is simple sentence (in percentage).

Fig. 4. Sentence structure in the corpus

### C. Corpus Annotation

To annotate the corpus with POS tags, Cognitive Computation Group POS tagger [20] has been used as it works on the basis of learning techniques like Sparse Techniques on Winnows (SNOW). The corpus is annotated with nine parts of speech include noun, pronoun, verb, adverb, adjective, preposition, coordinator, determiner, and modal. The phrasal structure of the corpus has been annotated by the slash-notation grammar rules defined by CCG. We developed seven XML tags including URL, date, sentence, word, stem, pos, and category and created an XML version of the corpus.

## IV. EVALUATION OF LEXICAL COMPONENTS

The evaluation of vocabulary and the grammar structure of the prototype are illustrated in this section. This section also refers to the efficiency in parsing and richness of lexical entries of the prototype.

### A. Evaluation of Vocabulary

The lexicon of the prototype is mapped on the unique words of the corpus. The words present both in the morphology and in corpus are called the vocabulary of the prototype. Initially, only five percent of the vocabulary was covered by the prototype (Table I).

TABLE I  
PRELIMINARY VOCABULARY COVERAGE OF THE TKM  
PROTOTYPE

| Words in Morphology and in Corpus | Unique Words in the Corpus | Vocabulary Covered |
|-----------------------------------|----------------------------|--------------------|
| 101                               | 1,902                      | 5%                 |

MORPHIX++, a second generation NLP system, covered 91 percent of word in the corpus developed to evaluate it. The reason behind this difference is the augmentation of the vocabulary of MORPHIX++ ran parallel with the development of the system. In contrast, the main focus during the development of the TKM prototype was to develop an operational system first rather than increasing its vocabulary.

We used the POS tags of the corpus to populate the lexicon. We retrieved every distinct word for each distinct POS from the corpus and we simply added it if that word was absent in the lexicon. The number of added entries into the lexicon is shown in Table II. On completion of the process, the vocabulary of the prototype covers 90 percent of the corpus (Table III).

TABLE II  
AUGMENTATION OF LEXICAL ENTRIES IN THE TKM  
PROTOTYPE

| POS              | Augmented Entries |
|------------------|-------------------|
| Determiner       | 19                |
| Coordinator      | 5                 |
| Noun and Pronoun | 2,094             |
| Adjective        | 364               |
| Preposition      | 71                |
| Adverb           | 177               |
| Verb             | 264               |

TABLE III  
VOCABULARY OF THE TKM PROTOTYPE

| Words in Morphology and in Corpus | Unique Words in the Corpus | Vocabulary Covered |
|-----------------------------------|----------------------------|--------------------|
| 1,783                             | 1,902                      | 90%                |

### B. Evaluation of Grammar Structure

The TKM prototype struggles to parse *modals* or *auxiliary verb* because CCG does not provide any specification to categorize modals into finite and non-finite [21]. We defined grammar formalisms for modals and adjusted the lexicon that increased the ability of the prototype to parse modals.

CCG does not have any mechanism for phrasal structures like *adjective-adjective-noun* although researches showed that numerous adjectives can be placed before a noun [22]. Moreover, CCG treats adjectives as qualifiers of noun (*np/n* or *n/n*) but in the sentence *when the lamps are connected in series, the more the lamps, the more dimmer they get*, *dimmer* is not particularly preceding any noun or pronoun. Except the regular adjectives, we defined grammar formalisms for noun equivalents (e.g., two *common* types of circuits), participle equivalent (e.g., the *connected* wire), gerund equivalents (e.g., the *conducting* material), and adverb equivalents (e.g., the *above* circuit is series circuit) of adjectives that increased the rate of parsing adjectives.

CCG has specification for pronoun by treating it as a noun without any anaphoric resolves [23]. For example, *it is placed in parallel-* CCG can parse this sentence by treating *it* as a *noun* but cannot obtain *voltmeter* as the subject. Moreover, CCG completely is not able to parse pronouns of other forms (e.g., *them*, *its*, *their*, *that*, *which*) and struggles to represent knowledge when pronouns represent indexicality. The anaphora depends on lexical semantics and its resolve depends on the reasoning through the ontology of the prototype.

CCG is unable to parse sentences that start and end with a prepositional phrase [23]. For example, *in series circuit, the current is a single current*- this sentence is not parsed by CCG. In contrast, *the current is a single current in series circuit*- is sometimes parsed by CCG. The lexicon the prototype is using has nine different types of prepositions. Sometimes, it is difficult to even identify regular prepositions. For instance, *the sum of potential differences in a circuit adds up to zero voltage*- Though in regular grammars, *up* is not treated as adverbs- these are called particles where prepositions have no objects and require specific verbs with them (e.g., throw out, add up). The parsing ability of the prototype increased as we defined grammar rules for such prepositions.

*Complementizer*, although it is a form of preposition, it is not recognized by CCG. *Adverbs*, on the other hand, have a strong coverage by CCG. In many cases, adverbs sit at the end of the sentence- CCG does not provide any category to define these adverbs although it has fully featured adverb categories for other two positions of an adverb in sentence- adverbs that start a sentence or that sit in the middle of a sentence. These issues have been resolved by adding new grammar rules.

The lexicon has two categories for *coordinators*- sitting at the beginning of a sentence (e.g., since, as) and relating two clauses (e.g., and, or). CCG defined that they can be in the middle of two noun phrases only with *np\vp/np* but the sentence *series and parallel circuits are the types of circuits* has the category *n\vp/n* rather than *np\vp/np*. CCG handles adverbs and conjunctions well but it seriously lags in handling sentences having similar verbs as in the sentence *the sum of current flowing into the junction is eventually equal to the sum of current flowing out of the junction*. The identical verbs *flowing* (*gerund*) appear twice with another verb (*be*) is concerning. Moreover, a verb has to be present in a sentence to form predicate argument structure but we discovered that there are sentences which do not have any verbs- *the bigger the resistance, the smaller the current*. Gerund of verb is known as noun. *Gerund* is formed by placing *ing* at the end of the verb. For example, *current flowing into a junction is equal to the current flowing out of the junction*- in this sentence, *flowing* is a gerund. Gerunds are not treated as nouns in CCG. In other words, gerunds, if treated as nouns in CCG, the sentence struggles to be parsed.

After creating grammar rules and phrasal structures and adding them into the lexicon and morphology of the prototype, the parsing ability of the prototype increased to 31 percent (Table IV). Although the prototype was tested with a limited dataset, it was unable to parse any sentence from the corpus before the evaluation.

TABLE IV  
PARSING ABILITY OF THE TKM PROTOTYPE

| State of the Prototype | Total Sentences | Parsed Sentences | Efficiency |
|------------------------|-----------------|------------------|------------|
| Preliminary            | 1,029           | 0                | 0%         |
| Evaluated              | 981             | 300              | 31%        |

We analyzed the 300 sentences parsed by the prototype and figured out the number of subject, object and verb they consist. In Fig. 5 we see that the prototype works well when the number of subjects and objects in a sentence do not exceed two and when the number of verbs does not exceed one.

Fig. 5. Number of subjects, objects and verbs in the sentences parsed by the prototype

The inefficiency of the prototype to parse sentence is due to the absence of phrasal structures (hence, the categories). 69 percent of the sentences in the corpus have phrasal structures that are not supported by the CCG structure. It should be noted that the prototype fails to parse sentences even for absence of just one category. For example, *One simple DC circuit consists of a voltage source (battery or voltaic cell) connected to a resistor* – this sentence is not parsed by the prototype for the absence of category of conjunction *or* (*np\vp/np*) and for the category of verb *connected* (*s\vp/pp*). In the corpus, these absent categories are identified so that modification of the lexicon becomes easier.

## V. CONCLUSION

In this paper, we represented a corpus-based evaluation of lexical components of a domain-specific NLP system. We proposed a stochastic approach to develop a domain-specific representative corpus. The linguistic resources of the corpus have been used to evaluate the lexical components of the system. As knowledge representation is the goal of the system and successful parsing and information retrieval is at the heart of knowledge modelling, we adjusted the lexical components of the

system to increase its parsing ability. This evaluation made the TKM prototype an ideal knowledge representation tool for the domain DC electrical circuit as it parses large number of text from the domain and the information retrieval process has been satisfactory. However, the evaluation on the knowledge model and knowledge representation depends on the human cognition of the domain and its representation based on the semantic and linguistic relations in text. We developed a conceptual structure and a framework of semantic relations for the domain [24] and the evaluation of its knowledge model will be accomplished once we are able to tie the significance of linguistic relations in the text with the conceptual structure for the domain.

**Abstract** — Clustering analysis is an important function of data mining. There are various clustering methods in Data Mining. Based on these methods various clustering algorithms are developed. A recent approach for clustering analysis is based on “Swarm Intelligence”. Based on this “Swarm Intelligence” an algorithm was proposed named “Ant-Cluster algorithm”. However, existing “Ant clustering” algorithm has a limitation in finding the value of two constant  $K_1$  and  $K_2$ , which is user defined, for computing the value of the picking up probability  $P_p$  and dropping probability  $P_d$ . In this paper our approach is to gain the value of  $P_p$  and  $P_d$  without giving the user defined value of  $K_1$  and  $K_2$ . We also intend to retain the  $P_p$  and  $P_d$  in between 0 to 1 in order to get optimized result.

**Index Terms** — Ant Clustering methods, Data Mining, Density, Swarm Intelligence.

## I. INTRODUCTION

Data mining is the task of discovering interesting patterns from large amounts of data, where the data can be stored in databases, data warehouses, or other information repositories. It is a young interdisciplinary field, drawing from areas such as database systems, data warehousing, statistics, machine learning, data visualization, information retrieval, and high-performance computing. Other contributing areas include neural networks, pattern recognition, spatial data analysis, image databases, signal processing, and many application fields, such as business, economics, and bioinformatics.

Clustering analysis is a kind of unsupervised learning method that groups a set of data objects into clusters. In these clusters, data objects are similar to one another within the same cluster and are dissimilar to the objects in other clusters [1]. Major clustering methods are classified into five categories, i.e.

- a) partitioning methods
- b) hierarchical methods
- c) density-based methods
- d) grid-based methods and
- e) model-based methods.

Some clustering algorithms integrate the ideas of several clustering methods. But each kind of clustering methods has its own limitation. For example,  $k$ -means algorithm, a widely used partitioning method, is sensitive to the initial objects that can induce local optimum, and needs user to specify the number of clusters.

Swarm intelligence is a kind of evolutionary algorithm inspired by the behaviors of social animals. It has some advantages and characteristics, such as self-adaptation, self-government, and parallel computing, etc.

For example, in these algorithms, the numbers of clusters need not to be specified by user, amount of calculation reduces due to calculating with local objects instead of all objects, and clusters with arbitrary shape can be discovered.

In “Ant-Cluster algorithm”, multi-population of ants with different moving speed is introduced and outlier objects are processed properly. Ants are the agents which can pick up or drop out the data objects or sets based on similarity or density of data objects. Ants are likely to pick up data objects that are either isolated or surrounded by dissimilar and then drop the picked ones in the similar types of data objects. Thus a proper clustering is achieved.

However in our research we found some limitations in “Ant Clustering” algorithm. The next proceedings of this paper will be focusing on basic of existing “Ant Clustering Algorithm” to solve the limitations and hence propose our newly developed method to find out the value of picking up probability  $P_p$  and dropping probability  $P_d$  without giving the user defined value of  $K_1$  and  $K_2$ .

## II. DATA MINING & CLUSTERING

Clustering is also called data segmentation in some applications because clustering partitions large data sets into groups according to their *similarity*. Clustering can also be used for outlier detection, where outliers (values that are “far away” from any cluster) may be more interesting than common cases. Applications of outlier detection include the detection of credit card fraud and the monitoring of criminal activities in electronic commerce. For example, exceptional cases in credit card transactions, such as very expensive and frequent purchases, may be of interest as possible fraudulent activity. As a data mining function, cluster analysis can be used as a stand-alone tool to gain insight into the distribution of data, to observe the characteristics of each cluster, and to focus on a particular set of clusters for further analysis. Alternatively, it may serve as a preprocessing step for other algorithms, such as characterization; attribute subset selection, and classification, which would then operate on the detected clusters and the selected attributes or features.

Fig 1 A 2-D form of cluster, where “+” denotes the center of a cluster.

## III. REVIEW OF ANT-CLUSTER ALGORITHM

The parameters and symbols used for ant clustering algorithm are illuminated as follows:

- $\alpha$ : swarm similarity coefficient;
- $r$ : observing radius of each ant;
- $N$ : the maximum of cycle times;
- $size$ : the size of the 2-dimension grid;
- $m$ : the number of ants in each population;
- $p$ : index of populations,  $p = 1, 2, 3$ ;
- $Pp$ : picking-up probability;
- $p_d$ : dropping probability;
- $p_r$ : random probability,  $p_r \in [0, 1)$ ;

$k_1$  and  $k_2$ : threshold constants for computing  $p_p$  and  $p_d$  respectively;

$ant_i$ : the  $i$ th ant;

$o_i$ : the  $i$ th data object;

$loaded$  and  $unloaded$ : state of ant. If there is a data object on an ant, its state is *loaded*; otherwise, its state is *unloaded*;

$v_{high}$ : the speed of ants in high speed population;

$v_{low}$ : the speed of ants in low speed population;

$v_{MAX}$ : the maximal speed in variable speed population;

$l$ : the maximum times of an ant moving with a same data object continuously.

### A. Algorithm :A High-Level Description of Ant-Cluster

Initialization phase: Initialize parameters ( $\alpha$ ,  $r$ ,  $N$ ,  $size$ ,  $m$ ,  $v_{high}$ ,  $v_{low}$ ,  $v_{MAX}$  and  $l$ ). Place data objects on a 2-dimension grid randomly, i.e. assign a pair of coordinates ( $x$ ,  $y$ ) to each data objects. Put three populations of ants with different speed on this 2-dimension grid. Initial state of each ant is *unloaded*;

while (cycle\_time  $\leq$   $N$ )

Adjust  $\alpha$  with specific step;

for ( $p = 1$ ;  $p \leq 3$ ;  $p++$ )

for ( $i = 1$ ;  $i \leq m$ ;  $i++$ )

if (ant encounter a data object)

if (state of ant is *unloaded*)

Compute the swarm similarity of the data object within a local region with radius  $r$ , and compute picking-up probability  $p_p$ . Compare  $p_p$  with a random probability  $p_r$ . if  $p_p > p_r$ , ant pick up this data object, and the state of ant is changed to *loaded*;

else

if (state of ant is *loaded*)

If ant has already moved with the same data object  $l$  steps, the data object is dropped and the state of ant is changed to *unloaded*. Otherwise, compute the swarm similarity of the data object within a local region with radius  $r$ , and compute dropping probability  $p_d$ . Compare  $p_d$  with a random probability  $p_r$ . if  $p_d > p_r$ , ant drops this data object, and the state of ant is changed to *unloaded*.

end

end

end

#### IV. GENERAL DESCRIPTION OF ANT-CLUSTER

In initialization phase, all parameters, including  $\alpha$ ,  $r$ ,  $N$ ,  $size$ ,  $m$ ,  $v_{high}$ ,  $v_{low}$ ,  $v_{MAX}$  and  $l$ , are given values by user. Data objects and three populations of ants with different speed are placed in a 2-dimension grid randomly. There is only one data object and/or one ant in a grid at most. Initial state of each ant is set *unloaded*.

In each of outer loop iteration, i.e. while loop, all ants on the 2-dimension grid move one time. Each of interior loop iteration corresponds to the behavior of one ant. An ant moves one step on the 2-dimension grid randomly with different speed according to different population at a time. When it encounters a data object and its state is *unloaded*, the swarm similarity and picking-up probability are computed for deciding whether or not to pick up the data object. When it does not encounter a data object and its state is *loaded*, the moving times with the same data object is compared with  $l$  at first. If the ant has already moved with the same data object  $l$  times, the data object is dropped. Otherwise, the swarm similarity and dropping probability are computed for deciding whether or not to drop the data object.

The swarm similarity is computed by following formula:

$$f(o_i) = \frac{1}{S} \sum_{o_j \in Neigh(r)} \left[ 1 - \frac{d(o_i, o_j)}{\alpha} \right] \quad (1)$$

where  $f(o_i)$  is a measure of the average similarity of object  $o_i$  with the other objects  $o_j$  present in the neighborhood of  $o_i$ .  $S$  is the number of objects  $o_j$ .  $d(o_i, o_j)$  is the distance between two objects  $o_i$  and  $o_j$  in the space of attributes measured with Euclidean distance. The swarm similarity is transformed to picking-up probability  $p_p$  and dropping probability  $p_d$  by following formulas respectively.

$$P_p(o_i) = \left( \frac{k_1}{k_1 + f(o_i)} \right)^2, \quad p_d(o_i) = \left( \frac{k_2}{k_2 + f(o_i)} \right)^2 \quad (2)$$

Wherein,  $k_1$  and  $k_2$  are two threshold constants assigned by users.

#### V. METHOD TO CALCULATE $P_p$ AND $P_d$ WITHOUT $K_1$ AND $K_2$

We will calculate the swarm similarity for all objects and average the swarm similarity  $f[o_{avg}]$  of all objects.

$$f(o_{avg}) = \{f(o_1) + f(o_2) + \dots \pm f(o_n)\} / n \quad (3)$$

Where,  $n$  is the number of objects in two-dimensional data grid. Here, we use the formula [1] to calculate the swarm similarity of each object.

Then we have to calculate the value of  $IP_i$  and  $ID_i$  for each object  $O_i$  by the following formula :

$$IP_i = f(o_i) / f(o_{avg}) \quad (4)$$

and

$$ID_i = f(o_{avg}) / f(o_i) \quad (5)$$

Here  $i=1, 2, 3, \dots, n$

Then we have to calculate  $IP_{avg}$  and  $ID_{avg}$  by the following formula:

$$IP_{avg} = \sum_{i=1}^n IP_i / n \quad (6)$$

And

$$ID_{avg} = \sum_{i=1}^n ID_i / n \quad (7)$$

Here,  $i=1, 2, 3, \dots, n$ .

Where,  $IP_i$ ,  $ID_i$ ,  $IP_{avg}$ ,  $ID_{avg}$  are the intermediate variables.

Now we have to calculate the picking up probability  $P_p$  and dropping probability  $P_d$  for each object  $O_i$  using the following formula:

$$P_{p_i} = (IP_{avg} - IP_i)^2 \quad (8)$$

and

$$P_{d_i} = (IP_{avg} - ID_i)^2 \quad [9]$$

Here,  $i=1, 2, 3, \dots, n$ .

#### VI. EXPERIMENTAL RESULTS

For experimenting our method we have coded our newly developed formula in Turbo C. Here we have experimented 20 objects in two dimensional Data Grid with their  $x$  and  $y$  co-ordinate.

## ACKNOWLEDGEMENT

Last but not the least we would like to thanks all our faculty members of our university. Also gratitude to ICCIT to give proper guidelines to format this paper.

# An Intelligent Aviation Obstruction Warning light

Muhammad Mehedi Al Emran Hasan<sup>1</sup>, and Badal Chandra Sarker<sup>2</sup>

Dept. of CSE, East West University, Dhaka, Bangladesh<sup>1</sup>, Dept. of EEE, World  
University of Bangladesh<sup>2</sup>  
mehedi@ewubd.edu, 321badal@gmail.com

**Abstract** -- A scheme for aviation warning light is presented here. Unlike the conventional systems used for this purpose, the system presented here is using intelligent way of sensing daylight sensor fault, intelligent way of sensing light fault, intelligent way of activating standby light in case of the main light fault, ground cable monitoring and responding system with beep for any fault occurs. Microcontroller from 8051 family with tiny operating systems is implemented here for controlling and calculating in a multitasking environment so that the system becomes dependable with advanced feature.

**Index Terms** — Microcontroller, LDR, GCM, RTX51 tiny OS, stand by, line of sight.

## I. INTRODUCTION

The rapid growth of the cellular phone industry and other communication services will lead up to millions of new communication towers all over the Globe. These towers present hazards to flight paths of aircrafts. Aviation Obstruction marking requires especially in Telecom and Cellular Towers, TV and Radio Antennae Towers, High rise Power Transmission cable posts or lines and Pylons, High rise Chimneys, Cooling Towers, High rise Structures, Multistoried Buildings and on surrounding hills near the airports or heliports. The main purpose of providing the Obstruction Lights is for the safety of the flights by identifying any object or structure coming in line of sight and avoids any risk of mishap or accident. Conventional systems are using incandescent bulb which is lack of omni directional equal intensity of light and it fails the aircraft to warn in the line of sight.

Life time of lighting system is another great important parameter for aviation light warning system. Average on time of a light is about 10-12 hours per day. Normally available incandescent bulb is not suitable for this long duration operation. Because incandescent bulb has designed for household application, where it's average on time is about 5-6 hours. It is almost impossible to have a continuous observation on all these conventional warning lights. The warning light may not glow for any reason; it may fail to sense the day or night due to sensor fault, the warning light itself may be faulty or the ground cable may have cut. It would be safe if the system could decide the light fault by itself and glow the stand by light to avoid the risk in some crucial places.

To overcome the above mentioned problems associated with conventional systems we have used power saving LED, advanced features for checking sensors, lights, ground cable, a stand by light and beep against any fault. The aviation light unit consists of LED arrays. The average life time of LED is about 5-7 years with an average on time of a light is about 10-12 hours per day. System can be configured with optional advanced features according to the user for a) Single light normal with a stand by light, b) Single light flashing with a stand by light, c) Multiple light normal d) Multiple light flashing.

The system proposed here for Aviation Warning Lights conform to the specifications of International Civil Aviation Organization (ICAO) [1].

Figure 1: Functional Block Diagram of the System

## II. OVERALL SCHEME

The system comprise with one microcontroller based control circuit along with four sensor circuits, one LED driver circuit, one LCD module, one alarm circuit, and a number of LED arrays. Control circuit consists of one 8051 microcontroller [2], one 12 MHz crystal, some resistors and capacitors. Use of a microcontroller has simplified the design considerably by reducing the control complexity and the number of chips required to implement the system. An LCD segment has been used for displaying the measured data to reduce power consumption. Figure 1 shows the overall system. Day-night sensor circuit consists of photo cell or Light Dependant Resistor (LDR) [3] which will give a signal to the microcontroller if it is night to glow the light. The aviation light is consisting of LED arrays. This light will glow according to the signal generated from the microcontroller. Figure 2 shows a Printed Circuit Board of a actual control circuit.

Figure 2: PCB of Control Circuit

LCD module will show the status of the total system including the faults and beep. The fault alarm signal line can be directly connected to the data acquisition system and can be monitored remotely. The system indicates Power on, Tower Light Fault, Sensor Fault, Sensor Active and grounded cable cut signals. Figure 3 shows the controller system.

Figure 3: Overall system block diagram of controller

## III. DAY-NIGHT SENSOR

In order to determine day or night a photo conducting device such as Light Dependant Resistor (LDR) has been used in the system. LDR is one kind of semiconductor device in which resistance changes with the changes of light intensity. By using this variation of resistance a signal is produced to control warning light. Day-Night sensor circuit consists of one Light Dependant Resistor (LDR), one operational amplifier, one diode, some resistors and capacitors. Here operational amplifier is used as inverting amplifier. When day light is decreased the resistance of LDR increases and its corresponding voltage drop increases causing the out put of operational amplifier goes low (zero level). This zero level is fed to microcontroller and the microcontroller produces a signal to drive the LED display driver circuit.

To make the system dependable and robust it is very important to check whether the sensor is working. If the Day-Night sensor or Light Dependant Resistor is faulty then the system will be unable to detect day and night automatically and the system will be malfunctioning. In order to solve this problem we use day-Night sensor fault indicator. With the help of this sensor user can monitor the day-night sensor instantaneous status on the LCD module. When the LDR is unserviceable or disconnected, a variation of voltage is occurred in the circuit and by using this voltage we produce a signal which is fed to the microcontroller to generate alarm and also display on the LCD module. This day-night sensor fault detector circuit consists of one operational amplifier two diodes some resistors and capacitors. Here Operational amplifier is used as inverting amplifier.

## IV. WARNING LIGHT

Considering the parameters like power saving, low intensity lights and line of sight we have chosen LED arrays for constructing the warning light. 300 LED has been used in 60 parallel lines, arranging 5 LED in a series to construct the light. To confirm light intensity equal in omni directional, LED arrays are arranged in a hexagonal box so that the light will be in line of sight horizontally form any angle. A hexagonal plate also covers the hexagonal box to glow the light vertically. Figure 4 shows the hexagonal orientation of LED.

Figure 4: Orientation of LED arrays

If some or total LED of warning light is unserviceable, the intensity of light will be decrease and the visibility will be down. In order to solve this problem a sensor circuit has been used to monitor the instantaneous status of the indicator on the LCD module. If we placed a series resistor with the LED circuit, the total current through the LED is the same as through the resistor. If the intensity of LED is varied, the current through the series resistor also vary and by using this variation of current we produce a signal that signal is fed to the microcontroller and microcontroller produce an alarm signal and display on the LCD module.

Figure 6: A finished warning light

It is difficult to monitor grounding cable daily for any Mobile phone operators. But it is badly needed for telecommunication equipments. Without grounding cable protection, telecommunication equipments stay with serious risk for every moment. A serious damage may occur any time and the whole system remains unsecured. Grounding cable is much expensive that is stolen frequently, to prevent this ignorant and destructive activity a circuit has been used that produce a signal when the grounding cable is cut in any place, this signal is fed to the microcontroller and microcontroller generates an alarm signal and show this message on the LCD module. This signal can be connected in the data acquisition system so that it can be monitored centrally and allow the operator to repair or replace immediately. Figure 7 shows the GCM circuit. This fault detector circuit consists of one opto-isolator [4] along with some resistors and capacitors.

Power supply is a DC to DC converter it consists of four parts Pulse width modulation, out put stage, Error amplifier and Current sense short circuit protector. There are three outputs in this power supply 22 volt, 12 volts and 05 volt. Here we use a DC to DC converter Power supply. This power supply consists of four units Pulse width modulation, out put stage, Error amplifier and Short circuit protection circuit. There are three outputs in this power supply 22 volt, 12 volts and 05 volt. This Power supply itself is very intelligent in both input and output. Considering reverse polarity protection, Input terminal is designed with universal polarity that means you can connect any lead to any terminal of battery. This universal polarity [5] function is done by using a high Ampere rating Bridge Rectifier. Figure 8 shows the universal polarity circuit.

Figure 8: universal polarity circuit

The output is short circuit protected. If output terminal is short circuited by any means then output voltage will be reduced to near about zero so no current flow in the short circuited terminal and there is no damage to power supply. This function is done by using an operational amplifier and a series resistor. When the output current exceeds desired level then the short circuit protection circuit generate a signal that signal will stop the output of this power supply.

## VII. SOFTWARE AND ALGORITHM

Simultaneously checking several units, responding and running tasks in real time lead the software or the firmware for aviation warning light system to a multitasking environment. Many microcontroller applications require simultaneous execution of multiple jobs or tasks. For such applications, a real-time operating system (RTOS) [6, 7, 8] allows flexible scheduling of system resources, like the CPU and memory, and offers communication between tasks. RTX51 Tiny [9] is a powerful RTOS that is easy to use and that works with all 8051 derivatives. RTX51 Tiny programs are written using standard C constructs and compiled with the Keil C51 C Compiler [10]. Figure 9 shows the user system, hard ware and the operating system.

Figure 9: System with RTOS

RTX51 Tiny supports round-robin [9] and the use of signals for task switching which allows quasi-parallel execution of several endless loops or tasks.

Tasks are not executed concurrently but are time-sliced. RTX51 Tiny switches to another task that is ready to run and allows that task to execute for a while. The time slices are very short, usually only a few milliseconds. For this reason, it appears as though the tasks are executing simultaneously.

To starts the system, first system configuration is checked for different mode of light glowing, LCD initialized for displaying the configuration and then current status of the system. To get the status of the system and to respond according to the current status, the overall functionality of this system is divided into four major tasks. They are task1 named check system, task2 named run light, task3 named display and alarm and task4 named check light. RTX51 Tiny does not require you to have a main function in your program. It will automatically begin executing task 0. These entire four tasks have to be created with executing task0. After execution of task0, they will be running in round-robin fashion and with the use of signals between them. Figure 10 shows that the CPU sharing time with the tasks.

Figure 10: Aviation warning light system in a real time environment

Figure 11 shows the flowchart of task 1 that runs independently. First it checks the day-night sensor. If it is faulty then it starts the light permanently and sends a beep or alarm signal as long as the user is not resetting the beep. If the sensor is not faulty then it goes to check whether it is night. If it is night then it starts the light. But if it is day and there is no flag is on for a schedule testing of light it will stop the light. Subsequently it checks the ground cable. If the cable is cut then it will send a beep or alarm signal. Lastly it will check whether the beep has been reset. User has to press the alarm reset button for a few seconds to stop the beep. If it has not been reset, a flag for alarm or beep will be on and other tasks will be notified through the beep flag.

Figure 11: Task 1

If it is night or it is the schedule for checking light in day time, task2 for running light will be started. Light fault checking will be done here. If the light is fault it will immediately send a beep signal and will start the stand by light. Task2 will check the stand by light also. Incase of the failure of the stand by light it will send the alarm or beep signal again. Figure 12 shows the flowchart of task 2 and task3.

Task 3 will be waiting as long as no signal is received from task 1. It is responsible for checking and displaying the status of the system in the LCD module. After displaying it will send signal to task 4 to run.

Task 4 is responsible for a routine wise checking of the light. Before starting first time it will be waiting for a signal from task 3 and will start counting time. If it is night then task 4 has nothing to do but if it becomes day, task 4 will check the light after each thirty minute. This interval can be changed for different users. A flag for schedule test is set on before testing light each time. Figure 13 shows the flowchart of task 4.

For implementing the above mentioned algorithm, total 570 lines of code and 23 methods were written in ANSI C.

For practical implementation, a metal casing has been used for the controller circuit shown in figure 14.

Figure 12: Task 2 and Task 3

Figure 13: Task 4

Figure 14: Controller casing

## VIII. CONCLUSION

This system is very intelligent if any abnormalities occur such as grounding wire problem, LED intensity down, or problem regarding day-night sensor it will give alarm and notify about that fault in the LCD panel. During day time the system is able to test automatically itself in every 30 minutes and display the self test result in the LCD module. The system has been designed and developed in digital laboratory of East West University, Bangladesh and is being used by well known telecom operators in Bangladesh and is found to be in good

agreement as well. It is worth mentioning here that the total cost of developing the system is approximately US\$ 130 only, which is much lower compared to the devices used for the same purpose.

# Low-Cost Realization of Toffoli Gate for the Low-Cost Synthesis of Quantum Ternary Logic Functions

Md. Mehedi Hasan

Department of Electrical and Electronic Engineering, Bangladesh University of Engineering and Technology (BUET), Dhaka-1000, Bangladesh, Email: mehedibuet@gmail.com

**Abstract** — Reversible quantum computer system is one of the best choices for future computer systems. Multiple-valued logic especially ternary logic is a good candidate for the realization of reversible quantum computer. An efficient logic synthesis mechanism is essential for the low-cost realization. Toffoli gate is an important gate for quantum logic synthesis. It is the basic element for the Galois Field Sum of Product (GFSOP) expression based logic synthesis mechanism. So, for low-cost realization of any ternary logic function, a low-cost implementation of Toffoli gate is very necessary. This paper shows a low-cost, practically realizable, and efficient realization of 3-qutrit ternary Toffoli gate by using ion-trap realizable Muthukrishnan-Stroud gate. This realization is more efficient and less costly than other realizations.

**Index Terms** — Circuit synthesis, logic design, logic functions, minimal realization, multivalued logic.

## I. INTRODUCTION

Quantum computing technology is one of the most promising technologies for future computer systems [1]. As the quantum computer is based on the reversible logic, the power dissipation will be extremely low compared to the counterpart CMOS computer [2]. This computer is able to perform vast amount of computation [1], [3] and also able to solve some of the most unfeasible problems in computer science such as large integer factorization, discrete logarithms etc [4].

For realization of quantum circuits, three-valued logic (ternary logic) is a very good choice as the amount of information per bit for ternary logic is more than that for two-valued (binary) logic. For these reasons, ternary quantum logic synthesis is a very attractive research area in the recent years [5]-[15].

Ternary quantum logic functions can be realized as the network of Toffoli gates. Some synthesis algorithms or methods [5]-[7] are proposed for the realization of functions by using Toffoli gates. Toffoli gates can be realized by using the primitive (basic) gates. The only primitive gate which is physically realizable is Muthukrishnan-Stroud gate (MS gate) [8]. MS gate brings a great momentum in multiple-valued quantum research. Another gate called Generalized Ternary gate (GTG) is proposed in [9] which can be built from a subset of MS gates [15]. Therefore, Toffoli gate which is a very important gate for realization of any ternary logic circuit

must be realized by using physically realizable primitive gates such as MS gates and GTGs. The number of the primitive gates should be as small as possible to reduce the circuit cost.

In literature, several works such as [5], [10], [11] have been done to realize the ternary Toffoli gate using MS gates or GTGs. Khan et al. [5] presents a realization that uses 10 GTGs which is equivalent to 32 MS gates. The work [10] shows a realization which requires 8 GTGs. Another work [11] presents the equivalent MS gate realization of the GTG realization proposed in [10] which requires 42 MS gates.

To reduce the implementation cost, in this paper, we have proposed a very low-cost realization of Toffoli gate. In our design, we have used only 20 MS gates for realization which reduces the cost by 37.5% compared to [5] and 52% compared to both [10] and [11].

The rest of the paper is organized as follows. Section II presents the background on the reversible logic and different quantum gates. Section III presents the proposed realization of ternary Toffoli gate and also presents the explanation of the operation. Finally, section IV provides the conclusion.

## II. BACKGROUND

An  $n$ -input and  $n$ -output multiple-valued logic function is reversible if it maps each input into a unique output. So  $r^n!$  reversible functions is possible for the  $r$ -valued logic. For ternary system,  $3^n!$  reversible functions are possible. But all of them are not realized as a single gate. Muthukrishnan-Stroud gate, Generalized Ternary gate (GTG), Feynman gate, and Toffoli gate are some well-known gates which are used for synthesis.

### A. Muthukrishnan- Stroud gate

Muthukrishnan and Stroud proposed a group of 2-qutrit (quantum digit) primitive ternary gates which are ion-trap realizable [8]. Basically the success in the realization of these gates gives the hopes of building practical quantum computer. This group of gates is known as Muthukrishnan-Stroud (MS) gate.

Fig. 1 shows the MS gate for ternary system. Here,  $A$  and  $B$  are the controlling input and the controlled input respectively while  $P$  and  $Q$  are the outputs. If the logic

Fig. 1. Quantum ternary MS gate.

TABLE I  
VALUE AFTER QUANTUM Z-TRANSFORM.

| Quantum Z-Transform | Q when B= |   |   |
|---------------------|-----------|---|---|
|                     | 0         | 1 | 2 |
| Buffer              | 0         | 1 | 2 |
| +1                  | 1         | 2 | 0 |
| +2                  | 2         | 0 | 1 |
| 12                  | 0         | 2 | 1 |
| 01                  | 1         | 0 | 2 |
| 02                  | 2         | 1 | 0 |

value of  $A$  equals 2, the value of  $Q$  will be the quantum Z-transform of the input  $B$  and if  $A$  is not equal to 2, then  $Q=B$ . Different quantum Z-transforms are shown in Table I. For example, if Z-transform is +2,  $A=2$  and  $B=0$ ,  $Q$  will be 2.

### B. Generalized Ternary Gates (GTGs)

Fig. 2 shows a Generalized Ternary Gate [9]. Here, input  $A$  is the selector input in a conceptual multiplexer where  $B$  is the input which is processed by Z-transform shown in Table I. When  $A=0$ , the output  $P$  is the  $L$ -transform of the input  $B$ . Similarly, when  $A=1$ ,  $P$  is the  $M$ -transform of  $B$  and when  $A=2$ ,  $P$  is the  $N$ -transform of the  $B$  where  $L, M, N \in \{+1, +2, 12, 01, 02, \text{no-transform or buffer}\}$ . Depending on the six possible transforms for the each position of  $L, M, N$ , there are  $6^3$  or 216 GTGs possible.

However, GTGs can be realized by using MS gates. Fig. 3 shows the realization by using MS gates. Here, if  $A=0$ , the controlling input of the MS gate with  $N$ -transform is 0, so  $N$ -transform is not applied.  $M$ -transform is not also applied as the controlling input is 1. But, as the controlling input of the MS gate with  $L$ -transform is 2,  $L$ -transform is applied and the output  $Q$  becomes the  $L$ -transform of  $B$ . Similarly, if  $A=1$ , the controlling inputs of the MS gates are 1, 2, and 0 with  $N$ -transform,  $M$ -transform, and  $L$ -transform respectively. So  $M$ -transform is applied on input  $B$ . When  $A=2$ , the  $N$ -transform is applied on the input  $B$  and the output  $Q$  becomes the  $N$ -transform of  $B$ .

If  $L$ -transform is *buffer* or *no-transform* (for which the input and the output is the same), there is no need of MS gate for the  $L$ -transform. So, this two-transform GTG gate

Fig. 2. Generalized Ternary gate

Fig. 3. Realization of Generalized Ternary gate

Fig. 4. Realization of GTG with two-transform (L is buffer)

(where two transforms such as  $M$  and  $N$  are non-buffer) can be realized by 4 MS gates (Fig. 4). Similarly, the two-transform GTG where  $M$ -transform is buffer can be realized by using 4 MS gates. And the two-transform GTG with buffer in  $N$ -transform can be realized by using 5 MS gates. Again, one-transform GTG with  $L$ -transform (where  $M$  and  $N$  are buffer) can be realized by using 3 MS gates. One-transform GTG with  $M$ -transform can be realized by using 3 GTGs. And one-transform GTG with  $N$ -transform needs only 1 GTG. This conversion technique is used in the work [11] to convert the GTG realization of ternary Toffoli gate proposed in [10].

### C. Ternary Feynman Gates

Fig. 5 shows a ternary Feynman gate where  $A$  is the controlling input and  $B$  is the controlled input. The output  $P$  is equal to  $A$  and the output  $Q$  is equal to the Galois Field 3 summation (GF3 sum) of  $A$  and  $B$ . Ternary Feynman gate can be realized by using 4 MS gates[11].

### D. Ternary Toffoli Gates

Fig. 6 shows a ternary Toffoli gate. Here, the inputs are  $A, B$ , and  $C$ . The output  $P$  and  $Q$  are equal to the inputs  $A$  and  $B$  respectively. The output  $R$  is equal to  $A.B+C$  where

Fig. 5. Ternary Feynman gate

Fig. 6. Ternary Toffoli gate

. and + are the operators for Galois Field 3 (GF3) multiplication and addition respectively. The truth table for the ternary Toffoli gate are shown in Table II.

### III. REALIZATION OF TERNARY TOFFOLI GATE

Fig. 7 shows the proposed realization of ternary Toffoli gate whose symbol is shown in Fig. 6. The operation of the ternary Toffoli gate can be explained based on the understanding of MS gate as discussed in section II. Table III shows the logic conditions of the different nodes for all  $3^3 = 27$  types of inputs. The table also verifies the operation of the realization for all inputs. It also shows that for every input, the realization works correctly. To explain the operation, let us consider an example where  $A=1$ ,  $B=2$ , and  $C=1$ . Here,  $A_1$  becomes 2 due to +1-transform on the input  $A=1$  ( $1+1=2$ ) and the controlling input 2. Similarly,  $A_2$  becomes 0 due to +1-transform on the input  $A_1=2$  ( $2+1=0$ ). By the same way,  $A_3$  and  $A_4$  becomes 2 and 1 respectively.  $A_4$  is equal to  $A$ . For the line of input  $B$ ,  $B_1$  becomes 2 due to 01-transform of  $B=2$ . Then as the controlling input of next 12-transform is  $A_2=1$ , so the output  $B_2=B_1=2$ .  $B_3$  becomes 1 due to 12-transform of  $B_2=2$ . Similarly,  $B_4, B_5, B_6, B_7, B_8, B_9, B_{10}, B_{11}, B_{12}, B_{13}$  and  $B_{14}$  become 2, 2, 2, 0, 2, 2, 1, 2, 2, 0 and 2 respectively. Here  $B_6=2=B$  and  $B_{14}=2=B$ . From the node  $B_9$ , we get  $A.B=2$ . Now, let us consider the line for the input  $C$ . As  $C=1$ ,  $C_1$  becomes 0 due to the +2-transform of  $C$  where the controlling input is  $B_9=AB=2$ . Then,  $C_2$  becomes 0 as the controlling input of the next MS gate is  $B_{10}=1$  and  $C_1=0$ .  $C_2$  indicates the output  $A.B+C$ .

By the same way, the operation of the proposed Toffoli gate is verified for all 27 types of inputs and the logic condition of every node for each input is illustrated in Table III. For every input, the output we get is same as we have shown in the truth table of Table II.

In this design, we have used only 20 MS gates where the work [11] uses 42 MS gates for realization. The work [5] uses 10 GTGs and one Feynman gate. Among them,

TABLE II

| 2 | 2 | 0 | 1  | 1     |
| 2 | 2 | 1 | 1  | 2     |
| 2 | 2 | 2 | 1  | 0     |

there are 2 two-transform GTGs where  $L$  is buffer, 2 two-transform GTGs where  $N$  is buffer, 4 one-transform GTG with  $N$ -transform, 2 one-transform GTGs with  $L$ -transform, and 1 Feynman gate. So, according to the discussion of section II(B) and II(C), the total cost of realization of [5] is  $2 \times 4 + 2 \times 5 + 4 \times 1 + 2 \times 3 + 1 \times 4 = 32$  where cost is represented by the number of the primitive MS gates. Therefore, the proposed design reduces the realization cost by 52% compared to [11] and by 37.5% compared to [5].

### IV. CONCLUSION

In this paper, a new realization of ternary Toffoli gate is proposed. This realization reduces the realization cost significantly. As Toffoli gate is the basic element of realizing any ternary logic function for quantum computer, the reduction of the realization cost of Toffoli gate will reduce the total realization cost of the logic circuits significantly. So, this realization of Toffoli gate is more suitable for practical realization than other realizations.

**Abstract** — In this paper, we described the design and hardware implementation of an electronic voting machine. The main aim of this project is not to design a power efficient perfect device but is to design a mother device that can be adoptable to any recent technologies. The design of the machine and its usage is as simple as an illiterate common people can easily use it. A vote casting procedure is also proposed to use the machine where we prescribed a new procedure called DEMO vote casting which is a testing mechanism to test the device before vote casting and also at the run time. The vote casting system is almost similar to traditional system, only ballot box will be replaced by the device. The machine uses Voter ID to identify a valid voter and restrict multiple vote casting.

**Index Terms** — Election, Electronic Voting Machine, Electronic Voting System, Microprocessor, Vote

## I. INTRODUCTION

The Electronic Voting Machine is an electronic device that receives votes from the voters, stores the votes and counts the votes just after the vote casting process. Many other countries have developed Electronic devices to use in their Election system but those machines only reflect the aspects of their own country. To design such a machine for Bangladesh we have to consider the social facts, voting offences that influence our Election System. Our device considers no further change in the conventional vote casting system, only the ballot box will be replaced by the voting machine. It will partially automate the vote casting system. Its implementation will reduce most of the voting offences like ballot box hijacking and false voting. Higher security and testing mechanism are considered to ensure a free and fair election. The machine can be considered as a product which is customized to be used in third world countries like Bangladesh.

## II. LITERATURE REVIEW

Many countries around the world use electronic voting machine but those machines were developed considering their own country aspect [1]. Those designs are not suitable for developing countries because of the usage of high-tech technologies and cost per machine is too high to use them in national election in Bangladesh. Also while designing a voting machine for our country we have to consider literacy

rate, electricity availability, social facts which are not reflected in those machines.

We have to use the same type of machines that are used in developing countries. India introduced an electronic voting machine that reflects their social facts [2]. They used battery based machine using microprocessor which consists a control unit and a ballot unit. In Bangladesh there developed some computer and software based voting systems which are impossible to use in rural areas where no electricity is available. A microcontroller based voting machine [3] is also proposed but there is no feature of using Voter ID. No initial and run time checking procedure is proposed to check the functionality of the machine. In that system, a half minute delay is considered to prevent device hijacking and false voting that will slow down the process which can easily be solved using Voter ID.

## III. LIMITATIONS OF EXISTING ELECTION SYSTEM

- 1) The main limitation of our vote casting system is that it takes about two hours to count the votes. Sometimes the Authority has to recount the vote which is more time consuming.
- 2) It is also insecure because dishonest people can hijack the ballot box and can give false votes. There is no logical protection like password, voter verification etc.
- 3) The officers of the polling booth have to search the voter information from a list which is time consuming.

## IV. ELECTRONIC VOTING MACHINE

All the data found in the traditional ballot paper based voting system [4]-[6] have been analyzed and an optimized voting machine which will be fully adoptable to the traditional system is designed.

### A. Features

- 1) The Machine is fully adaptable to the existing System. The Symbol Panel acts like the ballot paper and the control panel acts like the ballot box.
- 2) It is more secured than ballot box. The presiding officer must activate the control panel by entering password. The control panel uses a removable storage to store program, database of the voters and candidates. It is easier to ensure

security of this small storage device than the bulky control panel.

3) It can accurately count the votes just after the vote casting process ended.

4) The machine has a DEMO vote casting feature to ensure each key in the symbol panel working properly. The increment of the total number of votes is displayed in the control panel and in an outdoor display which indicate that each key is functioning properly. This procedure can also be run during the vote casting time if the officer noticed that the total number of votes is not incrementing in the display or there is no successful vote casting sound.

5) Privacy in voting information is highly implemented. Neither election authorities nor anyone else can link any ballot to the voter who cast it.

6) NULL voting option is implemented. NULL vote means if a voter is not satisfied with the candidates who are participating in the election, then he can press the NULL key in the Symbol panel which means that he is not casting his vote to anyone. If in a region NULL vote is elected, then it means that the political parties have nominated those types of people who are disliked by the voters. So the Election Commission must rearrange an election again in that region where previously participated candidates cannot take a part again as a punishment and political parties must give nomination to eligible candidates. (It's a proposal)

7) We have found that maximum number of candidates in an election is not more than 22. Average number of candidates does not exceed 10 [4]. So, only 24 keys are placed in the panel for each post.

8) The presiding officer enters the voter ID in the control panel. If the voter has not cast his vote yet, the control panel automatically activates a symbol panel. If the voter has already cast his vote it displays a message on control panel and it does not activate the symbol panel. Thus it prevents false vote casting.

9) There will be an outdoor large display at the vote centre which will display total number of votes cast. Also, the control panel generates a loud sound after a successful vote casting. This will give the voter a mental satisfaction that the system is ok and the entire processing is going well.

### B. Schematic diagram

The Electronic Voting Machine contains a Control panel and one or two Symbol panels. The control panel is used by the presiding officer and assistant presiding officers of a polling booth.

1) The control panel: A display is used to show information to the officer. There are two status LEDs on the panel to show activity of the symbol panel. The panel consists of 10 numeric keys numbered from 0 to 9. These keys are used to enter password and voter ID. There are also some function keys like Start key, Test key, End key, Count Key, Enter key, Del key. (Fig. 1)

Fig. 1. Schematic Diagram of Electronic Voting Machine

2) Symbol Panel: The symbol panel is used by the voter to cast vote. Each switch is labelled with a symbol of a candidate (Fig. 1). It has two parts; each part indicates different post of the candidate. Each part has 24 keys which are mechanical keys with Encoders. So the total numbers of keys are 48. Each key represents a candidate. The panel is enabled by the control panel and disabled automatically after the voter has cast his vote.

3) Outdoor Display: An Outdoor large display will be used to show the total number of votes cast. The value is automatically incremented after a successful vote casting.

### C. Machine description

We used 8086 microprocessor to execute instructions. Several latches are used to latch address generated from microprocessor. Data buffers are used to control directions of data. Two EEPROMs are used as odd bank and even bank memory to store 16 bit data [7],[8]. These EEPROMs store the main operating system, acts like RAM during instruction execution and also store voting information. The EEPROMs are removable. An address decoder is used to enable display latch, control panel buffer and symbol panel buffer. The block diagram of the device is described in Fig. 2

In control panel and symbol panel key pad, encoders are used to encode key stroke. As we are using mechanical switch the circuit generates incorrect encoded value because of contact bouncing. A Mono stable Multi vibrator IC is used to prevent contact bounce. A Counter is used to indicate new data has arrived. Each keypad design is identical.

Fig. 2. Block diagram of Electronic Voting Machine

## V. ELECTRONIC VOTING SYSTEM

The electronic voting machine will introduce Electronic Voting System. The procedure in the voting poll slightly changes the traditional vote casting process.

### A. Voter ID

The Assistant presiding officer will insert the ID of the voter in the control panel. The machine will verify the voter according to the voter database. The machine will automatically activate one of the symbol panels if the voter has not given the vote yet.

### B. Vote casting procedure

The presiding officer starts the vote casting procedure. The assistant presiding officer and polling officers help him to run the procedure properly.

1) Start vote casting: At first, the Presiding Officer inserts the removable storage into the control panel. Then he powers on the control panel. The system boots automatically and waits for the Password of the Presiding Officer. After the successful entry of the password, the control panel is activated. Then he checks the centre name. After that, he runs DEMO vote casting process to ensure that the whole system is working properly. After that he starts Vote casting (Fig. 3).

2) DEMO vote casting process: DEMO vote casting process is a testing procedure which ensures the system is functioning properly. It is normally executed in the initial

phase of vote casting procedure. It can also be run to test functionality of Machine at any time.

To start DEMO process the Presiding officer presses the TEST button on the control panel. Then he presses every button on the Symbol panel and checks if it is displayed on the screen of the control panel. The control panel displays each symbol name and the number of DEMO vote of that symbol. Thus the Officer can determine which key is malfunctioning (Fig. 5).

Fig. 3. Initializing and testing the machine before vote casting.

3) Vote casting procedure: The vote casting procedure starts when the presiding officer presses the START button. The polling officers manually verify the voter first. After that the Assistant Presiding Officer enters the ID of the voter in the control panel. If the voter has not cast his vote yet, the control panel activates one of the symbol panels. The voter is then sent to the Symbol panel. After the successful vote casting, the symbol panel generates a sound and automatically disabled (Fig. 4).

4) Stop vote casting: When time is finished the presiding officer end the voting process. The presiding officer has to provide password for this purpose.

Fig. 4. Vote casting procedure

### C. Vote count

The presiding officer has to provide password to count the vote. After counting the vote no further vote casting process can be executed. All voting information is permanently stored in removable storage.

Fig. 5. The DEMO vote casting process.

## VI. COST

Total cost of the system is described in table I. But when large amount of device will be produced in industry the cost must be reduced.

## VII. PERFORMANCE ANALYSIS

Electronic Voting Machine enhances the performance of traditional voting system. It transforms the manual voting system into partially automated one reducing total time.

1) Implementation of the devices turns the Election system into automated system. The major manual process removed. Only a part of voter verification will remain manual. All other parts run automatically.

2) Voter ID number is considered. In our device the officer has to enter the ID manually using the control panel.

TABLE I  
TOTAL COST OF THE MACHINE

| PARTS NAME                                    | NUMBER | COST PER ITEM (TK) | TOTAL (TK)  |
|-----------------------------------------------|--------|--------------------|-------------|
| 8086 Microprocessor                           | 1      | 450                | 450         |
| EEPROM                                        | 2      | 200                | 400         |
| 16x2 Character LCD DISPLAY                    | 1      | 250                | 250         |
| Hex Inverter                                  | 1      | 15                 | 15          |
| Quad 2-Input OR Gate                          | 3      | 15                 | 45          |
| Clock Generator And Driver For 8086 Processor | 1      | 15                 | 15          |
| Monostable Multivibrators                     | 2      | 15                 | 30          |
| 3-To-8-Line Decoders                          | 1      | 15                 | 15          |
| Priority Encoders                             | 4      | 15                 | 60          |
| 3-State Octal Bus Transceiver                 | 4      | 15                 | 60          |
| 4-Bit Binary Counters                         | 2      | 15                 | 30          |
| 3-State Octal D-Type Transparent Latches      | 7      | 15                 | 105         |
| Crystal Oscillator                            | 1      | 20                 | 20          |
| Resistor                                      | 4      | 1                  | 4           |
| Capacitor                                     | 3      | 1                  | 3           |
| Switch                                        | 84     | 5                  | 420         |
| Others                                        |        |                    | 500         |
| <b>Total:</b>                                 |        |                    | <b>2422</b> |

In future, bar code reader may be implemented to automate this.

3) No need of electricity, it is a battery operated device. In case of power failure, the actual information will not be lost because the information is written immediately into the EEPROM. The officer can also be sure about successful vote casting by watching the incrimination of votes in the display of the control panel or hearing the sound of successful vote cast. He can take an immediate decision to recast the vote by the last voter.

4) The symbol panel is expandable up to 64 symbols. So it can accommodate 64 candidates.

5) In the last Parliament Election in 2001 there were 7, 50, 00, 656 voters and total cost was about 70 core taka [4]. Cost per voter was 9 taka .1, 45,000 ballot boxes needed. Each of our devices will not cost more than 2,500 taka. Total cost of 1, 45,000 machine is almost 35 core taka which is almost half of the previous cost

Fig. 6. Prototype of the Electronic Voting machine

- 6) The result can be published immediately. Traditional system takes minimum two hours.
- 7) A new testing system called DEMO voting procedure introduced which ensures accuracy and transparency of the system.
- 8) Another new concept, NULL voting option is added which may increase the freedom of the voters and decrease autocracy of political parties.
- 9) Removable storage improves security. Security is also implemented using password of the presiding officer. In conventional system no this type of security is implemented.

### VIII. CONCLUSION

Creating a user-friendly machine is a very complicated task because one has to design a machine which is more familiar with human behaviour. We proposed a procedure to use the machine which is very easy not only for the voter but also for the officers. In our device voter ID is used to verify the authenticity of the voter so it is usable with our recently introduced voter ID card. Although we were not able to fully implement all the features in software level but our proposed procedures can easily be implemented using Assembly Language by using the EEPROM programmer

which is developed by ourselves. The implementation cost of the machine is very low compared to total cost of an election. Also it improves security by using removable storage where data will be preserved for further usage.

**Abstract** — Reversible / Quantum circuits are believed to be one of the future computer technologies. In this paper, a Genetic Algorithm (GA) based synthesis of ternary reversible / quantum circuits using Muthukrishnan-Stroud gates is presented. The circuit generated by GA may contain redundant gates. We have used post GA reduction to eliminate these redundant gates. We have experimented with ternary half-adder circuit. The proposed GA converges for many combinations of crossover and mutation..

**Index Terms** — Reversible logic, half-adder, quantum circuit, post GA reduction..

## I. INTRODUCTION

Landaur [1] proved that binary logic circuit built using traditional irreversible gates leads inevitably to energy dissipation, regardless of the technology used to realize the gates. Zhirnov et al. [2] showed that power dissipation in future CMOS leads to impossible heat removal and thus the speeding up of CMOS devices will be impossible. Bennett [3] proved that for power not to be dissipated in a binary logic circuit, it is necessary that the circuit be built from reversible gates. A gate (or circuit) is reversible if it maps each input pattern to a unique output pattern. Bennett's theorem suggests that every future binary technology will have to use reversible gates in order to reduce power dissipation. This is also true for ternary technologies. Quantum technology is inherently reversible and is a promising technology for future computing systems [4].

Reversible/quantum circuit synthesis is more complicated than classical circuit synthesis. Reversible/quantum circuit synthesis is more complicated than classical circuit synthesis. In this paper, we have used GA with real – valued encoding of the chromosome using ordered 3-tuple [5]. GAs are very popular Soft Computing (SC) approaches for solving problems with no identified structure and high level of noise [5]-[7]. The reasons behind this popularity are, (i) a big problem space can be searched, (ii) the size of this search space can be moderated by parameters, (iii) a variety of new solutions can be produced and (iv) with long enough time solution can be obtained that is close to the optimal one. These advantages make GAs useful for synthesizing ternary reversible/ quantum circuit using cascade of

Muthukrishnan-Stroud gates, because the problem structure of such cascade is still unidentified and the search space itself is exponentially large.

## II. TERNARY REVERSIBLE GATE

There are three qudit (quantum digit) states in ternary quantum logic. These are  $|0\rangle$ ,  $|1\rangle$  and  $|2\rangle$ . Ternary 1\*1 gates operate on single qudit state. We represent a 1\*1 gate using the symbol of Fig. 1, where the operation  $y$  is one of the operations listed in Table I. In this paper the ternary operations i.e. the ternary 1\*1 gates are numbered from 0 to 5. For example, the operation +1 is numbered as gate number 1, the operation (12) is numbered as gate number 5 and etc.

where,  $y \in \{0, +1, +2, 12, 01, 02\}$

Fig. 1. Symbol of ternary 1\*1 gate family.

TABLE I  
TERNARY 1\*1 OPERATIONS

| A | A(0)<br>= A | A(+1)<br>= A+1 | A(+2)<br>= A+2 | A(01)<br>= 2A+1 | A(02)<br>= 2A+2 | A(12)<br>= 2A |
|---|-------------|----------------|----------------|-----------------|-----------------|---------------|
| 0 | 0           | 1              | 2              | 1               | 2               | 0             |
| 1 | 1           | 2              | 0              | 0               | 1               | 2             |
| 2 | 2           | 0              | 1              | 2               | 0               | 1             |

A ternary 2\*2 reversible/quantum gate has two inputs and two outputs. The two inputs are a controlling input ( $A$ ) and a controlled input ( $B$ ) as shown in Fig. 2. There are two parameters of the gate, the controlling value ( $x$ ) and the controlled value ( $y$ ). Let us use the notation  $\langle A, B, x, y \rangle$  to represent the gate.  $B$  is passed to the output if  $A \neq x$ , otherwise  $y$ th operation (Table I) is applied to  $B$ . Muthukrishnan et. al. [8] showed that  $\langle A, B, d-1, y \rangle$  gates are practically realizable in quantum ion trap technology for any  $d$ -valued logic. Therefore, according to [8], ternary  $\langle A, B, 2, y \rangle$  gates are practically realizable. Ternary  $\langle A, B, 2, y \rangle$  gates which is known as the Muthukrishnan-Stroud gates have been used and is shown

in Fig. 2, where  $x = 2$  and  $y$  is any operation from Table I.

Fig. 2. Symbol of Ternary Muthukrishnan-Stroud gate family.

### III. PROPOSED GENETIC ALGORITHM

Half-adder circuit is an important medium scale building block for digital circuit design. As there is no direct method to construct a ternary circuit using Muthukrishnan-Stroud gates, we have tried with GA based synthesis. Use of GA will allow us to find appropriate combination of the gates that realize (perhaps optimally) ternary logic functions. GA is very popular Soft Computing approach for solving problems with no identified structure and because a variety of new solutions can be produced.

#### A. Problem Encoding

In this work, the generated circuits have four input and four output lines each. The  $3^n$  different combinations (here  $n = 2$  as there are two primary inputs) of 0, 1 and 2 are inputs to the two primary input lines. These are reproduced at the first two output lines. The other two input lines have any constant values 0, 1 or 2 for a particular circuit. The other two output lines are the Sum (S) and Carry out ( $C_o$ ) of the half-adder circuit.

Each of the columns in the circuit is represented by an ordered 3-tuple consisting of controlling line number, controlled line number and controlled gate number (from Table I). Using this notation one chromosome is shown in Fig. 3. In Fig. 3, each of the columns in the circuit is a gene of the chromosome. The circuit corresponding to this chromosome is shown in Fig. 4.

#### B. Fitness Components

In the proposed GA, we have used two fitness components-

##### 1) Output Truth Vector Fitness

-The extent of representation of sum and carry out by the chromosome.

##### 2) Cost Fitness

-Proportional to the number of gates of the resulting circuit.

#### C. Flowchart of Proposed GA

Fig. 5 shows flowchart of proposed GA.

#### D. Genetic Operators

Genetic operators which are used in the proposed GA are discussed below:

##### 1) Selection:

Two different chromosomes are selected randomly as parents.

##### 2) Crossover:

In the proposed GA, based on the crossover probability, one-point classical crossover has been used to generate two offspring from the two selected parents. A crossover point (between one and length-1) is randomly selected.

Fig 3. Chromosome representing the circuit of Fig. 4.

Fig. 4. Ternary half-adder using ternary Muthukrishnan-Stroud gate family (Numeric representation of a column (gene) is controlling line number, controlled line number and controlled gate number, respectively).

### 3) Mutation:

Mutation is done on every gene based on the mutation probability. In the mutation process, a gene is replaced by another randomly generalized gene.

Fig. 5. Flowchart of the proposed GA.

In the proposed GA, if no replacement is done, then we say that the generation is stagnant. If consecutive G generation are stagnant, then we terminate the GA and re-run it with a new seed. The GA is re-run for N times.

## IV. EXPERIMENTAL RESULTS AND DISCUSSION

The proposed GA has been implemented in C programming language and experimented with the ternary half-adder circuit with different GA parameter combinations to see the effect of the parameters on the cost of the solution. The experimental results for ternary half-adder circuit are summarized in Table II.

The influences of different GA parameters on the performance of the GA are shown in Fig. 6 and 7. Fig. 6 shows the influence of population size on the average cost and average generation with fixed chromosome length. The influence of crossover probability on the cost with fixed population size and chromosome length is shown in Fig. 7.

(a)

(b)

Fig. 6. The influence of population size on (a) the average cost and (b) the average generation with fixed chromosome length, L=75.

Fig. 7. The influence of crossover probability on the cost with fixed population size,  $P=150$ .

It can be observed from Fig. 6 that population size  $P=200$  gives the best solution of average cost 33. Fig. 7 depicts that the middle crossover probability results in maximum cost, the lower and higher probabilities result in lower costs. Though there is an outlier at the crossover probability 0.8.

## V. POST GA REDUCTION

The circuit generated by the GA may have redundant gates. Post GA reduction is used to eliminate such redundant gates. There are three ways this elimination is done.

1) If two single - qudit gates are in cascade in the circuit, then two single - qudit gates are replaced by one single - qudit gate as shown in Fig. 8. Here,  $O = (A + 1) + 1 = A + 2$ . There are other possible eliminations using this approach [9].

Fig. 8. Two single - qudit gates in cascades is equivalent to one single - qudit gate.

2) If two controlled gates are in cascade in the circuit, then two controlled gates are replaced by one controlled gate as shown in Fig. 9. Here,  $O_2 = (B + 1) + 1 = B + 2$ .

There is other possible elimination using this approach [9].

Fig. 9. Two controlled gates in cascade is equivalent to one controlled gate.

3) If there are two single - qudit gates along the control line of a controlled gate - one before the controlled gate and the other after the controlled gate, then the three gates can be reduced to one single - qudit gate before the controlled gate and one controlled gate as shown in Fig. 10.

When  $A = 0$  or  $A = 1$  (that means the controlled gate is inactive), then  $O_2 = (B + 1) + 1 = B + 2$ . When  $A = 2$  (that means the controlled gate is active), then  $O_2 = ((B + 1) + 1) + 1 = (B + 2) + 1$ . This implies that a +2 uncontrolled gate followed by a controlled gate with +1 operation will replace the combination. There are other possible eliminations also [9].

Fig. 10. One single - qudit gate, one controlled gate and one single - qudit gate in cascade is equivalent to one single - qudit gate and one controlled gate.

Ternary half-adder circuit generated by our GA with cost 19 is shown in Fig. 11. There are two controlled gates in cascade in the circuit that is equivalent to one controlled gate. Fig. 12 shows reduced circuit with cost 18.

## VI. CONCLUSION

There are many software methods that synthesize ternary reversible/quantum circuits [10]-[11]. In this work, GA based synthesis method for ternary reversible/quantum circuit using Muthukrishnan-Stroud gates has been proposed. Experimental results show that the proposed GA can produce quantum/reversible circuits. The ranges of the parameter values for which the GA converges and the effect of the GA parameter on the performance of the GA have been shown. Post GA reduction to eliminate redundant gates from the results obtained by the GA has been also shown.

TABLE II  
PARAMETER SETTINGS THAT CONVERGE TO SOLUTION

| Population Size(P) | Chromosome Length(L) | Crossover Probability( $P_c$ ) | Mutation Probability( $P_m$ ) | Cost | No. of Generation(G) |
|--------------------|----------------------|--------------------------------|-------------------------------|------|----------------------|
| 50                 | 75                   | 0.3                            | 0.06                          | 41   | 68532                |
| 100                | 50                   | 0.1                            | 0.06                          | 23   | 67677                |
|                    |                      | 0.1                            | 0.09                          | 23   | 73877                |
|                    |                      | 0.2                            | 0.07                          | 28   | 77726                |

# New Methodologies for High Level Modeling and Synthesis of Low Density Parity Check Decoders

Syed Mahfuzul Aziz and Sunil Sharma

School of Electrical & Information Engineering, University of South Australia  
Mawson Lakes, SA 5095, Australia

**Abstract**—Low density parity check (LDPC) codes are the error-correcting codes which offer huge advantages in terms of coding gain, throughput and power dissipation. Error correction algorithms are often implemented in hardware in order to ensure fast processing. The hardware implementation of LDPC decoders using traditional hardware description language (HDL) based approach is a complex and time consuming task. This paper investigates new high level approaches to design and synthesis of LDPC decoders using a combination of high level modelling tools. It compares the high level design approaches to traditional HDL-based approach. The results presented in this paper provide some useful insight into the high level design approaches, their efficiencies and possible future directions with a view to develop an efficient design and modelling framework for hardware implementation of complex LDPC decoders.

**Index Terms** – Error correction coding, digital systems, digital communication, logic design, FPGA.

## I. INTRODUCTION

Transaction of information through a practical communication system is not free from noise. Information may rather be corrupted in transit by noise in the channel [1]. Therefore it is of paramount importance for communication systems to have adequate means for the detection and correction of errors in the information received over communication channels. Turbo codes and LDPC (low density parity check) codes are most commonly used for error detection and correction nowadays [2]. Both of these codes provide coding gains [3] close to Shannon's limit [4]. LDPC codes however outperform turbo codes in terms of coding gain for large SNR [5, 6]. LDPC code of length 1 million with a coding rate (ratio of information bits to the sum of information and parity bits) of 0.5 and BER of  $10^{-6}$  provides a capacity which is only 0.13db from Shannon's limit [5]. Further advantages of using LDPC codes are given in [7]. These include less computational complexity as compared to turbo codes, ability to pipeline the decoder to reduce delay at the cost of registers and some latency, and less number of iterations than turbo codes. Increased number of iterations reduces the throughput and increases power dissipation [5, 8]. The studies conducted in [7] and [8] indicate that lesser number of iterations in LDPC codes helps achieving higher throughput and decreases power

dissipation. Another factor which contributes in increasing the throughput of LDPC decoder is the degree of parallelism which is adjustable [9]. Another reason of using LDPC codes is that it is relatively easier to implement than turbo codes [10].

Despite all these advantages of LDPC codes the random parity check matrix makes the wiring between variable and check nodes complex, especially for large matrices. This leads to increased routing congestion in the decoder. Eventually the size of the LDPC decoder increases and speed decreases [11]. Complexity of practical implementation makes high throughput very difficult to achieve [12, 13]. Moreover, designing LDPC decoders in VHDL (Very high speed integrated circuit Hardware Description Language) becomes a cumbersome task when the size of the design increases. Huge amount of time and effort are required to model such large designs in VHDL [14]. It results in decrease in productivity. It becomes a nightmare for the designer to write VHDL code for thousands of connections and to make the changes required. Therefore, hardware implementation of LDPC decoder still remains a challenge.

This paper examines high level modelling and synthesis techniques of LDPC decoders using emerging industry tools. It compares the high level approaches with traditional hardware description language based approaches in terms of modelling complexity, efforts and time. It also compares the results obtained for a representative LDPC decoder design using the high level approaches and using a traditional HDL based approach.

## II. DESIGN APPROACH

This paper investigates a new high-level modelling and synthesis methodology for LDPC decoder using state of the art tools. As opposed to using only hand written VHDL codes for the entire design, this research examines high level design methods using Simulink, involving a combination of blocks designed with predefined library components and with embedded Matlab codes. A VHDL (VHSIC Hardware Description Language) code is generated automatically from the high level Simulink model using Mathwork's Simulink HDL coder (version 1.2). The entire design process is captured in Fig. 1.

Fig. 1. Proposed design flow.

Simulink HDL coder gives the flexibility of integrating different design approaches, namely Matlab programs, Simulink models and VHDL codes. Simulink and Matlab programs provide a much higher level of abstraction than VHDL. Therefore our design approach utilizes as many Simulink library blocks and Matlab blocks as possible to design various modules of the decoder provided these modules can be successfully processed by the HDL coder for automatic generation of VHDL codes. All the modules are then integrated in a top level Simulink model to produce the overall decoder model. VHDL code is generated automatically using Simulink HDL coder along with an optional test bench. This test bench can be used in ModelSim (a HDL simulator) to check correctness of the design. The auto-generated VHDL code can also be used in Altera's Quartus II or Xilinx ISE (Integrated Software Environment) for synthesis and implementation on desired FPGA (Field Programmable Gate Array). Automatic HDL code generation will lead to reduction in design efforts thereby increasing design productivity.

### III. OVERVIEW OF LDPC CODES AND DECODING ALGORITHM

Low density parity check (LDPC) codes are a class of linear block codes which are used for error detection and correction [15]. LDPC codes were first discovered by Gallager in 1962. In 1981, Tanner worked on LDPC codes and came up with important tanner graphs or bipartite graphs [16]. LDPC codes could not be implemented at the time of invention because the technology was not advanced, though they were studied again after almost three decades because they are more advantageous than any other error-correcting codes. LDPC codes are

extensively used in standards such as 10Gigabit Ethernet (10GBaseT) & digital video broadcasting (DVB-S2) [17].

There are different algorithms which could be used for decoding purposes. We used the min-sum decoding algorithm [12], which is a special case of sum-product algorithm [16]. Sum-product algorithm reduces the computational complexity and makes the decoder numerically stable [16]. Assume that the messages from the host communication system are represented by  $I$  and are passed on to the decoder for error correction. The LDPC decoder consists of a number of variable nodes ( $v$ ) and check nodes ( $c$ ). The operation of the min-sum algorithm can be summarised as follows [12]:

#### A. Variable Node Operation

A variable node performs the operation given in equation (1) and passes the outputs to check nodes.

$$L_{cv} = \sum_{m \in M(v) \setminus c} R_{mv} + I_v \quad (1)$$

where,  $I_v$  is the input to variable node  $v$ , also known as Log Likelihood ratio (LLR),  $L_{cv}$  is the output of variable node  $v$  going to check node  $c$ ,  $M(v) \setminus c$  denotes the set of check nodes connected to variable node  $v$  excluding the check node  $c$ ,  $R_{mv}$  is the output of check nodes going to variable node  $v$ .

#### B. Check Node Operation

A check node receives messages from variable nodes and performs the operation given by equation (2):

$$R_{cv} = \prod_{n \in N(c) \setminus v} \text{sign}(L_{cn}) \times \min_{n \in N(c) \setminus v} |L_{cn}| \quad (2)$$

where,  $R_{cv}$  is the output of check node  $c$  going to variable node  $v$ .

#### C. Parity Check

Every check node also checks whether the parity condition is satisfied by looking at the sign of the messages coming from the variable nodes. Until all the parity checks from all the check nodes are satisfied the messages are sent back to variable nodes and the variable nodes do the operation specified in part (A), otherwise the decoder stops the process.

Min-sum decoding algorithm uses soft decision. However, hard decision is taken on the new LLR ( $I_v$ ). If the new LLR is negative then the output bit would be a 1 otherwise a 0. Interested readers can find the details of the sum-product and min-sum decoder algorithms in [16].

#### IV. REPRESENTATIVE DECODER DESIGNS

LDPC codes can be represented by an  $M \times N$  sparse matrix, usually called  $H$  matrix. The  $H$  matrix contains mostly zeros and a small number of 1s [9]. It can also be represented by a graph called bipartite or tanner graph. Tanner graphs contain variable and check nodes. The decoder prototype designed in this research is based on the matrix shown in Fig. 2. It is a very small matrix compared to the real matrices. This  $10 \times 5$  matrix can be transformed into a tanner graph having 10 variable nodes and 5 check nodes as is shown in Fig. 3.

$$\begin{bmatrix} 1 & 1 & 1 & 1 & 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 0 & 1 & 0 & 0 & 1 & 1 & 1 \\ 1 & 1 & 0 & 0 & 1 & 0 & 1 & 0 & 1 & 1 \end{bmatrix}$$

Fig. 2. A  $10 \times 5$  sparse matrix.

The signals go from the variable nodes to the check nodes and from the check nodes back to variable nodes. Typically different sets of wires are used for the signals going from variable nodes to check nodes and vice versa. The process is iterative and goes until all the parity checks are satisfied. The messages in our prototype designs are 4-bit long.

Fig. 3. Tanner graph.

##### A. Design 1

The approach taken in the first decoder design was to use a combination of embedded Matlab blocks and Simulink library blocks. No handwritten VHDL blocks were used. A generic Simulink model was first developed for each of a variable node and a check node.

Variable node design in Simulink: The variable node, shown in Fig. 4, has been designed in Simulink using the basic *add* and *subtract* blocks from Simulink library. The

control block controls the operation of the variable node. This block has been coded in Matlab and incorporated in the Simulink model of the variable node as an embedded Matlab block. The variable node has four inputs, the first three come from various check nodes and the fourth one is the raw LLR, which is an external input supplied by the host communication system. It performs the operation given in equation (1) and passes the outputs to the check nodes to which it is connected. VHDL code can be generated automatically from this Simulink model, which can then be synthesized for a target FPGA.

Check node design in Simulink: The check node has been designed in the same way as the variable node. The Simulink model of the check node is shown in Fig. 5. It uses some of the blocks from Simulink library (absolute and bitwise XOR) and others are the embedded Matlab blocks. The check node finds the minimum of all the inputs and performs the parity checks. It contains a control block, which controls its operation.

10x5 LDPC decoder: An LDPC decoder with 10 variable and 5 check nodes has been designed using instances of the variable and check node components described above. The various nodes are interconnected in a way that corresponds to the tanner graph of Fig. 3.

##### B. Design 2

Design 2 uses a combination of embedded Matlab blocks, Simulink library blocks and VHDL/Link for ModelSim blocks. 'Link for ModelSim' is a utility that enables modules coded in VHDL to be embedded in Simulink models. Design 2 is different from the first design in that it uses serial communication of messages between variable and check nodes. This is achieved using SIPO (serial-in-parallel-out) and PISO (parallel-in-serial-out) registers at each input and output port in all the nodes. This greatly simplifies the interconnections by reducing the number of wires four times at the cost of some extra registers. The variable and check node components are same and are connected in the same way as in Design 1. The PISO and SIPO components are coded in VHDL and are used in the Simulink model with the help of the 'Link for ModelSim' utility (to link the VHDL blocks with ModelSim for simulation and code generation purposes). The way PISO and SIPO are used in a variable node is shown in Fig. 6. Check nodes have been modified in exactly the same manner. The inputs and outputs of all the variable and check nodes are now 1-bit long. The effects of using a VHDL block in a Simulink design are discussed in the next section. The HDL coder does not generate the VHDL code of the Link for ModelSim blocks. The VHDL code for these blocks needs to be added before synthesizing the code.

## V. RESULTS AND ANALYSIS

### A. Convergence

The convergence characteristics of the LDPC decoders presented in this paper have been tested using VHDL testbench and compared with that of a Matlab code for a functionally equivalent decoder. For this purpose the VHDL code automatically generated from the Simulink models were used. Fig. 7 shows the spread of the number of iterations for Design 2 by using plots of (mean number of iterations + standard deviation) and (mean number of iterations • standard deviation) versus SNR. It is clear that convergence is achieved in 6 iterations. This is consistent

with the convergence result of a functionally equivalent decoder shown in Fig. 8, designed using Matlab code.

Fig. 7. Spread of the number of iterations for Design 2 obtained from VHDL testbench.

Fig. 8. Spread of the number of iterations for a functionally equivalent Matlab code.

### B. Synthesis

Synthesis results for the high-level designs are given below and are compared with their 'VHDL only' counterparts. The results were obtained using Altera's Quartus II software with Cyclone II EP2C70F672C6 as the target device. Table 1 compares the resources used by Design 1 and its speed with a similar decoder designed using VHDL. Our design uses 2.1% of the FPGA's logical elements, only 120 registers and has a maximum frequency of 42.96MHz. Clearly this Simulink design uses much less resources and is faster than the VHDL design. Similar observations are made from Table 2, which compares our Design 2 with the VHDL only design. Design 2 uses 3.5% of the logic elements, which is slightly higher than the amount used by the VHDL design (2.8%). However, our Design 2 uses nearly half the number of registers used by the VHDL design and still achieves nearly the same maximum frequency ( $F_{max}$ ). Furthermore, our high level designs require much less effort and time as opposed to writing everything in VHDL.

TABLE I  
DESIGN 1 COMPARED WITH VHDL COUNTERPART

|                         | Design 1    | VHDL only   |
|-------------------------|-------------|-------------|
| Logical elements        | 1432 (2.1%) | 1492 (2.2%) |
| Combinational functions | 1432 (2.1%) | 1492 (2.2%) |
| Total registers         | 120 (0.2%)  | 686 (1%)    |
| Maximum frequency       | 42.96MHz    | 37.3 MHz    |

TABLE II  
DESIGN 2 COMPARED WITH VHDL COUNTERPART

|                         | Design 2    | VHDL only   |
|-------------------------|-------------|-------------|
| Logical elements        | 2416(3.5%)  | 1916 (2.8%) |
| Combinational functions | 2416 (3.5%) | 1916 (2.8%) |
| Total registers         | 480 (0.7%)  | 881 (1.3%)  |
| Maximum frequency       | 67.20MHz    | 67.72MHz    |

### C. Behavioural Simulation

Fig. 9 shows the functional simulation result for Design 2. A set of raw LLRs (6, 6, 2, 4, 7, 4, -2, 6, 4, 7) are applied to the variable nodes. The signals *end\_o\_vn* & *end\_o\_cn* are the control signals. The parity becomes 1 in the third iteration when all the parity checks are satisfied and the decoder stops the iterations. The corrected LLRs output by the variable nodes are 7, 7, 7, 7, 7, 7, -8, 4, 5, 7.

Fig. 9. Simulation results of Decoder Design 2.

### D. Analysis of the High Level Design Methods

The high-level design methodologies presented in this paper reduces design complexity, design effort and time. For example, to design the variable and check nodes of Figures 1 and 2 completely in VHDL a designer has to write behaviours of quite a few modules in VHDL and manually do the port mapping for the top level design. As the design gets larger and larger it becomes very difficult to code everything in VHDL. It not only takes huge effort and time, managing complex designs and reusing the designs are often quite difficult. A great deal of expertise and experience in VHDL is also required. For a large LDPC decoder with hundreds of nodes, the interconnections among the variable and check nodes could easily become a designer's nightmare if the entire design has to be coded in VHDL. An alternative, intuitive and highly productive design method has been a long standing desire of the engineers engaged in LDPC designs.

The high level methodology we have presented in this paper offers a very attractive alternative. The designs can be done intuitively in Simulink using predefined Simulink library blocks and blocks made from high-level Matlab code. The design complexity, effort and time are reduced drastically because the need for manually writing complex VHDL code is almost eliminated. Design reuse requires much less effort because changes are made either at block level in Simulink or in high-level Matlab code. In addition Matlab is a software programming language used much more widely than hardware description languages like VHDL and Verilog. Therefore designers without specific skills in hardware languages are able to design complex digital systems without much problem. Even software engineers and algorithm developers are able to quickly implement and test their high level designs due to the automatic conversion of Simulink models to HDL. This will surely offer great flexibility and efficiency in the design and reuse of complex LPDC decoders. There are some other benefits of the high level design methodology:

- Different parts of the model can be enveloped using the 'create subsystem' property of Simulink. It reduces the design complexity for large designs.
- User created Simulink library blocks provide great flexibility because the revisions made to the user defined library seamlessly propagate through the entire model.

The design methodology we have presented however requires the use of some emerging design tools and library functions, such as Simulink hardware library and embedded Matlab blocks, Link for ModelSim and HDL Coder tools. Because these are very recent developments the library of Simulink blocks supporting various functions a designer needs to implement a design is very limited at the present time. Similarly the capability of HDL Coder is limited to conversion of a few commonly used Simulink blocks and a few embedded Matlab blocks. Some of the specific limitations are discussed below.

### E. Current Limitations

Some common blocks in the Simulink library are not currently supported by the HDL Coder for automatic generation of VHDL code, e.g. flip-flops. Although we could build the PISO and SIPO registers easily in Simulink using the flip flops from its library the registers were not converted to VHDL by the HDL Coder. A careful selection of supported Matlab functions and Simulink library blocks may help addressing this type of problems, but not necessarily always. Some other limitations we experienced are listed below:

- Multiple instances of some modules (components) are used in the LDPC decoder, and in fact in most modular designs utilising a hierarchical design methodology. For example, in our LDPC decoder multiple instances of the check and variable nodes, and PISO and SIPO registers

are used. The HDL Coder dumps the full behaviour of each component as many times as it is instantiated in the design. This produces redundant instances of component behaviour in the generated VHDL code. It is necessary for the designer to edit the auto-generated code.

- There are some functions which are supported by the HDL Coder, but it produces the output in a particular data type. For example, the sign function of Matlab gives output only in 8-bit integer (int8) format. It is not possible to change these default data types in the current version. The only option is to manually edit the auto-generated HDL code.
- Link for ModelSim: This utility enables blocks designed in VHDL to be included in Simulink models. However the ports of the blocks that use Link for ModelSim get interchanged while simulating in Simulink. HDL code cannot be generated for the Simulink model in this situation. The code can be generated only after correcting the design. This makes the design process difficult and time consuming. The other drawback of blocks utilising Link for ModelSim is that these blocks may make changes in the auto-generated code. In case of the LDPC decoder these blocks changed the signals of type signed to unsigned. Once again this requires manually editing the auto-generated VHDL code.

## VI. CONCLUSION

In this paper a new high-level intuitive design methodology based on Simulink for modelling and synthesis of complex LDPC decoders has been presented. It utilises the higher level of abstraction offered by the Simulink modelling environment. The complete modelling, simulation and synthesis process utilises a combination of emerging design tools and associated library functions. These include the Simulink HDL Coder and 'Link for ModelSim' tools, and embedded Matlab and Simulink hardware library blocks. Two versions of 10x5 LDPC decoders have been designed, simulated and successfully synthesised to an Altera FPGA device. The high level design methodology offer great advantages in terms of design complexity, effort and time compared to a HDL-only design method. Designs completed using the new methodology used less FPGA resources and achieved better or similar performance level (Fmax) to those of HDL-only designs. We therefore envisage that with further enrichment of the Simulink Library blocks, and enhancements of HDL Coder and Link for ModelSim tools, design methodologies similar to the one presented in this paper will replace tedious HDL-based design approach. This will pave the way for cost effective design and reuse of a new generation of complex high performance LDC decoders.

## ACKNOWLEDGEMENT

The authors wish to acknowledge Mr Pham Minh Duc and Prof Bill Cowley of UniSA for model optimization and for the very useful suggestions/feedback respectively.

**Abstract** — Shape Memory Alloy (SMA) composites offer a great potential as actuators because of its excellent power to weight ratio, smooth motion and silent actuation. However, SMA actuated robotic manipulator systems have severe hysteresis, system nonlinearities, model and parametric uncertainties those are often responsible for position inaccuracy in a regulation or tracking system. A simple and upstanding control algorithm for tracking control of a SMA actuated robotic manipulator system is presented in this paper. The controller is developed based on the combination of a variable structure control approach and a heuristic based intelligent control approach like fuzzy logic control (FLC), so that the resulting control algorithms have a superior performance both in stabilization and tracking the desired trajectories. A desktop prototype of the robotic manipulator system is recalled from our previous work [1]. A nonlinear form of proportional – integral – derivative (PID) controller is also employed to the system for comparison of performance. Several experiments have been performed in tracking both stationary and periodically varied input signals. Experimental results from real time control verify the effective and robust performance of the controller.

**Index Terms** — Fuzzy Logic, Manipulator, Position control, SMA actuator, Sliding Mode control.

## I. INTRODUCTION

Shape memory alloy (SMA) is a smart alloy or memory metal that remembers its shape through shape memory effect. Below transformation temperature SMA has very low yield strength and can be deformed easily into any new shape, which it can retain. However, when it is heated above its transformation temperature it undergoes a solid state phase change which causes it to return to its original state. This unique property of SMA is a consequence of the reversible crystallographic phase transformation that occurs between the low temperature Martensite phase and the high temperature Austenite phase. These two phases have the same chemical composition but different crystallographic structures, and thus, different thermal, mechanical and electrical properties. Solid state phase transformation of SMA is accompanied by a large force against the applied stress and recovery of the inelastic strain. The combination of high stiffness, high strength and large recovery strain offers great potential for the use of SMA as actuators in a

variety of applications including robotic arms, space stations, automotive components, surgical devices and so on. Some typical examples can be found as mobile robot actuators [3], micro rotary actuator [5], linear smart actuator [6], and robot manipulator [4].

There is also an increasing demand of SMAs for developing small size and lightweight devices that will be able to produce large forces, large displacements, high speeds, and will be highly energy efficient. In addition, it is easy to drive a SMA actuator simply by passing an electric current through it, which then heats up SMA with resistive electrical (Joule) heating, and thus, SMA offers smooth motion, clean and silent actuation. But, the inherent nonlinear phenomenon associated with SMA is hysteresis [2], which often responsible for controlling the position and motion precisely.

However, tracking control of SMA actuators is essential in many applications such as robotic applications [7], [14] and vibration control [8], but due to the above reasons it is still a challenging task for the researchers. This paper thus motivated to find simple upstanding control algorithm on motion and position control of SMA actuators. Several control methods of SMA actuators have been investigated; these can be categorized as linear control [9], nonlinear control [7], intelligent control [10], [2] and variable structure control [11]. Among these variable structure control approaches have shown to be most effective with the control problems of SMA systems. This paper presents a two steps control algorithm, the first step of the control algorithm (FLC) ensures robustness against high frequency un-modeled dynamics and simultaneously the second step, Sliding Mode Control (SMC) ensures robustness against parametric uncertainty [12]. It is therefore possible to realize smooth and robust control avoiding the system's complexity in real time controls. The fuzzy algorithm is defined for two significant reasons, first, for reducing (eliminating) undesirable chattering of control signal by adjusting boundary layer thickness and second, for making the system modeling very simple. Because FLC works on a linguistic control approach that makes it insensitive to the unmodeled parameters and parameter uncertainties. Finally a nonlinear PID controller is applied to investigate the effectiveness and performance of the controller.

## II. SMA ROBOTIC MANIPULATOR

SMAAs can be conventionally fabricated into different desired shapes with different chemical compositions. SMA wire made of nickel and titanium (also called Nitinol or NiTi) is the most commonly used form of actuator because of its ease of use and convenient electrical activation. As illustrated with schematic diagram in Fig. 1, a SMA wire actuator is used to power the joint of a robot manipulator.

There are two ways of providing the bias force and therefore two types of SMA actuators. The first one, called bias type (or one-way actuator), is composed of a SMA element and a bias spring, and another, called differential type (or two-way actuator), and is composed of two SMA elements. In one-way actuators, the resulting torque is the difference between the bias torque and SMA wire torque. Considering the hardware limitations, in our design the manipulator is actuated by a bias type SMA wire actuator without bias spring, where the bias force (torque) is provided by the weight of the moving arm and payload. A photograph of the experimental setup is given in Fig. 2.

Fig. 1 Experimental setup of SMA manipulator.

TABLE I

LIST OF HARDWARE USED IN THE EXPERIMENTAL SETUP

| Name            | Model        | Manufacturer          |
|-----------------|--------------|-----------------------|
| SMA             | DM01         | MIGA mortor           |
| Rotary encoder  | S30-4-1024ZO | Metronix              |
| D/A board       | PCI 1711S    | Advantech             |
| Wiring Terminal | PCLD-8710    | Advantech             |
| A/D board       | PCI QUAD04   | Computing Measurement |
| Cooling fan     | SP1202512H   | INNOVATIVE            |

The SMA wire is heated with resistive electrical (Joule) heating by applying controlled input voltage, beyond the activation temperature it contracts due to the phase transformation from Martensite to Austenite. Upon cooling the wire's temperature falls and reverse phase transformation (from Austenite to Martensite) occurs, thus SMA wire is elongated under the action of bias force. The manipulator system is actuated using a DM01 Linear Shape Memory Alloy Actuator, such that the moving arm can rotate from  $0^\circ$  to  $150^\circ$ , and a rotary encoder is used to measure the joint angle of the moving arm. Note that, the

controller high and low voltages provided by power supply are  $V_h = 6$  V and  $V_l = 0$  V. A list of hardware used in the experimental setup is given in Table I.

## III. SMA CONTROL SYSTEMS

Shape memory alloy (SMA) miniature actuators have received significant attention in recent years because of their high power to mass ratio, silence and frictionless actuation, and simplicity of their mechanisms. Despite these special features, SMAAs have not been fully exploited by the researchers, particularly in devices employing feedback control systems. These devices are inherently nonlinear, characterized by a hysteresis loop and saturation. Although numerous analytical and phenomenological models have been developed for SMAAs over the last few decades, it is difficult to choose proper models for different applications. Furthermore a given model may contain many unknown parameters, discouraging from further attempts to design a model-based control system [4].

Fig. 2. Photograph of the experimental setup.

In this paper a novel two steps control system is presented for controlling of SMA actuated robotic manipulator. A nonlinear robust sliding mode controller is used to calculate the adjustable input voltage to the SMA and an intelligent fuzzy logic controller is used to estimate the boundary layer thickness for the control input based on position error. Finally a nonlinear PID control is applied to investigate the performance.

### A. Sliding Mode Control

Sliding mode control (SMC), a particular kind of variable structure control, is a robust nonlinear control algorithm in which an  $n$ th order nonlinear and uncertain system is transformed to a 1<sup>st</sup> order system. Considering the  $n$ th order SISO dynamic system,

$$\dot{x}^{(n)} = f(x) + b(x)u \quad (1)$$

Where scalar  $x$  is the output of interest, scalar  $u$  is control input and  $x$  is the state vector.  $f(x)$  and  $b(x)$  are the

unknown nonlinear dynamic function and control gain respectively. The control objective is to follow a desired state vector  $x_d$ , such that  $x_d(0) = x(0)$ . A time-varying surface  $s(t)$  in state space  $R^n$  can be defined as,

$$s(x; t) = \left( \frac{d}{dt} + \lambda \right)^{n-1} \tilde{x} \quad (2)$$

where  $\tilde{x} = x - x_d$  is the tracking error and  $\lambda$  is a positive constant. It can be shown that, tracking the desired state vector is equivalent to that of remaining on the surface  $s(t)$  [12]. The sliding condition to track specific time-varying desired state is,

$$\frac{1}{2} \frac{d}{dt} s^2 \leq -\eta |s|; \quad \eta \geq 0 \quad (3)$$

Further detail on sliding mode control can be found in [12].

### B. Fuzzy Logic Control

Sliding mode controller inherited chattering in applications. The use of boundary thickness in sliding mode control has been a common technique to reduce chattering of the control input. However, the constant width boundary layer design can reduce chattering of the control signals, but it decreases the control accuracy [13]. The compromise between smoothness of control signals and accuracy of control results is dictated by the proper adjustment of the boundary layer thickness. We thus choose a method of using fuzzy logic to control the width of boundary layer. Using error and rate of error as the control input, and the boundary layer thickness ( ) as the control output, the fuzzy control rules are set such that the system can get highest available input (voltage) initially to achieve the fastest possible response. The rule matrix of FLC is shown in Table II. The rules of the FLC relate position error and rate of error with boundary layer thickness so that the method can effectively eliminate chattering and ensure almost perfect control accuracy simultaneously.

TABLE II

FUZZY RULE MATRIX FOR 5 MEMBERSHIP FUNCTIONS

|           |      | $e$ |    |      |    |    |
|-----------|------|-----|----|------|----|----|
| $\dot{e}$ |      | NB  | NM | ZERO | PM | PB |
|           | NB   | VL  | L  | M    | S  | VS |
|           | NM   | L   | M  | L    | M  | S  |
|           | ZERO | M   | L  | M    | S  | M  |
|           | PM   | L   | M  | L    | M  | S  |
|           | PB   | VL  | L  | M    | S  | VS |

Where NB - negative big, NM - negative medium, PM - positive medium, PB - positive big, VL - very large, L - large, M - medium, S - small, VS - very small. We used five trapezoidal membership functions for each of control input and five Gaussian membership functions for control output with 'max-min' reasoning method, and center-of-gravity defuzzification method.

### C. Controller Design

The nonlinear behavior of SMA and its one-way actuation nature complicated the control problem since errors should be eliminated and full state feedback was not available. However, since the controller is model independent, we need to define proper sliding surface as well as the control law. Since only joint angle is measured using a rotary encoder, we can define a proper sliding surface as a function of position error and velocity error as,

$$s = \lambda_p \tilde{\theta} + \lambda_v \dot{\tilde{\theta}} + \lambda_i \int_0^t \tilde{\theta} dt \quad (4)$$

where,  $\tilde{\theta} = \theta_d - \theta$  and  $\dot{\tilde{\theta}} = \dot{\theta}_d - \dot{\theta}$ , subscript d stands for desired values, and an integral term in the sliding surface is added to minimize the steady-state errors. Adjusting the boundary layer thickness properly using FLC, the decision rule or control law for the sliding mode controller can be defined as,

$$u = \begin{cases} V_h & \text{if } \frac{s}{\phi} > 1 \\ s & \text{if } \left| \frac{s}{\phi} \right| \leq 1 \\ V_l & \text{if } \frac{s}{\phi} < -1 \end{cases} \quad (5)$$

where,  $u$  is the controlled input,  $V_h$  highest available voltage and  $V_l$  is the lowest voltage.

As we are using a bias type (one-way) actuator, the application of possible high voltage,  $V_h$  to the SMA actuator will force the trajectory to reach sliding surface expressed in equation (4). Once the sliding surface is reached, sliding mode controller keeps the states on the close neighborhood of the sliding surface (zero tracking error). This surface is asymptotically stable and the stability of the control system can be verified through sliding mode control theory [12]. The block diagram of the controller is shown in Fig. 3.

Fig. 3. Block diagram of the controller.

The surface defined in (4) incorporates position, velocity and integral tracking errors. Only position feedback results in a significant steady state error and slow response due to overshoot. The addition of velocity tracking errors to the surface eliminates overshoot and thus obtains fast response in the experiments. It also reduces the steady state errors. Finally integral tracking errors were added to further reduce

the steady state errors. So the controller is now able to follow the trajectories effectively [4].

#### D. Nonlinear PID Controller

Modifying the structure of a linear PID controller shown in equation (6) a novel nonlinear PID (NPID) controller is applied to the system. This controller comprises the sum of nonlinear terms of position error with a gain  $K_T$  that have significant effects in reducing settling time and overshoot of the system. The distinguished feature of this controller is that, for a relatively small amount of error, the cubic term tends to vanish but the quadratic term still produces a nonlinear control effort to minimize the errors. The control law of NPID controller in time domain is expressed in equation (7).

Fig. 4. Effects of control gain  $K_T$  on the NPID controller.

$$u(t) = K_P.e(t) + K_I.\int_0^t e(\tau)d\tau + K_D.\dot{e}(t) \quad (6)$$

$$u(t) = K_P e(t) + K_I \int_0^t e(\tau) d\tau + K_D \dot{e}(t) + K_T \left[ \text{sgn}(e).e^2(t) + e^3(t) \right] \quad (7)$$

The effects of gain  $K_T$  on the performance of NPID controller (7) are shown in Fig. 4. It is clear from Fig. 4 that, with proper tuning of the gain  $K_T$ , the system can achieve better performance.

#### E. Controller Parameters

Experimentally, we have found a suitable range of boundary layer thickness ( $\phi$ ) for the sake of avoiding chattering and overshoot from which the FLC assigned a value to  $\phi$ . The range selection of  $\phi$  is made through numerous iterative studies and some selected results are shown in Fig. 5. This Fig. shows that to avoid overshoot and chattering, the appropriate range of boundary layer thickness should be  $2^\circ$  to  $5^\circ$ .

Fig. 5. Effect of boundary layer thickness ( $\phi$ ) on the controller performance.

Numerous iterative studies also made to establish the sliding surface experimentally. However, we only present the final results of our trials. The effects of position, velocity and integral gain on the controller performance obtained experimentally are presented in Fig. 6, 7, 8 respectively. These results suggest that the optimal values of different gains of the surface would be  $\lambda_p \approx 5$ ;  $\lambda_v \approx 0.1$  and  $\lambda_i \approx 0.05$  for desired performance.

Fig. 6. Effect of position gain ( $\lambda_p$ ) on the controller performance.

Fig. 7 Effect of velocity gain ( $\lambda_v$ ) on the controller performance.

Fig. 8 Effect of integral gain ( $\lambda_i$ ) on the controller performance.

#### IV. RESULTS

A series of experiments have been carried out using both stationary and periodically varied reference trajectories and all experiments have been done through real time control in MATLAB/Simulink environment. Both stationary and periodic variable references are used in experiments. Fig. 9 shows the fuzzy-sliding mode controller can accurately follow the desired step, whereas, the nonlinear PID controller follows the trajectory with small steady state error. Fig. 10-11 verify the effective and superior performance of the both controller in tracking periodically varied reference signals of different frequencies and amplitudes.

Experimental results also confirm the selection process of controller gains as well as estimation of the range of boundary layer thickness. The contribution of FLC toward improved performance of the controller is also justified.

Fig. 11. Controller performance in tracking a sinusoidal trajectory (freq. 1/30 Hz, amp. 30 deg).

#### V. CONCLUSIONS

A model-independent position control algorithm is presented for a SMA actuated robot manipulator in which a heuristic based FLC works in conjunction with a robust SMC. It is thus possible to overcome the complexity in the course of modeling the SMA systems. The two parts of the controller have distinct task: a FLC provides the boundary layer thickness within the selected range and a SMC then calculates the desired input voltage to the SMA. The angular position of the manipulator is measured by a rotary encoder that is given as feedback to the controller. A sliding surface is designed based on the tracking errors, and the effects of different gains of the surface as well as the boundary layer thickness are investigated experimentally. In real time control, step and sinusoidal references are used in experiments, and the results show the effectuality of the controller. The first step of the control algorithm (FLC) ensures robustness against high frequency un-modeled dynamics simultaneously the second step (SMC) ensures robustness against parametric uncertainty. It is therefore possible to realize smooth and robust control avoiding the system's complexity in real time controls. Experimental results also verify the effective performance of nonlinear PID controller.

**Abstract**—In the integrated next-generation wireless systems (NGWS), users are always connected to the best available networks and used to switch between different networks based on their service needs. It is an important and challenging issue to support seamless handoff management in NGWS. The objective of this paper is to develop a seamless handoff management protocol for NGWS. In this paper, a fuzzy logic-based adaptive handoff (FLAH) management protocol is developed which is then integrated with an existing cross layer handoff protocol. Afterward, the handoff performance comparison of the existing protocol and our proposed protocol is carried out. The simulation results exhibit that, proposed fuzzy logic-based handoff management protocol has much better performance than conventional protocols for both intra and intersystem handoffs.

**Index Terms**— Call Admission Control, Fuzzy Logic, Hand-off Management, Intelligent Systems, Mobility Management, Wireless Networks.

## I. INTRODUCTION

In the integrated NGWS, users are always connected to the best available networks and switch between different networks based on their service needs, each of which is optimized for some specific services and coverage area to provide ubiquitous communications to the mobile users. In NGWS, mobile user can roam between a diverse set of wireless architectures like wireless local area network (WLAN), cellular, and satellite network [1]. Call admission control or handoff management of a mobile user while roaming through different wireless network architectures of NGWS is one of the important issues that needed to be solved. Mobility management contains two components: location management and handoff management [2]. Location management enables the system to track the locations of mobile users between consecutive communications. On the other hand, handoff management is the process by which users keep their connections active when they move from one Base Station (BS) to another. In NGWS, two types of handoff scenarios may arise:

- Horizontal Handoff: Handoff between two BSs of the same system. Horizontal handoff can be further classified into
  - Link-Layer Handoff: Horizontal handoff between two BSs that are under the same

Foreign Agent (FA).

- Intrasystem Handoff: Horizontal handoff between two BSs that belong to two different FAs and both the FAs belong to the same system and hence, to same Gateway Foreign Agent (GFA).
- Vertical Handoff (Intersystem Handoff): Handoff between two BSs that belong to two different systems and, hence, to two different GFAs.

However, seamless support of handoff management in NGWS is still an open research issue. The existing handoff management protocols are not sufficient to guarantee handoff support that is transparent to the applications in NGWS. Mobility management protocols operating from different layers of the network protocol stack (e.g., application layer [3], transport layer [4], network layer and link layer [5]) are proposed to provide seamless services. However, none of them alone are capable of supporting seamless mobility in NGWS. Therefore, recently the design of cross-layer mobility management protocols has gained significant attention [2]. Recently, new handoff algorithm are emerging based on advanced techniques like pattern recognition [8], neural networks and fuzzy logic system (FLS) [9]. These complicated algorithms are necessitated by the complexity of the handoff problem and dynamic conditions of wireless networks. In this paper, a fuzzy logic based handoff management protocol is introduced which is integrated with an existing Cross-Layer Handoff Management Protocol (CHMP) [2]. The simulation results reveal that, fuzzy logic based handoff management protocol has much better performance than conventional algorithms as well as CHMP for both intra and intersystem handoffs.

The remainder of the paper is organized as follows: we discuss analysis of handoff process in terms of handoff signaling delay and handoff failure probability in Section II. In Section III, we introduce our proposed fuzzy logic-based adaptive handoff management protocol and carry out its performance evaluation in Section IV. Finally, we summarize performance of FLAH management protocol in Section V.

## II. AN OVERVIEW OF HANDOFF

When a Mobile Terminal (MT) is moving from its serving Old Base Station (OBS) to New Base Station (NBS) with a speed  $v$ , the MT may learn about the possibility of moving into another cell when the Received Signal Strength (RSS) of OBS decreases continuously. When the MT discovers that it may enter into the coverage area of the NBS, the next challenge is to decide the right time to initiate Hierarchical Mobile IP (HMIP) registration procedures with the New Foreign Agent (NFA). The existing link-layer-assisted HMIP protocols [6] propose to initiate the HMIP registration when the RSS from the serving BS, e.g., OBS in Fig.1, drops below a fixed threshold value  $S_{th}$ .

Fig. 1. Analysis of handoff process.

During the course of its movement, when the MT reaches the point  $P$  (the distance of  $P$  from the cell boundary is  $d$ ) as shown in Fig. 1, the RSS from the OBS drops below  $S_{th}$ . Therefore, when the MT reaches  $P$ , it initiates the HMIP registration with the NFA. At this point, the RSS received by the MT from NBS shown as NRSS in Fig. 1 may not be sufficient for the MT to send the HMIP registration messages to NFA through NBS. Hence, the MT may send the HMIP registration messages to NFA through OBS. This is called pre-registration. For a smooth and successful handoff from OBS to NBS, MT's HMIP registration with NFA and link and MAC layer associations with NBS must be completed before the RSS of OBS drops below  $S_{min}$ , i.e., before the MT moves beyond the coverage area of OBS [2].

The need for handoff to NBS arises only if MT's direction of motion from  $P$  is in the range  $[\theta \in (-\theta_1, \theta_1)]$ , where  $\theta_1 = \arctan(\frac{a}{2d})$ . Otherwise, the handoff initiation is a false one. Therefore, the probability of false handoff

initiation is

$$\begin{aligned} p_a &= 1 - \int_{-\theta_1}^{\theta_1} f_{\theta}(\theta) d\theta \\ &= 1 - \frac{2\theta_1}{2\pi} = 1 - \frac{1}{\pi} \tan^{-1}\left(\frac{a}{2d}\right) \end{aligned} \quad (1)$$

The probability of handoff failure [2] is given by

$$P_f = \begin{cases} 1, & \tau > \frac{\sqrt{\frac{a^2}{4} + d^2}}{v} \\ \frac{1}{\theta_1} \cos^{-1}\left(\frac{d}{v\tau}\right), & \frac{d}{v} < \tau < \frac{\sqrt{\frac{a^2}{4} + d^2}}{v} \\ 0, & \frac{d}{v} \geq \tau \end{cases} \quad (2)$$

## III. PROPOSED FUZZY LOGIC BASED ADAPTIVE HANDOFF ALGORITHM

The proposed fuzzy logic based system initiates handoff using fuzzy logic; it uses mobiles speed and distance as input and received signal strength as output. The proposed algorithm is adaptive to velocity interference and distances, resulting in fewer dropped calls, better communication quality, potentially lower MT transmit power requirements, gives good performance at different MT speeds, and decreases handoff failure probability.

Fig. 2. Proposed fuzzy logic based handoff architecture.

We design an architecture to initiate handoff procedure that is adaptive to the link layer (Layer 2) and network layer (Layer 3) parameters. Then, we develop a handoff management protocol based on the architecture. As the proposed handoff management protocol uses information derived from different layers of TCP/IP protocol stack (e.g., speed information from link layer and handoff signaling delay information from network layer), we call it cross-layer handoff management protocol. The architecture of our proposed FLAH is shown in Fig. 2. Some of these modules collect the link and network layer information useful for handoff management and other modules use this information to decide the appropriate time to initiate and execute the handoff procedures using fuzzy logic system. The functionalities of these units are as follows:

- **The neighbor discovery unit** assists the MT to learn about the neighboring BSs.
- **The handoff signaling delay estimation unit** estimates the delay associated with intra and intersystem handoffs.
- **The speed estimation unit** estimates mobile's speed using VEPSD [7].
- **Fuzzy logic system unit** uses speed and handoff signaling delay information to estimate adaptive RSS threshold ( $S_{ath}$ ) as discussed in Section IV.
- **Handoff trigger unit** collects information from *RSS* measurement unit and when the *RSS* of the serving BS drops below  $S_{ath}$ , the handoff trigger unit sends a trigger to the handoff execution unit to start the HMIP handoff procedures.

Fig. 3. Fuzzy logic system unit in details.

Finally, the handoff execution unit starts the HMIP registration process at the handoff initiation time calculated by the handoff trigger unit.

#### A. Proposed Fuzzy Logic System

A fuzzy logic rule base is created based on the known sensitivity of handoff algorithm parameters (e.g., RSS threshold, signal to interference, traffic, etc). Fig. 3 shows the fuzzy logic system in details. The task of the fuzzifier is to map crisp value of *distance* and *velocity* to the fuzzy variables. The input fuzzy variable *speed* is assigned to one of the five fuzzy sets, “Slowest”, “Slow”, “Medium”, “Fast” or “Fastest”. This research utilizes the Mamdani FLS. Figure 4 illustrates the membership functions of the input fuzzy variable *velocity* for microcellular system. We used triangular and trapezoidal membership functions and considered 50% overlap of assigned fuzzy sets. Table I shows the rules used in the FLS for microcellular system. Similarly, we defined such rules for macrocellular system. The nonsingleton fuzzifier and the center of area defuzzification method is used.

For example, when the value of *velocity* is “fastest” and the value of *distance* is “short”, this condition indicates that handoff should be encouraged immediately. Hence, output threshold *RSS* is “very high”.

Fig. 4. Membership function of fuzzy variable velocity (microcellular system).

## IV. SIMULATION

### A. Simulation Criteria

Fuzzy logic system determines the value of adaptive *RSS* threshold ( $S_{ath}$ ) to initiate the HMIP handoff procedures using speed and handoff signaling delay information. Then performance is evaluated as follows: first, value of  $d$  is calculated for a desired value of probability of handoff failure  $P_f$  using (2) where  $v$  is MT's speed,  $d$  is MT's distance from the boundary of the serving BS, and  $\tau$  is the handoff signaling delay [2]. Then an approximate value of  $d$  can be calculated using

$$p_f = \frac{\cos^{-1} \frac{d}{v\tau}}{\tan^{-1} \frac{a}{2d}} = \frac{\frac{\pi}{2} - \frac{d}{v\tau}}{\frac{\pi}{2} - \frac{2d}{\sqrt{4d^2 + a^2}}}. \quad (3)$$

And the value of false handoff initiation probability can be calculated using (1).

For CHMP, the value of  $S_{ath}$ , when the MT is at a  $d$  distance from the cell boundary is given by

$$S_{ath} = 10 \log_{10}[P_r(a - d)]. \quad (4)$$

where  $P_r(a - d)$  is the received power at a known distance ( $a - d$ ), given by

$$P_r(x) = P_r(d_0) \left( \frac{d_0}{x} \right)^\alpha + \epsilon. \quad (5)$$

The typical value of  $d_0$  is 1 km for macrocells and 100 m for microcells. The numerical value of  $P_r(d_0)$  depends on different factors, such as frequency, antenna heights, and antenna gains.  $\alpha$  is the path loss exponent and its typical value ranges from 3 to 4 and 2 to 8 for a typical macrocellular and microcellular environment, respectively.  $\epsilon$  is a zero-mean Gaussian random variable that represents the statistical variation in  $P_r(x)$  caused by shadowing. Typical standard deviation of  $\epsilon$  is 8 dB. We simulate and analyze the relationship among *RSS* threshold value, mobile's speed and handoff signaling delay. Then we make comparison between FLAH and CHMP with respect to these relationships.

### B. Simulation Model

For simulation the following scenarios and parameters are considered: a macro-cellular system with cell size,  $a$ , of 1 km, a micro-cellular system with cell size,  $a$ , of 30m, macro-cell reference distance,  $d_0$ , of 100m, micro-cell reference distance,  $d_0$ , of 1 m were chosen. We assume that the target handoff failure probability,  $P_f$ , is 0.02. We consider that the maximum values of users' speed in micro-cellular and macro-cellular system are 14 km/h and 140 km/h, respectively. Moreover, we assume that the value of  $S_{min}$  is  $-64$  dBm.

### C. Simulation Results

1) *Relationship between  $S_{ath}$  and Speed*: The relationship between  $S_{ath}$  and MT's speed ( $v$ ) for different values of handoff signaling delay ( $\tau$ ) is analyzed. Fig. 5 shows

the relationship between  $S_{ath}$  and  $v$  for different values of  $\tau$  when the serving BS (OBS) belongs to a micro-cellular system. For Macro-cellular system we got similar result.

- Fig. 5 shows that for particular value of  $\tau$ , the value of  $S_{ath}$  increases as MT's speed increases. This implies that for a MT with high speed, the handoff initiation should start earlier compared to a slow moving MT to guarantee the desired handoff failure probability to users independent of their speed.
- Fig. 5 also shows that  $S_{ath}$  increases as  $\tau$  increases. This is because when  $\tau$  is high the handoff must start earlier compared to when  $\tau$  is small. The lower and higher values of  $\tau$  correspond to intra and inter-system handoff, respectively. Therefore, FLS calculates  $S_{ath}$  that is adaptive to both  $v$  and  $\tau$ .

Fig. 5. RSS threshold ( $S_{ath}$ ) for different speed when the OBS belongs to microcellular system.

Fig. 6. Relationship between handoff failure probability and speed when OBS belongs to a microcellular intrasystem for fixed  $RSS$ .

2) *Relationship between the Handoff Failure Probability of FLS and Speed:* We calculate  $S_{ath}$  using speed and handoff signaling delay information. Then, we use  $S_{ath}$  to determine the handoff failure probability.

- Fig. 6 shows the handoff failure probability of FLS and CHMP, for different values of speed when the serving BS belongs to a micro-cellular system.
- It shows that reduction in  $P_f$  is achieved in FLS compared to CHMP.
- Fig. 7 shows the results when the serving BS belongs to a macro-cellular intersystem. Similarly we also investigated the results when the serving BS belongs to a macro-cellular intrasystem. Comparison of the

Fig. 7. Relationship between handoff failure probability (Fuzzy) and speed when the OBS belongs to a macrocellular intersystem for fixed  $RSS$ .

results show that when FLS is used and MT's speed is known  $P_f$  is almost constant as the calculated  $RSS$  is adaptive to velocity and distance. On the other hand, for a particular value of fixed  $RSS$  threshold the numerical value of  $P_f$  is different and depends on the numerical value of  $S_{th}$ . This shows that the handoff protocols need to be adaptive irrespective of the type of handoff.

- Fig. 7 also shows that when the speed of the MT is known, 70% to 80% reduction in handoff failure probability is achieved in FLS compared to fixed  $RSS$  based Handoff management system.

Fig. 8. Relationship between handoff failure probability (Fuzzy) and handoff signaling delay.

3) *Relationship between the Handoff Failure Probability and Handoff Signaling Delay:* Figure 8 shows the handoff failure probability of FLS for different values of handoff

Fig. 9. Relationship between false handoff initiation probability (Fuzzy and Fixed RSS) and speed when the OBS belongs to microcellular system.

signaling delay ( $\tau$ ). The results show that unlike the fixed  $RSS$  based handoff protocols;  $P_f$  remains independent of  $\tau$  in case of FLS. This is because FLS considers  $\tau$  for the tuning membership function of dynamic  $RSS$  threshold. Fig. 8 shows that 70% – 80% reduction in  $P_f$  is achieved in case of FLS compared to the fixed  $RSS$  based handoff protocols. The lower and higher values of  $\tau$  correspond to intra and inter-system handoffs, respectively. Therefore, by incorporating the estimated value of  $\tau$  into dynamic  $RSS$ , the  $P_f$  is limited to the desired value irrespective of users speed and variation of handoff signaling delay.

4) *Relationship between False Handoff Initiation Probability and Speed:* Fig. 9 shows the comparison of the false handoff initiation probability of FLS with the fixed  $RSS$  threshold based algorithms when the serving BS belong to a micro-cellular system. For macro-cellular system similar result is achieved.

- The figure shows that the false handoff initiation probability of FLS is 5 percent to 15 percent less compared to the fixed  $RSS$  threshold based algorithms.
- Thus, FLS achieves up to 15% reduction in the cost associated with false handoff initiation. The use of adaptive  $RSS$  threshold initiates the handoff procedures in such a way that just enough time is there for the successful execution of the handoff.

- Therefore, an adaptive value of  $RSS$  threshold ( $S_{ath}$ ) avoids too early or too late initiation of the handoff process. The former limits the value of handoff failure probability. The later ensures that handoff is carried out smoothly. Thus, FLS optimizes the false handoff initiation probability and handoff failure probability.

## V. CONCLUSION

In this paper, a new fuzzy logic based adaptive handoff management algorithm for next generation heterogeneous wireless system is introduced. It uses mobile's speed and handoff signaling delay information to enhance the performance of hierarchical mobile IP (HMIP) handoff significantly. Performance analysis and simulation results show that FLS significantly enhances the performance of both intra and inter-system handoffs. It can estimate the right time to initiate handoff more precisely. It also significantly reduces the cost associated with the false handoff initiation because it achieves lower false handoff initiation probability than existing handoff protocols.

**Abstract** — There are many studies that collect and store life log for personal memory. The paper explains how a system can create someone's life log in an inexpensive way to share daily life events with family or friends through social-network or messaging. In the modern world where people are usually busier than ever, family members are geographically distributed due to globalization of companies and humans are inundated with more information than they can process, ambient communications through mobile media or internet based communication can provide rich social connections to friends and family. People can stay connected to their loving ones ubiquitously that they care about by sharing awareness information in a passive way. For users who wish to have a persistent existence in a virtual world – to let their friends know about their current activity or to inform their caretakers – new technology is needed. Research that aims to bridge real life and the virtual worlds (e.g., Second Life, Face book etc.) to simulate virtual living or logging daily events, while challenging and promising, is currently rare. Only very recently the mapping of real-world activities to virtual worlds has been attempted by processing multiple sensors data along with inference logic for real-world activities. Detecting or inferring human activity using such simple sensor data is often inaccurate, insufficient and expensive. Hence, this paper proposes to infer human activity from environmental sound cues and common sense knowledge, which is an inexpensive alternative to other sensors (e.g., accelerometers) based approaches. Because of their ubiquity, we believe that mobile phones or hand-held devices (HHD) are ideal channels to achieve a seamless integration between the physical and virtual worlds. Therefore, the paper presents a prototype to log daily events by a mobile phone based application by inferring activities from environmental sound cues. To the best of our knowledge, this system pioneers the use of environmental sound based activity recognition in mobile computing to reflect one's real-world activity in virtual worlds.

**Index Terms** — Ambient Communication, Life Logging, Virtual World, Activity Recognition, Sound Cues, Auditory Scene Analysis.

## I. INTRODUCTION

Life logs include people's activities performed in specific locations collected from various sources. We envision that with the proliferation of computing power of hand held

devices (HHD), availability of the Internet connectivity and improvements in communication technologies ambient communication will find a universal place at our daily life and allow us to create a vivid and intelligent online social network. Let's consider the following scenario.

*Scenario 1:* Rahman family (Mr. and Mrs. Rahman) lives in Khulna, one of the metropolitan cities of Bangladesh. They have three sons living overseas, one in Texas, another in Ottawa and the youngest one in Bonn of Germany. The Rahman family is now at their age of over 50 and Mr. Rahman had a massive heart operation last year. Mrs. Rahman is also ailing from several sicknesses like diabetics, high blood pressure, etc. The three sons are always worried regarding the well beings of their parents and consequently they often talk to their parents over the phones to know their whereabouts. Though calling to Bangladesh from USA, Canada, and Germany is relatively cheaper now-a-days than before, but having a phone conversation with their parents is not always possible due to various reasons, for example, due to inconvenience in time differences (e.g., when it is 10 am in Khulna it is 11:00 pm in Texas, 12:00 am in Ottawa and 6:00 am in Bonn) that is, when the sons have convenient time to call, their parents are usually sleeping or resting and vice versa. But they are often worried to know at least how their parents are doing everyday. Therefore, let's imagine that Rahman family has internet connectivity at their house and installed an inexpensive system capable of doing the following that may provide mental peace to their sons by providing ambient communications through the internet. The system makes life logging of daily activities by detecting and recognizing sound cues from the surrounding environments and sends email message(s) to their sons reporting their daily life-sketch. In this case, an example email message containing life log for a particular day as following might be very relieving to the sons. "Your parents woke up at 7:30 am today and they had breakfast around 8:15 in the morning. They watched TV several times in the day. Went out of home for two times and walked in the roads and parks. They took lunch and dinner at around 2 PM and 8 PM. Your mother went to

*toilet for 5 times and father went to toilet 6 times in a day. They had communicated with each other or other people by talking. It seems they are doing fine."*

### A. Background

The idea of a "life-log" or a personal digital archive is a notion that can be traced back at least 60 years [1]. Since then a variety of modern projects have spawned such as the *Remembrance Agent*[2], the *Familiar*[3,4], *myLifeBits*[5], *Memories for Life*[6] and *What Was I Thinking* [7]. In [8] the authors evaluate the user's context in real time and then use variables like current location, activity, and social interaction to predict moments of interest. Audio and video recordings using a wearable device can then be triggered specifically at those times, resulting in more interest per recording. Some previous examples of this approach are the *Familiar* and *iSensed* systems [3,4,8] which structure multimedia on the fly; the *eyeBlog* system [9] which records video each time eye contact is established; and the *SenseCam*[10] which records images and sound whenever there's a significant change in the user's environment or the user's movement. Life log includes people's experiences which are collected from various sensors and stored in mass storage device. It is used to support user's memory and satisfy user's needs for personal information. If he wants to inform other people of his experience, he can easily share his experience with them by means of providing his life log.

To collect life log (e.g., GPS based location, SMS, call, charging, MP3, photos taken, images viewed, and weather information, etc) smart phones (e.g., iPhone 3G) are usually used. Smart phone is a mobile device that includes color LCD screen, mass storage, large memory, and communicative function by using Wi-Fi, Bluetooth, and infrared. It also has a variety of software such as scheduler, address book, media player, and e-book. Mika Raento developed a framework for collecting contexts from smart phone [11], which collects GSM Cell ID, Bluetooth, GPS data, phone data, SMS data, and media information that are transmitted to the server. The contexts could be provided for other contents as additional information. Panu collects log data from mobile devices, and extracts features by pre-processing the log data [12]. The mobile device uses GPS log, microphone, temperature, moisture, and light sensor. MyLifeBits Project is one of the implementations of personal record database system [5]. Personal information is collected by PC, SenseCam and so on, and stored in database server with relationships among personal information. However, user faces difficulties to explore and search contents because of large amount of personal data. KeyGraph-based mobile contents management system was suggested to manage user's information in mobile device, which extracted important information using KeyGraph algorithm and provided searching or exploring contents [13]. The problem of the system is using only log data. If

analysis and inference of the data was added to the system, it would give better performance.

### B. Our Approach

Our approach is far different from others in terms of logging daily events by detecting real world activities (e.g., laughing, talking, traveling, cooking, sleeping, etc.) and situational aspects of the person's (e.g., inside a train, at a park, at home, at school, etc.). We focus how to perform daily life logging and to provide a virtual representation of humans in terms of activity and their surrounding by inferring human-activity from environmental and object-interaction related sound cues as well as common sense knowledge. We have collected 114 types of acoustic sounds that are usually produced during object interaction (e.g., cooking pan jingling sound while cooking) or by the environment itself (e.g., bus/car passing sound while on a road) or by a deliberate action of a person (e.g., laughing, speaking). These sample sounds serve as the underlying clues to infer a person's activity and one's surroundings with the help of common sense knowledge (e.g., while the system identifies cooking pan's jingling and chopping board sound as consecutive cues and system's local time indicates evening then from common sense database the system infers this activity as 'cooking'). As an implementation platform we plan to use Second Life (SL) [14] to simulate living and log daily life activities. SL is one of the most popular Internet-based virtual worlds in terms of subscribers with over 500,000 active users. Virtual world simulators represent one of the upcoming successful niches for online services for entertainment, advertisement, business, but also health and elderly care. However, in the usual interaction model, there is still a gap (between the virtual world and the real one) for users who wish to have a persistent existence in a virtual world to let their friends know about their current activity or to inform their caretakers. Specifically speaking, a user cannot automatically mirror/reflect his current movements, activities or surrounding environment (e.g., park, shopping mall, etc.) in his real life to the virtual life of his avatar. Only very recently [15] the mapping of real-world activities to virtual worlds has been attempted by processing multiple sensors data along with inference logic for real-world activities. Detecting or inferring human activity using such simple sensor data is often inaccurate and insufficient. Moreover deploying a ubiquitous sensor network at outdoor environment is expensive and not feasible.

## II. SYSTEM ARCHITECTURE

Fig. 1. serves as the top-level pipelined architecture of the system. Because of their ubiquity we plan to use mobile phones (e.g., iPhone) to deploy this application that will

capture environmental sound at some intervals to be processed. According to Fig. 1., a mixed signal is passed through a robust signal processing and sound classes are detected by trained HMM classifiers. Based on the detected sounds and common sense knowledge regarding human activity, object interaction, ontology of human life (e.g., daily life of a student, or a salary man etc.) and

temporal information (e.g., morning, noon etc.) are applied to infer both the activity and the surrounding of the person. This information is sent to the client application of SL as a text message and this message is parsed by SL client to map the activity of the person after rendering an appropriate virtual world for that activity.

Fig. 1. System Architecture (in brief)

#### A. Development Challenges

In order to develop this system we have the following challenges and concerns:

##### *Environmental sound corpus and features*

For simplicity our collected sound corpus is limited to sound cues related to certain genres like, cooking, bathroom activity, human physiological action, outdoor, home, etc. Since the recognition rate is the only performance measure of such system, it is hard to judge how suitable the selected feature is. To solve this problem, it is essential to analyze the feature itself, and measure how good the feature itself is. It is concluded that MFCC may be the best transformation for non-speech environmental sound recognition. A similar opinion was also articulated in [16,17]. These finding provide the essential motivation for us to use MFCC in extracting features for bathroom sound classification.

##### *Accuracy of Acoustic Event Detection/Classification*

Microphones that capture sounds with sufficient fidelity for automated processing are also much cheaper in comparison with other sensors. Acoustics-based behavioral understanding systems work from a distance: they do not constrain subjects by requiring them to wear special devices; a prerequisite for individuals with dementia. Computational auditory scene analysis (CASA)[18], the understanding of events through processing environmental sounds and human vocalizations, has become an increasing important

research area. There are however many classifier approaches in the literature, e.g., those based on Hidden Markov Models (HMMs), Artificial Neural Networks (ANN), Dynamic Time Warping (DTW), Gaussian Mixture Models (GMM), etc. From these options, we have chosen an approach based on HMM as the model has a proven track record for many sound classification applications [19]. Another advantage is that it can be easily implemented using the HMM Tool Kit (HTK) [20].

##### *Computing power of iPhone or Hand Held Devices*

The computing potentials of HHDs are increasing in a rapid manner with respect to memory and incorporation of full-fledged operating system but they are still inferior to personal computer comparing to the speed of data processing. Running of the core signal processing task requires high-end computing and therefore the processing should be done by means of external devices connected to the HHDs through the Bluetooth radio. Therefore in this case a light process to capture environmental sounds after some intervals will be running on the HHDs to be transmitted for activity detection.

##### *Privacy and Social Issues*

To manage their exposure, users should be able to disconnect from the virtual worlds at any time or be able to interrupt the sound capturing of their activities. The actual representation of users in the virtual world may be disclosed according to pre-configured user policies or users list. Additional privacy issues are related to the collection of environmental data by means of people carrying devices to different places and data collected

about them. We consider important privacy and security challenges related to people-centric sensing.

#### *Common sense knowledge base*

What this system try to create is a sense of presence that allows users to “see and feel” a remote place. From the analysis of captured signals the system gets aware of the objects available within the vicinity of the person carry the HHD. This object level information is mapped with a common sense knowledge base to infer the activity. For example, if the system detects that the sound cues represent frying pan, sink water, and chop board from consecutive input samples the developed common sense knowledge can infer a cooking activity. Moreover to minimize error in inference we incorporate temporal and ontology of daily life of an individual (e.g., student, salary man, old people etc.). For example, if system detects sound cues that initially inferred that the person is in the road, but according to the temporal information if it is at night 2:00 am on Monday and from the daily life ontology of a salary man (i.e., the user is a salary man in real world) the time frame indicates “resting”, the system may either show proactive behavior or ignore the initial inference.

#### *Scalability of the solution*

Our default approach is to run activity recognition algorithms on the mobile device to decrease communication costs and also to reduce the computational burden on the server. However, we recognize that signal processing based classification algorithms may be too computationally intensive for handheld devices and propose to run the classifier on a back-end server in this case. This may be particularly appropriate during the training phase of a classification model.

#### *B. Data Collection and Annotation*

Our collected sound samples are used to infer the location and activity being performed at that location by a person. Table 1 explains the list of activities and related locations of our interest. The sound clips are collected and annotated obliging such area of interest. For example, sound clips like, “Shower water falling” is annotated as a toilet event related to “taking shower” activity.

TABLE I  
SAMPLE SOUND CUES COLLECTED ACCORDING TO THIS LIST OF ACTIVITIES AND LOCATIONS OF INTEREST

| Location                 |                                  |            |                       |                   |                              |                               |                         |
|--------------------------|----------------------------------|------------|-----------------------|-------------------|------------------------------|-------------------------------|-------------------------|

| Singing/ Music           |                                  |            |                       |                   |                              |                               | Hanging<br>around park  |
| Sleeping                 |                                  |            |                       |                   |                              |                               |                         |
| Drinking Tea/<br>Coffee  |                                  |            |                       |                   |                              |                               |                         |
| Vacuum Cleaning          |                                  |            |                       |                   |                              |                               |                         |
| Sitting Idle at<br>home  |                                  |            |                       |                   |                              |                               |                         |

### C. Ontology of Daily Life

In this initial prototyping three types of users are considered and based on empirical study the ontology of daily life (listed in Table 2) of each user type is considered along with common sense knowledge base to perform legitimate inference. For example, if the system

detects a sound cue related to eating activity during BN (before noon) time frame on a weekday and if the user is a service-holder, it doesn't log the event because the user is not happened to be present in a kitchen around that time. We also plan to provide the flexibility to personalize such ontology of daily life on the basis of each respective user.

TABLE II  
ONTOLOGY OF DAILY LIFE BASED ON THE PRESENCE AT PARTICULAR PLACES AT PARTICULAR TIME

| Role             | Weekday |                |                   |                |                   |                      |         | Weekend |            |                |                   |                      |                   |         |

### III. SCHEMATIC SOLUTION

The system continuously listens to the environment and captures sound regularly at 20 seconds of interval for 10 seconds of duration. Each captured sound-clip is sent to a computer wirelessly where the clip is processed. Thus for a two-minute interval the system gets four sound clips. These four sound clips are considered to infer an activity at that moment. Each sound clip is processed by a HMM

network that outputs a particular sound class. Each sound class actually represents some real-word objects out of which interaction the sound maybe produced. For example, Let's assume that the system receives the following four sound clips (as shown in Fig. 2.) to process and the HMM classifies the four clips into the following four sound classes: "Cutting something on a Chop Board", "Water Falling on Sink", "Collision of Cooking pan and Spoon", and "Racking of Plates".

Fig. 2. A Schematic solution to infer "cooking" activity from sound cues

These four classes of sounds are pre-mapped as following,

- “Cutting something on Chop Board” → {Knife, Chop board}
- “Collision of Cooking pan and Spoon” → {Cooking pan, spoon, stirrer}
- “Water Falling on Sink” → {water sink, basin, water}
- “Racking of Plates” → {cup-board, plate, dishwasher, rack}

According to Fig. 2., the list of interacting objects is dealt with common sense knowledge. The common sense knowledge is extracted from ConceptNet [21] and outputs a probabilistic value representing a relationship between an activity and object. In the above example the objects yield a maximum probability of having a relationship with “cooking” activity and the near candidates are “eating”, “drinking tea/coffee”. From the ontology of daily life the system finds that it is likely to have “cooking” activity at the concerned time (Table 2). Therefore, the activity inference engine considers this event as a legitimate event and logs it by either animating this event on a virtual world or generating a text message.

#### IV. CONCLUSION

Software like Google Earth and Microsoft Virtual Earth map the real world with great accuracy in terms of geographical locations and local features. We believe that the next step is to enable a user to represent real world activities in this kind of virtual world whereby personal avatars will be able to reflect what the real persons are doing in the real world. This type of application is a source of fun for young generation while it has lots of potential regarding virtual shopping mall in e-commerce context, easy monitoring or life logging for elderly people for the caregivers etc.

**Abstract** — Vehicular travel which demands on the concurrent operations and parallel activities is increasing throughout the world. In this paper to control urban traffic, we study the optimization of traffic light controller in a city and present a fuzzy algorithm based on cellular automata. In existent system factors like priority of streets of intersection and width/length of streets are assumed equal. However, in real situations parameters like time during the day, density of vehicles of street and number of shopping centers have determinant effects on amount of traffic of streets. To overcome such limitations we propose a three leveled fuzzy system. At first level priority of street is computed based on fuzzy rules. At second level real velocity of vehicles is calculated. We use CA for simulating vehicles' density transmission. At third level by regarding priority of street and amount of density, decision for changing status of traffic light is done.

**Index Terms** — Cellular Automata Model, Fuzzy Control, Traffic Control, Traffic Light Control, Unidirectional Selective Cellular Automata, Urban Traffic.

## I. INTRODUCTION

Transportation research has the goal to optimize transportation flow of people and goods. As the number of road users constantly increases, and resources provided by current infrastructures are limited, intelligent control of traffic will become a very important issue in the future [6]. Optimal control of traffic lights using sophisticated sensors and intelligent optimization algorithms might therefore be very beneficial. Optimization of traffic light switching increases road capacity and traffic flow, and can prevent traffic congestions. In the recent years there were strong attempts to develop a theoretical framework of traffic science among the physics community. Consequentially, a nearly completed description of highway traffic [7, 11], e.g., the "Three Phase Traffic" theory, was developed. This describes the different traffic states occurring on highways as well as the transitions among them. Also the concepts for modeling vehicular traffic are well developed. Most of the models introduced in the recent years are formulated using the language of cellular automata (CA) [3,4,12,14-17]. Unfortunately, no comparable framework for the description of traffic states in city networks is present. In contrast to the highway networks, where individual highway segments can be

treated separated, the structure elements of city networks exert an immense influence onto the traffic dynamics [7].

In existent urban traffic systems priority of intersection streets and also width and length of streets are assumed equal; so they have no role in making decision for changing the status of the traffic light. To overcome such limitations, we propose a novel fuzzy system that momentarily computes priority of the street based on fuzzy rules and regarding to environmental factors. Furthermore, in the proposed system length of streets are not considered the same. Subsequently a cellular automaton is employed for modeling both density transmission and type of movement of vehicles. In fact each street forms a lattice and each member of this structure is regarded as a separate cell in cellular automata space.

The paper is organized as follows: in section II cellular automata is described concisely and then unidirectional selective cellular automata is introduced for further simulations. In section III we briefly review some existing traffic light controller systems. Our proposed system and its technical details are described in section IV. Simulation results are represented in section V and finally we draw conclusions in section VI.

## II. CELLULAR AUTOMATA

Cellular automata (CA) are a class of discrete dynamical systems [13], consisting of an array of nodes (cells) of some dimension,  $n$ . Each cell can be in one of  $k$  different states at a given tick of the clock. At each discrete tick of the clock, each cell may change its state, in a way determined by the transition rules of the particular CA [1,5]. The transition rules describe precisely how a given cell should change states, depending on its current state and the states of its neighbors. Let  $n$  be the dimension of the lattice,  $k$  the number of states,  $T$  the transition rule function,  $C_t(i_1, \dots, i_n)$  the state of the cell at position  $(i_1, \dots, i_n)$  at time  $t$ ,  $N_t(i_1, \dots, i_n)$  the values (given in a specific order) of the neighboring cells to this location at time  $t$ . Then the dynamics of the CA is completely specified by the initial states of all the cells,  $C_0$ , along with the recursion rule (Equation 1).

$$C_{t+1}(i_1, \dots, i_n) = T(N_t(i_1, \dots, i_n)) \quad (1)$$

### A. Unidirectional Selective Cellular Automata

General structure of CA is as follows:

Definition 1: A cellular automata is a 4-tuple  $CA = (Q, d, V, a)$  where:

1.  $Q$  is the nonempty state set that a cell can assume.
2. The dimension  $d$  of the cellular space, building a bounded subspace on  $Z^d$  ( $Z$  denoting the integers). Note that, when  $d = 1$ ; corresponds to the case of a linear array.
3. The neighborhood array  $(V_0, V_1, \dots, V_k), V_j \in Z; V_j \in [0, k]$ . Being  $x \in Z^d$  an automata location,  $V(x) = \{x + V_0, x + V_1, \dots, x + V_k\}$  describes the finite list of  $k + 1$  neighbors directly associated to it. In the case of a linear array,  $x = i \in Z$ ; the neighborhood array  $\{0, -1, +1\}$  index the central, the left and the right cells.
4. The transition function (or relation) defines the dynamical local state transformations to be applied to the cells. In standard automata without memory register the deterministic transitions are of the form  $: Q^{k+1} \rightarrow Q$ .

Based on urban traffic application, in this paper we change the basic characteristics of CA to define a new kind of it. Let us clarify our proposed CA visually. Fig.1 shows a street and each segment is a cellular space.

Fig. 1. Current and Next State of a Sample Street

a) While in classical CA, next state of each cell is defined according to state of its both left and right neighbors; in the proposed CA we take into account just the neighbors that are located in one side. For example in classical CA, when the neighborhood radius is 1, next state of  $n$ th cell is defined regarding to state of  $n$ th,  $n-1$ th and  $n+1$ th cells. Due to the fact that transmission of density is always in one direction in the street (in Fig.1 from right to left), one can say, only the right neighbors of each cell are effective in defining next state of it. Because of this new feature, proposed CA is named “Unidirectional”.

b) In the definition of CA, the neighbors of each cell are directly associated to it. However, in the proposed CA, neighbors of cell are selected based on a density transmission function at each step. This function is described in more details in section IV. It means that neighbors of  $n$ th cell are not necessarily  $n-1$ th and  $n+1$ th cells, but also they are selected via a predefined function. Due to this fact, the proposed CA is called “Selective”.

Combination of a and b features results in a new kind of cellular automata so-called Unidirectional Selective Cellular Automata (USCA). We use USCA at the second level of the proposed system toward simulating vehicles' density transmission function.

### III. RELATED WORK

Traffic dynamics bear resemblance with, for example, the dynamics of fluids and those of sand in a pipe. There are two common approaches for modeling traffic [6]; macroscopic and microscopic models.

- **Macroscopic Traffic Models:** Macroscopic traffic models are based on gas-kinetic models and use equations relating traffic density to velocity. These equations can be extended with terms for build-up and relaxation of pressure to account for phenomena like stop-and-go traffic and spontaneous congestions.

- **Microscopic Traffic Models:** In contrast to macroscopic models, microscopic traffic models offer a way of simulating various driver behaviors. A microscopic model consists of an infrastructure that is occupied by a set of vehicles. Each vehicle interacts with its environment according to its own rules.

Existent traffic prevention approaches can be categorized as follows [10]:

- **Global Strategies:** The considered global strategies are a “synchronized strategy”, a “green wave strategy” and a “random strategy”. In the case of the synchronized strategy all traffic lights switch synchronously to green (red) for the east (north) bound vehicles and vice versa. In the case of a green wave strategy, i.e., adjacent traffic lights switch with a defined offset. Additionally, an appropriate offset has to be determined for the green wave strategy; this is equal to the free flow travel time for the depicted case

- **Adaptive Strategies:** In the following three different adaptive strategies are presented. The first investigated adaptive strategy is the “switching based on the queue length”. Here a traffic signal switches if the length of a vehicle queue in front of a red light trespasses a certain value. Further investigated adaptive strategies are the “switching based on waiting time” and the “switching in analogy to a neural network”. In the first case a traffic light switches to red if the green phase is not used by a vehicle for a certain time. In the case of switching in analogy to a neural network the traffic lights act like integrate-and-fire neurons. After the switching process (fire) the potential is reset to zero again. The switching in analogy to a neural network strategy leads to similar results like the switching based on the waiting time [7, 8].

#### IV. THREE LEVELED FUZZY PROPOSED SYSTEM

In the proposed models utilize adjusting traffic light for urban traffic control, priority of streets of intersection and also width and length of streets are assumed equal. whereas in real world urban traffic, parameters like time during the entire day, density of vehicles of the street, number of shopping centers, offices that have plenty of clients; have determinant effects on amount of traffic of streets. Furthermore, the priority of each street is defined by considering these environmental factors. Taking into account these parameters we propose a fuzzy system that priority of each street is computed at each moment, also this system doesn't set any constraint on width and length of streets

Fig. 2. Proposed System Flow

The proposed system has three levels; at the first level priority of each street is computed momentarily. At the second level real velocity of vehicles of every street is calculated at specific moments. Then cellular automata model is applied to specify density transmission and also type of movement of vehicles in the cellular spaces of each street. And finally at the third level, decision is done for changing status of traffic light.

##### A. First Level of the Proposed System

In this paper, pausing coefficient is defined as a significant factor to determine priority of each street. Streets with larger quantity of stopped or paused vehicles have more priority. Pausing coefficient is totally distinctive among three following categories:

##### • Health and Commercial Centers:

In these centers, density of clients is computed momentarily. Since number of clients directly affects on

number of paused or stopped vehicles in the street, priority of street is dependant to amount of density of clients with a linear function. So fuzzy sets of health and commercial centers are defined as Fig. 3. Note that M1, M2, M3, M4, M5 fuzzy sets are related to low, high, medium, high and low densities respectively.

Fig. 3. Fuzzy Sets of Density of Clients of Health and Commercial Centers

##### • Official Centers:

In these centers density of clients at each moment could affect directly on priority of the street. Fuzzy sets of official centers are determined as Fig. 4. L1, L2, L3 fuzzy sets are related to low, high and low densities respectively.

Fig. 4. Fuzzy Sets of Density of Clients of Official Centers

##### • Shopping Centers:

Like two previous centers amount of clients of these centers, has determinant effect on priority of the street, fuzzy sets of these centers can be considered as Fig. 5. Notice that K1, K2, K3, K4, K5 fuzzy sets are related to low, high, medium, high and low densities respectively.

Fig. 5. Fuzzy Sets of Density of Clients of Shopping Centers

##### 1) Fuzzy Rules:

By definition of the input and output fuzzy sets, a total of 24 IF-THEN rules are defined as follows [2]:

$$\text{IF } (x_1 \text{ is } M1) \text{ and } (x_1 \text{ is } L1) \text{ and } (x_1 \text{ is } K1) \text{ then } F1=[A1*(1-y11)]*[A2*(1-y21)]*[A3*(1-y31)] \quad (2)$$

$$\text{IF } (x_1 \text{ is } M1) \text{ and } (x_1 \text{ is } L1) \text{ and } (x_1 \text{ is } K2) \text{ then } F2=[A1*(1-y11)]*[A2*(1-y21)]*[A3*y32] \quad (3)$$

$$\text{IF } (x_1 \text{ is } M1) \text{ and } (x_1 \text{ is } L2) \text{ and } (x_1 \text{ is } K1) \text{ then } F3=[A1*(1-y11)]*[A2*y22]*[A3*(1-y31)] \quad (4)$$

$$\text{IF } (x_1 \text{ is } M1) \text{ and } (x_1 \text{ is } L2) \text{ and } (x_1 \text{ is } K2) \text{ then } F4=[A1*(1-y11)]*[A2*y22]*[A3*y32] \quad (5)$$

$$\text{IF } (x1 \text{ is } M2) \text{ and } (x1 \text{ is } L1) \text{ and } (x1 \text{ is } K1) \text{ then} \\ F5=[A1*y12]*[A2*(1-y21)]*[A3*(1-y31)] \quad (6)$$

$$\text{IF } (x1 \text{ is } M2) \text{ and } (x1 \text{ is } L1) \text{ and } (x1 \text{ is } K2) \text{ then} \\ F6=[A1*y12]*[A2*(1-y21)]*[A3*y32] \quad (7)$$

$$\text{IF } (x1 \text{ is } M2) \text{ and } (x1 \text{ is } L1) \text{ and } (x1 \text{ is } K3) \text{ then} \\ F7=[A1*y12]*[A2*(1-y21)]*[A3*(1-|1-y33|)/2] \quad (8)$$

$$\text{IF } (x1 \text{ is } M2) \text{ and } (x1 \text{ is } L2) \text{ and } (x1 \text{ is } K1) \text{ then} \\ F8=[A1*y12]*[A2*y22]*[A3*(1-y31)] \quad (9)$$

$$\text{IF } (x1 \text{ is } M2) \text{ and } (x1 \text{ is } L2) \text{ and } (x1 \text{ is } K2) \text{ then} \\ F9=[A1*y12]*[A2*y22]*[A3*y32] \quad (10)$$

$$\text{IF } (x1 \text{ is } M2) \text{ and } (x1 \text{ is } L2) \text{ and } (x1 \text{ is } K3) \text{ then} \\ F10=[A1*y12]*[A2*y22]*[A3*(1-|1-y33|)/2] \quad (11)$$

$$\text{IF } (x1 \text{ is } M3) \text{ and } (x1 \text{ is } L2) \text{ and } (x1 \text{ is } K2) \text{ then} \\ F11=[A1*(1-|1-y13|)/2]*[A2*y22]*[A3*y32] \quad (12)$$

$$\text{IF } (x1 \text{ is } M3) \text{ and } (x1 \text{ is } L2) \text{ and } (x1 \text{ is } K3) \text{ then} \\ F12=[A1*(1-|1-y13|)/2]*[A2*y22]*[A3*(1-|1-y33|)/2] \quad (13)$$

$$\text{IF } (x1 \text{ is } M3) \text{ and } (x1 \text{ is } L2) \text{ and } (x1 \text{ is } K4) \text{ then} \\ F13=[A1*(1-|1-y13|)/2]*[A2*y22]*[A3*y34] \quad (14)$$

$$\text{IF } (x1 \text{ is } M3) \text{ and } (x1 \text{ is } L3) \text{ and } (x1 \text{ is } K2) \text{ then} \\ F14=[A1*(1-|1-y13|)/2]*[A2*(1-y23)]*[A3*y32] \quad (15)$$

$$\text{IF } (x1 \text{ is } M3) \text{ and } (x1 \text{ is } L3) \text{ and } (x1 \text{ is } K3) \text{ then} \\ F15=[A1*(1-|1-y13|)/2]*[A2*(1-y23)]*[A3*(1-|1-y33|)/2] \quad (16)$$

$$\text{IF } (x1 \text{ is } M3) \text{ and } (x1 \text{ is } L3) \text{ and } (x1 \text{ is } K4) \text{ then} \\ F16=[A1*(1-|1-y13|)/2]*[A2*(1-y23)]*[A3*y34] \quad (17)$$

$$\text{IF } (x1 \text{ is } M4) \text{ and } (x1 \text{ is } L2) \text{ and } (x1 \text{ is } K2) \text{ then} \\ F17=[A1*y14]*[A2*y22]*[A3*y32] \quad (18)$$

$$\text{IF } (x1 \text{ is } M4) \text{ and } (x1 \text{ is } L2) \text{ and } (x1 \text{ is } K3) \text{ then} \\ F18=[A1*y14]*[A2*y22]*[A3*(1-|1-y33|)/2] \quad (19)$$

$$\text{IF } (x1 \text{ is } M4) \text{ and } (x1 \text{ is } L2) \text{ and } (x1 \text{ is } K4) \text{ then} \\ F19=[A1*y14]*[A2*y22]*[A3*y34] \quad (20)$$

$$\text{IF } (x1 \text{ is } M4) \text{ and } (x1 \text{ is } L3) \text{ and } (x1 \text{ is } K2) \text{ then} \\ F20=[A1*y14]*[A2*(1-y23)]*[A3*y32] \quad (21)$$

$$\text{IF } (x1 \text{ is } M4) \text{ and } (x1 \text{ is } L3) \text{ and } (x1 \text{ is } K3) \text{ then} \\ F21=[A1*y14]*[A2*(1-y23)]*[A3*(1-|1-y33|)/2] \quad (22)$$

$$\text{IF } (x1 \text{ is } M4) \text{ and } (x1 \text{ is } L3) \text{ and } (x1 \text{ is } K4) \text{ then} \\ F22=[A1*y14]*[A2*(1-y23)]*[A3*y34] \quad (23)$$

$$\text{IF } (x1 \text{ is } M5) \text{ and } (x1 \text{ is } L3) \text{ and } (x1 \text{ is } K4) \text{ then} \\ F23=[A1*(1-y15)]*[A2*(1-y23)]*[A3*y34] \quad (24)$$

$$\text{IF } (x1 \text{ is } M5) \text{ and } (x1 \text{ is } L3) \text{ and } (x1 \text{ is } K5) \text{ then} \\ F24=[A1*(1-y15)]*[A2*(1-y23)]*[A3*(1-y35)] \quad (25)$$

In the above rules, x1 is input of the system and shows daytime, y1j,y2j,y3j demonstrate membership functions of Mj,Lj,Kj fuzzy sets respectively. Note that A1,A2,A3 are constant coefficients for Health/Commercial, Official and Shopping centers respectively.

## 2) Defuzzification

In this system defuzzification procedure is performed by using equation (26). Output of defuzzifier is considered as output of first level of system and shows priority of the street.

$$F = \frac{\sum_{i=1}^{24} Fi}{n} \quad (26)$$

In the above equation, Fi is output of ith rule (i=1...24), n is number of rules that have nonzero output and F is defuzzifier output (output of first level of system). Keep in mind that F is used as one of the inputs of second level of the system.

## B. Second Level of the Proposed System

In this step real velocity of vehicles of every street is calculated at specific moments and then type of transmission of density of vehicles is evaluated. Real velocity of vehicles is obtained by regarding three factors:

- Priority of Street: That's calculated dynamically based on fuzzy rules at the first level and on specific moments.
- Density of Vehicles: Since low-priority streets have low pausing coefficients, most of vehicles would be paused behind intersections. So if adjustment of the traffic light is done only based on priority of the street, vehicles may pause behind intersections for a long duration. To prevent this problem, number of existent vehicles in the street is also regarded as one of the inputs.
- Standard Velocity of Vehicles of Street: Since number of vehicles behind intersections, is a determinant factor for specifying distance between location of paused vehicle and traffic light, we used cellular automata for segmentation of street from intersection to end of street. So type of movement of vehicles from entrance time till pausing time behind intersection is achieved by using transition rules of cellular automata. One may say since standard velocity of vehicles (Standard velocity is constant for all vehicles of each street and computed based on width and length of street) must be specific while applying transitions rules so it's considered as third factor. So velocity of each vehicle is computed as follows:

$$V=(1-\gamma)(1-\alpha)*V_N+\epsilon \quad (27)$$

In the above equation,  $\gamma$  is priority of the street,  $V_N$  is standard velocity of the street,  $\alpha$  is a constant value (5km/h in this paper) and  $\epsilon$  is density of the street that's obtained from equation 28:

$$\alpha = \frac{N}{W * L * A} \quad (28)$$

Where W and L are width and length of the street respectively, A is the average occupied area by each vehicle, N is the number of available vehicles in the street (N is calculated as follows: W\*L is multiplied by summation of densities of cellular spaces). Equation 28 shows that more density or more priority of street, leads in

less velocity of vehicles. Based on this velocity, transition rules of cellular automata are determined.

#### 1) Cellular Automata Rules

Since velocity and displacement have a linear dependency ( $x=v*t$ ), we used a linear transition function. Because of extra computations, discrete time method is applied instead of continuous time approach and system is updated at specific seconds. In this paper, velocities of vehicles are divided in intervals of length 5 and length of each cell is considered as 10 meters. So at every 7.2" time interval, the vehicle moves 10 meters in a fixed 5km length(Updating progress is also done every 7.2 seconds). Based on these comments, we used specific transition function for obtaining cellular rules of density transmission in the street: In the proposed unidirectional selective cellular automata model, width of cell is regarded as width of the street and length of cell is set to a constant number (10). Note that transmission of density of vehicles means transmission of vehicles from one cell to another one, type of this transmission is specified as Fig. 6.

Fig. 6. Density Transmission Function Based on USCA Model

Maximum density of each cell is 1 and it is related to number of available vehicles at each cell. Maximum number of vehicles of each cell is computed as follows:

$$N = \frac{w * 10}{15} \quad (29)$$

In the above equation, W is width of the street, 10 is length of the street and 15 shows estimated area allocated for a vehicle. If number of available vehicles of each cell exceeds the maximum value (Obtained using equation 30), the surplus is transferred to previous cell. Note that in this paper all of the streets are bidirectional.

#### C. Third Level of the Proposed System

In this paper two factors are considered for adjusting traffic light. Priority of the street and number of complete traffic cells are inputs of third level of the proposed system. Since density and traffic in high-priority streets have more undesirable effects, priority of the street must be considered for adjusting traffic light. Furthermore,

number of paused vehicles behind intersections is the main factor for determining the time that status of traffic light is changed. This factor is illustrated by traffic cells and regarded as input of system.

In this proposed system two conversion functions are used for priority and number of traffic cells to determine time duration that green light is active.

Multiplication of outputs of two functions represents the time duration that traffic light is green for each street:

$$G = T_c * \gamma \quad (30)$$

Where G shows the time interval that green light is active,  $T_c$  is number of traffic cells and  $\gamma$  is priority of the street. G is computed for all of streets of intersection. Pay attention that these calculations are done concurrently and independently, eventually street with the highest G enables the green light and uses G seconds from it. To prevent consecutive variations of status of the traffic light equation 32 is employed:

$$\text{If } G_{\max} \geq 2 * G_{\text{green\_light}} \text{ THEN} \quad (31) \\ \text{Change Traffic light}$$

Where  $G_{\max}$  is the maximum value of G in every updating progress (Among streets of an intersection) and  $G_{\text{green\_light}}$  is the updated value of G for the street with green light. Indeed Change Traffic Light instruction activates green light for the street that has  $G_{\max}$ . In the proposed approach, at each moment the light green is active only for one of the streets.

## V. SIMULATION RESULTS

The proposed method was simulated with specific inputs and more desirable results were obtained in comparison with based adaptive method.

Fig. 7. Result of Fuzzy Proposed Approach for Representing Complete Traffic Cells Considering 1st Street as High-priority and 4th Street as Low- priority Street

Fig. 8. Result of NN-based Approach for Representing Complete Traffic Cells Considering 1st Street as High-priority and 4th Street as Low- priority Street

when priorities of streets are different from each other and density of vehicles of streets of intersection streets is not the same, results of NN-based method don't change at all (Fig.8). Due to the fact that NN-based method doesn't consider priority of streets, so density of high-priority streets would increase and this matter leads to traffic increment throughout the street. Whereas in the proposed three leveled fuzzy approach, changing priority of streets and density of each street causes to significant changes in traffic light scheduling and also traffic cells. (Fig.7). This change causes to the street with more density and higher priority is selected to adjust the traffic light and eventually the traffic load and street density will be balanced.

Results of our proposed system and NN-based approach are shown in Table I:

Table I  
COMPARISON BETWEEN FUZZY PROPOSED SYSTEM  
AND NN-BASED METHOD

| Streets       | Fuzzy Proposed Method |                 |                 |                 |
|---------------|-----------------------|-----------------|-----------------|-----------------|
|               | 1 <sup>st</sup>       | 2 <sup>nd</sup> | 3 <sup>rd</sup> | 4 <sup>th</sup> |
| Traffic Cells | 2                     | 2               | 3               | 4               |
| Density       | 0.5834                | 0.5741          | 0.5208          | 0.4917          |
| Streets       | NN-based Method       |                 |                 |                 |
|               | 1 <sup>st</sup>       | 2 <sup>nd</sup> | 3 <sup>rd</sup> | 4 <sup>th</sup> |
| Traffic Cells | 2                     | 2               | 3               | 3               |
| Density       | 0.9571                | 0.7840          | 0.6425          | 0.5403          |

Although inconsiderable density has been added to 4th street, but density decrement is completely sensible in 1st, 2nd and 3rd streets. While existent systems only consider specific limited segment behind the intersection for adjusting the traffic light, our proposed system can control density of vehicles and traffic load throughout the street, also it prevent heavy traffics noticeably.

## VI. CONCLUSIONS

In this paper a three leveled fuzzy system was proposed for urban traffic control by adjusting the traffic light. Using this approach results in traffic decrement and also steady traffic dispreading all over the city. In the proposed system priority and length of streets are considered variable. Also real velocity of vehicles is computed based on fuzzy rules in different hours during the day. Considering mentioned factors leads to traffic load balancing throughout the city. Another dominant note in this paper is that priority of streets and also the maximum allowed velocity of the street are obtained by fuzzy sets with regard to urbanism principals. This matter also reduces traffic significantly.

# Bangla Vowel Sign Recognition by Extracting the Fuzzy Features

Mohammad Sarwar Kamal, Mohammed Moshiul Hoque, Md. Monjur Ul Hasan and Mohammad Shamsul Arefin

Department of Computer Science & Engineering, Chittagong University of Engineering & Technology, Chittagong-4349, Bangladesh

**Abstract** — This paper presents a fuzzy based Bangla vowel sign recognition system. Vowel and consonant are the main criteria to express any language. Exceptionally, Bangla has some vowel sign which are used to express Bangla word. Therefore, to recognize any Bangla word, at first it is necessary to recognize which vowel sign is used to express that word. Due to its low computational requirement and very high accuracy, fuzzy logic system is probably the most efficient method available for on-line vowel sign recognition. The most important task for this implementation is the building of the rule base using fuzzy logic that would describe the recognized vowel sign, which is more complicated as different people write the same vowel sign in completely different ways. In this paper, we propose a system that uses automatically generated fuzzy membership value that describes the handwritten Bangla vowel sign written by different individuals.

**Index Terms** — Vowel Sign, Geometric Features, Positional Features, Segmentation.

## I. INTRODUCTION

With the increasing the interest of computer applications, modern society needs the handwritten text into computable readable form. Since, exceptionally Bangla has some vowel sign, which are used to express Bangla word, so, to recognize any Bangla word; at first it is necessary to recognize which vowel sign is used to express that word. Generally, the objective of handwritten character recognition is the recognition of data that describe handwritten object. On line handwritten recognition deals with a time ordered sequence of data. It is relatively simple to write a computer program within a single document. The problem is complicated as different people write the same character in completely different ways. So, any system designed for the recognition of handwritten character must be extremely robust in term of being able to ignore differences in writing style. Although many works on character recognition have been done, works on Bangla character recognition are few. But, there is no task on recognition of Bangla vowel sign. Many methodologies have been developed for the recognition of handwritten characters. Some of the most commonly used techniques are Neural network [1], genetic algorithm [2], Bayesian inference [3], stochastic HMM [4], Fuzzy logic [5], Bangla handwritten character recognition [6], Handwritten alphanumeric character recognition [7]. Due

to the wide variety of different writing styles, all the proposed techniques have fall in some problem. The objectives of this paper are to segment the Bangla vowel sign by calculating angle difference and calculate the geometric features of each segment for recognizing the vowel sign.

The rest of the paper is organized as follows. Section II illustrates about fuzzy set and membership function. Section III describes proposed model for Bangla vowel sign recognition. Section IV depicts the experimental result and performance of proposed system. Finally section V concludes the paper.

## II. FUZZY SET AND MEMBERSHIP FUNCTION

The object and its membership value express fuzzy set. If a number between 0 and 1 indicates the degree of membership to a set then it is called fuzzy set [8]. A membership function maps every element of the universe of discourse  $X$  to the interval  $[0, 1]$  and is denoted by  $\mu_A(x)$ . We formally write this mapping as

$$\mu_A(x) : X \rightarrow [0, 1]$$

The notation of above equation is read as follows: there exist a function  $\mu_A(x)$  mapping every element of the set  $X$  to the set of interval  $[0, 1]$ .

### A. Different Types of Membership Function

There are different types of membership functions are in used. These are  $\Pi$ - shaped function, bell shaped function, triangular shaped function, trapezoidal shaped function etc. In this paper, we use the most popular membership function is triangular membership function which is represented by  $\Delta$  which have three parameters. This function defined as:

$$\Delta(x; b, c) = \begin{cases} 1 - 2 * |(x - c) \div c| & \text{if } (c - b \div 2) \leq x \leq (c + b \div 2) \\ 0 & \text{otherwise} \end{cases}$$

The triangular membership function is depicted in Fig.1.

Fig. 1. Triangular Membership Function

Here  $c$  is the central point and  $b$  is the bandwidth of the triangular membership function and  $x$  is the determining variable.

### III. PROPOSED MODEL FOR BANGLA VOWEL SIGN RECOGNITION

The basic methodology of the online Bangla vowel sign recognition system is depicted in Fig. 2.

Fig. 2. Proposed architecture for Vowel Sign recognition

Here, the input of the model is drawn vowel sign that is passes through the different phases of the proposed model and generate output of the model, which is recognized standard format of vowel sign.

#### A. Segmentation Process

In segmentation phase, every vowel sign is divided into a number of segments. The pseudo code for the segmentation of vowel sign is depicted below:

```

Begin segmentation:
Step-1: Suppose a variable no_points. Set no_points = 0.
Step-2: If Pen down, initialize new segment
Step-3: Store co-ordinates of initialized segment, Set
 no_points = no_points + 1
Step-4: Get next co-ordinates
Step-5: If Pen up, store co-ordinates and Go to Step-1
ELSE
If abrupt change in direction and no_points > 4
Set no_points = 0 and Go to Step-2
ELSE
Go to Step-3
End segmentation

```

According to above algorithm we can divide the bangla

vowel sign 'ঠ', into two segments for the sample depicted in Fig. 3.

Fig. 3. Segmentation of Bangla vowel sign 'ঠ',

The segmentation method is based on the movement and angle differences between first four point connected line and consecutive second four point connected line. If the angle difference between two lines is more than 90 degrees, then first line is recognized a new segment. When electronic pen or mouse is up, we recognized also a new segment.

#### B. Fuzzy Features

Fuzzy feature are divided into three categories: global features, positional features and geometric features. Global features are the common for whole vowel sign. These global features are necessary for calculating the both positional features and geometric features.

##### B1. Global Features

Global features belong to whole vowel sign. Some global features are given below:

$$\min X^{seg(n)} = \min(x_i) \quad \max X^{seg(n)} = \max(x_i)$$

$$\min Y^{seg(n)} = \min(y_i) \quad \max Y^{seg(n)} = \max(y_i)$$

The global features of segment 1 of vowel sign 'ঠ', which is depicted in Fig. 3 can be describe by the Fig. 4.

Fig. 4. Global feature of segment 1 of vowel sign 'ঠ'

##### B2. Positional Features

The universe of discourse is divided into two linguistic variables which are Vertical position (VP) and Horizontal Positional (HP). The Vertical Position is divided into three linguistic terms: {Top, Middle, Bottom} and the

Horizontal position is divided into three linguistic terms: {Left, Center, Right). Then the relative position of the identified segment is expressed by the following equations:

$$\mu_{HP} = \frac{(centreX^{seg(n)} - \min X^{seg(n)})}{(\max X^{seg(n)} - \min X^{seg(n)})} \quad (3)$$

$$\mu_{VP} = \frac{(centreY^{seg(n)} - \min Y^{seg(n)})}{(\max Y^{seg(n)} - \min Y^{seg(n)})} \quad (4)$$

### B3. Geometric Features

The geometric features are divided into two main categories, which are straight line and arc. The membership function for straightness and arc ness of the every segment are calculated by the following equation.

$$\mu_{straightness} = [d_{P(0)P(N)} / \sum_{K=1}^N d_{P(K)P(K+1)}] \quad (5)$$

Here,  $d_{P(k)P(K+1)}$  stands for the straight-line distance between point  $k$  and point  $(k+1)$  on the  $n^{th}$  segment.  $N$  depicts the number of element in the segment.

$$\mu_{Arcness} = 1 - \mu_{straightness} \quad (6)$$

If  $\mu_{straightness}$  is greater than 0.6 then the segment is straight line and otherwise it is an arc. Some geometric features are given below:

For vertical line:

$$\mu_{VL} = \max(\Delta(x, 90, 45), \Delta(x, 90, 270)) \quad (7)$$

For horizontal line:

$$\mu_{HL} = \max(\Delta(x, 90, 0), \Delta(x, 90, 180), \Delta(x, 90, 360)) \quad (8)$$

For positive slant

$$\mu_{PS} = \max(\Delta(x, 90, 45), \Delta(x, 90, 225)) \quad (9)$$

For negative slant

$$\mu_{NS} = \max(\Delta(x, 90, 135), \Delta(x, 90, 315))$$

The equation of the A-like curve is

$$\mu_{AL} = \min(1, \sum I_y / n) \quad (10)$$

Where  $I_y = 1$  if  $y > (y_s + y_e) / 2$  ; Otherwise 0

The equation of the U-like curve is

$$\mu_{UL} = \min(1, \sum I_y / n) \quad (11)$$

Where  $I_y = 1$  if  $y < (y_s + y_e) / 2$  ; Otherwise 0

The equation of the C-like curve is

$$\mu_{CL} = \min(1, \sum I_x / n) \quad (12)$$

Where  $I_x = 1$  if  $x < (x_s + x_e) / 2$  ; Otherwise 0

The equation of the D-like curve is

$$\mu_{DL} = \min(1, \sum I_x / n) \quad (13)$$

Where  $I_x = 1$  if  $x > (x_s + x_e) / 2$  ; Otherwise 0

The equation of the O-like curve is

$$\mu_{OL} = (\sum_{K=1}^N d_{P(K)P(K+1)}) / (2 * 3.1416 * r) \quad (14)$$

Where  $r$  is the radius of the curve.  $x_s, x_e$  is the start point and end point of segment respectively in the X axis.  $y_s, y_e$  is the start point and end point of segment respectively in the Y axis. Different types of curve and corresponding equation are given in the Table I.

TABLE I  
DIFFERENT TYPES OF GEOMETRIC FUZZY  
FEATURES

| Shape | Name            | Function                                                                                     |
|-------|-----------------|----------------------------------------------------------------------------------------------|
|       | Vertical line   | $\mu_{VL} = \max(\Delta(x, 90, 45), \Delta(x, 90, 270))$                                     |
| —     | Horizontal line | $\mu_{HL} = \max(\Delta(x, 90, 0), \Delta(x, 90, 180), \Delta(x, 90, 360))$                  |
| /     | Positive slant  | $\mu_{PS} = \max(\Delta(x, 90, 45), \Delta(x, 90, 225))$                                     |
| \     | Negative slant  | $\mu_{NS} = \max(\Delta(x, 90, 135), \Delta(x, 90, 315))$                                    |
| ∩     | A-Like Curve    | $\mu_{AL} = \min(1, \sum I_y / n)$ Where $I_y = 1$ if $y > (y_s + y_e) / 2$ ;<br>Otherwise 0 |
| ⊂     | C-Like Curve    | $\mu_{CL} = \min(1, \sum I_x / n)$ Where $I_x = 1$ if $x < (x_s + x_e) / 2$ ;<br>Otherwise 0 |
| ⊃     | D-Like Curve    | $\mu_{DL} = \min(1, \sum I_x / n)$ Where $I_x = 1$ if $x > (x_s + x_e) / 2$ ;<br>Otherwise 0 |

After calculating all fuzzy features the next step is to map these values into Linguistic terms according to predefined range. The range of value of membership function for evaluating angle difference and different linguistic term are shown in Fig. 5.

Fig. 5. Membership function for evaluating angle difference

### C. Creation of Fuzzy Rule Base

The rule base is depends on the number of segment contained in the given vowel sign.

There are a lot of rule in this works for vowel sign recognition. Each rule is unique for each vowel sign. The general format of fuzzy rule base for each vowel sign which are stored in the database is the features of a segment is combined with logical AND operator and the features of different segments is combined with logical OR operator.

#### D. Modes of Vowel Sign Recognition

There are two modes of operation for online handwritten Bangla vowel sign recognition technique. These are the Learning mode and the Recognition mode that are described in subsequent section.

##### D1. Learning Mode

In learning mode, user draws the image / vowel signs in the drawing pad. Now, we describe the learning mode by step by step.

**Step 1:** The segmentation process is explained by the algorithm described in section A

**Step 2:** Then fuzzy features extractions are occurred according to the equations described in section B.

**Step 3:** The important linguistic term is is described in TABLE II. In this table  $\mu_{ARC}$ ,  $\mu_{VF}$ ,  $\mu_{DL}$  and  $\mu_{CL}$  are stand for arcness, vertical position, D-like and C-like respectively. For sample 1 the value of  $\mu_{ARC}$ ,  $\mu_{VF}$ ,  $\mu_{DL}$  and  $\mu_{CL}$  are M, NB, VH and VL which are standing for 'medium', 'nearly bottom', 'very high' and 'very low' respectively.

TABLE II  
IMPORTANT LINGUISTICS TERM FOR ANY FEATURES

| SAMPLE  | $\mu_{ARC}$   | $\mu_{VF}$     | $\mu_{DL}$     | $\mu_{CL}$     |
|---------|---------------|----------------|----------------|----------------|
| 1       | M             | NB             | VH             | VL             |
| 2       | H             | BC             | VH             | VL             |
| 3       | M             | BC             | VH             | VL             |
| 4       | M             | B              | VH             | VL             |
| 5       | M             | BC             | VH             | VL             |
| 6       | VH            | BC             | VH             | VVL            |
| 7       | L             | C              | VH             | L              |
| 8       | M             | BC             | VVH            | VL             |
| Total=8 | Important = M | Important = BC | Important = VH | Important = VL |

**Step 4:** Then the store mechanism for fuzzy features into databases is happened according to created fuzzy rule base that are described in section C.

##### D2. Recognition Modes

The system architecture of recognition or output mode is described in below step by step.

**Step 1:** Recognition mode segmentation is same as the learning mode segmentation.

**Step 2:** Recognition mode feature extraction is same as the learning mode extraction.

**Step 3:** Store mechanism of data into array are described by the following source code:

```

If uol(i) <= 0 Then
 uolc(i) = "Z"
ElseIf uol(i) > 0 And uol(i) <= 0.125 Then
 uolc(i) = "VVL"
ElseIf uol(i) > 0.125 And uol(i) <= 0.25 Then
 uolc(i) = "VL"
End If
End If

```

**Step 4:** In comparison stage, array data are compared with the rule base data.

**Step 5:** Highest value is calculated from step 4 as percentage.

The vowel sign, which contains the highest recognition rate, is the recognized vowel sign.

## IV. EXPERIMENTAL RESULTS AND DISCUSSION

In the experimentation, we have collected twenty samples for each vowel sign from ten individuals. In Bangla, there are ten vowel signs. Therefore, the total numbers of samples are 2000. We got the very high recognition accuracy for the proposed system, which is more than 90%.

#### A. Segmentation Results

To find out attractive fuzzy features it is necessary to divide each vowel sign into a number of meaningful segments. In this paper, each vowel sign can be divided into maximum fifteen segments. But maximum accuracy is found in different specific number of segments for each different vowel sign. The segmentation result of Bangla vowel sign 'ঢ' is depicted in Fig. 6.

Fig. 6. Segmentation result of Bangla vowel sign 'ঢ'

#### B. Positional Features Extraction

The positional features of Bangla vowel sign 'ঢ', 'ঢ়' and 'ঢ়্' are shown in the TABLE III. This table describes the  $\mu_{HP}$  and  $\mu_{VP}$ , which are standing for horizontal and vertical position respectively. For vowel sign 'ঢ', the horizontal position of segment - 1 and segment - 2 is LC stand for

‘left corner’ and the vertical position of segment – 1 and segment – 2 are B stand for ‘Bottom ’ and C stand for ‘corner’ respectively.

TABLE III  
A SMALL FRAGMENT OF POSITIONAL  
FEATURES OF BANGLA VOWEL SIGN

| Sample of vowel sign | No. of Segment | Segment serial | μ <sub>up</sub> | μ <sub>vr</sub> |
|----------------------|----------------|----------------|-----------------|-----------------|
| ৳                    | 2              | 1              | LC              | B               |
|                      |                | 2              | LC              | C               |

| ৳                    | 4              | 1              | L               | BC              |
|                      |                | 2              | LC              | C               |
|                      |                | 3              | RC              | BC              |
|                      |                | 4              | R               | C               |

### C. Geometric Features

The straightness features of Bangla vowel sign ৳, ৳ and ৳ are shown in TABLE IV. This table describes the  $\mu_{ST}$ ,  $\mu_{VL}$ ,  $\mu_{HL}$ ,  $\mu_{PS}$ ,  $\mu_{NS}$ ,  $\mu_{HLEN}$ ,  $\mu_{VLEN}$  and  $\mu_{SLEN}$  which are standing for straightness, vertical line, horizontal line, positive slanted, negative slanted, horizontal length, vertical length and slanted length respectively. For vowel sign ‘৳’,  $\mu_{ST}$ ,  $\mu_{VL}$ ,  $\mu_{HL}$ ,  $\mu_{PS}$ ,  $\mu_{NS}$ ,  $\mu_{HLEN}$ ,  $\mu_{VLEN}$  and  $\mu_{SLEN}$  of segment – 1 are E, M, E, H, VL, VL, L, L which are standing for ‘Excellent’, ‘Medium’, ‘High’, ‘Very low’ and Low’ respectively. The ‘-’ means that there is no straightness features because the selected segment contains the arcness fuzzy features.

TABLE IV  
STRAIGHTNESS FEATURES OF BANGLA VOWEL  
SIGN

| Sample of vowel sign | No. of Segment | Segment serial | μ <sub>ST</sub> | μ <sub>VL</sub> | μ <sub>HL</sub> | μ <sub>PS</sub> | μ <sub>NS</sub> | μ <sub>HLEN</sub> | μ <sub>VLEN</sub> | μ <sub>SLEN</sub> |
|----------------------|----------------|----------------|-----------------|-----------------|-----------------|-----------------|-----------------|-------------------|-------------------|-------------------|
| ৳                    | 2              | 1              | E               | M               | E               | H               | VL              | VL                | L                 | L                 |
|                      |                | 2              | VVH             | H               | H               | E               | M               | VVL               | VL                | VL                |
| ৳                    | 4              | 1              | H               | VH              | VVH             | L               | M               | VL                | VVL               | E                 |
|                      |                | 2              | E               | VL              | Z               | VL              | VVL             | L                 | M                 | VH                |
|                      |                | 3              | H               | VH              | VVH             | L               | M               | VL                | VVL               | E                 |
|                      |                | 4              | Z               | -               | -               | -               | -               | -                 | -                 | -                 |
| ৳                    | 5              | 1              | H               | VH              | VVH             | L               | M               | VL                | VVL               | E                 |
|                      |                | 2              | H               | VH              | VVH             | L               | M               | VL                | VVL               | E                 |
|                      |                | 3              | Z               | -               | -               | -               | -               | -                 | -                 | -                 |
|                      |                | 4              | E               | VL              | Z               | VL              | VVL             | L                 | M                 | VH                |
|                      |                | 5              | H               | VH              | VVH             | L               | M               | VL                | VVL               | E                 |

Similarly, we can describe the arcness fuzzy features by tabular form.

### C. Recognition Accuracy of Bangla Vowel Sign

The recognition accuracy Bangla vowel sign ৳, ৳

and ৳ are shown in TABLE V. This table contains the 1<sup>st</sup>, 2<sup>nd</sup>, and 3<sup>rd</sup> highest percentage value for each vowel sign that are collect from different individuals. The original sign is selected as highest percentage of accuracy. Such as for ‘৳’, which consists three segments, 95% adjust with ‘৳’, 90% adjust with ‘৳’ and 80% adjust with ‘৳’. So, highest value of percentage of accuracy is 95%, which is adjust with ‘৳’. So, the recognized vowel sign is ‘৳’.

TABLE V  
RECOGNITION ACCURACY OF DIFFERENT  
BANGLA VOWEL SIGN

| Vowel Sign | No. of Segment | 1 <sup>st</sup> Recognized | 2 <sup>nd</sup> Recognized | 3 <sup>rd</sup> Recognized | Original sign |
|------------|----------------|----------------------------|----------------------------|----------------------------|---------------|
| ৳          | 3              | ৳ 95 %                     | ৳ 90 %                     | ৳ 80%                      | ৳             |
| ৳          | 4              | ৳ 80 %                     | ৳ 75 %                     | ৳ 67.5%                    | ৳             |
| ৳          | 9              | ৳ 71.6 %                   | ৳ 68.8 %                   | ৳ 67.2%                    | ৳             |
| ৳          | 7              | ৳ 53.5 %                   | ৳ 52.8 %                   | ৳ 52.1%                    | ৳             |
| ৳          | 6              | ৳ 85 %                     | ৳ 77 %                     | ৳ 67%                      | ৳             |
| ৳          | 7              | ৳ 70 %                     | ৳ 64 %                     | ৳ 57%                      | ৳             |

### E. System Performance

The performance of the system is described by the curve of number of segments versus percentage of accuracy for each individual sign, which are shown in Fig. 7. The highest, lowest and average percentage value of accuracy for each vowel sign with respect to number of segments has been mentioned in this figure. Such as for ‘৳’, for number of segment 1, the percentage of accuracy is 85%, for segment 2, the percentage of accuracy is 95%, for segment 3, the percentage of accuracy is 78%. Here, for ‘৳’, it is shows that the highest value of percentage of accuracy is found for segment 2 which is 95%, it is called potential point.

Fig. 7. Curve of number of segments versus percentage of accuracy

Now, we draw the curve for number of segments versus highest percentage of accuracy to find out the average system performance. The curve is depicted in Fig. 8. This figure describes the potential point at which segment, the percentage of accuracy is high. The numbers of segments along X axis are 2, 3, 8, 4, 3, 5, 7, 6, 8, and 2 which are standing for  $\text{ত}$ ,  $\text{ফ}$ ,  $\text{শ}$ ,  $\text{অ}$ ,  $\text{এ}$ ,  $\text{ক}$ ,  $\text{খ}$ ,  $\text{গ}$ ,  $\text{ট}$ , and  $\text{ঙ}$  respectively. The values along Y-axis are the corresponding highest percentage of accuracy.

Fig. 8. Average system performance

#### V. CONCLUSION

With the increasing the interest of computer applications, modern society needs the handwritten text into computable readable form. So, handwritten recognition is a very interesting input method. The goal of this system is to develop an idea and to make software in order to recognize Bangla vowel sign regardless of various writing style. The recognition rate and speed are very good than others. This proposed system could be used to recognize the vehicle nameplate in Bangladesh. A cache system may introduce in further work. If Unicode can

improve it without Bangla software, then it will do with very easily. If the learning mode and recognition mode can be combined into a single mode, then this work performs better. That is the performance-improved dramatically.

**Abstract** — In this paper we will show the construction of acoustic active noise control in ear defenders by the help of Filtered-x Least Mean Squares structure and using a low power fixed point digital signal processor. This system is implemented for 20dB to 30dB attenuation of broad band noise and ca 60dB for sinusoidal interference. This is well suited for industrial applications.

**Index Terms** — Attenuation, Adaptive filters, Digital Signal Processors, Digital filters, Microphones

## I. INTRODUCTION

In any workplace i.e. construction sites or factories sound and noise are emitted and that noise is so much unhealthy for human. This noise might cause of giant damage to the hearing and impair the overall health of personnel. So they need protection. Traditional ear defenders can protect from upper range of frequencies but for lower range (below 500Hz) it is inadequate. In that kind of ear defenders the passive protection is used [1]. But for higher protection we need active methods. So, to make it better we are using Active Noise Control (ANC) method within the ear cup so that the sound pressure level is minimized.

Fig.1. Basic structure of ANC in Ear defender.

Analog techniques are highly cost effective and have less efficiency [4]. Now this days reconfigurable digital solution is used which is based on Digital Signal Processor. Now we are using FXLMS algorithm to make the system more effective.

This contribution presents and evaluates a fixed point ANC implementation in ear defenders using low power Digital Signal Processor.

## II. ACTIVE CONTROL OF NOISE USING FXLMS

The basic setup of ear defender given in Fig. 1. shows the primary design of ANC system. In this section we introduce some necessary terms and the details of the setup.

Fig. 2. ANC in ear-muffs.

We see a transfer function transferred from reference microphone to error microphone through the primary path  $H(w)$  in Fig. 2. There is another path denoted as forward path,  $C(w)$ , through which another transfer function travel from the input of the loud speaker to the error microphone [6, 7].

So, there are two acoustic signals in the microphone, noise signal and anti-noise signal and the model is a linear summation of these two signals. But path from the loud speaker to the external reference microphone can be neglected due to the characteristic of the ear-muffs [5, 8].

The implementation of FXLMS is shown in Fig. 3.

Fig. 3. Model of ANC using FXLMS.

Here a forward path estimate is,  $\hat{C}(w)$ , with an impulse response,  $\hat{c}(n)$ , which recompense for the delays creates by the forward path [6,8]. We can have the following expressions by the derivation of the FXLMS structure.

$$y(n) = \sum_{k=0}^{K-1} w_n(k)x(n-k) = \mathbf{w}_n^T \mathbf{X}_n \quad (1)$$

$$x_c(n) = \sum_{m=0}^{M-1} \hat{c}(m)x(n-m) = \hat{\mathbf{C}}^T \mathbf{X}'_n \quad (2)$$

Here,

Adaptive filter coefficient,

$$\mathbf{w}_n = (w_n(0), \dots, w_n(K-1))^T \quad (3)$$

Forward path estimate,

$$\hat{\mathbf{C}} = (\hat{c}(0), \dots, \hat{c}(M-1))^T \quad (4)$$

The size of  $\mathbf{x}_n$  and  $\mathbf{x}'_n$  is K and M respectively and they contain present and former reference signal values.

The adaptive filter coefficient update is,

$$\mathbf{w}_{n+1} = \mathbf{w}_n + \mu e(n) \mathbf{X}_{c,n} \quad (5)$$

Here,  $\mu$  = Algorithm step size.

$$\mathbf{X}_{c,n} = (x_c(n), \dots, x_c(n-(K-1)))^T \quad (6)$$

Because of the interaction of the adaptive filter,  $\mathbf{w}_n$  and the forward path estimate,  $\hat{\mathbf{C}}$  the robustness to the forward path estimate error is high [8].

### III. FIXED POINT FXLMS IMPLEMENTATION

To implement the FXLMS structure we will use a fixed point processor [3, 8]. We are using the processor which uses 16 bit for arithmetic calculation and can extend capability up to 48 bit.

Digital signal processing unit consist of two vital parts [3]:

- i. Digital Filter.
- ii. Adaptive Algorithm.

During the architecture we may face some problems. The secondary path introduces delay that causes instability to the standard LMS algorithm since the error signal is not correctly “aligned” in time with the reference signal [4, 5]. In Fig. 4. the utilization of LMS update algorithm has been shown with a 2-ADC/1-DAC configuration.

Filtering the reference signal with an estimate of the secondary path resolves the instability and results in the FXLMS algorithm. The estimate of the secondary path is performed off-line prior to the adaptation.

Feedback can be resolved by introducing an extra canceling filter in parallel to the feedback path and employing adaptive Infinite Impulse Response (IIR) filter [2, 7].

Now, adaptation is a sensitive issue. If the filter co-efficient update is stopped then an undesirable result can occur. To minimize this problem adaptive filter co-efficient are stored in an 32 bit format [8],

$$\mathbf{W}_n = 2^{16} \mathbf{W}_n^{hi} + \mathbf{W}_n^{lo} \quad (7)$$

Where,  $W_n^{hi} = 16$  bit and  $W_n^{lo} = 16$  bit.

Though the whole 32 bits are used in adaptation phase in the filtering phase only 16 bits are used. It can be expressed [8] as,

$$y(n) = \left\lfloor 2^{-8} \sum_{k=0}^{K-1} W_n^{hi} x(n-k) \right\rfloor = \left\lfloor 2^{-8} W_n^{hi^T} X_n \right\rfloor \quad (8)$$

Floor operator " $\lfloor \rfloor$ " only allow the floor values of a function. By using floor operator the filter co-efficient can be expressed as  $2^{-8} W_n^{hi}$ .

Fig. 4. A 2-ADC/1-DAC configuration with no high-speed gain taps.

The adaptive filter co-efficient update is

$$W_{n+1} = W_n + \mu_q e(n) x_{c,n} \quad (9)$$

Here  $\mu_q = \left\lfloor 2^{-8} \mu \right\rfloor$  is the adaptive filter step size but the actual size is

$$\mu = 2^{-8} \mu_q \quad (10)$$

#### IV. EXPERIMENTAL SETUP

To design experimental circuit we need:

- i. Printed Circuit Board (PCB).
- ii. Micro Controller.
- iii. Low pass Filter.

Printed Circuit Board (PCB):

For designing the experimental circuit of the fixed point FXLMS a PCB is manufactured. Block diagram of the PCB is shown in Fig. 5. The PCB can support two input and output channels.

Fig. 5. Block Diagram of the PDB.

Micro Controller:

We are using MSP430F169 micro processor [3] which is situated on the PCB (Fig. 6.).

Fig. 6. MSP430F169 (1<sup>st</sup> image), Processor on board (2<sup>nd</sup> image).

The maximum clock speed of the processor is 8Mz [3, 7]. Average execution rate is 2 MIPS. The micro controller has eight Analog-to-Digital Converter (ADC) and dual Digital-to-Analog

Converter (DAC) on board and both are of 12 bits.

Low pass Filter:

Properly configured 10<sup>th</sup> order low pass filter LTC1569-6 is situated on board prior to ADC and after DAC [8]. It is for aliasing reduction and signal re-construction.

The range of input output signal is  $\pm 1.25V$ . Externally there are micro amplifiers and anti noise loud speakers [6]. The positions in the ear-cup are shown in Fig. 7.

Fig. 7. Ear-cup

We can see the passive attenuation performance where attenuation  $> 20\text{dB}$  and frequencies  $> 500\text{Hz}$ . in Fig. 8.

Fig. 8. Passive Attenuation Performance.

Hence, the sampling frequency,  $F_s = 100\text{Hz}$  and the maximum number of coefficients for the adaptive filter and forward path estimate is 40.

## V. RESULT

The basic idea of Active noise control to generate a signal (secondary noise) is equal to a disturbance signal (primary noise) in amplitude and frequency, but has opposite phase. Combination of these signals results in cancellation of the primary (unwanted) noise. For example,

$$W_{opt}(\omega)C(\omega) = -H(\omega) \quad (11)$$

where  $W_{opt}(\omega)$  is the Fourier transform of the adaptive filter coefficients after convergence. In Fig. 9. we can see the filter chain which is presented after convergence.

We can also see the power spectral density [8] of the error microphone signal with and without the control algorithm applied in a broad band noise case in Fig. 10. Corresponding power spectrum of the spectra is shown in Fig.11. for suppression of tonal interference (sinusoidal at 200 Hz).

Fig. 9. Filter chain of the converged adaptive filter.

Fig. 10. Power spectral density of the error signal without (dashed) and with (solid) active noise control.

Fig. 11. Power spectrum of the error signal without (dashed) and with (solid) active noise control. Tonal interference sinusoidal at 200Hz.

**Abstract** — Digital Image processing has become ubiquitous in our daily life and the demands to produce and process images are ever increasing. Large amounts of space are required to store these images. Image compression techniques are in high demand as they allow reduction in this storage space. The basis for image compression, as is for most other compression techniques, is to remove redundant and unimportant data. Lossless image compression techniques retain the original information in compact form and do not introduce any errors when decompressed. In this paper, we discuss such a lossless technique using a data structure that we name “Generic Peano Pattern Mask Tree”. It is an improvement over a previously discussed Lossless Image compression technique – “Peano Pattern Mask Tree”. Both these structures are based on the data structure – Peano Mask Tree.

**Index terms** — Lossless Image Compression, Peano Tree, Peano Mask Tree, Peano Pattern Mask Tree, Generic Peano Pattern Mask Tree, Data mining Ready.

## I. INTRODUCTION

For many applications lossless image compression is extremely important to be able to store more images in a given amount of disk or memory space at the same time to retain the original image. Such applications include medical images, legal papers or image scans made for archival purposes, aerial photography from satellites etc. In these cases a perfect reproduction of the original image is necessary and any sort of degradation cannot be tolerated [2, 3].

There are basically two types of Image Compression methods: *Lossy* and *Lossless* [4]. Lossy compression involves the loss of some information that makes it capable of achieving much higher compression at the cost of accuracy. When the information from the compressed data using lossy technique is reconstructed, it introduces compression artifacts. In lossless compression schemes, the

reconstructed image, after compression, is numerically identical to the original image. A perfect reproduction of the original image can be achieved using it.

In this paper we are proposing a method of lossless image compression technique which is an improvement over a previous work done by Shams Mahmood et. al. [1] and Fazle Rabbi et. al. [2]. In the next sections of the paper we are giving a short description of Peano Count Tree, Peano Mask Tree and Peano Pattern Mask Tree. Also we will discuss how these data structures can be used in lossless image compression. After that we will introduce the improved version of Peano Pattern Mask Tree which we call ‘Generic Peano Pattern Mask Tree’ and its application in lossless image compression.

## II. PEANO TREES AND ITS VARIATIONS

### A. The Peano Count Tree

Peano Count Tree (P-tree) is a lossless, compressed, and data-mining ready data structure. The P-tree is a quadrant-based tree representation of the original spatial data [5, 6]. The general concept of P-tree is to recursively divide the entire spatial data into quadrants and to record the count of 1-bits for each quadrant, thus forming a quadrant count tree. Using P-tree structure, all the count information can be calculated quickly. For example, a P-Tree for the given  $8 \times 8$  image of single bit in figure 1 is explained below. Corresponding P-Tree is shown in figure 2.

```

1 1 0 0 1 0 1 1
0 1 0 0 1 0 0 1
1 1 1 1 1 0 1 0
0 1 1 1 1 0 1 0
1 1 1 1 1 1 1 1
1 1 1 1 0 1 1 1
1 1 1 1 1 1 1 0
1 1 1 1 0 1 1 0

```

Fig. 1. 8-bit by 8-bit image.

Fig. 2. P-Tree for data in figure 1.

In this example, 47 is the number of 1's in the entire image which is stored in root node which is labeled as level 0. The numbers 10, 9, 16, and 12 found at the next level (level 1) are the 1-bit counts for the four major quadrants in raster order, or Z order (upper left, upper right, lower left, and lower right). This process of storing the count of the number of ones for each of the major quadrants is repeated. When quadrants are composed entirely of 1-bits (called pure-1 quadrants), sub-trees are not needed, and these branches terminate. Similarly, quadrants composed entirely of 0-bits (called pure-0 quadrants), also cause termination. A quadrant which is neither pure-1 nor pure-0 is called mixed quadrant. This pattern is continued recursively using the Peano-ordering, or Z-ordering (recursive raster ordering), of the four sub-quadrants at each new level. Eventually, every branch terminates (since, at the "leaf" level, all quadrants are pure either pure-1 or pure-0).

#### B. The Peano Mask Tree

A variation of the P-tree data structure is the Peano Mask Tree (PM-Tree) in which masks, rather than counts, are used. In a PM-tree, we use three valued logic to represent pure-1, pure-0, and mixed quadrants. (A 1 denotes pure-1; 0 denotes pure-0; and M denotes mixed.) The PM-Tree for the previous

example is given in figure 3. We can easily construct the original P-tree from its PM-tree by calculating the counts from the leaves to the root in a bottom-up fashion.

This PM-Tree data structure was used for compression in [2]. It is obvious that this method will work excellent when neighborhood pixels share the same bit values with high probability. This is usually the case in higher-order bits for pixels in image data. However, neighboring lower order bits have different values due to precision difference. The PM-Tree structure does not provide good compression, if any at all, for such lower order bits. This happens as quadrants that are mixed are introduced and recursive definition of data quadrants goes on till pure-1 or pure-0 quadrants are one bit long. The above mentioned paper thus chose to use only the higher four bits to construct the PM Tree. However in instances where these higher order bits lack a high degree of correlation a similar problem to the one just described might occur. A PM-Tree has three states; at least two bits are required to save the information for each node of the tree. Two bits are able to provide us with four combinations; hence, one combination remains unexploited in the PM-Tree method. This lacking was addressed in [1] which proposed a new data structure, The Peano Pattern Mask Tree.

Fig. 3. PM-Tree for data in figure 1.

### C. The Peano Pattern Mask Tree

The Peano Pattern Mask Tree (PPM-Tree) is another variation of the P-Tree. It shares many features of the PM-Tree and addresses some unexplored area of the PM-Tree [1]. However, instead of using three-value logic, the PPM-Tree uses four-value logic. We name this fourth logic as P, for pattern. This pattern is not fixed like pure-1 or pure-0, but rather assumes dynamic values depending on the tree constructed. In fact, the pattern state is a special case of a mixed state. An example will help us better understand the method. To construct a PPM Tree for any data set, we first need to construct a PM Tree for the same data set. Once the PM Tree is created, we search through the leaf level quadrants to look for the most frequently occurring four-bit combination. In the example for PM Tree shown in figure 3, we see that “1101” is the most frequently occurring quadrant at the leaf level. We make this our Pattern and change the original PM Tree. All M nodes having the Pattern Parent property are transformed into a P node and all children removed. This search is carried out in a bottom-up manner where nodes at the lowest levels are transformed before any node at a higher level is transformed. As a result of this, we finally get the PPM Tree as shown in figure 4.

### D. Opportunities Unexplored in PPM-Tree

As mentioned earlier lower order bits for pixels in images share the same bit values with a low probability. As a result quadrants in the PM-Tree and PPM-Tree can usually be 1-bit long, which usually means no compression at all. Also due to the low probability of sharing bit values in neighborhood pixel, pure-0 and pure-1 quadrants are also rare. Hence the decision to stick with pure-0 and pure-1 as two of the four states do not help in compressing, i.e.

reducing the number of levels, the tree structure. We intend to address this lacking in the PPM-Tree structure and propose a new data structure, The Generic Peano Pattern Mask Tree.

### III. THE GENERIC PEANO PATTERN MASK TREE

The Generic Peano Pattern Mask Tree (GPPM-Tree) is another variation of the P-Tree. It shares many features of the PPM-Tree and addresses some unexplored areas. Like the PPM Tree, the GPPM uses four-value logic. Like the PPM-Tree there is one state reserved for the mixed (M) type. However unlike the PPM-Tree there are no fixed patterns, like the pure-0 and pure-1 in the PPM-Tree. Hence there are three states available for dynamic patterns which we name pattern-1 (P1), pattern-2 (P2), and pattern-3 (P3). P1, P2 and P3 are determined dynamically during the tree is created to result in maximum compression of the tree.

The GPPM-Tree improves on the PPM-Tree by being able to choose three of the available sixteen patterns. In the PPM-Tree we were able to choose only one of available fourteen patterns, “0000” and “1111” being reserved as pure-0 and pure-1 states respectively. It can be clearly seen that the GPPM-Tree structure is a more “generic” version of the PPM-Tree as none of the available sixteen patterns are given any special privilege prior to the construction of the tree. An example will help us understand better the GPPM-Tree structure. Consider the 8-bit by 8-bit image of Figure 1. When broken down to the leaf levels in the PM-Tree structure we get the tree in figure 5. We then perform a frequency distribution of the bit patterns in the leaf nodes. (Result in Table I.)

Fig. 4. PPM-Tree for data in figure 1.

an  $n$  pixel image. In our proposed scheme, we first construct  $24 \times n \times n$  dimensional arrays using each of the 24 bits of each pixel. We then create a GPPM tree for each of these arrays. If two of the patterns for the GPPM-Tree turn out to be “0000” and “1111”, then we store the tree as a PPM-Tree avoiding the overhead of storing the two additional patterns, else we store the tree as a GPPM-Tree. Next we decide if storing this GPPM-Tree/PPM-Tree for the corresponding data set from which it was generated requires lesser space than the raw data. If so then the tree is stored, else the original raw data is stored. We require a header file to keep track of which sets are stored in raw or one of the two compressed forms. Since we have three forms of storing the data we need two bits to store this information. The header file format is described below in table 2:

TABLE II  
PROPOSED FILE FORMAT

| Description                                                                                                        | Size in bytes |
|--------------------------------------------------------------------------------------------------------------------|---------------|
| Length of original image as a power of 2                                                                           | 1             |
| Bits representing which segment are stored in raw or compressed form.<br>[ $24 \times 2$ bits = 48 bits = 6 bytes] | 6             |
| Data for Red Component (8 Segments)                                                                                | Variable size |
| Data for Green Component (8 Segments)                                                                              | Variable size |
| Data for Blue Component (8 Segments)                                                                               | Variable size |

While storing the GPPM-Tree, we store the patterns in the first twelve bits (represented in bold in the figure 7) and then store the nodes of the tree in breadth-first order. Since we do this, we do not require storing a count of the number of nodes in the tree. While decoding the tree, decoding stops when all nodes are non-mixed nodes or nodes with quadrant size of 1 bit are reached. We can summarize the results of storing the raw bit pattern in Table 3.

|                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>1111 1101 1010</b> 11 11 11 00 11 01 11 01 00<br>10 01 10 10 01 00 01 10 0000<br><br>The first three 4-bit (bolded text) segments are the three chosen patterns. The next series of 2-bits (normal text) are representations for each of the non-1-bit length nodes/quadrants. The last series of 4-bits (emphasized text) are the patterns of the 1-bit length quadrants. |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

Fig. 7. Bit Representation of the GPPM-Tree of figure 6.

## V. EXPERIMENTAL RESULTS

In this paper we only compared the performance of our method to the compression scheme using PPM-

Tree which is mentioned in [1]. The superiority of PPM-Tree over PM-Tree is shown in [2]. A program was written for implementing the image compression scheme using GPPM-Tree. The result is summarized in Table IV. The images used in this experiment can be found at:

[http://picasaweb.google.com/shams.mahmood/AdvancedPPTImages?authkey=K7eg9oaO\\_p4](http://picasaweb.google.com/shams.mahmood/AdvancedPPTImages?authkey=K7eg9oaO_p4)

TABLE III  
SPACE REQUIRED IN STORING THE BIT PATTERN OF  
FIGURE 1 IN VARIOUS FORMATS

| Techniques | Number of bit requirements                                           |
|------------|----------------------------------------------------------------------|
| Raw data   | <b>64</b> bits                                                       |
| GPPM-Tree  | $(3 \times 4) + (17 \times 2) + (1 \times 4)$ bits = <b>50</b> bits. |
| PPM-Tree   | $(1 \times 4) + (17 \times 2) + (4 \times 4)$ bits = <b>54</b> bits  |
| PM-Tree    | $(17 \times 2) + (9 \times 4)$ bits = <b>70</b> bits.                |

The experimental results show that our proposed algorithm performs better than method in [1]. We see significant compression improvements have been achieved in certain cases (Jupiter\_Aurora and Bangladesh). We consider this as a quite significant improvement as the PPM-Tree structure was previously thought to be a mature and optimal evolution of the P-Tree structure. We also proof with the help of our results that the GPPM-Tree is a further improvement for storing data using P-Trees

TABLE IV  
EXPERIMENTAL RESULTS

| Image Name     | Image Dimension | Size in KB | Size using PPM-Tree | Size using proposed GPPM-Tree |

| Dell-wallpaper | 512 x 512       | 768.0      | 453.462             | 453.458                       |

## VI. CONCLUSION

P-tree has been successfully applied in data mining applications ranging from Classification and Clustering with K-Nearest - Neighbor, to Classification with Decision Tree Induction, to Association Rule Mining [7-10]. The P-Tree based decision tree induction method is significantly faster than existing classification methods [10, 11]. P-Tree

data structure allows computing the Bayesian probability values efficiently. Bayesian classification with P-trees has been used successfully on remotely sensed image data to predict yield in precision agriculture [7]. Experimental results showed that using p-tree techniques in an efficient association rule-mining algorithm, P-ARM has significant improvement compared to FP-growth and A-priori algorithms. [7]. Basic P-Trees can be constructed from the compressed file trivially after reconstruction of the GPPM Tree. Once the basic P-Trees have been created, we get data mining ready structure that facilitates efficient data mining tasks [1]. Thus the proposed scheme, the GPPM-Tree structure, is also a data mining ready structure providing it an upper hand over other compression techniques when used in data mining applications.

**Abstract** – Tissue-motions can represent the strength of artery pulsation of a newborn baby for pediatrics diagnosis. In this paper, we propose a novel method to estimate the tissue-motion quantitatively by combining local and global motion estimation methods, namely combined local-global (CLG) optical flow technique in cranial ultrasonogram of newborn babies. Tissue motions are estimated in different coronal sections successfully. Further, we analyze the time variant tissue-motion by using discrete Fourier transform. We also observed the pulsation in the time variant motion images and strong pulsation is observed in the harmonic frequency of tissue-motion that has a relation to the heartbeat frequency of a newborn baby.

**Index Terms** — Tissue-motion, artery pulsation, newborn baby head, CLG optical flow, cranial ultrasonogram.

## I. INTRODUCTION

Ultrasonogram is routinely used at the various sites of medical diagnosis because of its convenience, easy to use, low cost in compared with magnetic resonance imaging (MRI) and X-ray computed tomography (CT). Cranial ultrasound scans are essential part of the routine investigation during neonatal intensive care. The scan ultrasound image sequences are not only use for real-time diagnosis but also recorded for future diagnosis. Pediatricians use an ultrasonogram to find the cranial abnormalities in a newborn baby, since they can observe the brain tissue through the anterior fontanel [2, 5]. A key point of diagnosis is whether there is the artery pulsation accompanied with blood flow or not [5, 6]. However, there are a few attempts were taken to analyze the tissue-motion from the moving images of ultrasonogram for pediatrics diagnosis. In order to detect artery pulsation from a series of noisy ultrasound echo images of newborn baby head for pediatric diagnosis, a digital image processing system was developed by using the algorithm based on Fourier transform [6]. In order to observe artery pulsation in neonatal cranium at the site of diagnosis, a real time processing system was developed for continuous

display and detection of artery pulsation from moving images of neonatal cranial ultrasonogram [10]. The entire algorithms used above were mainly based on the time sequence variation of pixel value (intensity) in a series of ultrasound echo images. However, the pixel value can easily vary. Therefore, the above methods were very sensitive to the brightness of the original ultrasonogram movie. In this paper, we calculate the tissue-motion due to artery pulsation in cranial ultrasound image sequences by using CLG optical flow technique, which is not sensitive to image brightness change. This is very helpful for quantitative characterization of artery pulsation. Moreover, the time variant tissue-motions are analyzed by using Fourier transform, emphasizing that the tissue-motion at a particular frequency has a relation with heartbeat frequency of newborn baby.

The rest of the paper is organized as follows: Section II gives a brief introduction of brain tissue-motion and artery pulsation. Section III describes the CLG optic flow technique for estimating tissue-motion. In section IV, the proposed analysis of tissue-motion by Fourier transform is illustrated. Some experimental results of our method are illustrated in section V. Finally, we conclude this paper in section VI.

## II. TISSUE-MOTION AND ARTERY PULSATION

The velocity experience by brain tissue due to blood flow is known as *tissue-motion velocity*. The nature of the tissue motion velocity is periodic due to periodic nature of heartbeat and it varies time to time, baby to baby, and it depends on physical conditions. Therefore, tissue motion contains many harmonic components of the pulsation frequency. The tissue-motion velocities repeat themselves due to the periodic nature of heartbeat. Since the heartbeat also varies due to physical condition of newborn babies, the tissue motion velocities vary from time to time, baby to baby.

*Artery pulsation* is the periodic beating of arteries as blood pumps through arteries, and pulsation strength

represents the rating of blood flow to the brain-tissue through essential arteries in the brain. The tissue motion velocity is associated with blood flow. Therefore, pulsation strength can consider as the magnitude of tissue motion velocity, and therefore, a relationship exists between motion and heartbeat interval. Therefore, pulsation strength is lower or higher depends upon the blood flow rate or flow velocity.

### III. ULTRASOUND IMAGE TISSUE-MOTION ESTIMATION

It is well known that all motion estimation techniques are application-dependant and B-mode echocardiography motion estimation itself is a special frame work which is completely different from well-known ground truth sequences. Echocardiography signal has a particular speckled texture that is derived from the primary tissue microstructure and motion detection is based on this primary pattern displacements. Our contribution in this paper is implementing a combined form of optical flow based on two previous famous motion estimations methods (Lucas-Kanade and Horn-Schunck) using image moments instead of primary image pixels. To do that, appropriate window sizes and moment orders and sizes were obtained.

The cranial ultrasound image sequence of a newborn baby is taken as noisy, speckle-like gray scale image including non-rigid tissues such as cerebrums and arteries with local motion due to artery pulsation of blood flow [2]. Therefore, the tissue-motion may vary with time and place. For our analysis, we assume that artery in the cranial ultrasound is locally rigid and keeps its structure during instantaneous motion. Several methods [1, 3, 8] are available for estimating object motion. In order to calculate tissue-motion as the instantaneous optical flow over a local region, we use a combined local-global approach.

We use the optical flow to estimate local motion, because it can precisely establish the motion at any pixel. We calculate the optical flow velocity of any pixel within the region of interest by using the CLG optical flow technique [7]. The CLG optic flow method has complementary advantages over either the global [4] or local [9] method alone, due to its robustness against noise and the combination of local-global optical flow.

#### A. Global Motion Estimation (Horn and Schunck)

The general differential formulation of optical flow computation consists of assuming that the intensity of a particular point in a moving pattern does not change with time and we can write,  $p_x u + p_y v + p_t = 0$  [3]. In global optimization, a functional is defined where a smoothness constraint is used to regularize the solution of a partial differential equation and the smoothness

constraints is weighted with a positive constant. The functional is defined as:

$$\iint \left( (p_x u + p_y v + p_t)^2 + \alpha^2 (\|\nabla u\|^2 + \|\nabla v\|^2) \right) dx dy \quad (1)$$

where,  $p$  is pixel intensity with gradients toward spatial and temporal dimensions of the image, and  $u$  and  $v$  is the motion vectors toward  $x$  and  $y$  directions and  $\alpha$  is a weighting parameter [1, 3]. However primary global methods have visually attractive motion fields but lack the discontinuity preservation property.

#### B. Local Motion Estimation (Lucas-Kanade)

To overcome the sub-dimensionality of the optical flow formulation in Equation (2), Lucas-Kanade [9] proposed equation (3) to solve the problem on small local windows where the motion vector is assumed to be constant. We ought to minimize this equation:

$$\sum W^2 (p_x v_x + p_y v_y + p_t)^2 \quad (2)$$

where,  $p$  is pixel density and  $W$  is a weighted window and  $u$  and  $v$  are the motion vectors towards  $x$  and  $y$  directions [9].

#### C. Combined Local Global (CLG) Motion Estimation

As discussed before, to solve the problem of sensitivity to noise, Bruhn et al. [7] proposed a method to combine local [9] with global [3]. To give a combined local-global method, let us reformulate the previous formulae: We consider spatio-temporal CLG motion,  $w = [u, v, 1]^T$  at a pixel  $x = (x, y)$  in time  $t$ , velocity gradient:

$$\nabla w = [\nabla u, \nabla v]^T, \text{ intensity gradient } \nabla_3 p = (p_x, p_y, p_t)^T,$$

and motion tensor :  $J_p(\nabla_3 p) = K_p * (\nabla_3 p \nabla_3 p^T)$ .  $K_p$  is the smoothing kernel (spatial or spatial-temporal). It is evident that Lucas-Kanade minimizes the quadratic form:

$$\begin{aligned} E_{LK} &= K_p (p_x u + p_y v + p_t)^2 \\ &= \begin{bmatrix} u \\ v \\ 1 \end{bmatrix} \cdot \begin{bmatrix} p_x^2 & p_x p_y & p_x p_t \\ p_x p_y & p_y^2 & p_y p_t \\ p_x p_t & p_y p_t & p_t^2 \end{bmatrix} \cdot \begin{bmatrix} u & v & 1 \end{bmatrix} \quad (3) \\ &= w^T J_p(\nabla_3 p) w \end{aligned}$$

where,  $K_p$  is the local kernel (usually a Gaussian),  $E_{LK}$  is the energy function of Lucas-Kanade and  $p_x, p_y, p_t$  denote the image intensity gradient with respect to Cartesian and temporal dimensions. We have a similar formulation for Horn and Schunck with an iterative recursion:

$$E_{HS}(w) = \int_{\Omega} (w^T J_0(\nabla_3 p)w + \alpha |\nabla w|^2) dx dy \quad (4)$$

where,  $E$  is the energy function of HS (Horn-Schunck),  $J$  is the motion tensor and  $w$  is the motion vector [10]. Then we can rewrite:

$$\nabla_3 p = (p_x, p_y, p_t)^T = J_p(\nabla_3 p) = K_p * (\nabla_3 p \nabla_3 p^T) \quad (5)$$

By replacing the structure tensor  $J_0(\nabla_3 p)$  instead of matrix  $J_p(\nabla_3 p)$ , we will have:

$$\Delta u - \frac{1}{\alpha} (p_x^2 u + p_x p_y v + p_t p_x) = 0 \quad (6)$$

$$\Delta v - \frac{1}{\alpha} (p_x p_y u + p_y^2 v + p_t p_y) = 0 \quad (7)$$

Its minimization induces below equation which satisfies Euler-Lagrange formula:

$$\Delta u - \frac{1}{\alpha} (K_p(p_x^2)u + K_p(p_x p_y)v + K_p(p_x p_t)) = 0 \quad (8)$$

$$\Delta v - \frac{1}{\alpha} (K_p(p_x p_y)u + K_p(p_y^2)v + K_p(p_y p_t)) = 0 \quad (9)$$

Now, the spatiotemporal combined local-global approach is defined as:

$$E_{CLG}(w) = \int_{\Omega} (w^T J_p(\nabla_3 p)w + \alpha |\nabla w|^2) dx dy \quad (10)$$

Combining the temporal extended variant of both [4] and [12] method, we obtain a spatio-temporal version of the combined local-global functional which is given by,

$$E_{CLG}(w) = \int_{video} (w^T J_p(\nabla_3 p)w + \alpha |\nabla w|^2) dx dy dt \quad (11)$$

Therefore, based on Lagrange equations, we have:

$$0 = \sum_{j \in N(i)} \frac{u_j - u_i}{h^2} - \frac{1}{\alpha} (J_{11i} u_i + J_{12i} v_i + J_{13i}) \quad (12)$$

$$0 = \sum_{j \in N(i)} \frac{v_j - v_i}{h^2} - \frac{1}{\alpha} (J_{21i} u_i + J_{22i} v_i + J_{23i}) \quad (13)$$

for  $i = 1, 2, \dots, N$  and  $N(i)$  denote the set of neighborhood of pixel  $i$ . After a simple calculation, the iterative formulations in (14) and (15) are resulted.

$$u_i^{k+1} = (1 - \omega) u_i^k + \omega \frac{\sum_{j \in N^-(i)} u_j^{k+1} + \sum_{j \in N^+(i)} u_j^k - \frac{h^2}{\alpha} (J_{12i} v_i^k + J_{13i})}{|N(i)| + \frac{h^2}{\alpha} J_{11i}} \quad (14)$$

$$v_i^{k+1} = (1 - \omega) v_i^k + \omega \frac{\sum_{j \in N^-(i)} v_j^{k+1} + \sum_{j \in N^+(i)} v_j^k - \frac{h^2}{\alpha} (J_{21i} v_i^k + J_{23i})}{|N(i)| + \frac{h^2}{\alpha} J_{22i}} \quad (15)$$

where,  $N^-(i) = \{j \in N(i) | j < i\}$ ,  $N^+(i) = \{j \in N(i) | j > i\}$ , and  $|N(i)|$  is the number of neighborhood pixel region for implementing Gauss-Seidel iteration. Here,  $i$  and  $j$  indices determine the backward and forward Gauss-Seidel iterative pixels and  $k$  defines the iteration number [7]. From motion components, the absolute value of tissue-motion,  $V(x, y, t) = \sqrt{v_x^2 + v_y^2}$  and the phase angle,  $\phi = \tan^{-1}(v_y / v_x)$  is determined.

#### IV. DFT ANALYSIS OF MOTIONS

The discrete Fourier transform is meaningful to inspect magnitude versus frequency plot for changes the discrete tissue motion versus time at a particular frequency than to observe the tissue-motion with time variation. Since time variant tissue-motions contain different frequency components, so the analysis by Fourier transform is helpful to detect such frequency in which pulsation occurs. The tissue-motion at any pixel position  $V(x, y, t)$  can be stated as  $V(k\delta t)$  at any position  $(x, y)$  with sampling interval,  $\delta t$  where  $k$  is the sample index  $[0 \leq k \leq n-1]$ . Now, the discrete Fourier transform,  $V(f)$  of  $n$ -number of samples, time variant tissue-motion as one-dimensional function,  $V(k\delta t)$  is defined as [4]:

$$V(f) = \sum V(k\delta t) e^{-\frac{j 2 \pi f k}{n}} \quad (16)$$

where,  $f$  = frequency index. At a particular frequency  $V(f)$  has two parts; i.e. one is real part that contains cosine term,  $R(f) = \Re[V(f)]$  and the other is imaginary term,  $I(f) = \Im[V(f)]$  and therefore the power spectral density of motion,  $P(f)$  is given by:

$$P(f) = |V(f)|^2 = R^2(f) + I^2(f) \quad (17)$$

Pulsation frequency,  $f_p$  at which the maximum spectral density occurs, evaluates among different frequency components by the following relationship:

$$f_p = \max_{1 \leq f \leq n/2} \{P_f(x, y)\} \quad (18)$$

where,  $P_f$  is the power spectrum at any position in the harmonic image.

## V. EXPERIMENTAL RESULTS AND DISCUSSION

The original cranial ultrasound images of the newborn baby head were taken in B-mode by using an ultrasound probe of 5 MHz and recorded on video tapes at the site of pediatricians, which is shown in Fig. 1.

Fig. 1. Cranial Ultrasonogram of newborn baby head with an image of coronal section II.

Then a series of ultrasound echo images (32 frames,  $640 \times 480$  pixels/frame, 8 bits/pixel, 33 ms/frame) was captured by a PCI-based PC with video digitizer. Figure 1 (c) shows a typical image in the anterior coronal section (section II) in the cranial ultrasonogram. We also show the region of interest (ROI) by the white border line in Fig. 1 (d). The detailed scheme of essential tissue in this section is shown in Fig. 2. In Fig. 1 (d), the necessary tissues and organs are shown within a white boundary line. Outside it, there are cranial bones and echo artifacts. The coronal image shows the symmetrical property with left and right parts.

Fig. 2. The essential tissue-scheme in the anterior coronal section (section II). 1: Corpus callosum, 2: Lateral ventricle, 3: Head of caudate nucleus, 4: Sylvian fissure, 5: Lenticular nucleus, 6: Middle cerebral artery, 7: Body of sphenoid bone, 8: Temporal lobe.

Therefore, we can use a portion of the image [square block with enhanced brightness in Fig. 1(d)] in a sequence of our analysis. As preprocessing steps, we have checked several critical conditions of the image sequence, such as (i) sway of the ultrasound probe, (ii) sway of the head of baby, (iii) discontinuity of the image frames, and (iv) completely dark or bright of any image frame in the sequence.

Fig. 3. Different coronal section images with tissue-motion overlapping on the images. (II, III, IV, and V mean coronal sections). Green color vectors show the motion.

We calculate the tissue-motion velocity at each pixel by using a combined local global method for all the coronal sections in consecutive two frames of cranial ultrasound echo images of the newborn baby head by using the spatial and temporal gradients. The ultrasound images as well as the tissue-motions overlapping the images are shown in Fig. 3. We also show the tissue-motion vector of the ROI and the precise vector diagram of the specified region of Fig. 1 is shown in Fig. 4. In the arterial region, the motions have significant value.

Fig. 4. Two-dimensional maps of tissue-motion vectors in the anterior coronal section of cranial ultrasonogram of newborn baby head.

Fig. 5. Time-variant tissue-motion velocities

For computing the frequency components of tissue-motion, we use fast Fourier transform [8]. We do not consider the motion appeared outside cranial bone. In addition, no motion is found in the region of cranial bone.

For simplicity, we have used a portion of the image in the sequence, since it contains the essential tissues and organs such as middle cerebral artery, sylvian fissure and temporal lobe, is shown as enhanced in Fig.1.

Figure 5 shows the two-dimensional maps of time-variant tissue-motion vector of the portion of cranial ultrasonogram. The magnitude of tissue-motion vectors are normalized so that the distance between two neighbor pixels in the map corresponds to 0.5 pixels/frame. The tissue-motion vectors vary with place and its magnitude becomes up to a few pixel/frame at several region within

the cranial bone. The middle cerebral artery is one of the essential arteries in the brain and there are fine arteries around sylvian fissure and corpus callosum. The spatial distribution of large motion vectors has found in the above regions. On the other hand, motion vectors become zero on the cranial bone and at such tissues as lenticular nucleus which is also shown in Fig. 4. Furthermore, the maximum vectors are aligned to the same directions at many regions of the images.

The motion vectors do not vary only place but also with time, which is shown in Fig. 5. Pulsation regions were found with strong pulsation and the magnitude of motion is high in the region of middle cerebral artery and near region. Thus, it is very useful to observe the periodical variation of motion as well as the magnitude of tissue motion over time in different area where different organs are involved.

Fig. 6. Power spectrum of tissue-motion at different frequency.

The heart rate of the typical baby is 140 per minute observed at the time of image sequence capturing. Therefore, the heartbeat interval of this typical baby is 429ms. The corresponding pulsation frequency is 2.33Hz. By using sampling interval 33 ms and the number of samples 64, the frequency resolution is obtained at 0.47 Hz. Therefore, fundamental frequency of the heartbeat occurs in between 4th and 5th harmonic frequency of tissue-motion. This is illustrated in Fig. 6, where the power spectrum of tissue-motion at different frequency is shown.

We show only a few images out of a large number of images. The strong pulsation is found in the image that corresponds to the frequency of 1.84Hz and 2.35 Hz. Therefore, strong pulsation is found in a frequency, which is not the fundamental frequency of heartbeat frequency but the harmonic frequency of pulsation frequency.

This fact represents that pulsation is not sinusoidal, and the period of Fourier transform is not equal to the integer time of the period of heartbeats. The normalized power spectral density is shown in Figure 6 at different

frequency. Here 8 frequency components are shown. It is clear that tissue-motion contains several harmonic pulsation frequency components. From Fig. 7, it is clear that the strong pulsation occurs at 4th harmonic frequency of heartbeat frequency and the tendency of the neighbor frequency is high enough. We have tested several sections, using both 32 and 64 samples, several cranial ultrasonogram images of newborn babies, and find the similar results. The babies exhibit different pulsation, since their physical conditions were different. The plot in Fig. 9 shows the normalized power spectrum of some babies at different pulsation frequency.

Fig. 7. Histogram showing the power spectral density at different frequency.

## VI. CONCLUSIONS

We successfully computed the tissue-motion by using a combined local-global optical flow method for characterizing artery pulsation quantitatively without losing the benefits of local and global method. Since tissue-motion is not affected by spatial variation of image brightness, therefore the strength of artery pulsation can be quantitatively estimated by using the magnitude of tissue-motion velocity. From frequency analysis, it is found that pulsation is associated with blood flow is periodically changed with heartbeat is verified by using Fourier transform of time variant motion. Strong pulsation is found at a harmonic frequency, which is related to heartbeat frequency, and the tissue-motions are not sinusoidal. Our future work includes precise and automatic detection and estimation of artery pulsation from noisy cranial ultrasound image sequences.

**Abstract** — Existing vertex-based shape coding algorithms use a number of different distortion measurement techniques including the *shortest absolute distance* (SAD), *distortion band* (DB) or *tolerance band* (TB), *accurate distortion measurement technique for shape coding* (ADMSC) and *distortion measurement based on chord-length-parameterisation* (DMCLP). Among these techniques DMCLP is computationally the fastest. It however, is a relaxed measurement technique and does not fully utilise the admissible distortion within the rate-distortion optimisation. This paper presents a novel *distortion measurement technique based on arc-length-parameterisation* (DMALP) within the vertex-based shape coding framework. Experimental results vindicate its superior performance over the existing geometric distortion measurement techniques.

**Index Terms** — Image coding, image/video coding and transmission, video coding.

## I. INTRODUCTION

Despite facilitating increasingly effective retrieval, manipulation and interactive editing functionality for both natural and synthetic video sequences, object-oriented video coding using shape information remains a challenging research topic [1-4]. The universal pursuit for efficiency in existing communication technologies means that applications such as video-on-demand, video streaming over the Internet, real-time applications and mobile video transmissions for handheld devices as well as real-time identification and authentication systems will derive significant benefits from strategies enabling fast shape coding.

The rigorous review of shape coding algorithms presented in [1] draws the conclusion that the classical vertex-based shape coding framework is optimal in an *operational rate-distortion* (ORD) sense. With both polygonal and quadratic B-splines (BS) based strategies being deployed, it has become the core for several other shape coding algorithms [2-5]. The broad aim of these algorithms is that for some prescribed distortion, a shape contour is optimally encoded in terms of the number of bits, by selecting a set of *control points* (CP) that incurs the lowest bit-rate and vice versa. Distortion measures thus play a vital role in these algorithms, as evidenced in [1], either the *shortest absolute distance* (SAD) or

*distortion band* (DB) measure is applied. A generalisation of DB is the *tolerance band* (TB) which supports a variable *admissible distortion* (AD) [2, 4], though it inherits the same performance characteristics of the DB including the propensity for trivial solutions. Furthermore, while both SAD and DB guarantee all points on the approximating curve are bounded by the peak distortion, they do not ensure that each boundary point maintains the AD particularly at shape corners. This anomaly has been solved by the new *accurate distortion measurement technique for shape coding* (ADMSC) [5]. Since distortion measurement is seamlessly integrated into the ORD optimal shape coding framework, the overall computational complexity of these algorithms is highly dependent on the distortion measurement overhead. In order to ensure computationally efficient encoding, it is essential to employ a fast technique. For both polygon and BS-based encoding, the DB and TB incur  $O(N_B^2)$  computational complexity, where  $N_B$  is the number of boundary points. Additionally, the computational impost for DB and TB proportionally increases with AD as the width of the respective admissible bands widens. In contrast, the SAD and ADMSC measures require  $O(N_B)$  time for polygonal encoding, but still mandate  $O(N_B^2)$  time for BS-based encoding. BS encoding is mostly used since it affords a twofold superiority over its polygonal counterpart, in firstly requiring a lower bit-rate since higher degree curves are used and secondly curve smoothness, due to the inherent parametric continuity of BS. To address these issues a new distortion measurement technique based on chord-length-parameterisation (DMCLP) [6] was proposed. DMCLP incurs only  $O(N_B)$  computational cost for both polygon and BS-based shape coding.

Since DMCLP is based on *chord-length-parameterisation* (CLP), it determines a value of  $u$  for each contour point, which is then employed to obtain the approximating BS (or polygon) point for that contour point. The location of these approximating points are not only dependent on  $u$ , but also dependent on the distance between the consecutive CP. Concentration of these points is greater in the area close to a smaller control polygon edge than a large one. Consequently, DMCLP over-

calculates (the calculated distortion is more than the actual distortion) the distortion and can reject a candidate CP set on the ground that it did not maintain AD, despite being maintained the opposite. Therefore, it can lead to an unnecessarily high bit-rate requirement. To overcome this problem this paper presents a novel *distortion measurement technique that utilises the arc-length-parameterisation* (DMALP). In fact, *arc-length-parameterisation* (ALP) produces an equal unit distance between the consecutive BS-points, which resembles the one unit distance between consecutive contour points on a one pixel neighbourhood. In this technique the values of  $u$  are calculated based on a modified CLP and then combined with the weights obtained from the ALP [7]. Experimental results confirm the superior performance of DMALP compared with the DMCLP and the others. It should also be noted that alike DMCLP, DMALP incurs only  $O(N_B)$  computational time for both polygon- and BS-based shape coding.

The rest of this paper is organised as follows: Section II provides a short overview of the existing distortion measurement techniques within the vertex-based shape coding framework. Section III details the new DMALP technique for both BS and polygon based encoding. Section IV provides a thorough discussion on the empirical results and performance comparison with DMALP embedded into the original ORD framework. Some concluding remarks are given in Section V.

## II. EXISTING DISTORTION MEASUREMENT TECHNIQUES WITHIN THE VERTEX-BASED ORD OPTIMAL SHAPE CODING FRAMEWORK

Existing ORD optimal shape coding algorithms seek to determine and encode a set of CP representing a particular shape. Let the contour  $B = \{b_0, b_1, \dots, b_{N_B-1}\}$  be an ordered set of points.  $S$  is an ordered set of CP used to approximate  $B$  with  $S \subseteq C$ , where  $C$  is the ordered set of vertices in the admissible CP band. The original ORD framework detailed in [1-3], is valid for both polygon and BS-based models and determines an optimal  $S$  for  $B$  within RD constraints. As the choice of the distortion metric clearly has a significant impact upon both computational speed and quality of this framework, the existing distortion measurement techniques will now be briefly examined.

*The shortest absolute distance:* This is the most straightforward and widely used geometric shape distortion measurement technique [1]. With SAD, distortion for any arbitrary shape point is defined as the perpendicular distance of that point from the corresponding line segment (or its extension) of the approximated shape polygon. Though it is simple to

compute, this metric however does not always accurately reflect the true distortion since the perpendicular distance may not always correspond to the actual distance for all shape points. For instance, when the shortest absolute distance from the extended part of a line segment is considered to be the minimum distance between a shape point and the line, it fails to represent the actual distance [5]. Apart from this, while the overall computational complexity of SAD is  $O(N_B)$  for polygonal encoding, it requires  $O(N_B^2)$  cost for BS-based coding.

*Tolerance band:* TB works as follows [2, 4]: draw a circle around each  $b_r$  of radius  $T[r]$  which is the AD at  $b_r$  and is determined from the prescribed admissible bounds ( $T_{\max}$  and  $T_{\min}$ ); TB consists of the set of all points that lie inside the circles; check the distortion, if all points on a candidate edge (curve) lie inside the TB, it is considered that the candidate edge (curve) maintains the distortion criterion. Thus, every point on the candidate edge (curve) is required to be checked to see whether it belongs to the TB points set. The number of points compatible with the TB-grid on a candidate edge (curve) is of  $O(N_B)$  while TB itself comprises a set of  $O(N_B)$  points, so the entire checking process for a candidate curve necessitates  $O(N_B^2)$  computational cost in the worst case. However, as the distortion of each individual associated boundary point is not tested to see if it lies within TB, this inherits the same accuracy measurement problems as DB [5].

*Accurate distortion measurement technique for shape coding:* ADMSC [5] considers all possible relative positions of a point with respect to an edge, it always measures the distortion accurately. Hence, the inaccuracy problems associated with both SAD and TB techniques are solved with this ADMSC. In polygonal encoding, the edge-distortion for all associated boundary points are calculated from the candidate edge and checked against the corresponding AD which takes  $O(N_B)$  computational time. BS encoding however, requires  $O(N_B^2)$  cost to check the distortion because a BS curve is in fact a concatenation of piecewise polygon-edges and so for each boundary point associated with a candidate curve, the individual distortion has to be measured from all edges that form the curve. The minimum edge-distortion is then taken as the distortion for that particular boundary point and checked with the corresponding AD.

*Distortion measurement using chord-length-parameterisation:* The philosophy in DMCLP [6] is that if there is an associated approximated point to each contour point, distortion can be measured as the Euclidean distance between these two points. Therefore, for each contour point it determines a value of BS control parameter  $u$  and thus an approximating BS point.

Figure 1: Illustration of the problem with the DMCLP.

It is computationally the most efficient amongst these distortion measurement techniques and incurs  $O(N_B)$  time for both polygon and BS-based encoding. However, DMCLP over-calculates the distortion. The location of BS points does not only depend on  $u$ , but also on the distance between consecutive CP. The concentration of these points is greater in the area close to the smaller control polygon edge than the large edge. For instance, as in Figure 1, the concentration of BS points is higher in the part close to the edge  $s_k s_{k+1}$  than that of  $s_k s_{k-1}$ . It shows the 17<sup>th</sup> point of both the contour and the approximating BS curve encircled. It is clearly visible that despite the distortion at the 17<sup>th</sup> contour point with respect to the entire approximating BS curve is much lower than the point to point distance obtained by DMCLP. Therefore, despite producing a smaller distortion, DMCLP can reject this CP set and hence lead to an unnecessarily high bit-rate requirement. To overcome this problem the following section presents a novel distortion measurement technique based on ALP.

### III. DISTORTION MEASUREMENT TECHNIQUE USING ARC-LENGTH-PARAMETERISATION

The philosophy behind the ALP is that it define a set of weights for the parametric curve coefficients so that the generated curve points obtain a ‘unit speed’ [7]. It alternatively means the distance between the consecutive curve points is ‘equal’. It resembles the fact that the contour points also form a chain in a one pixel neighbourhood. So if the number of BS points, i.e., the number of steps in  $u$  is equal to the number of contour points, then a BS point would lie within a close area of the corresponding contour point. The overall process is performed in two modules. In the first module the value of  $u$  is determined using a modified CLP. For an arbitrary curve segment having start and end indices  $k_1$  and  $k_2$  respectively of the associated boundary points in  $B$ , the values of  $u$  can be determined as:

$$u_r = \begin{cases} 0 & \text{if } r = k_1 \\ \frac{|b_{k_1} b_{k_1+1}| + |b_{k_1+1} b_{k_1+2}| + \dots + |b_{r-1} b_r|}{|b_{k_1} b_{k_1+1}| + |b_{k_1+1} b_{k_1+2}| + \dots + |b_{k_2-1} b_{k_2}|} & \text{otherwise} \end{cases} \quad (1)$$

where  $u_r$  is associated to  $b_r$ . In DMCLP  $|b_{r-1} b_r|$  is the Euclidean distance between  $b_{r-1}$  and  $b_r$ . However, this approach has a limitation. In this form  $u$  monotonically increases with the value of  $r$ . But in many cases, despite the fact that there is an increment in the contour point index, there is no real advancement of the position of the contour point with respect to the baseline (the line joining the two end control points). Consequently, though the contour point is not moved, the corresponding BS point is moved, and hence can lead to the over-calculation of distortion. This scenario can be explained with the example in Figure 2. It shows that for the 3<sup>rd</sup> contour point the BS point is quite close to it. But although for the next few contour points there is a little advancement in the direction of baseline, the BS points have moved away. For example, the 6<sup>th</sup> contour point and its corresponding BS point are encircled and the distance between them is quite high. To overcome this limitation, it is important to use the projection of the distance between  $b_{r-1}, b_r$  on the baseline, rather than using the geometric distance. If the angle is  $\beta$ , then the projection would be  $\text{distance}(b_{r-1} b_r) \cdot \cos(\beta)$ . Since, 1 pixel neighbourhood is considered for the contour chain, if the angle between the baseline and the global coordinate is also converted to the same pixel grid, depending on the angle the values of

$|b_{r-1} b_r|$  would be either 0 or 1.

Figure 2: Illustration of the problem with the CLP.

In the second module, ALP is performed to obtain the weights  $w$  so that an equal distance between the CP is achieved. As detailed in [7], for a quadratic curve ALP can be obtained as follows:

$$Q_6 = \left( |\Delta s_{k-1}|^2 + 6 \cdot |\Delta s_k|^2 + 3 \cdot |\Delta s_{k-1}| \cdot |\Delta s_k| \right) \quad \text{and} \\ -Q_0 = \left( 6 \cdot |\Delta s_{k-1}|^2 + |\Delta s_k|^2 + 3 \cdot |\Delta s_{k-1}| \cdot |\Delta s_k| \right)$$

where  $|\Delta s_k| = s_{k+1} - s_k$ .

$$\text{So } \alpha_{\min} = \left( 1 + \sqrt{-Q_6/Q_0} \right)^{-1}$$

Hence, the optimal parameterisation coefficients are

$$w_j = (1 - \alpha_{\min})^j \cdot (\alpha_{\min})^{2-j} \quad \text{for } j = 0, 1, 2. \quad (2)$$

The combination of these weights and the respective value of  $u$ , will be employed to calculate the approximating point corresponding to a contour point. The distortion is then calculated using point to point distance between them. The overall DMALP technique is formalised in Algorithm 1.

**Algorithm 1:** The proposed distortion measurement based on arc-length-parameterisation (DMALP).

Inputs:  $B$  - boundary,  $s_{k-1}, s_k, s_{k+1}$  - control points,  $T$  - AD,  $k_1, k_2$  - indices of the associated boundary points.  
Output: *Flag* - 1 means distortion criteria upheld; 0 means not upheld.

- 
1.  $Flag = 1$ ;  $chord\_len_{k_1} = 0$ ;
  2. FOR  $\forall r, k_1 < r \leq k_2$
  3.      $chord\_len_r = chord\_len_{r-1} + |b_{r-1}b_r|$  using (1);
  4. FOR  $\forall j, 0 \leq j \leq 2$
  5.     Determine  $w_j$  using (2);
  6. FOR  $\forall r, k_1 \leq r \leq k_2$
  7.      $u_r = \frac{chord\_len_r}{chord\_len_{k_2}}$ ;
  8.     Calculate the approximating point  $q$  using  $u_r$  and  $w$ ;
  9.      $dist = |qb_r|$ ;
  10. IF  $dist > T[r]$   $Flag = 0$ ;
- 

It will now be proven in Lemma 1 that DMALP maintains AD for all boundary points.

**Lemma 1:** If  $d[r]$  and  $T[r]$  are respectively the generated and AD for an arbitrary boundary point  $b_r$ , the DMALP technique always upholds the AD so that  $d[r] \leq T[r]$ .

**Proof:** By embedding DMCLP into the vertex-based ORD optimal shape coding framework, every boundary point will have a respective point on the encoded shape. If the distortion defined in Step 9 of Algorithm 1 at  $b_r$  is  $dist_r$  and distortion (shortest distance) for the same point with respect to the final approximated shape is  $d[r]$ , then  $d[r] \leq dist_r$ . In the distortion test (Step 10), for any curve segment to be included in the encoded shape,  $dist_r \leq T[r]$  must hold true, so that  $d[r] \leq T[r]$ .

**Computational complexity analysis:** In terms of the order of complexity of Algorithm 1, Steps 2-3 calculate

the cumulative chord-length of the boundary at a cost, in the worst case of  $O(N_B)$ , while Steps 4-5 determine the reparameterisation  $O(N)$  time, where  $N$  is the degree of the curve. For quadratic BS and polygon based approximation the value of  $N$  is 2 and 1 respectively. Steps 6-10 firstly determine the value of  $u$  and then generate the approximating point before checking to see whether the AD is maintained which also incurs  $O(N_B)$ . The overall complexity for Algorithm 1 in the worst case is therefore,  $O(N_B)$ , which is equal to the DMCLP and one degree less than all other existing distortion measurement techniques for BS based encoding. The main difference between DMALP and DMCLP is the calculation of reparameterisation coefficients in Steps 4-5 and their use in Step 8.

#### IV. RESULTS AND ANALYSIS

To analyse the performance of DMALP compared with the existing distortion measurement techniques, the ORD shape coding algorithms including the SW strategy were implemented in Matlab (R2007a) and applied to a number of test shape sequences. The experiment platform was 2.67GHz Pentium-4 microprocessor, with four Gigabyte RAM under Windows XP.

Figure 3(a) plots the rate vs distortion results for BS-based encoding upon the popular *Kids* video sequence (SIF, 300 frames) while Figure 3(b) provides a zoom-in of the section highlighted by the rectangle in (a). It should be noted that  $D_n$  is MPEG-4 standard distortion metric. From the plot it is apparent that DMALP produced superior rate-distortion (RD) results than the DMCLP. This is due to the ALP of the control parameter. DMALP also produced better RD results compared with TB/DB and SAD. ADMSC always produces the best rate-distortion result because it always calculates the actual distortion. However, when the computational time complexity is the concern, as shown in Figure 4, ADMSC is outperformed by both DMCLP and DMALP, which warrants the theoretical fact that ADMSC mandates  $O(N_B^2)$  time while both DMALP and DMCLP take only  $O(N_B)$  time. The slightly higher time requirement in DMALP compared with DMCLP is due to the additional computation required for reparameterisation of the weight coefficients. In terms of both bit-rate and computational time, DMALP outperforms TB and SAD.

Table I summarises the numerical results produced by the different distortion measurement techniques couple with polygon-based framework upon various test sequences for  $T_{\max} = 2$ ,  $T_{\min} = 1$  pixels. It shows that the RD performance of DMALP is consistently better than DMCLP. These results also exhibit that DMALP,

ADMSC and DMCLP always maintain the AD which is not the case for either SAD or TB.

Figure 3: Performance comparison – (a) rate-distortion and (b) zoom-in.

A cursory look may reveal that SAD and TB required fewer bits than the others. But it is not due to the efficacy of SAD or TB, it is rather due to the fact that they fail to maintain the AD (see Sections I and II, and [5] for details) and thereby saving a few bits at the cost of erroneous and

large distortion. Since the computational complexity of the distortion measurement process has a direct impact on that of the shape coding framework, a further series of experiments was conducted to compare the computational time requirements incurred by algorithm combinations for various AD pairs. Table II summarises the total *central processing unit* (CPU) time for various algorithm implementations.

Figure 4: Time-distortion performance comparison.

From the results in Table II, it is readily apparent that those algorithms using DMALP as their distortion measure were computationally faster compared with the respective SAD, TB and ADMSC counterparts and comparable to DMCLP, to underscore the theoretical time complexity analysis presented in Sections I and II. For instance, with  $T_{\max} = 3$ ,  $T_{\min} = 1$  pixels, *B-spline-SAD*, *B-spline-TB*, *B-spline-ADMSC*, *B-spline-DMCLP* and *B-spline-DMALP* respectively required 565 , 620.3 , 578.8, 312.5 and

313 seconds, so vindicating that while SAD, TB and ADMSC cost  $O(N_B^2)$  for BS-based encoding, the

| <i>B-spline-DMCLP</i>   | 270.20                             | 290.30                             | 297.00                             | 312.50                             | 314.30                             |
| <i>B-spline-DMALP</i>   | 271.05                             | 291.20                             | 297.50                             | 313.00                             | 315.20                             |

overhead for DMALP is only  $O(N_B)$ , which is the same as DMCLP. The slightly higher time requirement for DMALP compared to DMCLP is due to the reason of reparameterisation discussed in Section III. For polygon-based encoding, DMALP algorithms also required less time than their ADMSC based counterparts, while as expected TB algorithms consistently incurred a significantly greater time overhead because SAD, DMALP and ADMSC all are of order  $O(N_B)$  compared with  $O(N_B^2)$  for TB.

## V. CONCLUSION

This paper has presented a novel *distortion measurement* technique based on *arc-length-parameterisation* (DMALP) which can be seamlessly embedded into the classical vertex-based rate-distortion optimal shape coding framework to improve the overall RD performance without increasing the computational time complexity order. It has been proven that DMALP always maintains the admissible distortion. Experimental results have shown that among the existing distortion measurement techniques DMALP is the best next to DMCLP in terms of computational time requirement and has outperformed DMCLP in terms of RD with a much larger margin while it is comparable with the others.

**Abstract** – The efficiency of Hilbert spectrum (HS) in time-frequency representation (TFR) of audio signals is investigated in this paper. HS is derived by applying empirical mode decomposition (EMD), a newly developed data adaptive method for nonlinear and non-stationary signal analysis together with Hilbert transform. EMD represents any time domain signal as a sum of a finite number of bases called intrinsic mode functions (IMFs). The instantaneous frequency responses of the IMFs derived through Hilbert transform are arranged to obtain the TFR of the analyzing signal yielding the HS. A new frequency scaling method is introduced here for proper interpretation of the energy spectra in HS. The performance of HS is compared with well known and widely used short-time Fourier transform (STFT) technique for TFR. The experimental results show that HS based method performs better than STFT in time-frequency representation of the audio signals

**Index Terms** — Empirical mode decomposition (EMD), Hilbert-Huang transformation (HHT), instantaneous frequency, time-frequency representation (TFR).

## I. INTRODUCTION

The time-frequency distribution of a signal provides information about how the spectral content of the signal evolves with time, thus providing an ideal tool to dissect, analyze and interpret non-stationary signals. The need for a time-frequency representation (TFR) is stemmed from the inadequacy of either time domain or frequency domain analysis to fully describe the nature of non-stationary signals. The TFR of audio signal has many potential applications including blind signal separation, speech recognition, signal characterization and speech enhancement. A variety of methods for obtaining the energy density as a function of time and frequency simultaneously have been devised, most notably the short time Fourier transform (STFT), the wavelet transform (WT) and the Wigner-Ville distribution (WVD). The TFR is also used to clarify, and provide additional information about the behaviour of the non-stationary signals.

The short-time Fourier transform (STFT) localizes the signal by modulating it with a window function, before performing the Fourier transform to obtain the frequency content of the signal in the region of the window. Choosing the window to have roughly the same shape as the analyzing signals improves the performance although

these benefits are usually slight however [1]. Another popular method of TFR is the wavelet transform (WT) which expand the time domain signal in terms of wavelet functions which are localized in both time and frequency [2]. The wavelet function makes use of a dilation factor and a translation factor. It is a critical decision to select the proper wavelet basis function for decomposition based of the characteristics of the analyzing signals. For specific applications, the basic wavelet function can be modified according to the special need, but the form has to be given before the analysis [3]. Although, wavelet transform is widely used in TFR, it does not carry the exact phase information. The proper reconstruction of the signal after some further processing in time-frequency space is rather difficult without the phase information.

In this paper, the performance of Hilbert spectrum (HS) is explored as a technique for TFR of audio signals. Any signal is represented as a sum of bases called intrinsic mode function (IMF) obtained by applying EMD, a data adaptive method to analyze non-stationary and nonlinear signals [4]. The instantaneous frequency and amplitude of each IMF is derived by Hilbert transformation. Then the instantaneous responses of the IMFs are arranged to construct the HS i.e. time-frequency space corresponding to the time domain signals. A new frequency scaling method is introduced in deriving the HS using the instantaneous frequency vector. The basis functions of the EMD are directly derived from data. Each basis function has frequency response as a function of time preserving the non-stationarity of the original signal. The STFT assumes any signal as piecewise stationary and uses suitable window function to produce the short time spectral characteristics of the signal. Whereas, most of the real world signals including speech, audio, radar signals are non-stationary in nature. The Fourier transform (FT) based technique treat the signal as a sum of predefined harmonics. It performs better when the analyzing signal consists of harmonics and poorly performed otherwise. It is noted that the voiced speech signal contains some harmonics. When the application domain becomes broad (e.g. audio signals other than voiced speech) and the signal characteristics are unknown, a robust and adaptive TF representation method is the candidate for efficient analysis. The TFR using HS is based on EMD method is fully data adaptive and the signal decomposition is

performed without any pre-consideration of being harmonic or stationary. The segmental SNR and spectral distortion are used to measure the performance of TF representation. The performance of HS is compared with STFT and the experimental results show the superiority of Hilbert spectrum.

## II. EMD AND HILBERT SPECTRUM

Empirical mode decomposition (EMD) represents an time-domain signal into a finite set of AM-FM oscillator components which are the bases of the decomposition. The key benefit of using EMD is that it is an automatic decomposition and fully data adaptive. The principle of the EMD technique is to decompose a signal  $x(n)$  into a sum of band-limited functions,  $g_b(n)$ , called intrinsic mode functions (IMFs). Each IMF must satisfy two properties: (i) the number of extrema and the number of zero crossings are either equal or differ by one; (ii) the mean value of the envelope defined by the local maxima and the envelope defined by the local minima is zero. A special “sifting” process is employed to extract all of the IMFs [4, 5]. This sifting process is described as follows.

Firstly, the upper- and lower-envelopes of the signals  $x(n)$ , as well as their mean value  $\mu_1(n)$ , are calculated respectively. The first step of the sifting process is to calculate the difference  $h_1(n) = x(n) - \mu_1(n)$ . However,  $h_1(n)$  rarely satisfies the two IMF properties and is not taken as the first IMF of the signals straightway. Therefore, the sifting usually has to be implemented for more times, where the “difference” obtained in the previous sifting is taken as “signals” in present sifting. If after  $(k+1)^{\text{th}}$  sifting, corresponding difference  $h_k(n) = h_{(k-1)}(n) - \mu_k(n)$  satisfies the IMF properties, then it can be taken as the first IMF component, denoted by  $g_1(n)$ , that is,  $g_1(n) = h_k(n)$ . In practice, to determine whether or not  $h_k(n)$  well satisfies the IMF properties, we usually use so-called standard deviation ( $\delta$ ) criterion, that is, to check if the following inequality holds [4]:

$$\delta_k = \sum_{n=0}^{N-1} \left[ \frac{|h_{(k-1)}(n) - h_k(n)|^2}{h_{(k-1)}^2(n)} \right] \leq \sigma, \quad (1)$$

where  $N$  is the frame length and  $0.2 \leq \sigma \leq 0.3$ . Next, taking rest data  $r_1(n) = x(n) - g_1(n)$  as “new” signals and implementing the sifting process on it, we can obtain the second IMF  $g_2(n)$ . This procedure should be repeatedly used for  $B$  (total number of IMF components) times until the last residue  $r_B(n)$  becomes a monotonic function. When the decomposition procedure finished, the signals then can be expressed as

$$x(n) = \sum_{b=1}^B g_b(n) + r_B(n), \quad (2)$$

where  $g_1(n), g_2(n), \dots, g_B(n)$  are all of the IMFs included in the signals and  $r_B(n)$  is a negligible residue.

Fig 1. The illustration of EMD. A noisy speech signal at 10 dB SNR and its first 7 IMFs out of 15.

A noisy speech signal and some selected IMF components are shown in Fig 1. It can be observed that higher order IMFs contain lower frequency oscillations than that of lower order IMFs. This is reasonable, since sifting process is based on the idea of subtracting the component with the longest period from the data till an IMF is obtained. Therefore the first IMF will have the highest oscillating components; the components with the highest frequencies.

### A. Instantaneous Frequency

Instantaneous frequency (IF) represents signal's frequency at any time instance and it is defined as the rate of change of the phase angle at the instant of the “analytic” version of the signal. Every IMF is a real valued signal. The discrete Hilbert transform (HT) is used to compute the analytic signal for an IMF. The analytic version of the  $b^{\text{th}}$  IMF  $g_b(t)$  is defined as:

$$z_b(t) = g_b(t) + jH_d[g_b(t)] = a_b(t)e^{j\theta_b(t)} \quad (3)$$

where  $a_b(t)$  and  $\theta_b(t)$  are instantaneous amplitude and phase respectively of the  $b^{\text{th}}$  IMF and  $H_d[\cdot]$  denotes the discrete Hilbert transform.

The analytic signal is advantageous in determining the instantaneous quantities such as energy, phase and frequency. The discrete-time IF of  $b^{\text{th}}$  IMF is then given as the derivative of the phase  $\theta_b(t)$ -calculated at  $t$  i.e.

$$f_b(t) = \frac{d\tilde{\theta}_b(t)}{dt} \quad (4)$$

where  $\tilde{\theta}_b(t)$  represents the unwrapped version of instantaneous phase  $\theta_b(t)$ . The derivative in Eq. (4), is evaluated at discrete instant of  $t$ . It should be noted that such derivative introduces the abrupt fluctuations of IF and hence nonlinear smoothing is required. Here, the moving average smoothing filtering is used to remove such fluctuations. The filtering scheme improves the effectiveness of computing IF using discrete derivative. The instantaneous frequencies of the IMFs shown in Fig. 1 are illustrated in Fig 2.

Fig 2. Instantaneous frequencies of the seven IMF components shown in Fig 1.

### B. Frequency Scaling

The EMD is based on the simple assumption that any data consists of different simple intrinsic modes of oscillations. Each intrinsic mode, linear or nonlinear, represents a simple oscillatory mode as a counterpart to the simple harmonic function, but it is much more general. Instead of constant amplitude and frequency, as in a simple harmonic component, the IMF can have a variable amplitude and frequency as functions of time. The derived instantaneous frequencies are also a function of time. The method of deriving the IMF components is fully data adaptive; it does not employ any mathematical formulation. As EMD based IF does not have any specific scaling function. For any further processing e.g. to construct the Hilbert spectrum based time-frequency representation, it is required to normalize the IF vector by multiplying the elements of the vector with  $1/IF_{max}$  where  $IF_{max} = \text{Max}(f_1, f_2, \dots, f_b, \dots, f_B)$ .

Fig 3. Clean and noisy (0 dB) voiced speech signals and its frequency responses; (a) clean speech and its Fourier spectra, (b) IF response of the first four IMFs of clean speech, (c) noisy speech and its Fourier spectra, and (d) IF response of the first four IMFs of noisy speech.

The normalized IF vector does not make any noticeable difference for the signals of different spectral characteristics. Two signals of distinguishable spectra and their IF vectors are shown in Fig. 3. Observing the IF components, it is difficult to realize the real spectral components contained by the analyzing signals. A frequency scaling method is introduced here by concatenating white Gaussian noise with the analyzing signal. Let  $\mathcal{V}(n)$  be the uniformly distributed Gaussian noise (uGn). The Fourier spectra of uGn containing noticeable energy spectrum over the entire frequency range, and the spectra of its first four IMFs are shown in Fig 4.

Fig 4. Frequency response of uniformly distributed Gaussian noise (uGn) and its IMFs; (a) Fourier spectra of uGn, (b) frequency response of its first four IMFs.

Fig 5. Normalized IF response of the modified analyzing signals (MAS), (a) IFs of the first four IMFs of MAS corresponding to clean speech of Fig. 3(a); (b) IFs of the first four IMFs of MAS corresponding to the noisy speech signal as shown in Fig. 3(c).

If  $x(n)$  is the analyzing signal, the modified analyzing signal (MAS)  $y(n)$  is designed as:

$$y(n) = \begin{cases} x(n) & ; 1 \leq n \leq N_x \\ v(n) & ; N_x < n \leq N_x + N_v \end{cases} \quad (5)$$

where  $N_x$  and  $N_v$  are the length of  $v(n)$  and  $x(n)$  respectively and in this experiment  $N_v=100$ . It is already reported in [5] that the EMD works as dyadic filter-bank for fractional Gaussian noise (fGn).

The EMD is effectively a dyadic filter [6]. The normalized IF vectors of MAS corresponding to the signal shown in Fig. 3 are illustrated in Fig. 5. The left side of the vertical dashed line corresponds the scaled IF response of the original signal and the right side represents the IF response of the uGn which is discarded during any further processing of IF information. It is observed that the IF vector analyzing signal  $x(n)$  is properly scaled by the IF information of the concatenated Gn. The EMD technique does not include any mathematical formulation of IF scaling, and hence the proposed scaling method is useful for any further of the obtained IF information.

### C. Hilbert Spectrum

Hilbert spectrum represents the distribution of the signal energy as a function of time and frequency. It is also designated as Hilbert amplitude spectrum  $H(k,t)$  or simply Hilbert spectrum(HS). This process first normalizes the IF values. The bin spacing of the HS is  $0.5/F_c$ , where  $F_c$  is the number of desired frequency channels. The overall HS is expressed as the superposition of the individual IMFs' HSs defined as:  $H(k,t) = \sum_{b=1}^B H^{(b)}(k,t)$  for  $b=1, 2, \dots, B$  [7]. Hence, each element  $H(k,t)$  of the overall HS is defined as the weighted sum of the instantaneous amplitudes of all the IMFs at  $k^{\text{th}}$  frequency bin.

$$H(k,t) = \sum_{b=1}^B a_b(t) w_b^{(k)}(t) \quad (6)$$

where the weight factor  $w_b^{(k)}(t)$  takes 1 if  $f_b(t)$  falls within  $k^{\text{th}}$  band, otherwise is 0.

Fig 6. Hilbert spectrum (HS) of speech signals.

After computing the elements over the frequency bins,  $H$  represents the instantaneous signal spectrum in time-frequency space as a 2D table.

It is noted that the time resolution of  $H$  is equal to the sampling rate and the frequency resolution can be chosen up to Nyquist limit. Fig. 6 represents the Hilbert spectrum (in dB) of the voiced speech signal shown in Fig. 1 using 128 frequency bins.

### C. Performance of Inverse Transformation

In many speech processing applications including audio source separation, it is often required to reconstruct the time domain signal after performing the processing in time-frequency domain. The perfect reconstruction of the time domain signal is possible if the time-frequency transformation technique supports proper inverse transformation with minimum required parameters. The experiments demonstrate that EMD as well as Hilbert spectrum is a reversible representation. One can also reconstruct the time domain signal from the Hilbert spectrum. During the Hilbert transform the real part of the signal remains unchanged [8]. The time domain signal  $s_r(t)$  is easily be reconstructed by filtering out the imaginary part from the HS and summing over frequency bins as:

$$s_r(t) = \sum_k H(k, t) \cdot \cos[\phi(k, t)] + r_B(t) \quad (7)$$

where  $\phi(k, t)$  is the phase matrix of Hilbert spectrum and  $r_B(t)$  is the final residue of EMD. The phase matrix is saved during the construction of Hilbert spectrum to be used in re-synthesis. The signal  $s_r(t)$  reconstructed from the Hilbert spectrum is shown in Fig. 7. The reconstruction error (of the order  $1 \times 10^{-15}$ ) is considered as negligible in reality.

Fig 7. The speech signal (top), the reconstructed signal from HS (middle), the error between the original and reconstructed signal (lower one).

On the other hand, it is difficult to reconstruct the original time domain signal from the STFT representation, especially when the window function is used in an overlapping fashion. The inverse transformation becomes more troublesome when the tapered window is used instead of square one. It is also required to know the parameters (e.g. number of FFT points, window function and its length, amount of overlap) what are used in STFT for proper inverse transformation. Whereas, no parameter is required to get back the time domain signal from the corresponding HS.

The segmental SNR (SSNR) is a good measure of distortion in time domain between original and

reconstructed signals [9]. The SSNR of the  $i^{\text{th}}$  frame is defined as

$$SSNR(i) = 10 \log_{10} \left[ \frac{\sum_{t=0}^{T-1} |s^{(i)}(t)|^2}{\sum_{t=0}^{T-1} |s^{(i)}(t) - \hat{s}^{(i)}(t)|^2} \right], \quad (8)$$

where  $s^{(i)}(t)$  and  $\hat{s}^{(i)}(t)$  are the original and reconstructed signals respectively of the  $i^{\text{th}}$  frame. Then the average SSNR (avgSSNR) is expressed as

$$\text{avgSSNR} = \frac{1}{I} \sum_{i=1}^I SSNR(i), \quad (9)$$

where  $I$  is the total number of speech frames. The measure of SSNR is a direct time domain method to illustrate the difference between two signals. This error measure is quite well understood and mathematically tractable. Its main characteristic is that it puts great emphasis on large errors and little emphasis on small errors.

The measure of error between two signals can also be performed in the frequency domain and can be interpreted as a goodness of fit between a given signal spectrum and a model spectrum that approximates it. For determining the quality of the reconstructed power spectrum envelop, its segmental spectral distortion (SSD) is calculated over the power spectrum over the frequency plane as an objective measure. The SSD for the  $i^{\text{th}}$  frame is defined as in [10],

$$SSD(i) = \sqrt{\frac{1}{N} \sum_{k=0}^{N-1} \left( 10 \log_{10} \frac{S^{(i)}(k)}{\hat{S}^{(i)}(k)} \right)^2}, \quad (10)$$

where,  $S^{(i)}(k)$  and  $\hat{S}^{(i)}(k)$  are the original and reconstructed power spectrum for the  $i^{\text{th}}$  speech frame. Then the average SSD (avgSSD) is expressed as:

$$\text{avgSSD} = \frac{1}{I} \sum_{i=1}^I SSD(i), \quad (11)$$

where  $I$  is the total number of speech frames. The reduction of SSD indicates the spectral envelop estimate's level of accuracy. The minimization of the spectral distortion, we expect a better fit of  $\hat{S}^{(i)}(k)$  to  $S^{(i)}(k)$ .

### III. EXPERIMENTAL RESULTS AND DISCUSSION

To explore the performance of Hilbert spectrum (HS) in time-frequency representation of audio signals in terms of average segmental SNR average segmental spectral distortion, the experiments are conducted on the speech (male and female speech) signals from TIMIT database. All the speech signals are with 16 kHz sampling rate and 16 bits amplitude resolution. Each speech signal is transformed to time-frequency domain using HS and

STFT based methods. The simulation results are compared with the STFT based time-frequency representation.

In many applications of TF representation including audio source separation, it is required to reconstruct the time domain signal even after performing some processing in TF domain. The reconstruction from spectrogram outputs some spurious error comparing with the original signal. The signals reconstructed from HS are with very high SNR (greater than 300dB) which is treated as noise less. In the context of reconstruction error, the HS can be proposed as the reversible technique between time and TF domain. The EMD parameters i.e. number of IMFs, and the reconstruction error in terms of average SSNR (avgSSNR) and average SSD (avgSSD) with HS and STFT based TFR of some typical audio signals are presented in Table 1. It is observed that the HS offers better accuracy of inverse transformation to get back the time domain signals. It is noted that same parameters are used for STFT and its inverse transformation.

Table 1: Performance comparison between HS and STFT

| Audio signals | IMF | avgSSNR (dB) |       | avgSSD (dB) |       |
|---------------|-----|--------------|-------|-------------|-------|
|               |     | HS           | STFT  | HS          | STFT  |
| MS_1(25s)     | 16  | 315.50       | 30.92 | 1.01e-13    | 1.853 |
| MS_2 (28s)    | 17  | 314.82       | 29.84 | 2.02e-13    | 1.213 |
| FS_1 (30s)    | 16  | 325.41       | 31.32 | 1.52e-13    | 0.945 |
| FS_2 (25s)    | 15  | 330.94       | 30.71 | 1.71e-13    | 2.014 |
| Jazz (40s)    | 19  | 311.08       | 28.89 | 2.13e-13    | 2.776 |
| Flute (20s)   | 18  | 318.63       | 31.47 | 1.03e-13    | 2.012 |

The use of STFT is faced with the problem of resolution in both time and frequency axes at a time. Some researches argued that TF domain based audio signal separation technique has better separation efficiency with higher resolution in TF representation [11]. Narrow windows give good time resolution, but poor frequency resolution. Wide windows give good frequency resolution, but poor time resolution; furthermore, wide windows may violate the condition of stationarity. All the parameters required in STFT are signal dependent. The most difficulty is occurred when the signal characteristics are fully unknown. Whereas, in HS only one parameter, the number of desired frequency bins is involved. Moreover, STFT includes additional cross-spectral energy due to window overlapping. The use of HS is capable to overcome all of the mentioned limitations of the STFT based time-frequency representation.

#### IV. CONCLUSIONS

We have presented the effectiveness of Hilbert spectrum (HS) in time-frequency representation of audio

signals. The experimental results provide the evidence that Hilbert spectrum based TFR performs better. The specialty of Hilbert spectrum is that the time resolution can be as precise as the sampling period and the frequency resolution depends on the choice up to Nyquist limit. Hence it serves the effective resolution of TFR yielding better performance in different signal processing applications. Another major problem of STFT is that it includes a noticeable amount of cross-spectral energy terms during the use of window function with a overlapping fashion, whereas, HS does not make use of window function. Hence, HS performs better than STFT in time-frequency representation of audios signals.

# Server Consolidation Using OpenVZ: Performance Evaluation

Mohuiddin Ahmed, Showayb Zahda, Majed Abbas  
Computer Science Department  
International Islamic University Malaysia

**Abstract**—Virtualization is abstracting computer resources. It is the ability to run multiple operating systems simultaneously on a single physical machine. In this paper we evaluate the performance of the operating system level virtualization software (OpenVZ). The evaluation will be based on Web hosting, in other words, we evaluate the performance of Web servers on two different machines (dubbed as Baru and Lama) and we observe the behavior of OpenVZ and its scalability for Web servers on different architectures (32 bits and 64 bits). The study evaluates the CPU, Memory and Throughputs under different loading conditions.

**Index Terms** — OpenVZ, performance, server consolidation, virtualization.

## I. INTRODUCTION

“Server consolidation is an approach to the efficient usage of computer server resources in order to reduce the total number of servers or server locations that an organization requires”[1]. Simply put, server consolidation is the combination of several servers (i.e. Web Server, Mail Server, Java Server, etc) into one physical machine, in order to, save cost and utilize the computer resources.

One way to achieve server consolidation is to use virtualization. Virtualization as a word does not exist in most English dictionaries. However, the closest word to it in Oxford Concise Dictionary is “virtual” which means “Computing: not physically existing as such but made by software to appear to do so” [2]. However, virtual is not a new term in the computer jargons, it was used before such as virtual memory, virtual reality, etc.

Virtualization in our context according to [3] is defined as “the abstraction of computer resources” and “abstraction is the process of separating hardware functionality from the underlying hardware.” In other words, virtualization is sharing, and partitioning the resources of computer hardware amongst more than one running operating systems on a single physical machine simultaneously. Each one of the running operating systems is called a Virtual Machine (VM). Virtualization offers the ability to run multiple operating systems (Linux, Windows, MacOS X) on one physical machine at the same time.

Currently, virtualization is grabbing the attention of the data centers as well as the small and medium enterprises due to its enormous advantages. This led processor manufacturer mainly Intel and AMD to develop processors to support virtualization i.e. Intel VT and AMD-V respectively.

Indeed, virtualization brings a huge economical value to the organizations. Mainly, it reduces the Total Cost of Ownership (TCO) by consolidating a bunch of physical servers into one physical server. For example, 10 Web servers can use one physical machine instead of using 10 physical machines. This reduces a lot of cost -beside the cost of the machines- such as electricity bills, space, air conditioning, etc. In addition, organizations can couple virtualization with open source software solutions (e.g. OpenVZ, Xen) to achieve more reduction in TCO and not to bother anymore about licensing issues. This is handy when multiple virtual machines or virtual machine backups are kept online for redundancy, restoration, or disaster recovery purposes [4].

Virtualization technology can be implemented in several techniques namely, hardware emulation, full virtualization, paravirtualization, operating system level virtualization, application virtualization, and desktop virtualization. However, the discussion about the differences amongst them is beyond this paper. But, a brief discussion about operating system level virtualization will be provided in OpenVZ section.

Besides cost savings, virtualization in general has great advantages for the organizations, due to the fact that the virtualization layer isolates and separates the VMs. None of the VMs is aware about the existence of other VMs on the same machine. They seem to each other as if they were running on different physical machines. The isolation provides higher availability and security for the organization. If one of the VMs crashes or goes down, it has no effects on other VMs. Moreover, system administrators can fire up a VM in less than a minute. As for security, running different services on different VMs improves the security. For instance, if an intruder manages to hack one server, only that particular server goes down and others will remain running as if nothing happened.

Live migration of VMs is yet another great advantage of virtualization. Assume one of the VMs is exhausting the hardware resources, then the administrator can migrate the server into another physical machine in less than one minute. Or if the physical machine should go down for upgrade or maintenance, the VMs can be migrated to another machine. Therefore, migration boosts the availability of the running servers.

Software developers and testers use virtualization to run several platforms to develop and test the products on (i.e. Linux, Windows, MacOS X). It reduces the time of installing the platforms as well as increasing the number of platforms

---

[1] The corresponding author.

that can be used for testing and development.

Virtualization is indeed a very helpful technology for education purposes. Now, universities and educational institutions no longer need to buy extra machines to cater their student's need of running several operating systems. Moreover, each student can have a root access which allows them to have full authority over the system.

Virtualization has disadvantages too; a big damage to all the running servers might occur if the power of the host machine goes down. Or, if the administrator is upgrading the system hardware, he/she has to shutdown the machine. However, by using migration, the system administrators can easily migrate the VMs to another physical machine in less than one second. The rest of the paper is organized as follows: in section II OpenVZ is briefly described, in section III we describe the methodology of the performance evaluation, section IV describes the test bed and its components, in section V we analyze the test results followed by concluding remarks.

## II. OPENVZ

OpenVZ is a free and open source virtualization solution. It is the basis of the commercial virtualization solution Virtuozzo from Parallel (formerly known as SWsoft). OpenVZ implements the operating system level virtualization technique which virtualizes servers on the operating system (kernel) layer [5]. In other words, OS-level Virtualization adds a new layer on top of the operating system. This layer manages all the issues related to OpenVZ containers and resource management.

Fig. 1. Operating System level Virtualization [5]

OpenVZ has its own terminologies regarding virtualization technology. The physical machine that is running OpenVZ is called a Host System or Hardware Node. A running instance of the operating system that partitions and shares the resources of the hardware node is called a container, Virtual Environment (VE), and/or Virtual Private Server (VPS) [6]. In this paper we will refer to the running instance as a container.

Operating system-level virtualization shares the kernel amongst all running containers. The kernel (OpenVZ kernel creates the virtualization layer) bears the duty of managing and partitioning the resources of the computer, and isolating

the containers from each other. However, sharing one kernel introduces a drawback. In case the kernel crashes all the containers are down.

The performance of OpenVZ is closed to the native performance of the machine. The overhead only consumes about 1-3% of the resources. This indeed makes OpenVZ a good choice for server consolidation especially for web hosting [7].

OpenVZ is based on Linux operating system and it only runs in Linux distributions. Moreover, OpenVZ can also be tested without installation using OpenVZ LiveCD<sup>1</sup>.

It takes a few minutes to setup one container using OpenVZ. This is because of the usage of Operating System Templates. An OS-template is a set of packages from some Linux distribution used to populate a VE. With OpenVZ, different distributions can co-exist on the same hardware box, so multiple OS templates are available. [6]

Furthermore, changing the configuration of any container can be done on the fly. There is no need to restart any container in order to give or take from it some resources.

OpenVZ comes with a command line control utilities that allow the administrators to create, start, stop, destroy and migrate a container. The utilities also allow him/her to set the quota, manage the resources and execute commands on the containers from outside the container itself. For instance, "vzsplit" is a command that creates a configuration file which splits the resources of the computer equally amongst a number of containers the user specifies (vzsplit -n 4).

Fig. 2. WebVZ Management Tool

WebVZ is a web management tool for OpenVZ and was developed by the authors and available in [8] under GPL GNU. WebVZ allows system administrators to control the containers locally and remotely. Fig 2 shows a screenshot of WebVZ. Resource allocation among the containers is done on the basis of demand. If there is need to migrate a container to another server due to resource hogging, this can easily be attained by migration to a different machine which is lightly

<sup>1</sup> Live CD: is an operating system that runs without the need for installation on the hard disk and it does not have any effect on the existing data. Once the CD is ejected, everything goes back to its original state

loaded. Fig 3 shows the output of the command “vzlist” (list all containers)

### III. METHODOLOGY

In order to test the migration between containers we injected http queries from a server and then used a wrapper to increase the number of requests until the system chokes or crashes.

In order to evaluate the performance of the containers on OpenVZ kernel, first we evaluated the performance of both machines (we named them Baru and Lama respectively) as a single unit without running OpenVZ kernel so as to know how many requests per second each machine can handle and to find out the relationships between the containers and the Host System. Second, we evaluated the containers by scaling the number of containers from 4 to 8, and finally to 12 on the two machines. All the containers receive the same amount of requests per second concurrently. In other words, each container for example is receiving 100 connections per second at the same time.

In order to measure the performance of each running Web server we used a free and open source HTTP performance measurement tool from HP called “httpperf” version 0.9.0. According to the manual page of httpperf “httpperf speaks the HTTP protocol both in its HTTP/1.0 and HTTP/1.1 flavors and offers a variety of workload generators. While running, it keeps track of a number of performance metrics that are summarized in the form of statistics that are printed at the end of a test run. The most basic operation of httpperf is to generate a fixed number of HTTP GET requests and to measure how many replies (responses) came back from the server and at what rate the responses arrived.”

However, httpperf is limited to one test at a time which generates a fixed number of HTTP GET. In order to run httpperf several times and increase the number of HTTP GETs each time, another tool called “autobench” can be used which automates web server benchmarking using httpperf. According to autobench version 2.1.1 manual page “autobench runs httpperf against the specified host or hosts, ramping up the number of requested connections, and logging the results in TSV or CSV format files.”

In order to capture the reading of the CPU and the RAM we used “top -b -d 1” to read the values every second. While the throughput of each test was reported by “httpperf” for plotting and display the result, “bench2graph” is a tool comes with autobench, was used to plot the output of the tests.

This paragraph explains how autobench runs httpperf. (E.g. *autobench --single\_host --host1 192.168.0.1 --low\_rate 50 --high\_rate 100 --rate\_step 10 --timeout 7 --file ve1.tsv*). This command will run “httpperf” 5 times. First time httpperf initiates 50 connections per second until the total number of connections reaches 5000 connections (the default) which is the total number of connections that are initiated during one test, and each connection contains 10 requests (the default). In the second test httpperf initiates 60 connections per second until the total number of connections reaches 5000 and so on, each time the number of connections per second increases according to the specified rate step value. The output of httpperf is shown in Fig 4 which is extracted and tabulated by autobench as shown in Fig 5.

### IV. TESTBED

The tests were conducted on two different servers.

First server’s specifications (dubbed as Baru) were Intel Core 2 Duo 1.83 GHz, 2 GB of RAM, and 100 Megabit network interface (64 bit machine). And second server’s specifications (dubbed as Lama) were Intel Pentium 4 2.6 GHz, 1 GB of RAM, and 100 Megabit network interface (32 bits machine). Both machines hosted OpenVZ on Centos 5. The tests were conducted from two clients both running Ubuntu 7.10. Fig 6 portrays the architecture of the test bed.

The tests were conducted based on the instructions and practices of [9]. We conducted the tests in isolated network environment.

The following configuration of “autobench” was done to measure the performance. When we benchmarked the whole machine, the total number of connections to be sent to the machine was set to 20,000. The number of requests in each connection was set to 10. The client time out was set to 7 seconds. However, when we benchmarked the containers, for each container, 5,000 connections were sent in each test. And the rest of the configuration parameters were the same as above.

OpenVZ kernel version 2.6.18, and Centos 5 templates from OpenVZ website were used and Apache web server version 2.2.3 was used as the Web server. The http queries were generated by using Httperf version 0.9.0 and autobench 2.1.2. We conducted various tests by scaling the number of containers from 4 to 8 and finally to 12.

The configurations of Apache were left to the default except the “KeepAlive Off” which we changed to “On” in order to allow multiple requests in one connection.

Fig. 6. The Test Bed architecture

The configuration files of all the containers were the same and a sample is shown in Fig 7.

## V. DISCUSSION

### A. OpenVZ

There are general observations about OpenVZ that we would like to talk about in this section.

It is easy to fire up a new container using OpenVZ. It would take about one minute. Moreover, a container occupies only a small amount of memory. However, this depends on the size of the distribution as well as the running services. In our case, we only fired up the web server and the default services that run on the Centos 5 template from OpenVZ Website. We found that each VE takes around 25 MB of RAM and about 400 MB of hard disk. Accordingly only 20 containers can be running web servers using 450 MB of RAM and about 8 GB of hard disk.

We ran 55 containers on Baru and 23 on Lama at the same time. This almost filled the memory of each machine respectively. Moreover, we ran the containers with no application overhead within itself.

### B. The host machine (Baru)

After running “autobench” (from 1000 to 7000 requests per second), the machine managed to handle about 6000 requests per second with no error. This amount of concurrent requests has saturated the CPUs of the machine. However, the throughput was not saturated due to the size of the files (~80 Kilo bytes).

Figure 8 shows the results of “autobench” which uses httperf to benchmark the machines. In Fig 8 the X-axis represents the number of requests per second that httperf is supposed to send each test, and Y-axis represents different values that changes based on the figure’s keys. In the following paragraph, we will describe what each line means.

Sent request per second is the number of requests that was sent to the machine each second. Average reply rate per second is the average number of replies from the server per second. Response time is the reply time of the request in milliseconds. Throughput is the size of the bandwidth that was used during each test in Kilo bit per second. And finally we observed the percentage of errors for each test as packet loss.

As for Fig 8 we see that the first test sent 1000 requests per second and the replies were all intact. In the next test which was 1500 requests per second also it was fine. Autobench conducted 14 tests starting from 1000 requests per second and ending at 7000 requests per second. Each test autobench increases the number of requests per second by 500. So, we see that until 6000 requests per second everything was fine and no errors occurred. After 6000 requests per second we notice there is a drop in the number of requests sent to the server which is a bit steep. And so did every thing. The drop occurred due to the CPUs saturation which was utilized 100%. Fig 9 shows the CPU usage in relation with the time. X-axis represents the time line of the test. We captured the reading of the CPU each second for the whole duration of the tests. Y-axis shows the percentage of the idle CPU. Why the idle? Because the percentage of the idle CPU show the percentage of the free portion of CPU, we can see whether the whole system including the web server is utilizing the CPU or not.

Fig 9 shows the CPU idle percentage. We observe that at the beginning of the test the usage of the CPU was about 10%. This value keeps fluctuating each second and keeps going down until it reaches 0% which means that the CPU is fully used. In this test, this point was reached at approximately at 210 seconds and error occurrences were increasing from this point and onward (i.e. 6500 requests per second and beyond).

Fig 10 shows the usage of the RAM of the whole duration of this test.

The results indicate that Baru machine can handle about 6000 requests per second and the CPU was saturated. However, in reality, usually benchmarking is done up to 80% of the CPU usage.

### C. The host machine (Lama)

Since we are testing the performance of OpenVZ on two different machines, section A presented the results of the first machine (Baru) whereas this section presents the second machine (Lama). In this section we will not present the graphs and we will only mention the results.

After running “autobench”, the machine managed to handle about 3300 requests per second with no error. This amount of concurrent requests has saturated the CPU of the machine. However, the throughput was not saturated due to the size of the files (~80 Kilo bytes).

Fig. 8. The performance of Baru.

### D. OpenVZ on Baru and Lama

In this section we will describe the results of running OpenVZ on the two machines. The results are tabulated but brief discussion is provided here about the result for clarification.

As mentioned before we scaled the number of containers from 4 to 8 and finally to 12 and we conducted the tests on them so as to find the relationships between the machine and OpenVZ. Surprisingly, the two machines have had the same relationship with OpenVZ. The results are described first and later we show the relationship between the machine and OpenVZ.

#### Running 4 containers on Baru:

We set up Baru with 4 identical containers and we ran autobench against them concurrently.

In other words, all the containers receive the same load at the same time. Fig 11 shows the results of autobench on one of the containers (the other containers have almost an identical graphs so we present one of them here). As the graph shows autobench starts from 200 requests and ends at 2000 requests. However, the errors started to occur at about 1600 requests per second. This means that the machine is receiving about 6400 requests per second at the same time. Note that this number is about the same as the performance of machine Baru in section A. Surprisingly, the CPU usage (Fig 12) was almost the same as in section A and is saturated at the same the error occurrences. As for the RAM (Fig 13) it has also the same usage as in section A.

Fig. 9. CPU Usage of Baru

Fig. 10. RAM usage of Baru

#### Running 8, and 12 containers on Baru:

The results of 8 and 12 containers were almost the same as when we were using four containers. In 8 containers, each container handled about 750 requests per second, and in 12 containers, each container handles 500 requests per second with no errors. The graphs for the CPU and RAM were the same as Baru machine and 4 containers. Table 1 shows the relationship between the performance of Baru and 4, 8, and 12 containers. We can see from the table that OpenVZ has nearly 0% overhead. This means that we do not lose any hardware resources when we are running OpenVZ.

TABLE 1  
Performance of Baru and its containers

| Machine       | Number of servers | Requests per second | Total requests per second |
|---------------|-------------------|---------------------|---------------------------|
| Baru          | 1                 | ~6000               | ~6000                     |
| 4 containers  | 4                 | ~1600               | ~6400                     |
| 8 containers  | 8                 | ~750                | ~6000                     |
| 12 containers | 12                | ~500                | ~6000                     |

Fig. 11. Performance of one of the containers

Fig. 12. CPU usage of 4 containers

Fig. 13. RAM usage of the 4 containers

As for Lama we mentioned before that it handled about 3300 requests per second. So, when we ran 4 containers on it we found that 700 requests per seconds were handled by each container which means  $700 * 4 = 3200$  requests per second which is about the same number of requests that were handled by Lama. Note that we did not manage to run 12 containers on Lama due to RAM limitations.

TABLE 2  
Performance of Lama and its containers

| Machine      | Number of servers | Requests per second | Total requests per second |
|--------------|-------------------|---------------------|---------------------------|
| Lama         | 1                 | ~3300               | ~3300                     |
| 4 containers | 4                 | ~700                | ~3200                     |
| 8 containers | 8                 | ~400                | ~3200                     |

## VI.CONCLUSION

We found that when using OpenVZ, almost no overhead on the computer resources and it shares the resources of the computer fairly amongst the running containers. Moreover, we found that both machines (Baru and Lama) can handle about 6000 and 3300 requests per second respectively. And so do containers of OpenVZ when we run all of them concurrently on the both Baru and Lama. This means that OpenVZ performance does not change with the change of the architecture (32 bits and 64 bits). We can safely say that if we want to run 15 Web servers using OpenVZ containers, each VE can handle 400 requests per second at the same time (this is on Baru). The WebVZ is a very useful tool for administrating OpenVZ containers both locally and remotely.

**Abstract** — Evolutionary algorithm is more effective to gain optimal solution to solve equations than traditional methods. It also provides quick solution for solving large number of equations having huge parameters with less expense in distributed manner. This paper presents a new distributed evolutionary computation technique, which decomposes decision vectors into smaller components and achieves optimal solution in short time. In this technique, A Jacobi-based Time Variant Adaptive (JBTV) Hybrid Evolutionary Algorithm is distributed. Moreover, a new selection method named Best All Selection (BAS) is introduced for selecting best individuals. Experimental results show that optimal solution is achieved for different kinds of problems having huge parameters and considerably speedup is formed in proposed distributed system.

**Index Terms** — Master-Slave architecture, Linear Equations, Evolutionary Algorithms, Hybrid Algorithm, Speedup.

## I. INTRODUCTION

In recent years, application of evolutionary algorithms is increasing in a greater extent. Evolutionary algorithms (EAs) are stochastic search methods that have been applied successfully in many search, optimization and machine learning problems. Successful use of evolutionary algorithm for solving linear equations is applied in [1], [2], [3]. However, it is often very difficult to estimate the optimal relaxation factor, which is the key parameter of the successive over relaxation (SOR) method. Optimal solution is achieved quickly as relaxation factors are adapted automatically in evolutionary algorithm. Equation solving abilities was extended in [2], [3], [4] by using time variant parameter. The invention of hybrid evolutionary algorithm [5], [6] brought a greater benefit to have the solutions of linear equations within very short time. The hybrid algorithm combining the jacobi-based successive relaxation (SR) method with evolutionary computation techniques was implemented in C++ framework and the related speedup was calculated in [4]. In this case more computation time will be needed to solve the problems with huge parameters. Solving large number of equations with huge parameters needs high computational cost in case of single processor. One approach to overcome this kind of limitation is by formulating the problem into distributed computing structure.

Parallel and distributed systems are two of intrinsic natures of EAs. The main parallel achievements in the algorithmic families include the evolutionary computation, parallel models, and parallel implementations and are discussed in [7]. A distributed cooperative coevolutionary algorithm is developed in [8] which is beneficial for solving complex problems. A distributed technique [9] is proposed for parallelizing fitness evaluation time. Fitness evaluation time is high but other operations of evolutionary algorithm takes more time. This paper proposes a distributed technique in which mutation and adaptation times are distributed. So, a high quality speedup is achieved.

Fig. 1. Distributed Master-Slave Architecture.

Basic master-slave architecture is shown in Fig. 1 which is used in proposed distributed technique follows a server-client paradigm where connections are closed after each request. The basic approach of this system is to divide a large problem into many subproblems and to evolve subproblems separately. These subproblems are then combined and actual solution is searched. This process is continued until reaching the desired position.

The remainder of this paper is structured as follows: Section II mention Jacobi method of solving linear equations. Distributed model and timing calculation are discussed in section III. Section IV examines results of the experiment of various problems and provides a comprehensive comparison of single and distributed

system. Finally, Section V presents our concluding remarks.

## II. JACOBI METHOD OF SOLVING LINEAR EQUATIONS

Consider the following linear equations:

$$Ax = b \text{ or } Ax - b = 0 \quad (1)$$

Where  $A \in \mathbb{R}^n \times \mathbb{R}^n$  and  $x, b \in \mathbb{R}^n$

Let,  $A$  is  $n \times n$  matrix, where  $a_{ii}$  is the diagonal elements,  $a_{ij}$  is other elements of the  $A$  matrix and  $b_i$  is elements of  $b$  matrix. For solving linear equations Jacobi method is used [10].

Let,

Linear equations is  $Ax = b$  and  $|A| \neq 0$

Assuming without loss of generality that none of the diagonal entries is of zero; otherwise interchange it rows. Then

$$(D + U + L)x = b, \text{ Where } A = (D + U + L)$$

$$\text{or } Dx = b - (U + L)x$$

$$\text{or } x = D^{-1}b - D^{-1}(U + L)x$$

$$\text{or } x = H_j x + V_j$$

Where  $H_j = D^{-1}(-L - U)$  and  $V_j = D^{-1}b$

The linear equation can be written as

$$\sum_{j=1}^n a_{ij}x_j = b_j, (i = 1, 2, \dots, n) \quad (2)$$

In Jacobi method by using SR technique [11] is given by

$$x_i^{(k+1)} = x_i^{(k)} + \frac{\omega}{a_{ii}} \left( b_i - \sum_{j=1}^n a_{ij}x_j^{(k)} \right), (i = 1, 2, \dots, n) \quad (3)$$

In matrix form matrix-vector equation is

$$x^{(k+1)} = H_\omega x^{(k)} + V_\omega \quad (4)$$

Where  $H_\omega$  called Jacobi iteration matrix, and  $V_\omega$  are given successively by

$$H_\omega = D^{-1} \{ (1 - \omega)I - \omega(L + U) \} \quad (5)$$

And

$$V_\omega = \omega D^{-1}b \quad (6)$$

Iterative process is continued using equation (3) until the satisfactory result is achieved. Based on this method, different hybrid evolutionary algorithms are developed [1]

[2]. Problems of different categories will be generated by varying  $a_{ii}$ ,  $a_{ij}$  and  $b_i$ 's.

## III. PROPOSED MODEL OF DISTRIBUTED EVOLUTIONARY ALGORITHMS

In reality, the computation cost for evolutionary optimization in terms of time and hardware increases as the size of the problem increases. One approach to overcome such a limitation is to exploit the inherent parallel nature of EA by formulating the problem into a distributed computing structure suitable for parallel processing, i.e., to divide a task into subtasks and to solve the subtasks simultaneously using multiple processors.

### A. Distributed Technique

The availability of powerful networked computers presents a wealth of computing resources to solve problems with large computational effort. The distributed technique which is considered here, large problems are decomposed into smaller subtasks that are mapped into the computers available in a distributed system. The Distributed Hybrid Evolutionary Algorithm (DHEA) is as follows:

Fig. 2. Architecture of proposed model.

In Fig. 2; all steps of distributed hybrid algorithm are expressed using numbering system in each position. Step 1, 2, 6, 7 are completed in master processor and steps 3, 4, 5 steps occurred in slave processors.

1) *Initialization*: In step1, for a specific problem master (server) initializes with population and relaxation factor. Initial population  $X^{(0)} = \{x_1^{(0)}, x_2^{(0)}, \dots, x_N^{(0)}\}$  is generated randomly using normal distribution at master. Here  $N$  is the population size. Let  $k \leftarrow 0$  where  $k$  the generation counter is. This population is considered as parent. Relaxation factors according to individuals are also initialized at this position.

$$\omega^{(0)} = \{\omega_1^{(0)}, \omega_2^{(0)}, \dots, \omega_N^{(0)}\} \quad (7)$$

2) *Recombination*: In step 2, Recombination operation is performed on parent at master and population  $X^{(k+c)} = R(X^{(k)})^t$  is obtained.

Where  $R = (r_{ij})_{N \times N}$  and  $\sum_{j=1}^n r_{ij} = 1$  and  $r_{ij} \geq 0$  for  $1 \leq i \leq N$   
Matrix  $R$  is a stochastic matrix.

Population generated after recombination operation is distributed among slaves. Then mutation, fitness evaluation and adaptation operations are performed on that distributed subpopulations.

3) *Mutation*: In step 3, after completing recombination operation Mutation operation is performed on that subpopulation in slave processors and mutated subpopulation  $X^{(k+m)}$  is obtained. For each individual  $x_i^{(k+c)}$  ( $1 \leq i \leq N$ ) in subpopulation  $x^{(k+c)}$  produces an offspring using following equation

$$x_i^{(k+m)} = H_{\omega} x_i^{(k+c)} + V_{\omega}, (i = 1, 2, \dots, n)$$

Where  $H_{\omega}$  is called Jacobi iteration matrix.

Consider, number of slaves is  $M$  and number of individuals is  $N$ , then Number of individuals in each subpopulation,

$$N_{sub} = \frac{N}{M}$$

Mutation on subpopulation is

$$\sum_{i=1}^{N_{sub}} x_i^{(k+m)} = H_{\omega} x_i^{(k+c)} + V_{\omega} \quad (8)$$

4) *Fitness Evaluation*: After completing mutation operation, fitness evaluation is performed in step 4. Error function is

$$E = \sum_{i=1}^{N_{sub}} E_i \quad (9)$$

Where  $E = \sum_{j=1}^{N_{sub}} |a_{ij}(x_j) - b_i|, i = 1, 2, \dots, N_{sub}$

The fitness evaluation of an individual measures the accuracy of an individual for a particular problem and calculates the error rate which is used for selecting best individuals.

5) *Adaptation*: In step 5, adaptation is performed on mutated offspring according to fitness evaluation. Consider two individuals  $X$  and  $Y$ , corresponding errors  $\|e_x\|$  and  $\|e_y\|$  and relaxation factors  $\omega_x$  and  $\omega_y$ .  
If  $\|e_x\| > \|e_y\|$  then  $\omega_x$  is adapted to  $\omega_y$ .

$$\omega_x^m = (0.5 + p_x)(\omega_x + \omega_y)$$

Similarly if  $\|e_y\| > \|e_x\|$  then  $\omega_y$  is adapted to  $\omega_x$  and if  $\|e_x\| = \|e_y\|$  then no adaptation is performed.

In step 6, controller checks whether all offspring from all slaves have reached or not. If all offspring have reached then controller sends them to server otherwise looping is continued.

After reaching all offspring in server, selection operation is performed and best individuals are selected.

6) *Selection*: In BAS method, best individuals are selected among parent and all mutated offspring. At position 7, all mutated offspring from all slaves are combined and selection mechanism is performed on all parent and all offspring.

Mathematically,

$$Selection(i) = err_{\min} \{x_1, x_2, x_3, \dots, x_{2N-i+1}\} \quad (10)$$

$$Selection = \sum_{i=1}^N Selection(i) \quad (11)$$

In case of selection, direct competition is occurred among individuals and best individuals are selected according to error rate. If error is less or equal to threshold value then selected individuals are the solution for that problem. Otherwise this process is continuing until error is less than threshold value.

There is no direct communication among the subpopulations. All communications are performed between the subpopulation and the central server. Such communications take place in every generation before reaching the accurate result and communication increases linearly with respect to the number of computers.

#### B. Computation Time Analysis of Single Processor and Distributed Processors

All mathematics, comparison and assignment statements in the computer are executed in a particular time. For a specific optimization problem, recombination time, mutation time, fitness evaluation time, adaptation time and selection time can be denoted by  $T_r, T_m, T_f, T_a$  and  $T_s$  respectively. Total time in single processor is indicated by  $T_{single}$ . Time in single processor is represented as follows,

$$T_{single} = T_r + T_m + T_f + T_a + T_s \quad (12)$$

In case of distributed system, time is calculated in master and slaves separately. Then total time is calculated by combining master and slave time.

1) *Time in master processor*: For a particular problem, Recombination operation is performed on initial population and time  $T_r$  is calculated. Then the server distributes individuals among all slaves connected to it. Number of subpopulation is  $p$  which is distributed in slaves. In this case, Marshalling and transmission time is considered. Marshalling time is the time to construct data stream from object and transmission time is the time to place data stream in channel. Marshalling time of  $i^{th}$  individual is  $T_{mi}$  and Transmission time with  $i^{th}$  individual is  $T_{transi}$ .

If Marshalling and transmission time with  $p$  subpopulation =  $p[T_{mi} + T_{transi}]$

2) *Time in slave processors*: Mutation time, fitness evaluation time, adaptation time with  $p$  subpopulation is  $T_m$ ,  $T_f$  and  $T_a$  respectively.

After completing adaptation operation, slaves send mutated offspring to server. Unmarshalling time  $T_{umi}$  is considered here. Unmarshalling time is the time to create object from data stream. After reaching all offspring, selection operation is performed on mutated offspring and selection time  $T_s$  is obtained in master. The processing time in each slave is not equal because of communication delay. In experimental calculation maximum time is considered.

In BAS technique, selection mechanism is performed in master processor.

3) *Time in Master processor for selection*: Selection time with  $2N$  subpopulation is  $T_s$ ,  $N$  individuals for parent and  $N$  individuals for offspring so total is  $2N$  subpopulation. There is an important thing that maximum time is considered for calculating speedup among all slaves. Consider  $m$  is the number of slaves. Total time for distributed processors is as follows,

$$T_{Distributed} = T_r + p[T_{mi} + T_{transi} + \max_{1 \dots m}(T_m + T_f + T_a)] + pT_{umi} + T_s \quad (13)$$

Where  $T_{distributed}$  represents total distributed time,  $T_r$ ,  $T_{mi}$ ,  $T_{transi}$ ,  $T_m$ ,  $T_f$ ,  $T_a$ ,  $T_{umi}$ ,  $T_s$  represents recombination time, marshalling time, transmission time, mutation time, fitness evaluation time, adaptation time, unmarshalling time and selection time, respectively.

Speedup for distributed technique,

$$Speedup = T_{Single} / T_{Distributed} \quad (14)$$

Percentage of improvement, % = Speedup/Number of computer (15)

Computation time in distributed processors will be less than single processor. So, speedup will be gradually rising with increasing number of individuals in a population.

### C. Achieving Optimal Solution

Generally, problems can be solved using iterative methods or other conventional numerical methods but accuracy, effectiveness, less computation time etc. are the properties desirable to all of us. By adding evolutionary algorithm with conventional method, it is possible to get optimal solution because of its excellent capacity in case of changing the value of relaxation factor  $\omega$ . Accuracy is coming but a high amount time is needed for solving large number of equations having huge parameters. This situation will be removed using our proposed distributed technique in which large number of equations with huge parameters is solved within a short time. Table I sustains the efficiency of proposed distributed technique.

## IV. EXPERIMENTAL RESULTS

Using the proposed mathematical model we can see realistic experimental results. Consider a cluster with 20 homogeneous computers and 100 Mbits/sec Ethernet switch. Assume a population of 80 individuals and dimension 170 is evolved. This system is implemented in Java on a personal computer with Intel Pentium IV and 512MB RAM. Various results are displayed by considering different aspects. In our experiment, individual values are generated randomly. Here, random values are generated using normal distribution. -15 to 15 range is used for choosing random values. As normal distribution is used, result converges with few generations. Random values are generated with 80 individuals and 170 dimensions. Here, testing problem is  $a_{ii} = 20.0$ ,  $a_{ij} \in (0, 1)$ ,  $b_i = 10 * i$ ; that means P1 problem in Table I All graphs show the results of testing problem. Table I represents a few problems based on (1) and reflects performance and efficiency of distributed system.

In BAS method, marshalling and unmarshalling time is considered. When number of individuals are 30 and number of parameters are 100 for 15 number of computers in a cluster, then marshalling and transmission time is  $3.7 \times 10^{-3}$  sec, mutation time is  $7.6 \times 10^{-3}$  sec, fitness evaluation time is  $4.5 \times 10^{-3}$  sec, adaptation time is  $3.5 \times 10^{-3}$  sec and unmarshalling time is  $8.9 \times 10^{-4}$  sec. Number of individuals is 40 and number of parameters is 100 for 5 and 10 number of computers in a cluster.

Table I summarizes experimental results of various problems. In this experiment, number of computers in a

| P4             | $a_{ii} \in (-100, 100);$<br>$a_{ij} \in (-10, 10); b_i \in (-100, 100)$ | 20                | 80               | $1.64 \times 10^{-1}$              | $2.73 \times 10^{-2}$                   | $9 \times 10^{-2}$ |
| P4             | $a_{ii} \in (-100, 100);$<br>$a_{ij} \in (-10, 10); b_i \in (-100, 100)$ | 20                | 100              | No solution                        | $3.57 \times 10^{-2}$                   | $9 \times 10^{-2}$ |
| P5             | $a_{ii} = 5; a_{ij} = \{1, 0\};$<br>$b_i = 2;$                           | 20                | 50               | $1.53 \times 10^{-1}$              | $1.62 \times 10^{-2}$                   | $9 \times 10^{-2}$ |
| P6             | $a_{ii} \in (-70, 70);$<br>$a_{ij} \in (0, 7); b_i \in (0, 70);$         | 20                | 100              | $1.62 \times 10^{-1}$              | $1.60 \times 10^{-2}$                   | $9 \times 10^{-1}$ |
| P7             | $a_{ii} = 70; a_{ij} \in (-10, 10);$<br>$b_i \in (-70, 70);$             | 40                | 10               | $1.85 \times 10^0$                 | $2.13 \times 10^{-2}$                   | $9 \times 10^{-4}$ |
| P8             | $a_{ii} \in (2, 10);$<br>$a_{ij} \in (-2, 2); b_i \in (-5, 5)$           | 40                | 10               | $7.26 \times 10^{-1}$              | $4.30 \times 10^{-2}$                   | $9 \times 10^{-4}$ |

It is observed that P4 problem is tested in three cases and there is no solution in the last case for single processor but solution is occurred for distributed system because of computation complexity with huge parameters.

Fig. 3. Results for measuring speed according to number of computers in a cluster.

In Fig. 3. Using (14) speedup is shown that when number of slave computers is 5, 10 and 15 then, speedup is 3.36, 4.57 and 6, respectively. When number of slave computers is 5, 10 and 15 then percentage of improvement is sequentially 67.2 %, 45.7 % and 40 % is calculated based on (15). Fig. 4. Shows the time required for performing genetic operation in each slave. Here, number of slave computers in a cluster is 15 and individual is 30 and parameters are 100. There is no load balancing system so different slave computers need different time. Intuitively, workload balancing for a distributed system can be difficult because the working environment in a network is often complex and uncertain.

Fig. 4. Results for measuring time (seconds) according to computer number.

From Fig. 4, we can see that computer number 1 needs the highest computation time among all slaves. For calculating total distributed time, this maximum value is considered.

Fig. 5. Results for measuring generation number according to the number of parameters.

In Fig 5, generation number is considered for single and distributed processors according to parameter number. Here, number of slave computers in a cluster is 20 and individual is 80 and parameters are 130,150,160,170. To reach convergence generation number for single processor is 24, 27, 29, 30 and generation number for distributed processors is 12, 12, 15, and 15 according to number of parameters.

Fig. 6. Results for measuring error according to generation.

In Fig 6, error is considered according to generation. In this case, number of parameters is 100 and individual number is 40. Generation numbers are 40, 50 and 60.

Fig. 7. Results for measuring Time in distributed processors and single processor according to Individual.

Fig. 7 shows comparison of time between single and distributed processors. When individual is 40 and 80 then number of slave computers in a cluster is 10 and 20. When individual is 30 and 60 then number of slave computers in a cluster is 15. In this case, number of parameters is always 100.

## V. CONCLUDING REMARKS

It is easy to solve linear equations with less number of parameters in single processor but high computational cost is needed for large number of parameters. This cost is dramatically reduced using distributed system. This paper

introduced a new distributed algorithm for solving large number of equations with huge parameters. It also introduced a new selection method called BAS for selecting offspring. In this method, best individuals are selected and computation load is distributed in each slaves and mutation, fitness evaluation and adaptation operations are performed on distributed load. As distributed technique is used, computation time is reduced. Different problems are tested and high quality speedup is achieved in distributed system.

# Achieving Guaranteed Performance on Computational Grid

Ajanta De Sarkar, Dibyajyoti Ghosh, Rupam Mukhopadhyay and Nandini Mukherjee

Department of Computer Science and Engineering, Jadavpur University, Kolkata 700 032, West Bengal, India.

**Abstract:** For the dynamic nature of the Grid, the applications need to adapt to the changing resource status and usage scenarios. This is required to ensure that the performances of the components do not suffer. Objective of this paper is to present an adaptive execution scheme for achieving guaranteed performance as has been agreed upon through service level agreements (SLAs). The scheme has been implemented based on the notion of performance properties and by deploying a set of autonomous agents within an integrated performance-based resource management framework.

**Index Terms:** Adaptive Execution, Performance Properties, Grid

## I. INTRODUCTION

In a computational Grid environment, an application is executed as a set of jobs (components) [12], which are allocated to different resources in a heterogeneous and dynamic resource pool. The major objective is to achieve the performance of an application as desired by a client and as specified in the *service level agreements* set up between the client and the resource owners. However, Grid being a dynamic and complex environment, it is difficult to predict the appropriate set of resources, which will satisfactorily deliver the required performance. Often performance models are used to estimate the capabilities of the resource set and an application is mapped onto the resource set based on this model. But, such models generally fail because of the frequently changing resource load and resource usage scenario and the volatility of the resource pool, which resources may join and leave frequently. Thus, the initial mapping of the application components onto a set of selected resources may need to be reviewed and changed during run-time so that performances of any of the components do not suffer. Applications running on a Grid environment should therefore adapt themselves to certain changes in the environment so that any kind of performance degradation of any application component can be overcome.

This paper presents an adaptive execution scheme for achieving *guaranteed performance* of components (hereafter referred as jobs) of an application as has been agreed upon through service level agreements (SLAs). The scheme has been implemented by deploying a set of autonomous agents within an integrated multi-agent framework for performance-based resource management [12]. Within the framework, all the agents cooperate to

accomplish tasks like *resource brokering*, *performance monitoring and analysis* and *adaptive execution* of the jobs. A hierarchical agent framework is developed for performance analysis of these jobs at different levels [6]. The paper mainly deals with the adaptive execution strategies and algorithms within the multi-agent framework. Results of the adaptive execution scheme using local tuning techniques are implemented in this paper and adaptive execution scheme using migration technique is presented in [12].

The remaining part of this paper is organized as follows. Related work is discussed in Section 2. Section 3 presents the adaptive execution scheme. The concepts related to performance properties and their relevance in the current work are discussed in Section 4 and notion of severity along with its computation techniques are discussed in Section 5. Algorithms for maintaining quality of services and the agent interactions are described in Section 6. Section 7 and Section 8 give details of the experimental setup and results of the experiments that have been carried out to demonstrate the adaptive execution scheme and its effectiveness. Section 9 concludes with a direction of the future work.

## II. RELATED WORK

Adaptive execution has received a lot of attention from the Grid researchers. Grads project [2],[3] presents a program execution framework, which supports adaptive reallocation if performance degrades because of changes in the availability of Grid resources. It also implements rescheduling methods on the basis of resource selection model and monitors performance contracts using simple stop/migrate/restart strategy. The performance contracts specify the expected performance of modules as a function of available resources in Grid. In [5], a job-monitoring technique and an analyzer tool for automatic generation of the required job behaviour description are proposed. This work gathers resource access information, produces job behaviour description after the analysis. Then the job behaviour description is used to choose the scheduling algorithms of jobs in Grid. A low-cost rescheduling policy is proposed in [14]. With this policy, after the initial mapping, some jobs are selectively rescheduled on the basis of their run-time performance analysis. It considers rescheduling at a few, carefully selected points during execution. In this work, the change in the resource pool is not considered. In [17],

HEFT-based adaptive rescheduling algorithm is presented with collaboration between workflow planner and executor. In this approach, the executor will notify the planner about any run time event, through which planner gets information about resource unavailability or discovery of new resources. This research adapts the resource pool change to achieve better performance and reschedule the remaining jobs if necessary.

The OpenMP based adaptive parallelism is presented in [15]. In this system, task parallel OpenMP applications can execute on network of workstations (NOW) with a variable of nodes. Adaptive parallelism allows all processes to complete their current task, as processes do not have a compute-relevant private process state. The problem of resource selection and adaptation in grid environments is discussed in [16]. Adaptation of resources is done on the basis of degree of parallelism. In this work the adaptation coordinator periodically collects performance statistics and computes the weighted average efficiency. It compares the weighted average efficiency with certain threshold to add or remove processors from the cluster. The system, however, does not support run-time job migration.

Previous research works mainly concentrate on run-time job migration. On the other hand, the work presented in this paper supports adaptive execution either by application of local tuning techniques or through run-time job migration depending upon the specific situation. Our research focuses on an integrated multi-agent-based framework, in which agents (including mobile agents) are deployed to coordinate the adaptive execution of multiple concurrent jobs. This is also a novelty of our system. In order to detect the performance problem, we have used the notion of performance properties and their severities. Moreover, the algorithms and strategies presented in this work not only aims at maintenance of performance guarantee, but also attempts to keep the resource utilization cost as minimal as possible. Thus, any over-provisioning is controlled by iteratively measuring the severity of performance properties and taking appropriate action immediately (sometimes even decreasing the allocated resources). In the next section, we discuss the basic adaptive execution scheme.

### III. ADAPTIVE EXECUTION

In Grid environment, resources in a dynamic resource pool are owned by different resource-owners and are administered under multiple administrative domains. Status and load of the resources change frequently and the jobs need to adapt to the changes so that desired performance can be achieved. In this section, we present an adaptive execution scheme using local tuning techniques that is implemented within our multi-agent framework. However, adaptive execution scheme using

run-time job migration technique is discussed and implemented in [12].

#### A. Initial Allocation

Whenever, a client submits a batch of jobs (components of one or more applications), the client also specifies resource requirements for each of them. Along with the requirements, a job metadata, which describes the job, is also submitted. On the basis of the job requirements and the resource capabilities, a resource selection algorithm is run to select an initial set of resources to which the batch of jobs is allocated. For each job, an SLA is established between the selected resource provider and the client. The SLA provides detailed information about the requirements of the job and availability of resources, while job metadata contains information regarding significant parts (such as loops) of the job [7]. The SLA also contains the *expected completion time* ( $T_{est}$ ), which provides the basis of the performance guarantee for the job. Consequently, the next objective of the multi-agent framework is to maintain this performance guarantee by adaptively executing the job.

In general, a job may adapt to its current run-time environment depending on its own resource requirement and the present resource usage scenario. Additionally, adaptive execution may also be provided by automatic migration of the job in any of the following cases (but not limited to them) (i) performance degradation, (ii) changes in job requirements, (iii) resource failure, (iv) any kind of fault in the execution environment. Our multi-agent framework enables adaptive execution by considering the above two situations. It firstly applies local tuning techniques, i.e. attempts to improve the underlying execution environment as and when necessary and secondly supports automatic migration of the job to another appropriate resource provider when resource requirement cannot be fulfilled on the current resource provider.

#### B. Performance Analysis

Following the SLA establishment, each job is submitted onto the selected resource provider and a JobExecutionManager Agent (JEM Agent), which is a mobile agent, becomes associated with it and is deployed on the same host along with the job. A Node-level Analysis Agent (NA) [6] [7] sitting on the resource provider monitors execution of all jobs submitted to that resource provider and analyses their performances. Performance analysis for every job is done at periodic intervals. The NA instructs the JEM Agent to suspend the job after executing certain portion of it, gathers all relevant performance data at this point and analyses the data. In case the NA identifies a performance problem or predicts (explained in the next section) that the resource

provider may fail to maintain the performance guarantee, it invokes a Tuning Agent (TA).

### C. Tuning Actions

The TA decides either to locally tune the job or to migrate the job to a different resource provider. The decision regarding the next course of action (local tuning or migration) is taken on the basis of the nature of the performance problem and the resource availability and current status. Thus, the job may execute using more number of threads on more number of processors or may be tuned to reduce the load imbalance in case sufficient resources are available on the same resource provider. However, if resources on the same resource provider are overloaded or a resource provider with higher capability is required to achieve the guaranteed performance, then the job is migrated. The JEM Agent then selects (explained later) a new suitable resource provider and reschedules the job to this newly selected resource provider and resumes its execution from the point at which it has been suspended. The JEM Agent, being a mobile agent, moves along with the job, controls execution of the job and performs resource-brokering task when rescheduling is required.

## IV. PERFORMANCE PROPERTIES

One of the major differences of our work with other similar research works presented in literature is that it *depends on the notion of performance properties*. Performance properties have been introduced in [8] and thoroughly discussed in [9]. A performance property characterizes specific performance behaviour of a program, such as load imbalance, cache misses and communication. Every performance property can be checked by a set of conditions and is associated with a severity figure, which shows how important the performance property is in the context of the performance of an application. When the severity figure crosses a pre-defined threshold value, the property becomes a performance problem and the performance property with highest severity value is considered to be a performance bottleneck.

In our system, the resource provider defines a set of performance properties which are relevant for the machine architecture and the programming paradigm used for executing jobs. At the time of execution of a job these performance properties are checked at certain *measuring points* and for each, the severity value is computed. The severity values are computed on the basis of performance property specifications (define the condition, confidence and severity for each property), which are defined and stored on the resource provider. During the execution of a job, performance data are collected at certain intervals (at measuring point) and on the basis of this data and the performance property specifications, the severities of specified performance

properties are evaluated and a *Performance Details Report* is generated [6]. In order to evaluate the severity of certain performance property, some parameters from the SLA are also required (next section).

Two performance properties are used for the current work. First is the *InadequateResources* property that identifies the problem related to execution of a portion of job sequentially (or on less number of processors) when additional number of processors is required to achieve performance guarantee.<sup>1</sup> Second is the *LoadImbalance* property. Severity computation procedures for these properties are discussed in the next section.

## V. QOS AND SEVERITY COMPUTATION

In a computational Grid environment, *quality of services* (QoS) is primarily defined in terms of the execution performance of an application or the components of the application submitted by a client. QoS desired by a client and guaranteed by a resource provider is specified in an SLA. At the time of initial allocation of a job onto a resource provider, the client first sends *Task Service Level Agreement* (TSLA) to the resource broker component. The TSLA contains two parts; in the first part the requirements for a job (such as preferred start-time, expected completion time, number of processors) are specified and in the second part information about every significant region (loop) in the program (such as nesting level, loop bounds) are specified in the form of job metadata. A *Resource Service Level Agreement* (RSLA) containing information about the capabilities of a resource provider is sent by the resource provider to the resource broker component. When a specific resource provider is selected for a job [13], the SLA is finalized in the form of a *Binding Service Level Agreement* (BSLA) which is a tripartite agreement between the client, the resource provider and the brokering component of the system. BSLA contains information about the requirements of the job and availability of resources as committed by the resource provider.

The *expected completion time* ( $T_{ec}$ ) for a job is generally based on some pre-execution analysis of the job or on historical data gathered after any previous execution of it. Severities of the performance properties in some cases are computed using the information stored in the JobMetaData of the BSLA. For every job, a JobMetaData is submitted by the client that contains information about its significant regions. In this work only loops are considered as significant regions. Severity

---

<sup>1</sup> A property called *Non-parallelized code* has been used in [9] in order to capture the overhead due to sequential part of the program. However, the property defined by us not only captures the problem due to sequential part of a job, but also it detects performance problems when a job is running parallelly using less number of threads than it requires to use in order to maintain the guaranteed performance.

values are computed during the execution of these significant regions only. Whenever, a significant region starts executing, the NA introduces certain measuring points within the region by communicating a factor  $f$  to the JEM Agent which controls the execution of the job. The factor  $f$  indicates the distance between two measuring points (initially distance of the first measuring point from the start of the significant region). At each point, performance data regarding execution of the job are collected and sent to the NA for computation of severity values. Occasionally, NA may revise the factor  $f$  depending on the requirements.

In case of Inadequate Resources Property, the severity figure for a specific loop  $L_i$  is given by,

$$\text{sev\_resr}(L_i) = [T_{\text{fact}}^f(L_i) / T_{\text{fect}}^f(L_i)] \quad (1)$$

where, expected completion time of  $f$  portion of a loop ( $L_i$ ) is given by  $T_{\text{fect}}^f(L_i)$ , and actual completion time of  $f$  portion of the same loop ( $L_i$ ) (as measured at the time of execution) is given by  $T_{\text{fact}}^f(L_i)$ .  $T_{\text{fect}}^f(L_i)$  is computed using the information in the JobMetaData. Thus,

$$T_{\text{fect}}^f(L_i) = [L_{\text{frac}}^i * T_{\text{ect}} * f] \quad (2)$$

$L_{\text{frac}}^i$  is the proportionate execution time of the loop ( $L_i$ ) during its current invocation with respect to the total execution time of the job (we consider this to have been collected from historical data or through profiling and to be part of BSLA).

In case of Load Imbalance Property, execution times for every thread are measured. Thus, the severity figure for a loop  $L_i$  is given by

$$\text{sev\_load}(L_i) = [(T_{\text{max}}^f(L_i) - T_{\text{avg}}^f(L_i)) * 100] / T_{\text{max}}^f(L_i) \quad (3)$$

where,  $T_{\text{max}}^f(L_i)$  is the maximum time spent in a thread to execute  $f$  portion of the loop and  $T_{\text{avg}}^f(L_i)$  is the average taken over the times spent in all the threads to execute  $f$  portion of the loop.

Thus, when the above severity values are greater than a threshold (here greater than 1), the corresponding performance problem is detected. Such problems indicate that the QoS cannot be maintained, or in other words guaranteed performance cannot be achieved. Therefore, the agents involved with the process take some action so that the performance problem can be overcome. Next section describes the operations and interactions of the agents in order to explain how QoS is maintained in the system.

## VI. QOS MAINTENANCE

In this section, we focus on the services of the agents and their interactions from three different perspectives: (i) run-time performance analysis of jobs, (ii) run-time local tuning of jobs and (iii) run-time job migration to other resources.

### A. Performance Analysis

NAs are always active in each resource provider in the Grid and are responsible for run-time performance analysis of all the jobs running using the local resources. When execution of a job starts, the JEM Agent associated with it sends 'Registration' message to the NA. NA, in response sends a message back to the JEM Agent indicating the fraction of each significant region to be executed before collection of any performance data (the factor  $f$ ). JEM Agent collects performance data and sends the data to the NA and suspends the job. NA computes severities of different performance properties (such as  $\text{sev\_resr}(L_i)$  and  $\text{sev\_load}(L_i)$ ) the particular significant region. If any of the properties is detected as severe, NA invokes TA and sends 'Warning' message to the JEM Agent. In case, none of the measured properties are severe, NA sends 'Resume' message to the JEM Agent for resumption of the job. The 'Resume' message also carries a revised value of  $f$  that indicates the next portion of the significant region to be executed before arriving at a measuring point. NA continues this iterative performance analysis till the end of the job.

### B. Local Tuning

Like NAs, TAs are always active in each local resource provider in the Grid. A TA is invoked by NA and receives the severity message from NA containing the job\_id, performance property which has been identified as a performance problem and the severity value. TA checks the resource availability for tuning for the *InadequateResources* property on the local resource provider and if resources are available it sends a message indicating the required number of resources to the JEM Agent. If the resources are not available it sends an appropriate message to the JEM Agent. In case of *LoadImbalance*, local scheduling strategy to different threads may be changed. The TA instructs the JEM Agent to change the strategy, and the JEM Agent changes it and executes the remaining job with the new strategy. Currently, TA uses a simple algorithm because it handles only two performance properties. However, in a complicated scenario a better algorithm and a proper use of a knowledge base may be introduced.

### C. Job Migration

The major decision to be taken at the time of migration of the job is where the job is to be migrated. In the hierarchical agent framework, a higher-level agent, called Grid Site Agent (GSA) [7], is used to monitor all the grid resources located at a particular geographical site. A ResourceProvider Agent (RPA) [12], on the other hand, is responsible for maintaining information and

establishing SLAs with the client. Each JEM Agent carries a *ResourceProviderList*, which contains all the Resource Providers who can meet the requirements of the job (in ascending order of resource utilization cost [13]). During the execution of a job, if the TA indicates that migration is required, it sends the *ResourceProviderList* to the GSA. GSA checks resource availability and current load of each resource using Ganglia information provider [10]. It sends back a *RevisedResourceProviderList*, which contains only the resource providers who can currently fulfill the requirements of the job in order to achieve the guaranteed performance. Because Grid is a dynamic environment, this step helps to take into account any change in the resource pool. The JEM Agent selects a Resource Provider from the list, sends a BSLA to the corresponding remote RPA. If the RPA accepts the BSLA, job is migrated to the particular resource provider along with the JEM Agent; otherwise, the next Resource Provider from the list is contacted.

## VII. EXPERIMENTAL SETUP

The above adaptive execution scheme has been tested on a local Grid test bed that has been set up with heterogeneous nodes running in Linux. The Grid test bed is built with Globus Toolkit 4.0 (GT4) [11]. Ganglia Information Provider [10] is installed in each node of the Grid test bed. The multi-agent system (which includes the hierarchical analysis agent framework) is implemented on top of GT4. The agents (NA, JEM Agent, TA, RPA and GSA) are deployed on these nodes. These agents interact with different components of Grid. The agent framework is developed using Jade technology [1].

We have used Java codes with JOMP [4] directives as test codes, and executed them in the above environment. Next section demonstrates the results of running two test codes, one is LU factorization, and other is matrix multiplication. Experiments are primarily carried out on a HP ProLiant ML570 G4 with 4 Intel core2 Duo processors (referred as *HPserver*) and HP NetServer LH 6000 with 2 processors (referred as *Netserver*) in our local Grid test bed.

## VIII. RESULTS

We have experimented with periodic and iterative performance analysis and tuning techniques for both *InadequateResources* and *LoadImbalance* performance properties according to a given priority. As discussed in Section 6, the NA first checks the *InadequateResources* Property and then the *LoadImbalance* Property periodically. Each job starts executing with a single thread (on a single processor) and *static* scheduling strategy. Whenever, a performance problem is detected, a tuning action is taken. Fig. 1 and Fig. 2 compare the

expected completion time ( $ect$ , provided by the client), projected completion time ( $P_{act}$ , obtained after extrapolating the measured runtime after executing a portion of the job) and actual completion time ( $f_{act}$ , time needed to complete the job) for LU Factorization and Matrix Multiplication respectively.

Fig. 1: Result of the experiments with LU Factorization job

Fig. 2: Result of the experiment for Matrix Multiplication job

*Discussion* - The results demonstrate that using local tuning techniques we could achieve guaranteed performance within some tolerance level. If the tuning techniques were not applied, execution time of the job would be far more than what desired by the client (shown by  $P_{act}$ ). But tuning techniques have been applied (increasing number of processors and changing scheduling strategies) repeatedly on the jobs in order to eliminate the observed performance problems and therefore the actual completion time is close to (usually less than) the expected completion time. However we may not always achieve 100% guaranteed performance. The reason is that our algorithm supports run-time allocation of processors to the job, hence number of processors are increased and decreased dynamically (based on the severity values) and often in the last portion of the job, the guaranteed performance is slightly violated. In future, we will test our algorithm with several other test codes for guaranteed performance and

also attempt to add more sophisticated techniques. A major strength of our techniques is that, because of dynamic allocation, resource utilization cost is optimized.

## IX. CONCLUSION

An adaptive execution scheme based on a Hierarchical Analysis Agent framework is presented in this paper. The scheme supports performance analysis of components of applications executing parallelly on different resource providers and dynamically improving their execution performances. The scheme is based on the notion of performance properties, and supports both local tuning and migration of jobs depending on resource availability and the current resource usage scenarios. Some experiments have also been carried out which demonstrate the effectiveness of the framework. It has also been observed, that the agent control overheads are negligible even when multiple jobs are submitted concurrently onto the same resource provider. The work presented in this paper can be extended further to include more complicated situations and to exploit sophisticated knowledge base for appropriate tuning of the jobs.

**Abstract**— In this paper, we present a deadlock-free routing algorithm for the Tori connected mESH (TESH) network using 2 virtual channels – 2 being the minimum number for dimension-order routing – and evaluate the network's dynamic communication performance under the hot-spot traffic pattern, using the proposed routing algorithm. We evaluate the dynamic communication performance of TESH, mesh, and torus networks by computer simulation. It is shown that the dynamic communication performance of the TESH network is better than that of the mesh and torus networks. It is also shown that the relative difference in maximum throughput between torus and TESH networks decreases with the increase of hot spot traffic.

**Index Terms**— TESH network, deadlock-free routing, hot-spot traffic pattern, dynamic communication performance.

## I. INTRODUCTION

Interconnection networks are the key elements for building massively parallel computers. A TESH network [1] is an interconnection network for large-scale 3D multicomputers. It consists of multiple basic modules (BMs) which are 2D-mesh networks. The BMs are hierarchically interconnected by a 2D-torus to build higher level networks.

While the details of TESH networks are available in the literature [1–4], its major features can be summarized as follows: it is hierarchical, thus allowing exploitation of computation locality as well as easy expansion up to hundreds or thousands of nodes, it permits efficient VLSI realization, it is designed for fault tolerance by making use of redundancy for defect circumvention, it is well suited for 3-D stacked implementation, and it provides good dynamic communication performance under uniform traffic pattern. In this paper, we are specifically interested to investigate the effect of hot-spot traffic pattern in the TESH network.

Deterministic, dimension-order routing is popular in multicomputers because it has minimal hardware requirements and allows the design of simple and fast routers.

Wormhole routing [5] has become the dominant switching technique because it makes latency independent of the message distance. Virtual channels [6, 7] were originally introduced to solve the problem of deadlock in wormhole-routed networks. Since the hardware cost increases as the number of virtual channels increases, the unconstrained use of virtual channels is not cost-effective in parallel computers. In this study, we use a deadlock-free routing algorithm for the TESH network using 2 virtual channels – 2 being the minimum number for dimension-order routing.

The dynamic communication performance of the TESH network with a dimension-order routing algorithm under uniform traffic pattern using 2 and 4 virtual channels and hot-spot traffic pattern using 4 virtual channels was evaluated [4], and it is proved to be better than that of conventional mesh network, but not that of torus network. However, the details analysis of the dynamic communication performance on the TESH network under the hot-spot traffic patterns has not yet been studied. The main objective of this paper is to investigate the impact of hot-spot traffic pattern on the TESH network.

The remainder of the paper is organized as follows. In Section II, we briefly describe the basic structure of the TESH network. The dynamic routing algorithm is proposed in Section III and its freedom from deadlock is also proved using minimum number of virtual channels. The dynamic communication performance of the TESH network under hot-spot traffic pattern is discussed in Section IV. Finally, Section V presents the conclusion.

## II. INTERCONNECTION OF THE TESH NETWORK

### A. Architecture of TESH Network

The *Tori-connected mESH (TESH) Network* is a hierarchical interconnection network consisting of Basic Modules (BM) that are hierarchically interconnected to form a higher level network. The BM of the TESH network

is a 2D-mesh network of size  $(2^m \times 2^m)$ . In this paper, BM refers to a Level-1 network. Successively higher level networks are built by recursively interconnecting immediately lower level subnetworks in a 2D-torus network. A higher-level network is built using a 2D-toroidal connection among  $(2^{2m})$  immediate lower level subnetworks. A TESH( $m, L, q$ ), which by definition is constructed using  $2^m \times 2^m$  basic modules, has  $L$  levels of hierarchy. The last parameter  $q$  is the inter-level connectivity.

If  $m = 2$ , the size of the BM is  $(4 \times 4)$ , and in this paper, we focus attention on  $m = 2$  i.e.,  $(4 \times 4)$  BMs. A BM of  $(4 \times 4)$  is shown in Figure 1. As seen in the figure, the BM has some free ports in the periphery for higher level interconnection. All ports of the interior Processing Elements (PEs) are used for intra-BM connections. All free ports of the exterior PEs, either one or two, are used for inter-BM connections to form higher level networks.

In principle,  $m$  could be any positive integer value. However, if  $m = 1$ , then the network degenerates to a hypercube network. Hypercube is not a suitable network, because its node degree increases along with the increase of network size. If  $m = 2$ , then it is considered the most interesting case, because it has better granularity than the large BMs. In the rest of this paper we consider  $m = 2$ , therefore, we focus on a class of TESH( $2, L, q$ ) networks.

A  $2^m \times 2^m$  BM has  $2^{m+2}$  free ports at the contours for higher level interconnection. For each higher level interconnection, a BM uses  $4 \times (2^q) = 2^{q+2}$  of its free links,  $2(2^q)$  free links for vertical interconnections and  $2(2^q)$  free links for horizontal interconnections. Here,  $q \in \{0, 1, \dots, m\}$ , is the inter-level connectivity.  $q = 0$  leads to minimal inter-level connectivity, while  $q = m$  leads to maximum inter-level connectivity.

With  $q = 0$ , for example,  $L_{max} = (2^{2-0} + 1) = 5$ . Level-5 is the highest possible level for a  $(4 \times 4)$  BM. The limitation of having a maximum level of hierarchy is not a serious constraint. For the case of  $(4 \times 4)$  BM with  $q = 0$ , a network built with the highest level, Level-5, consists of 1 million PEs. Successive higher level networks are built recursively by interconnecting the immediately lower level sub-networks. A higher-level network having  $(2^m \times 2^m)$  BM is built using a  $(2^{2m})$  subnetworks using a 2D-toroidal connection. For example, considering  $(m = 2)$  a Level-2 subnetwork, can be formed by interconnecting  $2^{2 \times 2} = 16$  BMs. Similarly, a Level-3 network can be formed by interconnecting 16 Level-2 subnetworks, and so on. This phenomena is illustrated in Figure 2, a Level-2 TESH network can be formed by interconnecting 16 BMs as a  $(4 \times 4)$  2D-torus network. Each BM is connected to its logically adjacent BMs. To avoid clutter, the wraparound links of the BMs are not shown.

### B. Addressing of Nodes

Base-4 numbers are used for convenience of address representation. As seen in Figure 1, nodes in the BM

Fig. 1. Basic module of the TESH network

are addressed by two digits, the first representing the row index and the next representing the column index. More generally, in a Level- $L$  TESH network, the node address is represented by:

$$\begin{aligned}
 A &= A^L A^{L-1} A^{L-2} \dots A^2 A^1 \\
 &= a_{n-1} a_{n-2} a_{n-3} \dots a_2 a_1 a_0 \\
 &= a_{2L-1} a_{2L-2} a_{2L-3} a_{2L-4} \dots a_3 a_2 a_1 a_0 \\
 &= (a_{2L-1} a_{2L-2}) (a_{2L-3} a_{2L-4}) \dots \\
 &\quad \dots (a_3 a_2) (a_1 a_0)
 \end{aligned} \tag{1}$$

Here, the total number of digits is  $n = 2L$ , where  $L$  is the level number.  $A^L$  is the address of level  $L$  in row-major scheme, and  $(a_{2L-1} a_{2L-2})$  is the co-ordinate position of Level- $(L-1)$  for Level- $L$  network. Pairs of digits run from group number 1 for Level-1, i.e., the BM, to group number  $L$  for the  $L$ -th level. Specifically,  $i$ -th group  $(a_{2i-1} a_{2i-2})$  indicates the location of a Level- $(i-1)$  subnetwork within the  $i$ -th group to which the node belongs;  $1 \leq i \leq L$ . In a two-level network the address becomes  $A = (a_4 a_3) (a_1 a_0)$ . The first pair of digits  $(a_4 a_3)$  identifies the BM to which the node belongs, and the last pair of digits  $(a_1 a_0)$  identifies the node within that basic module.

## III. ROUTING ALGORITHM FOR TESH NETWORK

### A. Dynamic Routing Algorithm

Routing of messages in the TESH network is performed from top to bottom. That is, it is first done at the highest level network; then, after the packet reaches its highest level sub-destination, routing continues within the subnetwork to the next lower level sub-destination. This process is repeated until the packet arrives at its final destination.

Fig. 2. Interconnection of a TESH network

When a packet is generated at a source node, the node checks its destination. If the packet's destination is the current BM, the routing is performed within the BM only. If the packet is addressed to another BM, the source node sends the packet to the outlet node which connects the BM to the level at which the routing is performed.

We have considered the dimension order routing algorithm for the TESH network. We use the following strategy: at each level, vertical routing is performed first. Once the packet reaches the correct row, then horizontal routing is performed. Routing in the TESH network is strictly defined by the source node address and the destination node address. Let a source node address be  $s = (s_{2L-1}, s_{2L-2}), (s_{2L-3}, s_{2L-4}), \dots, (s_3, s_2), (s_1, s_0)$ , a destination node address be  $d = (d_{2L-1}, d_{2L-2}), (d_{2L-3}, d_{2L-4}), \dots, (d_3, d_2), (d_1, d_0)$ , and a routing tag be  $t = (t_{2L-1}, t_{2L-2}), (t_{2L-3}, t_{2L-4}), \dots, (t_1, t_0)$ , where  $t_i = d_i - s_i$ . Figure 3 shows the routing algorithm for the TESH network.

### B. Deadlock-Free Routing

A deadlock-free routing algorithm can be constructed for an arbitrary interconnection networks by introducing virtual channels. In this section, we investigate the number of virtual channels required to make the routing algorithm deadlock-free for the TESH network. We also present a proof that the TESH network is deadlock-free by these number of virtual channels. To prove the proposed routing algorithm for the TESH network is deadlock free, we divide the routing path into three phases, as follows:

- *Phase 1*: Intra-BM transfer path from source node to the outlet node of the BM.
- *Phase 2*: Higher level transfer path.

sub-phase 2.i.1 : Intra-BM transfer to the outlet PE of Level  $(L - i)$  through the  $y$ -link.

sub-phase 2.i.2 : Inter-BM transfer of Level  $(L - i)$  through the  $y$ -link.

sub-phase 2.i.3 : Intra-BM transfer to the outlet PE of Level  $(L - i)$  through the  $x$ -link.

sub-phase 2.i.4 : Inter-BM transfer of Level  $(L - i)$  through the  $x$ -link.

- *Phase 3*: Intra-BM transfer path from the outlet of the inter-BM transfer path to the destination PE.

The proposed routing algorithm enforces some routing restrictions to avoid deadlocks [6]. Since dimension-order routing is used in the TESH network, routing of message first performed in the vertical direction and then in the horizontal direction. The interconnection of the BM is a mesh network and the higher level network is a torus connection. The number of virtual channels required to make the routing algorithm deadlock-free for the TESH network is determined using Lemma 1 and 2.

*Lemma 1*: If the message is routed in the  $y \rightarrow x$  direction in a 2D-mesh network, then the network is deadlock free with 1 virtual channels. [9]

*Lemma 2*: If the message is routed in the  $y \rightarrow x$  direction in a 2D-torus network, then the network is deadlock free with 2 virtual channels. [9]

*Theorem 1*: A TESH network with 2 virtual channels is deadlock free.

*Proof*: In phase-1 and phase-3 routing, packets are routed in the source-BM and destination-BM, respectively. The BM of the TESH network is a 2D-mesh network. According to Lemma 1, the number of necessary virtual channels for phase-1 and phase-3 is 1. The routing of the message in source-BM and destination-BM is carried out separately. The virtual channels required in phase-1

Routing Algorithm for a Level-L TESH:

```

Routing(s,d);
source,s={s2L-1,s2L-2,...,s0}; destination,d={d2L-1,d2L-2,...,d0};
tag;t2L-1,t2L-2,...,t0; group;g;

for i = 2L-1:2;
 if (di-si+2m) mod 2m <= 2m/2 then
 routedir = plus; ti= (di-si+2m) mod 2m;
 else routedir = minus; ti= 2m- (di-si+2m) mod 2m; endif;

 g = get_group_number(s,d,routedir);

 while(ti!= 0) do
 if i is even number then
 outlet_nodex= outlet_x(g,i/2+1,H,routedir);
 outlet_nodey= outlet_y(g,i/2+1,H,routedir);endif;
 if i is odd number then
 outlet_nodex= outlet_x(g,i/2+1,V,routedir);
 outlet_nodey= outlet_y(g,i/2+1,V,routedir);endif;
 BM_routing(outlet_nodex, outlet_nodey);
 } (a)

 if routedir = plus then send packet to next BM;
 else send packet to previous BM; endif; } (b)

 ti= ti- 1;
endwhile;
endfor;

BM_routing(d1,d0); → (c)
end.

BM_routing(dx, dy);
source,sx,sy; destination,dx,dy;
tag;tx,ty;

tx= dx- sx;
ty= dy- sy;
while(ty!= 0) do
 if ty> 0 then move packet to upper node; ty= ty- 1; endif;
 if ty< 0 then move packet to lower node; ty= ty+ 1; endif;
endwhile;
while(tx!= 0) do
 if tx> 0 move packet to right node; tx= tx- 1; endif;
 if tx< 0 move packet to left node; tx= tx+ 1; endif;
endwhile;
end.

```

Fig. 3. Routing algorithm of the TESH network

and *phase-3* can share each other. Intra-BM links between inter-BM links are used in sub-phases 2.i.1 and 2.i.3. Thus, sub-phases 2.i.1 and 2.i.3 utilize channels over intra-BM links, sharing the channels of either *phase-1* or *phase-3*. The free links of the BM are used in inter-BM routing, i.e., sub-phases 2.i.2 and 2.i.4, and these links form a 2D-torus network for the higher level network. According to Lemma 2, the number of necessary virtual channels for this 2D-torus network is also 2. According to the structure of the TESH network, the inter-BM links other than the wrap-around links in the end-to-end node of the higher level networks used in sub-phases 2.i.2 and 2.i.4 routes messages like mesh network. Thus, the routing of messages in this part can share the channels of either *phase-1* or *phase-3*. And the wrap-around links uses the another links of the 2D-torus in the higher level networks.

Therefore, the total number of necessary virtual channels for the whole network is 2.

#### IV. DYNAMIC COMMUNICATION PERFORMANCE

The overall performance of a massively parallel computer system is affected by the performance of the in-

terconnection network, as well as by the performance of the nodes. Continuing advances in VLSI/NoC technologies promise to deliver more power to individual nodes. On the other hand, low performance of the communication network will severely limit the speed of the entire system. Therefore, the success of massively parallel computers is highly dependent on the efficiency of their underlying interconnection networks.

##### A. Performance Metrics

The dynamic communication performance of a massively parallel computer systems is characterized by *message latency* and *network throughput*. Message latency refers to the time elapsed from the instant when the first flit is injected to the network from the source, to the instant when the last flit of the message is received at the destination. In wormhole routing, it is the average value of the time elapsed between injection of the header flit into the network from the source, and reception of the last unit of the data flit at the destination. Network throughput refers to the maximum amount of information delivered per unit of time through the network. For the network to have good performance, low latency and high throughput must be achieved. When the dynamic communication performance of various networks are compared by computer simulation and wormhole routing is used, latency is measured in simulator clock cycles and throughput is measured in flits per node and per clock cycle.

##### B. Hot-Spot Traffic Pattern

Traffic patterns are pairs of nodes that communicate. In an interconnection network, sources and destinations for messages form the traffic pattern. Traffic characteristics such as message length, message arrival time, and destination distribution have significant performance implications. Message destination distributions vary a great deal depending on the network topology and the application's mapping onto different nodes. Depending on the characteristics of an application, some nodes may communicate with each other more frequently than with others. Consequently, non-uniform traffic patterns are frequent, and cause uneven usage of traffic resources, significantly degrading the dynamic communication performance of the network.

When a hot spot occurs, a particular communication link experiences a much greater number of requests than the rest of the links – more than it can service. In a remarkably short period of time, the entire network may become congested. Hot spots are particularly insidious because they may result from the cumulative effects of very small traffic imbalances. Hot spots often occur because of the burst nature of program communication and data requirements. For generating hot spot traffic we used a model proposed by Pfister and Norton [10]. According to this model, each node first generates a random number. If that number is less than a predefined threshold, the message will be

sent to the hot-spot node. Otherwise, the message will be sent to other nodes, with a uniform distribution. Here, in uniform distribution, message destinations are chosen randomly with equal probability among the nodes.

To observe the effect of non-uniformity, in this paper, we are specifically interested in how the hot-spot traffic pattern affects the dynamic communication performance of the TESH network.

### C. Simulation Environment

The total number of nodes in a TESH is  $N = 2^{2mL}$ . If  $m = 2$  and  $L = 3$  then the total number of nodes of the TESH is 4096. That is, Level-3 TESH network has 4096 nodes.  $64 \times 64$  mesh network and  $64 \times 64$  torus network have 4096 nodes. We have evaluated the dynamic communication performance of TESH, mesh, and torus networks with 4096-nodes.

To evaluate dynamic communication performance, we have developed a wormhole routing simulator. In our simulation, we use a dimension-order routing algorithm and hot-spot traffic pattern. The dimension-order routing algorithm, which is exceedingly simple, provides the only route for the source-destination pair. Two virtual channels per physical channel are simulated, and the virtual channels are arbitrated by a round robin algorithm. For all of the simulation results, the packet size is 16 flits. Two flits are used as the header flit.

In the evaluation of dynamic communication performance, flocks of messages are sent in the network to compete for the output channels. For each simulation run, we have considered that the message generation rate is constant and the same for all nodes. Flits are transmitted at 20,000 cycles; in each clock cycle, one flit is transferred from the input buffer to the output buffer, or from output to input if the corresponding buffer in the next node is empty. Therefore, transferring data between two nodes takes 2 clock cycles.

### D. Dynamic Communication Performance Evaluation

In real application, it may happen that there are some packets (hot-spot packets) which remain in the network, and request rates are very high. Here, the simulations were carried out under the condition that, for TESH network,  $\text{Node}(n_5, n_4)(n_3, n_2)(n_1, n_0)$  are source nodes and  $\text{Node}(n_5, n_4)(0, 0)(0, 0)$  are hot-spot nodes with the hot-spot flit generation probability  $P_h = 0.02, 0.05, 0.10$ , and  $0.20$ , i.e., the hot-spot percentages are assumed to be 2%, 5%, 10%, and 20% for all networks. For mesh and torus networks, we divide the networks into  $4 \times 4$  matrix. From each part, the node which is closest to the center is assumed to be the hot-spot node, with same hot-spot percentages as listed above.

Figure 4 depicts the message latency versus network throughput curves for the hot-spot traffic pattern with different hot-spot percentage. Figure 4(a) represents the

result of simulations using 2% hot-spot traffic. It is shown that the average transfer time of the TESH network is far lower than that of the mesh and torus networks. The maximum throughput of the TESH network is lower than that of those networks. Figure 4(b) represents the result of simulations using 5% hot-spot traffic. It is shown that the average transfer time of the TESH network is far lower than that of the mesh and torus networks. The maximum throughput of the TESH network is still lower than that of the mesh and torus networks. However, the relative difference in maximum throughput between TESH and mesh and torus networks is decreases with the increase of hot-spot traffic from 2% to 5%. Figure 4(c) represents the result of simulations using 10% hot-spot traffic. It is also shown that the average transfer time of the TESH network is far lower than that of the mesh and torus networks. The maximum throughput of the TESH network is higher than that of torus network and almost equal to that of mesh network. Figure 4(d) represents the result of simulations using 20% hot-spot traffic. As usual, it is shown that the average transfer time of the TESH network is far lower than that of the mesh and torus networks. The maximum throughput of the TESH network is far higher than that of the mesh and torus networks. Therefore, with the increase of hot-spot traffic percentage in hot-spot traffic pattern, the hierarchical TESH network yields better dynamic communication performance than that of the conventional mesh and torus networks.

One interesting point to be noted here is that the relative difference in maximum throughput between torus and the hierarchical TESH network decreases with the increase of hot-spot traffic, and it is shown in Figure 4(d) that with 20% hot spot traffic the maximum throughput of the TESH networks are higher than that of the torus network.

## V. CONCLUSION

A deadlock free routing algorithm using dimension-order routing with a minimum number of virtual channels has been proposed for the TESH network. It has been proved that 2 virtual channels per physical channel are sufficient for the deadlock free routing algorithm of the TESH network; 2 is also the minimum number of virtual channels for dimension-order routing. By using the routing algorithm described in this paper and the hot-spot traffic pattern, we have evaluated the dynamic communication performance of the TESH network as well as that of several other commonly used networks. The average transfer time of TESH network is lower than that of the mesh and torus networks. Maximum throughput of the TESH network is also higher than that of those networks with the increase of hot-spot traffic. A comparison of dynamic communication performance reveals that the TESH network outperforms the mesh and torus networks because it yields low latency and high throughput, which are indispensable for high performance massively parallel computers.

(a) 2% Hot-spot traffic

(b) 5% Hot-spot traffic

(c) 10% Hot-spot traffic

(d) 20% Hot-spot traffic

Fig. 4. Dynamic communication performance of dimension-order routing with hot spot traffic pattern on various networks: 4096 nodes, 2 VCs, 16 flits, and  $q = 0$

The performance degradation with the presence of large number of long length links is removed by replacing the long length electronic links by optical links. The performance evaluation of this opto-electronic TESH network is kept in mind as future works.

**Abstract**—Interconnection networks play a crucial role in the performance of massively parallel computers. Hierarchical interconnection networks provide high performance at low cost by exploring the locality that exists in the communication patterns of massively parallel computer systems. The *Tori-connected mESH (TESH) Network* is a 2D-torus network of multiple basic modules, in which the basic modules are 2D-mesh networks that are hierarchically interconnected for higher level networks. In this paper, we present a deadlock-free routing algorithm for the TESH network using 2 virtual channels – 2 being the minimum number for dimension-order routing – and evaluate the network's dynamic communication performance under various nonuniform traffic patterns, using the proposed routing algorithm. We evaluate the dynamic communication performance of TESH, mesh, and torus networks by computer simulation. It is shown that the dynamic communication performance of the TESH network is better than that of the mesh and torus networks.

**Index Terms**—TESH network, deadlock-free routing, nonuniform traffic patterns, dynamic communication performance.

## I. INTRODUCTION

Interconnection networks are the key elements for building massively parallel computers. A TESH network [1] is an interconnection network for large-scale 3D-multicomputer systems. It consists of multiple basic modules (BMs) which are 2D-mesh networks. The BMs are hierarchically interconnected by a 2D-torus to build higher level networks.

While the details of TESH networks are available in the literature [1–4], its major features can be summarized as follows: it is hierarchical, thus allowing exploitation of computation locality as well as easy scalable up to thousands or tens of thousands of processors, it permits efficient VLSI realization, it is designed for fault tolerance by making use of redundancy for defect circumvention, it is well suited for 3-D stacked implementation, and

it provides good dynamic communication performance under uniform and hot-spot traffic patterns with 4 virtual channels [4]. In this paper, we are specifically interested to investigate the effect of nonuniform traffic patterns in the TESH network with minimum number of virtual channels.

Deterministic, dimension-order routing is popular in multicomputers because it has minimal hardware requirements and allows the design of simple and fast routers. Wormhole routing [5] has become the dominant switching technique because it makes latency independent of the message distance. Virtual channels [6, 7] were originally introduced to solve the problem of deadlock in wormhole-routed networks. Since the hardware cost increases as the number of virtual channels increases, the unconstrained use of virtual channels is not cost-effective in parallel computers. In this study, we use a deadlock-free routing algorithm for the TESH network using 2 virtual channels – 2 being the minimum number for dimension-order routing.

The dynamic communication performance of the TESH network with a dimension-order routing algorithm under uniform traffic pattern using 2 and 4 virtual channels and hot-spot traffic pattern using 4 virtual channels was evaluated [4], and it is proved to be better than that of conventional mesh network, but not that of torus network. However, the dynamic communication performance of the TESH network under the various nonuniform traffic patterns has not yet been evaluated. The main objective of this paper is to investigate the impact of various nonuniform traffic patterns on the TESH network.

The remainder of the paper is organized as follows. In Section II, we briefly describe the basic structure of the TESH network. The dynamic routing algorithm is proposed in Section III and its freedom from deadlock is also proved using minimum number of virtual channels. The dynamic communication performance of the TESH

network under the various nonuniform traffic patterns is discussed in Section IV. Finally, Section V presents the conclusion.

## II. INTERCONNECTION OF THE TESH NETWORK

### A. Architecture of TESH Network

The *Tori-connected mESH (TESH) Network* is a hierarchical interconnection network consisting of Basic Modules (BM) that are hierarchically interconnected to form a higher level network. The BM of the TESH network is a 2D-mesh network of size  $(2^m \times 2^m)$ . In this paper, unless specified otherwise, BM refers to a Level-1 network. Successively higher level networks are built by recursively interconnecting immediately lower level subnetworks in a 2D-torus network. A higher-level network is built using a 2D-toroidal connection among  $(2^{2m})$  immediate lower level subnetworks.

If  $m = 2$ , the size of the BM is  $(4 \times 4)$ , and in this paper, we focus attention on  $m = 2$  i.e.,  $(4 \times 4)$  BMs. A BM of  $(4 \times 4)$  is shown in Figure 1. As seen in the figure, the BM has some free ports in the periphery for higher level interconnection. All ports of the interior Processing Elements (PEs) are used for intra-BM connections. All free ports of the exterior PEs, either one or two, are used for inter-BM connections to form higher level networks.

In principle,  $m$  could be any positive integer value. However, if  $m = 1$ , then the network degenerates to a hypercube network. Hypercube is not a suitable network, because its node degree increases along with the increase of network size. If  $m = 2$ , then it is considered the most interesting case, because it has better granularity than the large BMs. In the rest of this paper we consider  $m = 2$ , therefore, we focus on a class of TESH(2,  $L$ ,  $q$ ) networks.

A  $2^m \times 2^m$  BM has  $2^{m+2}$  free ports at the contours for higher level interconnection. For each higher level interconnection, a BM uses  $4 \times (2^q) = 2^{q+2}$  of its free links,  $2(2^q)$  free links for vertical interconnections and  $2(2^q)$  free links for horizontal interconnections. Here,  $q \in \{0, 1, \dots, m\}$ , is the inter-level connectivity.  $q = 0$  leads to minimal inter-level connectivity, while  $q = m$  leads to maximum inter-level connectivity.

With  $q = 0$ , for example,  $L_{max} = (2^{2-0} + 1) = 5$ . Level-5 is the highest possible level for  $(4 \times 4)$  BM interconnection. The limitation of having a maximum level of hierarchy is not a serious constraint. For the case of  $(4 \times 4)$  BM with  $q = 0$ , a network built with the highest level, Level-5, consists of 1 million PEs. Successive higher level networks are built recursively by interconnecting the immediately lower level sub-networks. A higher-level network having  $(2^m \times 2^m)$  BM is built using a  $(2^{2m})$  subnetworks using a 2D-toroidal connection. For example, considering  $(m = 2)$  a Level-2 subnetwork, can be formed by interconnecting  $2^{2 \times 2} = 16$  BMs. Similarly, a Level-3 network can be formed by interconnecting 16 Level-

Fig. 1. Basic module of the TESH network

2 subnetworks, and so on. This phenomena is illustrated in Figure 2, a Level-2 TESH network can be formed by interconnecting 16 BMs as a  $(4 \times 4)$  2D-torus network. Each BM is connected to its logically adjacent BMs. To avoid clutter, the wraparound links of the BMs are not shown.

### B. Addressing of Nodes

Base-4 numbers are used for convenience of address representation. As seen in Figure 1, nodes in the BM are addressed by two digits, the first representing the row index and the next representing the column index. More generally, in a Level- $L$  TESH network, the node address is represented by:

$$\begin{aligned}
 A &= A^L A^{L-1} A^{L-2} \dots \dots A^2 A^1 \\
 &= a_{n-1} a_{n-2} a_{n-3} \dots \dots a_2 a_1 a_0 \\
 &= a_{2L-1} a_{2L-2} a_{2L-3} a_{2L-4} \dots \dots a_3 a_2 a_1 a_0 \\
 &= (a_{2L-1} a_{2L-2}) (a_{2L-3} a_{2L-4}) \dots \dots \\
 &\quad \dots \dots (a_3 a_2) (a_1 a_0)
 \end{aligned} \tag{1}$$

Here, the total number of digits is  $n = 2L$ , where  $L$  is the level number.  $A^L$  is the address of level  $L$  in row-major scheme, and  $(a_{2L-1} a_{2L-2})$  is the co-ordinate position of Level- $(L-1)$  for Level- $L$  network. Pairs of digits run from group number 1 for Level-1, i.e., the BM, to group number  $L$  for the  $L$ -th level. Specifically,  $i$ -th group  $(a_{2i-1} a_{2i-2})$  indicates the location of a Level- $(i-1)$  subnetwork within the  $i$ -th group to which the node belongs;  $1 \leq i \leq L$ . In a two-level network the address becomes  $A = (a_4 a_3) (a_1 a_0)$ . The first pair of digits  $(a_4 a_3)$  identifies the BM to which the node belongs, and the last pair of digits  $(a_1 a_0)$  identifies the node within that basic module.

Fig. 2. Interconnection of a TESH network

### III. ROUTING ALGORITHM FOR TESH NETWORK

#### A. Dynamic Routing Algorithm

Routing of messages in the TESH network is performed from top to bottom. That is, it is first done at the highest level network; then, after the packet reaches its highest level sub-destination, routing continues within the subnetwork to the next lower level sub-destination. This process is repeated until the packet arrives at its final destination. When a packet is generated at a source node, the node checks its destination. If the packet's destination is the current BM, the routing is performed within the BM only. If the packet is addressed to another BM, the source node sends the packet to the outlet node which connects the BM to the level at which the routing is performed.

We have considered the dimension order routing algorithm for the TESH network. We use the following strategy: at each level, vertical routing is performed first. Once the packet reaches the correct row, then horizontal routing is performed. Routing in the TESH network is strictly defined by the source node address and the destination node address. Let a source node address be  $s = (s_{2L-1}, s_{2L-2}), (s_{2L-3}, s_{2L-4}), \dots, (s_3, s_2), (s_1, s_0)$ , a destination node address be  $d = (d_{2L-1}, d_{2L-2}), (d_{2L-3}, d_{2L-4}), \dots, (d_3, d_2), (d_1, d_0)$ , and a routing tag be  $t = (t_{2L-1}, t_{2L-2}), (t_{2L-3}, t_{2L-4}), \dots, (t_1, t_0)$ , where  $t_i = d_i - s_i$ . Figure 3 shows the routing algorithm for the TESH network.

#### B. Deadlock-Free Routing

A deadlock-free routing algorithm can be constructed for an arbitrary interconnection networks by introducing virtual channels. In this section, we investigate the number of virtual channels required to make the routing algorithm deadlock-free for the TESH network. We also present a

proof that the TESH network is deadlock-free by these number of virtual channels. To prove the proposed routing algorithm for the TESH network is deadlock free, we divide the routing path into three phases, as follows:

- *Phase 1*: Intra-BM transfer path from source node to the outlet node of the BM.
- *Phase 2*: Higher level transfer path.
  - sub-phase 2.i.1 : Intra-BM transfer to the outlet PE of Level  $(L - i)$  through the  $y$ -link.
  - sub-phase 2.i.2 : Inter-BM transfer of Level  $(L - i)$  through the  $y$ -link.
  - sub-phase 2.i.3 : Intra-BM transfer to the outlet PE of Level  $(L - i)$  through the  $x$ -link.
  - sub-phase 2.i.4 : Inter-BM transfer of Level  $(L - i)$  through the  $x$ -link.
- *Phase 3*: Intra-BM transfer path from the outlet of the inter-BM transfer path to the destination PE.

The proposed routing algorithm enforces some routing restrictions to avoid deadlocks [6]. Since dimension-order routing is used in the TESH network, routing of message first performed in the vertical direction and then in the horizontal direction. The interconnection of the BM is a mesh network and the higher level network is a torus connection. The number of virtual channels required to make the routing algorithm deadlock-free for the TESH network is determined using Lemma 1 and 2.

*Lemma 1*: If the message is routed in the  $y \rightarrow x$  direction in a 2D-mesh network, then the network is deadlock free with 1 virtual channels. [9]

*Lemma 2*: If the message is routed in the  $y \rightarrow x$  direction in a 2D-torus network, then the network is deadlock free with 2 virtual channels. [9]

*Theorem 1*: A TESH network with 2 virtual channels is deadlock free.

Routing Algorithm for a Level-L TESH:

```

Routing(s,d);
source,s={s2L-1,s2L-2,...,s0}; destination,d={d2L-1,d2L-2,...,d0};
tag;t2L-1,t2L-2,...,t0; group;g;

for i = 2L-1:2;
 if (di-si+2m) mod 2m <= 2m/2 then
 routedir = plus; ti= (di-si+2m) mod 2m;
 else routedir = minus; ti= 2m- (di-si+2m) mod 2m; endif;

 g = get_group_number(s,d,routedir);

 while(ti!= 0) do
 if i is even number then
 outlet_nodex= outlet_x(g,i/2+1,H,routedir);
 outlet_nodey= outlet_y(g,i/2+1,H,routedir);endif;
 if i is odd number then
 outlet_nodex= outlet_x(g,i/2+1,V,routedir);
 outlet_nodey= outlet_y(g,i/2+1,V,routedir);endif;
 BM_routing(outlet_nodex, outlet_nodey);
 } (a)

 if routedir = plus then send packet to next BM;
 else send packet to previous BM; endif; } (b)

 ti= ti- 1;
endwhile;
endfor;

BM_routing(d1,d0); → (c)
end.

BM_routing(dx, dy);
source,sx,sy; destination,dx,dy;
tag;tx,ty;

tx= dx- sx;
ty= dy- sy;
while(ty!= 0) do
 if ty> 0 then move packet to upper node; ty= ty- 1; endif;
 if ty< 0 then move packet to lower node; ty= ty+ 1; endif;
endwhile;
while(tx!= 0) do
 if tx> 0 move packet to right node; tx= tx- 1; endif;
 if tx< 0 move packet to left node; tx= tx+ 1; endif;
endwhile;
end.

```

Fig. 3. Routing algorithm of the TESH network

*Proof:* In phase-1 and phase-3 routing, packets are routed in the source-BM and destination-BM, respectively. The BM of the TESH network is a 2D-mesh network. According to Lemma 1, the number of necessary virtual channels for phase-1 and phase-3 is 1. The routing of the message in source-BM and destination-BM is carried out separately. The virtual channels required in *phase-1* and *phase-3* can share each other. Intra-BM links between inter-BM links are used in sub-phases 2.i.1 and 2.i.3. Thus, sub-phases 2.i.1 and 2.i.3 utilize channels over intra-BM links, sharing the channels of either phase-1 or phase-3. The free links of the BM are used in inter-BM routing, i.e., sub-phases 2.i.2 and 2.i.4, and these links form a 2D-torus network for the higher level network. According to Lemma 2, the number of necessary virtual channels for this 2D-torus network is also 2. According to the structure of the TESH network, the inter-BM links other than the wrap-around links in the end-to-end node of the higher level networks used in sub-phases 2.i.2 and 2.i.4 routes messages like mesh network. Thus, the routing of messages in this part can share the channels of either phase-1 or phase-3. And the wrap-around links uses the

another links of the 2D-torus in the higher level networks.

Therefore, the total number of necessary virtual channels for the whole network is 2.

#### IV. DYNAMIC COMMUNICATION PERFORMANCE

The overall performance of a massively parallel computer system is affected by the performance of the interconnection network, as well as by the performance of the nodes. Continuing advances in VLSI/NoC technologies promise to deliver more power to individual nodes. On the other hand, low performance of the communication network will severely limit the speed of the entire system. Therefore, the success of massively parallel computers is highly dependent on the efficiency of their underlying interconnection networks.

##### A. Performance Metrics

The dynamic communication performance of a massively parallel computer systems is characterized by *message latency* and *network throughput*. Message latency refers to the time elapsed from the instant when the first flit is injected to the network from the source, to the instant when the last flit of the message is received at the destination. In wormhole routing, it is the average value of the time elapsed between injection of the header flit into the network from the source, and reception of the last unit of the data flit at the destination. Network throughput refers to the maximum amount of information delivered per unit of time through the network. For the network to have good performance, low latency and high throughput must be achieved. When the dynamic communication performance of various networks are compared by computer simulation and wormhole routing is used, latency is measured in simulator clock cycles and throughput is measured in flits per node and per clock cycle.

##### B. Traffic Patterns

Traffic patterns are pairs of nodes that communicate. In an interconnection network, sources and destinations for messages form the traffic pattern. Traffic characteristics such as message length, message arrival time, and destination distribution have significant performance implications. Message destination distributions vary a great deal depending on the network topology and the application's mapping onto different nodes. Depending on the characteristics of an application, some nodes may communicate with each other more frequently than with others. Consequently, non-uniform traffic patterns are frequent, and cause uneven usage of traffic resources, significantly degrading the dynamic communication performance of the network.

When a hot spot occurs, a particular communication link experiences a much greater number of requests than the rest of the links – more than it can service. In a remarkably short period of time, the entire network may become congested. Hot spots are particularly insidious

because they may result from the cumulative effects of very small traffic imbalances. Hot spots often occur because of the burst nature of program communication and data requirements. Bit permutation and computation [11] is a class of non-uniform traffic patterns which are very common in scientific applications, where the source node sends messages to a predefined destination. Both dimension order routing and bit permutation & communication create significant congestion under dimension order routing in the network, and when congestion occurs, the network throughput decreases precipitously. To observe the effect of non-uniformity, in this paper, we are specifically interested in how the nonuniform traffic patterns affect the dynamic communication performance of the TESH network.

1) *Hot Spot traffic Pattern*: A hot spot is a node that is accessed more frequently than other nodes in the uniform traffic distribution. In hot-spot traffic pattern, each node generates a random number. If that number is less than a threshold, the message is sent to the hot spot node. Otherwise it is sent to other nodes with a uniform distribution. Here, in uniform distribution, message destinations are chosen randomly with equal probability among the nodes in the network.

2) *Complement Traffic*: The binary representation of the node address is  $b_{\beta-1}, b_{\beta-2} \dots b_1, b_0$ . In complement traffic, the node  $(b_{\beta-1}, b_{\beta-2} \dots b_1, b_0)$  communicates with the node  $(\overline{b_{\beta-1}}, \overline{b_{\beta-2}}, \dots \overline{b_2}, \overline{b_1}, \overline{b_0})$ .

3) *Perfect Shuffle Pattern*: The node with binary coordinates  $b_{\beta-1}, b_{\beta-2} \dots b_1, b_0$  communicates with the node  $(b_{\beta-2}, b_{\beta-3}, \dots b_0, a_{\beta-1})$ . That is, rotate left 1 bit.

### C. Simulation Environment

The total number of nodes in a TESH is  $N = 2^{2mL}$ . If  $m = 2$  and  $L = 3$  then the total number of nodes of the TESH is 4096. That is, Level-3 TESH network has 4096 nodes.  $64 \times 64$  mesh network and  $64 \times 64$  torus network have 4096 nodes. We have evaluated the dynamic communication performance of TESH, mesh, and torus networks with 4096-nodes.

To evaluate dynamic communication performance, we have developed a wormhole routing simulator. In our simulation, we use a dimension-order routing algorithm and various nonuniform traffic patterns. The dimension-order routing algorithm, which is exceedingly simple, provides the only route for the source-destination pair. Two virtual channels per physical channel are simulated, and the virtual channels are arbitrated by a round robin algorithm. For all of the simulation results, the packet size is 16 flits. Two flits are used as the header flit.

In the evaluation of dynamic communication performance, flocks of messages are sent in the network to compete for the output channels. For each simulation run, we have considered that the message generation rate is constant and the same for all nodes. Flits are transmitted at 20,000 cycles; in each clock cycle, one flit is transferred

from the input buffer to the output buffer, or from output to input if the corresponding buffer in the next node is empty. Therefore, transferring data between two nodes takes 2 clock cycles.

### D. Dynamic Communication Performance Evaluation

In real application, it may happen that there are some packets (hot-spot packets) which remain in the network, and request rates are very high. Here, the simulations were carried out under the condition that, for TESH network,  $\text{Node}(n_5, n_4)(n_3, n_2)(n_1, n_0)$  are source nodes and  $\text{Node}(n_5, n_4)(0, 0)(0, 0)$  are hot-spot nodes with the hot-spot flit generation probability  $P_h = 0.20$ , i.e., the hot-spot percentages are assumed to be 20% for all networks. For mesh and torus networks, we divide the networks into  $4 \times 4$  matrix. From each part, the node which is closest to the center is assumed to be the hot-spot node, with same hot-spot percentages as listed above.

Figure 4 depicts the message latency versus network throughput curves for various network models under hot-spot traffic pattern. It is shown in the Fig. 4 that the average transfer time of the TESH network is far lower than that of the mesh and torus networks. The maximum throughput of the TESH network is far higher than that of the mesh and torus networks. Therefore, with the hot spot traffic pattern, TESH network yields better dynamic communication performance than mesh and torus networks.

Fig. 4. Dynamic communication performance of dimension-order routing with hot spot traffic pattern on various networks: 4096 nodes, 2 VCs, 16 flits, and  $q = 0$

Figure 5 portrays the results of simulations for the various network models under complement traffic pattern. From Figure 5, it is seen that the average transfer time of the TESH network is far lower than that of the mesh network and significantly lower than that of torus network. The maximum throughput of the TESH network is far

Fig. 5. Dynamic communication performance of dimension-order routing with hot spot traffic pattern on various networks: 4096 nodes, 2 VCs, 16 flits, and  $q = 0$

Fig. 6. Dynamic communication performance of dimension-order routing with hot spot traffic pattern on various networks: 4096 nodes, 2 VCs, 16 flits, and  $q = 0$

higher than that of mesh network and noticeably higher than that of torus network.

Figure 6 shows the comparison of dynamic communication performance between TESH and torus network under perfect shuffle traffic pattern. It is shown that the average transfer time of the TESH network is far lower than that of the torus network. And, the maximum throughput of the TESH network is far higher than that of the torus network. Therefore, TESH network yields better dynamic communication performance than that of torus network.

## V. CONCLUSION

A deadlock free routing algorithm using dimension-order routing with a minimum number of virtual channels

has been proposed for the TESH network. It has been proved that 2 virtual channels per physical channel are sufficient for the deadlock free routing algorithm of the TESH network; 2 is also the minimum number of virtual channels for dimension-order routing. By using the routing algorithm described in this paper and various nonuniform traffic pattern, we have evaluated the dynamic communication performance of the TESH network as well as that of several other commonly used networks. The average transfer time of TESH network is lower than that of the mesh and torus networks. Maximum throughput of the TESH network is also higher than that of those networks under various non uniform traffic patterns. A comparison of dynamic communication performance reveals that the TESH network outperforms the mesh and torus networks because it yields low latency and high throughput, which are indispensable for high performance massively parallel computers.

The performance degradation with the presence of large number of long length links is removed by replacing the long length electronic links by optical links. The dynamic communication performance evaluation of this opto-electronic (hybrid) TESH network is kept in mind as future works.

**Abstract** -- Mobile agent offers a new programming paradigm in which a program can move from one node to another node in a network. Since data as well as code move at the same time, security issue becomes more important than traditional RPC system. To overcome the security hurdles, this paper presents a new model based on existing Aglets architecture. A new service agent along with a policy file is incorporated with the existing Aglets architecture. This novel service agent which controls & co-ordinates all communication between the agent and the platform provides an extra layer of security by a set of API. This extra layer of security in Aglets will enhance the overall security of the platform.

**Index Terms**-- Aglets, mobile agent, SAGLET, security, service agent.

## I. INTRODUCTION

A *mobile agent* is a program, which represents a user in a computer network and is capable of migrating autonomously from node to node in the network to perform some computation on behalf of the user. Its tasks are determined by the agent application. A mobile agent can roam the network and can either come back to their 'home site' after completing its intended task. Harrison et al. [1] identified several advantages of the mobile agent paradigm. These are:

- reduce network usage
- increase asynchrony between clients and server
- add clients-specified functionality to server
- dynamically update server interfaces

Various advantages are provided by the mobile agent. Advantages like reduce network usage, increase asynchrony between clients and server are obvious for its design structure. Though the mobile agent system provides various advantages, it can also add significant problem in the field of security. Malicious agents, similar to viruses and Trojan horses, expose these hosts to the risk of system penetration. Similarly, the agents should be protected from the hosts they visit.

Aglets is a Java based platform which is one of the most popular medium for developing agents. At present, there is no encryption service in the Aglets Framework. This paper discusses issue involved protecting the aglets' **state** (the data objects the aglet carries) from tampering, eavesdropping and replay attacks and other malicious activities. To ensure security this paper proposes a new security model 'SAGLET' for Aglets

platform. The main component of SAGLET architecture is the service agent. All communication between agents and platform are done through a defined message passing standard. Service agent provides services to other visiting agent. Service agent contains modules for Authentication manager, Message communication manager and Resource Manager. Authentication manager authenticates the visiting agent. Message communication manager defines the standard for message communication between service agent and visitor agent. Resource manager allocates resource to agent according to the policy file. Public/Private key is implemented for authentication and data encryption. In addition for long message encryption, symmetric key based encryption is used. This overall approach of this proposed model will provide a new direction towards agent security.

## II. WHY AGENT SECURITY?

Though the mobile agent system provides various advantages, it can also add significant problem in the field of security. The use of mobile agents requires that each cooperating host in the distributed system provide a facility for executing them. Malicious agents, similar to viruses and Trojan horses, expose these hosts to the risk of system penetration. Four threat categories [2] are identified: (1) threats stemming from an agent attacking an agent platform, (2) an agent platform attacking an agent, (3) an agent attacking another agent on the agent platform, and (4) other entities attacking the agent system.

## III. SECURITY IN AGLETS PLATFORM

Aglets uses an organizational approach whereby all agent systems in a certain domain are deemed trustworthy, and evaluates the authenticity of the agent depending on the domain in which it has been roaming around. A user first authenticates him/her to the system, and the system then issues the credentials of the user's agent. The agent system then evaluates the authenticity of the credentials, to determine whether or not they were issued within the same domain. Host based authentication is used to identify the domain to which the communicating agents belongs. Following security features are provided by the Aglets Framework.

- a) Authentication of domains.
- b) Integrity checked communication between servers within a domain.
- c) Fine-grained authorization similar to the JDK1.2 security model.

Aglets servers are able to authenticate whether the contacting server belongs to a certain domain. All servers that belong to one domain share a secret key, and can authenticate the contacting server by means of that secret key using MAC (Message Authentication Code). In current Aglets system, agent code is only identified by its codebase. Agent code signing is not supported at all.

#### A. Limitation of Security in Aglets:

For secure agent execution, the agent system must provide the following security services:

1. Authentication of the Sender, the Manufacturer and the Owner of the Agent.
2. Authorization of the Agent (or Its Owner)
3. Secure Communication between Agent systems.
4. Non-repudiation and Auditing of data and entity.

Current Aglets platform only provides authentication within a domain by a shared key. Therefore, it cannot uniquely identify the originator of the agent. For the same reason visiting agent's identity cannot be determined. This lack of authentication also creates non-repudiation problem.

### IV. PROPOSED SECURITY MODEL– SAGLET

The proposed new model enhances security for Aglets platform by adding an extra layer of protection. No change to the Main Aglets framework source code was carried out during the project. We only provide an extension of the frame work based on the existing one. Security is implemented in three major areas.

**User Authentication** - Strong user authentication is the first line of defense for an unattended, lost, or stolen device. Multiple modes of authentication increase the work factor for an attacker. This model adds public/private key base authentication.

**Content Encryption** - Content encryption is the second line of defense for protecting sensitive information. This model uses both symmetric key algorithm Rijndael and public/private key algorithm for data encryption.

**Controls** - Policy rules are enforced in the model for all programs regardless of associated privileges, protect critical components from modification and limit access to security related information. In SAGLET model shows the way of converting non-secure Aglets platform to secure Aglets platform. An extra layer of security is developed by a set of APIs for secure Agent communication. The working model of the proposed SAGLET's agent communication is shown in Fig. 1.

#### A. Working principle

Working principle of the Origin node and Visiting node are described below:

**Origin site:** According to the proposed model origin node is the owner of the Agent. Originator will decide what information it needs to collect, where the agent should go and what resources it will acquire from remote sites. Originator node will fill the path vector of the agent with addresses where it wants to visit. This filled Itinerary vector is signed by the owner node to prevent the possible modification by visiting nodes. In addition, origin node defines the resource collection mechanism. This is done through a new Message passing standard proposed in this model. Agents pass messages according to their need and services are provided for the request with consultation of policy file. Besides, Origin site node defines security profile to identify itself to the visiting platform. Authentication of agent is implemented by Digital signature approach.

**Visitor site:** Visitor's site is the node where agent visits to collect information. In the proposed architecture all visitors' node contains a Service agent named *TesterAglet*. Service agent works as a combination of service provider, authentication manager, resource manager and access control manager. *TesterAglet* provides a set of message passing standards. The standards are defined and published in well known secure site, so service requestor agent can implement the standard message rule. The agent that needs service must communicate to the service agent through standard message communication rule which should be agreed by the communicating parties. The first role the service agent performs is authentication of the incoming agent. It checks the Itinerary object and uses the public key of the originator node of the agent to unveil the Itinerary objects authenticity. After unveiling the itinerary object, visitor can check whether it is in the route path or not.

Fig. 1: Agent Data communication in SAGLET

Secondly, Service agent acts as a resource manager and access controller. For each originator node and signer Agent, Service agent contains a policy entry in the policy file. Access right and resources are allocated to the agent as defined in the policy file. Policy file is a hashed file maintained in each platform which contains policy entry for each agent in the system.

**Fig. 2: Agent Communication Model in SAGLET**

Authorization manager's job is to authenticate the visiting agent. It tests the sign of the visitor agent by consulting the security provider. Message communication manager defines the standard for message communication between service agent and visitor agent. Access control manager checks the specific access right for each signer. Resource manager handles the resource request from the visitor agent. Resources are allocated according to the access permission in the policy file.

To get resource access, Visitor node needs to communicate with service agent, authenticate itself and according to security policy the access is granted to the resources. If a visitor node has access right to resources(i.e. database, file system), it expresses its desire to the service agent, service agent do all the data collection from the home node and reply the data through message passing.

### B. SAGLET Architecture

SAGLET Architecture is based on existing Aglets [5] architecture. In addition, during implementation SAGLET uses Aglet API [5] and AgletSec API [4]. It works on application level. The main component of SAGLET architecture is service agent. Service agent contains modules for Authorization manager, Message communication manager and Privacy manager and Resource Manager. The design is modularized so that it can be enhanced later on with little effort.

### C. Message Communication Standards

Communication between service agents and visitor agent is done by message passing standard which is known to all the communicating parties. Some of the mostly used commands used by the Agent and Service provider are given below.

**msg: access-** This command is used by Service provider to check the signer of the agent.

**msg: accessDB-** This is used by visitor agent to access database resource of the visiting platform. Additional information is sent by argument setting.

**msg:accessFile:** This is used by visitor agent to access File resource of the visiting platform. Additional information is sent by argument setting.

### D. Prevention of known Attacks in proposed architecture

Now, let's see how the new model prevents known attacks on agents and agent platform.

**a) Replay attacks:** An attack in which a service is already authorized and completed is forged by another "duplicate request" in an attempt to repeat authorized commands. This model used two separate mechanisms to prevent Repay Attacks. First one is TTL (time to live): when an agent is dispatched from the Origin node, the originator defines the time duration – the time it will alive. After the time duration, the agent simply dies. So the service agent will deny any further request from this agent.

Second method is random number generation by origin node at the agent's creation moment. When an agent arrives at a visiting node, it must send the random number to the Service Agent. Then Service Agent stores this random number for a specific period defined in the TTL. So any replay attack within this time is successfully revealed through checking the random number duplication. Random number generation also prevents cut & paste attack in some cases.

**b) Eavesdropping and Wiretapping, Impersonation:** The term eavesdrops implies overhearing without expending any extra effort. An attacker can pick off the contents of a communication passing in the clear format. In this model, when information is inserted into the agent, visitor node encrypts the data by symmetric key. This symmetric key is encrypted by the agent originator node's public key, so that only the originator node can access the data. In an impersonation one host pretends to be another. Public/Private key use for object protection & identification removes impersonation problem. But if some agent can impersonate itself during key distribution process then the whole system will be compromised.

**c) Man in the Middle Attack:** In man-in-the-middle attack one entity intrudes between two other entities. Successful use of Public key cryptography will spoil the man-in-the-middle attack. Key distribution is the most sensitive part for preventing man-in-the-middle attack. If the attacker somehow passes his key instead of the intended one, then the intruder is successful in attack.

## V. BENEFITS OF PROPOSED SYSTEM OVER EXISTING SYSTEM

**Privacy:** Privacy means that sender and receiver expects confidentiality. Existing Aglets platform doesn't support any encryption API. In addition, Aglets designers are not concerned about privacy/confidentiality issues. The new proposed system provides a Security API. Using this API visiting platform encrypts the data by symmetric key during sending information

**Fig 3: SAGLET-Architecture Model**

from the visitor platform. This encryption mechanism ensures that privacy is maintained in communication system.

**Integrity:** **Integrity** implies that data must arrive at the receiver as they were sent by the sender. Data integrity is not supported directly by Aglets platform. Any agent platform or hostile agent can compromise the data it carried along the way. In our proposed system, itinerary object is signed by the originator. Agent or agent platform having the originator's public key can view the path vector. Only public key of the originator can open the itinerary object. If some middle party modifies the signed itinerary object, then sign of the object also changed. Thus it will destroy the integrity of the path vector. So, signing Itinerary object ensures integrity of the path vector. Now, when data comes back from the visiting platform to the originator node, data is encrypted. If some middle party modifies the Agent's data, the decryption key cannot open the object. So the use of encryption during agents' communication ensures integrity of data.

**Non-repudiation & Authentication:** The term **Non-repudiation** reveals the fact that a receiver must be able to prove that a received message came from a specific sender. As Code signing is not supported in Aglets, it has no way to prove that an agent comes from a specific sender. Signing any object provides non-repudiation. Signing is used in two phases, firstly, during the agent creation time; the path vector's authenticity is set. Secondly, when information comes back to the Origin site, data are encrypted by symmetric key. This key is signed by private key of the visiting platform user. As the private key of the visiting platform ensures the signer's identity, there is no way to deny his/her activity after signing. **Authentication** means to prove his/her identity. Using the above signing process the model supports authentication of both the originator and visitor nodes.

**Reduction of vulnerabilities:** Mobile agent moves from one platform to another platform. Agent moves from one platform, collects data and goes to another platform. In normal case, an agent accesses data directly from the visitor platform. It means malicious agent can maneuver the platform. In our proposed system, authentication means to prove his/her identity. All resource collection is done by service agent for the visitors. Thus it creates a sandbox, which gives enhanced security to the platform.

**Mobility:** **Mobility** is the most important feature of mobile agents. Some security models [6] proposed a set of constraints on mobility feature for security reasons. Our proposed system does not define constraint on mobility. Agents can come from any platform and free to go from that platform to another one.

**Isolation:** *Instead* of interacting with any of the user host platforms, the interacting agents migrate to a multi-agent computing service platform. All the agents that arrive at a platform act like an isolated agent, all communication is done through service agent.

## VI. PERFORMANCE OVER EXISTING SYSTEMS

In the existing Aglets platform, communication to the Agent platform is achieved by directly calling aglets API. So it requires less time to execute than proposed security model. As the new model has an extra layer of protection mechanism it certainly creates some overhead. On the other hand, SeMoA [7] uses jar signing of the code. SeMoA also includes too much security in file & folder level. Thus encryption and signing is performed many times to ensure security in SeMoA platform. That's why SeMoA is much slower than SAGLET platform. In case of another mobile agent system Concordia developed by Mitsubishi Electric, it implements a weak mobility mechanism requiring the agent to be serialized. There is also a project named TACOMA that does not rely on any specific language to guarantee the host integrity. It uses the underlying operating system mechanism to accomplish it. This characteristic increases flexibility but can also impact performance, depending on the operating system.[8]

However, our proposed system uses Digital Signature for signing itinerary object. Itinerary object only contains the URL's the agent wants to visit. This itinerary object is signed by originator platform. As we know that typically an itinerary object is not very large, signing it requires less time. When the object returns from the visitor's node to the home site, data are encrypted by symmetric key algorithm. Symmetric key encryption takes less time than asymmetric encryption. This key is signed by the visitor node. The signed key and the platform's IP address are merged together and encrypted by the public key of the originator to ensure authenticity & privacy of the key. As this key signing algorithm is applied to a small number of data, the required time is less than those algorithm which uses public/private key encryption on the whole data.

Performance enhancement can also be gained by choosing appropriate encryption and signing algorithm. For each environmental context, the new architecture can use different type of algorithm to enhance performance of the security model.

## VII. FUTURE SCOPE OF THE PROPOSED SYSTEM

1. Denial of service (DOS) attack is a major threat for agent & agent platform. Excessive message generation and too many agents in a platform can overwhelm the whole system. Therefore, in future models may contain DOS prevention. We provide a DOS prevention algorithm that is based on "Agent based Distributed Denial of Service Prevention" [9]. In existing implemented model of SAGLET, replay attack prevention technique meets some requirement of DOS prevention. Besides the model will incorporate the following strategy:

Service agent monitors message activities of the visitor agent. If visitor's agent sends too many messages or if it doesn't follow standard message rule then visitor's agent is simply discarded. Service agent also tracks all the agents in the platform, if it finds some agent is doing malicious activities, it is discarded. If platform is overwhelmed by too many agents then message is sent from service agent to the upper level router to discard agents from malicious hosts.

2. Proposed system should include key distribution mechanism in agent architecture. We need to define which key distribution model best suit the security model.

3. Enhancing message communication standard. We need to think more about formation of message standard that will lead to a security model which will serve the interest of all types of request.

4. Prevention of *cut & paste* attack.

5. Enhancing thread mechanism in agent architecture. Multiple requests can be serviced at a time if we enable thread mechanism in service agent.

6. Access control policy should be improved. Policy setting should be based on agent manufacturer, agent owner, context service provider, domain authority.

7. Security model need to include context level security [10]. When agents try to arrive from another platform, security policy should be enforced at that time.

## VIII. CONCLUSION

Agent reveals a new technological arena for Internet users. This emerging technology will replace the existing one if we can remove the flaw in it. Security is the main hurdles for implementing agent technology in large scale. To remedy this problem the paper discusses a modular architecture where service agent deals all communication between agent platform and agents. Service agent works as controls authentication and manages other resources. Policy file is used by service agent for resource management. Service agent also performs the message communication and resource allocation job. Authentication part is enhanced by using public/private key cryptography.

Combining this whole approach, this implementation will ensure security in agent communication.

# Side Channel Attack Prevention for AES Smart Card

Mohammad Zahidur Rahaman and Mohammad Akram Hossain  
rmzahid@juniv.edu, akram864@yahoo.com

**Abstract**—This paper describes an AES Smart Card implementation highly tamper resistant to side channel attacks. Smart Cards are gaining popularity in applications that require high security and store sensitive information. Modern Smart Cards, highly capable of complicated cryptology, provide a high assurance of tamper resistance and thus commonly used in payment application. Although advanced Smart Cards can not protect attackers from being defrauded by different side channel attacks. Small, embedded integrated circuits (ICs) such as Smart Cards are vulnerable to side-channel attacks (SCAs). We describe the development of differential power attacks and describe how to perform differential power kind of side-channel attack on an AES implementation, using simulated power traces. We also discuss the security prevention from such corresponding attacks, such as randomized masking techniques for software implementations.

**Index Terms**—AES, DPA, cryptanalysis, SCA, power consumption model, DPA prevention.

## I. INTRODUCTION

Most attacks in the past have centered on the mathematics of the algorithm including differential[1], [2] and linear cryptanalysis[1]. It has long been assumed that if the algorithm itself is secure then any implementations of it also secure. The truth is that a hardware implementation of an encryption scheme is weakness to several types of attacks where important information is leaked during cryptographic operations. These attacks, typically referred to as side channel[4] attacks include timing attacks, simple power analysis and differential power analysis. All of the above mentioned side channel attacks work because there is a correlation between what is measured and the internal operations of the device, which relate to the secret key [3]. Here provides a brief introduction to differential power attacks. The focus of this work will be on techniques to DPA attack on cryptographic algorithms AES implemented in hardware.

## II. CRYPTANALYSIS

The science of cryptology is driven by two opposed, but complementary disciplines, cryptography [4] and cryptanalysis. While cryptography is the science of developing mathematical algorithms and protocols for protecting information, cryptanalysis is the science of breaking cryptographic schemes. The cryptographic system is no longer considered as a black-box with two inputs and one output, but as complex system that has other inputs and other output as well. As these additional input and output channel are considered are more attack platform become possible. These additional input and output channel called side-channel. Side channel attacks

are the attacks that are based on “Side Channel Information”. Side-channel information is information that can be manipulated from cryptographic devices. Side-Channel attacks exploit information that leaks from a cryptographic device.

### A. Side-Channel Analysis (SCA)

SCA is a method for extracting information from electronic devices through analyzing their physical characteristics. In other word, Side-channel analysis is observing the behaviors of the electronic circuit. The analysis is often applied to encryption devices in order to investigate the leakage of secret data, such as keys and PIN codes. Side-channel analysis is an important device in the product development and estimate cycle of Smart Cards. Common cryptographic implementations software, dedicated hardware and Smart Card.

In side channel cryptanalysis, the attacker objective is key recovery.

### B. DPA Attack on AES S-box

AES operates on 128-bit data blocks and supports three key sizes (128, 192, and 256 bits). AES has been designed with the limited resources of a typical 8-bit processor of a Smart Card in mind and most operations are byte oriented. Therefore, 8 state bits can be predicted using a guess on 1 key byte. For the attack, the influence of 1 state byte in the datapath on the power consumption of the AES core is estimated [5].

DPA attacks to block cipher are usually performed separately on each operation block, guessing the secret key used in the first or last state round. In the AES algorithm, since most operation are byte oriented, the key is guessed 8 bits per time and represent a part of the round key, which is given by the key scheduler. For simplicity reason, the attacker attacks as target byte the output of an S-Box, so that its value can be easily predicted from the plain text in input and the key guess.

After successful attacks to every S-Box at the first or last round algorithm the secret key is completely known. Therefore in this project we describe differential power analysis attacks to a single S-box using simulated power trace.

## III. STATISTICAL POWER ANALYSIS

Statistical Power Analysis is a more powerful platform of power analysis attack. It can be further sub-categorized into Differential Power Analysis and Correlation Power Analysis.

Statistical power attacks are based on the relationship between the power consumption and the Hamming weight of data being manipulated at a given point in time. The differences in power consumption are potentially extremely small, and cannot be identified individually, as the information will be lost in the noise incurred during the acquisition process [6].

The first implementation of this type of attack is known as Differential Power Analysis [1], and works by amplifying the differences in the power consumption.

#### A. Model of the Power Consumption

Abstract model of the instantaneous power consumption of a CMOS circuit. The power consumption of a circuit at a particular time  $t$  is the sum of the power dissipated by all gates at this time. We can state this more formally as :

*Simple Power Model:* let  $t$  denote the time, and  $n(t)$  be a normal distributed random variable which represents the noise components. Let  $f(a,t)$  denote the power consumption of gate  $a$  at the time  $t$ . Then a simplified power model for the power consumption is the function

$$P_{los} = \sum_g f(a,t) + n(t) \quad (1)$$

If we consider the function  $f(a,t)$  as random variable from an unknown probability distribution, what can we say about  $P_{los}(t)$ ? If all  $f(a,t)$  are randomly and independently drawn from this probability then the Central Limit Theorem says that  $P_{los}(t)$  is normally distributed. In a DPA attacks the attacker divides the power measurements in two or more difference between these sets in order to verify the oracle [8].

*The Hamming Weight Model:* The simplest model, initially proposed in [6], [14] attaches an affine relationship between the power consumption and the Hamming weight of the data being manipulated at a given point in time. This is largely caused by the bus on the microprocessor that consumes a vast amount of power compared to any other single feature on the chip. This can be expressed as,

$$p_{los} = dH(I) + n \quad (2)$$

Where  $p_{los}$  is the power consumption,  $I$  is the value of the data being manipulated, and  $H$  is a function that calculates the Hamming weight. The variable  $n$  includes the acquisition noise and the variation from one clock cycle to another, as the commands being executed by the CPU change [6].

*The Hamming Distance Model:* Another model was proposed in [6], [15] that modified the Hamming weight model. This model is similar but with an addition of another variable,  $J$ . The model is

$$p_{los} = dH(J \oplus I) + n \quad (3)$$

This model operation is the same as described in the Hamming weight model, and the value  $J$  represents some previous state. The justification for this model is that the Hamming weight model is only valid if the bus is set to 0 between each value sent. If this value is not set to 0 then there

is a transition from state  $J$  state  $I$ , so the change in value of the bus can be modified by XOR between the two values.

Both models are used in Statistical Power Analysis. In Differential Power Analysis it is not necessary to consider the Hamming Distance Model, as this will only change the sign of the peak produced. The later model becomes more necessary when use Correlation Power Analysis, where a more complete model of the chip is required.

#### B. Differential Power Analysis (DPA)

By the word "differential", the DPA takes the differences of power consumptions among different samples with different operations or with different data processed [8], [9], [17]. For Differential Power Analysis, an attacker does not need information about the analyzed hardware nor about the points in time during processed of information. Using DPA, the adversary doesn't have to know implementation details of the attacked device. If Smart Cards are unprotected against DPA, it is possible to reveal the secret key by measuring and analyzing the power consumption .

#### C. Cryptanalysis Procedures

Having a look at the first round of AES, one can see that a bitwise XOR operation followed by substitutions with the S-boxes are performed. As described in [16], AES is defined with keylength of 128. So the first XOR and respectively the substitution will, in case of the 128 bit Key, be performed with the whole secret key. As an attacker only needs to attack an 8-bit subkey at once, which leads to a key space of  $2^8$  that means 256 possible keys, he only has to repeat his attack for the remaining 15 S-boxes to get the full 128 bit key.

An adversary can gain partial key value and then the entire key value can be extracted. The algorithm for performing a DPA attack is given now [10]:

- 1) An attacker mounts a DPA attack by running the cryptosystem for  $M$  random plaintext values with the same key  $K$ . The plaintext value is denote as  $I_i$ , where  $i$  from 1 to  $M$ . For each plaintext input, the power consumption curve  $C_{ij}$  is measured in discrete time. The power trace  $C_{ij}$  is the power consumption while processing the cryptographic algorithm. The  $i$  index corresponds to the input  $I_i$  and  $j$  index corresponds to the processing time.
- 2) Considering applied cryptographic algorithms and effects upon the secret key, a selection function is chosen. Therefore, one target bit is determined, which becomes the value of isolated bit. The particular bit  $a$  depends on some bits of the secret key in evidence.
- 3) Under the hypothesis using the selection function, attacker can calculate the theoretic value of  $a$  by known plaintext  $I_i$  and partial guessed key. By exploiting the theoretic value, the collected power traces  $C_{ij}$  are separated into two sets. The sets including all the traces are presented as the following eq<sup>n</sup>.

$$S_0 = \{C_{ij} | a = 0\} \quad (4)$$

$$S_1 = \{C_{ij} | a = 1\} \quad (5)$$

Accordingly,  $S_0$  and  $S_1$  are the sets of power traces being separated by isolated bit 0 and 1 respectively. The amount of power curves in  $S_0$  is denoted  $|S_0|$ . The sum of  $|S_0|$  power curves is denoted  $\sum c_{ij}$  and the sum of the traces from each set is equal to the number of random plaintext values. Thus

$$|S_0| + |S_1| = M. \quad (6)$$

- 4) The average power trace for each set,  $C_{a0j}$  and  $C_{a1j}$  is computed.

$$C_{a0j} = \frac{1}{|S_0|} \times \sum C_{ij} \text{ for some } C_{ij} \in S_0 \quad (7)$$

$$C_{a1j} = \frac{1}{|S_1|} \times \sum C_{ij} \text{ for some } C_{ij} \in S_1 \quad (8)$$

After subtracting the averages, differential power signal  $D_j$  is obtained in discrete time

$$D_j = C_{a0j} - C_{a1j} \quad (9)$$

The selection function is selected for the intermediate bit  $a$ . While the data including such bit is calculated, the amount of power consumption will become a little difference  $\in$  owing to the bit being zero or one. Provided that instructions computing the bit occur at time  $j'$ , the following expected differential equation results in time  $j = j'$ .

$$E\{C_{ij}|a = 0\} - E\{C_{ij}|a = 1\} = \in \quad (10)$$

When time  $j$  is not equal to  $j'$ , the cryptosystem is calculating other bits and power consumption is independent of this bit. While  $j \neq j'$ .

$$E\{C_{ij}|a = 0\} = E\{C_{ij}|a = 1\} = E\{C_{ij}\} \quad (11)$$

then

$$E\{C_{ij}|a = 0\} - E\{C_{ij}|a = 1\} = 0 \quad (12)$$

- 5) For each guessed key, attacker performs a new separation for the power traces and obtains a new bias signal. If correct value for key bit is selected, the differential power signal will present significant peaks. If guesses key value is not selected correctly, the differential power signal will not show any biases. Increasing the number of plaintexts, the differential power signal converges to the expectation equation.

$$\lim D_j = E\{C_{ij}|a = 0\} - E\{C_{ij}|a = 1\} \quad (13)$$

With enough measurements, the differential power signal is  $\in$  at time  $j'$  and will converge to zero all other times. Consequently, average can recover a very weak signal that is in the presence of noise. In reality, the DPA bias signal will not always converge to zero, but the largest biases will occur at times  $j'$ .

The actual results from monitoring Smart Card power signals is presented by D. Messerges *et al.* and the techniques improve maximize power signals is introduced by J. Kelsey *et al.* The DPA attack has been successfully applied to many existing implementations of cryptographic algorithms [10].

#### D. DPA-Prevention Techniques

Here, we discuss the different methods that have been proposed in order to mask implementations of the AES. In our masked software implementation of AES the inputs and outputs of each operation are masked additively. In the following functions we briefly describe how the masked operation of the four AES operations have been implemented.

**Masked AddRoundKey:** The AddRoundKey operation does not change the mask and therefore it does not require special attention in our masked implementation. Essentially, we use the same AddRoundKey operation as in an unmasked implementation.

**Masked SubBytes:** We mask the SubBytes operation  $SUB$  with values  $B$  and  $B'$  (the masks). Therefore, we have to derive a new masked S-box  $SUB'$  with the property that

$$SUB'(A \oplus B) = SUB(A) + B' \quad (14)$$

#### IV. DPA COUNTERMEASURE

This section discusses countermeasures that have been proposed in the literature since the announcement of DPA. Most solutions proposed involve changes in software, and to date very few have addressed solutions in hardware.

##### A. Masking Method

Random masking operations process masked input data and result in masked output data. For example, the following illustrates secure implementations of two operations, where data  $D$  masked with random value  $R_d$  results in a secure data  $D'$ .

**Boolean mask:** For bitwise Boolean function, the XOR operation is in the use of Boolean masking operation as shown in eq<sup>n</sup> 15.

$$D' = D \oplus R_d \quad (15)$$

**Arithmetic mask:** Addition or subtraction module  $2^{32}$  is employed as arithmetic masking operation as shown in eq<sup>n</sup> 16.

$$D' = (D \pm R_d) \bmod 2^{32} \quad (16)$$

By using masking operations to construct cryptosystems, the transaction between two different masking operations must be performed with secure and efficient algorithm.

##### B. Secure Masking of S-box

This section also discusses masking techniques with a special focus on the AES S-box. Masking Advanced Encryption Standard means masking the intermediate bytes which are executed in an AES mathematical calculation [11].

AES consists of four transformations, SubBytes(), ShiftRows(), MixColumns() and AddRoundKey(). Except for SubBytes(), all transformations are linear, i.e., they have the property that  $f(a+m)=f(a)+f(m)$  [11], [12]. Hence, for such transformations, it is an easy task to compute how the mask  $m$  has changed during the transformation. As a consequence, it is also simple to re-establish the original mask  $m$  after a (sequence of) transformation(s). is non-linear,

re-establishing the mask after a SubBytes() transformation is difficult [11]. This is because

$$SubBytes(a + m) = SubBytes(a) + m' \quad (17)$$

and

$$SubBytes(a + m) \neq SubBytes(a) + SubBytes(m) \quad (18)$$

Here we review the different methods that can be used to mask SubBytes().

*Re-computation of SubBytes Function:* The SubBytes() transformation can be implemented as a table lookup[12]. Suppose we want to define a masking such that

$$SubBytes(a + m) = SubBytes(a) + m \quad (19)$$

In order to achieve this with a table lookup we have to compute a corresponding table MasSubBytes() for the mask  $m$ .

---

**Algorithm 1** MasSubBytes Function

---

```

INPUT: m
OUTPUT: MasSubBytes(a+m) = SubBytes(a) + m,
for $l \leftarrow 0$ to 255 do
 MasSubBytes($l+m$) = Subbytes(l) + m
end for
return MasSubBytes

```

---

Such a table needs to be computed for each mask value  $m_l$ . If  $l$  different masks  $m$  are used, then the complexity of this procedure is  $l*256$ . If we ensure, that the same masks  $m_l$  are re-established before the SubBytes() operation in each round, the same  $l$  tables can be used throughout the complete AES calculation [11].

*Implementation of Countermeasure:* The proposed algorithm is given below

---

**Algorithm 2** MasSubBytesby using Arithmetic Mask

---

```

INPUT: m
OUTPUT: MasSubBytes
for $l \leftarrow 0$ to 255 do
 MasSubBytes (l, m) = ((SubBytes(l) $\pm$ m) $\pm$ $RND()$)
 mod 2^{32}
end for
return MasSubBytes

```

---

The above figure indicate that the algorithm of the conversion data from Boolean masking to arithmetic masking.

This algorithm process input  $m$  where

$$m' = m \oplus rnd_m. \quad (20)$$

and performs output  $Y$ , where

$$Y = m - rnd. \quad (21)$$

Above eq<sup>n</sup> employing a random select bit, the algorithm randomly processes  $m$  or ones complement of  $m$  to prevent power analysis.

## V. SIMULATION MODELS

### A. Experimental Simulation Results

In the MatLab experiment simulation environment, DPA attacks are presented and 5000 power signal are collected. For accomplishing DPA attacks, the experimental result is exhibited to monitor at least 5000 power traces. The vertical axis indicates the differential power trace (voltage). The horizontal axis indicates the amount of data obtained by MatLab simulation. The value of horizontal coordinate divided by MatLab workplace's sample creates equal execution time.

1) *Experimental result of Straightforward AES implementation:* In this attack, the differential power signals have obvious peaks. Since the guessed key is wrong, the calculated bit for partitioning power traces is not the exact intermediate data. After performing the statistic analysis, the average power consumptions for both sets are balanced and then the differential power signal will not have any obvious peaks.

#### Attacking a key Bit in a S-Box:

The most simple Differential Power Analysis attack exploits a decision function that uses a single target bit of the predicted output of an S-Box. The guess however have to consider all key values that are involved during the output computation. However it does not produce effective attacks because the single target bit is too weakly related to power consumed.

#### Attacking Several Key Bits in a S-Box:

The decision function on a single key bit can be naturally extended to work with bit pairs or even more bit values. However, when attacking several bit at the same time, the decision function may not be binary anymore. Because all relevant information for attacking the power consumption model was given in section 3.1 before, here some figures for better understanding are given. Differential curve of the calculated secret key.

2) *Experimental results of masking method:* The design experiment mounting DPA attacks on two encryption algorithms: AES and AES with masking countermeasure. After comparing each experimental result, the AES implementation with masking countermeasure indeed prevents DPA attacks. The experimental results not only demonstrated the security of AES could be achieved by using improved transformed masking method but also examine the practicality of DPA attacks on straight forward AES.

## VI. CONCLUSION

In this project, we showed that massive security increases are possible in small 8-bit processors by using of arithmetic masking method.

In the previous section, we have discussed different Statistical Power Attacks on the unmasked and on the two masked AES implementations on AES S-box output. The targets of these attacks were the S-Box operations in the first round of AES.

We have analyzed this truth based on simulations of MatLab of all S-Box implementations. These simulations have shown that the number of transitions that occur in the S-Boxes

depends on the S-Box input. Even in the masked cases, this dependency has been observed.

If no countermeasures are taken, power analysis may be very effective against many applications. So it is obvious that the DPA of the unprotected AES implementation is successful, since a distinct correlation peak is contain the correct key hypothesis. Finally we conclude that algorithmic countermeasures to secure the AES algorithm against side-channel attacks have not been resistant all first-order differential power attacks.

# An Energy-Efficient Data Security System for Wireless Sensor Network

Md. Anisur Rahman and Mitu Kumar Debnath

Department of Computer Science & Engineering, Shah Jalal University of Science & Technology,  
Sylhet, Bangladesh. {anis112, debnath68}@gmail.com.

**Abstract** — Wireless sensor networks are a new type of networked systems, characterized by severely constrained computational and energy resources, and an ad hoc operational environment. Because sensor networks may interact with sensitive data and operate in hostile unattended environments, it is imperative that these security concerns be addressed from the beginning of the system design. However, due to inherent resource and computing constraints, security in sensor networks poses different challenges than traditional network security. There is currently enormous research potential in the field of wireless sensor network security. In this paper we introduce a Message Expansion Problem which can be solved by a Data Link-layer security architecture called ‘Cipher-text Stealing method’ for wireless sensor networks. Conventional security protocols tend to be conservative in their security guarantees, typically adding 16-32 bytes of overhead. With small memories, weak processors, limited energy, and 30 byte packets, sensor networks cannot afford this luxury. TinySec addresses these extreme resource constraints with careful design; we explore the tradeoffs among different cryptographic primitives and use the inherent sensor network limitations to our advantage when choosing parameters to find a sweet spot for security, packet overhead, and resource requirements.

**Index Terms** — Security, Wireless, Sensor, Message Expansion, Cipher text Stealing.

## I. INTRODUCTION

Sensor networks consist of hundreds or thousands of self-organizing, low-power, low cost wireless nodes deployed masses to monitor and affect the environment. Potential applications include burglar alarms, inventory control, medical monitoring and emergency response, monitoring remote or inhospitable habitats, target tracking in battlefields, disaster relief networks, early fire detection in forests, and environmental monitoring. Sensor networks are typically characterized by limited power supplies, low bandwidth, small memory sizes and limited energy. This leads to a very demanding environment to provide security. Public-key cryptography is too expensive to be usable, and even fast symmetric-key ciphers must be used sparingly. Communication bandwidth is extremely dear: each bit transmitted consumes about as much power as executing 800–1000 instructions, and as a consequence, any message expansion caused by security mechanisms comes at significant cost.

We foresee TinySec will cover the basic security needs of all but the most security critical applications. As a part of this, we were motivated by an observation about 802.11 wireless networks: several studies report that 50-80% of all 802.11 wireless networks operate in the clear, without any cryptographic protection whatsoever [16, 21 and 22].

## II. SECURITY ISSUES AND THREAT MODELS

Wireless communications are difficult to protect; they are by nature a broadcast medium. In a broadcast medium, adversaries can easily eavesdrop on, intercept, inject, and alter transmitted data. In addition, adversaries are not restricted to using sensor network hardware. They can interact with the network from a distance by using expensive radio transceivers and powerful workstations. Adversaries can repeatedly send packets to drain the nodes' batteries and waste network bandwidth. Since sensor networks will be deployed in a variety of physically insecure environments, adversary can steal nodes, recover their cryptographic material, and pose as authorized nodes in the network. However, we do not address these threats. Our focus is on guaranteeing message authenticity, freshness, integrity, and confidentiality. We do not address resource consumption attacks, physical tamper resistance, or node capture attacks.

## III. MOTIVATION FOR LINK LAYER SECURITY IN SENSOR NETWORKS

In conventional networks, message authenticity, integrity, and confidentiality are usually achieved by an end-to-end security mechanism such as SSH [5], SSL [3] or IPSec [4] because the dominant traffic pattern is end-to-end communication; intermediate routers only need to view message headers and it is neither necessary nor desirable for them to have access to message bodies. This is not the case in sensor networks. The dominant traffic pattern in sensor networks is many-to-one, with many sensor nodes communicating sensor readings or network events over a multihop topology to a central base station. To prune these redundant messages to reduce traffic and save energy, sensor networks use in-network processing such as aggregation and duplicate elimination [17,18]. Since in-

network processing requires intermediate nodes to access, modify, and suppress the contents of messages, it is unlikely we can use end-to-end security mechanisms between each sensor node and the base station to guarantee the authenticity, integrity, and confidentiality of these messages. A link-layer security architecture can detect unauthorized packets when they are first injected into the network. For the above reasons, we decided on a link-layer security architecture for TinySec. Link-layer security mechanisms guarantee the authenticity, integrity, and confidentiality of messages between neighboring nodes, while permitting in-network processing.

#### IV. SECURITY GOALS

A link layer security protocol should satisfy some basic security properties such as:

- Access Control and Message Integrity
- Message Confidentiality
- Data Authenticity
- Data Freshness

#### V. OUR SECURITY PLATFORM

We expect higher level security protocols will rely on the link-layer security architecture as a primitive. For example, key distribution protocols, some of which utilize public key cryptography, could use Tiny-Sec to create secure pair wise communication between neighboring nodes. To reduce the effort in implementing these protocols, Tiny-Sec must provide the right set of interfaces to facilitate their development.

#### VI. OUR SECURITY DESIGN

##### A. Encryption

Using semantically secure encryption typically requires two design decisions: selecting an encryption scheme and specifying the IV format. In our design of TinySec, we use a specially formatted 8 byte IV, and we use cipher block chaining (CBC). In this section, we introduce the structure of our IV format and argue why CBC[8] is the most appropriate encryption scheme for sensor networks.

##### B. TinySec Initialization Vector (IV) Format

The length of our IV [2], and the way we generate IVs, can have a dramatic effect on both security and on performance. If the IV is too long, we will add unnecessary bits to the packet, which translates to a significant cost in

overall throughput and in energy drain. At the same time, if the IV is too short, we run the risk that the IV will repeat, and then our security warranty is void. How long is long enough? By the pigeonhole principle, a  $n$ -bit IV is guaranteed to repeat after  $2^n + 1$  packets are sent, no matter how we choose the IV. If we use a  $n$ -bit counter, repetitions will not occur before that point. However, for some IV generation strategies, repetitions may occur earlier. If we choose each IV as a random  $n$ -bit value, then by the birthday paradox, we expect (probabilistically) to see the first repetition after roughly  $2^{n/2}$  packets have been sent. Therefore, we use a counter in our IV, and we transmit it in the packet so that the receiver can learn the value of the counter. The structure of the IV is

$$\text{dst} || \text{AM} || l || \text{src} || \text{ctr}$$

where *dst* is the destination address of the receiver, *AM* is the active message (AM) handler type, *l* is the length of the data payload, *src* is the source address of the sender, and *ctr* is a 16 bit counter. The counter starts at 0, and the sender increases it by 1 after each message sent.

#### VII. MAJOR COMPONENTS OF RESEARCH: SECURITY ANALYSIS

##### A. Message Integrity and Authenticity

The security of CBC-MAC is directly related to the length of the MAC. Conventional security protocols use MACs of 8 or 16 bytes, again erring on the side of caution. We show here that our choice of a 4 byte MAC is not detrimental in the context of sensor networks. We can model TinySec's CBC-MAC as a function that produces 4 bytes of output [9]. Given a 4 byte MAC, then, an adversary has a 1 in  $2^{32}$  chance in blindly forging a valid MAC for a particular message. If an adversary repeatedly attempts blind forgeries, she should succeed after about  $2^{31}$  tries. Note that adversaries cannot determine offline if a forgery will be successful or not; an adversary can only test the validity of an attempted forgery by sending it to an authorized receiver. This implies she must send about  $2^{31}$  packets before she can succeed at forging the MAC for a single malicious packet. However, in sensor networks, this may provide an adequate level of security. Adversaries can try to flood the channel with forgeries, but on a 19.2kb/s channel, one can only send 40 forgery attempts per second, so sending  $2^{31}$  packets at this rate would take over 20 months. Battery-operated sensor nodes do not have enough energy to receive that many messages.

##### B. Confidentiality

The security of CBC mode encryption reduces to the length of the IV, but this security assumes no IV reuse. With an 8 byte counter or 16 byte random IV, avoiding repetition is relatively easy. Although TinySec uses an 8 byte IV, we limited ourselves to 4 additional bytes of overhead in the

packet to represent the IV. The other 4 bytes of the IV borrow from the existing header fields: the destination address, the AM type, and the length. TinySec partitions the last 4 bytes of the IV into  $\text{src}||\text{ctr}$ , where  $\text{src}$  is the source address of the sender and  $\text{ctr}$  is a 16 bit counter starting at 0. Having every node generate IVs from a 4 byte counter starting at 0 is bad idea; the first packet sent from one node will reuse the same IV as the first packet sent from all other nodes. Generating IVs randomly is also a poor choice; the birthday paradox implies we can expect a collision after  $2^{16}$  total packets in the network. Our format for the last 4 bytes strives to maximize the number of packets each node can send before there is a global repetition of an IV value. The  $\text{src}||\text{ctr}$  format of the last 4 bytes guarantees each node can send at least  $2^{16}$  packets before IV reuse occurs. For a network of  $n$  nodes all sending packets at approximately the same rate, this results in about  $n \cdot 2^{16}$  total packets before we expect an instance of IV reuse. At one packet per minute per node, IV reuse will not occur for over 45 days. IV reuse is only a problem when we reuse the same IV with the same key. The first 4 bytes of the IV,  $\text{dst}||\text{AM}||\text{l}$ , help prevent information leakage during the unfortunate event of a counter on a node repeating. If a counter value for a particular source address is reused, there is only potential information leakage when the  $\text{dst}||\text{AM}||\text{l}$  values are exactly the same for both messages. CBC mode for encryption enables Tiny-Sec to provide strong confidentiality guarantees for applications in sensor networks.

#### C. Message Expansion problem in TinySec using CBC mode

Naively using CBC mode for encryption with a 8-byte block cipher results in cipher-texts which are multiples of 8 bytes. This may result in message expansion[7], which increases power consumption. We use a technique known as cipher-text stealing to ensure the cipher-text is the same length as the underlying plaintext. Encrypting data payloads of less than 8 bytes will produce a cipher-text of 8 bytes because cipher-text stealing requires at least one block of cipher-text. However, the fixed overhead of sending a message generally discourages short messages.

#### D. Analytical result for message expansion overhead

Our communication bandwidth is extremely short. So communication is more expensive. It has seen that each bit transmitted consumes power as 800-100 CPU instructions. So if we send a 30 byte packet and for encryption process if the overhead is 8 byte per packet, then the percentage of overhead for the whole packet is approximately 26% which is too much expensive in case of energy efficiency.

### VIII. PROPOSED TECHNOLOGY: CIPHER-TEXT STEALING METHOD

#### A. Cipher text stealing

In cryptography, ciphertext stealing (CTS) [6] is a general method of using a block cipher mode of operation that allows for processing of messages that are not evenly divisible into blocks without resulting in any expansion of the ciphertext, at the cost of slightly increased complexity of the MAC.

#### B. General characteristics

Ciphertext stealing is the technique of altering processing of the last two blocks of plaintext, resulting in a reordered transmission of the last two blocks of ciphertext and no ciphertext expansion. This is accomplished by padding the last block (which is possibly incomplete) with the high order bits from the second to last ciphertext block (stealing the ciphertext from the second to last block). The (now full) last block is encrypted, and then exchanged with the second to last ciphertext block, which is then truncated to the length of the final plaintext block, removing the bits that were stolen, resulting in ciphertext of the same length as the original message size. In all cases, the processing of all but the last two blocks is unchanged. Cipher text stealing for CBC mode doesn't necessarily require the plaintext to be longer than one block.

#### C. Cipher text stealing mode description

In order to encrypt or decrypt data, use the standard block cipher mode of operation on all but the last two blocks of data. The following steps describe how to handle the last two blocks of the plaintext, called  $P_{n-1}$  and  $P_n$ , where the length of  $P_{n-1}$  equals the block size of the cipher in bits,  $B$ , the length of the last block,  $P_n$ , is  $M$  bits, and  $K$  is the key that is in use.  $M$  can range from 1 to  $B$ , inclusive, so  $P_n$  could possibly be a complete block. The CBC mode description also makes use of the ciphertext block just previous to the blocks concerned,  $C_{n-2}$ , which may in fact be the IV if the plaintext fits within two blocks.

For this description, the following functions and operators are used:

- $\text{Head}(\text{data}, a)$ : returns the first  $a$  bits of the 'data' string.
- $\text{Tail}(\text{data}, a)$ : returns the last  $a$  bits of the 'data' string.
- $\text{Encrypt}(K, \text{data})$ : use the underlying block cipher in encrypt mode on the 'data' string using the key  $K$ .
- $\text{Decrypt}(K, \text{data})$ : use the underlying block cipher in decrypt mode on the 'data' string using the key  $K$ .
- XOR: Bitwise Exclusive-OR. Equivalent to bitwise addition without use of a carry bit.
- $||$ : Concatenation operator. Combine the strings on either side of the operator.
- $0^a$ : a string of  $a$  0 bits.

#### D. CBC ciphertext stealing

In CBC, there is already interaction between processing of different adjacent blocks, so CTS has less conceptual impact in this mode. Error propagation is affected.

##### a) CBC encryption steps

- $X_{n+1} = P_{n+1} \text{ XOR } C_{n+2}$ . Exclusive-OR  $P_{n+1}$  with the previous ciphertext block,  $C_{n+2}$ , to create  $X_{n+1}$ . This is equivalent to the behavior of standard CBC mode.
- $E_{n+1} = \text{Encrypt}(K, X_{n+1})$ . Encrypt  $X_{n+1}$  to create  $E_{n+1}$ . This is equivalent to the behavior of standard CBC mode.
- $C_n = \text{Head}(E_{n+1}, M)$ . Select the first  $M$  bits of  $E_{n+1}$  to create  $C_n$ . The final ciphertext block,  $C_n$ , is composed of the leading  $M$  bits of the second-to-last ciphertext block. In all cases, the last two blocks are sent in a different order than the corresponding plaintext blocks.
- $P = P_n \parallel 0^{B \cdot M}$ . Pad  $P_n$  with zeros at the end to create  $P$  of length  $B$ . The zero padding in this step is important for step 5.
- $D_n = E_{n+1} \text{ XOR } P$ . Exclusive-OR  $E_{n+1}$  with  $P$  to create  $D_n$ . For the first  $M$  bits of the block, this is equivalent to CBC mode; the first  $M$  bits of the previous block's ciphertext,  $E_{n+1}$ , are XORed with the  $M$  bits of plaintext of the last plaintext block. The zero padding of  $P$  in step 4 was important, because it makes the XOR operation's effect on the last  $B \cdot M$  bits equivalent to copying the last  $B \cdot M$  bits of  $E_{n+1}$  to the end of  $D_n$ . These are the same bits that were stripped off of  $E_{n+1}$  in step 3 when  $C_n$  was created.
- $C_{n+1} = \text{Encrypt}(K, D_n)$ . Encrypt  $D_n$  to create  $C_{n+1}$ . For the first  $M$  bits, this is equivalent to what would happen in CBC mode (other than the ciphertext ordering). For the last  $B \cdot M$  bits, this is the second time that these data have been encrypted under this key (It was already encrypted in the production of  $E_{n+1}$  in step 2).

##### b) CBC decryption steps

- $D_n = \text{Decrypt}(K, C_{n+1})$ . Decrypt  $C_{n+1}$  to create  $D_n$ . This undoes step 6 of the encryption process.
- $C = C_n \parallel 0^{B \cdot M}$ . Pad  $C_n$  with zeros at the end to create a block  $C$  of length  $B$ . We are padding  $C_n$  with zeros to help in step 3.
- $X_n = D_n \text{ XOR } C$ . Exclusive-OR  $D_n$  with  $C$  to create  $X_n$ . Looking at the first  $M$  bits, this step has the result of XORing  $C_n$  (the first  $M$  bits of the encryption process'  $E_{n+1}$ ) with the (now decrypted)  $P_n \text{ XOR } \text{Head}(E_{n+1}, M)$  (see steps 4-5 of the encryption process). In other words, we have CBC

decrypted the first  $M$  bits of  $P_n$ . Looking at the last  $B \cdot M$  bits, this recovers the last  $B \cdot M$  bits of  $E_{n+1}$ .

- $P_n = \text{Head}(X_n, M)$ . Select the first  $M$  bits of  $X_n$  to create  $P_n$ . As described in step 3, the first  $M$  bits of  $X_n$  contain  $P_n$ . We queue this last (possibly partial) block for eventual output.
- $E_{n+1} = C_n \parallel \text{Tail}(X_n, B \cdot M)$ . Append the tail ( $B \cdot M$ ) bits of  $X_n$  to  $C_n$  to create  $E_{n+1}$ . As described in step 3,  $E_{n+1}$  is composed of all of  $C_n$  (which is  $M$  bits long) appended with the last  $B \cdot M$  bits of  $X_n$ . We reassemble  $E_{n+1}$  (which is the same  $E_{n+1}$  seen in the encryption process) for processing in step 6.
- $X_{n+1} = \text{Decrypt}(K, E_{n+1})$ . Decrypt  $E_{n+1}$  to create  $X_{n+1}$ . This reverses encryption step 2.  $X_{n+1}$  is the same as in the encryption process.
- $P_{n+1} = X_{n+1} \text{ XOR } C_{n+2}$ . Exclusive-OR  $X_{n+1}$  with the previous ciphertext block,  $C_{n+2}$ , to create  $P_{n+1}$ . Finally, we reverse the XOR step from step 1 of the encryption process.

#### E. Ciphertext stealing encryption and decryption

##### a) CBC cipher text stealing encryption using a standard CBC interface:

- Pad the last partial plaintext block with 0.
- Encrypt the whole padded plaintext using the standard CBC mode.
- Swap the last two ciphertext blocks.
- Truncate the ciphertext to the length of the original plaintext.

##### b) CBC cipher text stealing decryption using a standard CBC interface:

- $D_n = \text{Decrypt}(K, C_{n+1})$ . Decrypt the second to the last ciphertext block.
- $C_n = C_n \parallel \text{Tail}(D_n, B \cdot M)$ . Pad the ciphertext to the nearest multiple of the block size using the last  $B \cdot M$  bits of block cipher decryption of the second-to-last ciphertext block.
- Swap the last two ciphertext blocks.
- Decrypt the ciphertext (except the now last block) using the standard CBC mode.
- Truncate the plaintext to the length of the original ciphertext.

#### F. Keying Mechanism

The appropriate keying mechanism for a particular network depends on several factors such as the target threat model, ease of use, and the networking and security requirements of applications. In cryptographic design, a good rule of thumb is to use different keys for different applications. When we refer to a TinySec key, we mean a pair of Skipjack [8] keys, one for encrypting data, and one for computing MACs. The simplest keying mechanism is to

use a single network wide TinySec key among the authorized nodes.

#### IX. OUR PROPOSED IMPLEMENTATION STRATEGY

TinySec currently runs on the Mica, Mica2, and Mica2 Dot platforms, each using Atmel processors; the Mica sensor node uses the RFM TR1000 radio, while the Mica2 and Mica2Dot nodes use the Chipcon CC1000 radio [15]. Additionally, TinySec is integrated into the TOSSIM simulator [12], which runs on an Intel x86 platform. Others have ported TinySec to a Texas Instruments microprocessor.

##### A. Components of a Sensor node

Researchers at UC Berkeley were the first to come up with the concept of intelligent wireless sensors and sensor networks. They have developed sensor devices called 'motes' and an operating system called 'Tiny OS' [9] which is specifically designed to run on the motes. The term 'mote' is used to refer the sensor node as whole. However, it's the hardware component of the sensor node. The software component includes the TinyOS operating system and various applications and protocols developed on top of it.

##### B. Motes

A mote is essentially a microcontroller along with a number of sensors attached to it. Some motes have integrated sensors. These motes are very small in size due to the nature and purpose of sensor networks applications. Some examples of motes are Telos, Rene, Mica and Mica2. Mica2 is the most representative of all and the majority of the research done today in the field of wireless sensor networks use Mica2 motes [19].

Fig. 1. Mica2

##### C. Mica2 Components

The main block of Mica2 is the microcontroller or processor - Atmel Atmega128 AVR [11]. AVR is an 8-Bit Harvard architecture, with separate instruction and data memory. AVR micro controllers provide several sleep modes. The purpose of these modes is to provide a way of suspending program execution when necessary, thereby reducing power consumption. The microcontroller unit (MCU)[10] is

responsible for control of the sensors and the execution of communication protocols and signal processing algorithms on the gathered sensor data. The microcontroller interfaces with Radio, LEDS, Flash Memory and Sensor board/Programming interface [14].

##### D. Sensing Hardware

The continuous size and cost reduction of electronic devices is gradually making the vision of ubiquitous wireless sensors networks a reality [1]. The modular design of the motes allows a wide range of analog and digital sensors to be attached to the mote. However, the reference sensor board for the mica platform is the "Mica Sensor board". A variety of these sensor boards are available. They allow for a range of different sensing modalities as well as interface.

##### E. TinyOS

TinyOS is a small event-driven, component based operating system, designed specifically for supporting the concurrency intensive operations required by networked sensors with minimum hardware requirements. The TinyOS framework contains numerous pre-built sensor applications and algorithms e.g. multihop ad-hoc routing [13] and supports different sensor node platforms. TinyOS is optimized in terms of memory usage and energy efficiency. It provides defined interfaces between the components which reside in neighboring layers.

#### X. CONCLUSION

We explored some of the tradeoffs between performance, transparency, and cryptographic security, and propose a design that meets the needs in sensor networks. After going through it we have found that it has been experiencing a drawback of message expansion which in turn reduces the power of resource-constrained motes. As a result, whole sensor network will starve for adequate energy and it will gradually become a vulnerable network. We proposed a system that will retain the size of message after encryption. And it is "ciphertext stealing system". This way unnecessary power consumption due to encryption will be reduced.

#### ACKNOWLEDGEMENT

All complements to the almighty Allah who gives us the ability and knowledge to do this hard work. We express our greatest gratitude, appreciation and profound respect to our supervisor Md. Khairullah, Lecturer, Dept. of CSE, Shah Jalal University of Science & Technology, Sylhet, Bangladesh for his continuous, proper & perfect guidance and invaluable suggestion.

**Abstract**—Although conventional cryptographic security mechanisms are essential to the overall problem of security, the openness of wireless medium poses both threats and opportunities for securing transmission. Information theoretic security is attracting researchers for its robust nature. In this paper, a Gaussian multiple input multiple output multiple eavesdropper (MIMOME) channel is considered where a transmitter is communicating to a receiver in the presence of an eavesdropper. The transmitter is equipped with multiple antennas, while the receiver and the eavesdropper also contains multiple antennas. We present a technique for determining the secrecy capacity of the MIMO channel under Gaussian noise. To do so, we transform the channel into multiple single input multiple output (SIMO) Gaussian wiretap channel and then use scalar approach using standard techniques of communications theory. Then we consider the effect of fading and found out the limiting values of the secrecy capacity.

**Index Terms**—Secrecy capacity, MIMO, wiretap channel, covariance matrix, fading.

## I. INTRODUCTION

Wireless media is an open medium for communication and is vulnerable to eavesdropping. The openness of the transmission medium makes eavesdropping extremely easy and anyone within communication range can listen to the traffic in the air, and possibly extract information. However, the unique properties of wireless medium might provideways of combating such security threats. For example, due to random fading, the intended receiver will have a channel different from an eavesdroppers when she is at a reasonable distance away. This difference can be utilized to secure the communication between the transmitter and the intended receiver. The eavesdropping attack was first studied by Wyner in [1], where he considers a single-user wire-tap channel. The measure of secrecy is the message equivocation rate at the wire-tapper, which is defined as the entropy of the message at the wire-tapper, given the wire-tappers observation. Wyner models the wire-tappers channel as a degraded version of the channel from the transmitter to the legitimate receiver, which is a reasonable assumption in a wired channel. For this channel, Wyner

identifies the rate-equivocation region and therefore, the secrecy capacity. Wyners result was extended to the Gaussian wire-tap channel in [2], and it was shown that Gaussian signalling is optimal. The secrecy capacity was found to be the difference between the capacities of the main and the eavesdropping channels. Csiszar and Korner [3] studied the general, i.e., not necessarily degraded, single-transmitter, single-receiver, single-eavesdropper, discrete memoryless channel with secrecy constraints, and found an expression for the secrecy capacity, in the form of the maximization of the difference between two mutual informations involving an auxiliary random variable. The auxiliary random variable is interpreted as performing pre-processing on the information. The explicit calculation of the secrecy capacity for a given channel requires the solution of this maximization problem in terms of the joint distribution of the auxiliary random variable and the channel input. The use of multiple transmit and receive antennas has been shown to increase the achievable rates when there are no secrecy constraints [4]. The Gaussian multiple-input multipleoutput (MIMO) wire-tap channel is a special case of the single-transmitter, single-receiver, single-eavesdropper wire-tap channel. Since the Gaussian MIMO channel is not degraded in general, finding its secrecy capacity involves identifying the optimum joint distribution of the auxiliary random variable representing pre-processing and the channel input in the Csiszar-Korner formula. However, solving this optimization problem directly for non-degraded channels is difficult, forcing researchers typically to follow a two-step solution, where in the first step a feasible solution is identified (an achievable scheme), and in the second step a tight upper bound that meets this feasible solution is developed (tight converse). The first paper studying secrecy in MIMO communications is [5], which proposes an achievable scheme, where the transmitter uses its multiple transmit antennas to transmit only in the null space of the eavesdroppers channel, thereby preventing any eavesdropping. Reference [6] studies the Gaussian single-input multiple-output (SIMO) wire-tap channel, and shows that it is equivalent to a scalar

Fig. 1. Wiretap channel

Gaussian channel, and gives the secrecy capacity using the results of [2]. An achievable scheme has been proposed for the Gaussian multipleinput single-output (MISO) wiretap channel in [7], and independently and concurrently in [8]. In both of these papers, the achievable secrecy rate is obtained by restricting the 2 channel input to be Gaussian, with no pre-processing of information. The secrecy rate found in [7,8] is shown to be the secrecy capacity of the Gaussian MISO wire-tap channel in [9,10]. Further, [9, 10] allow the eavesdropper to have multiple antennas (MISOME). In all these papers, no one has tried to find the secrecy capacity of MIMO wiretap channel using the scalar gaussian channel.

In this paper we are trying to find out the secrecy capacity of a MIMO channel using a scalar gaussian approach. We consider the MIMO channel a combination of several SIMO channel and find out the secrecy capacity. We use the following notations throughout this paper: Bold face lower and upper case letters are used to represent vectors and matrices, respectively.  $\mathbf{x}^\dagger$  denotes the conjugate transpose of the complex vector  $\mathbf{x}$ . Whether a variable is deterministic or random will be clear from the context.

The remainder of this paper is organized as follows: In section II, wiretap channel is analyzed where gaussian wiretap channel is also discussed. In section III, System model for the MIMO channel is introduced where the mathematical model is also developed. In section IV, we consider a fading channel and develop a boundary condition for secrecy capacity. Then section V concludes this paper.

## II. WIRETAP CHANNEL

The wiretap channel is a degraded form of a broadcast channel, where the goal is to maximize the transmission rate in the main channel while making negligible the amount of information leaked to the cascade (wiretapper) channel. The secrecy capacity is the maximal rate at which this goal is achieved. We are considering two discrete memoryless channels (DMC) as the ones depicted in Figure 1. The encoder takes the input sequence  $U^k = (U_1, \dots, U_k)$  and transforms it into a  $n$  symbols sequence  $X^n = (X_1, \dots, X_n)$ . The rate of the code is  $R = k/n$ . The security engineer must design an encoder/decoder

pair that ideally maximizes the transmission rate of the legitimate user, subject to the constraint that the rate at which the wiretapper learns the sequence is as small as possible. The wiretapper knows the encoding used, and its ignorance about the source depends only on the noise realization present in the channels. The source is assumed to be stationary and ergodic, and takes its values over a finite alphabet. The probability of block decoding error is denoted by

$$P_e = \Pr\{U^k \neq V^k\} \quad (1)$$

The wiretapper uncertainty about the source is measured by the equivocation

$$H(U^k|Z^n), \quad (2)$$

after observing the output of the channel.

Definition 2.1: The fractional equivocation

$$\delta = \frac{H(U^k|Z^n)}{H(U^k)} \quad (3)$$

The rate of the code

$$R = \frac{H(U^k)}{n} \quad (4)$$

Definition 2.2: (Achievability) The pair  $(R^*, d^*)$  is said to be achievable if for all  $\epsilon > 0$  there exists an encoder/decoder pair such that

$$\begin{aligned} R &\geq R^* - \epsilon \\ \delta &\geq d^* - \epsilon \\ P_e &\leq \epsilon \end{aligned} \quad (5)$$

Theorem 2.1: [1]. The set of achievable pairs  $(R, d)$  can be characterized as follows

$$\mathcal{R} = \{(R, d) : 0 \leq R \leq C_M, 0 \leq d \leq 1, R_d \leq C_S\} \quad (6)$$

where  $C_S$  is the secrecy capacity and its value is

$$C_S = C_M - C_W \quad (7)$$

where  $C_M$  is the main channel capacity and  $C_W$  is the eavesdropper channel capacity.

Although Wyner's work only considered discrete-time channels, Leung and Hellman [11] proved that the results also hold in a particular case of continuous-time channel. A Gaussian wiretap channel is wiretap channel where the noise is additive white and Gaussian, such that the

Fig. 2. A communication system with multi-antenna transmitter, receiver and eavesdropper

channel is power limited (P) and the noise processes are independent and have components that are i.i.d.  $\mathcal{N}(0, \sigma_1^2)$  and  $\mathcal{N}(0, \sigma_2^2)$  respectively. The achievable region of the Gaussian wiretap channel is the same as defined in eq. 6 with

$$\begin{aligned} C_M &= \frac{1}{2} \log\left(1 + \frac{P}{\sigma_1^2}\right) \\ C_W &= \frac{1}{2} \log\left(1 + \frac{P}{\sigma_1^2 + \sigma_2^2}\right) \end{aligned} \quad (8)$$

### III. SYSTEM MODEL

Figure 2 shows a communication system, with a transmitter equipped with a transmitter, a receiver and an eavesdropper, each with multiple antennas. The user and eavesdropper channel attenuations can be represented by  $N_t \times N_r$  and  $N_r \times M_r$  vectors  $\mathbf{H}$  and  $\mathbf{G}$ , where  $N_t$  is the number of transmit antennas whereas  $N_r$  and  $M_r$  are the number of receive antenna at the legitimate receiver and eavesdropper. We are considering the degraded multiple input multiple output (MIMO) channel depicted in Figure 3. We will determine the secrecy capacity of the MIMO Gaussian wiretap channel. For every  $N_t$  transmitting antenna, Alice sends symbols that have limited average power  $P > 0$ , i.e.,

$$\frac{1}{K} \sum_{k=0}^{K-1} E\{x^2[k]\} \leq P \quad (9)$$

Bob uses  $N_r$  receive antennas and Eve uses  $M_r$  receive antennas to recover Alice's message. Alice sends no message to Eve, so there are no common messages. The channel parameters are represented by  $\mathbf{H}$  with dimension  $N_r \times N_t$  and  $\mathbf{G}$  with dimension  $M_r \times N_r$ .

Fig. 3. Degraded broadcast channel

The received signals at the receiver and the eavesdropper at  $k$ -th time slot are

$$\mathbf{y}[k] = \mathbf{H}\mathbf{x}[k] + \mathbf{n}[k] \quad (10)$$

$$\mathbf{z}[k] = \mathbf{G}\mathbf{y}[k] + \mathbf{w}[k] \quad (11)$$

where  $\mathbf{n}$  and  $\mathbf{w}$  are independent random vectors, each one of them being complex and jointly Gaussian distributed with mean 0 and non-singular covariance matrices  $\Sigma_1$  and  $\Sigma_2$  respectively.  $\mathbf{H}$  and  $\mathbf{G}$  are known and fixed. When the main and eavesdropper channel experiences fading,  $\mathbf{H}$  and  $\mathbf{G}$  are assumed to be a vector of i.i.d. zero mean unit-variance complex circularly symmetric Gaussian random variables.

Our goal is to show that the channel described by eq. (10) can be represented by a summation of several scalar channels and that such representation is in fact a parallel Gaussian wiretap channel. Eq. (10) can be the addition of  $N_t$  parallel single input multiple output (SIMO) channel and can be written as

$$\begin{aligned} \mathbf{y}[k] &= \sum_{i=1}^{N_t} \mathbf{y}_i[k] \\ &= \sum_{i=1}^{N_t} (\mathbf{h}_i \mathbf{x}_i[k] + \mathbf{n}_i[k]) \end{aligned} \quad (12)$$

After putting the value of  $\mathbf{y}[k]$  in the eq. (11) we get

$$\mathbf{z}[k] = \mathbf{G} \sum_{i=1}^{N_t} (\mathbf{h}_i \mathbf{y}_i[k] + \mathbf{n}_i[k]) + \mathbf{w}[k] \quad (13)$$

The multiple input multiple output multiple eavesdropper (MIMOME) channel can be seen as a multiple parallel single input multiple output multiple eavesdropper (SIMOME) channel. Every SIMOME channel can be converted to a corresponding scalar channel [6]. The  $i$ th main channel and the eavesdropper channel at SIMOME looks like the following

$$\mathbf{y}_i[k] = \mathbf{h}_i x_i[k] + \mathbf{n}_i[k] \quad (14)$$

Replacing  $\mathbf{y}[k]$  by  $\mathbf{y}_i[k]$  in eq. (11) we get

$$\begin{aligned} \mathbf{z}_i[k] &= \mathbf{G}(\mathbf{h}_i x_i[k] + \mathbf{n}_i[k]) + \mathbf{w}[k] \\ &= \mathbf{G}\mathbf{h}_i x_i[k] + \mathbf{G}\mathbf{n}_i[k] + \mathbf{w}[k] \end{aligned} \quad (15)$$

Multiply the equation (14) by  $\mathbf{h}_i^\dagger \Sigma_{1i}^{-1}$  we get

$$\mathbf{h}_i^\dagger \Sigma_{1i}^{-1} \mathbf{y}_i[k] = \mathbf{h}_i^\dagger \Sigma_{1i}^{-1} \mathbf{h}_i x_i[k] + \mathbf{h}_i^\dagger \Sigma_{1i}^{-1} \mathbf{n}_i[k] \quad (16)$$

both the sides are now  $1 \times 1$  in dimension and in fact scalar. Now taking  $\mathbf{h}_i^\dagger \Sigma_{1i}^{-1} \mathbf{y}_i[k] = y_i[k]$ ,  $\mathbf{h}_i^\dagger \Sigma_{1i}^{-1} \mathbf{h}_i = h_i^2$  and  $\mathbf{h}_i^\dagger \Sigma_{1i}^{-1} \mathbf{n}_i[k] = n_i[k]$  we get the equation (16) like the followings

$$y_i[k] = h_i^2 x_i[k] + n_i[k] \quad (17)$$

Again multiplying eq. (15) by  $(\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1}$  we get

$$\begin{aligned} (\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1} \mathbf{z}_i[k] &= (\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1} \mathbf{G}\mathbf{h}_i x_i[k] \\ &\quad + (\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1} (\mathbf{G}\mathbf{n}_i[k] + \mathbf{w}[k]) \end{aligned} \quad (18)$$

both the sides are now scalar as it was in the previous case. Now taking  $(\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1} \mathbf{z}_i[k] = z_i[k]$ ,  $(\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1} \mathbf{G}\mathbf{h}_i = g_i^2$  and  $(\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1} (\mathbf{G}\mathbf{n}_i[k] + \mathbf{w}[k]) = w_i[k]$  we get

$$z_i[k] = g_i^2 x_i[k] + w_i[k] \quad (19)$$

Eq. (17) and eq. (19) shows the scalar representation of this MIMOME channel. In the next section, we will derive the secrecy capacity using these results.

#### IV. SECRECY CAPACITY

The equivocation rate  $R_e$ , is the conditional entropy of the transmitted message, conditioned on the received signal at the eavesdropper. The equivocation rate is a measure of the amount of information that the eavesdropper can attain about the message, and quantifies the level of secrecy in the system. The secrecy capacity,  $C_S$ , is the largest rate  $R$  achievable with perfect secrecy, i.e.,  $R_e = R$ .

The main channel capacity for SIMOME can be written like the following

$$\begin{aligned} C_{M_i} &= \frac{1}{2} \log(1 + h_i^2 P) \\ &= \frac{1}{2} \log(1 + \mathbf{h}_i^\dagger \Sigma_{1i}^{-1} \mathbf{h}_i P) \end{aligned} \quad (20)$$

Again the eavesdropper channel capacity for SIMOME is

$$\begin{aligned} C_{W_i} &= \frac{1}{2} \log(1 + g_i^2 P) \\ &= \frac{1}{2} \log(1 + (\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1} \mathbf{G}\mathbf{h}_i P) \end{aligned} \quad (21)$$

So the main channel and eavesdropper channel capacity for MIMOME channel is given by

$$\begin{aligned} C_M &= \sum_{i=1}^{N_t} C_{M_i} \\ &= \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + \mathbf{h}_i^\dagger \Sigma_{1i}^{-1} \mathbf{h}_i P) \end{aligned} \quad (22)$$

$$\begin{aligned} C_W &= \sum_{i=1}^{N_t} C_{W_i} \\ &= \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + (\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1} \mathbf{G}\mathbf{h}_i P) \end{aligned} \quad (23)$$

Positive secrecy capacity indicates successful secret communication and the secrecy capacity of the MIMO Gaussian wiretap channel can be written as

$$\begin{aligned} C_S &= C_M - C_W \\ &= \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + \mathbf{h}_i^\dagger \Sigma_{1i}^{-1} \mathbf{h}_i P) \\ &\quad - \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + (\mathbf{G}\mathbf{h}_i)^\dagger (\mathbf{G}\Sigma_{1i}\mathbf{G}^\dagger + \Sigma_2)^{-1} \mathbf{G}\mathbf{h}_i P) \end{aligned} \quad (24)$$

Considering  $\Sigma_{1i} = \sigma_{1i}^2 \mathbf{I}_{N_r}$  and  $\Sigma_2 = \sigma_2^2 \mathbf{I}_{M_r}$ , eq. 24 is rewritten as

$$\begin{aligned}
C_S = & \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + \mathbf{h}_i^\dagger (\sigma_{1i}^2 \mathbf{I}_{N_r})^{-1} \mathbf{h}_i P) \\
& - \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + (\mathbf{G} \mathbf{h}_i)^\dagger (\mathbf{G} (\sigma_{1i}^2 \mathbf{I}_{N_r}) \mathbf{G}^\dagger \\
& + (\sigma_2^2 \mathbf{I}_{M_r}))^{-1} \mathbf{G} \mathbf{h}_i P)
\end{aligned} \quad (25)$$

Again  $\mathbf{G}$  is unitary [6], we get

$$\begin{aligned}
C_S = & \sum_{i=1}^{N_t} \frac{1}{2} \log \left( 1 + \frac{\|\mathbf{h}_i\|^2}{\sigma_{1i}^2} P \right) \\
& - \sum_{i=1}^{N_t} \frac{1}{2} \log \left( 1 + \frac{\|\mathbf{h}_i\|^2}{\sigma_{1i}^2 + \sigma_2^2} P \right)
\end{aligned} \quad (26)$$

Taking  $\frac{P}{\sigma_{1i}^2} = \text{SNR}_i$  we get

$$\begin{aligned}
C_S = & \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + \|\mathbf{h}_i\|^2 \text{SNR}_i) \\
& - \sum_{i=1}^{N_t} \frac{1}{2} \log \left( 1 + \frac{\sigma_{1i}^2 \|\mathbf{h}_i\|^2}{\sigma_{1i}^2 + \sigma_2^2} \text{SNR}_i \right)
\end{aligned} \quad (27)$$

From the previous equation it can be shown that  $\sigma_2^2 > 0$  makes  $\frac{\sigma_{1i}^2}{\sigma_{1i}^2 + \sigma_2^2} < 1$  and in turn makes  $\sum_{i=1}^{N_t} \frac{1}{2} \log(1 + \|\mathbf{h}_i\|^2 \text{SNR}_i) > \sum_{i=1}^{N_t} \frac{1}{2} \log \left( 1 + \frac{\sigma_{1i}^2 \|\mathbf{h}_i\|^2}{\sigma_{1i}^2 + \sigma_2^2} \text{SNR}_i \right)$ . So the secrecy capacity  $C_S$  becomes positive. An interesting conclusion is that the secret communication is possible when the eavesdropper channel is noisy.

## V. FADING CHANNEL

We assume that the channel of the intended receiver is complex Gaussian fading, while the eavesdroppers channel is constant. Considering the main channel as a fading channel eq. (27) becomes

$$\begin{aligned}
C_S = & E_{\mathbf{h}_i} \left[ \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + \|h_i\|^2 \text{SNR}_i) \right] \\
& - E_{\mathbf{h}_i} \left[ \sum_{i=1}^{N_t} \frac{1}{2} \log \left( 1 + \frac{\sigma_{1i}^2 \|h_i\|^2}{\sigma_{1i}^2 + \sigma_2^2} \text{SNR}_i \right) \right]
\end{aligned} \quad (28)$$

It can be observed that, since the function  $f(x) = \log(1 + ax)$  is concave, using Jensens inequality [12], we have

$$\begin{aligned}
E_{\mathbf{h}_i} \left[ \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + \|h_i\|^2 \text{SNR}_i) \right] & \leq \\
\sum_{i=1}^{N_t} \frac{1}{2} \log(1 + E_{\mathbf{h}_i} \|h_i\|^2 \text{SNR}_i)
\end{aligned} \quad (29)$$

And similarly

$$\begin{aligned}
E_{\mathbf{h}_i} \left[ \sum_{i=1}^{N_t} \frac{1}{2} \log \left( 1 + \frac{\sigma_{1i}^2 \|h_i\|^2}{\sigma_{1i}^2 + \sigma_2^2} \text{SNR}_i \right) \right] & \leq \\
\sum_{i=1}^{N_t} \frac{1}{2} \log \left( 1 + \frac{\sigma_{1i}^2}{\sigma_{1i}^2 + \sigma_2^2} E_{\mathbf{h}_i} \|h_i\|^2 \text{SNR}_i \right)
\end{aligned} \quad (30)$$

if  $\sigma_{1i}^2 \ll \sigma_2^2$  then the secrecy capacity  $C_S$  in eq. (28) leads to

$$C_S = E_{\mathbf{h}_i} \left[ \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + \|h_i\|^2 \text{SNR}_i) \right] \quad (31)$$

The boundary value of secrecy capacity for this particular case will be

$$C_S \leq \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + E_{\mathbf{h}_i} \|h_i\|^2 \text{SNR}_i) \quad (32)$$

But if  $\sigma_2^2 = 0$  ie. the eavesdropper channel is noiseless, the secrecy capacity  $C_S$  will be equal to 0. So, the limiting value of the secrecy capacity depending on the noisy condition of the eavesdropper channel can be shown as

$$0 \leq C_S \leq \sum_{i=1}^{N_t} \frac{1}{2} \log(1 + E_{\mathbf{h}_i} \|h_i\|^2 \text{SNR}_i) \quad (33)$$

## VI. CONCLUSION

A MIMOME channel is considered where a transmitter is communicating to a receiver in the presence of an eavesdropper. The transmitter is equipped with multiple antennas, while the receiver and the eavesdropper also contains multiple antennas. We present a technique for determining the secrecy capacity of the MIMO channel under Gaussian noise. To do so, we transform the channel into multiple SIMO Gaussian wiretap channel and then use scalar approach using standard techniques of communications theory. We also have introduce the effect of fading in this MIMO channel and have derived the limiting value for secrecy capacity. One particular direction corresponds to the case where the broadcast channel is no longer degraded, such as the one considered by I. Csiszar and J. Korner [3]. Our next step will be to work with non degraded broadcast channel.

# A Practical Analysis of the Robustness and Stability of the Network Stack in Smartphones

Sheikh Mahbub Habib, Cyril Jacob and Tomas Olovsson

Department of Computer Science & Engineering, Chalmers University of Technology, Gothenburg,  
SE-41296, Sweden

**Abstract** - Smartphones are widely used nowadays and their popularity will certainly not slow down in the near future due to improved functionality and new technology improvements. Becoming more and more similar to PCs and laptops, they will also begin to face the same security problems especially in terms of network security. In this paper, we provide an overview of security issues for smartphones and give a brief introduction of the network stack architecture of Windows Mobile 5.0 platform in order to motivate and plan for efficient penetration tests against Windows Mobile 5.0 powered smartphones. Furthermore, a number of attacks have been done against different layers of the network stack and a list of supporting penetration tools are provided for interested practitioners. Detailed results are provided from the penetration tests performed which should be very useful for security vendors, researchers and OS vendors to give more attention to security architectures and development of security software (e.g. firewalls, antivirus) for the mobile operating systems. In a whole, robustness and stability will be assessed for the mobile OSs used by the smartphones throughout the paper.

**Index terms** - Network stack, Network scanning, Penetration testing, Smartphones, Vulnerability scanning.

## I. INTRODUCTION

Smartphones combine the functionality of mobile phones and Personal Digital Assistants (PDAs). These types of devices are becoming increasingly popular in our daily life and decrease the need to carry several devices to get similar functionality. Almost all the latest smartphones implement network technologies such as IEEE 802.11 (WLAN), Bluetooth, Infra-red and GSM/3G. When compared to regular phones, these devices have extra functionality and offer more services which will make them more vulnerable. Smartphones also enable service providers to quickly introduce more and new services to mobile users to satisfy their needs, often without really considering security. Security in these devices is often neglected due to too much attention given to the development and quick release of new functionality and services. As a result, smartphones are likely to be vulnerable both through their services and due to their relatively new and untested network stacks.

Since most operators today use NAT for connections through GSM, GPRS, 3G, etc., it is not possible for

attackers to directly scan and find the devices and the services they may offer from the Internet. This may change in the future, but at present, this offers some protection for the users. WLAN access, though, is different and the IP address being used on the WLAN may be accessible for users all over the Internet. In addition, because of vulnerabilities in the link layer and above, for example when using WEP encryption [1], attackers may be able to spawn link-level attacks via a wireless access point as well.

We should not only consider attacks against the Smartphone but also consider that it may be used as a bridge to connect to systems on the networks behind the device. It may, for example, be possible to reach corporate networks where the Smartphone is used as man-in-the-middle bridging two networks together, a scenario which was shown in enterprise networks using Blackberry devices [2].

Smart phones are used in many situations by professionals in situations where good and reliable communication is a key factor. Typical examples include voice and data communications in crisis management, for example as the only means for communication between rescue workers. It is therefore essential to know what level of stability, robustness and security these devices can provide. A typical problem we don't want to see is that a single malicious network packet from the Internet causes the devices to freeze, crash or even enable attackers to install their own software on the devices. The work provided here should be seen as a first step in the direction to develop procedures for testing and evaluation of the services offered by Smartphones.

The main target of the analysis in this paper is the Windows Mobile 5.0 operating system's network stack. Testing includes fingerprinting, port scanning, and running exploit tools in order to test the different layers of the stack.

## II. TCP/IP Architecture of Windows Mobile 5.0

Since this paper is targeting the network stack of Windows Mobile 5.0 which in turn is based on the Windows CE 5.1 platform, an understanding of the TCP/IP stack is useful when planning penetration tests and in order to analyze and understand the implications of possible security problems. All operating systems prior to Windows Vista and Windows 2008 server including the Windows

Mobile 5.0 platform use the same TCP/IP stack that was designed in the early 1990's by Microsoft [3][4]. Although this stack has been patched a number of times since then, vulnerabilities are still found in the different desktop operating systems using it. For this reason it is evident that Windows Mobile 5.0 may suffer from the same type of vulnerabilities as the other desktop operating systems like Windows XP/2000/ME/NT/98/95 have had before being patched. Moreover, Windows CE 4.1 and later versions include a dual stack architecture [5] that makes them vulnerable to attacks not only against IPv4 but also the IPv6 implementation.

In the next section, we will discuss test methodologies in order to develop a suitable methodology to test Smartphones, not only Windows Mobile based but also other platforms will be tested with the same methodology in the future.

### III. TEST METHODOLOGY

When evaluating and testing the devices, we have based our work on a scheme developed by NIST [8] containing nine techniques useful when evaluating security for a network. These are network scanning, vulnerability scanning, penetration testing, password cracking, log review, integrity checkers, virus detection, war dialing and war driving. Some of the tests are manual where an individual has to initiate and conduct the test and some of the tests are automated requiring no human involvement. Several of the above mentioned tests are often used together to get a more complete assessment of the achieved level of security. However, in this study, the test environment will mainly focus on the network stack of Smartphones, so password cracking, log review, integrity checkers, virus detection, war driving and war dialing will be irrelevant regarding practical analysis of network stack.

*Network scanning, vulnerability scanning and penetration testing* will be enough for the security testing of the network stack performed here but they will not give the full picture when the device is used in a real life scenario. These three testing techniques are discussed more in detail in the following paragraphs.

#### A. Network Scanning

In network scanning, a port scanner is used to identify all targeted hosts on a network and the services they offer to other hosts on the network. There are some specific services which are very common in smartphones such as netbios-ns (netbios name service) and the wap-push protocol. The port-scanning tool makes it possible to create a complete list of active ports and thus list all services running on the device. A high-level human interpretation is then needed to analyze the results which will be used when planning the vulnerability scanning. The Nmap tool [9] was used to perform port scanning of the targeted Smartphones.

#### B. Vulnerability Scanning

Vulnerability scanners use a similar concept as port scanners but try to go deeper and get a more realistic view about the target device. These types of scanners identify open ports and hosts and also provide information regarding possible vulnerabilities through the different ports, often application level protocol problems or problems in the application itself. Moreover, vulnerability scanners help to identify out-of-date software versions, lack of applicable patches or system upgrades and applications running on devices are compared with known vulnerabilities. Vulnerability scanners often have large databases of vulnerabilities used to identify flaws in the operating systems and applications. The results from these type of tests are valuable when selecting the right tools for actual penetration tests. The results from our port scanning tests showed that the Nessus vulnerability scanner [10] would be a good choice in order to check what vulnerabilities are actually present in our Smartphones.

#### C. Penetration testing

Penetration testing is the third and final step in the security testing where specially designed tools, often targeted against a special network stack, its implementation and other services offered on the platform, is used. In order to further analyze the possible vulnerabilities indicated by the vulnerability scanning process, commonly known attack tools were used to do the actual attacks against the smartphones. The services detected during the Nmap and Nessus testing guided us to select other penetration tools and exploit tools. In addition, Wireshark [11] was used as a network packet capture tool to analyze the results.

### IV. PENETRATION TEST RESULTS AND DISCUSSION

All the tests are initiated from two clients, one running Windows XP and one with Ubuntu Linux. The target was an XDA Exec device with Windows Mobile 5.0 OS. Wireshark was used as packet capture software to analyze the results. In the next few sections, results will be reported according to the test methodology described earlier.

#### A. Network scanning

In the network scanning performed, the Nmap "host discovery technique" [9] was used to find the MAC address and IP address of the Smartphone and to find all open/filtered/closed ports on the device. This is a technique which may reveal services even if protected by a device's firewall or built-in security barrier, if present. Moreover, a fingerprinting technique was used to more exactly identify the operating system running on the target, something which enabled us to more closely see how close its behavior is to other Windows operating systems (such as TTL, window size, initial sequence numbers, etc.). These tests gave several hints about the internal network stack

TABLE I  
NETWORK SCANNING RESULTS

| Name of the scan         | Port    | Command                  | Results                                                                                                                                                                               |
|--------------------------|---------|--------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Host discovery-ping scan | ICMP    | # nmap -sP 192.168.1.102 | Target device is found alive and MAC address shown.                                                                                                                                   |
| Host discovery-SYN ping  | TCP     | # nmap -PS 192.168.1.102 | None of the tcp ports were open. Target host was shown alive in the network.                                                                                                          |
| Ports discovery-SYN scan | TCP     | # nmap -sS 192.168.1.102 | Same result as SYN ping.                                                                                                                                                              |
| Ports discovery-UDP scan | UDP     | # nmap -sU 192.168.1.102 | <b>PORT - STATE - SERVICE</b><br>137/udp open filtered netbios-ns<br>138/udp open filtered netbios-dgm<br>1034/udp open filtered activesync-notify<br>2948/udp open filtered wap-push |
| OS fingerprinting        | TCP,UDP | # nmap -O 192.168.1.6    | Device type: webcam switch general purpose. Running: AXIS embedded, Cisco embedded, IBM MVS, Microsoft Windows 2003/.NET NT/2K/XP 95/98/ME.                                           |

architecture of the device and the services it offers. The detailed test results are given in Table I.

In Table I, the port discovery technique shows that the system has four services running which are *netbios-ns*, *netbios-dgm*, *activesync-notify* and *wap-push*, all using UDP ports. The tests show that the Netbios-ns service discloses the netbios-name of the machine, the netbios-datagram service(netbios-dgm) offer support for connection-less file sharing activities, activesync-notify is a service used to synchronize the device with workstations or laptops and wap-push is used to handle the multimedia message service (MMS). All these services are enabled by default.

By examining the results of the OS fingerprinting test from Table I, according to database of Nmap, an exact match of the OS cannot be found due to absence of the fingerprint of Windows Mobile OS. But after examining the output more in detail, Nmap suggests that it can be a Microsoft Windows Operating System. Moreover, some packets were captured to investigate the TCP and IP headers. This investigation showed that it is reasonable to

assume that the device has a network stack architecture which is similar to other Microsoft Windows operating systems for desktop systems. Therefore, similar attacks to those being successful in the past against Windows systems should be done further on when performing the penetration testing.

In the next section, Nessus [10] vulnerability scanner will be used to list the possible known vulnerabilities in the targeted smartphone via different ports and services running.

#### B. Vulnerability scanning

To perform vulnerability scanning, Nessus Server and Client were used to scan the remote device in order to find different ports and services running in that particular device. We have summarized the results regarding smartphone's vulnerability in Table II.

TABLE II  
VULNERABILITY SCANNING RESULTS

| Port name           | Synopsis                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                       | Risk factor & Reference ID                                                                                                           |

### C. Penetration testing

The most revealing problem detected here is the Etherleak vulnerability [12]. Etherleak used to be a common problem present in many operating systems early 2003, and the target system still has this vulnerability. In short, this means that the Ethernet driver leaks information found in the memory of the operating system, particularly contents from a previously received packet. Attackers on the same subnet can collect this information from the target, for example by sending ICMP echo messages. Desktop operating systems have received patches to this problem, but not Windows Mobile 5 devices.

In the penetration testing phase, we have performed many attacks against the target. The following paragraphs show the detailed results from these tests.

#### 1. ARP spoofing

We observed that the target is vulnerable to a denial-of-service attack when receiving a gratuitous ARP for its own IP address. Also, we observed that traffic can be hijacked between the target and router/access point using forged ARP reply packets.

Table III

## PENETRATION TESTING RESULTS

| Attack name & network stack level                     | Command to initiate the attack            | Result                                                                                                                                        |
|-------------------------------------------------------|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| ARP spoofing(IP level attack)                         | # arpspoof -t 192.168.1.100 192.168.1.100 | DOS attack observed. Cannot assigned IP address to the device until the attack tool stopped.                                                  |
| Session hijacking using ARP Spoofing(IP level attack) | # arpspoof -t 192.168.1.100 192.168.1.1   | Hijack the traffic between router (AP) and target. Here, DOS attack was observed after some time. No warning message shown in the smartphone. |
| ARP spoofing using Broadcast(IP level attack)         | # arpspoof 192.168.1.100                  | No changes observed in the target.                                                                                                            |
| IP Options attack (IGMPv3 exploit)                    | # ./exploit 192.168.1.100 192.168.1.4     | Target device completely hanged after receiving the crafted IGMP packet. Soft reset needed to put the target into normal state.               |

We used the arpspoof tool from the dsniff 2.3 suite [13] for the IP tests. Testing was performed on the Ubuntu Linux host as the attacker, one LinkSys router/gateway as victim (whose ARP entry was being spoofed), and one smartphone to which the gratuitous ARPs were sent to. The hosts were 192.168.1.104 (attacker), 192.168.1.100 (target), 192.168.1.101 (victim). Results are shown in Table III.

## 2. IP Options attack

The system also turned out to be vulnerable against a well-known exploit, the “IGMP V3 DoS vulnerability” [14]. We used the Linux machine as the attacker with the smartphone as the target in a LAN environment where both machines were connected to internet through a LinkSys router. Moreover, a real exploit tool [15] was used after being modified to gcc compatible code to suite our Linux system. The result is shown in Table III.

The device hangs after receiving a specially crafted IGMP packet. This can be sent to the target system and cause it to hang until it is reset. It is easy for an attacker to continuously send such packets to the target and render it completely useless. Some reports also suggest that the vulnerability could be used to execute arbitrary code on affected systems. There is no patch available in Microsoft’s security bulletin website related to this attack for Windows Mobile 5.0 [19].

## 3. Other attacks

Some other well-known attacks such as Land attack, Ping of Death, Teardrop, IP/TCP Fuzzing, Blat, Bonk, Boink, Naptha, Newtear/Open tear, Nuke and many other attacks

were performed in the testing of the network stack’s stability and robustness. These tests were successfully handled by the device.

Since the target device has a dual stack architecture, Neighbor discovery spoofing can be performed. It is an attack where a malicious user conducts a spoofing attack through the Neighbor discovery protocol present in IPv6. The vulnerability discloses sensitive information and results in a DOS (Denial of Service). The vulnerability is caused due to a bug in the implementation of Neighbor discovery protocol while processing neighbor solicitation request. It can be exploited by someone adding a faked entry to the neighbor’s cache via an ND solicitation request, which may contain spoofed IPv6 address.

## VI. LIMITATIONS

This paper is just a beginning of an important research area which needs a lot of attention from researchers and developers. First of all, the tested Smartphone had no antivirus or firewall installed during the tests. A personal firewall on the device may have stopped some of the vulnerabilities found here, but this has not been tested by us.

The tests mentioned in this paper have only focused on the WLAN connectivity of these kinds of devices. Many smartphones today communicate not only using WLAN but also via GSM, GPRS and other more “phone-related” protocols as well as via Bluetooth. All these protocols should also be tested in order to have a full picture of the device.

## VII. CONCLUSIONS

In this paper, we have analyzed the stability and robustness of a Windows Mobile 5.0 Smartphone. We have also conducted tests to find necessary tools to aid in this work. The paper also contains a description of the TCP/IP stack architecture of the device since it has affected the planning phase of the security analysis work and guided us in the tool selection part.

We have included a discussion about test methodology and how we have acted in order to find out suitable tests for Smartphones. Careful selection of tools and attacks is important both for our own analysis as well as for future work with analysis of other devices. Detailed test results from our penetration tests are given here revealing some problems resulting from lack of robustness in the network stack of the tested device. Some rather well-known vulnerabilities which used to be present in desktop operating systems, like Etherleak, ARP spoofing, session hijacking using ARP spoofing and the IP options attack (IGMP V3 vulnerability) were found to be present in the tested system. It seems that the network stack in this type of device contains several vulnerabilities and is not fully capable to operate in complex and hostile network environments.

We will continue this work with more tests which will include penetration tests against Smartphones from other vendors like SonyEricsson and Nokia with completely different operating systems and different network architectures. Even though we have not yet performed any tests against these devices, we believe that they are likely to contain many more vulnerabilities than the tested system since Windows Mobile systems are based on rather well-tested implementations used many years in desktop operating systems.

We believe that our findings will be beneficial to the vendors to release the patches, security researchers and practitioners and security vendors who are developing firewalls, antivirus, and intrusion detection systems for the smartphones. The work should also be useful for end-customers who need to know what level of security and stability these devices offer and it makes it possible for them to know in what situations these devices should or should not be used.

**Abstract**—A number of measures of canonical correlation coefficient are now used in pattern recognition in the different literature. Some robust forms of classical canonical correlation coefficient are introduced recently to address the robustness issue of the canonical coefficient in the presence of outliers and departure from normality. Also a few number of kernels are used in canonical analysis to capture nonlinear relationship in data space, which is linear in some higher dimensional feature space. But not much work has been done to investigate their relative performances through simulation and also from the view point of sensitivity. In this paper an attempt has been made to compare performances of kernel canonical correlation coefficients (Gaussian, Laplacian and Polynomial) with that of classical and robust canonical correlation coefficient measures using simulation and influence function. We investigate the bias, standard error, MSE, qualitative robustness index, sensitivity curve of each estimator under a variety of situations and also employ boxplots and scatter plots of canonical variates to judge their performances. We observe that the class of kernel estimators perform better than the class of classical and robust estimators in general and the kernel estimator with Laplacian function has shown the best performance for large sample size.

**Index Terms**—Pattern Recognition, Robust CCA, KCCA, Monte Carlo Simulation, Influence Function and Sensitivity Curves.

## I. INTRODUCTION

The main goal of pattern recognition is supervised or unsupervised classification. It is the study of how machines can observe the environment, learn to distinguish patterns of interest from their background, and make a sound and reasonable decisions about the categories of the patterns. The statistical approach has been most intensively studied to meet up this goal properly [1]. In this approach each pattern is represented in terms a number (such as  $s$ ) of features or measurements and is viewed as a point in a  $s$ -dimensional space. The aim is to choose those features that allow pattern vectors belonging to different categories to occupy compact and disjoint regions in a  $s$ -dimensional feature space. The effectiveness of the representation space (feature set) is determined by how well patterns from different classes can be separated. To do this, the measure of the relation between distinct features is essential. Classical

CCA is a multivariate procedure for assessing the linear relationship between two sets of variables (or features). Canonical correlation was developed by Hotelling [2]. His basic elegant paper on the topic, “Relations between two sets of variables” appeared in 1936. In this paper, Hotelling described an example where one set of variables consists of mental tests and the other of physical measurements on a group of people. Then it acquired popularity and many statisticians, biometricians, economists, social scientists, and many other researchers applied it in diverse field of knowledge. During the last one decade the use of CCA is utmost popular method in the area of computer science such as generic object recognition, image analysis, image retrieval, machine translation, image segmentation, computer vision, pattern recognition, and facial expression recognition. Now-a-days KCCA are used in different fields such as computer science, information technology and so on. There are some limitations of KCCA as complexity of transformation, dimensionality (dimension is larger than sample size) and time complexity to calculate. Most of the KCCA researchers, namely [3], [4], [5] etc. tried to overcome limitations of KCCA. In a recent work [6], the influence function of kernel PCA and a robust KPCA has been theoretically derived. One observation of their analysis is that KPCA with a bounded kernel such as Gaussian is robust in that sense that the influence function does not diverge, while for KPCA with unbounded kernels such as polynomial the IF goes to infinity. This can be understood by the boundedness of the transformed data in the feature space by a bounded kernel. While this is not a result for CCA but for PCA, it is reasonable to expect that KCCA with a bounded kernel is also robust. This consideration motivates us to do some empirical studies on the robustness of KCCA. It is very important to know how KCCA is effected by outliers and to develop measures of accuracy. Therefore, we do intend to study a number of conventional robust estimates and KCCA with different functions.

In this article we consider five canonical correlation coefficients and investigate their performances by simulation, influence function and sensitivity curve. We

briefly discuss the classical, robust and kernel canonical correlation coefficients that we consider in our study in section II and III. Section IV offers the simulation as well as influence function results of the canonical correlation coefficients and finds the overall best performer. The final section gives conclusion.

## II. CLASSICAL AND ROBUST CANONICAL CORRELATION ANALYSIS

Classical CCA can be seen as the problem of finding basis vectors for two sets of variables such that the correlation between the projections of the variables onto these basis vectors are mutually maximized. The classical covariance and correlation matrices as well as eigenvector and values are highly sensitive to outlying observations as was shown in the context of CCCA. An obvious approach to robustify CCA is to estimate the population, sample covariance or correlation matrix. A number of approaches for robust canonical correlation analysis except the one just mentioned were compared and discussed by Branco[7] and Taskinen [8] obtained influence function and asymptotic distributional properties of CCCA based on robust estimates of the covariance matrix. Many researchers [7], [8] and [9] developed a few number of robust methods in CCA and suggested that from the view point of robustness and computation the performance of minimum covariance determinate (MCD) estimator is the best [7]. In our paper, we consider MCD estimator as an estimator of class of robust method.

## III. KERNEL CANONICAL CORRELATION ANALYSIS (KCCA)

At the beginning of this century there have been advances in pattern recognition of data using kernel methods [10], [11]. It is a method that generalizes the classical CCA to nonlinear setting in a nonparametric way. The kernel-based canonical correlation analysis no longer requires the Gaussian distribution assumption on observation and, therefore, enhances the applicability of CCA greatly. Basics idea of KCCA is as follows: first the original pair of multivariate variables  $x$  and  $y$  are mapped into  $\phi_x(x)$  and  $\phi_y(y)$ , elements of some high (possibly infinite) dimensional Hilbert spaces  $\mathcal{H}_x$  and  $\mathcal{H}_y$  respectively through a suitable kernel function without calculating  $\phi(\cdot)$ 's in order to get benefit of the simple fact-what is non-linear in a vector space may be linear in a transformed high dimensional space. Resorting to kernel trick through forming kernel matrix linear transformation similar to classical case is implemented in the transformed high dimensional space. Using about similar calculation that, in fact, can find more complex transformation than CCA in original space (summarized in Fig. 1).

Fig. 1. System of Kernel CCA.

### A. Derivation of the Kernel Canonical Correlation

Let us consider linear dependence of two multivariate data set  $(x_i, y_i)$  be the  $p$  dimensional and  $q$  dimensional  $x$  and  $y$  sets of variables having  $i = 1, 2, \dots, n$  observations respectively. The classical canonical correlation is find the directions  $a$  and  $b$  so that the correlation between the projections of  $X$  onto  $a$  and that of  $Y$  onto  $b$  is maximized such that

$$\begin{aligned} \rho &= a \in \mathbb{R}^p, b \in \mathbb{R}^q \frac{Cov[a^T X, b^T Y]}{\sqrt{Var[a^T X] Var[b^T Y]}} \\ &= a \in \mathbb{R}^p, b \in \mathbb{R}^q \frac{a^T \hat{V}_{xy} b^T}{\sqrt{a^T \hat{V}_{xx} a} \sqrt{b^T \hat{V}_{yy} b}} \end{aligned} \quad (1)$$

where  $\hat{V}_{xx}$ ,  $\hat{V}_{yy}$  and  $\hat{V}_{xy}$  are the sample variance and covariance matrices respectively. Classical canonical correlation is highly depend on linearity assumption, because of this assumption it gives us naive measurement in case of nonlinear data set. Even robust method can fail to find worthy relationship in such type of data. We have to seek such a method that gives us accurate measurement in case of nonlinear data. Kernel canonical correlation is a such type of powerful tool that offers us an alternative solution for nonlinear data by first projecting the data into a higher dimensional feature space (Hilbert space). Let  $\{(x_i, y_i) ; i = 1, 2, \dots, n\}$  be the training sample with  $x_i$  and  $y_i$  taking values in  $\mathcal{X}$  and  $\mathcal{Y}$  respectively. Let us prepare kernels  $k_x$  on  $\mathcal{X}$  and  $k_y$  on  $\mathcal{Y}$  as  $x_1 \dots x_n \rightarrow \phi_x(x_1), \dots, \phi_x(x_n) \in \mathcal{H}_{k_x}$  and  $y_1 \dots y_n \rightarrow \phi_y(y_1), \dots, \phi_y(y_n) \in \mathcal{H}_{k_y}$ . Now we

apply classical CCA on Hilbert space  $(\mathcal{H}_x, \mathcal{H}_y)$

$$f \in \mathcal{H}_x, g \in \mathcal{H}_y \frac{\sum_{i=1}^n \langle f, \tilde{\phi}_x(x_i) \rangle_{\mathcal{H}_x} \langle g, \tilde{\phi}_y(y_i) \rangle_{\mathcal{H}_y}}{\sqrt{\sum_{i=1}^n \langle f, \tilde{\phi}_x(x_i) \rangle_{\mathcal{H}_x}^2} \sqrt{\sum_{i=1}^n \langle g, \tilde{\phi}_y(y_i) \rangle_{\mathcal{H}_y}^2}} \quad (2)$$

where  $\tilde{\phi}_x(x_i) = \phi_x(x_i) - \frac{1}{n} \sum_{i=1}^n \phi_x(x_i)$  and  $\tilde{\phi}_y(y_i) = \phi_y(y_i) - \frac{1}{n} \sum_{i=1}^n \phi_y(y_i)$  Without any lose of generality, we can assume that  $f = \sum_{i=1}^n \alpha_i \tilde{\phi}_x(x_i)$  and  $g = \sum_{i=1}^n \beta_i \tilde{\phi}_y(y_i)$

$$\rho = \alpha \in \mathbb{R}^n, \beta \in \mathbb{R}^n \frac{\alpha^T \tilde{K}_x \tilde{K}_y \beta}{\sqrt{\alpha^T \tilde{K}_x^2 \alpha} \sqrt{\beta^T \tilde{K}_y^2 \beta}} \quad (3)$$

where  $\tilde{K}_x^2$  and  $\tilde{K}_y^2$  are the centered Gram matrices. It is equivalent to performing CCA on two vectors of dimension  $n$  with covariance matrix equal to  $\begin{bmatrix} K_x^2 & K_x K_y \\ K_y K_x & K_y^2 \end{bmatrix}$ . Thus we observe that we can perform a kernelized version of CCA by solving the following generalized eigenvalue problem.

$$\begin{bmatrix} 0 & K_x K_y \\ K_y K_x & 0 \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \end{bmatrix} = \rho \begin{bmatrix} K_x^2 & 0 \\ 0 & K_y^2 \end{bmatrix} \begin{bmatrix} \alpha \\ \beta \end{bmatrix} \quad (4)$$

based on the Gram matrices.

#### B. Different Kernel Functions for KCCA

The kernel function is used in training and predicting. The parameter of this function can be set to any function of class kernel that computes the inner product in feature space between two vector arguments. In this work we consider, Gaussian RBF kernel,  $k(x_i, x_j) = \exp(-\frac{\|x_i - x_j\|^2}{\sigma^2})$ , Laplacian kernel function,  $k(x_i, x_j) = \exp(-\frac{\|x_i - x_j\|}{\sigma})$  and Polynomial function,  $k(x_i, x_j) = (\langle x_i, x_j \rangle + c)^d$ .

### IV. RESULTS

In this section we consider the simulation, influence function, and estimate of influence function results respectively. We generate multivariate normal (MVN) data by considering two covariance matrices  $CVM_1$  and  $CVM_2$  that are given below. We also generate data from uniform distribution having  $[-\pi, \pi]$ . After that we transform generated data by sin and cos function in different way. We find bias, standard error, mean square error, qualitative robustness index(QRI)[12] of the canonical correlation estimators at different models as well as transformed data. The results are represented in different tables and boxplots.

$$\begin{bmatrix} 1.0 & 0.8702 & -0.3657 & -0.3896 & -0.4931 & -0.2263 \\ 0.8703 & 1.0 & -0.3529 & -0.5522 & -0.6456 & -0.1915 \\ -0.3657 & -0.3529 & 1.0 & 0.1506 & 0.2250 & 0.0349 \\ -0.3896 & -0.5522 & 0.1506 & 1.0 & 0.6957 & 0.4957 \\ -0.4938 & -0.6456 & 0.2250 & 0.695 & 1.0 & 0.6692 \\ -0.2263 & -0.1915 & 0.0349 & 0.4957 & 0.669 & 1.0 \end{bmatrix}$$

and  $CVM_2 = \begin{bmatrix} 1.000 & 0.505 & 0.569 & 0.602 \\ 0.505 & 1.000 & 0.422 & 0.467 \\ 0.569 & 0.422 & 1.000 & 0.926 \\ 0.602 & 0.467 & 0.926 & 1.000 \end{bmatrix}$

#### A. Simulation Results

Here we report a simulation study of different correlation coefficients. In our study we consider three different sample sizes (50, 500, and 1000) with different types of Multivariate models. To perform simulation study we consider three experiments as follows.

*Experiment-1 (Data generated from multivariate normal(MVN) and MVN with 6%contamination):* In this experiment we generate data from MVN as ideal model and MVN with 6% fixed outlier as contaminated model. We consider three sample size  $n = 50$ ,  $n = 500$  and  $n = 1000$  and simulated 1000 times. In case of  $n = 1000$  we take fewer replications in order to avoid much calculation. After that we calculate bias, standard error, MSE as well as QRI which are given in the Table I and Table II respectively. From Table I, we see that, although in case of bias (Minimum values as bold) the performance of classical and robust are better but over all, we may conclude that kernel estimators are better than classical as well as robust estimators specially at contaminated models and large sample size.

*Qualitative Robustness Index (QRI):* To measure the effect of contamination on different estimators at different contamination models we use qualitative robustness index;

$$QRI = \frac{1}{\sum |\xi(s)_{100\alpha} - \xi_{100\alpha}^{(s)c}|} \quad (5)$$

where  $\xi_{100\alpha}^{(s)} = 100^{th}$  percentile of the simulated sampling distribution of the estimators at standard model, and  $\xi_{100\alpha}^{(s)c} = 100^{th}$  percentile of the simulated sampling distribution of different estimators at contaminated model. We consider  $\alpha = 0.005, 0.01, 0.025, 0.05, 0.1, 0.5, 0.9, 0.95, 0.975, 0.99, 0.995$  for our standard model and contaminated model. By considering qualitative robustness index (Maximum values as bold)in Table II, we see that both robust and kernel method perform better than classical method.

*Experiment-2 (Data generated from multivariate normal and transformation with  $CC = 0.79$  and  $CC = 0.63$ ):*

In this experiment we generate data by using  $CVM_1$  and  $CVM_2$  and take transformation in the following way. In case of  $CVM_1$ , the data of x-set with three variables  $x_1, x_2$  and  $x_3$  transform by  $\sin(2x_1), \cos(x_2)$  and  $\sin(3x_3)$  as well as y-set as  $\cos(2y_1), \sin(y_2), \cos(3y_3)$ . For  $CVM_2$  we take transformation as  $\sin(x_1), \sin(3x_2)$  and  $\cos(2y_1), \cos(3y_2)$  for both x-set and y-set data respectively. By using canonical coefficient we sketch the boxplots of five estimators, which are given in Fig. 2a, and Fig. 2b. having first population  $CC = 0.79$  and  $CC = 0.63$  respectively. From the Fig.2, we observe that in both cases classical and robust method give very naive estimates over all sample sizes. But the performace of kernel method is the best. For

sample  $n = 50$  the kernel estimator with Gaussian (KG) function gives smallest bias, on the other hand, for large sample Laplacian function (KL) gives smallest bias along with minimum variation in the both cases.

#### Experiment-3 (Generated from uniform distribution ):

In this section we generate data according to [4], [5] but size is 100. At first  $\theta$  is generated from the uniform distribution on  $[-\pi, \pi]$  after that a pair of two dimensional variables  $x$  and  $y$  are generated by  $x = [\theta, \sin 3\theta]$  and  $y = e^{\theta/4}[\cos 2\theta, \sin 2\theta]$ . Form Fig. 3, we see that classical

method does not give linear relationship, robust method gives higher coefficient but relation for first canonical variates are nonlinear.

| $KP$       | 0.0102        | 0.0083        | 0.0024        |

Fig. 3. Scatter plot of first canonical variate of data generated from uniform distribution with size  $n = 100$ .

Fig. 4. Box plot of 200 numbers generated from  $SCn(v; T_n : V)$  where follows a) Multivariate normal and b) Transformation of Multivariate normal having  $n = 50, 500$  and  $1000$ .

On the other hand, kernel method shows the best performance providing linear relationship of canonical variates. Especially kernels with Gaussian (KG) and Laplacian function are found as the best ones in offering linear relationship. We have also observed that similar scatter plot for second canonical variate.

### B. Sensitivity Analysis

In this section following [13], we perform a simulation study to confirm some aspects of our findings with the help of sensitivity curves. Firstly we generate 200 samples of size  $n = 50$ ,  $n = 500$  and  $n = 1000$  from a MVN using  $CVM_1$  and compute  $SC_n(v, T_n; V)$  for each of these samples. We also consider an outlier values  $v = 500, 1000, 1500$  and  $0.5, 0.1, 0.15$  for x-set and y-set respectively. That is, the sample sizes are  $n = 51, n = 501$  and  $n = 1001$ . Boxplots of these 200 numbers are shown in Fig. 4a, for MVN using  $CVM_1$  and we repeat the work by taking a transformation as  $\sin(2x_1)$ ,  $\cos(x_2)$ ,  $\sin(3x_3)$  and  $\cos(2y_1)$ ,  $\sin(y_2)$ ,  $\cos(3y_3)$  for x-set and y-set respectively; boxplots of the values target are given in Fig. 4b, of classical estimator (CC), robust estimator (RC) kernel with Gaussian function (KG), kernel with Laplacian function (KL) and kernel with polynomial (KP).

## V. CONCLUSION

In this paper we compare the performances of five (classical, robust and kernel with three functions) estimators of canonical correlation coefficient that are commonly used in the statistical literature as well as in pattern recognition. Their performances are investigated through simulation and influence function. We report a simulation where sampling distributions are taken as multivariate normal with two covariance matrices,  $CVM_1$  and  $CVM_2$  and its contaminated forms, and we also consider uniform distribution with three different sample sizes (50, 500 and 1000) and in different way of transformation. The estimators are compared with regard to bias, standard error, MSE and QRI. Over all, the class of kernel estimators, especially the Gaussian function for small sample and Laplacian function for large sample perform better than the class of classical as well as robust estimators. A study based on sensitivity curves shows that outliers have the least effect on kernel estimator. We recommend using as a measure of kernel canonical correlation coefficient especially when the sample is large and contamination is likely.

## ACKNOWLEDGMENT

The authors wish to acknowledge the various helpful comments, assistance and support of the reviewers and Publication Committee.

nuru\_ku\_02@yahoo.com

**Abstract** — In this paper we present an efficient system for face recognition with high recognition rate. In our proposed method, at first we detect the face from an image, then two main significant edge lines – chin-line and nose-line are determined and next we apply third order polynomial regression on these two lines to get a third order polynomial equation with four coefficients for each line. Here we use Laplacian operator to determine the curve of chin line and nose line. Then we measure distances from the middle point of the nose curve to the chin line horizontally and vertically, the width of the two eyebrows, the width of forehead and the distance from pupil to eyebrow. We also determine two regions – eye-region and nose-region. For each of these regions, we determine the average value of each three basic colors: red, green and blue. We then store the coefficients of the detected edge lines, the average values of the three basic colors and other distances and perform the task of recognition process. The existing face is recognized for which the weighted error is minimum and higher than a predefined threshold value. Experimental results show that our proposed method successfully recognizes face at a very high rate.

**Index Terms** — Gauss Jordan Method, Independent Component Analysis (ICA), Polynomial Regression, Laplacian Operator, Principal Component Analysis (PCA).

## I. INTRODUCTION

Pattern recognition and matching consists of processing the input, classifying, and matching it with a known pattern. Face recognition is a very complex form of pattern recognition. Classifying a pattern with high dimensions requires a restrictively large number of training samples. This is known as the 'Curse of Dimensionality'. A number of ways have been proposed to solve this problem [1]-[7]. Finding an effective means to reduce the dimensionality is the first step in face recognition.

We have proposed a system for face recognition, which is very efficient. Here we have used second order Laplacian operator for determination of curve and then polynomial regression as a curve fitting mechanism. Beside we have used the width of forehead and eye-brow and also determined the distance between the pupil and

eyebrow. Last of all we have determined the average RGB values of forehead and nose region. In our method, we have used the curves of nose line and chin line because the curves of nose and chin are expressions invariant. Our system has a good recognition rate with high performance.

## II. LITERATURE SURVEY

Ashish Kapoor and Rosalind W. Picard in their paper [8] described PCA and their capability of face recognition in different context. In the paper they describe a fully automatic system that tracks eyes and eye-brows in real time. The pupils are tracked using the red eye effect by an infrared sensitive camera equipped with infrared LEDs. Templates are used to parameterize the facial features. The template parameters are recovered by PCA analysis on these extracted images using PCA based method. For fully automatic facial expression their system performs better.

Srinivas Gutta et al. in their paper [9] used partial faces for identification. In their approach they consider an ensemble of Radial Basis Function (RBF) Networks. They showed that the accuracy rate of their approach is (a) 96% on the partial-face identification task and (b) 97% on the full-face identification task. They used RBF of partial faces and proved that using RBF is the most promising method for face recognition.

Qingshan Liu et al. in their paper [1] used Fisher linear Discriminant Analysis (FLDA) for face recognition. FLDA is based on a linear projection from the image space to a low dimensional space by maximizing the between-class scatter and minimizing the within-class scatter. In this paper, they represent to use kernel based FLDA for face recognition. The kernel trick is used firstly to project the input data into an implicit space called feature space by nonlinear kernel mapping, and then FLDA is adapted to this feature space, thus a nonlinear discriminant can be yielded in the input data. They compared its performance with kernel PCA and FLDA and found that the recognition rate is higher than kernel PCA. For face recognition it gives better performance.

Dominique Valentin et al. [10] in their paper have integrated psychological and physiological information for recognizing faces. Their recognition system is view based. Recognition performance increases with the number of views. According to them the recognition or identification of a face from a new orientation can be achieved efficiently by interpolating between two extreme orientations.

Yongbin Zhang et al. [7] in their paper have used subspace projection method using the concept that a test face may have some expressions not present in the training images of the same face. In this case they have separated different portions or subspaces from a face-image and then weighted these spaces such that the subspaces that show little change in different expressions will get greater weights than those which show huge changes. They have used PCA, ICA and LDA for projecting subspaces and proved that LDA is the most promising method.

Bruce A. Draper et al. [11] in their paper have described the comparison between PCA and two architectures of ICA methods. They have shown us that PCA decorrelates input data using second order statistics and generate compressed data with minimum mean-squared re-projection error where ICA minimizes both second order and higher-order dependencies in the input. For some cases PCA gives us better results than ICA and for some other cases ICA performs better. They have shown ICA as the generalization of PCA.

### III. EDGE DETECTION AND FITTING OF CURVE

In our proposed method we have used a second-order Laplacian operator to detect edge. The Laplacian of a function  $f(x,y)$ , denoted by  $\nabla^2 f(x,y)$ , is defined by the equation no.1 as follows:

$$\nabla^2 f(x,y) = \frac{\partial^2 f(x,y)}{\partial x^2} + \frac{\partial^2 f(x,y)}{\partial y^2} \quad (1)$$

Here we have used discrete difference approximations to estimate the derivatives and represent the Laplacian operator by the following 3 x 3 convolution mask which is shown in Fig. 1:

|   |    |   |
|---|----|---|
| 0 | 1  | 0 |
| 1 | -4 | 1 |
| 0 | 1  | 0 |

Fig. 1. Convolution Mask

We should note that first derivative operators exaggerate the effects of noise. Second derivatives will exaggerate noise twice as much if no directional information about the edge is given.

#### A. Curve Fitting and Co-efficient Determination

Curve fitting and co-efficient determination is our root method for recognizing faces. By using this method we introduce the process of taking shape knowledge of a face. In our method we have performed several tasks that result the final recognition. For determination of the training value we take N different faces of the same person. From each face we cut the chin-lines and nose-line. For these lines polynomial regression is applied for obtaining third order polynomial equations. Suppose n coordinates for an edge are:  $(x_1, y_1), (x_2, y_2), \dots, (x_n, y_n)$ .

Then the equation is generated for each of the lines which take the form as:  $Y = A + Bx + Cx^2 + Dx^3$

From this equation the coefficients A, B, C and D are stored. For N faces related to the same person we have determined the edge equations and for each of the edges we have N values relating to the coefficient A, N values relating to the coefficient B and also for C and D. We determine the averages for each of the coefficients that are stored in the database.

Suppose we are at a point x some where in the image. We have three basic colors for this point. Now suppose this point corresponds to the middle element '-4' of the convolution matrix (Fig. 1). We consider 9 pixel elements of the image, the current pixel x being the middle of the 3x3 matrix. Then we add red colors of these 9 pixels with the corresponding coefficients multiplied with the red colors. This resultant color divided by 9 will be the color of the middle point that is the pixel x. Thus we determine the green and blue color of x. Now this RGB color got from the calculation is assigned to the pixel x. This operator does not give the edge lines but gives gray colored edge on a black back ground. A main face, its detected face by matrix convolution method and the detected chin-line are given here in Fig. 2.

Fig. 2. Main face, Detected face and Chin Line respectively.

TABLE I  
SAMPLE RESULT FOR COEFFICIENTS OF CHIN LINE

#### B. Co-ordinate Equalization System

The same curve placed at two different places in a graph will have two different equations though these two can give the same equation. If we select a direction for the curves to start from and go through, then by subtracting the x and y coordinate values of the first point from all the x and y coordinate values of all the points, we can make the two curves such that they both are generated from the (0,0) point of the coordinate system. Thus the same curves that were giving two different equations will now give identical equations. For edge detection in our approach this technique is used. So the two edges for the same person that might give two different equations for two different templates will give the almost same equations.

Fig. 4. Coordinate system equalization.

The two curves in the two graphs in Fig. 4 denoted by P11-P12 and P21-P22 will show different equations but by the above coordinate-system these two will give the same equations.

#### IV. ARCHITECTURE OF FACE RECOGNITION SYSTEM

The overall processing steps of the training phase of our proposed system as shown in Fig. 5.

Fig. 5. Architecture of the Training Module of the System.

#### A. Determination of horizontal and perpendicular distances between nose line and chin line

We have deter-mined the horizontal distance between middle point of the nose line and chin line as illustrated in Fig. 6. We have a taken a point on the chin line which has the same x-coordinate value. Then the distance is determined by simply deducting the y-coordinate value between these two points.

Fig. 6. Horizontal and perpendicular distances between nose and chin line.

Table III shows the experimental values of the two distances for the image shown in Fig. 7.

TABLE III  
EXPERIMENTAL VALUES OF HORIZONTAL AND PERPENDICULAR DISTANCES

|                                                                                                 |    |
|-------------------------------------------------------------------------------------------------|----|
| Horizontal distance from the middle point of the nose curve to chin line                        | 18 |
| Perpendicular distance from the middle point of the nose curve to the lowest point of chin line | 27 |

Here all the distances are in number of pixels.

The perpendicular distance between middle point of the nose line and the lowest point of the chin line is determined by simply deducting the x-coordinate value between these two points. In this way we have got two distances in pixels and then a rational measurement is calculated by dividing the amount of distances by the face length which is calculated as follows:

1. (Horizontal distance / total face length)\*100
2. (Perpendicular distance / total face length)\*100

#### B. Determination the width of forehead and eyebrow

We have calculated these measurements after face detection and for this we have completed the following tasks.

Start from the highest point of the face and determine the RGB color values of the blackest point in the region. The points that are very near to this most black point considering the color values are converted to fully black points by setting their RGB values to (0,0,0). Respectively the vertical beginning and ending points of the forehead are determined as we check black points of the face beginning from the top to bottom. We get two horizontal limits indicating the y co-ordinates of the vertical beginning and ending of the forehead. The distance of these two limits give us the width of the forehead. We get eyebrow region after the forehead region as we proceed from the top of the face. Accordingly we determine the two horizontal limits of this region and from the distance of these two limits we determine the eyebrow-width. The features that we have taken are as below:

1. (Forehead width / total face length)\*100
2. (Eyebrow width / total face length)\*100

The Fig. 7 shows a main face, the detected face and the determined forehead and eyebrow width.

Fig. 7. Determination of forehead and eyebrow region.

#### C. Determining the distance between the pupil and eyebrow

The vertical beginning of the eye region is the ending horizontal line of eyebrow as we check black points of the face beginning from the top to bottom. We also get a horizontal limits which passes through the middle points of pupil and the difference of y coordinates of these two vertical line gives the distance between pupil and eyebrow which is shown in Fig 8.

Fig. 8. Determining the distance between the pupil and eyebrow.

Table III represents the calculated four distant features of the face shown in Fig. 8.

TABLE III  
VARIOUS DISTANCE FEATURES OF A FACE

| Features                                         | Measured Value (in pixels) |
|--------------------------------------------------|----------------------------|
| Horizontal distance from nose curve to chin line | 17                         |
| Vertical distance from nose curve to chin line   | 25                         |
| Width of forehead                                | 26                         |
| Width of eyebrow                                 | 5                          |
| Distance between the pupil and eyebrow           | 8                          |

#### D. Detection of region and determination of color component

We also take into account the nose region like the forehead region. The nose region covers two horizontal lines one at the distance of (total perpendicular length \* 0.54) from the head top position and the other remains at the distance of (total perpendicular length \* 0.71) from the head top. We have determined three average values of red, green and blue colors for these regions according to (2). After determining these three average values, the values are stored in the database.

$$RCA = \frac{\sum_{i=0}^{TP} C(i)}{TP} \quad (2)$$

Where, RCA = Region Color Average, TP = Total number of Pixels, C(i) = i-th pixel color value.

TABLE IV  
RGB VALUES FOR TWO REGIONS

|          | Red | Green | Blue |
|----------|-----|-------|------|
| Forehead | 128 | 128   | 255  |
| Nose     | 153 | 153   | 255  |

Table IV shows an example of calculated RGB values according to (2) of the face shown in Fig. 8.

## V. RECOGNITION

For recognition purpose we have used weighting mechanism. For a face, we determine the four coefficients which we get from each of the chin-line and nose curve, the width of eyebrow and forehead, the horizontal and perpendicular distance between the nose line and chin line, the distance between the pupil and eyebrow and the average RGB values of forehead and nose region. For each of the stored faces we determine the absolute differences for the corresponding values of the face to be recognized. These differences are multiplied with predefined weight values and then are summed together. We determine the exact absolute differences for the chin-line and nose-line coefficients and these differences are added to the weighted-error. We have also defined a threshold value for this purpose which is used in such a way that if the lowest weighted error is less than or equal to the threshold value then the face corresponding to the lowest weighted error is de-fined as the recognized face. The face with the lowest total weighted error is taken as the matched face.

## VI. EXPERIMENTAL RESULTS

### A. Time Complexity

The time complexity of our method is  $O(n^2)$ . Here the execution time of our method is slightly high than real time face recognition using polynomial regression by Mondal [12], which is shown in Fig. 9, but recognition rate is much higher than real time face recognition using polynomial regression method [12] or PCA based method which is represented in Fig. 10.

Fig. 9. Comparison of Time performance of the proposed method.

### B. Recognition Efficiency

The detection efficiency of our method is much higher than the real time face recognition using polynomial regression and PCA based method. For different expressions the previous method gives very low performance where as our method gives a relatively high performance. The Table V shows the percentage of detection efficiency of our method, real time face recognition method and PCA based method.

Fig. 10. Detection efficiency of the proposed method.

In Fig. 10, the graphical representation of the efficiency of our method, real time face recognition method and PCA method for about seventy faces is shown.

## VII. DISCUSSION ON PERFORMANCE

Beside a very high detection rate, our method also overcomes some problems that exist in real time face recognition methods which are described in the papers [12] and [6]. If the faces between two or three images are displaced in image template, existing real time face recognition methods give very low performance. Also for different expressions the performance of the existing method is not good. If the faces are placed at angled position at image template then previous methods again show very low recognition rate and at some stage they are totally unable to recognize. But in this case our method survives.

There is a draw back of our method which is that we take the average red, green, and blue color values for each region. As we have taken average values there is a risk of false recognition. The average color values of two distinct regions may be the same or very near. For this issue we have got some wrong results from our method in recognizing faces. But it is the fact that we have removed some drawbacks which were possessed by the previous methods. We have also tried with gradient based method but the method some times produces too much

TABLE V  
DETECTION EFFICIENCY FOR DIFFERENT EXPRESSIONS

| Method                                                            | Number of faces |     |     |       |     |     |     |
|-------------------------------------------------------------------|-----------------|-----|-----|-------|-----|-----|-----|
|                                                                   | 10              | 20  | 30  | 40    | 50  | 60  | 70  |
| Proposed method                                                   | 95%             | 89% | 80% | 75.5% | 59% | 55% | 51% |
| Polynomial regression<br>method for Real Time Face<br>Recognition | 75%             | 70% | 65% | 56%   | 48% | 40% | 33% |
| PCA based method                                                  | 55%             | 50% | 47% | 40%   | 30% | 23% | 15% |

complexity. So our proposed method is certainly an improvement over the traditional techniques.

### VIII. CONCLUSION

Recognition rate of our method is relatively high than other existing methods though its time and run time storage complexity is a little bit higher than polynomial regression method. Our method works properly for different expression of a human face. As our process integrates shape determination technique with the knowledge of color component distribution of sub-regions, this survives in many critical situations where the PCA or the ICA based methods fail to recognize. For improved and more accurate recognition rate fourth, fifth or even any higher order polynomial regression can be used. In this process we have used second order edge detection operator that is Laplacian operator which detect the edges effectively. We have determined two distances from the nose curve to the chin line horizontally and vertically. We have also determined the width of eyebrows and the distance between eye pupil and eyebrow. Since the features that we have used are over all expression invariant hence our method is effective and successful for recognizing faces in different expressions.

# An Effective Term Weighting Method Using Random Walk Model for Text Classification

Md. Rafiqul Islam and Md. Rakibul Islam

Computer Science and Engineering Discipline, Khulna University, Khulna-9208, Bangladesh

**Abstract** — Text classification may be viewed as assigning texts in a predefined set of categories. However there are many digital documents that are not organized according to their contents. So it is difficult task to find relevant documents for a user. Automatic text classification problem can solve this problem. In this paper we introduce a new random walk term weighting method for improved text classification. In our approach to weight a term, we exploit the relationship of local (term position, term frequency) and global (inverse document frequency, information gain) information of terms (vertices). Moreover, we weight terms by considering co-occurrence and semantic relation of terms as a measure of dependency. To evaluate our term weighting approach we integrate it in Rocchio text classification algorithm and experimental results show that our method performs better than other random walk models.

**Index Terms** — Text classification, random walk model, semantic relation, information gain.

## I. INTRODUCTION

Most of the today's organizations consist of unstructured textual information in electronic form. Users are facing the challenge of organizing, analyzing and searching the ever growing amounts of documents. A primary application of text categorization is to assign subject categories to documents to support information retrieval, or to aid human indexers in assigning such categories [5]. Categorization can also be used to build a personalized net news filter, which learns about the news-reading preferences of a user. Text categorization can ease the organization of increasing textual information, in particular Web pages and other electronic form documents [5].

The random walk ranking algorithm on a graph proposed by Brin and Page in [7], has been used in citation analysis, social networks and analysis of the link structure of the web [1]. A graph-based ranking algorithm is a way of deciding the importance of a vertex within a graph, by taking into account global information, recursively computed from the entire graph, rather than relying only on local vertex-specific information. The basic idea implemented by a random walk algorithm is that, when one vertex links to another one, it is basically casting a vote for other vertex [2]. The higher the number of votes that are cast for a vertex, the higher the importance of the vertex. Term weighting is one of the most important considerations for various language

processing applications. The purpose of a term weighting method is to classify the terms by assigning them weights corresponding to how well they improve both recall and precision. In [2] several variations of random walk ranking algorithm are discussed and experimental results show that the new random-walk based approaches outperform the traditional term frequency method. Hassan et al. argue that the bag-of-words model may not be the best technique to capture term importance [2]. Here the new measure of term weighting integrates both the locality of a term and its relation to the surrounding context using a co-occurrence relation in which terms that co-occur in a certain context are likely to share between them some of their importance. Co-occurrence, dependency and semantic networks are three ways to build graph of given text, are discussed in [9]. In co-occurrence network two words are linked if they appear together within the same sentence or predefined window Again in semantic network terms or meanings are the nodes and various semantic relationships are the links. In our approach to weight a term, we exploit the relationship of local (term position, term frequency) and global information (inverse document frequency, information gain) of vertices. Moreover, we weight terms by considering co-occurrence and semantic relation of terms as a measure of dependency. To evaluate our term weighting approach we integrate it in Rocchio [3] text classification algorithm and experimental results show that our method performs better than other random walk models discussed in [2].

## II. RANDOM WALK MODEL - TEXTRANK

The basic idea implemented by a random-walk algorithm is that of "voting" or "recommendation." When one vertex links to another one, it is basically casting a vote for that other vertex. The higher the number of votes that are cast for a vertex, the higher the importance of the vertex [2]. Moreover, the importance of the vertex casting a vote determines how important the vote itself is, and this information is also taken into account by the ranking algorithm. There are several random-walk algorithms that have been proposed in the past and between these algorithms, TextRank is previously found successful in a number of applications, including Web link analysis,

social networks, citation analysis, and more recently in several text processing applications [2].

Given a graph, let  $V_a$  be the set of vertices that point to vertex  $v_a$  (predecessors), and  $V_b$  be the set of vertices that vertex  $v_a$  points to (successors). The TextRank score associated with the vertex is defined using the equation 1.

$$s(v_a) = (1-d) + d \times \sum_{b \in \text{In}(v_a)} \frac{s(v_b)}{|\text{Out}(v_b)|} \quad (1)$$

Where  $s(v_a)$  = score of vertex  $v_a$ ,  $s(v_b)$  = score of vertex  $v_b$ ,  $\text{In}(v_a)$  = indegree of vertex  $v_a$ ,  $|\text{Out}(v_b)|$  = outdegree of vertex  $v_b$  and  $d$  is a parameter that is set between 0 and 1 [2].

The score of each vertex is recalculated upon each iteration based on the new weights that the neighboring vertices have accumulated. Neighbors of a vertex are determined by window size  $N$ . If  $N$  is 3 then consecutive forward and backward three vertices are neighbor. The algorithm terminates when the convergence point is reached for all the vertices, meaning that the error rate for each vertex falls below a pre-defined threshold. This vertex scoring scheme is based on a random-walk model, where a walker takes random steps on the graph, with the walk being modeled as a Markov process. Under certain conditions, the model is guaranteed to converge to a stationary distribution of probabilities associated with the vertices in the graph. Intuitively, the stationary probability associated with a vertex represents the probability of finding the walker at that vertex during the random-walk, and thus it represents the importance of the vertex within the graph [2].

### III. RELATED WORK

Salton is a standard weighting scheme based on “term vector model” to represent documents in terms of vectors [4]. The Salton's approach is used to assign weights to terms by considering local significance of a term exists for individual documents, denoted by  $tf$ , where it indicates term frequency. Global significance of a term appearing across different documents is denoted by  $idf$ , also known as the inverse document frequency. Hence, the weight (term frequency inverse document frequency) is a weight often used to evaluate IR systems [4].

$$W_i = tf_i * \log(D / df_i) \quad (2)$$

Where  $df_i$  = document frequency or number of documents containing term  $i$ ,  $D$  = number of documents in the corpus.

Two new random walk methods discussed by Hassan et al. in [2] used for text classification. Hassan et al. introduce a system that models the weighting problem as a

“random-walk” rather than “random choice” [2]. They assume an imaginary reader who steps through the text on a term by term basis. In this setting, the importance of the term is determined by the probability of the random-walker to encounter the target term in the text during the walk. In this paper, the various best random-walk based term weighting models are summarized

This model represents an undirected graph approach that uses the weighted edge version of PageRank with a variable damping factor. The weight of an edge is calculated by the equation 3.

$$E_{v_1, v_2} = tf \cdot idfv_1 \times tf \cdot idfv_2 \quad (3)$$

Where  $E_{v_1, v_2}$  is the edge connecting  $v_1$  to  $v_2$  and  $tf \cdot idfv_1$ ,  $tf \cdot idfv_2$  represent the term frequency multiplied by the inverse document frequency respect to vertices  $v_1$  and  $v_2$ . The damping factor is expressed as a function of the ‘incoming edges’ weight, calculated as follows:

$$d_{E_{v_1, v_2}} = E_{v_1, v_2} / E_{\max} \quad (4)$$

where  $d_{E_{v_1, v_2}}$  is the damping factor and  $E_{\max}$  represents the highest weight for an edge in the graph. Thus the score of a vertex can be calculated by the formula in [2] is as follows:

$$s'(v_1) = \frac{(1-d)}{|N|} + \sum_{v_2 \in \text{In}(v_1)} C \times \frac{d_{E_{v_1, v_2}} \times s(v_2)}{|\text{Out}(v_2)|} \quad (5)$$

where  $s'(v_1)$  = score of vertex  $v_1$ ,  $N$  = total number of nodes,  $C$  = scaling constant [2]. Here the new measure of term weighting integrates both the locality of a term and its relation to the surrounding context.

$W_{e.oc}$ : This model is similar to the above approach however the damping factor for an edge is estimated in terms of the bigram co-occurrence frequency of the two nodes connected by the edge. For example, if the bigram “free software” occurred four times in a document then the weight of the edge connecting ‘free’ and ‘software’ is four.

### IV. TERM WEIGHTING METHOD USING GRAPH BASED RANDOM WALK MODEL

This section describes the method we use to weight terms to classify text. In our proposed method to draw graph of document's text we consider two relations of terms; co-occurrence and semantic relations. After constructing graph we apply our term weighting method. The details of our method are given below.

#### A. Term Weighting Method

1) To identify the text units (terms), the document is tokenized using text operations - stopword removals, stemming and each token is annotated with part of speech tags. We use the list of stop words enlisted in the Smart System [8] to remove stop word from graph. We add only noun and adjective tagged terms to build text graph. To avoid excessive growth of the graph size by adding all possible combinations of sequences consisting of more than one lexical unit (ngrams), we consider only single words as candidates for addition to the graph.

2) For each term in the processed documents, we calculate and random-walk weights ( ). To calculate the of each vertex, we use the method described by Yue-Heng Sun et al. [6]. The terms in the title should have higher importance than those in the abstract; similarly the terms in the abstract should have higher importance than those in the text, and so on. Therefore in [6], computing method of uses some factors to reflect the importance of term position, shown in the equation 6.

$$tf_{ij} = \alpha tf_{ij1} + \beta tf_{ij2} + \gamma tf_{ij3} \quad (6)$$

Where,  $tf_{ijk}$  is the frequency of a term in the  $k^{th}$  area and  $\alpha, \beta, \gamma$  are the factors that can be adjustable according to pre-experiments. Here  $\alpha > \beta > \gamma > 1$ .

Moreover, to give more importance to a term that has discriminating power to identify a document, Yue-Heng Sun *et al.* introduce information gain ( $IG_j$ ) for a term  $j$  [6]. We calculate  $tf \times idf$  according to the equation 7 given in [6].

$$tf_{ij} \times idf_j = \frac{tf_{ij} \times \log\left(\frac{N}{n_j} + 0.01\right) \times IG_j}{\sqrt{\sum_{i \in d} \left[ tf_{ij} \times \log\left(\frac{N}{n_j} + 0.01\right) \times IG_j \right]^2}} \quad (7)$$

Where  $tf_{ij}$  = frequency of term  $j$  within document  $i$ ,  $idf_j$  = inverse document frequency of term  $j$ ,  $n_j$  = number of documents holding term  $j$ ,  $N$  = total number of documents in the corpus. The  $tf_{ij} \times idf_j$  value of each selected term reflects their importance within the document and corresponds to whole documents corpus.

Weight of an edge is calculated using equation 3. Weight of each edge is required to determine the damping factor  $d_{E_{v1,v2}}$  in equation 4. The value of damping factor  $d_{E_{v1,v2}}$  varies in equation 5 to reflect importance of term. The more the value of damping factor, the term is more important to retrieve the related information. After constructing the graph we iterate the random walk

algorithm until convergence. The threshold value of convergence is 0.0001

3) Vertices are sorted on their final score. For ranking decision, we use the scores associated with each vertex. Once a final score is obtained for each vertex in the graph, vertices are sorted in reversed order of their score.

### B. Method of Building Text Graph

Generally a term can only be represented by one node in the graph. Terms that co-occurs within a given window size are connected by an edge to represent the co-occurrence relation of those terms. For a given term, all the terms that fall in the vicinity of this term are considered dependent terms [2]. This is represented by a set of edges that connect the term to all the other terms in the window. We remove the stop words and stem the remaining words to construct the graph.

To connect the terms using semantic relation, we follow the method described in [9]. In [9] two words in the text are linked only if they have semantic relations and the weights of the links which represent the relatedness of two words can be computed by the following formula:

$$Sim(W_1, W_2) = \max_{i=1 \dots n, j=1 \dots m} Sim(S_{1i}, S_{2j}) \quad (8)$$

$W_1$  has  $n$  senses  $S_{1i}$  ( $i = 1 \dots n$ ) and  $W_2$  has  $m$  senses  $S_{2j}$  ( $j = 1 \dots m$ ). Then semantic similarity between  $W_1$  and  $W_2$  can be approximately computed by maximum similarity between their senses, which can be measured by Wordnet or HowNet [9].

## III. EXPERIMENTAL RESULT AND DISCUSSION

To evaluate our term weighting approach we integrate it in Rocchio [3] text classification algorithm. The Rocchio text classification method uses standard term weighted vectors to represent documents, and builds a prototype vector for each category by summing up the vectors of the training documents in each category [2]. Test documents are then assigned to the category with the closest prototype vector, based on cosine similarity.

In [2] three standard datasets: WebKB, LingSpam and 20Newsgroups are used in text classification evaluations. The WebKB dataset contains seven class labels: Project, Student, Department, Faculty, Staff, Course, and Other. For the evaluation purpose Hassan *et al.* divide the WebKB dataset into two sets - WebKB4 which consists of Project, Student, Faculty, and Course since they represent the largest categories and WebKB6 which additionally consists of Staff and the Department classes. We also use these three datasets organizing WebKB dataset as Hassan *et al.* to compare our result with the result of [2]. In [2] results are given in micro average and macro average and

TABLE I  
MICRO-AVERAGE RESULTS FOR DIFFERENT  
RANDOM-WALK MODELS

| Data Sets    | $rw_e \cdot idf$ | $rw_{e.oc}$ | Our Method |
|--------------|------------------|-------------|------------|
| WebKB4       | 87.7             | 87.5        | 88.3       |
| WebKB6       | 84.2             | 84.3        | 84.6       |
| LingSpam     | 98.3             | 98.5        | 98.5       |
| 20Newsgroups | 93.8             | 94.3        | 94.7       |

best results are obtained using the  $rw_e \cdot idf$  and  $rw_{e.oc}$  random walk models with window size 2. So we do our experiment with window size 2 and compare the obtained results with these two random walk models.

Table I and Table II summarize the experimental results of various random walk models including our method where window size is 2. There are several parameters we use for the evaluation purpose such as *damping factor*  $d = 0.85$ , *scaling factor*  $c = 0.95$ . We set the value of  $\alpha = \beta = \gamma = 1$ , as the data sets we sue are not augmented with position information (title, abstract, body etc). From the result sets we can claim that our method performs reasonably well than other random walk methods. .

## V. CONCLUSION

Text classification, broadly defined as determining and assigning topical labels to content, is a fundamental operation in digital collection. In this paper we propose a new random walk method for term weighting which can be used for text classification. In our approach to weight a term, we exploit the relationship of local (term position, term frequency) and global information (inverse document frequency, information gain) of vertices. Moreover, we weight terms by considering co-occurrence and semantic relation of terms as a measure of dependency. Using WebKB, LingSpam and 20Newsgroups data sets we test our method to compare with previous random walk models discuused in [2]. The experimental result shows that our method achieves better result than other methods.

In this paper we test our method using Rocchio text classification algorithm with window size 2. In future we want to test our approach with SVM [2] text classification algorithm and with window size more than 2.

TABLE 2  
MACRO-AVERAGE RESULTS FOR DIFFERENT  
RANDOM-WALK MODELS

| Data Sets    | $rw_e \cdot idf$ | $rw_{e.oc}$ | Our Method |
|--------------|------------------|-------------|------------|
| WebKB4       | 86.7             | 86.7        | 87.9       |

# Vision System for Human-Robot Interface

Md. Ezharul Islam, Nasima Begum and Md. Al-Amin Bhuiyan

Jahangirnagar University, Savar, Dhaka, 1342, Bangladesh

**Abstract** — A vision system has been developed for human-robot symbiosis. The two novel contributions of this paper are 1) Detection of human faces and 2) Localizing the eye. The method is based on visual attributes of human skin colors and geometrical analysis of face skeleton. This paper introduces a spatial domain filtering method named ‘Fuzzily skewed filter’ which incorporates Fuzzy rules for deciding the gray level of pixels in the image in their neighborhoods and takes advantages of both the median and averaging filters. The effectiveness of the method has been justified over human-robot interaction system.

**Keywords** — Human-Machine Interface, Face Detection, Skin Color Segmentation, Eye Localization, AIBO.

## I. INTRODUCTION

When robots are working cooperatively with human beings, it is necessary share and exchange their intentions and interests. Since the communication between humans and robots is established by means of visual perceptions, eye tracking and gaze directions, are important clues for this interaction. Development of an intelligent vision system is, therefore, a vital issue for robotics research.

A fair amount of techniques have been introduced recently literature on face detection, eye localization, eye tracking and gaze detection, for example, geometric modeling [1], auto-correlation [2], neural networks [3], principal component analysis [4] and so on. Model based approaches assume that the initial location of the face is known. Color based approaches reduce the search space in face detection algorithm. The neural network-based approaches require a large number of face and non-face training examples, and are designed primarily to locate frontal faces in grayscale images. Sung and Poggio [5] have developed an example-based approach for locating frontal views of human face in complex scenes. Since this method has been developed for vertical frontal view faces, faces with other orientations cannot be detected. Rowley et al. [3] have developed a neural network-based frontal face detection system where a retinal connected neural network has been employed to justify the small windows of size 20×20 of an image whether it contains a face or not. Lam and Yan [6] have used snake model for detecting face boundary. Although the snake provides good results in boundary detection, but the main problem is to find the initial position. Moghaddam and Pentland

[7] employed principal component analysis for describing the face pattern with lower-dimensional feature space.

This paper explores a face detection and eye localizing system which integrates the detection of human faces in different lighting conditions and localization of eyes on it, as shown in Fig. 1.

Fig. 1. Architectural design of the human-robot interaction system.

Face detection is established by a two step method: (i) skin color segmentation and (ii) morphological operations. The system is based on the determination of the approximate location of the face area and thresholding the image by color segmentation. The exact location of the face is then determined by employing morphological operations. Then eye is then localized from the knowledge of the face geometry. Experimental results indicate that the system is capable of detecting face and locating the eye position from complex backgrounds with a high degree of variability in lighting conditions, pose and illumination.

The remainder of this paper is organized as follows. Section 2 describes the vision system for human-robot interface. Face detection and eye localization methodologies are also illustrated. Section 3 presents experimental results and performance. Section 4 draws the overall conclusions of this paper.

## II. FACE DETECTION

Face detection is concerned with determining which part of an image contains face. Face detection is achieved by employing by skin color segmentation. The main steps employed for the face detection process is discussed in detail in the following sections.

### A.1 Preprocessing

The original image is obviously a color image. It is first converted into gray scale image and being normalized to same scale, orientation and position. Each normalized image is then subjected to some image processing operations to account for different lighting conditions and contrast.

### A.2 Histogram Equalization

The face images may be of poor contrast because of the limitations of the lighting conditions. So histogram equalization is used to compensate for the lighting conditions and to improve the contrast of the image [8]. Let the histogram  $h(r_i) = p_i / n$  of a digital face image consists of the color bins in the range  $[0, C-1]$ , where  $r_i$  is the  $i$ -th color bin,  $p_i$  is the number of pixels in the image with that color bin and  $n$  is the total number of pixels in the image. For any  $r$  in the interval  $[0,1]$ , the cumulative sum of the bins provides with some scaling constant. Histogram equalization is performed by transforming the function  $s = T(r)$  which produces the mapping with the allowed range of pixel values, i.e., a level  $s$  for every pixel value  $r$  in the original image [9] and  $0 \leq T(r) \leq 1$  for  $0 \leq r \leq 1$

### A.3 Fuzzily Skewed Filter

Various sources of noise may exist in the input image. The fine details of the image represent high frequencies

which mix up with those of noise. So low-pass filters are used to obliterate some details in the image. This paper introduces a new filter named “fuzzily skewed” filter to suppress the noise. This method incorporates the advantages of both the median filter and averaging filter. For  $k=0$ , it acts like median filter and for  $k/2 \leq n/2$ , it acts like neighborhood averaging filter. This method can successfully reduce noise that results to sharp transitions in the gray values, and it does not make the resultant image as blur as the neighborhood averaging filter.

In the fuzzily skewed filter, fuzzy rules are applied for deciding the gray level of a pixel in the image from the neighborhood of that pixel. This is a variation of the Median filter and Neighborhood Averaging filter. The decision process includes the following steps:

- 1) At first the gray values of the neighborhood pixels ( $n \times n$  neighborhood) are stored and then sorted in ascending or descending order.
- 2) Fuzzy membership value is assigned for each neighbor pixels. This step has the following characteristics:
  - (i) A  $\Pi$ -shaped membership function is used.
  - (ii) The highest and lowest gray values get the membership value 0.
  - (iii) Membership value 1 is assigned to the mean value of the gray levels of the neighborhood.
- 3) Consider only  $2 \times k + 1$  pixels ( $k/2 \leq n/2$ ) in the sorted pixels, and they are, the median gray value and  $k$  previous and forward gray values in sorted list.
- 4) Select the gray value that has the highest membership value and place as output.

### A.4 Skin Color Segmentation

Skin color segmentation is based on visual information of the human skin colors from the image sequences in YIQ color space. For this, the dominant and perceptually relevant skin colors extracted in RGB space from images, are converted into the YIQ space. Images are being searched in YIQ space depending on the amount of color content of these dominant colors, that is, whether the skin color value is substantially present in an image or not.

In the YIQ color model a color is described by three attributes: luminance, hue and saturation. The YIQ produces a linear transform of RGB which generates Y representing luminance channel and I, Q representing two chrominance channels to carry color information. The transformation matrix for the conversion from RGB to YIQ is given by [10]:

$$\begin{bmatrix} Y \\ I \\ Q \end{bmatrix} = \begin{bmatrix} 0.299 & 0.587 & 0.114 \\ 0.596 & -0.275 & -0.320 \\ 0.212 & -0.523 & 0.311 \end{bmatrix} \begin{bmatrix} R \\ G \\ B \end{bmatrix} \quad (1)$$

where R,G, B are the red, green, and blue component values which exist in the range [0,255].

Since the human skin colors are clustered in color space and differ from person to person and of races, so in order to detect the hand parts in an image, the skin pixels are thresholded empirically [10]. In this experiment, the threshold value is chosen by the following equation:

$$(60 < Y < 200) \text{ and } (20 < I < 50) \quad (2)$$

The detection of face region boundaries by such a YIQ segmentation process is illustrated in Fig. 2.

The exact location of the face is then determined from the image with largest connected region of skin-colored pixels. The connected components are being determined by applying a region-growing algorithm at a coarse resolution of the segmented image. In this experiment, 8-pixel neighborhood connectivity is employed. In order to remove the false regions from the isolated blocks, smaller connected regions are assigned by the values of the background pixels. After thresholding the image may be encountered by some holes in the face skin region. In order to remove the false regions, the face region is subjected to morphological dilation operation with a 3×3 structuring element several times followed by the same number of erosion operations using the same structuring element. The dilation operation is used to fill the holes and the erosion operations are performed on the dilation results to restore the shape of the face [10]. Then the largest connected component was calculated to find out the actual face area and eliminate other face-like regions.

Fig. 2. Skin color segmentation. (Clockwise from top-left) (a) Original image (b) Enhanced image (c) Skin color segmented (d) Face area.

## B. Eye Localization

Once the face is found in an image, the eyes are then searched around the restricted area inside the face. The face image block is then divided into four parts and the left and right eyes are then searched in the upper left and upper right sub-blocks of the facial image, respectively. Here assumed a frontal view of the face and the original face images are subjected to some image processing operations as Histogram equalization and gray level slicing.

After these image processing operations and detecting the face, eyes are then extracted from this face area, assigning a unique tag to each isolated candidate block by labeling the binarized image. These tag points are the representatives of each image feature block.

Let  $P_j = (x_i, y_i), (j \in [1,2])$  be the two tag points of the image blocks of the left eye and right eye, respectively. Since in the binary image, all of the pixels have got the intensity value of 0 and 255 only, these tag points are assigned with their respective representative numbers. The first tag point, i.e., the tag point for the left eye, is determined by searching for the first white pixel (intensity value of 255) from bottom to up and right to left in the top left quadrant of the image window and assigning it with the value of 128. The algorithm for this searching method is as follows:

[Step 1] Compute the center point of the face:

[Step 2] Starting from the center point, search the first black pixel and assign it with the value of '128' (first tag value) as follows:

```
For $i \rightarrow x_{\max} / 2$ to 1 step -1
 For $j \rightarrow y_{\max} / 2$ to 1 step -1
 If $\text{Pixel}[i][j] = 0$ then $P_i = 128$
 return
```

[Step 3] Search the entire window for the tag value '128' and assign all connected pixels with '128'.

Similarly, the above operation is done for the 2nd tag point. These tag points and representative numbers are starting positions of two eyes.

## C. Calculating Gravity Center of Eye

Since the exact location of the pupil is very confusing, so instead of searching the pupil point, we are determining the position of the gravity center of the eyes from the black portions of the irises of the segmented image. If the gray level at each point  $(x, y)$  of the given area E of an eye is considered as the "mass" of  $(x, y)$ , we can define the center of gravity of that component, as well as the moment of inertia about specified points or lines. The pq-th moment of area E about the origin (0,0) is given by:

$$m_{pq} = \sum \sum_{(x,y) \in E} x^p y^q \quad (3)$$

where  $(x, y)$  are the coordinates of the pixel included in area E. The 0-th moment  $m_{00}$  represents the area E and the center of gravity of E is the point  $(\bar{x}, \bar{y})$  whose coordinates are given by [10]:

$$\bar{x} = \frac{m_{10}}{m_{00}} = \frac{\sum_{(x,y) \in E} xy^0}{\sum_{(x,y) \in E} x^0 y^0} \quad (4)$$

and

$$\bar{y} = \frac{m_{01}}{m_{00}} = \frac{\sum_{(x,y) \in E} x^0 y}{\sum_{(x,y) \in E} x^0 y^0}. \quad (5)$$

On detection and localization of eyes, the gaze positions are estimated. Robots are then instructed depending on the movement of the eyes.

### III. EXPERIMENTAL RESULTS AND PERFORMANCE

Face images were analyzed to demonstrate the feasibility of the proposed method. The effectiveness and robustness of this approach is justified using different images with various kinds of lighting conditions.

Fig. 3. Eye detection at different environments. Upper image at dark environment and lower image at cloudy environment.

Experiments were carried out on a Pentium IV 2.2MHz PC with 256 MB RAM, and the SONY VISCA camera. The algorithm has been implemented using Visual C++. When a complex image is subjected in the input, the face detection result highlights the eyes of the image, as shown in Fig. 3. Experiments were carried out to justify the system with different input images at different environments and lighting conditions. The main application of this method is, here, face detection and eye locating is done successfully with images of different persons with various kinds of lighting conditions and environment both in shiny and gloomy weather. Most of the images were taken using a digital camera, but some are from scanner, and some from video tapes recorded from different television channels. The algorithm is capable of detecting single face in an image. For multiple faces, the system finds the dominant face only, i.e. the face containing more number of skin colored pixels.

Fig. 4. Comparison between 'Fuzzily skewed' filter and Averaging and Median Filter

TABLE I  
EYE TRACKING COMMANDS TO CONTROL AIBO

| Eye Positions | Actions        |
|---------------|----------------|
| Left Top      | Turn Light Off |
| Center Top    | Move Forward   |
| Right Top     | Turn Right     |
| Left Middle   | Turn Left      |
| Center Middle | Start walking  |
| Right Middle  | Dance          |
| Left Down     | Turn Light On  |
| Center Down   | Move Backward  |
| Right Down    | Sing a song    |
| Eye close     | Stop walking   |

First, the response of the proposed fuzzily skewed filter has been analyzed. A graphical comparison between the 'Fuzzily skewed' filter and averaging and Median filter is shown in Fig. 4. The graphical analysis imply that the fuzzily skewed filter snatches the advantages of both the median filter and averaging filter. This method can successfully reduce noise that results to sharp transitions in the gray values, again, it does not make the resultant image as blur as the neighborhood averaging filter.

Fig. 5. Eye tracking command to motivate AIBO to start walking.

The system has been implemented by eye tracking program running in server PC and it considered AIBO as a client. The communication link has been established through TCP-IP protocol. The human-robot interaction results are: (i) turn light off, (ii) move forward, (iii) turn right, and so on, according to the eye positions at left top, center top, and right top, respectively. Ten eye tracking commands were executed to justify the robustness of the system and these commands and their corresponding actions are furnished in Table I. Finally, a real time human-robot interaction system has been implemented on eye tracking commands. One of the actions of the robot as a result of eye movement is shown in Fig.5.

## V. CONCLUSIONS

This paper presents a fast face detection and eye localization method depending on color segmentation. Detection of faces and facial features using machine vision techniques has many useful applications. Though human beings accomplish these tasks countless times a day, they are still very challenging for machine vision. In this paper, Face detection is established by skin color segmentation and morphological operations. Here, eye localization is done by calculating largest connected area from the skin color segmented image and then

calculating the tag positions of the two eyes. Finally the gravity centers of eyes are also calculated. Our next approach is to extend the algorithm for multi-face detection and overlapping faces in images and images with obstacles in front of eye (e.g. spectacles) with different orientation and pose and image with more complex backgrounds.

A fuzzy rule based spatial domain filter is also proposed in this project. Experimental result justifies that it incorporates the advantages of median and averaging filter with minimizing their limitations. Our main target is to instruct operations to robots and make them understand the human intensions and interests over facial expressions and gaze detection so that they are capable of grasping with more intelligence while working cooperatively with human beings.

[jayasil@hotmail.com](mailto:jayasil@hotmail.com)

**Abstract** ---- The techniques of machine vision are extensively applied to agricultural science, and it has great perspective especially in the plant protection field, which ultimately leads to crops management. The paper describes a software prototype system for rice disease detection based on the infected images of various rice plants. Images of the infected rice plants are captured by digital camera and processed using image growing, image segmentation techniques to detect infected parts of the plants. Then the infected part of the leaf has been used for the classification purpose using neural network. The methods evolved in this system are both image processing and soft computing technique applied on number of diseased rice plants.

**Index Terms** -- Fractional zooming, leaf blast (*Magnaporthe grisea*), brown spot (*Cochiobolus Miyabeanus*), rice diseases detection, SOM,

## I. INTRODUCTION

Research in agriculture is aimed towards increase of productivity and food quality at reduced expenditure and with increased profit, which has received importance in recent time. One of the vital components of crop management is accurate diagnosis and timely solution of the field problem. Diagnosis is a most difficult task to perform manually as it is a function of a number of parameters such as environment, nutrient, organism etc. With the recent advancement in image processing and pattern recognition techniques, it is possible to develop an autonomous system for disease classification of crops.

Use of various pesticides for controlling the diseases actually damages the rice field. Most common rice diseases are [1],[2],[12] *leaf blast* [5],[7] (*Magnaporthe grisea*), brown spot (*Cochiobolus Miyabeanus*), leaf blight, sheath rot, steam rot, kernel smart, etc. and most common pests includes yellow stem borer, rice leaf folder, rice bug. The visual symptoms of the damages caused by the pests vary with the severity of the diseases. We have restricted our work within the rice diseases only and considered the most two common diseases in the North East India, namely Leaf Blast (*Magnaporthe grisea*) and Brown Spot (*Cochiobolus Miyabeanus*).

Unprecedented growth in research in the area of image processing and computer vision has been observed during the last two decades, yet no remarkable application of the

techniques found in the field of agriculture. However, the International Rice Research Institute (IRRI) has developed a software named Rice Doctor [2] that suggest name of the diseases by taking the manually observed information about the infected plant. In a recent project a prototype system of automatic identification of cotton insect pest and intelligent decision based on machine vision has been developed [3] while remote sensing technique is being used experimentally for farm pest management [6]. Another effort found in literature that tries to determine the mineral deficiency based on the color texture analysis of rice leaf [4]. The proposed work is to identification of the pest and/or disease depending on the damage symptoms obtained from the infected parts of the plants using image processing and pattern analysis methods. Thus, the system will able to timely diagnosis the field problem and the suggestion helps the farmer to take the appropriate measures to increase the quality of crops and reduce the development cost, which save the environment too.

The paper has been divided into five sections. Section II describes the feature extraction methods that include region segmentation, boundary detection and spot detection of images. Section III narrates the proposed zooming algorithm used to interpolate points in the detected spots, which are subsequently applied for classification of diseases along with the results illustrated in section IV. Conclusions are summarized in section V.

## II. FEATURE EXTRACTION

The samples of the infected rice leaves have been collected from different parts of East Midnapur, a major rice producing district of South Bengal, India.

The images have been grabbed using Nikon COOLPIX P4 digital camera in macro mode. The samples of the rice leaves affected by Blast and Brown spots are shown in the Fig.1.

### A. Segmentation

Acquired images are enhanced by increasing brightness and contrast and then transformed to Hue Intensity Saturation (HIS) model for segmentation. Entropy based bi-level thresholding method [10] has been invoked for

segmenting the images to facilitate identifying the infected parts of the leaf. The segmented images are presented in Fig.2.

Fig. 1. Original images of infected rice leaves

Fig. 2. Segmented Images Corresponding to Fig. 1

### B. Boundary Detection

Boundary detection algorithm using 8-connectivity method [9] has been applied on the segmented images of figure 2(a) and (b), and outputs are shown in Fig.3.

### C. Spot Detection

Boundaries of the segmented images are obtained with varying image sizes 300×300 to 1500×1500. The ratio of the

Fig. 3. Images after boundary detection

average value of the green components and intensity of the pixel lies in between 1.15 to 1.40 respectively and the measurement is used to identify the infected spots. The reason of selecting the green component is based on the observation that when the infection occurs in the leaf, the greenness of the leaf is affected most. Instead of considering only the green value we have taken the ratio of green component with the intensity to make the spot detection invariant of the brightness of the images and the age of the leave. The values have been determined heuristically based on the experiments of the hundred of infected leave, shown in Fig. 4.

Fig.4. Label (a) to (d) represent the spots of blast and label (e) to (h) represent the brown spots.

## III. ZOOMING ALGORITHMS

Self organizing map (SOM) neural network has been employed for classification [8], [11] of the images where gray value of the pixels of spot images are fed as input. Segmented spots have been normalized to the 100×80, which is determined by the average size of the spots, detected in the previous section to apply it in SOM. There are two possible methods to make the input vector of same size. First one is the padding of zeros in the input vector and the second one is the interpolation of missing points to make the input vector of same size. Since there is wide difference

amongst the spot sizes, the missing points are often more than the original points, which may cause a significant effect in the classification process, if the former method is opted. Thus, interpolation method has been applied for fractional zooming to normalize the spots size.

The interpolation algorithm works as follow:

Step 1. Determine the scaling factor  $s_x=100/m$  and  $s_y=80/n$  where  $m \times n$  is size of the original image.

Step 2.

- (i) All points of the original image located at  $(i,j)$  position are placed in the  $((i*s_x - s_x/2), (j*s_y - s_y/2))$  position as shown by yellow points, with gray values  $a, b, c$  and  $d$  ( figure 5).
- (ii) Scan first row wise, then column wise and calculate the gray value of intermediate points, like  $x$  (shown in figure 5) by using equation  $(a*d_1+b*d_2)/(d_1+d_2)$  where  $d_1$  and  $d_2$  is the distance from  $a$  to  $x$  and  $x$  to  $b$  respectively.
- (iii) Scan row wise and any points with gray value  $y$ , which not computed yet (figure 5) is calculated as the average value of its four neighbor. Note that, only the points whose gray values are already computed in the previous steps, used to compute the gray value of  $y$ .

Fig. 5. Illustration of zooming algorithm

The results obtained after zooming, shown in Fig. 6.

#### IV. CLASSIFICATION USING SOM

After obtaining spots of uniform size, unsupervised learning technique SOM is used. Here we have used  $100 \times 80$  input nodes and 2 output nodes, 300 training patterns and 50 epochs to train the network. Here the gray values of the

pixels are applied as the input vector. After performing training with the above mention datasets and 50 epochs, we

Fig. 6 Zoomed images corresponding to Fig.4

have tested the system with 300 input datasets for each of the cases separately, given below :

- Case 1: Use the RGB of the spots for classification.
- Case 2: Use the Fourier transform of the spot.
- Case 3: Use the Arbitrary rotation of the 50% spot.
- Case 4: Use the Fourier transform of the 50% rotating spots.

The result has been shown below obtained after applying.

TABLE I  
CLASSIFICATION RESULTS

| Category | Percentage of successful classification |
|----------|-----------------------------------------|
| Case1    | 92%                                     |
| Case2    | 84%                                     |
| Case3    | 82%                                     |
| Case4    | 70%                                     |

#### V. CONCLUSION

In the paper, the diseased rice images are classified using SOM neural network where train images are obtained by extracting features of the infected parts of the leave while four different types of images are applied for testing purposes. The zooming algorithm extracts features of the images using simple computationally efficient technique, which results satisfactory classification for test images. It has been observed that the transformation of image in the frequency domain does not yield a better classification compare to the original image.

# Geospatial Web Services in Environmental Planning

Iftikhar U. Sikder

Department of Computer & Information Science, Cleveland State University,  
2121 Euclid Ave. BU 336, Cleveland OH 44115, USA

**Abstract-** As more and more mapping resources are becoming available, the Web is becoming a confluence of collaborative interactions, negotiations and planning platforms. The integration of Web services with Geographic Information Systems (GIS) has triggered a new wave of interest for using the Web to compose dynamic mapping services for environmental planning. Web services could offer a framework for service integration and composition for collaborative environmental modeling. By wrapping geo-processing services of interoperable standards of XML and SOAP, we demonstrate a prototype implementation of environmental decision support systems GEO- ELCA (Exploratory Land Use Change Analysis) where Web service-enabled middleware adds core functionality to a Web mapping service. The system demonstrates how geo-processing services can be integrated with environmental simulation models using OGC (Open GIS Consortium) compliant connectors that support WMS (Web Mapping Service) and WPS (Web Processing Services).

**Index Terms** — Geographic Information Systems, Web Services, Environmental Planning, Interoperability

## I. INTRODUCTION

In the face of the growing trend of organizations moving towards a flatter structure, environmental resource managers are facing an increasing need to involve multiple stakeholders in spatial decision-making to bridge the gap resulting from differential access to information and resources. The traditional production of geospatial data and models has been relatively centralized [1]. In recent years, there is a growing interest in making access to geospatial information and services available to decision makers and planners to promote Collaborative Spatial Decision Making (CSDM)[2]. CSDM and public GIS involve a "bottom-up" planning model reflecting the stakeholders' perspective to explore scientifically projected planning scenarios. The vision requires a broad understanding of organizational settings against the backdrop of the distributed information architecture for a closer involvement of multiple stakeholders from different geographic locations and social orientations. It presupposes systems that provide stakeholders with the

ability to continuously make plans [3], have it pre-empted by collaborative actions, and evolve based on any new contexts. This service-oriented approach has triggered a new wave of enthusiasm in the composition of complex services in a meaningful way involving not only traditional alphanumeric data but complex geographic data and services [4].

One of the functional requirements of collaborative modeling is the development of reusable generic geospatial procedures, which can be made to communicate each other in distributed systems in a heterogeneous environment. For instance, the user may wish to view relationships among several geographically separate datasets and perform varying degrees of analysis and invoke different geo-processing services (e.g., perform spatial proximity analysis combined with geocoding procedures and specialized cartographic visualization in a given area). From the planning point of view, comparing individual preferences with the collective scenario is a group process that essentially requires geospatial service composition in a collaborative framework and a distributed environment. Hence, the service-oriented architecture (SOA) becomes inevitable for collaborative GIS systems that would then define the use of services to support the requirements. By having such services distributed all over the Internet and accessible in a uniform standard manner, it is possible to envision the integration of several spatial services (chaining of services) to provide higher levels of functionality to existing services[5, 6]. Equally important is the ability to locate and obtain someone else's data with minimal human intervention in the process of system interoperability. In this respect, the OpenGIS Consortium's endorsed standards and specifications for geographic data encoding GML/Geography Markup Language), geographic data publishing (WFS-Web Feature Service), and map publishing (WMS/Web Mapping Service) and Web Processing Service (WPS) are being received in the industry. These standards are becoming key elements of collaborative planning in urban information systems.

While Web services require minimal standards-based protocols such as HTTP or SMTP for use in other applications, they essentially offer communication among systems without requiring centralized planning or control mechanisms to integrate a heterogeneous mix of platforms [7]. This unique advantage of Web services can be well utilized in developing decentralized distributed planning systems as envisioned in collaborative spatial decision making in the NSF-funded Project Varenus [2]. Current researchers lack a theoretical framework for understanding how features of Web services can be related to implementation standards and protocols of distributed planning systems; they also lack a theoretical framework for understanding how such features can be exposed in geospatial service composition for collaborative planning.

## II. MULTI-USER CONTEXT IN SPATIAL PLANNING

In view of decision support frameworks, collaborative modeling presupposes multiple parties with different perspectives working together in a complex emergent environment. These parties (henceforth termed as “agent”, “decision maker”, or “stakeholder” interchangeably) must have integrated data access from heterogeneous sources to integrate with transparent high performance computing resources to compose decision models dynamically. However, in real life situations, it is often difficult to achieve the stakeholders’ views or effective patterns of social interactions in the planning process. For example, decisions on how current land use should be changed depend on legal, environmental, and regulatory constraints, as well as on biases and preferences of different groups or institutions. In particular, understanding urban land use dynamics involves consideration of the complex behavior of individual decision makers and the interaction of local and regional institutions in multiple scales. Moreover, such decisions are inherently spatial in nature because the change in a particular parcel may have direct or indirect consequences to the neighboring parcels.

For example, the EPA’s Brownfields development program involves the expansion, and redevelopment of urban areas that may be complicated by the potential presence of a hazardous substance, pollutant, or contaminant [8]. While cleaning up and reinvesting in these properties takes development pressures off of undeveloped, open land and improves the environment, evaluating a candidate property to determine if it meets the criteria for redevelopment is inherently a collective decision process. For instance, an individual landowner may act from his or her individual interest; however, in

the long run, the overall land use scenario may be undesirable to everyone. Moreover, changes in land use may create concern for environmental impact in the surrounding region. While land-use changes are often identified as a major driving force of ecological changes, with the conversion of land use from one category to another, there is an overall change of hydrological characteristics resulting from the changes of impervious areas. Consequently, the increase in volume and peak flow means a possible increase in the concentration of pollutants that could potentially cause the environment to deteriorate. Hence, a centralized planning process is essentially inadequate to reflect group dynamics. Such group-individual dilemmas make them ideally suited for collaborative planning in a distributed environment, particularly regarding the integration of Web-services in accessing geospatial data and models for environmental monitoring.

## III. WEB SERVICES AND MAPPING STANDARDS

As a precursor to Web services, CORBA and Microsoft’s DCOM or Java-based RMI were often used for distributed access and query of spatial data, sometimes integrated with SDSS. However, being “tightly coupled” with native data structure, the broker-based services are unable to make sure that whenever an organization makes changes in its native data structure or services, the corresponding change is automatically reflected in all other organizations sharing the same resource. Moreover, middleware-based access through a broker relies on a standard definition of “interfaces”. Geo-processing services can become very cumbersome in the absence of such interface. From the decision support point of view, having data access at the client’s end without robust geo-processing capabilities amounts to having little help. In a broker-based solution, the client has to pull a massive amount of data at his/her end and manage it locally. Such approaches assume the client’s explicit ability to manipulate the server connection and remote objects. Thus, frequent spatial processes, such as spatial join between data from two different servers, need to be coordinated at the client’s end. Such object-level manipulations of spatial process often fail to provide high-level views to application developers. Paradoxically, in a spatial decision support system, the user’s or decision maker’s view on spatial features or geometry needs to be realized at a higher level of abstraction while at the same time maintaining the transparency of system processes.

In Web services, a series of protocols such as eXtensible Markup Language (XML); Simple Object Access Protocol (SOAP); Web Service Description Language (WSDL); and Universal Description, Discovery, and Integration (UDDI) provides standards

for communication and collaborative processing capacity among Web-service compliant architecture. A key advantage is that various GIS layers can be dynamically queried and integrated while still maintaining independence in a distributed environment. From an organizational point of view, this feature may be very appealing; for local governments, such as counties and other organizations, can still independently collect and manage data locally and still integrate information and services using Web services. A client, for example, like a transportation company, could directly access a local government's base map without maintaining its own. At the same time, the client can update the local government's data from its own record. As far as data interoperability is concerned, extended collaboration and partnerships using Web Services could provide opportunities to open interfaces and communication mechanisms for distributed computing.

Open GIS Consortium (OGC) has been in the forefront of developing a set of interoperability standards to guide the development of web mapping programs. All service specifications of OGC are collectively known as OGC Web Services (OWS) and adhere to the same communication protocol of HTTP. OWSs are subject to somewhat similar operational interfaces. The interfaces have common operations such as GetCapabilities, which provide service level information; Get operation allows users to access data in a given context and Describe operation provides a description of data or attributes. OGC's Web Map Server (WMS) implementation information specifies that a mapping service should be able to at least produce a map (as a picture, series of graphical elements, feature data) and answers basic queries and finally inform other programs about its capabilities. The three operations defined for a Web Map Service are as follows:

GetCapabilities – obtains machine-readable service metadata

GetMap - returns a map upon receiving request

GetFeatureInfo – optional operation that provides additional feature information (e.g., more information about features in the pictures of maps that were returned by previous map requests).

The Web Processing Service (WPS) interface specifies WPS operations that can be requested by a client and performed by a WPS server. The GetCapabilities and DescribeProcess of WPS are implemented through WSDL which is an XML format for describing Web Services.

### III. WEB SERVICE FRAMEWORK FOR DISTRIBUTED COLLABORATIVE MODELING

In a distributed planning environment, the server side component can expose its functionality through web services, which could provide the benefits of interoperability and open standards. Figure 1 illustrates a stranded-based framework for integrating collaborative models using Web services. In such a system, UDDI will allow any client to discover spatial services (e.g., using the UDDI nodes as FGDC compliant geospatial metadata servers for registered Web services). Typical geoprocessing services may include data management tools like projection and transformation, or topology manipulation, indexing and spatial join, etc.

Figure 1. Standard-based Web-service integration framework for collaborative support

Analytical services may include spatial proximity analysis, spatial overlay, feature extraction, geo-statistical analysis services, and so forth. Each geoprocessing service can advertise its XML protocol or SOAP API using WSDL for discovery. To integrate these services with a local application, the Web application developer needs to wrap an application with a SOAP API to invoke or serve a request. Integrating services can be realized by developing OGC compliant middleware that supports access to the Web Mapping Service (WMS) and Web Processing Service (WPS) or Web Feature Services (WFS). Since Web services build stateless or loosely coupled environments, nodes can be dynamically connected whenever needed, thus multi-user access to data and services are basically “just in time”.

### IV. SERVICE ORIENTED ARCHITECTURE: GEO-ELCA

What follows is an illustration of a prototype implementation of a Web service-based spatial decision support system for collaborative planning of urban land use change. GEO-ELCA (Exploratory Land Use Change Analysis) offers a collaborative platform for multiple

stakeholders with exploratory tools to evaluate the environmental consequences of land use changes. GEO-ELCA supports the evaluation of the pollutant flow as a consequence of land use changes. The system allows an exploratory model to evaluate the hydrological scenarios in response to land use changes as a result of stakeholders' different options. The Web interface allows a user to select graphically a land use type and change it to a different category and then visualize the effect of different pollutants. The system allows the dynamic selection of a feature type (i.e., polygon – land use class) interactively so that a user can change attribute items and identify a feature property. A user can initiate a change in land use type by graphically selecting a polygon. The server side application processes the request and makes necessary updates in the database to reflect the corresponding changes of the pollutant coefficients. Every request to change in land use type results in the recalculation of the mass export of pollutants and corresponding statistics. The processed result is sent back to the Web server and then to the client side. The consequences of user decisions initiate the simulation model to estimate the yearly pollution load. The system integrates a simulation model commonly used in urban hydrology--the so-called "Simple Method"[9] for estimating exports of various pollutants' runoff from different land uses. The resulting pollution map can be visualized with multiple theme overlay. The system logs individual user's input preferences into mediating algorithms to resolve conflict among user preferences of land use choice.

(which is typically a light viewer such as a browser); the Web mapping server sends WMS Request (GetMap, GetCapabilities, GetFeatures) and WPS Execute Operation (changeLandUsageType) messages which are XML encoded and enclosed in SOAP 1.1 messages. The construction of SOAP messages is accomplished using client side scripting such as JavaScript, VBScript and can also makes use of advanced features such as AJAX. These messages are received by the web server which exposes a web service interface and has already published its service end point interface in a WSDL file. The SOAP message is decoded and passed on to the middleware solution. The middleware is responsible for decoding the request messages which were in OGC Compliant message formats into a format understood by the web mapping server (see Figure 2). In our case, since the web mapping server is ArcIMS, we need to communicate with it using ArcXML. Hence the middleware solution provides a mapping from the OGC WMS Request message to appropriate ArcXML requests. The ArcXML equivalent of OGC Web Mapping Service Operations is shown in Table 1.

Table 1. OGC's WMS operations and their mapping with ArcXML request

| OGC WMS Operation | ArcXML Request Operation |
|-------------------|--------------------------|
| GetCapabilities   | GET_SERVICE_INFO         |
| GetMap            | GET_IMAGE                |
| GetFeatures       | GET_FEATURES             |

Figure 2. Service Integration Framework in GEO-ELCA

GEO-ELCA uses ArcXML (native XML encoding of spatial object) to communicate between the custom middleware and the Web mapping server of the client

Figure 3. User specific planning scenario of land use change analysis

The response received from the web mapping server is also in ArcXML and needs to be converted into a format compliant with OGC WMS Response message format. The middleware solution performs this mapping. Hence the request issued to the web map server is a GET\_IMAGE request (as always in ArcXML). The web map server renders the map based on the specific user's state of data and this Map Image is returned all the way back to the user. Hence the client visualizes user specific maps. Once again the middleware solution is responsible for ensuring that the response from the web map server (URL of Map Image encoded within an ArcXML response) is returned back to the client in an OGC GetMap compliant response. The mapping performed for WPS messages is similar to that performed for WMS messages with the tasks performed being the same.

## V. THE COLLABORATIVE CONTEXT OF GEO-ELCA

The "virtual" private user workspace provided by GEO-ELCA offers a mechanism to log an individual user session. An individual user session is achieved by means of a relational data model that provides each user a 'virtual private' workspace. Each individual user is

associated with a native profile database, while, in fact, the actual visualization is rendered from a single dataset. Thus, user specific visualization and data editing is possible in real time. For example, when a user's request to change a land use type is received by middleware, it updates the specific user's data. Then it forwards the request for a map to the web map server after converting the request to ArcXML-- a format understandable by the web map server. The web map server queries the data store to retrieve the data it needs to generate the map. The records returned consist of the current user's data and the map. Then a map image is generated using the updated (current user's) data and the map image is returned to the middleware solution, while the master data is restored to original values by updating records from backup data store. Finally, the middleware returns the map image (or URL) of the newly generated user specific map.

Thus, user specific planning profiles can be achieved and communicated in real time. As illustrated in Figure 3., the Web-based planning interface offers user-specific individualized explorative options where a user graphically selects a polygon and chooses a land use category from the pop up list to change its category and simulate the "what if" kind of pollution scenario. The simulation model estimates the pollution potential (e.g.,

total nitrogen, BOD load, etc.) resulting from a user's decision to change land use and graphically display the estimated pollutant. In a multi-user context, each user's planning scenario and corresponding simulation result are achieved in a relational table. As a result, cartographic visualization and representation can be locally customized by user. For example, the same area can be visualized by different user with different options. A user has the option to visualize the confidence limit and standard deviation classification of selected pollutant categories and choose the color scheme or color ramp for classification and hence dynamic map legend rendering. A color ramp is calculated on the fly and a corresponding visualization of the map and the accompanying legend is generated. At present, the system does not offer any group negotiation tool that allows the convergence of a consensus decision. However, such utilities can be easily implemented in the given architecture by integrating multi-objective optimization services (e.g., a discrete decision choice model like the Analytic Hierarchic Process or evolutionary algorithm for group decision making).

## VI. CONCLUSION

Since Web services avoid problems of tightly coupled distributed object techniques and expose an application programming interface over the Web, they hold promise for distributed resource sharing and collaborative environmental planning. By wrapping and dynamically integrating remote geo-processing services from multiple sources, one can develop an emergent collaborative system using interoperable standards of XML and SOAP. We introduced some architecture for Web service-based collaborative modeling applications for environmental planning. The prototype system is based on the conversion of the OGC compatible GIS services to Web Services for flexible collaboration. The significant advantage of the architecture is that it provides a means for self-describing services in which end users through any WMS/WPS client can invoke a set of services (e.g., catalog services of spatial map). Consequently, user specific plan profiling and customized cartographic visualization are rendered dynamically. The consequence of a user's decision is simulated graphically to estimate the yearly pollution load as a result of individual decision. Each user's planning profile can finally be compared for further modification. The collaborative model suggested here is geared towards archiving different opinions in a manner suited to visualization and negotiation.

# Implementation of E-Governance: Only Way to Build a Corruption-Free Bangladesh

S. A. Ahsan Rajon and Sk. Ali Zaman

Computer Science and Engineering Discipline, Khulna University, Khulna-9208, Bangladesh.  
TMRAFM, Khulna-9100, Bangladesh.

**Abstract** — This paper focuses on various aspects of implementing e-governance in developing countries like Bangladesh. In this paper, we present a comparative analysis of present government architecture and the prospects and problems of implementing e-governance in Bangladesh emphasizing on the usage and effectiveness of e-governance to eradicate corruption from various sectors of governance. We especially present the adaptability of e-governance in the prime sectors of government and provide a methodical study on the strategies of involving mass people in the governance process improving information and service delivery with their participation in overall decision-making. The potential to ensure highest level of transparency in all the sectors of government with the implementation of e-governance is also presented in this paper. Moreover, we provide specific recommendations for implementing the e-governance in the most effective and efficient manner.

**Index Terms** — E-Governance, Decision-making, Adaptability, ICT Infrastructure, E-Commerce, E-learning, M-Governance, E-Transparency, E-Administration.

## I. INTRODUCTION

Present century is the age of Information and Communication Technology. The prime concern of this decade is to establish and ensure a better way of management, communication and development with the use of information and information oriented services. Crossing the boundary of personal computations and communications, the uses of digital media for greater levels of management has been initialized early in the century. E-Governance may simply be considered as an extension of this trade. With the enhanced facilities of technology for providing smart and easy living, E-Governance has become a prime demand in the world for ensuring transparency, effectiveness, accountability and efficiency throughout the various sectors of government including decision-making, public policy building, access to information etc.

The paper is organized into eight sections. The following section provides the definition of e-Governance. A study on current status of Bangladesh in the point of view of implementation of e-governance is presented in section three. Section IV presents the necessity of e-Governance and m-Governance in developing countries.

The effectiveness of e-Governance in fighting and eradicating corruption is depicted in section V. Section VI is devoted to provide a framework for implementing e-governance in various leading sectors of the government of Bangladesh. A brief recommendation with concluding remarks is provided in section eight.

## II. E-GOVERNANCE

A number of definitions of e-Governance exist emphasizing on specific activities and functionalities. E-government and e-democracy are the mostly adapted criteria for defining e-Governance. The term e-democracy refers to the processes and structures that encompass all forms of electronic interactions between the government and the citizens in terms of information coverage and decision-making. E-Government is a form of e-business in governance and refers to the processes and structures needed to deliver electronic services to the public (citizens and businesses), collaborate with business partners and to conduct electronic transactions within an organizational entity. Taking the above two into concern, e-Governance is defined as the application of electronic means to improve the interactions between government and citizens and government and business as well as to employ electronic means in internal government operations to simplify and improve democratic government and business aspects of government with the primary goal of boosting administrative efficiency [1]. Overall sectors of e-Governance is basically pointed as G2G (Government to Government), G2B (Government to Business) and G2C (Government to citizens) in terms of service with prime importance in G2C for establishing e-democracy [2][3].

In a very short span, we may define e-Governance as the process of adapting electronic means in possible sectors and stages of government to ensure legitimate mass-access of administrative and service oriented information with the potential to establish transparency and accountability of government activities and maximum service by redesigning and redistributing the administrative and operating system of government. Adaptability, Awareness-building and Accessibility are the most important concern in establishing e-governance.

Here adaptability and accessibility involves the socio-economic status of the citizens especially the economical strength and educational status of the people. Literatures in [1], [3], [4], [5] provide explanations regarding e-governance and related issues with specific sector-based implementation approach.

E-Governance doesn't only mean to have a website in the internet rather to provide online services and information that increase mass-participation in decision making, accountability of the authority, transparency of affairs involving public interests and domestic concerns. Though a good milestone towards establishing e-government has been made in the USA, Europe and other developed westernized countries such as Australia, Singapore, Canada, the developing countries too, are putting steps for implementing e-Governance in various sectors with a number of limitations, challenges and debates.

The prime objective of e-Governance is essentially to ensure good governance and strengthening democratic process providing equal access to information, freedom of constructive expression, greater equity, service efficiency, stable rapid economic growth and social inclusion. The successful integration of e-Governance in the developed countries has already illustrated the demonstrable and tangible evolutionary impact on increasing government functionality, efficiency, improving citizen participation and quality of life as a result of multi-stakeholders partnership. [4]

### III. CURRENT ICT INFRASTRUCTURE OF BANGLADESH

Bangladesh, a small developing country with enormous prospects realizes the importance of implementing e-governance in Bangladesh. However, because of its financial backwardness and the ill-fate of being affected by natural disasters frequently, it is still now in the initializing step of implementing e-Governance.

TABLE I. ICT INFRASTRUCTURE OF BANGLADESH

|                              |                   |
|------------------------------|-------------------|
| Population (Million)         | 150.4 (July 2007) |
| Literacy rate                | 51.6%             |
| Poverty                      | 50%               |
| Tele-density                 | 23.3              |
| Growth of Cellular Phone     | 135%              |
| Household access to computer | 1.36              |
| Household with electricity   | 44.23             |

From the above table it is evident that, the implementation of e-Governance in Bangladesh is not so an easy task, rather it would be a time consuming step for Bangladesh. In Bangladesh ICT has been declared as the thrust sector. In e-Governance introducing step, a number of ministries, which are the highest governing authority,

have already presented their websites [4]. To provide quicker service, Bangladesh government has already made a number of forms available through internet, which is really an appreciable step towards implementing e-Governance [4].

Fig.1. Statistics of the websites of various government organizations in Bangladesh.

### IV. POTENTIAL OF M-GOVERNANCE TO IMPLEMENT E-GOVERNANCE IN BANGLADESH: THE WAY FORWARD

Cellular Phone has revolutionized the telecommunication infrastructure in Bangladesh. It is really amazing that, since 1989; especially within the last decade, mobile phone service has provided about forty million people with telecommunication services resulting a tele-density of 23.3% [4]. The following figure indicates the growth of mobile communication.

Fig. 2: Telecommunication Status of Bangladesh.

As mobile communication has got a massive use, it may be an effective way to utilize mobile phone oriented services in awareness building for establishing e-governance. In decision making processes and providing essential administrative information we may use cellular phones both in voice and text communication services. Various service-oriented information may also be communicated to all levels of people through mobile communication. The means of seeking services to the government by the citizens may also be ensured through mobile phones. Various add-on services like internet facility using mobile phone may mobilize the process of implementing e-Governance in Bangladesh. It is necessary to mention here that, from the perspective of Bangladesh m-Governance may be considered as the prime media or gateway of implementing e-Governance.

#### V. E-GOVERNANCE: SCOPE AND POTENTIAL TO FIGHT CORRUPTION

The total world, especially the developing countries are in a great challenge to fight corruption that has got rise because of improper administrative transparency, lack of accountability and absence of monitoring processes. The fundamental rights of the citizens are also been suppressed due to manual paper-based administrative system. In this section, a field-specific analysis is provided indicating the scope of implementing e-Governance with its applications.

##### *A. E-Governance in Central Government Process*

The central government, which works as the basis of all prime activities must provide legitimate information on public issues through electronic communications. Major decisions may be taken by conducting online-surveys as well as traditional surveys. This availability of information is a great aspect in establishing accountability and transparency. Publishing accurate fiscal statistics may be the easiest way of restricting corruption in financial sectors, though a number of doubts exist in this concern. Sadly speaking, the constitution and even the basic documents stating public laws are still now not available to the citizens of Bangladesh. Without providing electronic means, it is not at all possible to make these documents available.

##### *B. E-Governance in Public Administration*

Public Administration possesses the power of administering, managing and implementing the decisions-taken by supreme authority. Often this management process is biased and due to corruption, the implementation of development activities derived from public demand are not completely and accurately

performed. Even allegations from citizens regarding the corruption issues do not reach to proper authority. That is, due to the intermediate authority, public concerns are often disregarded. Implementing e-covernance and e-communication may at least echo the public voices to the supreme authority for considerations.

##### *C. E-Governance in Education Sector*

Education, which is the backbone of a nation, is often fatally pointed as a corrupted sector. As, education is the fundamental need, a major portion of budget is spent in development of this sector. But, the history sadly says that, a major portion of this budget often goes into the pocket of some corrupted personnel. Unnecessary and ill-motivated delay in granting various scholarships of the students, meaninglessly harassing the teachers in granting remunerations and other bills are some common objections of the concerned parties. The absence of monitoring in application and implementation is one of the reasons behind these, which may be partially eradicated by providing the information regarding distribution of funds and other operational and statistical data. The debates that often arise in modifying the curriculum may also be solved by integrating the facility of providing public remarks through electronic means before taking final steps of curriculum specification. Publishing the results of public examinations has established a well suited means of automatic verification and hence ensured greater transparency.

##### *D. E-Governance in Judiciary*

Solely administration or solely Judiciary may never ensure a sound running of government. It is must to have proper co-ordination and respect between the parts. It is note-worthy that the independent judiciary is taking initiatives to redesign judiciary with electronic aspects. Still now, there is a lot of scope of ensuring transparency in judiciary by making each step clear to the citizens, which is of no doubt, echoes e-governance.

##### *E. E-Governance in Economy*

The Economy of Bangladesh has faced a lot of difficulties because of corruption. The lack of efforts and weak policy of maintenance with absence of accountability has wasted the major amounts of annual budget. Denying public interest, often political decisions has been implemented, that has simply resulted in weakened economical structure. But, an effective feasibility study maintaining overall robust system analysis and design would demonstrate acceptable and fruitful sectors of economical interest.

#### *F. E-Governance in Agriculture*

Being an agricultural country, Bangladesh should emphasize on enhanced and productive agriculture. Because of the alarming livestock crisis, the whole world is now facing a great challenge regarding the arrangement of food. Price hike is the hottest concern all over the world. The middlemen-ship is also a resultant of poor-governance. In this situation, if we fail to implement enhanced mechanisms of achieving maximal production, the overall existence may be extremely threatened. This enhanced mechanism includes the tasks of making the most fruitful technology available to the users, making the basic operational information available to the agriculturists in the shortest possible time. This dissemination of essential information including market demand-supply analysis is only effectively and efficiently possible through implementation of e-governance. E-agriculture focuses on agriculture informatics, agricultural development and entrepreneurship and provides the agri-services through internet and related technologies. Moreover, if various subsidies on agriculture are provided through internet making all the steps monitor able for public, transparency may be achieved at the highest level saying a goodbye to corruption. This achievement may also bring a horizon in e-marketing or e-commerce attracting the investors of both home and abroad which may enlarge the scope of the growth of economy. Effective study regarding the positive impact of implementing e-agriculture is provided by FAO in [6]. It is now essential for developing countries like ours to present their agricultural products in the world market effectively, which is only possible by adapting e-governance and e-commerce.

#### *G. E-Governance in Bidding*

The dreadful hostile occurrences regarding bidding often costs of valuable lives, which is about a regular headline in the pages of newspapers. The stretch of corruption in analysis and selection process is well known to all. But e-governance may facilitate both the parties by transforming the overall process into an electronic system. If from the invitation of tenders to selecting the best offer, e-governance is employed, the interested parties may get rid from the threats of miscreants in the tender collection and submission process as well as the selection and rejection process may be free and fair.

#### *H. E-Governance in Other Sectors*

Besides the above mentioned sectors, we have a lot of opportunity in establishing transparency and accountability as well a mobilizing the development process by adapting e-governance. For example, providing

a dynamic internet application stating aspects of lands like information regarding proprietary, statistics of the amount of land, map or related statistics describing the perfect and accurate condition of land area may prevent all types of corruptions in this sector. Public safety may also be established in this way. In the election process, which is basically the most important affair for founding a good-governance and sound-democracy, e-governance may facilitate a lot by providing accurate and un-tampered information regarding the candidates. If information regarding criminals, smugglers, loan-infringers, tax-hoaxers is made available through the e-governance supporting processes of law-and order enforcing organizations and other concerned authorities, at least it would be possible to present the real and internal characteristics of the candidates before the citizens to help them in correct and accurate decision making. Thus Citizen Information System *i.e.* e-governance may change the appearance of the whole country giving a new dimension in democracy.

The above-mentioned sectors are presented as the prefect-sectors facilitating overall governance. It is necessary to mention here that, only installation of computers or having a web-site doesn't mean e-governance. It may only be ensured when, the legitimate tasks and affairs is made available through internet and people are accepted to access information regarding those with proper facility of providing constructive remarks is integrated ensuring participation of citizens in decision making and policy building activities. There is no way left of getting relief from the hassle in getting citizen-services from government without implementing e-governance. Specifically, it is of no doubt that, a machine may never provide biased and corrupted effort unless it is instructed by human. Thus, it is a must to have some supreme authority to monitor all the affairs regarding the e-governance initiatives. Information tempering and other issues may be prevented through their monitoring activities. A powerful task force with ICT experts may ensure such activities.

### **VI. PROPOSED APPROACH FOR IMPLEMENTING E-GOVERNANCE IN BANGLADESH**

From the above discussions, it is evident that, there is no feasible and optimal way of fighting the corruption without adapting, implementing and establishing e-governance in Bangladesh. Here we present some specific guidelines for implementing e-governance in Bangladesh.

#### *A. Stage-Setting Steps for Establishing E-Governance*

In order to facilitate e-governance, we must have proper infrastructure. This infrastructure support must be

affordable and effective for the country. In order to establish internet facility, we may employ Broadband over Power Line Communication (BPLC) [7], [8] strategies, as the most available infrastructure is electricity in comparison with tele-density.

In this stage-setting step, we also intend to emphasize on awareness building. E-governance is aimed for good-governance, and this good-governance is aimed for the social, political, economical that is overall uplift of the citizens. This necessity and functionality of e-governance should be communicated to the people so that they may realize and evaluate e-governance. situations.

#### B. Analyzing the sectors for Implementing E-governance

As a developing country, it is not possible for Bangladesh to establish e-governance in all the sectors at a time. It is essential for Bangladesh to implement e-governance hierarchically. Consequently, we are to prioritize the sectors in terms of effectiveness, functionality and liability of providing services. The failure to identify the priority sectors may jeopardize the total scheme of implementation of e-governance. This prioritization process should also consider the interdependence and intercommunication among various service-providing sectors for ensuring a consistent, functional and effective analysis to implement e-governance. This feasibility analysis process should must involve citizens as well as system analysts and government officials of all levels.

#### C. Framework for Implementing E-Governance

One of the main issues for implementing e-governance in developing countries is expense. The huge expense of implementing e-governance often turns the e-governance implementation project into an abandoned one. But, this may be easily handled by involving universities and other organizations in implementation process. The universities and other ICT related organizations may provide major support by providing their experienced IT-experts and concerned human resource. This may also bring a new dimension of research in the organizations. As in Bangladesh, there are more than hundred universities (both public and private) among which about all the universities possess courses and degrees regarding computer science and information technology, there is a great scope to engage large amount of human resource into the design and development of e-governance system for various sectors of government. Selecting renowned universities to perform this job with the supervision of honorable experienced teachers may ensure a successful, effective and efficient design, development and implementation of e-governance system. The universities may also be benefited with the scope of e-governance

analysis and implementation related research support. Basically, this may be the only driving force to install the framework for e-governance in minimum expense.

#### D. Design issues for implementing e-governance

The design and implementation of e-governance should must take the social, economical and educational issues into concern. The adaptability and effectiveness of the e-governance depends mainly on the citizens, as they are the stakeholders of e-governance. It should be taken into consideration that, the first language of Bangladesh is Bengali. So that, it would be most effective to ensure the use of Bengali in implementation of e-governance for conveying information. The use of Unicode in representation of Bengali text is also expected to facilitate uniform and massively accessible platform. The integration of the facility to provide comments and other information through internet may guarantee the participation of citizens in decision-making and various multidimensional service-oriented processes. We propose to use a Phonetic based encoding scheme for obtaining the information from the concerned parties. Figure 5 presents a typical screenshot of proposed phonetic based approach of Bengali text composition.

Fig. 3: Keyboard mapping less and Phonetic based approach for online Bengali-Unicode text composition.

E-Governance is a large-scale activity which requires large scale data warehouses to be implemented. For faster, reliable and consistent database applications regarding development of e-governance, distributed database management may be the most effective. It is also necessary to consider WAP-support for all levels of design and development of services relating e-governance.

#### E. Communicating E-governance

E-Governance is dedicated to establish the participation of the citizens in decision-making, policy building, objective selection and quickest service delivery fostering good governance in corruption-free and progress and success-oriented environment. This goal can only be achieved if people are informed about the sectors and services of e-governance. This communication can be made using traditional communication medias. SMS may be an effective approach in communicating the adaptation of e-governance in various sectors. Providing citizen-incentive lucrative facilities and services electronically through e-governance may bring rapid attention of the citizens.

#### VII. E-GOVERNANCE TO M-GOVERNANCE: THE JOURNEY BEGINS

The increase of mobile communication in Bangladesh has made a silent revolution in all the sectors. The spread of the networks has now reached even into the extreme-rural areas. As, people are now more flexible with mobile oriented services, the adoption of m-governance which is to some sense a bridge between e-governance and mobile communication with the use of WAP or SMS [10]. M-Governance is also a great concern because of its extreme growth, availability and flexibility. Considering mobiles as a communication tool for all types of service-request and information possessing from citizens may mobilize the e-governance process.

#### VIII. CONCLUSION

In this paper, we have presented an overview on the sectors for adapting e-governance from the point of view of the democratic governance in Bangladesh. We also describe the specific issues of corruption in various government sectors and have provided the feasibility study for reducing corruption from the corresponding sectors by adapting e-governance. The overall analysis on the usefulness and effectiveness to establish e-Government, e-Administration and e-Democracy in the form of e-Governance has been elaborately provided here.

A detailed approach for implementing e-governance has also been presented in this paper. We also provide specific recommendations for designing, developing and managing the e-governance system in Bangladesh. The implementation of e-Governance is the only way left to uplift the country into a corruption-free developed nation.

**Abstract** — A major challenge in a collaborative environment is to devise an efficient file sharing and adaptation mechanism. Through this, the users at different nodes can achieve the highest degree of collaboration. Some authors have already proposed file sharing and adaptation framework. As per their proposed framework, users are allowed to share adapted files among them, invoking their file sharing and adaptation service built on the top of advanced collaborating environment (ACE). For file adaptation, a hybrid approach has been mentioned for adapting files which considers user's preferences as well as user's device capabilities. The goal of this adaptation approach is to provide the best possible adaptation scheme and convert the file according to the user's preferences and device capabilities.

In this paper, we propose some new features for file sharing and adaptation framework to have faster and more efficient and meaningful collaboration among users in advanced collaborating environment. We are proposing a Key based registration system as well as an algorithm for Key generation to automate the registration process for slave ACE nodes. We also propose an automated mechanism to distinguish trusted (registered) Slave ACE nodes, which are privileged for p2p file sharing under certain conditions. This approach will completely eliminate the manual intervention in the purposive node selection process. Moreover there would be a network traffic monitoring process which will radically reduce the network overhead to the master ACE node and introduce faster network collaboration in a distributive manner. Consequently, the approach leads towards better collaboration among the users of ACE.

**Index Terms** — P2P File Sharing, Node Registration, Authentication, Collaboration, Cache Optimization.

## I. INTRODUCTION

The notion of advanced collaborating environment is essential to provide interactive communication among a group of users. The advancement in the field of networking and multimedia technology has outmoded the traditional video conferencing concepts. The 3R factor that is- Right People, Right data and Right time, is the major concern of ACE, in order to perform a task, solve a problem, or simply discuss something of common interest [1].

Figure 1 depicts the concept of Advanced Collaborating Environment (ACE), where media, data, applications are shared among participants joining a collaboration session via multi-party networking [2]. Each ACE node has a couple of audio/video/interaction devices,

LCD/projector/tiled display systems, and a number of support machines. Some early prototypes of ACE have been mainly applied to large-scale distributed meetings, seminar or lectures and collaborative work sessions, tutorials, training etc [3], [4].

Access Grid is a group-to-group collaboration environment with an ensemble of resources including multimedia, large-format displays, and interactive conferencing tools. It has very effectively envisioned the implementation of ACE in real life scenario. Venue server and venues concepts come from the Access Grid multi party collaboration system [4], [5]. Venue server is the server component for venues. Node represents the aggregation of hardware and software for participating in a meeting which is same as ACE nodes in ACE environment. Moreover, Venue Server has Data Store for each venue registered to it. Venue Data Store holds all the shared files from different users in the venue.

We would like to define two new terms which will be used for the rest of our paper.

- **Master ACE Node:** It is a kind of ACE node which has the capability to directly communicate to Venue through venue client as well as Venue Server. From the device configuration point of view, it has higher configuration as accessories like HD camera, microphone etc. are attached to this node.

- **Slave ACE Node:** Slave ACE node has less capabilities compared to Master ACE Node in terms of device configuration as well as it cannot communicate to Venue and Venue Server directly. Slave ACE node will be connected to a Master ACE node and all the functionalities needed for users in Slave ACE node are achieved through Master ACE node.

Services built for ACE environment also have been integrated to Access Grid. Here, it may be noted that, we use both the term 'node' and 'device' which are actually contain the same meaning in the later portion of the thesis. The rest of the paper is organized as follows. Section 2 begins the discussion of related work. In Section 3, the Problem Statement is specified clearly. In section 4, our contribution through this paper is evidently described. Section 5 describes our proposed mechanism followed by implementation progress and issues in section 6. Finally, we draw conclusion and talk about some of our future works in section 7.

Fig. 1 Advanced Collaborating Environment (ACE)

## II. RELATED WORK

Much research has been initiated in the area of context-aware computing in the past few years. Many projects have been initiated for developing interactive collaboration. These projects enable users to collaborate with each other for sharing files and other media types.

The Gaia [8], [9], [10] is a distributed middleware infrastructure that manages seamless interaction and coordination among software entities and heterogeneous networked devices. A Gaia component is a software module that can be executed on any device within an Active Space

Gaia a number of services, including a context service, an event manager, a presence service, a repository and context file system. On top of these basic services, Gaia's application framework provides mobility, adaptation and dynamic binding of components.

Aura [11], [12] allows a user to migrate the application from one environment to another such that the execution of these tasks maximizes the use of available resources and minimizes user distraction. Two middleware building blocks of Aura are Coda and Odyssey. Coda is an experimental file system that offers seamless access to data [10] by relying heavily on caching. Odyssey includes application aware adaptations that offer energy-awareness and bandwidth-awareness to extend battery life and improve multimedia data access on mobile devices.

The work on user-centric content adaptation [13] proposed a decision engine that is user-centric with QoS awareness, which can automatically negotiate for the appropriate adaptation decision to use in the synthesis of an optimal adapted version. The decision engine will look for the best trade off among various parameters in order to reduce the loss of quality in various domains. The decision has been designed for the content adaptation in mobile computing environment.

## III. PROBLEM STATEMENT

In this thesis, we have tried to enhance the efficiency of file sharing and adaptation framework described in [6], [7] by introducing Key based registration and automated trusted node identification to facilitate systematic file uploading and sharing, cache optimization techniques for

effective and efficient handling of files. These new features will establish the framework as an organized system and allow users at Slave ACE nodes to share files in an efficient and faster way. Thus our problem statement may be summarized as follows:

*To provide secured registration as well as to set observation based privileges to nodes for efficient file uploading and sharing. Also to provide effective cache optimization techniques for better and intelligent collaboration among the users and efficient handling of files.*

## IV. OUR CONTRIBUTION

File Sharing and Adaptation Framework illustrated in [6], [7] include file sharing and data adaptation service. File sharing service is demonstrated by the realization of data adaptation service. These two services are very much necessary to provide effective collaboration among users in advanced collaborating environment. But there are some problems associated with this approach. As for example, in the existing framework, the slave ACE nodes are registered by their MAC addresses which are not unique in every cases. Again another drawback is, the node registration for uploading files was a completely manual process executed by the network admin, which doesn't have strong ground on historical data analysis. Moreover, frequent requests from different nodes could potentially increase the network overhead towards Master ACE node and there is no systematic solution of this problem.

In this paper, we tried to identify these problems and provide some effective solutions to address these issues. To ensure a secured registration we propose a **key based** mechanism for **user registration** to solve the problem with the MAC address. To increase the efficiency of the whole system we introduce **automated trusted node registration** which encompasses different observation phases. For solving the **cache optimization** issues, we have proposed some methods related to cache optimization so that the overall framework can work more efficiently.

Thus, the comparison shows that our work will definitely encompass a meaningful advancement over the aforementioned work in the issues of secured user registration, node registration automation, reducing the network traffic at a central point of the system and increased collaboration among users through P2P file sharing to some extent.

## V. PROPOSED MECHANISM

### A. Definitions:

#### User Registration:

In Access Grid Collaboration Environment the User Registration is normally done by providing Email address along with other necessary information. As per our proposed system, each user will be given a Key for

registration to avoid the complexity with the MAC address based registration.

#### Algorithm for Key Generation:

For generating a unique key we simply append the registration date and time with the given MAC address of the user. Thus the string becomes:

Unique Key = Registration date-time + MAC address.

#### Observation for trust-based nodes:

In our proposed mechanism the observation is done upon some specific criteria.

**Pre-trusted Node:** The system keeps track on the login period and downloaded file amount of a registered node. According to this data analysis some nodes get identified as Pre-trusted Nodes. Now they can upload files to the venue server up to a limited extent.

**Trusted Node:** For trusted node identification the system keeps track on the login period, downloaded file amount along with upload amount and frequency. Being a Trusted Node, a user can upload unlimited amount of files to the venue server also get privileged for p2p file sharing.

#### Requested node:

A Slave ACE node that requests for a file to Master ACE node is termed as Requested Node.

Fig. 2 Action flow of Updating node privilege.

#### B. Action Flow of Prototype Implementation

##### Action Flow for Updating Node Privilege:

In this process the master node performs a periodical check to the database to update the list of the trusted nodes. There are three different conditions. Firstly, for an un-trusted node, if the login time and download limit exceeds, it gets a promotion to be noted as pre-trusted node. Secondly, for a pre-trusted node, if the download limit and login time exceeds the given bound then it is promoted as trusted node. Finally, in case of a trusted node, if the user uploads any malicious file ever, it is demoted to the un-trusted state. Otherwise the state remains same. Figure 2 depicts the mechanism for updating the node privilege.

##### Action Flow for File Uploading Mechanism:

At first, user connects from Slave ACE node to Master ACE node. S/he needs to provide e-mail address, the assigned unique key and Master ACE node address. Then, the system checks whether the user already has a valid account with the system or not. If not then a **unique key**, generated for that particular node and user profile form are provided to that user for getting registered.

Fig. 3 Action flow of File Uploading mechanism.

If the node has already been registered then the system checks whether the node is trusted or not. If trusted then the user can upload any amount of files to the venue server. If not trusted then the system checks whether it is pre-trusted or not. If not then, the user is identified as a normal node and cannot upload any file.

Now if the user is a pre-trusted node, then the system checks if it is below the assigned limit for uploading files then allowed uploading new files. Otherwise upload is restricted. Figure 3 depicts the File Uploading mechanism of the system.

##### Cache Optimization Mechanism:

According to [7] file cache was maintained considering the hit ration of any requested files. A periodic checking (once per week) was mentioned for accomplishing the deletion of the files. The problem is an important factor, Cache size was not taken into account in that instance. Basically the deletion of the files from cache should be based on the availability of space in the cache.

When the number of hot files is increased then the cumulative size of these files would be an issue. For handling such circumstances a ranking using the hit ratio formula  $H = (\text{File counter value} / \text{Total Number of requests arrived}) \times 100\%$  should be maintained. These

files are sorted according to the rank and maintained in a queue.

The size of the cache is to be given by the system Admin. A list is maintained and the cache is filled up according to the descending rank order of the list. The list is updated each time a new file is requested and as its hit ratio increases the order may reshuffled. The least popular files are deleted from the cache. Thus the cache is always occupied by the most popular adapted files.

Previously in [7] all the adapted versions of a single file were kept in the cache. In our proposed system only the most frequently requested adapted versions will be kept in the cache. Other versions would be removed from the cache. To clarify this thing an example is given in Table 1.

TABLE I  
Example of hit\_counter (see figure 6 ) Table

| hit_file_id | counter | file_id | adapted_scaling | adapted_sharpness | adapted_color |
|-------------|---------|---------|-----------------|-------------------|---------------|
| 1           | 18      | 5       | 30              | 25                | 30            |
| 2           | 2       | 5       | 40              | 25                | 28            |
| 3           | 1       | 10      | 30              | 25                | 55            |

Suppose, a file (file\_id 5) with dimensions (30,25,30) is requested 18 times for download. Then same file (file\_id 5) with dimension (40,25,28) is requested twice. Since the dimension is different there is a new entry in the table, though the file is same. Now as the adapted version (30,25,30) is more frequently requested, so the other entry of the file is removed from the cache. So the status on\_cache for the adapted version (40,25,28) is given false.

## VI. IMPLEMENTATION PROGRESS & ISSUES

### A. Currently Implemented Modules

**Master File Sharing Service:** It had been implemented as an AG shared application. That is why, it implemented in Python. This module retrieves file from Data Store at venue server and sends this file for appropriate adaptation.

**Slave File Sharing Service:** It had been implemented as stand-alone application. It was implemented in Python. It provides the interface to the user for entering venue URL and selecting the desired file.

**Data Adaptation Service:** It is a stand-alone application. It had been also implemented in python. That module has a decision engine which provides the appropriate adaptation scheme for converting the original file. At the beginning, the user enters his/her e-mail address and preferred file type for sharing. Then, he/she presses the appropriate button for connecting Master ACE node (see figure 5). After pressing the connect button the master file sharing service will connect to the venue data store and retrieves file of user mentioned type. Then, the user will select one of the files. The specified file will be downloaded through the master file sharing service, the decision engine takes the decision of selecting appropriate adaptation method and then it will be passed to the data adaptation service. The function DataAdapter() takes the file and convert it based on the decision provided by the decision engine. Then adapted file will be sent to Slave

### B. Methods to Follow for Implementing New Features

Figure 6 shows the overall design of our proposed framework to enhance the already developed framework described earlier. The basic requirement of the file upload feature is the trusted node authentication. As per our proposed mechanism the Pre-trusted and trusted nodes are automatically validated by the system based on some periodic data analysis. As depicted in the schema diagram (see figure 7), the unique\_key is the main factor which is set by the key generation algorithm, used to identify each of the nodes separately. The Pre-trusted nodes can upload the files up to a limit. The limit can be set depending on the application environment. The trusted nodes are facilitated with an unlimited amount of file uploading capability.

There are features of the frame work given in [7] like, hot file and cold file identification based cache updating, hit ratio based advertise multicasting etc are kept intact in our system. Additionally here the system keeps track of the downloaded file in the downloaded\_file\_tracking table.

Another feature of our proposed system is to optimize the cache automatically. This method has been stated clearly in the earlier section. Cache optimization technique will surely reduce the burden to the system to store so many files as well it will increase the throughput of the overall system.

Fig. 4 Screen Shot of Previous work in [6]

Fig. 5 Block Diagram of the Proposed System

Fig. 6 Schema Design for Backend Database

## VII. CONCLUSION & FUTURE WORK

In this paper, we have presented automated and network efficiency related features for file sharing and data adaptation framework in ACE. Our proposed features have made the framework more organized and enables the users to share adapted files faster and intelligently. Moreover, cache optimization technique has added a new dimension for effective handling and storage of files. These features together realize the improved file sharing service.

Lots of interesting works are to be done in the near future for efficient file sharing and adaptation service. An interesting filed can be Context Aware System that deals with issues like pattern matching and user requirement prediction, which will ensure higher degree of user collaboration.

We believe that our effort will certainly play a leading role for overcoming the deficiencies of this framework and also break new ground for more advancement in this field of research. Hopefully, our prototype implementation will be considered as a leading work in this domain in near future.

**Abstract** — Reengineering a legacy system to provide Web Services is a great challenge. Wrapping legacy systems is a proper solution to expose legacy program functionalities as Web Services. In this paper we propose a new approach in two phases to integrate legacy programs written in legacy languages such as C or Pascal into Web Services. This will be done by analyzing the legacy program and creating a Service Bus Class. Also, an automatic wrapping tool is developed to generate Web Services and related source code in Microsoft .Net environment. To evaluate this approach a legacy student learning program was wrapped into Web Services.

**Index Terms** — Legacy Programs, Service Bus Class, SOA, Web Service, Wrapping.

## I. INTRODUCTION

The software portfolio of many organizations consists of legacy systems which cannot be simply discarded [1]. These systems are valuable assets for organizations. They have been evolving with new emerged technologies in rapidly changing business environment. On the other hand, Web Services technology and Service-Oriented Architectures (SOA) are rapidly developed and widely supported. However SOA architecture implementation requires IT organizations to evaluate their systems architectures and determine how they will deliver Web Services. One aspect of this great issue is to deal with legacy applications which are running smoothly and performing critical tasks, but were built without taking the advent of new technologies. These applications built at high cost during several years have knowledge locked within them and need to be adapted to SOA.

Indeed, the more application software is used the more reliable it will be. Apparently, organizations prefer not to miss their existing reliable application software when applying new technologies to extend their software capabilities. On the top of that it is not economical to discard application software which has been developed and completed within a period of time by spending high expenses. Therefore, it is observed that application software developers seek for cost-effective approaches to support new business needs by leveraging and extending

existing software systems. Organizations should allow flexible and loosely coupled integration and communication between business entities. Tightly coupled applications should be transformed into flexible reusable building blocks of future systems. To achieve this, web service layers could be wrapped around existing program components, such that the component could be accessed through the web services [1][2][3]. An interesting classification of approaches for integrating legacy systems in modern environments has been presented by Zhang and Yang [18] who distinguished between the classes of black-box re-engineering techniques, which integrate systems via adaptors that wrap legacy code and data and allow the application to be invoked as a service and the class of white-box re-engineering techniques, which require analysis and modification to existing code in order to expose the system as Web Services.

Here, the main challenge is to remove the burden of handing code custom wrappers and connectors for legacy programs. Custom coding needs time, resources, and money. Although, there are some automatic and semi-automatic tools to wrap legacy programs, these tools are mostly dependent on their vendors and there is not enough accessible information about them. Also they usually work on specific programming languages.

The importance of Wrapping and Web Services motivated us to propose a new approach and an automatic wrapping tool to expose legacy program functionality written in legacy languages such as Pascal into Web Services. The proposed approach consists of two stages of analyzing and web service wrapping of legacy code. In the analysis stage reverse engineering techniques is applied to extract the functions within a given code. The extracted methods are then presented to the user to select a number of them. In the wrapping stage, a class comprising the selected methods is created. This class is then scanned by our web service wrapping tool, to convert the class methods into web services.

The paper is organized as follows: The proposed approach is presented in Section 2; the design and

implementation of Wrapper tool is demonstrated in Section 3; an example of wrapping a legacy program into Web Services and evaluation is presented (given) in Section 4; section 5 concludes the paper with suggestion for the future work.

#### A. Related Works

There are some works done on wrapping mechanism of existing programs to work in modern environments. For example, authors in [3] analyzed the different ways in which a web-based solution could be provided for the technological requirement of legacy systems and focused on the web-based development solutions. Some of the challenges inherent in migrating to Web Services are outlined in [4].

In [5] Authors used XWrap software migrating web sites and generating web services, automatically. A mechanism of Web Service gateways in which existing web sites are wrapped by several Web Service wrappers is proposed in [6]. Some of the approaches convert web sites by the means of XML and the legacy valuable functions are extracted and wrapped [7].

The efforts on the AgentEvo project, which develops an evolution approach to reengineer legacy systems into agent-based Web Services are reported in [8]. Also, Microfocus has developed a DLL object. The object can be uploaded in MS IIS to supply ASP programs with the access and call to COBOL subroutines [9].

Canfora Method can be used for the system includes user interface and has appropriate interaction with users. In this approach, a user interaction model is created and a wrapper is generated that uses a Finite State Automata to simulate different system states on the basis of the user interaction [10].

Indeed, the authors in [11] uses a gradually migration strategy to keep object oriented programs and legacy system components all together, simultaneously. In this strategy, a wrapper presents a user interface that enables new programs to communicate with legacy system components by message interchanging.

Sneed in [12] has defined a methodology to wrap legacy applications for reuse in a Service Oriented Architecture. He has approved that business functions can be extracted from existing programs, wrapped and integrated into an e-business application framework.

The authors in [13] designed a Web service conceptual architecture to be used as a template to make legacy applications available as Web Services. They have shown how it is possible to change proprietary interface into those based on open standards as needed for dynamic e-business. They also described how transaction management can be handled, without changing the existing system used by the legacy application.

A web service wrapper is implemented in [14] to extend the functionality of a JAVA RMI application hosted in an organization Intranet such that it can be executed by clients outside the Intranet using standard Protocols such as HTTP and SOAP.

## II. APPROACH REVIEW

For companies to stay competitive, it has become important to interconnect seamlessly their databases, applications and legacy systems to a coherent IT infrastructure [15]. Web Services are regarded as the key technology for implementing widely distributed applications based on loosely coupled systems [16]. It is a very efficient way for developers to reuse existing core business in a legacy system. The summary of the proposed approach is shown in Fig.1.

Fig.1. Wrapping Legacy Program Review

The main goal is to surround legacy programs with a wrapper and make it accessible in SOA.

#### A. Proposed Approach for Wrapping

In order to make legacy programs to be accessible with modern web based application, we propose a new approach. Our approach is proposed in two phases: The first phase includes analyzing the legacy program and determining the way of using its functions to the web environment. There are four steps to do this: Evaluation, Conversion, Reengineering and Web Service Generation. The result of this phase is a new code that contains the valuable functions of the legacy program. The analysis of the system in White Box method is shown in Fig.2.

Fig. 2. Migrate legacy code in White Box method

This phase can be done through eVolution 2000 – the product of TSRI Company [17]. If the Black Box method and reverse engineering is used, the above process will be changed and there is no need to reengineer and generate object oriented model.

In the second phase, by using Visual Studio .NET and a proposed developed tool, wrapping legacy program into Web Services can be done. The Service Bus Class prepares the interested functions to be wrapped into Web Services. This process is shown in Fig.3.

Fig. 3. The proposed process of wrapping legacy function into Web Services

### B. The Service Bus Class

The Service Bus Class acts as an intermediate between legacy system and Web Services. Its main duty is migrating legacy function to external environment. This class must conform to the following characteristics:

- (1) Since only public classes are accessible from outer classes, the accessibility of this class must be public.
- (2) The methods name of this class and legacy functions must be the same. Also, they should have the main parameters of legacy function.
- (3) If legacy function contains global variable and the White Box method is used to migrate legacy code, this variable should be added to the method call parameters.
- (4) All the communication problems with legacy program should be solved in this class and its methods.

### C. Web Service Wrapper Operation

Web Service wrapper is used to enable communication between legacy program and web based one. The task of the wrapper is to wrap the legacy function into Web Services and generate related source code directly. The designed wrapper is divided into two layers: Display Layer and Function Layer. Fig.4 shows the structure of the wrapper.

Fig. 4. Wrapper Structure

The Display Layer is to show the web service code created by the function layer. The Function Layer of wrapper implements the wrapping of method. It contains code generator. Code generator generates the Web Services code according to the properties of Web Services and Web Service Methods. Wrapper accepts the Web Service requests as a SOAP message and deserializes it, then calls the corresponding function. It also receives the response and parses and serializes it, then sends it back to the requestor as a SOAP message. Also, this approach enables asynchronous function calls. Web Services can be called asynchronously, by using asynchronous pattern call in .NET.

### III. TOOL IMPLEMENTATION

Visual studio .NET environment is extendable. Add-in projects are one of these extending methods. To create an appropriate tool in developing applications, Visual Studio .NET automation model can be used. This model is also known as extensibility model. It is a programming interface which enables accessibility to the underlying Microsoft Visual Studio procedures and manipulates them. In the other words, Add-in programs are compiled ones changes the programming environment. We used this facility to generate Web Service wrapping code. This tool enables us to select a method in the Service Bus Class and generate Web Service code, automatically. The generated web service code will be inserted to a Web Service project. Executing Web Service project makes Web Service methods to be accessible on the web.

The designed tool consists of two parts: Analyzing area of source code and assistant display area.

Analyzing area: by reading project file, developed tool parses the source code in the selected Microsoft .NET Solution, and specifies the file structure composing of Namespaces, Classes, Methods, Parameters, types of parameters, and return values of methods.

Assistant display area: The tool shows the wrapped source code of a function and displays them in the assistant display area. When a function is wrapped into Web Services, the wrapped Web Services code is displayed here. Fig.5 shows a sample code wrapped into a Web Service.

Fig. 5. Web service wrapped code

On the basis of the analysis of the legacy application, developers will decide which methods can be wrapped into Web Services methods according to the needs of

integration. This tool can simply be installed in the programming environment.

### IV. EVALUATION

To evaluate the proposed solution, we took a Student learning system written in Pascal language. Its source code and executable file is also accessible. Based on the analyzing and understanding of the legacy application, we encapsulated the necessary application functions into Web Services and provided the methods for other systems to access these Web Services.

In the student learning system, the methods of inquiring and analyzing the student personal information are encapsulated to the Web Services and are accessible to the modern web based applications. Fig.6 presents this program call of a part of this system in DOS environment.

Fig. 6. Dos student learning system call

As the picture shows, the program is command line executable by entering required parameters. Below statement shows this program call.

C:\>StudentNew.exe 4 8404001-3 output.txt

According to the above analysis, there is no need to analyze program source code and the functions are available through that statement. So, we use Black Box method and only program inputs and outputs and their calling method would be specified in Service Bus Class.

After identifying the above result, the program should be entered into Visual Studio environment and wrapped into Web Services. To do this, according to the proposed approach, the functions should be identified. Then a Service Bus Class should be created and the interested functions should be wrapped and conveyed to the web with the proposed tool. At this step, a Service Bus Class named ServicePortClass1 is created. This class has a method named GetStudent. Input parameters of this class are in the form of DOS calling format. The first Parameter

is the type of execution, the second parameter is StudentID and the third one is the response result (Student Information). In this sample the input and output files should be ready for legacy program execution .So, before execution starts the input file is uploaded on the server and new Web Service named UploadFile is added to the Web Services. To generate Web Services the proposed tool will be used. The following code is generated automatically:

```
#region Wrappings For GetStudent
[WebMethod]
public string GetStudent(int type,string SID,string OutFileName)
{
 StudentNew.ServicesPortClass1 theServicesPortClass1=new
 StudentNew.ServicesPortClass1();
 return theServicesPortClass1.GetStudent(type,SID,outFileName);
}
#endregion
```

By adding this code to a Web Service project and executing it, the service will be available on the web. To access the Web Service, different applications in diverse platforms can be used. For example a win32 application in C# language was created to use the produced service. Fig.7 shows the user interface of the client program:

Fig. 7. The sample client program to call produced Web Service

This program calls the generated Web Service and makes the legacy DOS based function to execute.

By using the proposed approach legacy programs can reuse as a service in the web environment. Modifiability, Portability, Flexibility, and Interoperability are the main motivators behind the use of wrapping as Web Services. Developers of Web Services need not know exactly how these services are used in terms of user interfaces. They should focus on implementing business logic or server resources accessing functions with clearly defined program interfaces. Front-end applications may call Web

Services to access these important business functions and resources remotely. By publishing their Web services via UDDI or other registries, companies can offer “software as a service.” They can provide their Web services on a subscription or per-usage charge basis to generate a new revenue stream.

Our approach allows the users to submit a request and then continue his/her work without being blocked. Therefore, the response time for the clients is the sum of the time the request sent to the application server, the time the Application Server allocates a unique handle for the request, and the time for the handle to travel back to the clients. We recorded the response time in the scenario of executing program in its local legacy environment and in web environment by wrapping it into web services through our proposed tool. The analyzed server runs on the windows server platform with 2 GHz CPU and 1 MB RAM. As shown in Fig.8, our approach has some overhead in executing legacy program, because of the network traffic and wrapping operation. This overhead can be ignored because of the benefits of making legacy functionalities accessible to the web environment and provide flexibility for other web services and clients to consume legacy services.

Fig. 8. Running time evaluation of legacy program

## V. CONCLUSION

Vast majority of the enterprises consists of the legacy applications. Re-architecting IT infrastructure to Service Oriented Architecture is impossible without taking these legacy applications along. The evolution of IT industry produced numerous automated tools to design and deploy Web Services. However, the approaches used by those tools were not explicitly pointed out. In order to help software developers to use legacy systems with Microsoft .Net, and generate Web Services or Web Services code according to the properties of Web Services and Web Services method, this paper designs and develops an aided tool to wrap legacy functions as Web Services. According

to the above implementation, the integration cost of legacy systems with modern technologies and programs decreases noticeably, Because the existing tools was used and the black box method which does not contain the source code analysis is also used to expose legacy functions to modern environments. Indeed low migration time increases the performance of the generated Web Services.

There is possible to extend the existing tools. The possibility of making changes in Service Bus Class with modern technologies and advances without making any changes of the old system is the other advantage of this approach.

#### A. Future Works

Although an unified approach for the proposed tool with Microsoft .Net has been presented, there are still issues to be addressed:

- (1) More common programming languages such as Java can be used to extend this process.
- (2) Because of the weak quality of legacy code, the more qualified code generation in automatic wrapping and executing will increase effectiveness.

# Speech Enabled Operating System Control

Md. Abdul Kader, Biswajit Singha, and Md. Nazrul Islam

Department of Computer Science and Engineering  
Khulna University of Engineering & Technology  
Khulna-9203, Bangladesh

E-mail: {kdr2k4, biswa2k4cse, kuet\_nazrul2k}@yahoo.com

**Abstract** — Our goal is to provide the computer with a natural interface, including the ability to understand human speech. For this purpose, we propose a way how to operate an Operating System with voice command. At first, the user initiates a given command by his voice through the microphone then the recognition software of the proposed system will take over to recognize the command. If the recognition is succeeded or matched with one of the given voice command then it will perform the operation on the Operating System according to speaker's speech command. In our proposed system we have used Markov chain model for voice recognition process and Voice-XML for creating the voice grammar in the software part. It has the flexibility to work with the speech of any user means and remove the problem of 'hesitation' which is very effective for spontaneous speech recognition. The proposed system minimizes the error rate up to 30% which is very precise for any speech recognition system.

**Index Terms** — Voice recognition, Voice-XML Operating System, Speech, Voice command.

## I. INTRODUCTION

Recent years it has been seen that the improvements in the quality and performance of speech-based human-machine interaction is steady. The next generation of speech-based interface technology will enable easy to use automation of new and existing communication services, making human-machine interaction more natural. For the disabilities people the absence of the data bases and diversity of the articulator handicaps are major obstacles for the construction of reliable speech recognition systems, which explains poverty of the market in systems of speech recognition for disabilities people [1].

If someone is unable to handle mouse and keyboard or the ports of mouse and keyboard are not functioning, properly there exist some other means to access operating system. "Speech" may act as one of them. There is a growing demand for systems capable of controlling Operating System using only the voice of a person. And this paper represents a way how to control the OS by using voice command. First of all, speech is recognized by the system software and if the speech or voice command is recognized then each and every command executes the

corresponding operation upon the Operating System. The desirable characteristics of such a system include scalability that is the efficiency of the process of speech recognition and executing the commands. When we speak, a microphone takes the analog signal and converts the analog signal from our voice into digital chunks of data that the computer analyzes. From this data the computer must extract enough information to confidently guess the word being spoken. This is not, however a small task! In fact, in the early 1990s, the best recognizers were yielding a 15% error rate on a relatively small 20,000 dictation tasks, so the controlling process is very poor. But here an efficient method is used for speech recognition, so the recognition process works very efficiently. And after getting the command the software executes the corresponding operation, so the Operating System operated very smoothly with a user's speech.

The later part of this paper shows the efficient recognition process, Markov model, voice command execution process and an example of the process for controlling the Operating System.

## II. METHODOLOGY

### A. Voice Recognition Process:

#### Step 1: Extract Phonemes

The process of speech recognition starts with a sampled speech signal. This signal has a good deal of redundancy because the physical constraints on the articulators that produce speech—the glottis, tongue, Lips, and so on—prevent them from moving quickly [4]. Phonemes are best described as linguistic units. They are the sounds that group together to form our words, although quite how a phoneme converts into sound depends on many factors including the surrounding phonemes, speaker accent and age. English uses about 40 phonemes to convey the 500,000 or so words it contains, making them a relatively good data item for speech engines to work with. Here are a few examples of phonemes and words:

|    |                 |    |                   |
|----|-----------------|----|-------------------|
| Aa | F <u>a</u> ther | T  | T <u>a</u> lk     |
| Ae | C <u>a</u> t    | Th | Th <u>i</u> n     |
| Ah | C <u>u</u> t    | Uh | B <u>o</u> ok     |
| Ao | D <u>o</u> g    | Uw | T <u>oo</u>       |
| Aw | F <u>ou</u> l   | Zh | plea <u>s</u> ure |
| Ng | S <u>i</u> ng   |    |                   |

Fig-1: Some phonemes and words

Phonemes are often extracted by running the waveform through a Fourier Transform. This allows the waveform to be analyzed in the frequency domain. It is probably easier to understand this principle by looking at a spectrograph. A spectrograph is a 3D plot of a waveform's frequency and amplitude versus time. In many cases though, the amplitude of the frequency is expressed as a color (either grey scale or a gradient color). The spectrograph of saying "Generation5" is given by the following Fig-2:

Fig-2: spectrograph of saying "Generation5"

For comparison purpose, another spectrograph of the "ss" bit of assure (this is a phoneme) is also given by the following Fig-3:

Using this, can anybody identify where is "Generation5" and the "sh" of Generation5 in the spectrograph? Note that the timescales are slightly different on the two spectrographs, so they look a little different. It is relatively easy to match up the amplitudes and frequencies of a template phoneme with the corresponding phoneme in a word. For computers, this task is obviously more complicated but definitely achievable [3].

Fig-3: spectrograph of saying "ss"

## Step 2: Markov Models

Now that the computer generates a list of phonemes, then obviously these phonemes have to be converted into words and perhaps even the words into sentences. This can be very complicated indeed, especially for systems designed for speaker-independent, continuous dictation. However, the most common method is to use a Hidden Markov Model (HMM). Basically, think of a Markov Model (in a speech recognition context) as a chain of phonemes that represent a word. The chain can branch, and if it does, is statistically balanced. For example the following Fig-4 shows a Markov chain:

Fig-4: Markov chain

Note that the Markov Model in Fig-4 represents both the American English and the (real) English methods of saying the word "tomato". In this case, the model is slightly biased towards the English pronunciation. This idea can be extended up to the level of sentences, and can greatly improve recognition. For example:

Recognize speech  
Wreck a nice beach

These two phrases are surprisingly similar, yet have wildly different meanings. A program using a Markov Model at the sentence level might be able to ascertain which of these two phrases the speaker was actually using through statistical analysis using the phrase that preceded it. For speech recognition this process adopts all the above processes.

## B. Command Execution Process:

Fig-5: Working Procedure of this software

**User:** At first user is giving command.

**Microphone:** In this step the command is received by microphone and the microphone converts sound wave into electrical pulse.

**Sound Card:** In this step the sound card converts electrical pulse into digital signal.

**Speech Recognition Engine:** In this step Speech Recognition Engine converts digital signals into phonemes.

**Command:** Finally we get text command.

**Operations:** For every command the software performs the corresponding operations.

There are about hundred commands exists for this software, some pre-commands & corresponding operations given in the following table 1:

| Command        | Operation                      |
|----------------|--------------------------------|
| MyComputer     | Explore My Computer            |
| StartMenu      | Explore Start Menu             |
| Up             | Arrow Key up one unit          |
| Down           | Arrow Key down one unit        |
| Left           | Arrow Key right one unit       |
| Right          | Arrow Key left one unit        |
| CursorUp       | Mouse pointer up               |
| CursorDown     | Mouse pointer down             |
| CursonLeft     | Mouse pointer left             |
| CoursorRight   | Mouse pointer right            |
| Back           | Back space                     |
| CloseTheWindow | Close window                   |
| Enter          | Enter                          |
| Ok             | Mouse left button single click |

Table-1: some commands and corresponding action

### Example of some commands action:

At first microphone receives our speech as sound wave. This sound wave is converted into digital signal by the sound card. This digital signal is converted into phonemes by speech engine. This phoneme is our text command. And this text command is executed by our Java program. We can describe this by some examples.

### Example-1:

If we want to explore my computer, we have to give command **“My Computer”**. And after command execution we can see the following Fig-6.

Fig-6: My computer exploration

### Example-2:

If we want to explore start Menu, we have to give command **“Start Menu”**. And if we want to access any kind of programs from the Start Menu, we have to give different kinds of commands such as **“Left”, “Right”, “Up”, “Down”, “Enter”**. If we give **“Up”** command then the selection moves one unit up from its current position. Giving such command we can select our destination program and to explore this program we have to give **“Enter”** command. Thus we can explore other programs according to our choice. Fig-7 shows start menu after the **“Start Menu”** command execution.

Fig-7: Start Menu exploration

After exploring **“My computer”**, if we want to open different drives we have to access these drives following the process stated in above step i.e. using **“Left”, “Right”, “Up”, “Down”, “Enter”** commands.

### Example-3:

To create a new folder we have to give **“File”** command. After opening **“File Menu”** (Fig-8) we have to give **“Down”** command. By giving **“Down”** command

we have to select the “New”. Then we have to give “Enter” command to create a new folder. Thus we can create a new folder and so on.

Fig-8: Browse file menu of MS word

To delete a folder we have to give “File” command. After opening “File Menu” we have to give “Down” command. By giving “Down” command we have to select “Delete”. Then we have to give “Enter” command. And thus we can delete a folder. We can also control the different kinds of media player by using voice command in this software.

Example-4:

If we want to search any kind of file or folder, we have to give “Start Menu” command. After exploring “Start Menu” we have to select “search” giving “Up” command. Now we have to give “Enter” command to explore “Search” after select it. We can also see this process following Fig-9.

Fig. 8: Searching a file or folder  
Example-5:

We can also write anything opening notepad or Microsoft word document. We can also access any kind of options of Microsoft word document by this software. Fig-9 and Fig-10 shows the text editors.

Fig-9: Writing in notepad

Fig-10: Writing in MS word

Example-6:

We can move the cursor from one position to another position of the window. If we want to move the cursor from:

1. Left to Right we have to give “**Cursor Right**” command.
2. Right to Left we have to give “**Cursor Left**” command.
3. Up to down we have to give “**Cursor Down**” command.
4. Down to up we have to give “**Cursor Up**” command.
5. Left Up corner to Right Down corner we have to give “**Right Down**” command.
6. Left Down corner to Right Up corner we have to give “**Right Up**” command.
7. Right Down corner to Left Up corner we have to give “**Left Up**” command.
8. Right Up corner to Left Down corner we have to give “**Left Down**” command.

After giving any of the above cursor related command we have to give the units (10,20,30,40,50,60,70,80,90, 100, 200,300,400,500) to move the cursor.

We can also maximize and minimize the window giving the “*Maximize*” and “*Minimize*” command respectively. Following such method stated above steps we also access another options of our Operating System.

### III. TECHNOLOGY & FEATURES

We have developed our software in Visual C++ & Java [6]. For voice control purpose we have used Microsoft Speech SDK (Speech Development Kit) [5] SAPI. We have also used the internal Speech Engine for Recognition purpose and XML [2] grammar formation for creating grammar file. There are some features of this software:

1. It is Speech Application Programming Interface (SAPI) implemented software.
2. This software is designed to control Operating System according to the command of a person’s voice.
3. By using this software a number of operations on the Operating System are executed.
4. It can be used as Voice Controlled Operating System software.
5. It is user friendly, so any user can handle it easily.

### IV. UTILITIES & LIMITATIONS

Natural voice recognition system faces the complex problem of spontaneous voice recognition, namely hesitations, out of vocabulary. An efficient dialogue design can greatly improve the performance of the voice interface.

This software helps those people who are physically disable and doesn’t have the liberty of using mouse and keyboard as external input device.

If the ports of mouse and keyboard do not work properly then one can also operate operating system using this software. It may save our cost from purchasing of mouse and keyboard.

Speech Recognition Engine takes some acoustic signals which are not required for our command. For such acoustic signals sometimes our command cannot be recognized properly and is executed in a changed manner. This is the main limitation of this software.

### V. FUTURE PLAN

We believe that we are quite successful in our initial stage. But there are some limitations in our software. We are hoping that we will overcome these limitations and

add extra features in future if possible. Some of the developments that we intend to do in near future are given below that is we are determined:

1. To develop our voice command in Bengali language besides English.
2. To use Bluetooth Technology for the voice command input.
3. To remove the acoustic signals that is not expected in our software.

### VI. CONCLUSION

The interface of the software is user friendly. This software is applicable for Windows XP operating system. As maximum computer users feel comfortable to use this operating system, our software may satisfy their need to access operating system through their voice command which will save time and make life easier. It is capable of meeting the requirements of people unable to use their hands. We are hoping that if we can release our software commercially in software market then it could take a good standing among other similar projects. And if we are provided with sufficient technical and financial help, we can develop this software more effectively and take it to next level. We are looking forward to improve our software’s efficiency and application to make it truly platform independent.

### ACKNOWLEDGEMENT

The authors wish to acknowledge the Professor **Dr. M.M.A. Hashem**, Head of the department of CSE, KUET and lecturer **Tanay Dey**, Dept. of CSE, KUET.

# Short Text Compression for Smart Devices

Md. Rafiqul Islam<sup>1</sup>, S. A. Ahsan Rajon<sup>1</sup> and Anonda Podder<sup>2</sup>

<sup>1</sup>Computer Science and Engineering Discipline, Khulna University, Khulna-9208, Bangladesh.

<sup>2</sup>Leads Corporation, Dhaka, Bangladesh.

**Abstract** — Short Text Compression is a great concern for data engineering and management. The rapid use of small devices especially, mobile phones and wireless sensors have turned short text compression into a demand-of-the-time. In this paper, we propose an approach of compressing short English text for smart devices. The prime objective of this proposed technique is to establish a low-complexity lossless compression scheme suitable for smart devices like cellular phones and PDAs (Personal Digital Assistants) having small memory and relatively low processing speed. The main target is to compress short messages up to an optimal level, which requires optimal space, consumes less time and low overhead. Here we propose a new static-statistical context model to obtain the compression. We also propose an efficient probabilistic distribution based content-ranking scheme for training the statistical model. We analyze the performance of the proposed scheme as well as the other similar existing schemes with respect to compression ratio, computational complexity and compression-decompression time. The analysis shows that, the required number of operations for the proposed scheme is less than that of other existing systems. The experimental results of the implemented model gives better compression for small text files using optimum resources. The obtained compression ratio indicates a satisfactory performance with reduced memory requirements and lower complexity. The compression time is also lower because of computational simplicity. In overall analysis, the simplicity of computational requirement encompasses the compression effective and efficient.

**Index Terms** — Short Text Compression, Syllable, Statistical Model, Text-ranking, Static Coding, Smart Devices.

## I. INTRODUCTION

Twenty-First century is the age of information and communication technology. Science through its marvelous achievements has converted this world into information and communication based global village. The prime aspect of present technology is to ensure a better way of communication throughout the world in a more convenient, easy and cost-effective way. With the aspects of cost, facility and reliability a new trend of introducing small sized devices with some sorts of computing and communicating power has established its place in the arena of research. With the voyage of introducing smart devices, the challenge of adorning them with greater and effective use has come into question. It is now a great concern to embed maximum applications within these smart devices where it is an extreme problem to provide a

low-complex and low-memory consuming version for smart devices of some prime necessary applications like data compression, which generally requires large memory and greater processing speed. Mobile communication that is a great gift of modern technology introducing the era of digital communication also suffers from the same limitation. Though crossing the boundary of voice communication, short messages communication has established its robust place in the arena of digital communication, Short Message Service (SMS) providers (usually Telecommunication Companies) have a constraint that each message should be not more than of 160 characters. This constraint is really a great limitation for frequent communication using SMS. In order to overcome this limitation, compression of the short message is a well policy. That is why; our aim is to make “Short” messages “Shorter”, expressing “Larger” feelings in “Smaller” expense.

Here we introduce a scheme of compressing short English text for smart devices like cellular phones and wireless sensors having small memory and relatively low processing speed communicating with lower bandwidth *i.e.* channel capacity. We have employed a new statistical model with a novel approach of integrating text ranking or component categorization scheme for building the model. Modified syllable based dictionary matching and static coding is used to obtain the compression. Moreover, we have employed a new theoretical concept of choosing the multi-grams, which has facilitated us to obtain mentionable compression ratio using a small number of knowledgebase entries than other methods, consuming less resource.

## II. LITERATURE SURVEY

The following sections give a glimpse of the most recent research developments on short text compression for small devices.

The recent literature regarding short text compression titled “Compression of Short Text on Embedded Systems” by Rein *et al.* proposes a low-complexity version of PPM (Prediction by Partial Matching). They use statistical models with hash table lengths of 16384, 32768, 65536 and 131072 elements requiring two bytes for each element, which results an allocation of 32, 64, 128 and

256 Kbytes of RAM respectively. If this memory requirement may be substantially decreased, we may achieve more efficient compression and hence may make the scheme usable to even very low-quality cellular phones. Another concerned approach by Rein *et al.* is “Low Complexity Compression of Short Message” [1] with “Low Complex and Power Efficient Text Compressor for Cellular and Sensor Networks” [11] are variations of [10].

“Compression of Small Text Files Using Syllables” proposed by Lansky *et al.* [2, 7] concerns on compressing small text files using syllables. To implement their concept they created database of frequent syllables. In this scheme, the primary knowledgebase size is more than 4000 entries initially. For low memory devices, it is obviously difficult to afford this amount of storage as well as to facilitate a well suited mechanism of searching; which leads our proposed scheme to redefine the knowledge base span as short as possible and hence to reduce the scope of loosely choosing the syllables or n-grams. Moreover, it may be a good idea to have specific consideration of syllable involving spaces. In [2, 7], all the training syllable entries are stored without any categorization. This often results for coding redundancy, which can be handled by integrating text ranking or component categorization scheme with syllable selection.

The model proposed by M. R. Islam *et al.* [3] uses the advantages of greedy sequential grammar transform with block sorting to compress data. However, this scheme is highly expensive in terms of memory consumption and thus not suitable for low memory devices.

In [1] the compression starts for text sequences larger than 75 Bytes, and in [10] the starting point is 50 Bytes. If it is possible to make the lower threshold value into less than ten characters, the compression may really be a “very small text” supported one that may place a new milestone in very small text file compression era. That is, our prime aim is to design such an effective and efficient “very short text compression” scheme.

### III. SHORT TEXT COMPRESSION FOR SMART DEVICES

The prime concern of this paper is to implement a lossless compression of short English text for smart devices in a low complexity scheme. The idea behind this is to make it possible to communicate more efficiently by making proper and minimum utilization of bandwidth of wireless and sensor networks for small and embedded devices. More precisely saying, the main concern is to develop a low-complexity compression technique suitable for low-power consuming small-memory smart devices especially for wireless sensors and mobile phones.

The proposed scheme is concerned with two parts. The first one consists of training the statistical model and the second provides a compression-decompression technique. Specifically saying, in analyzing step we count the frequency of representable ASCII characters. Then, we proceed by identifying the syllables (as defined by [2, 7]) of length two, three, four and five. We consider <space> as a distinct vowel and include this while counting the frequency of syllables, that is, searches for <space> either at the beginning or ending of syllable. In the step of boosting the statistical model, we consider the substrings (which were not grabbed in the phase concerning syllables) with length two to five and count frequency of each. In the second step, we employ the provided text-ranking scheme for each entry and calculate the entry index. For entries with same index, we simply sort them. In the phase of choosing entries, we give emphasis on probability distribution based text ranking, which is computed with the help of its neighbor characteristics.

As in most cases, it is unusual to have frequent match of substrings with length more than four characters, we consider maximum of five (extra one for <space>) levels to train the statistical model. In each level, multiple entries with same weightage are simply sorted over. Resultant entries are assigned with non-conflicting binary stream. When we are to compress any text, the input text is successively compared with the statistical model and for any match, the binary stream is returned as output and for mismatch in any level, the level below it is forwarded.

The total compression-decompression is expected to be performed in the following manner.

#### A. Compression Process

In the first step, we plan to employ Modified Multi-grams or Syllable Matching proposed by Lansky *et al.* [2, 7]. A static dictionary based compression scheme uses approximately the same concept as that of character masking. It reads in input data and searches for symbols or groups of symbols that are previously coded or indexed in the dictionary. If a match is found, a pointer or index into the dictionary can be output instead of the code for the symbol. Compression occurs if the pointers or index requires lower space (in terms of memory usage) than the corresponding fragments. [1, 10, 2] Though it is the basic idea behind multi-grams, we use it in a slightly modified fashion. The Knowledgebase for the multi-grams are constructed with the help of the statistics obtained by analyzing the corpuses. We have selected a number of strings and substrings, which are most frequently used in short messages (as well in as usual purposes) and have calculated the probability of using those by considering the average of the probability they appeared with their individual occurrence.

In the second step of compression, we use Static Coding. However, here the modification is made in such a way that, in spite of calculating on-stage codes we use predefined codes in order to reduce the space and time complexity. The codes for dictionary entries are also predefined. The total message is encoded by a comparatively small number of bits and hence, we get a compressed outcome. The prime fact of static coding is that, in case of dynamic coding we are to calculate the frequencies in an elegant manner. Moreover, as the dynamic codes are determined and the lengths are varied through the frequencies of the symbols it is a must to submit the codes along with the compressed data. This is a limitation of dynamic coding if the total arena of compression is low spanned and the total number of symbols is not huge. Compression of short message also suffers in this context while using other similar semi-dynamic coding. Consequently, we are to move towards static coding scheme to obtain compression of short messages. For this concerned study, we have analyzed the corpora- Bib, Book1, Book2, News, Paper1, Paper2, Paper4 and Paper5 from Calgary and Canterbury Corpus.

#### B. Decompression Process

The decompression process is performed through the following steps:

- Step 1: Grab the bit representation of the message,
- Step 2: Identify the character Representation,
- Step 3: Display the decoded message.

As all the symbols are to be coded in such a fashion that, by looking ahead several symbols (Typically the maximum length of the code) we can distinguish each character (with the attribute of Static Coding). In step 1, the bit representation of the modified message is performed. It is simply analyzing the bitmaps. The second step involves recognition of each separate bit-patterns and indication of the characters or symbols indicated by each bit pattern. This recognition is performed on the basis of the information from fixed encoding table used at the time of encoding. The final step involves simply representing i.e. display of the characters recognized through decoding the received encoded message.

#### IV. THEORETICAL ASPECT OF TRAINING THE PROPOSED STATISTICAL MODEL

The proposed scheme achieves better compression ratio with relatively low complexity by means of computational simplicity and effective expert model, which is used to train the statistical context. Firstly, the prime modification is performed in the syllable selection section of [2, 7] proposed by Lansky *et al.* In their papers, only syllables were considered by defining maximal subsequence of

vowels including pseudo-vowel 'y'. Here we propose to consider <blank space> as a *Prime Syllable*. Using <space> as a *prime syllable* may dramatically reduce the total number of characters needed to represent the message through sophisticated encoding. Secondly, the paper [2, 7] does not clearly express the criteria of choosing the training syllables for the model. The term used in [2, 7] to define the criteria of choosing syllables was simply "frequentness". However, we employ a new theoretical perspective on "Text Ranking or Component Ranking" method to choose the syllables for training our proposed model. We, in the first step count the frequency of each vowel from the standard Text Calgary Corpora. In the second step, we count the number of vowels having space either at  $(i - 1)$  or  $(i + 1)$  position with itself at position  $(i)$ . The reason of adding the with-space vowels is simply to increase the weightage of the corresponding vowels. These entries having vowels are also inserted in the knowledgebase as separate entity. In this step, we also count the statistics of consonants in order to build the dictionary or multi-grams entries. In the step of extending primary knowledgebase, proposed in papers [2, 7] the criteria was that, the frequency would be 1:65000, which results a knowledgebase size of more than 4000 entries initially. For low memory devices, it is obviously difficult to afford this amount of storage as well as to facilitate a well suited mechanism of searching, which leads our proposed scheme to redefine the knowledge base span as short as possible and hence to reduce the scope of loosely choosing the multi-grams. In the phase of choosing multi-grams, we give emphasis on Probability Distribution, which is computed with the help of its neighbor characteristics.

We employ a new Text Weighting or Component Ranking scheme to select the multi-grams that facilitates us to efficiently construct the knowledgebase. The proposed text weighting or component ranking is obtained through the following equation:

Suppose we choose a multi-grams  $D$  consisting of characters  $C_1 C_2 C_3 \dots C_n$  of length  $n$ . Thus,

$$\partial(D_{C_1, C_2, C_3, \dots, C_n}) =$$

$$\sum_{i=1}^n (\partial(D_{C_i}) - 1) - \partial(D_{C_1, C_2, C_3, \dots, C_{n-1}}) + \lambda \lambda_{C_1, C_2, C_3, \dots, C_n})$$

for  $i > 1$  and,  $\partial(D_{C_i}) = \lambda(C_i)$  for  $i = 1$ , where  $\lambda(C_i)$  is the frequency of the character  $C_i$  with assumption that each character of the alphabet must exist in the training data. And the value of  $\partial(D_{\phi})$  indicates the multi-grams index of character  $D_{\phi}$ . Here, we refer the multi-gram index obtained from  $\partial(D_{C_1, C_2, C_3, \dots, C_n})$  as the

resultant text-weightage for the text  $C_1 C_2 C_3 \dots C_n$ . For example, we want to have the probability distribution of multi-grams "and".

The steps will be: Let  $\partial(a) = x_1$ ,  $\partial(n) = x_2$ ,  $\partial(d) = x_3$ ,  $\partial(an) = x_4$ .  
Therefore,  $\partial(ana) = (\partial(a) - 1) + (\partial(n) - 1) + (\partial(d) - 1) - \partial(an) + \lambda(C_{abc}) = x_1 + x_2 + x_3 - x_4 + x_5$

Static coding is defined as a set  $S = \{B_1, B_2, B_3, \dots, B_{n-1}, B_n\}$  of binary streams, where each element of the set  $B_1, B_2, B_3, \dots, B_{n-1}, B_n$  are uniquely identifiable providing that,  $B_1, B_2, B_3, \dots, B_{n-1}, B_n$  are not necessarily to be of equal bit length. As all the elements of the sets supports our three basic points of concern- identifiability, uniqueness and variability of any encoding scheme, we are interested to use static coding. This theoretical aspect let us do not consider updating the model throughout the compression, because, firstly, updating a larger knowledgebase using a very short data is not computationally affordable and effective, secondly, a larger portion of the source code may be saved if the update is avoided resulting faster execution [1,10,11] and finally, if the training statistical data is not permitted to be updated as well as to be expanded, we may ensure a constant and consistent memory optimization for the overall compression process. That is, there is no possibility to expand the knowledgebase arbitrarily and thus there is no risk of arising the overloaded memory problem or out-of-memory problem. As the knowledgebase is not updated, the use of static coding is also perfect for the same.

## V. PERFORMANCE ANALYSIS

Though it is a general idea that compression and decompression time should have an inter-relation, the proposed scheme demonstrated a little exception. The points behind that may be summarized through the following discussions.

### A. Performance Analysis of Compression Process

Let the total number of training entries for the statistical model be  $N_g$ , where  $N_g$  is a non-negative integer and the maximum level for statistical modeling is  $L$ . The first level of the statistical model will must contain the single characters, where the total number of distinct character is  $l_1$ . For levels 1, 2, 3, ...,  $n-1$ ,  $n$  the total number of distinct multi-gram entries are  $l_1, l_2, l_3, \dots, l_{n-1}, l_n$  respectively.

When any text is to be compressed, it is hierarchically compared with each level of statistical model starting from the highest order. If there is any match, the corresponding static coding for multi-gram entry is assigned for the text. If the multi-gram entry is not found throughout the level, it is forwarded to the next level. This assignment uses efficient searching procedures. Let the code  $m$  is found at the  $i$ -th level with offset  $k$  resulting a search cost of  $S_m(l_j) + k_m$ , where  $k_m < l_i$  and,  $j=L, L-1, \dots, i-1$  with respect to search space. Here  $j$  limits from  $L$  to  $(i-1)$  instead of  $i$

decreasingly because, as we find the code in somewhere of  $i$ -th level not requiring to search the whole element-space of the  $i$ -th level, rather searching through an offset value  $k$  for  $i$ -th level, the overall search-space is  $L$  to  $(i-1)$ . That is why, for the above consequences, the total searching appears search overhead for  $(i-1)$  number of levels with additional search overhead of  $k$  elements. Here the term "search overhead" stands for the search space complexity as well as other related computational requirements. When the code matches, it is placed in output stream as character representation. This step requires padding the bit-stream and then conversion into character stream. Assume that, the process of overall conversion for each successful entry occurs with the overhead  $B$ . That is, for any multi-gram matching, the required overhead is,

$$C_1 = \sum_{j=L}^{i-1} (S_1(l_j)) + k_1 + B_1$$

Similarly,  $C_2 = \sum_{j=L}^{i-1} (S_2(l_j)) + k_2 + B_2$ , and

$$C_n = \sum_{j=L}^{i-1} (S_n(l_j)) + k_n + B_n$$

In such a way if a total of  $n$  multi-grams are identified and then encoded, the required resultant number of operations in compression process is:

$$T = \sum_{y=1}^n C_y = \sum_{y=1}^n \sum_{j=L}^{i-1} (S_y(l_j)) + \sum_{y=1}^n k_y + \sum_{y=1}^n B_y \quad (1)$$

### B. Performance Analysis of Decompression Process

For the decompression process, the text to be decompressed is converted into binary stream. If the largest code is of length  $c_{max}$  and the smallest code is of length  $c_{min}$  then the decompression process will start the searching with the  $c_{max}$  number of bits and search through the codes up to  $c_{min}$  bits by reducing one bit in each step for unsuccessful match. It is necessary to mention that, the codes with same bit length does not essentially comprise any specific level. So, to reveal the character representation for each entry  $d$  if a switch of  $h$  levels are required, where  $c_{min} \leq h \leq c_{max}$  where the maximum level is  $p$  with the matching offset for corresponding level  $k_d$ , and the assignment of the code with character representation for each successful match requires an overhead of  $B_d$ , then the overall requirement for comparing through the each level settings results (= Overhead of Searching through level + Overhead for Searching through offset + Overhead of Representation). For detecting first character the overhead is,

$$E_1 = \sum_{q=p}^h (S'_1(l'_q)) + k'_1 + B'_1$$

Similarly, for detecting the second character, the level-wise overhead will be:  $E_2 = \sum_{q=p}^h (S'_2(l'_q)) + k'_2 + B'_2$

$$\text{Hence, } E_n = \sum_{q=p}^h (S'_n(l'_q)) + k'_n + B'_n \quad (2)$$

Here,  $p = \text{maximum level}$ , and  $S'$  is a function that denotes the search-overhead for searching in element space provided as parameter of the function and  $h = \text{minimum level}$ . The computation progresses through  $p, p-1, p-2, \dots, h+2, h+1, h$ . Here the subscript  $n$  is used to denote the level-wise overhead for detecting one character representation with respect to level.

In order to detect a single multi-grams  $f$ , the total search-overhead with respect to search space for level-wise calculation is,  $\sum_{q=p}^h (S'_f(l'_q)) + k'_f$

because we are to start with maximum level  $p$  and then proceed decreasingly towards the downward levels  $h$  (as explained above). If  $S'$  is the search-overhead function, then searching from level  $p$  to  $h$  will result  $\sum_{q=p}^h (S'_f(l'_q))$  where  $f$  is the multi-grams, which

is being revealed. For the matching level, as only a partial number of elements are to be searched, the offset  $k$  is used to denote the offset.

After checking through the levels, the procedure follows searching through the bit-wise statistics for any unsuccessful match in level-wise statistics. If there are a total of  $u$  bit-phases, we are to perform searching through the search-space consisting of starting from the maximum bit phase to the minimum bit phase decreasingly. Because of any unsuccessful match in any bit-phase, a bit switch is performed and level wise calculation for that level is forwarded. That is, an overhead of  $\sum_{b=d}^g (E_b)$  is incurred

for each level-wise analysis. Consequently, the overhead of unit step will be,  $C'_1 = \sum_{b=d}^g (E_b)$  where  $d$  and  $g$

are maximum and minimum bit phases respectively and  $d \geq g$ . Substituting the value of  $E_b$ , we get,

$$C'_1 = \sum_{b=d}^g \sum_{q=p}^h (S'_{1,b}(l'_q)) + \sum_{b=d}^g k'_{1,b} + \sum_{b=d}^g B'_{1,b}$$

Similarly, we get,

$$C'_2 = \sum_{b=d}^g \sum_{q=p}^h (S'_{2,b}(l'_q)) + \sum_{b=d}^g k'_{2,b} + \sum_{b=d}^g B'_{2,b}$$

$$C'_n = \sum_{b=d}^g \sum_{q=p}^h (S'_{n,b}(l'_q)) + \sum_{b=d}^g k'_{n,b} + \sum_{b=d}^g B'_{n,b}$$

Here, we use the subscript  $1$  with  $k$  and  $B$  in order to

denote that, the calculations are for detecting unit code only where the calculation is performed starting from  $d$  to  $g$  in decreasing order, that is, in the order of  $d, (d-1), (d-2), \dots, (g+2), (g+1), g$ . If we are to reveal  $n$  number of codes, then the total overhead becomes:  $T' = \sum_{y=1}^n C'_y$

As for each bit wise overhead calculation, we must include level-wise calculations; we may omit the subscript notation for search overhead function for simplicity,

$$T' = \sum_{y=1}^n \sum_{b=d}^g \sum_{q=p}^h (S'_{y,b}(l'_q)) + \sum_{y=1}^n \sum_{b=d}^g k'_{y,b} + \sum_{y=1}^n \sum_{b=d}^g B'_{y,b} \quad (3)$$

## VI. EXPERIMENTAL RESULTS AND DISCUSSIONS

The performance evaluation is performed on the basis of the file “book1”, “book2”, “paper4”, “paper5” and “paper6” from “Calgary Corpus”. As the prime aspect of our proposed Compression Scheme is not to compress huge amount of text rather to compress texts with limited size affordable by the mobile devices i.e. embedded systems, we took blocks of texts less than five hundred characters chosen randomly from those files ignoring binary files and other non-text files and performed the efficiency evaluation.

Recent study involving compression of text data are:

1. “Low Complex and Power Efficient Text Compressor for Cellular and Sensor Networks” (Mode 2) by Rein *et al.* [1, 10] and,
2. “A modification Of Greedy Sequential Grammar Transform based data Compression” by Islam *et al* [3]

We denote the above three methods as DCM-1 and DCM-2 respectively.

The simulation was performed in a 2.0 GHz Personal Computer with 112 MB of RAM with the object oriented programming language Java. The average compression ratio for three random execution results for different size of blocks of text is as follows:

Table 2: Compression Ratio:

| Corpus         | Number of Characters Considered | Compression Ratio (%) for DCM-1 | Compression Ratio (%) for DCM-2 | Compression Ratio (%) for proposed scheme |
|----------------|---------------------------------|---------------------------------|---------------------------------|-------------------------------------------|
| <b>paper 4</b> | 108                             | 44.01                           | 44.03                           | <b>42.94</b>                              |

The compression ratio is a metric to describe how many compressed units are required to describe one unit of data. The lower the presented value is the better is the compression. A general observation is that higher modes

lead to better compression ratios even if the difference with higher orders becomes smaller.

The prime achievement of our proposed scheme is, it is even capable to compress texts with only five characters. Though the compression ratio is deteriorated for that case, it is an evolutionary step for small text compression.

## VII. CONCLUSION AND RECOMMENDATION
