Data preprocessing procedure is cleaning the data from unwanted noise and transform it into a workable format. Normalization procedure is used for preprocessing data. Here, the real-time multivariate datasets are used, some of the data values may be missing and all of the datasets are not scaled well. To scale all the data, PCA is applied for normalization of the dataset.

V. TIME COMPARISON STUDY ON CLUSTERING ALGORITHMS

This section represents the comparison among selected clustering algorithms based on the relation of execution times and the number of clusters.

From Fig. 1, FCM requires less time than other algorithms. Other algorithms take much more times than FCM. So, the FCM clustering algorithm provides a better solution for Wisconsin Breast Cancer dataset.

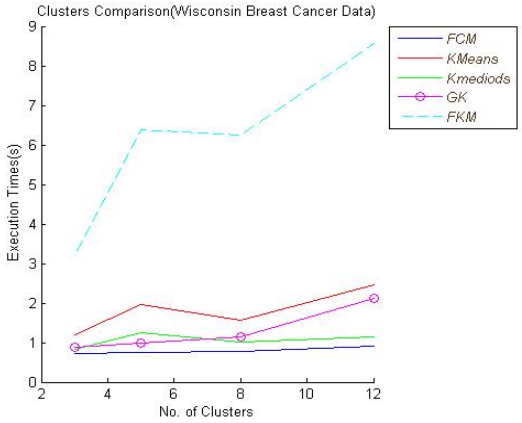

Fig. 1. Algorithms Execution Time comparison on the Wisconsin Breast Cancer dataset.

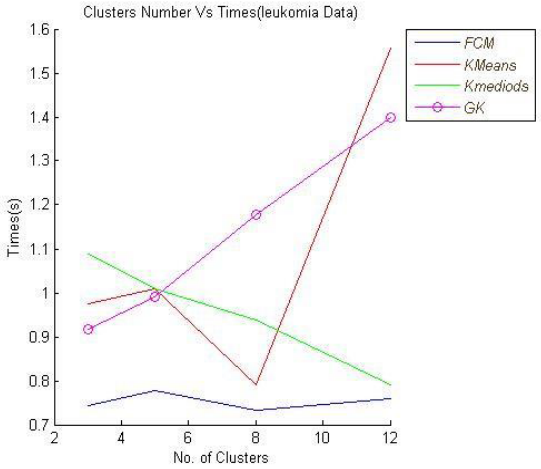

Fig. 2. Algorithms Execution Time comparison on the Leukemia dataset.

From the performance comparison graph of Leukemia dataset in Fig.2, the time requirement for K-Mediods algorithm decreases with the increase of the number of clusters and time requirement graph for GK algorithm is opposite. On the other hand, FCM requires shorter times for execution and does not change much with the increase of cluster number. So, the FCM algorithm suits for Leukemia dataset.

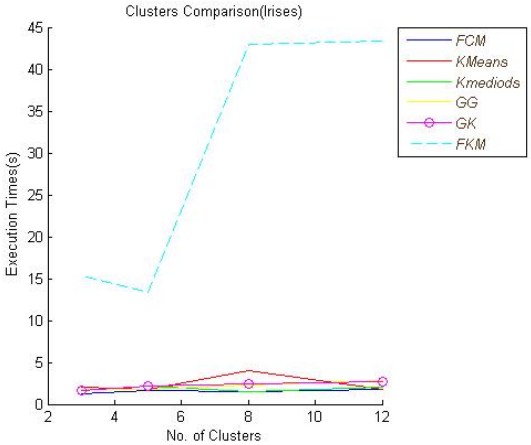

Fig. 3. Algorithms Execution Time comparison on the Iris dataset.

In Fig. 3, Except FKM (Fuzzy K-Means) other algorithms, require nearly the same time for execution with the change of the number of clusters.

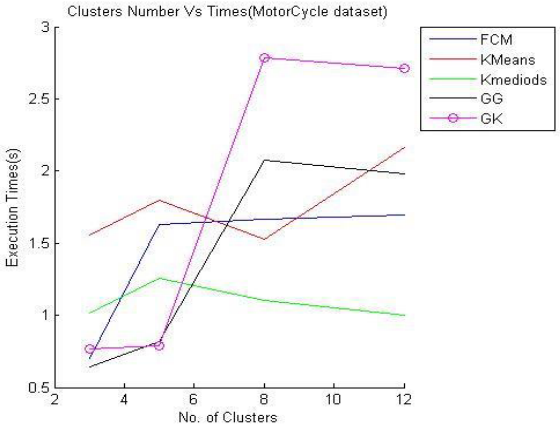

Fig. 4. Algorithms Execution Time comparison on the Motor Cycle dataset.

In Fig.4, FCM, GG and GK algorithm takes longer time for execution with the increased number of clusters. Time requirement varies less with the number of clusters for K-Means and K-Mediods algorithms and K-Mediods takes less time. So, for Motor Cycle dataset, K-Mediods algorithm provides an acceptable solution.

VI. Cluster Validation

Cluster performance has been evaluated based on Partition Coefficient (PC), Classification Entropy (CE), Separation Index(S), Partition Index (SC), Xie and Beni's Index (XB), Dunn's Index (DI), Alternative Dunn Index (ADI) techniques. For WBC and Motor Cycle dataset considered the number of clusters is three and, for Iris and Leukemia dataset it is two. Comparative study on validation indexes of selected algorithms for the four datasets is stated below:

TABLE I. Validation Indexes of Wisconsin Breast Cancer dataset.

Algorithm	PC	CE	SC	S	XB	DI	ADI
FCM	0.84	0.294	0.951	0.002	2.572	0.102	0.000

K-Mediods	1.0	NA	0.57	0.008	INF	0.368	0.022

Finding the optimal number of cluster is another study goal. Clustering is an unsupervised task and it is sometimes impossible to get the optimal number of cluster for the unknown datasets. In this paper, above-mentioned cluster validation techniques are applied for searching the optimal number of cluster. The higher values of PC and lower values of CE indicates the optimal number of cluster. The lower values of SC, S & XB indexing represents better clustering performance and the highest values of DI and ADI indicates the accurate number of clusters. So, upon considering all the mentioned validation criteria on the above-selected algorithms, attempts are taken to find the optimal number of cluster for the selected datasets. The outcomes are three clusters for WBC dataset, two clusters for Leukemia dataset, two clusters for Iris dataset and three clusters for Motor Cycle dataset.

VII. Cluster Validation Comparison

Study on validation results versus the number of the clusters on the applied clustering algorithm for the different dataset is as follow:

A. WBC dataset

Fig. 5 shows that the FCM algorithm provides a feasible solution and K-Mediods provides the highest accuracy for WBC dataset. Because FCM curves become steady after riching pick values and other curves are stepping downward.

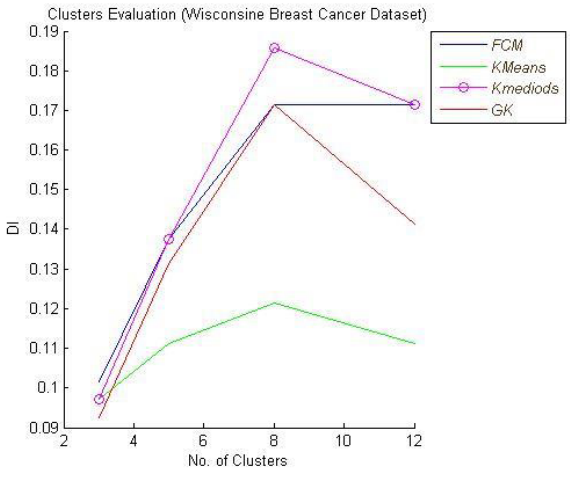

Fig. 5. Validation comparison using DI index on WBC dataset.

B. Leukemia dataset

Fig.6. reveals, the FCM algorithm provides a better result than other algorithms for the Leukemia dataset. Because FCM curves are increasing which shows better results and others are not following any pattern.

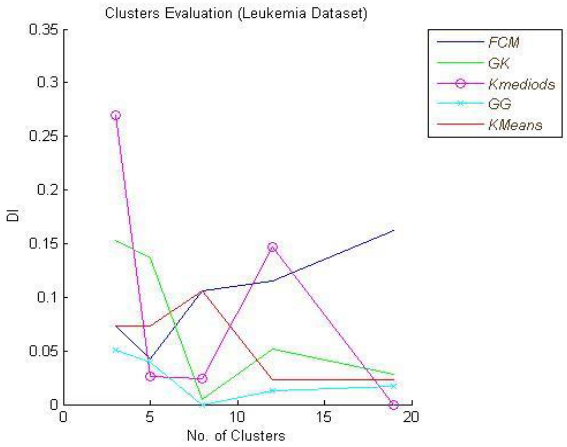

Fig. 6. Validation comparison using DI index on Leukemia dataset.

C. Iris dataset

From Fig.7, GG algorithm provides a better result than other algorithms for the clustering of the Iris dataset. Because only GG curve provides higher values than other curves which represent better clustering.

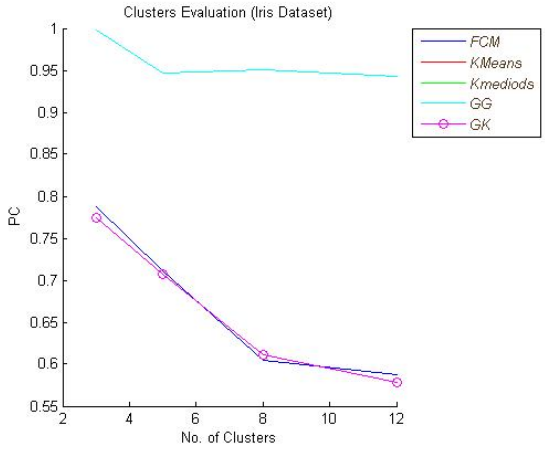

Fig. 7. Validity comparison using PC index on Iris dataset.

D. Motor Cycle dataset

From Fig.8, FCM algorithm provides a better result than other algorithms on the Motor Cycle dataset because only FCM curve shows increasing values of DI, which indicates good cluster. Rest of the algorithm curves does not follow any defined pattern.

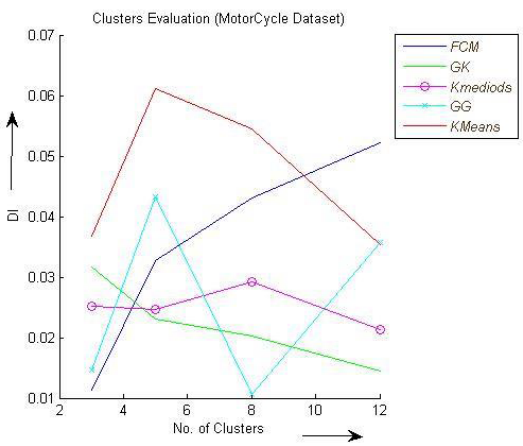

Fig. 8. Validity comparison using DI index on Motor Cycle dataset.

VIII. Analysis of Validation Results

Table I to Table IV shows validation indexing values for different clustering algorithm for selected datasets. Study on validation criteria on the selected datasets for finding their optimal values has been represented in Fig. 5 to Fig. 8. If the clustering is performed accurately, the output will be optimum. In the case of hard clustering, PC is always constant indicating the behaviour of hard partitions. Comparative studies are focused on the values of PC because of the selected datasets are overlapping in nature and PC provides the fuzzy partition for these datasets. Performance of algorithms on selected datasets based on execution time and validation indexes evaluated as - For WBC dataset, FCM clustering algorithm is best if we consider less execution time. But, if we consider the Dunn Indexing as the validation performance criteria, then K-Mediods algorithm produces the highest accuracy. For Leukemia dataset, the FCM algorithm is best by considering both criteria. For Iris dataset, GG algorithm is preferable by considering both criteria. For Motor Cycle dataset, K-Mediods is the suitable algorithm from time comparisons but Dunn Indexing validation measurements indicate the K-Means algorithm.

IX. Conclusion

In this paper, a comparative study among five algorithms which are widely categorized by hard and soft clustering schemes for four datasets have been covered based on executions times and cluster validation techniques. This reveals an effective way of selecting a suitable clustering algorithm for the particular dataset. For WBC dataset, fuzzy clustering gives more accurate result than hard clustering. When the number of clusters is increased, the PC index of FCM indicates fluctuation in results and for lower values, it increases. So for the higher number of clusters, the performance becomes poor. In GK algorithm, the result is constant after the four cluster is obtained. In case of Iris dataset, PC index of FCM shows justifiable results for two clusters. For Leukemia dataset, the highest and lowest values of PC indexing indicates good result for two clusters. From the analysis of Motor Cycle dataset using GK and FCM algorithms, PC shows the highest values near three and also the lowest value of CE near three indicates three number of cluster produce an acceptable solution.

***Abstract*—This work proposes new linear regression models for total body water (TBW) measurements for both male and female human being based on bioelectrical impedance analysis. In this research total 2817 (1397 male and 1420 female) data have been used. Age, height, bioelectrical impedance at 100 kHz frequency, body mass index (BMI) have been used for the development of mathematical models. The proposed models have been analyzed statistically and the results show that the correlation (Pearson) coefficients are 0.998 ($p<0.001$) for male and 0.997 ($p<0.001$) for female individuals which denote excellent matching with actual data. Besides intervals of LOA is only -1.36 L to 1.59 L and -1.17 L to 1.12 L for male and female data respectively and most of the data follows such a small limit of agreement. The absolute errors (mean ± Standard Deviation) are (0.64 ± 0.41) L and (0.48 ± 0.32) L for male and female data respectively whereas the bias are 0.11 L for male and -0.02 L for female population only. The RMSE are also very low and which are 0.76 L for male and 0.58 L for female people. Comparing the results of this research with existing models it is seen that the proposed models can be more suitable for TBW measurement.**

***Index Terms*—Bioelectrical impedance analysis, body compositions, linear regression, total body water**

I. Introduction

Fluid content in blood, tissue, bones and elsewhere is defined as body water in physiology. Total body water (TBW) is the summation of the water content of various fluid compartments along with different ratios making significant portion of human body, both by weight and by volume. The average percentage of total body water with respect to body weight varies according to gender. In general, the amount of total body water in human adult male and female are approximately 60% and 55% respectively [1]. Different parameters like age, height, weight, sex, health condition etc. have great impact on the variation of the normal percentage of water in body. To set the normal range of total body water in different people, numerous statistical analysis were conducted over different community people considering physical parameters like age, weight, height, sex and the figure for water portion by weight was found to be 58±8% for males and 48±6% for females [2]. Health condition is also a prominent factor for the amount of total body water, for example, newborn infants have 93% water whereas some obese people have 15% water by weight [3]. These statistical analysis cannot be fixed for all population due to many reasons like number of people, variations of physical parameters, methodology and so on. Different types disease have effect on the deviation of the normal volume of the total water in the human body such as hydration status, anorexia nervosa (eating disorder), cancer, kidney related diseases etc. [4]–[7].

Bioelectrical impedance analysis (BIA) is the procedure which results the electrical impedance i.e. the opposition to the flow of electric current in the body and this procedure is commonly used for the analysis of body composition non-invasively. The procedures which are not involve in the break or damage of skin, organ and tissues for measurement purposes are called as non-invasive ways. There are several mathematical models for TBW measurement by non-invasive based on both anthropometry and bioelectrical impedance analysis and this models are based on different numbers of people along with comparison with respect to pathological tests. But there are different types of limitations of these models such as insufficient number of data, level of accuracy, disease dependency etc. In this paper, two linear regression models for TBW measurement based on bioelectrical impedance analysis have been developed (one for male and another for female) considering adequate number of data with better accuracy which can be implemented in any health condition.

II. Materials and Methods

A. Subjects

To develop TBW measurement models, 2817 (1397 male and 1420 female) participant's data have been used from National Health and Nutrition Examination Survey (NHANES), 2003-2004 (version 7, updated in July 2016) conducted over US citizen [8]. United States Department of Health and Human Services, Centers for Disease Control and Prevention and National Center of Health Statistics operated this survey in their Mobile Examination Center (MEC) and documented all the results jointly. This survey published different types of pathological tests results along with physical parameters data and electrical data. For model development and validation, deuterium oxide (D_2O) based pathological test for TBW measurement were considered. HYDRA Bio-Impedance Spectrum Analyzer (Model 4200) manufactured by Xitron Technologies, Inc., San Diego, California was used for bioelectrical impedance data collection. The examinations were performed

by trained health technicians maintaining protocol which was written in the Body Composition Procedures Manual on the NHANES website.

B. Pathological Test for TBW Measurement

To determine the amount of TBW, deuterium oxide (D_2O) is used as criterion for pathological test. Using D_2O, TBW can be determined in two ways. In one method describe in [9], a dose of D_2O (1 g/kg of lean body weight, estimated from anthropometric measurements) is given into the body to mix up with blood and then blood samples are taken when steady state is reached after greater than four hours. Urine is simultaneously collected to determine net loss of heavy water as well as plasma water was separated out from the blood samples using an ultrafiltration technique that is performed by centrifugation at 2110×g for two hours in centrifuge tubes with a 5000 D cut-off membrane. The volume of TBW is calculated by following formula:

$$TBW = \frac{1}{N}\sum \frac{M - Lt}{(D_2O)t} \tag{1}$$

where M equals the ingested mass of D_2O (g), $[D_2O]$ equals the serum concentration of D_2O at time t, L equals the sum of urine loss at time t, and N equals the number of samples taken after the four-hour equilibration period.

TBW can be determined using flowing after glow mass spectrometry measurement of deuterium abundance in breath samples from individuals [10]. A known dose of deuterated water (Heavy water, D_2O) is ingested and allowed to equilibrate within the body water. The FA-MS instrument then measures the deuterium-to-hydrogen (D:H) ratio in the exhaled breath water vapor. The total body water is then accurately measured from the increase in breath deuterium content in relation to the volume of D_2O ingested. These pathological tests are invasive which require more time and conditions are applicable.

C. Antropoemtry

Maintaining well-defined standard procedures and well trained persons are prime concern for anthropometric measurements [11]. Weight is measured to closest 0.01 kg by portable electronic scale and height is measured adjacent to 0.01 cm using stadiometer, a portable gauge (Seca, Germany). There are several anthropometric mathematical models for TBW models. Hume *et al*. [11] proposed two models for TBW measurement (one for male and another for female).

$$TBW(male) = -14.01 + 0.19h + 0.30w \tag{2}$$

$$TBW(female) = -35.27 + 0.34h + 0.18w \tag{3}$$

Watson *et al*. [12] also proposed two models for TBW measurement.

$$TBW(male) = 2.45\text{–}0.09a + 0.10h + 0.34w \tag{4}$$

$$TBW(female) = -2.10 + 0.11h + 0.25w \tag{5}$$

Chumlea *et al*. [13] showed another two anthropometric equations for TBW measurement.

$$TBW(male) = -18.37\text{–}0.09a + 0.34w + 0.25h \tag{6}$$

$$TBW(female) = -16.71\text{–}0.05a + 0.22w + 0.24h \tag{7}$$

Medoua *et al*. [14] showed following anthropometric equations for total body water (TBW) measurement considering 40 Cameroonian hemodialysis patients along previous related models, but the accuracy was not satisfactory.

$$TBW = 13.90 + 0.002a + 0.329w + 1.85s \tag{8}$$

Where, a = age in years, w = weight in kg, h = height in cm, s = sex (1 for male and 0 for female).

D. Bioelectrical Impedance Analysis (BIA)

Bioelectrical impedance analysis is a tetra electrodes based method in which two electrodes are connected on right hand and another two electrodes are connected in right foot [5]. In right hand, one electrode is connected on wrist and another is connected on the bone of little finger and in the right foot, one is connected on bone of big toe side of ankle and another is connected on base of the second toe. Two electrodes are for sending constant current to human body and another two electrodes are for measuring voltage drop. Using voltage drop and sending current, bioelectrical impedance analyzer computed different types of impedance related values which are available in the databases.

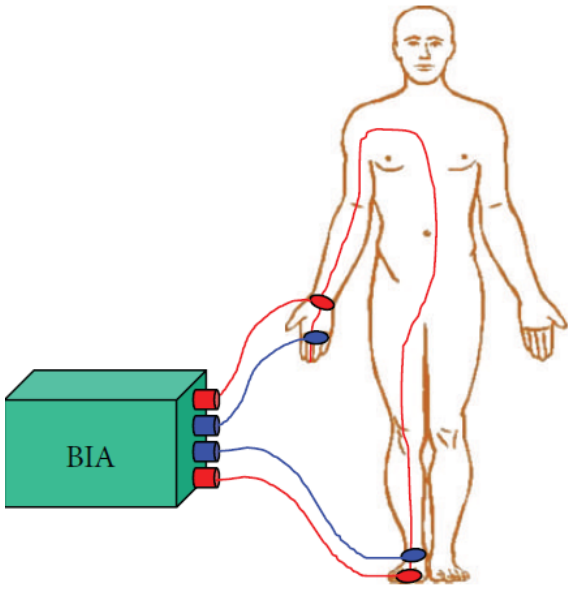

Fig. 1. Bioelectrical Impedance Analysis [5]

E. BIA Based Existing Models for TBW Measurement

Several regression models based on bioelectrical impedance analysis for TBW measurement were also developed. Deurenberg *et al*. [15] showed two mathematical models considering

50 kHz and 100 kHz frequency. For development of following equations, 139 patient's data were used and D_2O was used as pathological criterion.

$$TBW(L) = 6.69 + 0.35h^2/Z_{100} + 0.17w – 0.11a + 2.66s \quad (9)$$

$$TBW(L) = 6.53 + 0.37h^2/Z_{50} + 0.18w – 0.11a + 2.83s \quad (10)$$

Here, h = height in cm, Z_{100} = impedance at 100 kHz frequency, Z_{50} = impedance at 50 kHz frequency, w = weight in kg, a = age, s = sex (1 for men and 0 for women). Cornish $et\ al.$ [16] also developed a mathematical model using 60 participant's data and compared with results found from D_2O based pathological tests. The equation is given below-

$$TBW(L) = 0.6 + 0.50h^2/R_0 + 0.186w \quad (11)$$

Where, h = height in cm, R_0 = resistance at zero frequency in kΩ, w = weight in kg. Later Sun $et\ al.$ [17] developed two models (one for male and another for female) to measure TBW from 1829 individual's data (734 for male and 1095 for female) and the equations are-

$$TBW(male, L) = 1.203 + 0.449h^2/R_{50} + 0.176w \quad (12)$$

$$TBW(female, L) = 3.747 + 0.450h^2/R_{50} + 0.113w \quad (13)$$

Where, h = height in cm, R_{50} = resistance in kΩ at 50 kHz frequency, w = weight in kg. Liu $et\ al.$ [18] proposed a model for TBW measurement considering 50 kHz frequency using 948 individual's data. But this equation was applicable only for children and the equation was-

$$TBW(L) = -4.57 + 0.23h^2/R_{50} + 0.18w + 0.13a + 0.06h + 0.5s \quad (14)$$

Where, h = height in cm, R_{50} = resistance in kΩ at 50 kHz frequency, w = weight in kg, a = age in years, s = sex (1 for male and 0 for female). Then Algago $et\ al.$ [19] developed another model for TBW measurements in adults considering 50 kHz frequency based on 250 participant's data and the equation was-

$$TBW(L) = 5.68 + 0.27h^2/R_{50} + 0.23w – 0.05a + 4.42s \quad (15)$$

Where, h = height in cm, R_{50} = resistance in kΩ at 50 kHz frequency, w = weight in kg, a = age in years, s = sex (1 for male and 0 for female). Recently A. Diouf $et\ al.$ [20] built a mathematical model for TBW measurement using 151 participant's data. But, this equation was also for children (school going children, age 8 to 11 years) which was-

$$TBW(L) = -2.28 + 0.07h + 0.08w + 0.38h^2/Z_{50} – 0.47s \quad (16)$$

In this model, height (h) in cm, weight (w) in kg, sex (s =1 for male 2 for female), impedance (Z_{50}) in kΩ at 50 kHz frequency were considered.

F. Statistical Analysis

For validation and checking the robustness of the proposed model, statistical analysis is major indicator in which the correlation coefficient (Pearson coefficient), 95% confidence interval (95% CI), 95% limit of agreement (95% LOA), bias (difference between actual and measured values), p-value ($p<0.05$ indicate statistical significance) are measured. General characteristics of subject's data are expresses in terms of mean ± standard deviation (SD), 95% CI and p-value. Besides root mean square error (RMSE) is also calculated using following formula.

$$RMSE = \sqrt{\frac{\sum(x - x')^2}{n}} \quad (17)$$

Where, x denotes measured or given value and x' denotes predicted value. All types of statistical analysis have been done for this research using IBM SPSS v25.0 and MATLAB 2015b. The 95% LOA is used in Bland-Altman plot which is used to estimate the agreement between the predicted values and measured values in which limits of agreement have been determined by summing and subtracting the average differences from 1.96 times of standard deviation [21], [22].

III. Results

A. Proposed Linear Regression Models for TBW Measurment

For the development of linear regression models for TBW measurement, data set has been divided into two parts separating male and female and then each data set has been divided into more two parts (one for model development and another for model validation). To develop the TBW measurement model for male people, 720 male participant's data have been used and rest of 677 male participant's data have been used for model validation. On the other hand, 735 female participant's data have been used for TBW model development for female people and rest of 685 female participant's data have been used for model validation. In these proposed models, bioelectrical impedance at 100 kHz frequency along with age, height, body mass index (BMI) have been used and the general characteristics of participant's data have been given in the Table I to Table IV. Using the data sets, two new equations have been proposed for TBW measurement.

$$TBW(male, L) = -11.25 + 0.011a + 0.46b + 0.005Z_{100} + 0.60h^2/Z_{100} \quad (18)$$

$$TBW(female, L) = -10.56 - 0.002a + 0.36b + 0.006Z_{100} + 0.60h^2/Z_{100} \quad (19)$$

Here, a = age in years, b = BMI in $[kg/m^2]$, h = height in cm, Z_{100} = bioelectrical impedance at 100 kHz frequency. After implementing the new developed equations into the validation data sets, it is seen that the predicted values of TBW are close enough to the actual values which have been explained in details in the performance evaluation section.

B. Performance Evaluation

The performance evaluation of the proposed models have been done according to the results of the statistical analysis. From the point of view of correlation coefficient (Pearson coefficient), the more closer to unity the more matching will be found among the actual values and the measured values. The proposed mathematical models exhibit the correlation coefficient 0.998 and 0.997 ($p<0.001$) for male and female respectively. Besides, the correlation coefficient, the lower range of 95% CI, 95% LOA of errors are also required along with lower value of bias and absolute error for proper validation of the models. The 95% CI are 0.06 to 0.17 L and -0.07 to 0.18 L for male and female data. The 95% LOA for male data are -1.36 to 1.59 L and for female data are -1.17 to 1.12 L. The values of bias and RMSE are 0.11 L and 0.76 L for male people and -0.03 L and 0.58 L for female data which indicate lower values. The linear correlation curves for both male and female have shown in Fig. 2 and Fig. 3 respectively. TBW (female) Using the averages of actual and predicted

Deurenberg *et al.* [15] (100 kHz frequency)	0.950	-5.48 to 2.07	2.20 ± 1.32	-1.70	2.57
Deurenberg *et al.* [15] (50 kHz frequency)	0.950	-5.60 to 1.84	2.30 ± 2.68	-1.88	2.68
Cornish *et al.* [16]	0.850	-3.4 to 1.00	1.40 ± 0.86	-1.20	1.64
Sun *et al.* [17]	0.840	-3.79 to 1.54	1.51 ± 0.90	-1.12	1.76
Liu *et al.* [18]	0.88	-5.10 to 2.46	1.85 ± 1.42	-1.32	2.33
Aglago *et al.* [19]	0.92	-4.36 to 1.96	1.68 ± 1.11	-1.20	2.00
Diouf *et al.* [20]	0.890	-3.43 to 5.64	1.91 ± 1.71	1.10	2.56
Proposed	0.998	-1.17 to 1.12	0.48 ± 0.32	-0.02	0.58

that the correlation curves show the almost exact matching between actual values and predicted or measured values. On the other hand, the Bland-Altman plots show that the almost all the averages of actual and measured data with respect to errors are present within the 95% LOA. So, it can certainly be said that the proposed regression models can be used for TBW measurement with excellent accuracy.

IV. DISCUSSION

The robustness of the proposed models are also done by comparing the correlation coefficient, absolute errors (mean ± SD), bias with 95% CI, RMSE and 95% LOA found from proposed models and existing models through the data sets used for validation purposes. All the results have been given in Table V and Table VI. The proposed models, developed for male and female people have been compared with existing models (anthropometry and bioelectrical impedance based models) where it is seen that the proposed models show closest matching with actual results as the correlation coefficients are 0.998 and 0.997 for male and female respectively whereas other models show coefficient values below 0.90 except one model. The correlation coefficient found in [15] is 0.950, but the 95% limit of agreement (LOA) is high which is not expected as the lower range of LOA is expected. Besides this model, other models also show larger range of 95% LOA. From the error analysis, it is seen that, the proposed models show lowest absolute error, bias and root mean square (RMSE), numerically the values are 0.64 ± 0.41 L, 0.11 L and 0.76 L respectively for male and 0.48 ± 0.32 L, -0.02 L and 0.58 L respectively for female whereas these values are higher for other models than new ones. The maximum values of different errors have been found in [14] and the minimum have been found in [18] which are greater than the errors of proposed models and hence certainly it is seen that the models proposed in this models can be used for TBW measurement with better accuracy.

V. CONCLUSION

To propose any model, there are some prerequisites such as number of data used, accuracy along with maintaining of the standard range of different types of statistical analysis like correlation coefficient, bias, absolute error, 95% confidence interval of limit of agreement, root mean square error. The models proposed here have fulfilled almost all the required criteria and from the comparison with other existing models it is seen that newly proposed models can easily be implemented for practical implementations with better accuracy. As the measurement of TBW has significant importance for checking nutrition condition, detecting diseases detection in medical sciences, these proposed models will be helpful for accurate

measurement within very short time. Bioelectrical impedance analysis is well known quick and easy non-invasive method. So, proper modeling using bioelectrical impedance will be helpful to render latest medical technology at low cost to the mass people of the world as the large number of population in the world cannot afford the treatment related costs.

***Abstract*— Stream data, obtained from the various sensors and devices with high speed, used daily, are indispensable parts in our day-to-day life. There is an immense necessity to store these data comprising of large volume. Data compression is one of the effective ways of storing data efficiently. In this paper, different data compression techniques such as PCA, APCA have been improved and thus we propose a new hybrid model. In the proposed model, the window size is fixed but data can be compressed efficiently than PCA. Besides, the delay time is minimized compared to the other existing techniques since the model is developed by considering both the delay time and several data points to be compressed. Our experiment shows that the proposed method performs twice as better than PCA in terms of compression and minimizes RMSE by 10%-25% compared to APCA method.**

Keywords—Data Compression, Stream data, Window

I. INTRODUCTION

Stream data has entrusted to be one of the most valuable concepts in Modern information technology. Experts are predicting that the content of stream data will become a huge amount of data that has been collected from social media or any other online resources [5], [12]. As Stream data are ejected from cell phones, vehicles, appliances, buildings, meters, machinery, medical equipment and many other machines continuously [3], it becomes huge data and turnout cumbersome to store this large volume of data. Sometimes new data removes old data due to lack of space in storage. Compression of data activates quick processing of data by accessing queries immediately over compressed data [1], [2], [10] using few I/O as compressed data usually stored using lessen number of disk pages [4], [6]. Our aim is to compress the continuously coming stream data to make the memory space free from over-burdened data [3] and Data should be compressed in such way that compressed value should be close to actual value [9]. The data values are divided into certain segments, which are known as windows and a threshold to support error rate is considered. An improved of Piecewise Constant Approximation (PCA) technique is being followed, where window size of data is fixed-length but it gives optimal result in consideration of delay time and total compressed data points on running process rather than PCA [7], [8].

II. RELATED WORK

Piecewise Constant Approximation (PCA) & Adaptive Piecewise Constant Approximation (APCA) are two exoteric techniques to compress data optimally in model-based compression [9], [10]. Model Based Compression depends on two main properties, which are continuity of the sampling methods or processes and interrelations of different sampling processes [11].

PCA distributes the entire dataset into piecewise fixed length segments, which are known, as windows [7]. For each window, if the difference between the maximum and minimum value of respective windows is less than twice of the maximum error rate threshold than the whole window will represent one single average value. PCA algorithm gives more data points as window size is fixed. However, the delayed time of PCA is low.

APCA is not as straightforward as PCA [8]. Here, the window sizes vary according to the condition. It scans data in a selective order and inserts data into a window until the difference between maximum and minimum value is less than twice of maximum error rate threshold. If we consider the best case where all off the data values maintaining threshold value, the device will not get any data for a long time. Though APCA gives fewer data points but the time, which can be delayed of through APCA is higher.

III. PROPOSED METHOD

Like PCA, this method also divides the entire dataset into piecewise fixed length segments known as windows, W and it is users define value. A maximum error support threshold, € is also in under consideration. The maximum value, 1 ϵ W and the minimum value, V_{min} ϵ W of each window is calculated. If the maximum and minimum value of the window is less than twice of the maximum error rate threshold then the data values will be compressed.

The equation looks like the following.

$$V_{max} - V_{min} < 2 * €$$ (1)

The above equation can be named as "**Compression Condition**". If the above condition is true, all the data points, $V_i \in W$ is represented by a constant. That constant can be named as "**Representative Value**".

$$\text{Representative Value, } V = \frac{V_{max} + V_{min}}{2}$$ (2)

A. Phases of the Model

The whole method is partitioned into two phases. One is Merge phase and another is a Split phase. Initially, if the data points of the window follow the compression condition, then it will go to the Merge phase. Otherwise, it will go to the split phase.

a) Merge Phase: When the values of a window follow the compression condition then the window is saved into the buffer and the next window is formed with next consecutive data points. Now, V_{max} & V_{min} are calculated from this current window and buffer elements. If the difference between V_{max} & V_{min} is also followed the compression condition, then these two windows will be merged together and temporarily store the window in the buffer and form the next window in the same manner and follow the same process. After each window is compressed, the value of the buffer will be updated by adding the current window's data points. If the compression condition is not violated for at most N consecutive windows, then the data points of these N consecutive windows will be merged and a representative value will be calculated that will be sent to the server. Here N indicates at most how many windows will be merged. It is an arbitrary number and user input. If the values of N consecutive windows do not meet the compression condition, then after each window is compressed, the window stored in the buffer will calculate its representative values and will send into the server. Then it clears the buffer.

b) Split Phase: If the compression condition breaks in PCA, then the full window is sent to the server. But in this method, instead of sending the whole window, it splits the data points of the current window and tries to compress them. Thus, data points are reduced by more than PCA. It also scans data points of a window into a selective order like APCA. Initially, V_{max} & V_{min} of the current window and their differences are calculated. Temporarily the current window is saved in the buffer. After that, the difference violates compression condition or not, is checked. There may be two types of cases at this stage. If V_{max} & V_{min} the current window does not violate the condition, then it will go case 1 otherwise the current window will go the split phase in case 2.

In the first case, since data points of the current window follows the condition, it forms the next window and checks the next window is eligible for merging or not in the previously described way. If the next window will not eligible for merging data points, then a representative value of the window that stored into the buffer will be calculated and sent to the server. After that, it clears the buffer.

In the second case, the first two data points of the buffer element are compared and it is seen that if those data points break the compression condition or not. If the condition breaks, the first data is sent is to the server and the second and third data are compared and again check the condition and thus, the process continues, if there are values in the above window. And if the first two data points of the buffer fulfill the compression condition, then those data points will be compared with the third data. In this way, all the values of that window will be checked sequentially until the buffer becomes empty and compare it to see if the compression condition is met or not. If the condition satisfies then data will be compressed. Finally, the buffer is cleared.

B. Flow Chart

As the entire process is partitioned into phases, it has three flow charts.

a) Main Procedure

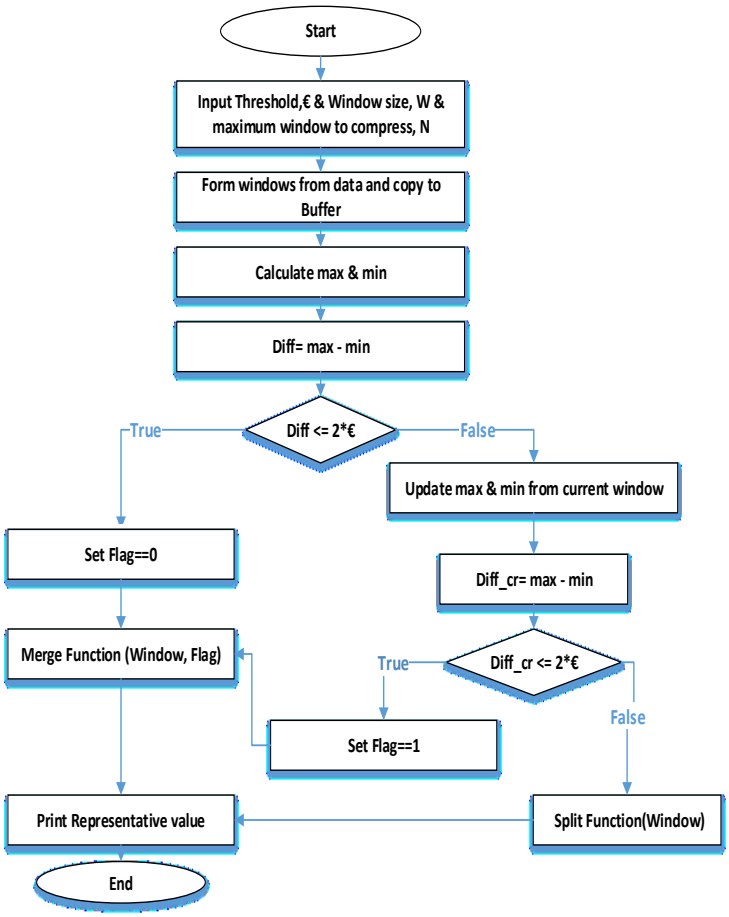

Fig. 1. Flowchart of the Main Procedure

Fig. 1. explains the complete workflow of our proposed method. Initially, the program takes input window size as W; at most how many windows can be merged as N & threshold as € from users. Then build windows from the dataset and copy the window to the buffer. Now, the maximum and minimum value of the window and their differences are

calculated and if the difference is less than twice of threshold and it initiates flag=0 and then calls the merge function with window and flag as an argument. Otherwise maximum and minimum is updated from the buffer the last window and their difference is calculated. If the updated difference is less the twice of threshold then it set flag=1 and call the merge function but if the difference is not less than 2*€ call the split function with a window as an argument. The representative value that calculated finally will send to the server or user.

b) Merge Phase

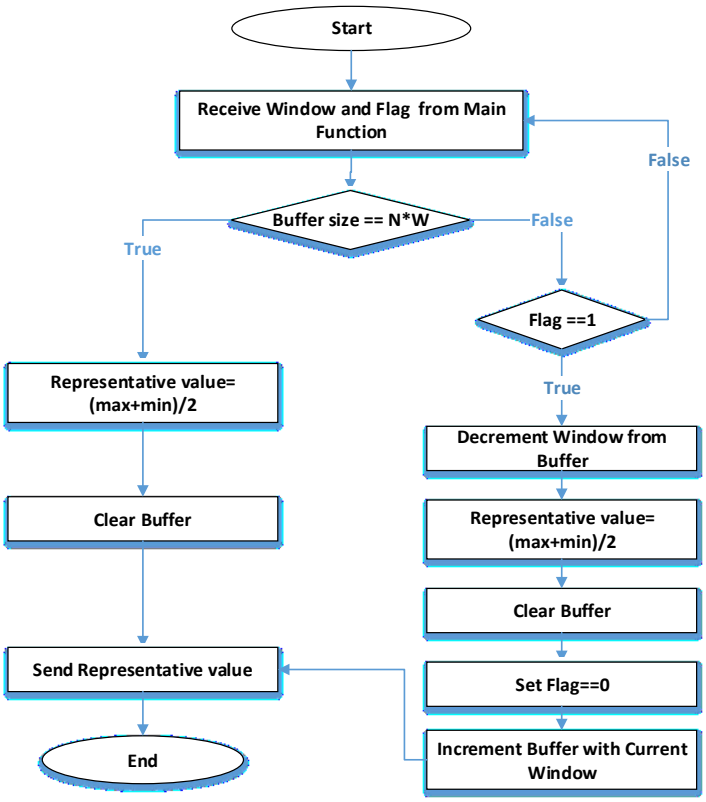

Fig. 2. Flowchart of the Merge Phase

Fig. 2. shows the operations during the merge phase. In the Merge phase, receiving window and flag value it is checked that if buffer size and N*W are equal then the representative value will be calculated directly because buffer size is full. Then it will clear the buffer and sent the representative value to the main function as a return value. If buffer size and N*W are not equal, then it will check flag value. If flag=1 that means current window violates the compression condition, so it decrements the current window from the buffer, calculates the representative value and clears the buffer. After that flag will set as 0 to indicate that buffer can receive window now and increment buffer with current window value and finally representative value will send to the main function as a return value.

c) Split Phase

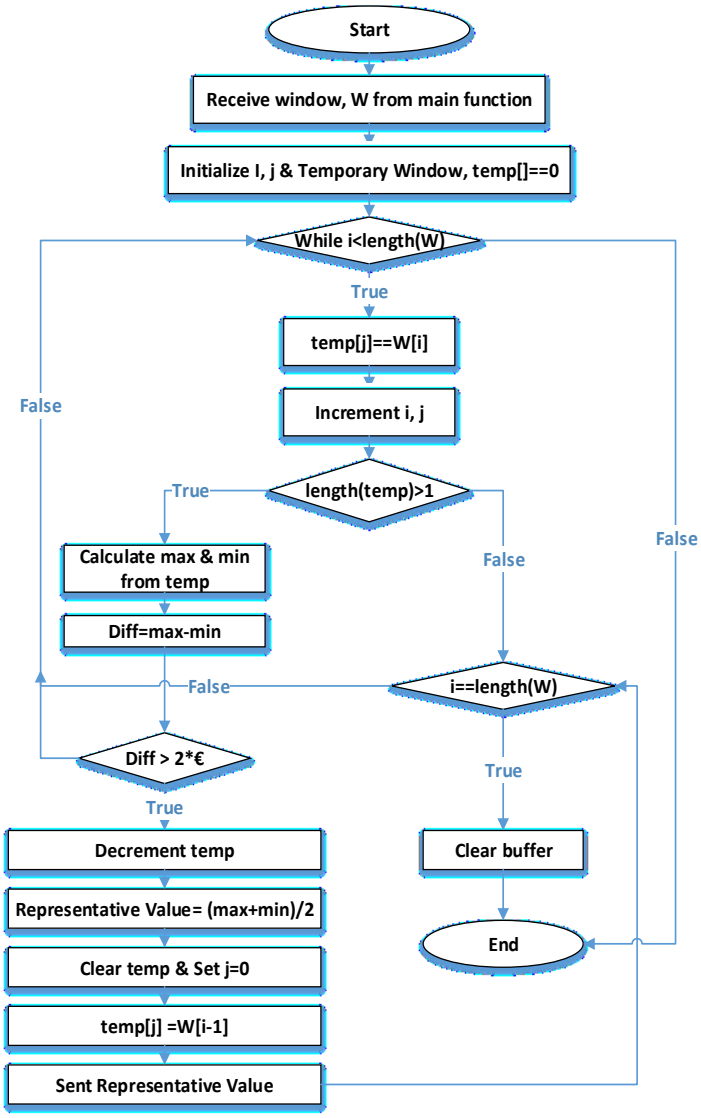

Fig. 3. Flowchart of the Split Phase

Fig. 3. shows the operations during the split phase. In the Split phase, window will receive as an argument from the main function. Then a temporary array is initiated and data of window will be copied to this temporary array. When there is more than one data in the temporary window then it will calculate the difference between the maximum & minimum value of the array. If the difference is less than 2*€ then it will go for next data otherwise pop the last value and calculate the representative value. After that clear the temporary array and current data point will be assigned into its zero indexes. This process will continue for every data point in the window. After scanning all data point's window will be cleared from the buffer.

IV. IMPLEMENTATION

In this method, fewer data points are sent to the server compare to PCA. In APCA, data values are sequentially searched. In the best case all the data values are followed compression condition then the algorithm will execute continuously. If the dataset is too large and a large number of data values are followed compression condition, the server will get any data for a long time so that delay time of APCA is larger. It is necessary to find results in an optimal way. This method is proposed considering both delay time and the number of data points. In PCA, data points are more but less delay time but in APCA data points are low but delay time is high.

A. Datasets

For evaluating Model-based Compression, the data values those have low spike those data will give the optimal result. Basically, we have taken three types of the environmental dataset from Kaggle. A variant number of stream data signals are contained by each and every data set. We have taken water's pH value as our first dataset. Around 10500 a number of data points in total. Their range is in between 0 to 7. We have chosen the second dataset is the one-year temperature of a country. There are roughly 11 thousand data points in total. The third dataset contains 5 years of high temporal resolution (hourly measurements) data of air pressure with more than 21000 number of data points.

B. Running Example

Data source generates data continuously. Here, window size, W is 5, error support threshold, € is 0.5 and N is 3 that indicates at most 3 windows can be merged for compression. Initially, first window forms with consecutive 5 data points from a data source which are 7.3, 7.7, 7.5, 7.2 and 7.1 as the window size are 5 and the window is saved to the buffer. The maximum value, V_{max} & the minimum value, V_{min} of the first window, is 7.7 & 7.1. While the difference between V_{max} & V_{min} is 0.6 which is less than 2*€ so this window can be compressed. Now, it checks the next window is eligible for merging or not.

Again, the second window formed with next consecutive 5 data points for example 7.4, 7.5, 7.6, 7.1, and 7. Now, V_{max} & V_{min} are calculated from this current window and buffer elements. Here, V_{max} is 7.7 & V_{min} is 7. As the difference is 0.7 so it can also be compressed. Temporarily this window also stores in the buffer and form the next window.

In a similar way, the third window is formed with next consecutive 5 data points for instance 7.4, 7.5, 7.6, 7.1, and 6.5 then again, V_{max} & V_{min} is calculated from this current window and buffer elements. Now, V_{max} is 7.7 & V_{min} is 6.5 and their difference is 1.1 so that it violates the compression condition. But it first two windows didn't violate the condition. Hence, at first, we merge the window of the buffer; calculate the representative value from windows that stored in the buffer and send a single representative value to the server instead of sending 10 data points. After that, it clears the buffer.

Now, V_{max} & V_{min} of the current window and their differences are calculated. After that, the difference violates compression condition or not, is checked. There may be two types of cases at this stage. If V_{max} & V_{min} of the current window does not violate compression condition, then it will go case 1 otherwise the current window will go the split phase in case 2.

Case 1: As V_{max} & V_{min} of current window do not violate compression condition, temporarily this window saves in the buffer, form the next window and checks the next window is eligible for merging or not in the previously described way. In this example, the data points of the current window break the compression condition.

Case 2: Since the difference of V_{max} & V_{min} violates the condition, this window is not compatible to compress. In split phase, temporarily this window saves in the buffer and it scans each data points and checks with the compression condition. Initially, the first two data points which are 7.4 & 7.5 is got and is checked whether the difference between these two data points follows the condition or not. The difference is less than twice of € and It maintains the condition. Now, it takes the next data point, 7.6 and checks if the difference between these three data points follows the condition or not. The similar process continues until the data points breaks the compression condition. Here, for the first 4 data points of the window, the compression condition is not violated.

The last data point, 6.5 violates the conditions so it makes a window from the first 4 values and sends a representative value to the server. The last data point also sends to the server. Then it clears the buffer and takes the next window. In this case, only two data points are sent to the server instead of sending 5 data points for this window. If more data points come, then the rest of windows will follow the same process of merging and splitting windows. Thus, compression occurs in the proposed method.

C. Prototype Development

We have made a desktop application with a user interface where the user can select any data source and select a window size, maximum window to compress as Max Window, error threshold value according to their wish. The application calculated total compression data, their compression ratio and RMSE of compression using this proposed technique.

V. EXPERIMENTAL RESULTS

The proposed compression method is evaluated based on various performance factors like compressed data points, Compression ratio and approximation error.

A. Evaluation Measure

a) Compressed Data Points: Compressed data points indicate total how many values are compressed for all the data. Lessen compressed data points indicate the optimal result.

b) Compression ratio: The fraction of data storage values among compressed data and similar original data can be prescribed as compression ratio. The higher compression ratio indicates the higher ability to data compression.

$$\textbf{Compression ratio} = \frac{\textbf{size_of_actual_data}}{\textbf{size_of_compressed_data}} \quad (3)$$

c) Approximation Error: At the point when compression methods demonstrate identical performance, approximation error can turn into a subordinate measurement to consider. To consider this viewpoint, the approximation errors of data compression are illustrated using the root mean square error (RMSE). RMSE generally used to assess the quality of data approximation.

$$\textbf{RSME} = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(V_i - \widehat{V_i})^2} \quad (4)$$

Here, v_i means a raw data value in a given sensor data signal, and $\widehat{v_i}$ means the relating approximated value in the compressed signal. Better approximation occurs when the value of RMSE is low. As every stream data signal contains specific range where data values are limited, we standardized the RMSE esteems (from 0 to a given error tolerance €) at each and every experiment set, to have a typical view to exploring the experimental results.

B. Experimental Results

The evaluation is measured with various usages of compression techniques and error support threshold is computed. The absolute error changes over a generally unique range since every data set pass through different domain values. In this manner, it becomes difficult to compare all compression techniques in a similar way. To give the general picture, the relative error is used in the experiments. Besides, in the Merge Phase of the technique, the maximum number of consecutive windows that can be combined together depends on the machine. This varies for a different machine. For our three chosen dataset, we consider Error support threshold is 0.5, the maximum window to compress is 4 and the window size is 5. The results are presented in Table I and Figure 4, 5, 6.

As Table I shows, for dataset 1, dataset 2 and dataset 3 PCA gives the maximum compressed data points compared to the other two techniques. The proposed method gives much fewer data points compared to PCA.

Compare to the other two techniques APCA gives the highest value for each of the datasets. So APCA gives the most optimal result as we know the higher compression ratio indicates a higher ability to compress data.

Fig. 4. shows the experimental results in terms of total data points after the compression. APCA performs better than our proposed method which is not surprise, since it is optimal in terms of total data points after compression. However, our proposed method performs 100% better than PCA which is a major improvement. Fig. 5. shows the compression ratio obtained from these results.

Fig. 6. shows the experimental results in terms of RMSE of the compression algorithms. The RMSEs of data compression is computed to reflect the quality of compression. PCA gives the lowest RMSE value. The RMSE value of PCA and proposed methods is very close. As the lower RMSE value is the better approximation so PCA and proposed method the provides better result than APCA.

The proposed technique gives better result when considering all the performance parameters. It gives much less compressed data points than PCA and it gives higher compression ratio compared to PCA. Besides, RMSE value of this technique is smaller APCA. However, in a few cases, delay time and RMSE of compression is higher than PCA.

TABLE I. EXPERIMENTAL RESULTS

PCA			
	Dataset 1	Dataset 2	Dataset 3
Compressed Data Points	4765	4453	12519
Compression Ratio	2.27	2.41	1.71
RMSE of compression	0.21	0.20	0.30

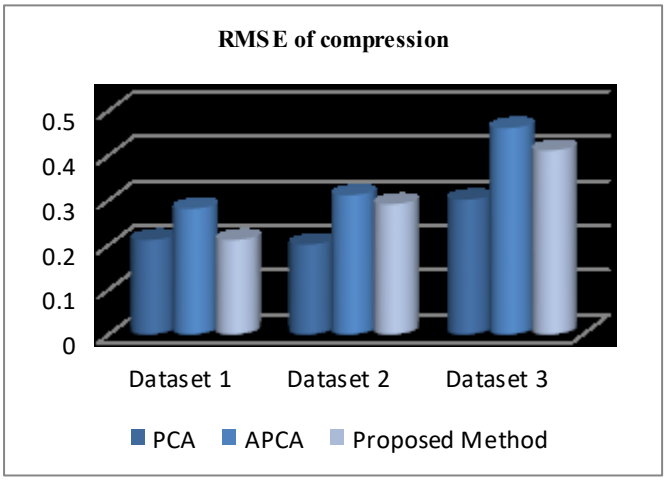

Fig. 6. Comparison of RMSE of Compression

VI. Conclusion and Future Work

This proposed technique is an improvement over PCA. Like PCA, widow size is constant here, but data point is also minimized notably. Considering two criteria such as compression ratio and RMSE value of compression this proposed technique gives most optimal result. Besides the delay time of this method is quite low so that machine or server does not wait long to get the values. Our future concentration is that the machine can automatically take decision about the window size which provides to get optimal result and that window size will be taken accordingly while algorithm will be run. Besides, we will try to apply this algorithm in diverse dataset and minimum more data points as much as can.

Mathematical Models for Fat Free Mass Measurement Based on Bioelectrical Impedance Analysis

Tahasin Ahmed Fahim and Md. Shamim Anower
Department of Electrical and Electronic Engineering
Rajshahi University of Engineering & Technology, Bangladesh
Email: tahasin.fahim.bd@ieee.org

***Abstract*—This paper shows new mathematical models for fat free mass (FFM) measurements for both male and female people through bioelectrical impedance analysis. In this research 1300 male and 1350 female (total 2650) data have been considered. Bioelectrical impedance at 100 kHz along with physical parameters like age, height, body mass index (BMI) have been used for the model development. The proposed models have been analyzed statistically. In the statistical analysis, correlation (Pearson) coefficients, 95% limit of agreement (LOA), absolute errors, bias, root mean square error (RMSE) have been used. The results show that the correlation (Pearson) coefficients are 0.998 ($p<0.001$) for male and 0.997 ($p<0.001$) for female people which indicate very good matching with actual data. The intervals of LOA are only -1.90 kg to 1.82 kg and -1.61 kg to 1.56 kg for male and female data respectively and most of errors found by proposed models remain within the limit of agreement. The absolute errors (mean ± Standard Deviation) are (0.81 ± 0.45) kg and (0.69 ± 0.44) kg for male and female data respectively whereas the bias are -0.03 kg for both male and female population only. The RMSE are also very low and which are 0.91 kg for male and 0.79 kg for female people. Comparing the results of this research with existing models it is seen that proposed mathematical models give better results and hence the proposed models can be used for FFM measurement.**

***Index Terms*—Bioelectrical impedance analysis, body compositions, fat free mass, fat free mass index**

I. Introduction

Body composition is the combination of fat mass (FM) and fat free mass (FFM). Comparatively lower portion of body fat and the higher portion of fat free mass are desirable for propoer body composition. Fat free mass consists of total body water, visceral protein, and bone minerals [1]. Generally muscle tissue, under skin and around organs contain fat. The body fat is considered as a proportion of total body weight then the ratio of fat mass and fat free mass can easily measured. American Council on Exercise (ACE) fixed the normal range of body fat percentage for different categories [2]. According to ACE, 2% to 5% body fat for male and 10% to 13% body fat for female are required as essential body fat, 6% to 13% for male athletes and 14% to 20% for female athletes, 14% to 17% for fitness of male and 21% to 24% for fitness of female, 18% to 24% for male and 25% to 31% for female are the maximum acceptable range and the obesity condition is considered beyond the maximum acceptable ranges of body. There are many diseases which occur due to obesity, but no specific disease can be detected by body fat percentage. Besides body mass index (BMI) which is the ratio of body weight to square of height is another parameter for obesity identification, but it is not also specific parameter for diseases. The ratio of fat free mass to square of body height is called fat free mass index (FFMI) and the normal range of FFMI is 18.2 to 20 kgm^{-2} for male and 15 to 16.6 kgm^{-2} for female people [3]. It is one of the prime parameter for different diseases detection.

Fat free mass has significant effects on various types of diseases like cardiac related diseases, anorexia nervosa (eating disorder), chronic obstructive pulmonary disease (COPD), end stage renal disease etc. [4-7]. Fat free mass index is one of the major parameter for chronic heart failure and cardiac complications after cardiac surgery prediction [4]. So, for the correct prediction or detection of such diseases, proper measurements of FFM and FFMI are necessary and if FFM can be estimated correctly then FFMI can easily calculated dividing by the square of the height. Usually, FFM is measured by one of the three methods such as densitometry, dual energy x-ray absorptiometry (DXA) and bioelectrical impedance analysis. Bioelectrical impedance analysis is the more easier and quicker method to measure FFM comparing other methods, but to use bioelectrical impedance analysis accurately, proper model development is mandatory. The accuracy is not still satisfactory for the existing FFM measurement models using bioelectrical impedance analysis. In this paper, new mathematical models for FFM measurement have been developed and validated.

II. Materials and Methods

A. Subjects

From National Health and Nutrition Examination Survey (NHANES), 2003-2004 (version 7, updated in July 2016) performed over US citizen, a data set of 2650 (1300 male and 1350 female) participant's data have been considered for FFM measurement model development [8]. United States Department of Health and Human Services, Centers for Disease Control and Prevention and National Center of Health Statistics conducted this survey in their Mobile Examination Center (MEC) and documented all the results jointly. This survey was operated based on various types of clinical tests results along

with physical and electrical data. For model development and validation, the results of FFM found from dual energy x-ray absorptiometry (DXA) of NHANES data set have been used as standard method for reference. HYDRA Bio-Impedance Spectrum Analyzer (Model 4200) developed by Xitron Technologies, Inc., San Diego, California was used for bioelectrical impedance data collection. The examinations were conducted by expert health technicians maintaining protocol which was mentioned in the Body Composition Procedures Manual on the NHANES website.

B. Dual Energy X-ray Absorptiometry (DXA)

Usually bone mineral density (BMD) is measured by Dual-energy X-ray absorptiometry in which two different energy level x-ray beams are sent to the patient's bones [9]. Measurement of body composition using DXA is possible with satisfactory accuracy, but this procedure is not suitable for all time due to high cost and requirement of complex setup to perform experiment. A low resolution of fat shadow image can be found by DXA from which the total amount of fat mass can be estimated. Finally, after subtraction of fat mass from body mass, fat free mass is found [10].

C. Bioelectrical Impedance Analysis (BIA)

Bioelectrical impedance analysis is a tetra polar electrodes based method. Among four electrodes, two electrodes were connected on right hand. An electrode was connected on wrist and another was connected on the bone of little finger of right hand. Rest of two electrodes were connected on the right foot. One was connected on bone of big toe side of ankle of the right foot and another was connected on base of the second toe of the right foot. A pair of electrodes was for sending constant current to human body and another pair was for measuring voltage drop. Using voltage drop and sending current, bioelectrical impedance analyzed [11, 12].

D. BIA Based Existing Models for FFM Measurement

There are many linear regression models for FFM measurement based on bioelectrical impedance analysis though the accuracy levels are not satisfactory. Among them, four current models of FFM measurement based on bioelectrical impedance analysis have been demonstrated in this section which show better accuracy comparing with other existing models. Kyle $et\ al.$ [13] showed mathematical model for FFM measurement at 50 kHz frequency on the basis of 343 patient's data which were applicable for both male and female individual. The model equation is given below.

$$FFM(kg) = -4.10 + 0.518h^2/R_{50} + 0.23w + 0.13X_{C50} + 4.23s \quad (1)$$

Here, h = height in cm, R_{50} = resistance in kΩ at 50 kHz frequency, X_{C50} = reactance in kΩ at 50 kHz frequency, w = weight in kg, s = sex (1 for men and 0 for women). Sun $et\ al.$ [14] developed two models (one for male and another for female) to measure FFM from 1829 individual's data (734 for male and 1095 for female) and the equations are:

$$FFM_male(kg) = -10.68 + 0.65h^2/R_{50} + 0.26w + 0.02R_{50} \quad (2)$$

$$FFM_Female(kg) = -9.53 + 0.70h^2/R_{50} + 0.17w + 0.02R_{50} \quad (3)$$

Where, h = height in cm, R_{50} = resistance in kΩ at 50 kHz frequency, w = weight in kg, a=age in years. A Liu $et\ al.$ [15] built a mathematical model for FFM measurement using 948 participant's data. But, this equation was for school going children (age 8 to 11 years) which was given below

$$FFM(kg) = -6.95 + 0.29h^2/R_{50} + 0.25w + 0.26a + 0.09h \quad (4)$$

In this model, height (h) in cm, age (a) in years, weight (w) in kg, resistance (R_{50}) in kΩ at 50 kHz frequency were considered. Later K.E. Aglago $et\ al.$ [16] developed a mathematical model for FFM measurement using 250 participant's (adult) data which was given below.

$$FFM(kg) = 7.47 + 0.37h^2/R_{50} + 0.31w - 0.06a + 0.09h + 6.04s \quad (5)$$

In this model, height (h) in cm, age (a) in years, weight (w) in kg, sex (s =1 for male 0 for female), resistance (R_{50}) in kΩ at 50 kHz frequency were considered. Kafri $et\ al.$ [17] used multi frequency bioelectrical impedance analysis to measure FFFM in stroke or transient ischaemic patients (250 patients) but no specific model was presented by measuring at 5, 50, 100 and 200 kHz frequencies. Recently Geesje $et\ al.$ [18] showed mathematical model for FFM measurement at 50 kHz frequency on the basis of 103 patient's data which were applicable for both male and female individual. The model equation is given below.

$$FFM(kg) = -1.87 + 0.53h^2/Z_{50} + 0.31w \quad (6)$$

Here, h = height in cm, $Z_{50} = resistance in k\Omega$ at 50 kHz frequency, w = weight in kg.

E. Statistical Analysis

Different types of statistical analysis such as the correlation coefficient (Pearson coefficient), 95% confidence interval (95% CI), 95% limit of agreement (95% LOA), bias (difference between actual and measured values), p-value ($p<0.05$ indicate statistical significance) and root mean square error (RMSE) have been considered for model validation. The general characteristics of people's data have been expressed as mean ± standard deviation (SD), 95% CI and p-value. The formula of RMSE is given below.

$$RMSE = \sqrt{\frac{\sum(x - x')^2}{n}} \quad (7)$$

Where, x indicates the actual data and x' indicated measured data. IBM SPSS and MATLAB software have been used for all types of statistical analysis have been performed for the model development and validations. Bland-Altman plot has been drawn to verify the agreement between the measured data and actual data where agreement limit has been calculated through addition and subtraction of the differences of mean from 1.96 times of standard deviation [19].

III. Results

A. Proposed Mathematical Models for FFM Measurment

To propose the mathematical models for FFM measurement, age, BMI, bioelectrical impedance at 100 kHz frequency and impedance index have been considered. To develop the model, 700 male and 700 female data have been considered. After model development, male FFM model has been validated by 600 data and female FFM model has been validated by 650 data. Table I to IV represent the general characteristics of subject's data which have been used for model development and validation Following equations have been proposed for FFM measurement. have been proposed for FFM measurement.

$$FFM(male, kg) = -13.14 - 0.017a + 0.62b + 0.004Z_{100} + 0.60h^2/Z_{100} \quad (8)$$

$$FFM(female, kg) = -10.52 - 0.004a + 0.47b + 0.004Z_{100} + 0.60h^2/Z_{100} \quad (9)$$

Here, a = age in years, b = BMI in kg/m^2, h = height in cm, Z_{50} = bioelectrical impedance at 50 kHz frequency.

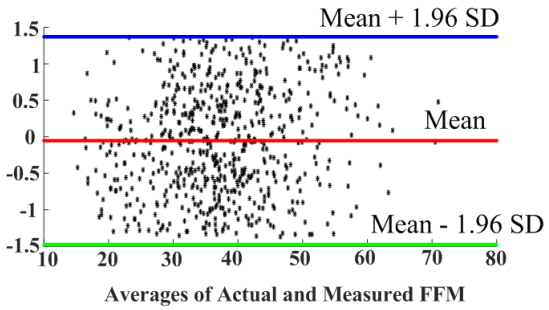

Fig. 4. Bland-Altman plot of FFM (female).

absolute error, bias and root mean square error (RMSE). The proposed FFM models exhibit the correlation coefficient 0.998 and 0.997 ($p<0.001$) for male and female respectively. The 95% LOA for male data are -1.90 to 1.82 kg and for female data are -1.61 to 1.56 kg. The values of absolute error (mean ± SD), bias and RMSE are 0.81 ± 0.45 kg, 0.03 kg and 0.91 kg for male people and 0.69 ± 0.44 kg, -0.03 kg and 0.79 kg for female data which indicate lower values. The linear correlation curves for both male and female have shown in Fig. 1 and Fig. 2 respectively. Bland-Altman plot has been shown in Fig. 3 and Fig. 4 by the averages of actual and predicted values of FFM and the 95% LOA. All the results follow the standard limit or range of statistical analysis parameters. So, it is expected that the proposed regression models can be used for FFM measurement with better accuracy.

IV. DISCUSSION

The proposed models have been compares with five related models. All types of statistical analysis have been performed over all the models which have been selected for comparison with proposed models. Table V and Table VI show all the results found from the comparative analysis. From the analysis it is observed that the values of correlaion coefficients are lower than the proposed models. The smallest correlation coefficient value has been found in the reference [14]. The largest value of correlation coefficient among the current models has been estimated to be 0.97 in reference [13] which is lower than proposed models. For the proposed models, the 95% limits of agreement are also small and all the errors remain within the limit whereas the other models show larger 95% limit of agreement. In reference [13], for male model, the abosute error has been found maximum whereas for the female model, the RMSE has been found maximum. In reference [15], for male model, the RMSE has been found maximum whereas for the female model, the absolute error has been found maximum. The values of bias have been found maximum in reference [13]

for male and in reference [15] for female. Comparing all the results of the models it can be said that the proposed models for FFM measurement for both male and female people will be helpful for the implementation of the bioelectrical impedance analysis based diagnosis scheme practically.

V. Conclusion

To monitor the health condition along with disease detection, fart free mass is one of the major parameter of the body composition. Generally, DXA is used to measure body fat distribution from which fat free mass is estimated, but this process complex and costly procedure and require huge space for arrangement. So, bioelectrical impedance based method will be a good alternative method due its simplicity, portability and quick process. The main concern issue of bioelectrical impedance based method is the accuracy. From the analysis, it can easily be said that the implementation of the proposed models will greatly improve the accuracy of the bioelectrical impedance analysis method. The fat free mass index, another parameter measured from fat free mass is also important for disease detection. The proper measurement of fat free mass index depends on the fat free mass. Using the propose models, the measurement of fat free mass index will also be possible with better accuracy. Since the validation results through the statistical analysis for both male and female people have proper results, these models can be used for every person to measure FFM as well as the different types of algorithms to detect different types of diseases can be developed in future based on this models.

***Abstract*—Human sentiments, the attitudes, thoughts, or the judgments backed by feelings are the most important factors for the field of science and business which can be expressed through the web. The rapid growth of unstructured sentiment data has created a very big challenge to provide a fast and cost-efficient model for sentiment analysis. The aim of this paper is to find positive and negative emotions from the public comments rapidly and effectively. In this paper, to vectorize the text reviews and to reduce the dimension of the vectorized data, Term Frequency-Inverse Document Frequency (TF-IDF) and Truncated Singular Value Decomposition (TSVD) is used respectively. An efficient approach has been provided using the logistic regression algorithm employed in a vector space model of affective knowledge which gives fast learning speed. In result, this proposed method has reduced the learning time by 42.63% with the reduction of dimension from 12209 to 100 and has reported almost the same accuracy which is 85.7% and 89.3% for the movie review and yelp restaurant review dataset respectively. In comparison to existing methods, this method has shown almost the same accuracy after dimension reduction. Our result showed that our proposed system is useful.**

***Index Terms*—Sentiment Analysis, Logistic Regression, Truncated Singular Value Decomposition, Vector Space Model**

I. Introduction

In this modern era, people are very much dependent on social networks, blogs and other online media for expressing their opinions and sentiments. The availability of these web communities gives opportunity to people for sharing their opinions and ideas in a cost and time efficient way. This huge source of information and opinions has provided a powerful communication medium to share knowledge and to get advantage from others experience. At present, it is a key factor for the organizer to distill the knowledge from unstructured web data of public opinions and identify the mind of the customers about their products, policies, and organizations.

Sentiment analysis is a process of extracting positive and negative opinions from the review of people about anything. But the review of people which means the unstructured web data is hardly accessible to computers and for this, extraction the reviews into positive and negative is difficult. For solving this problem, a different type of machine learning algorithm exists. Such algorithms are very good at retrieving text, splitting them into parts, counting their words and finally giving a positive or negative result [1], [2]. Most of the researchers have only focused on which algorithm is superior to others for extracting reviews but they have not considered time and cost [10]–[16]. But as the amount of social data is increasing rapidly, time and cost is also a big issue for sentiment analysis.

In this paper, we have focused on not only extracting positive and negative reviews but also the optimal use of time, storage space, and cost. There are several types of feature extraction method and dimension reduction technique. Among them, Term Frequency-Inverse Document Frequency(TF-IDF) and Truncated Singular Value Decomposition(TSVD) have been used for feature extraction and dimension reduction respectively which perform the main role in reducing time and cost. Logistic regression has been used as a machine learning algorithm for extracting sentiment for its fast learning speed. Present related works and their limitations, our proposed framework, evaluation the performance have been described in the next sections subsequently. Finally, we have concluded our research with future work.

II. Related Works

Sentiment analysis is one of the recent hot topics for social, political, scientific and business world. Sentiment analysis depends on the natural language texts. Natural language texts are using in a wide range from questions and answering to mathematical word problem solving [3]. For classify the

sentiments, Support Vector Machine (SVM) [4]–[6], Nave Bayes (NB) [7], [8] and Maximum Entropy (ME) [9], [10] are the most popular machine learning algorithms.

In paper [11], 82.9% accuracy has been got for movie reviews using SVM with a bag of words feature sets. Nave Bayes, ME have also been used but SVM is superior among them. In paper [12], they have trimmed out objective content from movie reviews and used SVM and NB bag of words classifier to determine review polarity with an accuracy of 87.15%. They have examined the relation between subjectivity detection and polarity classification. For subjectivity detection, a graph has been built where source and sink corresponded to the class of subjective and objective sentences, respectively. Semi-supervised learning for imbalanced sentiment classification has been addressed in [13]. They have only focused on the imbalanced problem in the initial labeled data.

A novel approach using SVM to find out the overall positive and negative scores for a particular feature has presented in [14]. SVM has been showed as a best than other machine learning algorithm. In paper [15], Delta TF-IDF has been introduced for subjectivity detection and sentiment polarity classification, as well as documents of varying sizes. They have shown their improved result using SVM. Different corpora available for scientific research in opinion mining have been compared in [16]. They have applied machine learning algorithm (SVM) for different corpora.

For aspect-based sentiment analysis in [17], SVM and Logistic Regression [21] have been used as supervised machine learning algorithm. But they analyzed their result only for higher dimension. After analyzing above papers, we can see that in most paper researchers used SVM as a machine learning algorithm for sentiment mining. But in this paper, we have used logistic regression algorithm and compared with SVM using dimension reduction technique.

III. Proposed System

The goal of our system is to analysis sentiment with cost-effective way. Fig. 1 gives the overview of our proposed system.

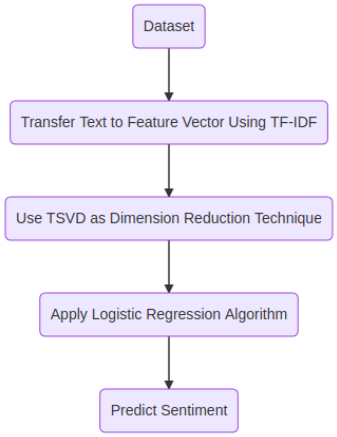

Fig. 1. Flow of the proposed system

In the following sections, we discussed the detailed methodology:

A. *Dataset:*

We have used the movie review dataset and the yelp restaurant review dataset [24]. Movie review dataset is derived from the benchmark corpus developed by Pang and Lee [18]. Those corpus includes 1000 positive and 1000 negative movie reviews. We have divided the datasets into train set and test set using 10 fold cross-validation.

B. *Text to Feature Vector:*

Vector space model represents the text documents as vectors of identifiers. It is used in information filtering, information retrieval etc. Term Frequency-Inverse Document Frequency (TF-IDF) [20] is one of the examples of vector space model. It is used for transforming text to feature vector. Actually, TF-IDF is a numerical statistics that determines how important a word is in a corpus. As 83% of text-based recommended systems in the domain of digital libraries use TF-IDF, we have selected it.

Suppose, we have a set of English text document. The term frequency of a term(word) in this document is proportional to the number of occurrence of the term in this document. So it can be defined as $tf(t,d) = F(t,d)$ where $F(t,d)$ is number of occurrences of term, t in document, d. Inverse document frequency diminishes the weight of terms that occur very frequently in the document set and increases the weight of terms that occur rarely. It is defined as the (1):

$$idf(t,D) = \log \frac{N}{N_{t \in D}} \tag{1}$$

Here, N is the total number of files in the corpus D and $N_{t \in d}$ is the number of files in which term, t is present. Finally, *tf-idf* is calculated as the following (2):

$$tf - idf(t,d,D) = tf(t,d) \times idf(t,D) \tag{2}$$

C. *Dimension Reduction:*

Truncated Singular Value Decomposition (TSVD) reduces the time and storage space by converting higher dimension into the lower dimension [23]. By removing multi-collinearity, it improves the performance of machine learning algorithm. We have selected 100 as the lower dimension. TSVD is preferred to other dimension reduction technique for its simplicity and relatively low computational cost. It is particularly suitable for measuring cross-correlations between affective word or concept.

D. *Logistic Regression Algorithm:*

Logistic Regression has proven highly effective in natural language processing and text classification [20], [21]. It was developed by David Cox in 1958 [22].

We have chosen the approach in [20] for Logistic Regression algorithm cause this approach simultaneously avoids overfitting and maintains high learning speed. It is also appropriate when the dependent variable is binary. As we require a binary

efficient classifier, we have chosen it. Besides this, it works by maximizing posterior class probability. So, for the lower dimension, it works efficiently in terms of time and accuracy.

Logistic regression measures the relationship between the categorical dependent variable and one or more independent variables by estimating probabilities using a logistic function.

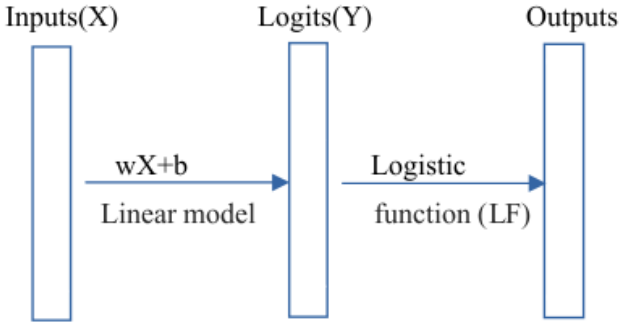

Fig. 2. Model of Logistic Regression Algorithm

where, weight of the corresponding input, w and bias input, b and *LF* represents Logistic Function as follow (3):

$$LF = \frac{e_y}{1 + e_y} \tag{3}$$

IV. Performance Evaluation

For sentiment analysis using machine learning algorithm most of the existing system have used SVM and they have proved that SVM is superior to others. But most of them have not used any dimension reduction technique and have not considered time, dimension and cost. So, we have compared our system with SVM with dimension reduction technique. Time has also been considered in this performance evaluation. Finally, we have compared our result with the results of the existing systems.

A. *Hardware and Software Configuration:*

- **Operating System:** Linux
- **Programming Language:** Python 2.7
- **Processor:** Intel Core i5-3317U CPU @ 1.70GHz
- **RAM:** 4GB

B. *Result Analysis and Comparison:*

Dimension of the training data has been evaluated before using TSVD. Then 10 fold cross-validation has been used. We have got the following result from Logistic Regression and SVM. We have also shown the confusion matrix for both algorithms in I.

TABLE I
Confusion Matrix Without Dimension Reduction

Movie Review Dataset					
		Actual			
Predicted		Neg.		Pos.	
	Classifier	SVM	LR	SVM	LR
	False	850	864	150	136
	True	154	137	846	863
Yelp Restaurant Review Dataset					
		Actual			
Predicted		Neg.		Pos.	
	Classifier	SVM	LR	SVM	LR
	False	907	907	93	93
	True	117	106	883	894

From confusion matrix, we can measure the accuracy like the (4).

$$Accuracy = \frac{T_p + T_n}{T_p + T_n + F_p + F_n} \tag{4}$$

where, T_p =True Positive, T_n = True Negative, F_p = False Positive, and F_n = False Negative.

TABLE II
Result Analysis without Dimension reduction

Movie Review Dataset			
Classifier	**Accuracy(%)**	**#Features**	**Training Time**
SVM	84.8	12209	8.1166726
LR	**86.35**	12209	**0.0763286**
Yelp Restaurant Review Dataset			
Classifier	**Accuracy(%)**	**#Features**	**Training Time**
SVM	89.5	12209	1.4578088
LR	**90.05**	12209	**0.069607299**

After the dimension reduction, we have shown the fixed dimension and the training time for both algorithms in the following table III.

TABLE III
Confusion Matrix after Dimension Reduction

Movie Review Dataset					
		Actual			
Predicted		Neg.		Pos.	
	Classifier	SVM	LR	SVM	LR
	False	818	849	182	151
	True	208	135	792	865
Yelp Restaurant Review Dataset					
		Actual			
Predicted		Neg.		Pos.	
	Classifier	SVM	LR	SVM	LR
	False	846	901	154	99
	True	103	115	897	885

TABLE IV
RESULT ANALYSIS AFTER DIMENSION REDUCTION

Movie Review Dataset			
Classifier	**Accuracy(%)**	**#Features**	**Training Time**
SVM	80.5	100	0.5638779
LR	**85.7**	100	**0.0437935**
Yelp Restaurant Review Dataset			
Classifier	**Accuracy(%)**	**#Features**	**Training Time**
SVM	88.65	100	0.5866717
LR	**89.3**	100	**0.0398641**

Now comparing Table II and Table IV, we can see that accuracy of Table IV slightly decreases. But in terms of dimension and training time, Table IV is superior. When SVM has been used without reducing dimension, it is better than Logistic Regression in terms of accuracy. But when dimension has been reduced, Logistic Regression is better than SVM.

Fig. 3 shows the comparison of training time before and after the dimension reduction for SVM and LR.

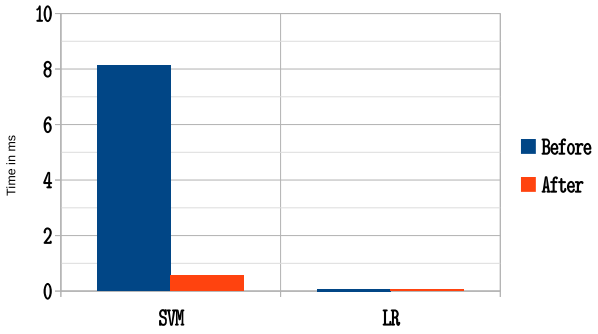

Fig. 3. Comparison of Training Time

Dimension of movie review data has been decreased from 12209 to 100 using TSVD. For this, storage space and cost both have been decreased. Besides this, from table IV we can see that Logistic Regression is 42.63% fast according to training time but the accuracy is almost same.

In terms of the number of features, our proposed system uses 100 features which is reduced by TSVD. On the otherhand, previous two methods [11], [14] have not used any dimension reduction techniques. Fig. 4 shows the comparison of features.

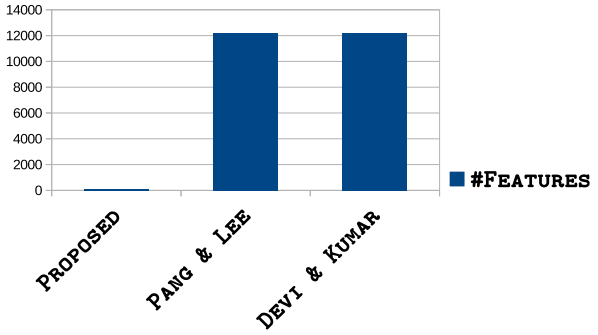

Fig. 4. Comparison of Features

For movie review dataset, our proposed systems shows an accuracy of 85.7% while [11] was 82.9%. Compared to [11], our system is superior. But [14] was 90.85% accurate which is superior to our system and [11]. Fig. 5 depicts the comparison:

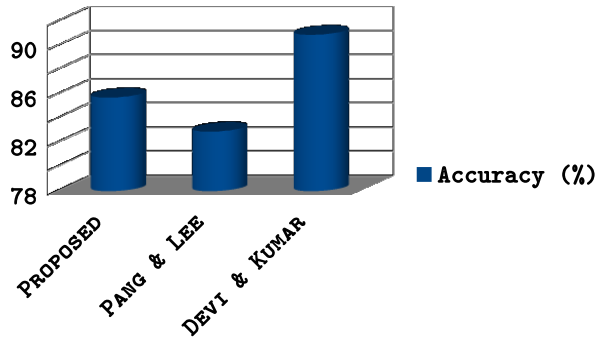

Fig. 5. Comparison of Accuracy

In conclusion, our proposed system is more accurate than [11] and [14] for movie review dataset in terms of features.

V. CONCLUSION AND FUTURE WORK

The main goal of this paper is to introduce a new framework for sentiment analysis which is both time and cost efficient by dimension reduction. The dimension also increases for sentiment analysis from large-scale data. For this learning time of any algorithm increases which is an important factor for measurement performance of any system. The system with faster speed and reasonable accuracy are more appropriate for sentiment analysis than the slower system with high accuracy. By analyzing above result, we can come to a conclusion that the accuracy of our system is almost same to the system using SVM after using dimension reduction technique. But in terms of training time, Logistic Regression is better than SVM. Besides this, the dimension of the proposed system is comparably very low. So our system is cost-effective and we have successfully provided a time and cost efficient model for sentiment analysis.

Unigram TF-IDF has been used for transforming text to feature vector. Bigram TF-IDF and deep learning can be used in future for more accurate result.

***Abstract*—Infant Mortality Rate (IMR) is one of the key indicators for a developing country, Bangladesh in particular, to measure the health and social status of its population. Many risk factors are associated with IMR that requires close investigation. This paper aims to build predictive models by identifying such potential risk factors responsible for infant mortality in Bangladesh. The World Bank data repository, based on "World Development Indicator (WDI) 2015", has been analyzed. We identify significant factors, build multiple stepwise linear regression models, and evaluate cross-coefficient model performances using MAE, MRE and MSE under the shed of k-fold cross validation technique. The performance of the final prediction model yields significant outcome towards the policy makers that could eventually reduce the infant mortality rate in Bangladesh.**

Keywords—Data Mining, Multiple Linear Regression, Risk Factors, Infant Mortality.

I. INTRODUCTION

Bangladesh has an estimated population of 160.996 million which ranks 8th in the world and population density of 1033 people per square [5]. Children who are one of the most vulnerable parts in society have an important role in the health system for each country. Therefore, Infant Mortality Rate (IMR) is a powerful indicator on the nation's health because it is often associated with other health factors and it is also considered as a serious challenge for health systems in developing countries like Bangladesh. Infant mortality is the death of an infant before his or her first birthday. The IMR, defined as the number of newborns dying under a year divided by the number of live births during a year, has in the past been regarded as a highly sensitive (proxy) measure of population health[1]. It is also part of United Nations development index and therefore becomes important to describe it for purposes of evaluation and outlining of health policies. Infant Mortality Rate varies based on changes in socioeconomic, geographic, biologic, demographic, cultural and environmental factors [2]. It is closely related to the well-being of the community and its development. According to these studies, maternal mortality ratio, newborns protected against tetanus, birth rate, crude, population, female, rural population growth, adolescent fertility rate, improved sanitation facilities, improved water source, labor force participation rate, female, population growth, low-birth weight babies, prevalence of anemia among pregnant women and children, smoking prevalence females, Pregnant women receiving prenatal care , GDP per capita (constant LCU), GDP per capita growth, employers female, parental education factors are commonly measured and demonstrated in World Bank data repository where IMR is relatively more serious in Bangladesh which have suffered with health inequalities, unsuitable socioeconomic condition and unfavorable environmental factors tends.

Data mining is the process of sorting through large data sets to identify patterns and establish relationships to solve problems through data analysis and it holds great potential to improve health systems. In Bangladesh health system there is a huge amount of untapped data that can be turned into useful information. In this proposed system, we are tend to investigate more reasonable factors out of literature and data repository that have been unexplored and to build predictive models using high risk factors to solve infant mortality problem through these untapped data analyses [3].

This paper attempts to identify the factors which influence number of children dying before reaching age one year in Bangladesh and also establishes temporal trends in attribute ability by factor as well as Bangladesh for the period 1990-2013; data is used from the "World Bank Indicator (WDI) 2015. In the following, we present the existing works completed under the same roof. Next, we discuss our proposed system following by the system implementation, discussion on result and analyses and finally, concluding with some insights.

II. LITERATURE REVIEW

Infant mortality is a powerful indicator on the nation's socio-economic and health because it is often associated with the number of different analytical frameworks in which affect the outcome through some proximate determinants factors namely socioeconomic variables (i.e. parental education, socio- economic status, place of residence , parental work status) , demographic factors(i.e. age of the mother at the time of birth, adolescent fertility, birth order, birth interval, sex of the child),environmental factors(i.e. source of drinking water, toilet facilities, housing construction material, type of bathing facility) health-seeking behavior (i.e. prenatal care; place of birth; tetanus injection before birth and contraceptive use; vitamin A dose received; low-birth weight babies) [4][5][6].

The multivariate Proportional Hazards framework is a flexible parametric framework for analyzing the impact

variables on infant [7]. Cross-tabulation, simple and multiple logistic regression techniques have been used to investigate the important factors of infant (below 12 months) mortality of Bangladesh, data from the "Bangladesh Demographic and Health Survey (BDHS) 2011" [5]. All these studies, which census data to measure the effect of socio-economic factors, environmental demographic factors, health and maternal behaviors to be significantly related to infant and child mortality [5]. To assess the effects of maternal and environmental factors on infant mortality in Kenya, data selected and analyzed from the" Kenya Demographic and Healthy Survey 2014" was used Mosley and Chen framework (1984, they distinguished fourteen proximate determinants and categorized them into four groups: maternal [fertility] factors, environmental sanitation factors, availability of nutrients to the infant, injuries, and personal illness control factors) to conceptualize the research and for data analysis methods, descriptive statistics and logistic [2].

One of the socio-economic variables is parental education which is strongly linked or related to infant mortality risk and known to have a reverse relationship with infant mortality [2]. Type of place of residence (urban, rural) where poor socio-economic status lead to under privileged health and living conditions especially for mothers and their children [2]. Africa is confronted with numerous health of its population; especially those living in urban areas have access to modern health facilities. Maternal and child mortality is very high, and mostly caused by long distances to health facilities shortage of trained health professionals, high cost of healthcare, and inadequate funding to purchase modern equipment for hospitals, build new hospitals , and recruit enough qualified doctors or specialists. As concerns the demographic variables (Age of the mother at the time of birth) the patterns for mortality by maternal age and birth generally take a U-shaped .Higher mortality risks occurring to children who are born to both relatively old and young mothers. Receiving tetanus injection and vitamin A has strongly highly significant influence on infant mortality [2][5]. Environmental factors on the households, source of water and sanitation facility has a significantly negative influence on infant mortality. Source of water and sanitation facility will have two categories safe/unsafe water and no sanitation facility/presence of sanitation facility respectively. In the household, both two variables are constructed from the mothers' response question on type of source of drinking water and sanitation facility [8]. HIV prevalence among adults aged 15 to 49 years, GDP per capita(in US$), adolescent fertility rate, female literacy rate, maternal mortality, birth rate, crude (per 1,000 people), health expenditure per capita (current US$), was the highest relative risk factors of infant mortality [9][10].

III. Proposed System

The proposed system works on infant mortality to explore risk factors and builds predictive models on infant mortality in Bangladesh. Figure1 shows the proposed system architecture. The system consists of several steps and includes important components. In the following, we describe each component to provide more clear view of the system.

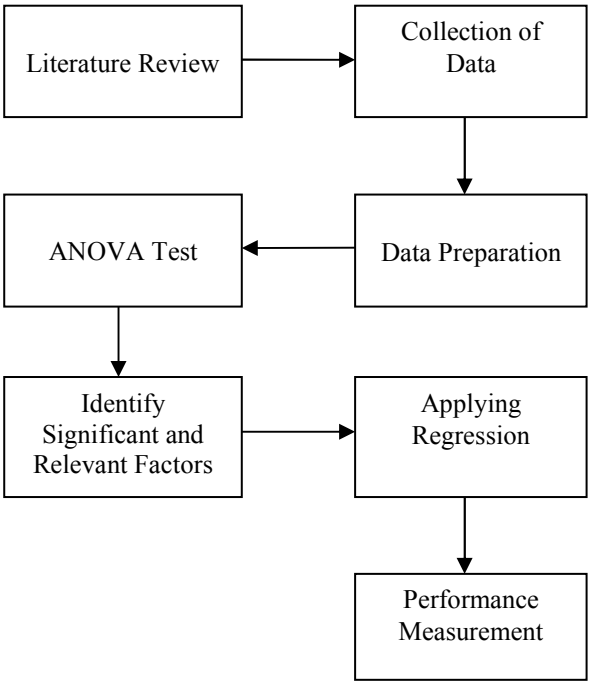

Figure1. Proposed System Model

A. Literature Review

We explore a significant amount research papers on infant mortality accessible via Google Scholar, IEEE, Willy, Elsevier, ACM Digital Library, and Springer Open. Later, the number of papers is narrowed down to relevant papers based on reviewing paper title, abstract and keywords. Then, we dive deep into the rest of the papers to identify various factors that have significant effects on infant mortality and involve both direct and indirect techniques to investigate infant mortality.

B. Source of Data

This study utilizes the data extracted from the "World Development Indicator, 2015 (WDI-2015) "database for Bangladesh [11]. The WDI represents the most accurate development data for each country and for this research the database includes data spanning up to 55 years- from 1960 to 2015.

C. Data Preparation

The database for this study includes data up to 55 years from 1960 to 2015. However, not all indicators have full values across these years. So, we filter out some indicators based on the number of data available in the repository. That eventually brings some indicators for the period 1990-2013.

D. ANOVA Test

After the first attempt on filtering indicators, we analyze significant testing on risk factors of infant mortality. We apply Analysis of Variance (ANOVA) test with an F-statistic measurement.

E. Identifying Significant and Relevant Factors

After ANOVA test, we obtain some significant and relevant factors for infant mortality used in building the model. In the data set we use in this research, some factors that are identified in the literature are not available; so we exclude them from the primary identified list. To investigate the factors that are absent in the literature but could have importance in the real life problems, we dig deeper into the data set and identified some factors that are significant across the IMR. However, not all the significant factors are relevant to the IMR; we exclude them as well. Finally, we include the filtered list of factors identified in the data set to the factors list available in the prior stage.

F. Building Regression Models

Once the factors are identified, we apply stepwise linear regression method using identified significant and relevant factors. Linear Regression is a well known supervised learning algorithm which is used in prediction problems. It finds the target variable by finding a best suitable fit line between the independent and dependent variables. The best fitted line has minimum error from all the points and has high efficiency. The stepwise linear regression is widely used methods for checking the linearity of the correlation among significant factors towards building models and often used as base model to provide insights and to compare with some other prediction algorithms. In this paper, we aim to find the base models with some of its variations and compare among them.

The stepwise regression model consists of considering one or more factors analyzed together and check whether the whole model becomes significant. Following the process, we build enormous amount of models and check which models have higher performance over others based on the predefined performance measurement criteria. A regression equation of the form is shown in equation (1).

$$y = \varepsilon + x_1\beta_1 + x_2\beta_2 + \cdots + x_k\beta_k \qquad (1)$$

where the value of a dependent variable y in terms of a set of k observable variables in $x = [x_1, x_2,\ldots,x_k]$ and an unobservable random variable ε.

E. Performance Measurement Criteria

Measuring performance is a challenging task. We choose some popular error measurement formulas for analyzing the performance of the built models. Those are: Mean Absolute Error (MAE), Mean Relative Error (MRE) and Mean Squared Error (MSE).

$$MAE = 1/n\sum (|\, y_a - y_p|)$$

$$MRE = 1/n\sum((|y_a - y_p|)/y_y)$$

$$MSE = 1/n\sum(|\, y_a - y_p|)^2$$

In the above equations, y_a denotes the actual value from the data set and y_p is the predicted value generated from the model. Moreover, we observe the model R-squared and Adjusted R-squared values for the accuracy of the model.

IV. IMPLEMENTATION

A. Data Preparation

The WDI-2015 dataset contains 1350 indicators and includes data up to 55 years from 1960 to 2015. Indicators are the standards based on which the ups and downs of a country can be evaluated. In data preparation, we extract approximately 650 indicators based on the availability of 25 data for each indicator where the indicators may or may not be completely related to the target problem we deal with in this paper. We ignore indicators that have very small amount of data that would have less significance in building significant models. Indicators are analogous to our future identified factors.

B. Identifying Significant Factors

Among 650 indicators, we are only interested in significant ones, have sufficient data and relevant to the problem. Therefore, we narrow down the indicators further to 550 where data were available for the period of 1990-2013. From the dataset, we apply ANOVA to identify significant factors. Setting the significant testing with p-value < 0.1, we identified 15 factors that do not all exist in literature but have significance on infant mortality.

Further, based on the proposed method, we exclude the significant but irrelevant factors identified from the dataset. The remaining significant factors from the set are added to the list of factors identified in the literature. That becomes totally six factors to be suitable for building the regression model. The histograms of these factors are displayed in Figure 2 to Figure 7.

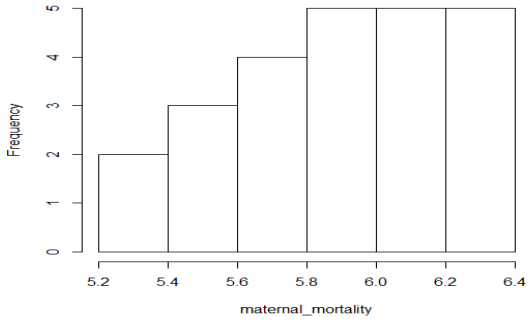

Figure 2: Histogram of Maternal Mortality Rate

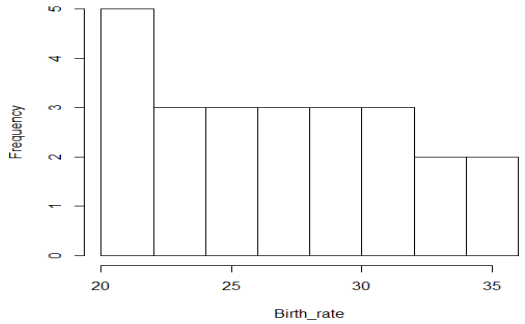

Figure 3: Histogram of Birth Rate

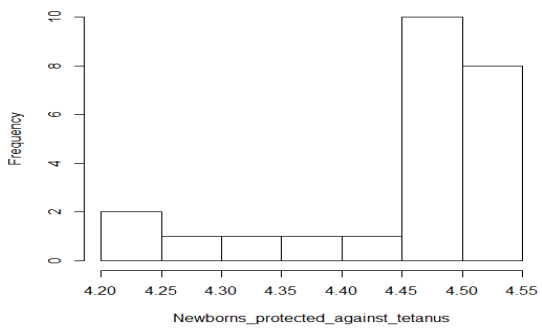

Figure 4: Histogram of Newborns Protected Against Tetanus

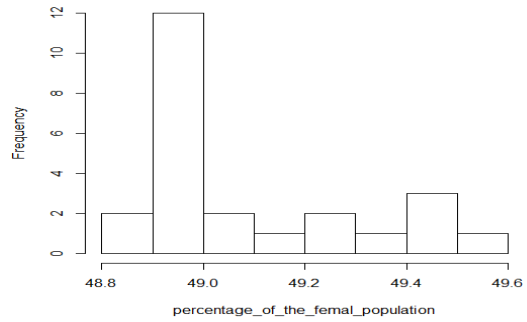

Figure 5: Histogram of Percentage of Female Population

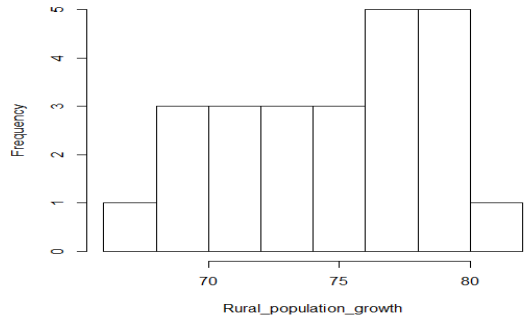

Figure 6: Histogram of Rural Population Growth

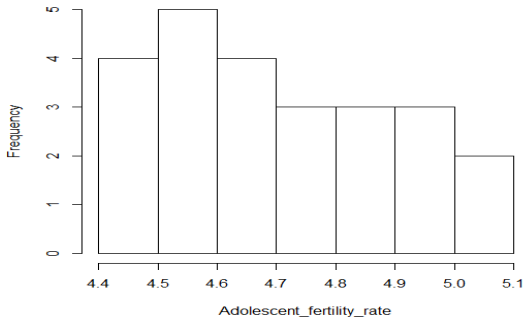

Figure 7: Histogram of Adolescent Fertility Rate

C. Building Models

After stepwise regression analysis we obtain a model consisting six factors: maternal mortality ratio (MMR), newborns protected against Tetanus Injection (TI), Birth Rate crude (BR), Population Female (PF), Rural Population Growth (RPG), Adolescent Fertility Rate (AFR). A set of coefficients are determined from the regression model are shown in Table I and the regression model is presented in equation (2).

$$IMR = 1793575.52 + (135.38 * MMR) - (101.95 * TI) + (12927.15 * BR) - (36006.51 * PF) - (3244.07 * RPG) + (411.94 * AFR) \quad (2)$$

TABLE I: ASSOCIATION BETWEEN INDICATORS AND INFANT MORTALITY

Indicators	Coefficients	P-value
Maternal mortality ratio (modeled estimate, per 100,000 live births).	135.38	0.043
Newborns protected against tetanus (%)	-101.95	0.017
Birth rate, crude (per 1,000 people)	12927.15	0.000
Population, female (% of total)	-36006.51	0.000
Rural population growth (annual %)	-3244.07	0.002
Adolescent fertility rate (births per 1,000 women ages 15-19)	411.94	0.084
Intercept	1793575.52	0.000
R-squared	1	
Adjusted R-squared	1	

Based on the model built using linear regression, we plot residuals vs fitted graph in Figure 8. The normal Q-Q graph has been depicted in Figure 9.

.

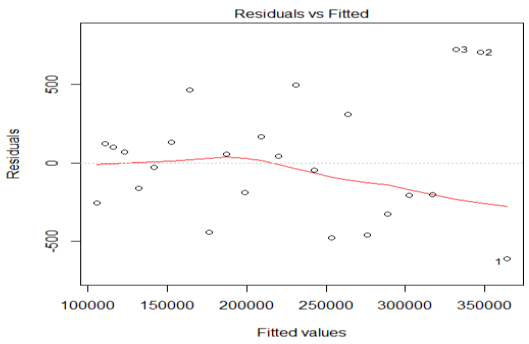

Figure 8: Residual vs Fitted

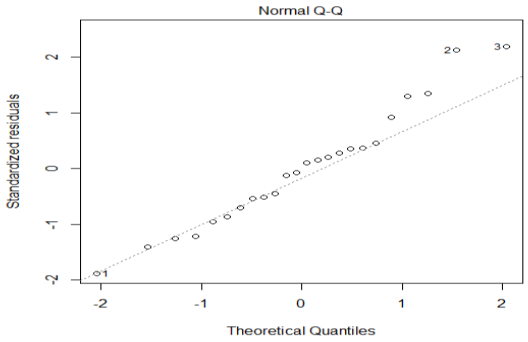

Figure 9: Normal Q-Q Plot

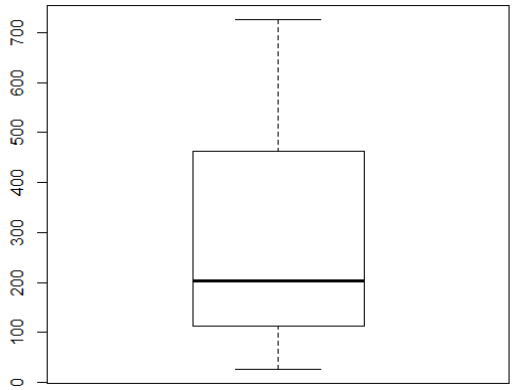

Figure 10: Boxplot of MAE

V. Result and Discussion

The results of main determinant of infant mortality rate in Bangladesh (1990 to 2013) are presented in Table II. The result of R2 statistics showed that the independent variables of model were good predictors for infant mortality rate and also showed that that there were high correlation among dependent variable and explanatory variables which is 1. Regression model parameters displayed in Table I yields from k-fold cross validation where we use k = 4.

TableII : Sample division for K-fold cross validation

Case No.	Testing Set	Testing Set
1	1996-2013	1990-1995
2	1990-1195,2002-2013	1996-2001
3	1990-2001,2008-2013	2002-2007
4	1990-2007	2008-2013

From the above 4 cases, we obtain four different models using the training set and validated using testing set. The resultant values based on the performance criteria have been shown is Table III in row 2. For a deeper analysis, we take two best models from the 4-fold cross validation and the coefficients of these models are applied to the base model to check whether the model has any effect on that particular set of coefficients. The results from those models are presented in row 3 and 4 respectively.

Table III: Performance Comparison

No.	Model	Mean Absolute Error(MAE)	Mean Relative Error(MRE)	Mean Squared Error(MSE)
1	Base	282.921	0.00125	124314.095
2	4-fold Cross Validation	3507.004	0.01051	14824769.5
		461.860	0.00181	328821.992
		262.719	0.00151	94283.755
		1774.334	0.01545	3878313.33
3	Best1	287.985	0.00128	126525.711
4	Best2	323.661	0.00146	164003.317

From Table III, we see that our base model provides more accuracy based on the performance criteria set. The box plots of the errors are presented in Figure 10 to Figure 12. The box plots have shown the error rates are minimal and within range.

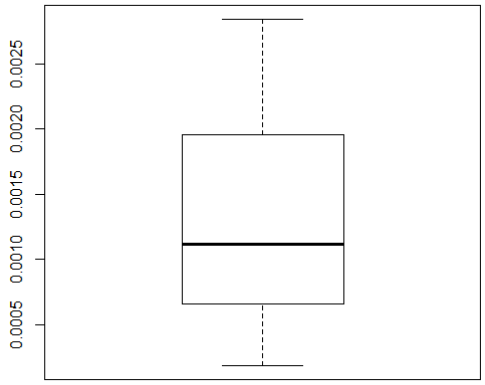

Figure 11: Boxplot of MRE

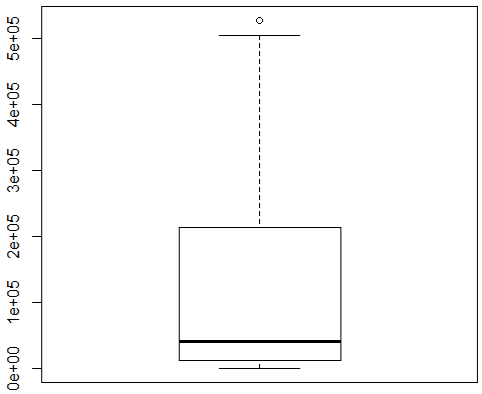

Figure 12: Boxplot of MSE

According to the model, decreasing values in variables such as maternal mortality ratio, birth rate, crude (per 1,000 people), population, female (% of total), rural population growth (annual %), adolescent fertility rate (births per 1,000 women ages 15-19) caused the infant mortality reduction. Tetanus injection is highly significant effect on risk of infant mortality. The results of this study show that tetanus injection is an inverse association with infant mortality. Decreasing rural population growth, population female were associated with a significant lowering of infant mortality rate. The empirical analysis shows that the maternal mortality, adolescent fertility rate and birth rate have a

positive effect on infant mortality rate and infant mortality has been decreased by decreasing values of these variables. In this study, factors such as sanitation facilities, water facilities, Labor force participation rate female, GDP per capita, GDP per capita growth were not significantly related to the infant mortality rate.

VI. Conclusion and Limitation

Infant mortality rate is commonly used as one of the most important indicators of the level of socio-economic development of our country. This indicator is associated with well-being of a population and the one of the main items of the millennium development goals. So, the purpose of this study is to assess the effect of maternal mortality ratio, adolescent fertility rate, birth rate, rural population growth, population female on mortality rate of infant in Bangladesh. This study is designed as a predictive model to identify the factors that significantly influence the risk of infant mortality in Bangladesh. The cross validation and multiple stepwise regression analysis suggests that among the 16 factors only 6 factors are significant. It is recommended that the future study focuses on the predictors of provincial infant mortality rate in Bangladesh along with comparison of the proposed base model with some other popular prediction algorithms.

This study has some threats to the validity. To extract data from WDI-2015 for the period 1990-2013, some data were not available during the period and could not be possible to include them due to the absence of most relevant indicators for infant mortality. For instances, parental education, receiving vitamin A, smoking prevalence female, pregnant women receiving parental care, low birth-weight and similar. The performance can be further investigated by filling the missing values of the factors identified. Overall, the proposed model has a good accuracy on the data set available for identified factors from literature and the WDI-2015 data source, and provides insights on the changes in infant mortality rate with the change in significant factors responsible for the cause.

Dhaka-1205, Bangladesh
*email: ashraf.siddiquee.1996@gmail.com

***Abstract*— In this paper, a modular multilevel converter of twenty one level is designed by using a three level submodule block. The submodule block can be half-bridge or full bridge. In a half bridge submodule block, the switching configuration is more efficient than the full bridge submodule block. But there is problem of DC fault current. Half bridge submodule block is not capable of blocking the DC fault current. In this paper, we have designed such kind of submodule block which is a combination of half bridge and flying capacitor. A capacitor which is floating with the half bridge circuit that is called flying capacitor. We have designed many modular multilevel converters of different levels using this submodule block but the twenty one level modular multilevel converter gives the best output. A simple control mechanism is implemented in this design. So, our proposed design of modular multilevel converter is simple and it shows better performance.**

I. INTRODUCTION

In the previous years, for power transmission, however it is long distance power transmission or short distance power transmission, Alternating Current(AC) power transmission was used. However nowadays it is found in research that for long distance power transmission (more than 700km), Direct Current(DC) power transmission is more cost efficient and safe than Alternating Current power transmission. In the DC power transmission, high voltage DC is used. For high voltage DC, low voltage DC has to be converted to high voltage DC. However transformer can only operate in AC. So, for voltage level conversion, DC has to be converted to AC and AC has to be converted to DC. For AC-DC conversion, rectifier is used and for DC-AC conversion, inverter is used. For making pure sinusoidal wave with low harmonic distortion, number of level of the sinusoidal wave has to increased[4]. So, modular multilevel converter is used.

Nowadays, for modular multilevel converter half bridge or full bridge submodule blocks are used. The main drawback of the half bridge submodule block is that the submodule block cannot have any DC fault blocking capability. So, in this paper, the modular multilevel converter is designed using a such kind of submodule block which is a combination of half bridge and flying capacitor. This submodule is a five level submodule[1,2,3], however there is a problem of two level in this five level, which are not stable. So, in this paper the submodule block is used as a three level submodule block. This three level submodule block has the capability of DC fault current blocking.[4,5,6]

Moreover, in this paper, for controlling purpose comparison of reference sine wave is used. Comparing the reference sine wave, by using digital signal processing, the controlling mechanism is implemented in Matlab Simulink. In the previous papers[7,8,9,10], PI control mechanism was implemented. However this control mechanism is not so good for this inverter design due to high high computational time. Again, model predictive control algorithm[11,12] was trying to implement, however that controlling mechanism is too much time consuming for processing the code. For this reason, a simple mechanism is implemented by comparing the reference sinusoidal wave. So, our designed module multilevel converter is simple, cost efficient and better performance.

II. TOPOLOGY OF MODULAR MULTILEVEL CONVERTER

The main topology of three phase modular multilevel converter is shown in figure 1.

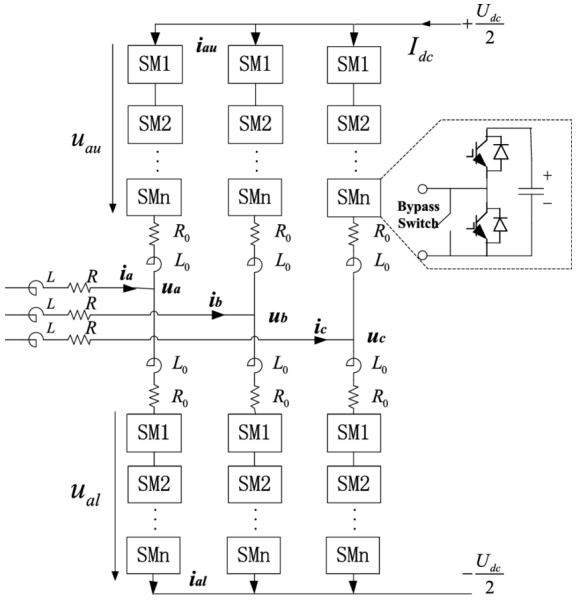

Fig. 1. Topology of Modular Multilevel Converter

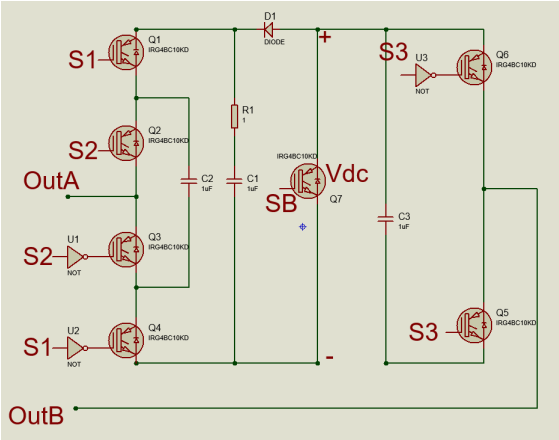

Fig. 2. Three Level Sub-module Block Schematic

Typical MMC topology consists of three-phase legs, each divided in two arms (upper and lower). Further, each arm is a stack of N series connected identical submodules and an arm inductor arm L. A submodule can perform three modes of operations: (i) inserted, (ii) bypassed, and (iii) blocked. When an SM is inserted, it permits current to flow through capacitor and to charge/discharge it. In bypassed mode, switches of SMs operate in such a way that it allows current flow through SM, however bypassing the capacitor, the capacitor remains charged and in block mode of operation, all the switches of SM are off, and current can flow only through anti-parallel diodes, if possible.Any particular submodule can be inserted or bypassed or blocked at any instant, based on switching commands, and thus, any number of SMs can be inserted at a time corresponding to switching scheme, and therefore, with appropriate switching schemes, an alternating voltage can be generated.

III. TOPOLOGY OF THREE LEVEL SUBMODULE BLOCK

In this paper, the modular multilevel converter is designed using a three-level submodule block. The circuit diagram of the three-level submodule block is given in figure 2. This submodule block has two parts. One is a flying capacitor unit and another is half bridge submodule unit. In a previous paper[13], it is proposed that the submodule block will work as a five-level submodule block. However in Matlab Simulink simulation it is seen that the submodule block can work for three-level properly. Other two levels are not stable, that why in this paper, it is used as a three-level submodule block.

There are total 8 switches in this submodule block. They are s1,s2,s3,sB and their compliment switches. So, we have to control 4 switches, then the other complimentary switches will be automatically controlled. Moreover, between these 4 switches, sB will be always on. For this reason, the main concern is to control the other three switches. One of the most useful features of this submodule block is that it has DC fault blocking capability and the full mechanism of the blocking the fault current is described in the paper[14].

TABLE I

The parameters of the submodule block is given in table I. The switched controlling output of the submodule block is given in Table II.

IV. CONTROL MECHANISM

In the previous papers to control the modular multilevel converter, PI control mechanism is used. There are many control mechanisms. The popular control mechanisms are model predictive control mechanism, normal switch control mechanism,PI control, PID control etc[15,16,17]. Model predictive control mechanism one of the most popular mechanism, and it is highly used in the control mechanism of the modular multilevel converter. However there is a drawback in the model predictive control mechanism. If the number of levels of the modular multilevel converter is increased, then model predictive control cannot work properly due to high computation. So, model predictive controlling mechanism needs high computation. For this reason, though this control mechanism is used in the previous papers in this paper, this control mechanism is omitted. In this paper, a new control mechanism is proposed, which is very simple to compute.

Model predictive control is used in those cases where the output does not follow any kind of pattern.[18] However in a inverter, the output is known. For this reason, a reference sinusoidal wave is used to predict the output. The full control mechanism is described in this section.

A. Reference Sinusoidal Wave

For controlling purpose, a reference sinusoidal wave is used. The reference sinusoidal wave configuration is given in table III.

B. Controlling Unit

In the control unit, a processor is needed to compute the mathematical calculation. The sampling frequency of the computational time is $2.5 * 10^{-5}$ seconds. There is total 21 levels in this modular multilevel converter. From 0 volt to 200 volt there is 11 levels, from 0 volt to -200 volt there is 11 levels and 0 is a level. That's why there is total 21 level. The more the level the less the harmonics, however if the number of levels is increased, then there is a lag in the output sinusoidal wave. For this reason, the best output is found in the 21 levels. Further it will be discussed more elaborately.

Every sampling time, the reference sinusoidal wave is compared with the levels of output voltage. Then it is decided that in which level the output wave should come. In this process, this sinusoidal wave is generated.

V. BLOCK DIAGRAM AND OTHER ANALYSIS

The circuit is divided into mainly two sections. One is control unit another is sub-module unit. In the control unit, there are two units, one is comparison and level decision unit and another is switching sequence generator unit[19].

A. Control Unit

1) Comparison and Level Decision Unit: In this unit, every sampling time, reference sinusoidal wave is located in which level of the output sinusoidal wave, it is decided. So, in this section comparison of the level with reference sinusoidal wave is done and the decided level is the output of this section.

2) Switching Sequence Generator Unit: In this unit, using the number of level, a switching sequence is generated for the submodule blocks. So, for 21 levels, there is total 10 submodule blocks. Switching sequence for each block is generated in this unit and the switching sequence is sent to the submodule blocks.

B. Submodule Blocks Unit

In this unit, for 21 levels there are total 10 submodules[20]. If there is n submodules, then the number of levels is 2n+1. In this paper, we used total 10 submodule blocks. These 10 blocks are divided into two sections, the upper 5 submodule blocks are for the positive half cycle of the output sinusoidal graph and the lower 5 blocks are for the negative half cycle of the output sinusoidal graph[13].

The DC input of the each sinusoidal graph is 40 volt. If we want 140 volt, then the situation of the submodule blocks is shown in Table IV. Again for -80 volt output, then the configuration of the submodule blocks is shown in Table V.

VI. OUTPUT CIRCUIT

In the output side a series RLC circuit is used. In the RLC circuit the output parameters is set using the written values in table VI. The output circuit is given in figure 3.

TABLE IV

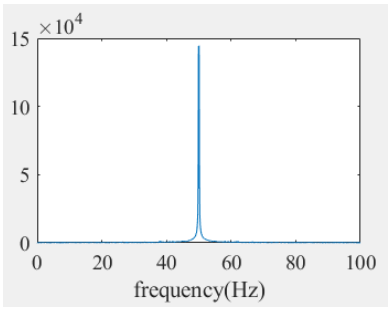

Fig. 10. Spectrum Analysis Graph of 33 Level Modular Multilevel Converter

TABLE VII
TOTAL HARMONIC DISTORTION FOR EVERY OUTPUT OF MODULAR MULTILEVEL CONVERTER

Number of Levels	THD(%)
11	9.42
21	3.97
33	3.42

In this figure, the reference sinusoidal wave is in blue color and the output voltage is in orange color. In this figure, we can see that the output is slightly lagged from the reference sinusoidal wave. This happened because high computation in the processor. However if we decrease the number of

levels, then the output graph will be better. Output graph of 11 levels MMC is given in figure 5. However there is a problem, if we decrease the number of levels, then the Total Harmonic Distortion will be higher. Again, for lower THD if we increase the number of levels, then there will be huge lag in the computation time. For this reason, the output voltage will be too much lagged from the reference sinusoidal wave. The output graph of 33 level MMC is given in figure 6. In this figure, the total harmonic distortion will be lower, however due to high computation time, it is clearly seen that the output wave has huge time lag from the reference voltage. So, lag time of the output sinusoidal wave from the reference sinusoidal wave versus no of levels graph is given in the figure 7. Here we can see that, the more the levels, the more the lag time. After comparing all the matters, total harmonic distortion, time lag etc, we can see that the 21 level modular multilevel converter is best among the others. In this paper, different levels of modular multilevel converter is simulated. From different number levels output, we can see that, the more the level, the better the output. Different spectrum analysis output of different number of levels are shown in figure 8, figure 9 and figure 10. Here it is shown that the best output is for the 33 level modular multilevel converter. Again the total harmonic distortion is determined for every output. The output of THD for every analysis is given in table VII. So, we can see that, the best output is for 33 level. However, in previous it is shown that time lag of the output graph is maximum for the 33 level MMC. So, after all types of analysis, spectrum analysis and time domain analysis, it is decided that the 21 level MMC gives the best output.

VIII. CONCLUSION

This paper proposes a design of twenty-one level Modular Multilevel Converter using a three-level Submodule block. This block is very much helpful for DC fault current blocking. Moreover, in this paper, it also analysed that the best output of a Modular Multilevel Converter is seen for 21 level MMC. Nowadays High Voltage Transmission is very much popular and design of efficient Inverters is very important. So, this paper will help to implement a low cost and more efficient Modular Multilevel Converter. That will help the whole mankind. Further, it is hoped that, practical implementation of the proposed design will be done and then the design will be more practical and more efficient and more beneficial for all of us.

***Abstract*—Comparative study of enhancing stability of a wind farm that is grid connected has been done by moderating voltage fluctuation and achieving reactive power compensation using STATCOM (Static Synchronous Compensator). To control STATCOM a voltage control loop with a PID controller is used. To maintain the control system of STATCOM a PWM technique has been introduced. By using different approach, comparative study regarding stabilization of a wind farm has been performed (i.e. by using capacitor bank only, using STATCOM or using STATCOM along with PID controller during wind speed change. STATCOM with PID controller deals better performance with improved stability.**

Keywords—STATCOM, PID Controller, Capacitor Bank.

I. INTRODUCTION

Recent statistics say that sustainable power source has turned into a period of colossal examination due to constrained characteristic assets. Natural gas (24%) is the fundamental wellspring of vitality in Bangladesh, that is probably going to be exhausted continuously 2020 [1]. Renewable energy sources like wind energy, ocean wave energy[2] etc. are needed to use because these sources of energy are environment friendly.

For power system utilities voltage stability has become a vital concern with respect to the ups and downs in power systems like increase of load, genset reaches reactive power borders [4] etc. In wind turbine generator, induction generator (IG) utilized in light of the fact that it can recoup energy with moderately straightforward controls, it is likewise practical and strong. Since the active power produced by steady speed wind turbines is varied because of the impacts of turbulence, the breeze inclination, the pinnacle shadow and the reactive power request of these squirrel-cage induction generators have likewise fluctuated. Thus, the reactive power and active power varieties can cause change of voltage in the purpose of basic coupling (PCC). Therefore, settled speed wind turbines present testing impacts on the grid performance. In spite of the fact that a bank of capacitors is utilized to keep up reactive power at enduring position, it can't legitimately be controlled to keep the voltage steady. For balancing out the wind generator SVC (static var compensator), unified power flow controller (UPFC), STATCOM with the presence of VSC (voltage source converter) etc. are utilized. In wind farms, STATCOM gives the voltage which is steadier and it is likewise cost-effective. With the ever-increasing use of renewable energy [5] resources, the use of STATCOM has become absolutely essential [6-8].

In this paper, we propose a utilization of six-pulse STATCOM for generating wind energy which is connected to the grid, gives speedier reaction time maintaining prevalent voltage bolster ability. Because of the smooth task of voltage and speedier reaction PID controller have been utilized. The PSCAD simulation comes about demonstrate the relative execution of wind farm utilizing just capacitor bank and utilizing STATCOM or utilizing STATCOM alongside PID controller. Examination of result demonstrates that STATCOM with PID controller offers better execution.

II. MODELLING THE SYSTEM

Wind turbine setup contains the necessary equipment needed to grab the wind's energy. Fig. 1 shows a typical grid-connected wind system where the wind's energy turns 2 or 3 propeller-like vanes prevailing a rotor. The rotor that is associated with the main shaft, simply rotates a generator to generate electricity. For stability enhancement it is very important to design a wind turbine properly.

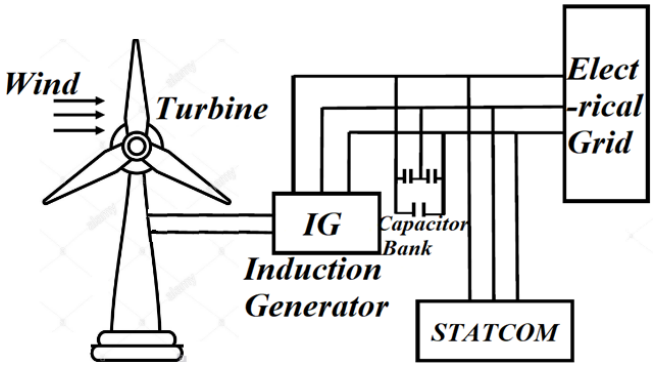

Fig. 1. Induction Generator and Grid connected Wind turbine

III. STATCOM

STATCOM is the device in the family of Flexible AC Transmission Systems (FACTS) used for power flow control, improving transient stability, enhancement of power factor, enrich voltage stability etc. There is a var control mode operation in where STATCOM's output power (reactive) is constant and parameters (different) are independent. Time response of STATCOM is better than static Var Compensator (SVC) [9]. Fig. 2 shows a very simple construction of statcom with six IGBTs and a shunt capacitor. In this study, STATCOM is used to enhance the voltage stability.

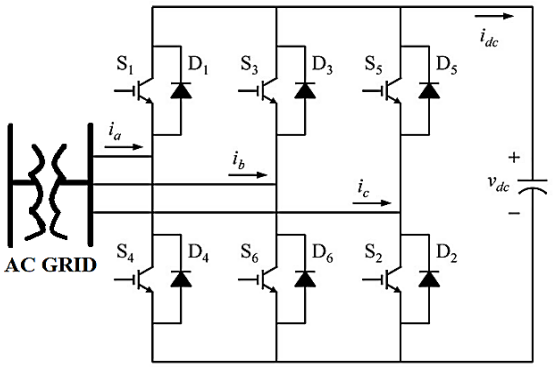

Fig. 2. Circuit Diagram of STATCOM

IV. STATCOM CONTROL STRATEGY

The control strategy basically follows vector control principles [10]. It is applied to the three-phase grid-connected converters. The VSC in STATCOM is produced from a DC link capacitor, in order to reduce converter losses the DC link voltage is controlled by modulating direct axis current of converter. To modulate the transmission of reactive power from STATCOM towards the grid, the voltage of the grid can be controlled by the quadrature current of converter [11]. Lowest fault condition operation rating is the subject to the ratio of connection point's short-circuit power and wind farm rated power [12]. In this paper mainly two types of control strategies are discussed. One is Voltage Control System using PID controller and another is pulse width modulation.

A. Voltage Control Using PID (Proportional-Integral-Derivative) Controller

The PID Controller is a type of control loop feedback system which is mainly used for control systems in light of industrial purpose and continuously modulated control systems. From a research, PID controllers are used in industrial automation at near about 95%. In closed-loop operations, PID maintains the zero error among variable parameters and output [13]. In PID controller there are three terms.

Proportional term is the term where the output changes proportionally with the recent error value. Controller output becomes zero if the error value is zero. When the proportional gain stands high enough the system can become unstable and control action might be too less when the gain is too low.

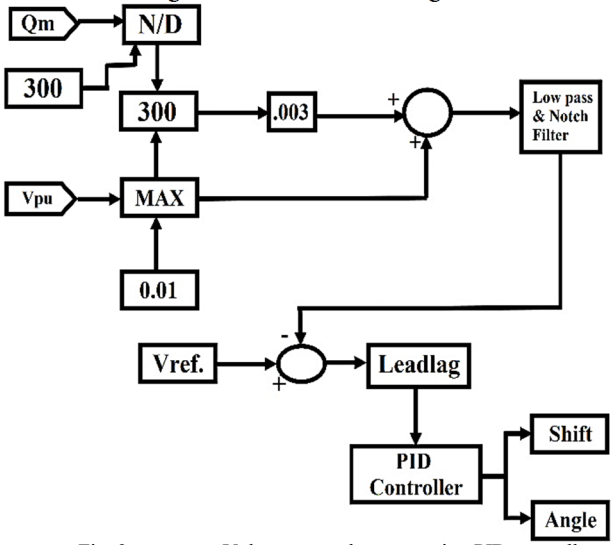

Fig. 3. Voltage control system using PID controller

The integral terminology depends upon both the magnitude and duration of the error. In proportional term, there is a steady state error which is eliminated in this term. It continuously does integration of the error till error value is zero. It has no ability of detecting forthcoming behavior of error.

By anticipating the forthcoming value of error the derivative term resolves the problem. The error is determined from the slope of the error and multiplication of the derivative gain with rate of change. Improving settling time derivative term enhances the stability [13].

For generation of angle order voltage control loop is used. Through the disputation between the reference and filtered voltage, the value of error voltage is found. The filtered voltage passes the reactive power and measured voltage by the notch filter. After that, the error voltage is filtered by PID controller (Fig. 3). In this paper, Voltage Control System has been used both with PID controller and without PID controller. Without PID controller there are voltage fluctuations and the system is unstable. But with PID controller the voltage fluctuations are less and the desired output is gained. This gives a better performance and makes the system stable.

B. Pulse Width Modulation (PWM)

PWM is a system for controlling DC power to an electrical device. It is additionally used to control the power that is provided to the different sorts of electrical devices, for example, AC/DC motors. For the power loss in the exchanging device of the PWM is low. There is for all intents and purposes no currents present when the switch is turn off. When it is on there will be no voltage drop over the switch and power will be exchanged to the load. So the power loss in the two cases will be near zero.

PWM has two principle parts. The initial segment of the PWM is known as the age of the triangular waveforms and the second piece of the PWM is the age of the reference waveforms.

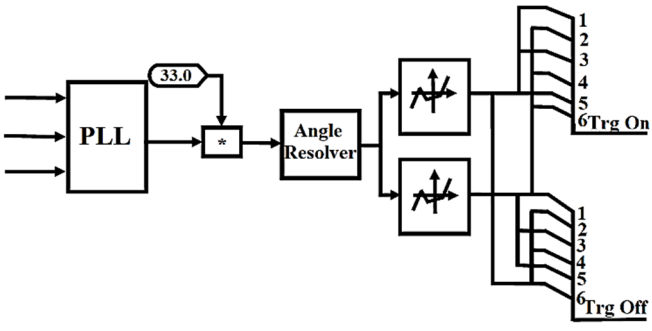

Fig. 4. Part 1: Generation of Triangular waveform.

Part 1: Fig. 4 shows the PLL (Phase Locked Loop) that makes an edge which is called theta and it is multiplied by the carrier frequency. The multiplication result is associated with a client characterized part which is called edge resolver. There is likewise trigger on and trigger off pulse which is utilized for setting off the pulse of the STATCOM.

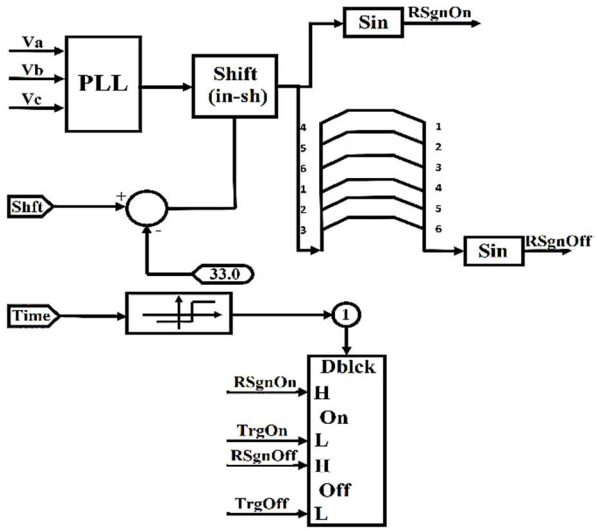

Fig. 5. Part 2: Reference waveform Generation

Part 2: Here again in Fig. 5 theta is made from another Phase Locked Loop (PLL). The yield of the voltage control loop and yield of PLL are associated with a client characterized segment which is meant by six-dimensional arrays.

V. Results and Simulation

In this part, utilizing PSCAD simulation of a wind farm that is connected to the grid alongside induction generator is demonstrated. To repay the reactive power, the wind farm is associated with capacitor bank and STATCOM which is controlled by a PID controller. A similar investigation of stability enhancement is examined. Simulation comes about have been contrasted along and important diagrams.

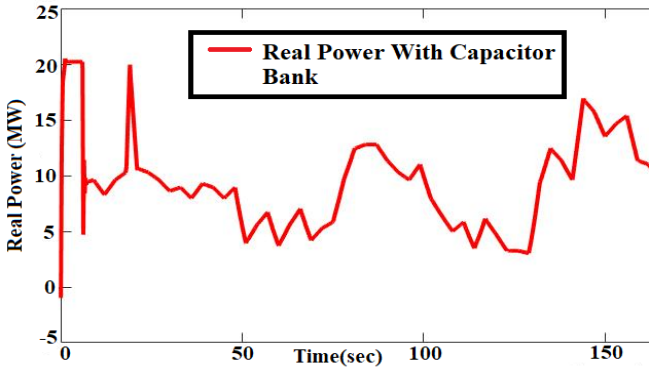

Fig. 10. Real Power with capacitor bank (MW)

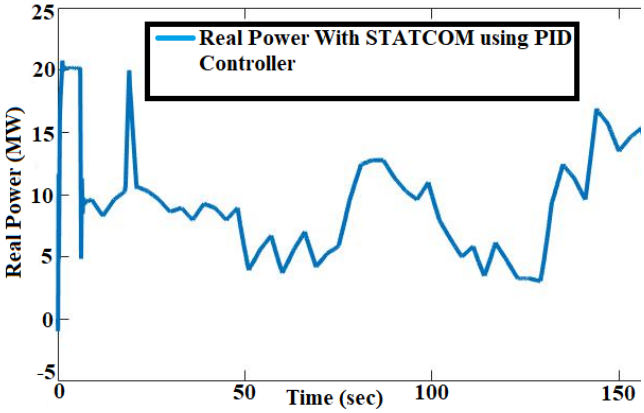

Fig. 11. Real Power with STATCOM using PID Controller (MW)

Fig. 6 demonstrates the RMS voltage information utilizing STATCOM with PID controller and just Capacitor bank. The steadier waveform has been found if there should be an occurrence of STATCOM with PID controller than

Capacitor bank. Fig. 7 shows the nature wind speed variance. Fig. 8 demonstrates the terminal voltage of induction generator utilizing STATCOM with PID controller and Capacitor bank. There is a vacillation estimation of the terminal voltage picked up when capacitor bank is utilized. In any case, when STATCOM alongside PID controller is utilized the terminal voltage vacillation is expelled and it indicates more steady esteem however the wind speed is fluctuating in nature. A superior consequence of a terminal voltage is picked up by utilizing STATCOM instead of Capacitor bank. Fig. 9 demonstrates reactive power with STATCOM and Capacitor bank and Fig. 10 and Fig. 11 demonstrates the real power also.

VI. Conclusion

This study deals with the enhancement of the stability of a wind farm that is grid connected by mitigating voltage fluctuation and attaining reactive power compensation. Different approach has been adopted like adding capacitor bank, STATCOM or using STATCOM along with PID controller etc. to enhance the stability of a wind farm during wind speed change. STATCOM control strategy involves a voltage control loop with a PID controller and a PWM technique. Comparative study showed us that STATCOM with PID controller offers better performance with enhanced stability then that of using only capacitor bank.

***Abstract*—We consider the electrical load scheduling problem for a multi-chambered refrigerated warehouse with each chamber consisting of a screw compressor operating under load-unload control. Considering loading and unloading time duration of the compressors to be fixed, we propose a simple load scheduling scheme where the loading of the compressors starts with a uniform time delay. We provide analytical models to calculate the cumulative load of the warehouse compressors at any given time and the electricity cost under dynamic pricing considering the proposed load scheduling scheme. We then validate the analytical models via simulations. As a benchmark, we consider a warehouse system where the loading time of the compressors starts randomly. We investigate that the total load under the proposed scheduling scheme do not vary significantly with time. However, the traditional system has significant variation in total load with time. We compare the electricity cost of warehouses for the proposed and the traditional systems under a dynamic pricing model. We find that the proposed load scheduling scheme significantly reduces the electricity cost compared to the traditional system. However, the cost reduction decreases with increasing the loading-unloading duty cycle, i.e., with increasing the ratio of loading time duration to the total loading-unloading time duration.**

***Index Terms*—Smart grid, demand management, real time pricing, load scheduling, refrigerated warehouse, screw compressor, load-unload control**

I. Introduction

The conventional electrical grid infrastructure is a centralized system where current flows unidirectionally through the transmission and distribution lines from the plant to the customer. Thus, the intelligence only exists in central locations and partially in substations, not at all in the terminal (i.e. loads) areas. The smart grid, as it is aptly dubbed, is a loose integration of complementary components, subsystems, functions, and services under the pervasive control of highly intelligent management-and-control systems that uses information, two-way, cyber-secure communication technologies, and computational intelligence in an integrated fashion across electricity generation, transmission, substations, distribution and consumption [1]. They enable, among others, new approaches in grid management by applying demand side management and providing grid energy storage, needed for load balancing and for overcoming energy fluctuations caused by the intrinsic nature of renewable energy sources, preventing widespread power grid cascading failures [2], and enabling the integration of plug-in hybrid and electric vehicles (PHEV and PEV) [3].

In the smart grid, two-way flow of electricity and information are supported, which lay the foundation for realizing various functions and management objectives, such as energy efficiency improvement, operation cost reduction, demand and supply balance, emission control, and utility maximization. This paves the way for the demand to be able to be matched with the supply instead of the conventional opposite scenario. One of the ways to execute this is to utilize load side management (LSM).

LSM refers to the shifting of load to accommodate the supply of the grid generation. LSM can shift peak load to off-peak periods which can reduce the cost of a consumer significantly and shifts the pressure of the load to a more convenient period [4]. In this case, the participants offer the flexibility to the operator of the demand-side management system to decrease cost of energy or to maximize their benefits of energy consumption [5]. In order to shift loads during off-peak periods appliances that act automatically, called 'smart appliances' are required [6]. With the development of smart grid, which enables reliable and real-time communications between the energy providers and the consumers, the price can be provided to the consumers daily, hourly, or in even shorter intervals [7]. One of the approaches used for load side management is load scheduling which can reduce overall load of a system as opposed to an unscheduled system, especially if a system is running in an on-off scheme [8].

Refrigerated warehouses are significant consumers of electrical energy in the food industrial sector. It has been estimated that this sector is responsible for 20% of the total electric energy consumption of the food industry [9] and 15% of all energy consumption worldwide [10]. Within cold storage facilities, 60-70% of the electrical energy may be used for refrigeration In general, compressor controls seek to maintain the compressed air discharge pressure within a specified range. With load-unload control, a compressor runs fully loaded, producing compressed air at maximum efficiency until the discharge pressure reaches the upper activation pressure setting, which causes the compressor to unload. When unloaded, the compressor no longer adds compressed air to the system, but the motor continues to run [11].

In [12], the authors propose a control scheme for all refrigeration systems in a supermarket that performs short term

adjustments to achieve overall peak reduction by using an applied control approach that performs short-term adjustments on the refrigeration power demand, while taking into account the temperature limitations of air and stored commodities. In [13], the authors propose a cooperative demand response (CDR) scheme for load management in smart grid for a refrigerated warehouse and via numerical results it is demonstrated that the CDR scheme can reduce the electricity costs and the total energy consumption in comparison with the non-cooperative demand response scheme. The approaches taken for peak reduction are either predictive and real time pricing feedback schemes, or algorithms presented for non-industrial applications. These approaches are very complex and difficult to implement. Developing a very simple load scheduling scheme for avoiding operation complexity is the main motivation of this research work.

In this paper, a multi-chambered refrigeration warehouse is considered for applying a non-predictive load scheduling scheme to reduce overall peak demand. Each chamber of the warehouse consists of one compressor per chamber operating under the same rated power. All compressors operate under the load-unload control scheme with a fixed load-unload time duration. The contributions in this paper are as follows.

- We propose a simple scheduling scheme of the compressor's electric loads of the warehouse where the initial loading of the compressors begins with a uniform delay.
- We provide an analytical model to calculate the total electric load of the compressors under the proposed load scheduling scheme at any instant of time and validate the model via simulation.
- We provide closed form expression of electricity cost under dynamic pricing considering the proposed load scheduling scheme. We also validate the model via simulation.
- The performance of proposed scheduling scheme is compared with the performance of a traditional electric load operation scheme under dynamic pricing and it is demonstrated that the proposed scheme can reduce the variation of electrical load with time and the electricity cost significantly.

The rest of the paper is organized as follows. In Section II, we review the different LSM methods that have been applied in cold storages, refrigerated warehouses and in similar cases. In Section III, we describe the refrigerated warehouse system and propose load scheduling scheme. The analytical models are developed in Section IV. In Section V, we analyse the the performance of the proposed scheme. Section V concludes the paper.

II. Related Work

In the previous studies, some algorithms and methods are proposed for LSM to specifically accommodate the refrigerated warehouse system and other relevant cases and scenarios. The Ernest Orlando Lawrence Berkeley Laboratory [14] explores various reduction techniques and permanent changes in the system to achieve demand response. Detailed energy audits are carried out by Evans and Gigiel [15] on a small number of cold stores and it is shown that energy consumption can dramatically exceed often by at least double. These audits also demonstrate that energy savings of 30-40% are achievable by optimizing the usage of the stores, repairing current equipment and by retrofitting of energy efficient equipment. In [16], the authors consider the case of a typical household user operating a set of appliances and provide a mixed integer linear programming (MILP) model and a heuristic algorithm for optimal scheduling. In [10], the authors develop a 24-hour load-forecast model to achieve dynamic system response to the variations in the ambient weather conditions. In [13], the authors use a CDR scheme for load management in case of refrigerated warehouses which also has an incentive-compatible trigger-and-punishment mechanism to avoid the non-cooperative behaviours of the selfish consumers. In [17], the authors study the application of demand response for thermal storages in various cases. There are also many studies on load scheduling. However, most of the load scheduling schemes have been implied in cases of domestic equipment which have varied rated load and often are not multiple in quantity or not even identical. Such approaches are not suitable for implementation at the industrial level, where in many cases, there are often multiple identical equipment with similar rated loads and hence, a complicated load scheduling scheme might hinder the overall production to a certain degree.

III. System Model and the Proposed Load Scheduling Scheme

A. Refrigerated Warehouse System

We consider a refrigerated warehouse of N compressors. The compressors operate in parallel to meet the aggregate cooling load requirements of the system. The rate and size of all the compressors are assumed to be the same. The set of the compressors is denoted by $\mathcal{N}$.

We assume that each compressor is controlled by a load-unload scheme. The load-unload mode of operation usually generates a distinct step type power signature, ranging between 105-115% of the rated power in the load state and 15-30% of the rated power in the unload state as shown in Fig. 1 labelled as "Actual" [18]. For simplicity, the load-unload process is considered as an on-off process with a fixed duration T. We also consider that the load time and unload time are fixed. The load and unload times are denoted by T_{on} and T_{off}, respectively and hence, $T = T_{on} + T_{off}$. The effective representation of the load-unload control model of a compressor with on-off process is exhibited in Fig. 1 labelled with "Approximation". Thus, on-off process can closely approximate the actual process. Let the power consumption levels during the load and unload periods be L_{on} and L_{off}, respectively. The duty cycle of the on-off process is defined as $d = \frac{T_{on}}{T}$.

B. Real Time Pricing Scheme

For the pricing scheme, a parabolic real time pricing approximation is used where the price of electricity consumption per

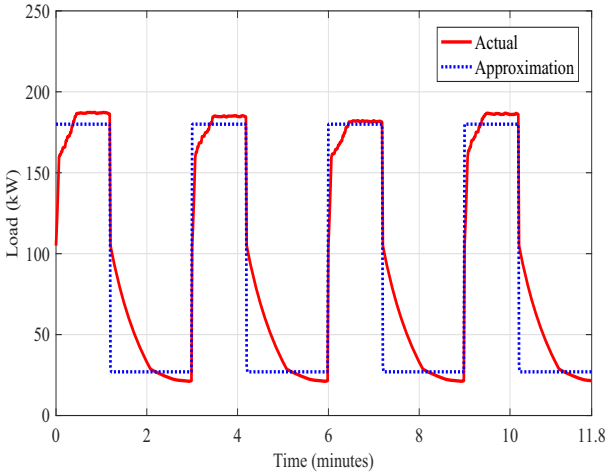

Fig. 1. Load unload operation of a 180 kW screw compressor and comparison with on-off model.

unit varied with the load by a simple parabolic expression as follows.

$$P(t) = aL^2(t) \tag{1}$$

where, $P(t)$ is the price per unit of electricity at time t, $L(t)$ is the total load of the warehouse system at time t and a is a pricing parameter. The electricity cost during a time duration T_d is given as

$$C = \int_0^{T_d} \frac{P(t)L(t)}{3600} dt. \tag{2}$$

Using (1) in (2), we obtain

$$C = \frac{a}{3600} \int_0^{T_d} L^3(t) dt. \tag{3}$$

C. Proposed Load Scheduling

We assume that all the compressors are numbered arbitrary from 1 to N and they are ordered as ascending order in set $\mathcal{N}$, i.e., $\mathcal{N} = \{1, 2, \ldots, N\}$. The proposed scheduling scheme is very simple. The initial loading time, i.e., starting time of a compressor $n \in \mathcal{N}$ is $\frac{(n-1)T}{N}$. The compressor n remains at loading state from time $\frac{(n-1)T}{N}$ to $\frac{(n-1)T}{N} + T_{on}$ and then unloads. The first unloading duration of the compressor n is from $\frac{(n-1)T}{N} + T_{on}$ to $\frac{(n-1)T}{N} + T_{on} + T_{off}$, i.e., $\frac{(n-1)T}{N} + T$. Then, the loading and unloading of the compressor n repeats at time interval T.

IV. Analytical Models

A. Analytical Model of Cumulative Load

Let Δ be the time delay between the loading times of two consecutive compressors, i.e., $\Delta = \frac{T}{N}$. Define, $m = \frac{T_{on}}{\Delta}$. The analytical model is separated into two forms based on the relation of T_{on} and Δ. One form is developed for the integer values of m and the other form is developed for the non-integer values of m.

1) The value of m is Integer: During time 0 to T_{on}, m compressors start one after another and all the compressors remain in loading state after their starting. Thus, power consumption during the time 0 to T_{on} can be written as

$$L(t) = rL_{on}; \quad (r-1)\Delta \le t < r\Delta \tag{4}$$

where, $r = 1, 2, ..., m$. At time T_{on}, i.e., $m\Delta$, two events occur simultaneously: the $(m+1)^{th}$ compressor starts operating and the first compressor drops to unload mode of operation. Since the power consumption of a compressor at unload mode is L_{off}, the increment on the total load at this point is L_{off}, i.e., $L(t)$ at this time is $mL_{on} + L_{off}$. This is the total load until the same event occurs again, i.e., the second compressor goes into unload state and the $(m+2)^{th}$ compressor starts operating at loaded state, resulting in increment of load L_{off}. The time difference between these two events is Δ. Thus, the load function in these cases can be described as,

$$L(t) = \begin{cases} mL_{on} + L_{off}; & m\Delta \le t < (m+1)\Delta \\ mL_{on} + 2L_{off}; & (m+1)\Delta \le t < (m+2)\Delta. \end{cases} \tag{5}$$

This pattern, i.e., starting of one compressor and going into unload mode of operation by another compressor lasts until the N-th compressor starts. The N-th compressor starts at time $(N-1)\Delta$. Thus, power consumption during the time $m\Delta$ to T can be written as

$$L(t) = mL_{on} + qL_{off}; \quad (m+q-1)\Delta \le t < (m+q)\Delta \tag{6}$$

where, $q = 1, 2, ..., (N-m)$.

Once all the compressors start their operation, at Δ time interval one of the compressors shifts to unload mode from load mode and one of the compressors shifts to load mode from unload mode. As a result, for $t \ge T$ the total power consumption is given as

$$L(t) = mL_{on} + (N-m)L_{off}; \quad t \ge T. \tag{7}$$

Thus, the total power consumption of a warehouse is given by

$$L(t) = \begin{cases} rL_{on}; & (r-1)\Delta \le t < r\Delta \\ mL_{on} + qL_{off}; & (m+q-1)\Delta \le t < (m+q)\Delta \\ mL_{on} + (N-m)L_{off}; & t \ge T \end{cases} \tag{8}$$

where, $r = 1, 2, \ldots, m$ and $q = 1, 2, \ldots, (N-m)$ if m is integer.

2) The value of m is Non-integer: Let $M = \lfloor m \rfloor$. If m is not integer, then the process of the load scheduling is the same as described in sub-section IV-A1 from time 0 to $M\Delta$. At time $M\Delta$, the $(M+1)$-th compressor starts, however, the first compressor does not go to unload operation mode until the time reaches to $m\Delta$. Thus, during the time $M\Delta$ to $m\Delta$, the power consumption is $(M+1)L_{on}$ and during the time $m\Delta$ to $(M+1)\Delta$, the power consumption is $ML_{on} + L_{off}$. Similar process continues until the time reaches to T. Thus, the expression of power consumption between time 0 to T can be written in (9), where $r = 1, 2, \ldots, M$ and $q = 1, 2, \ldots, (N-M)$.

$$L(t) = \begin{cases} rL_{on}; & (r-1)\Delta \le t < r\Delta \\ (M+1)L_{on} + (q-1)L_{off}; & (M+q-1)\Delta \le t < (m+q-1)\Delta \\ ML_{on} + qL_{off}; & (m+q-1)\Delta \le t < (M+q)\Delta \end{cases} \tag{9}$$

$$L(t) = \begin{cases} rL_{on}; & (r-1)\Delta \le t < r\Delta \\ (M+1)L_{on} + (q-1)L_{off}; & (M+q-1)\Delta \le t < (m+q-1)\Delta \\ ML_{on} + qL_{off}; & (m+q-1)\Delta \le t < (M+q)\Delta \\ (M+1)L_{on} + (N-M-1)L_{off}; & (N+p)\Delta \le t < (m+p+N-M)\Delta \\ ML_{on} + (N-M)L_{off}; & (m+p+N-M)\Delta \le t < (N+p+1)\Delta \end{cases} \tag{10}$$

When all compressors start to operate at time $(N-1)\Delta$, the power consumptions are $(M+1)L_{on}+(N-M-1)L_{off}$ from time $(N-1)\Delta$ to $(N-1+m-M)\Delta$ and $ML_{on}+(N-M)L_{off}$ from time $(N-1+m-M)\Delta$ to $N\Delta$ (i.e., T). This periodic power consumptions repeats at Δ time interval. Thus, the expression of power consumption for non-integer n can be written as in (10), where $r = 1, 2, \ldots, M$, $q = 1, 2, \ldots, (N-M)$ and $p = 0, 1, 2, 3....$ and so on.

B. Analytical Model of Total Cost

According to the model of the cumulative load, the total power consumption is $mL_{on} + (N-m)L_{off}$ for $t \ge T$ if m is integer. If we assume that T is negligible compared to the total system operation time, i.e., $T_d >> T$, then we can assume that the total load is always $mL_{on}+(N-m)L_{off}$ for an integer value of m. Thus, from (3), the cost can be found as

$$C = \frac{aT_d}{3600}\left(mL_{on} + (N-m)L_{off}\right)^3 \tag{11}$$

when the value of m is integer.

For a non-integer value of m, the instantaneous power consumption is periodic with interval Δ for $t \ge T$. During the interval Δ, the power consumption is $(M+1)L_{on}+(N-M-1)L_{off}$ for a duration $(m-M)\Delta$ and the power consumption is $ML_{on}+(N-M)L_{off}$ for a duration $(M+1-m)\Delta$. Thus, from (3), for a non-integer value of m, the cost can be found as

$$C = \frac{aT_d}{3600}\left[\left((M+1)L_{on} + (N-M-1)L_{off}\right)^3 (m-M) + \left(ML_{on} + (N-M)L_{off}\right)^3 (M+1-m)\right]. \tag{12}$$

V. Results

A. System Parameters

To evaluate the performance of the proposed compressor scheduling scheme, the number of compressors N is taken to be 9. The load-unload period T is considered to be 3 minutes with different duty cycle. The power consumptions of load and unload operation states are taken to be 180 kW and 27 kW, receptively. We consider two different values of pricing factor a, 0.000021 and 0.00021.

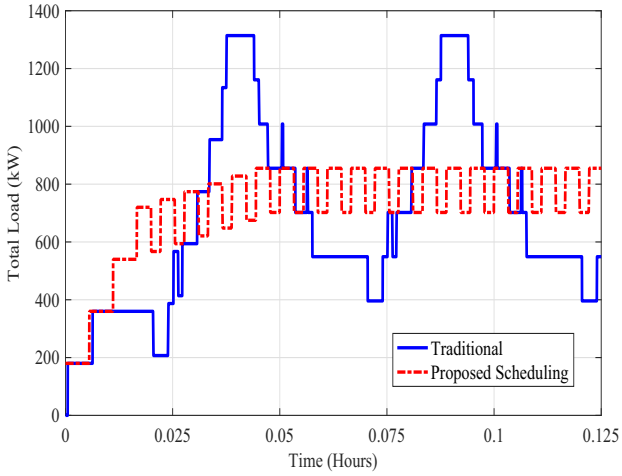

Fig. 2. Instantaneous load of warehouse with 40% duty cycle.

B. Instantaneous Load under the Proposed Load Scheduling Scheme and the Traditional Scheme

To investigate the effect of the proposed load scheduling scheme on the total load, refrigerated warehouse systems are simulated by using the tool Matlab under the proposed scheduling scheme and the traditional operation scheme. Note that in traditional operation the loading time of the compressors start randomly. The 40% duty cycle is considered as an ideal situation for demonstration of total load, price and cost. The instantaneous load of the warehouse is presented in Fig. 2. The results show that the instantaneous load of the traditional system vary significantly. However, the variation of the instantaneous load under the proposed scheduling scheme is not significant. Thus, the stability of the warehouse connected grid can be enhanced by using the proposed load scheduling scheme.

C. Validation of the Analytical Models

In order to validate the analytical model of cumulative load function, the computed values of the instantaneous loads are compared with the simulated values for the both integer and non-inter values of m comprising the values of m to be

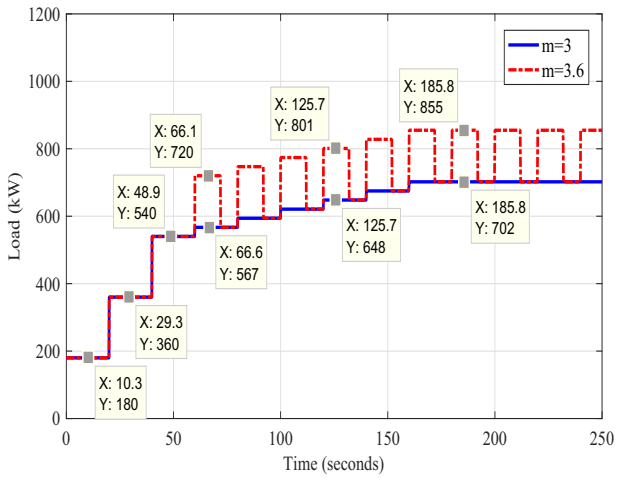

Fig. 3. Instantaneous load obtained by simulation for integer and non-integer values of m.

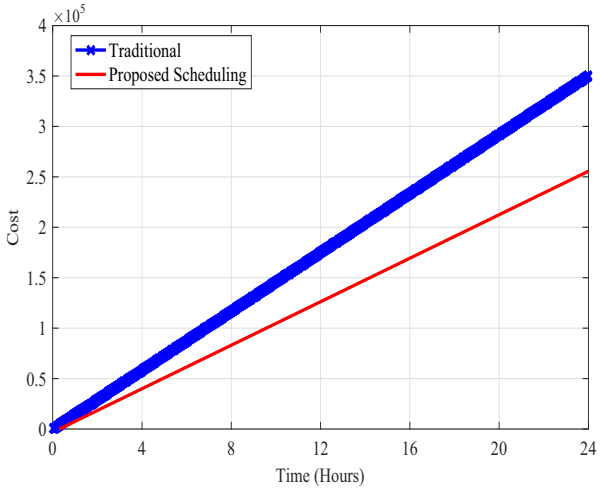

Fig. 4. Cumulative cost progression of the system operating for a day.

TABLE I
ELECTRICITY COSTS USING THE ANALYTICAL MODEL AND SIMULATION

m	Simulation	Analytical	% Difference
3	173160	174200.89	0.60
3.6	256580	258516.48	0.75

3 and 3.6. The duty cycle is adjusted accordingly. In Fig. 3, we present the simulation results and the values of the instantaneous loads are marked at the different time instants. The power consumptions values of those time instants are determined by using the analytical model and found to be the exactly same.

Considering $T_d = 24$ hours, we determine the electricity cost during time T_d using the analytical model and simulation for the two values of m. The comparison of the results is presented in Table I. The results show that the analytically calculated costs are little bit higher than the costs obtained by simulation since higher value of power consumption is considered in analytical model between time 0 to T. However, the difference is limited by 1%. Thus, the developed analytical model of cost is very accurate.

D. Electricity Costs under the Proposed Load Scheduling Scheme and the Traditional Scheme

We compute the instantaneous values of total costs under the proposed load scheduling scheme and the traditional operation scheme considering $a = 0.000021$ and d=40%. The results are shown in Fig. 4, where the thicker line represent the traditional scheme. The results show that electricity cost under the proposed load scheduling scheme is significantly lower compared to the traditional operation and the electricity cost reduction increases with time. We find that the reduction of electricity cost is 27.042% at 24 hours of operation.

E. Cost Reduction by the Proposed Scheduling Scheme

Since the tradition operation is based on random starting of the compressors, the cost reduction by the proposed scheme

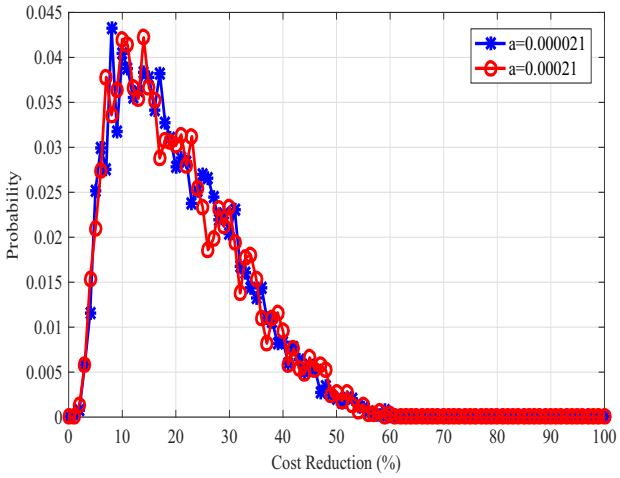

Fig. 5. Probability distribution function of cost reduction.

depends on the random starting times of the compressors. To evaluate the cost reduction statistically, for the traditional scheme, simulations are run for 15,000 times for two values of pricing factor ($a = 0.000021$ and $a = 0.00021$) with 40% duty cycle and electricity costs at 24 hours are determined. The probability distribution function (PDF) of cost reduction by the proposed load scheduling scheme with respect to the traditional operation is then determined from the 15,000 samples of cost reductions which is shown in Fig. 5. Here, only the integer values of the percentage of cost reduction are considered, i.e., PDF is similar to probability mass function (PMF). PDF of x% cost reduction is determined as $N_x/15000$, where N_x is the number of samples provides cost reduction between $(x-1)$% to x%. The results show that the percentage of cost reduction does not significantly depend on the pricing factor a since the costs are simply scaled by the pricing factor in the both systems. Probabilities of cost reduction between 10% to 30% are found to be higher.

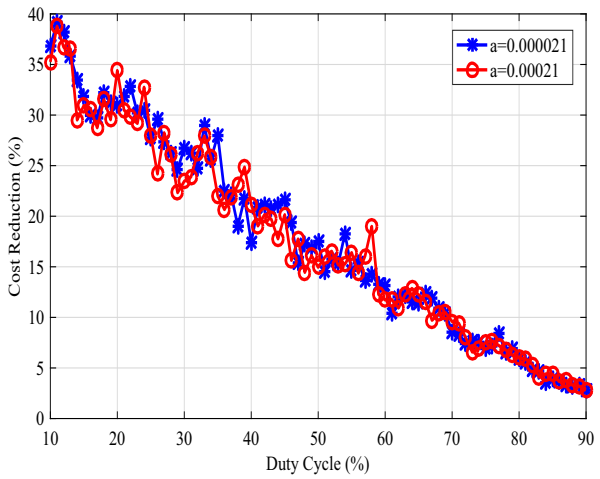

Fig. 6. Cost reduction by the proposed load scheduling scheme by varying the duty cycle.

F. Effect of Duty Cycle on Cost Reduction

To investigate the effect of duty cycle on the percentage of electricity cost reduction, the duty cycle is varied from 10% to 90%, the costs under the proposed load scheduling scheme and the traditional operation are determined. For averaging the randomness of the starting time of the compressors under the traditional operation, 40 simulations are run and averaged for each of the duty cycles. The percentage of electricity cost reductions for different duty cycles are presented in Fig. 6 for the two values of pricing factor. The results show that the effect of pricing factor on the percentage of cost reduction is negligible as shown before. We find that for an increasing duty cycle the percentage of cost reduction decreases. It is due to the fact that load time overlapping of the compressors increases with increasing the duty cycle even when the proposed load scheduling scheme is considered. As a result, the peak load difference between the traditional and the proposed schemes decreases and the percentage of cost reduction decreases if duty cycle is increased.

VI. Conclusion

We have proposed a simple load scheduling scheme for a warehouse of homogeneous refrigerators. We have provided the models for instantaneous load and electricity cost under dynamic pricing considering the proposed load scheduling scheme. We have demonstrated that the proposed load scheduling scheme reduces the peak load as well as the electricity cost significantly. However, the percentage cost reduction decreases if duty cycle of the compressors is increased. The proposed load scheduling scheme can be implemented easily due to its simplicity. This study focuses on only the evaluation of the reduction of peak load and electricity cost under the proposed load scheduling scheme. The future work related to this work is to evaluate the stability of power system under the proposed load scheduling scheme and its comparison with the stability of traditional system.

***Abstract*—Power system is turning into smart grid for ensuring efficient, reliable and economic operation. But, cyber–attack is being introduced because of involvement of cyber infrastructure in modern grid. In this paper, impacts of cyber–attack on proportional integral derivative controlled automatic voltage regulator have been analyzed. A control scheme has been proposed for compensating voltage disruption during cyber–attack. A controlled switching unit has been used in the proposed control scheme which ensures normal operation during an attack.**

***Index Terms*—Smart grid, Cyber–attack, Automatic voltage regulator (AVR), Voltage disruption, Controlled switching unit (CSU).**

I. Introduction

Power system, a complex and critical infrastructure, is responsible for generation, transmission and distribution of electrical energy. At present, the concept of smart grid (SG) is being introduced for achieving optimized use of facilities and improving quality of services of the system by using cyber infrastructure with physical infrastructure [1]. SG enhances efficiency and reliability by using information, communication technologies and computational intelligence. In SG, two–way communication for measurement and control purposes is achieved using smart devices, which leads to automated operation of the system. Utilization of information and communication technologies (ICT) in physical infrastructure has opened up new possibilities including vulnerabilities, which emphasizes on physical application security as well as cyber infrastructure security [2].

ICT introduces possibilities of cyber–attack during data transfer via communication network. An attack may cause cyber switching or data manipulation to hide physical attack using communication network [3], [4]. If the attacker has proper knowledge about the system, reduction in efficiency and increase in operational cost may be caused by false data injection (FDI) [5], [6]. Again, there is possibility of delaying data communication between sensors and controller during cyber–physical attack [7]. There is also risk of cyber–attack on bus and line protection system settings and parameters [8].

Besides these types of attacks, an attack may be launched to disrupt normal operation of the system by disturbing voltage and frequency. The impact of injecting false data for voltage violation in distributed grid system has been discussed in [9], [10]. Impacts of Denial of service cyber–attacks on voltage control schemes in SG has been discussed with countermeasures in [11]. Again, an attacker may attack distributed energy resources control for voltage violation [12], [13]. There is also possibility of attacker with on–line learning ability to find optimal strategy for attacking automatic voltage control of a power system [14].

A. Contribution of This Work

Though there are several studies regarding cyber–attack in power system, there are less concerns about attack for manipulating parameters of control unit. In our previous work [15], impacts of cyber–attack on vulnerable parameters of proportional–integral–derivative (PID) controlled AGC have been analyzed with countermeasure. In this study, cyber–attack on automatic voltage regulator (AVR) has been discussed. A controlled switching unit (CSU) has been proposed as a countermeasure which detects attacks and takes necessary steps to prevent the impacts. The major contributions of this paper are: analyzing the impacts of cyber–attack on PID controlled AVR and proposing a protective model of AVR using a CSU for compensating voltage disruption.

The reminder of this paper is organized as follows: Different models of AVR are discussed and compared briefly in Section II. Vulnerabilities and impacts of cyber–attack on PID controlled AVR are discussed in Section III. The model of CSU based AVR for a single unit of a power system is presented in Section IV. Finally, the paper is concluded in Section V.

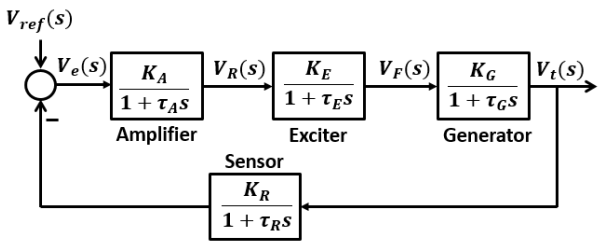

Fig. 1: Block diagram of simplified AVR [16].

II. Model of Automatic Voltage Regulator

During generation, transmission and distribution of electric energy, it is important to maintain stable terminal voltage.

Fluctuation of terminal voltage is related to fluctuation of reactive power. There are several means to maintain stable voltage operation or control reactive power such as field excitation system, transformer load–tap changers, switched capacitors, step–voltage regulators and static var control equipment. The primary way of controlling generator reactive power is using AVR.

In simple AVR (see Fig. 1) voltage magnitude is sensed and compared with reference set point. Then, the error signal is amplified, which controls the exciter field to change exciter terminal voltage. After that, the exciter terminal voltage changes current of the generator, which results in change in generated emf. In this way, the reactive power is adjusted to maintain stable voltage.

A system with following parameters is considered (based on [16]):

TABLE I: PARAMETERS OF AVR SYSTEM

Name	Gain	Time constant
Amplifier	K_A = 10	τ_A = 0.1 s
Exciter	K_E = 1	τ_E = 0.4 s
Generator	K_G =1	τ_G = 1.0 s
Sensor	K_R = 1	τ_R = 0.05 s

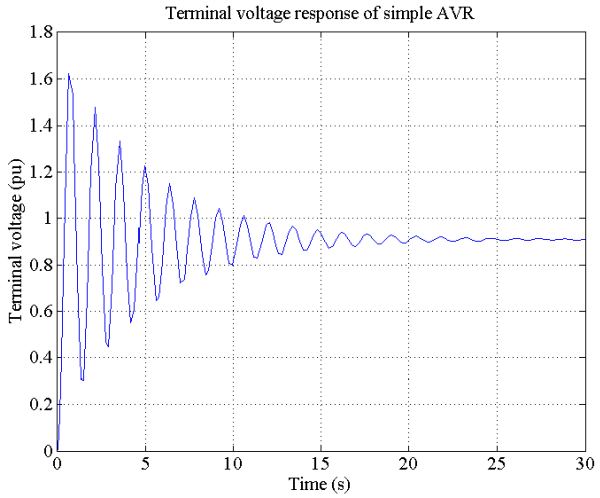

Fig. 2: Step response of simple AVR.

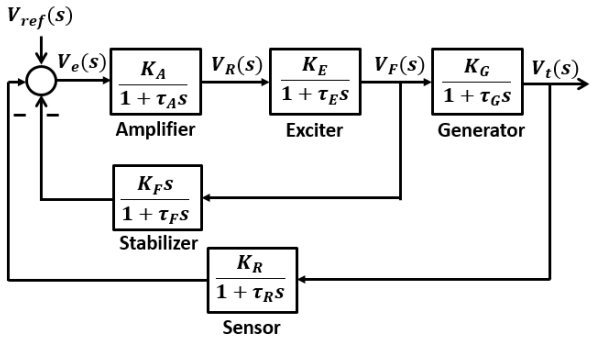

Fig. 3: Block diagram of rate feedback controlled AVR [16].

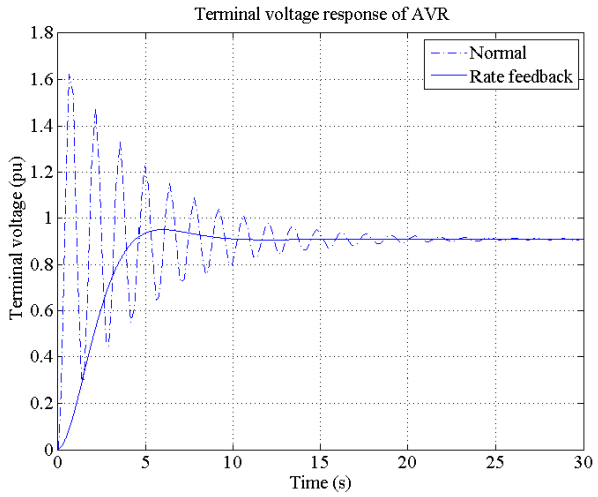

Fig. 4: Comparison of step responses of normal and rate feedback AVR systems.

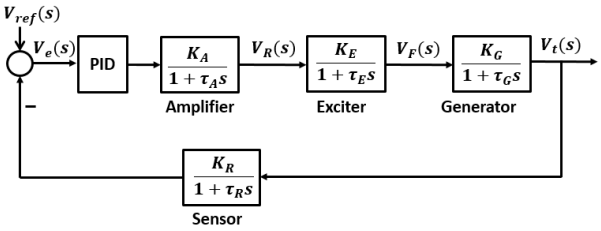

Fig. 5: Block diagram of PID controlled AVR [16].

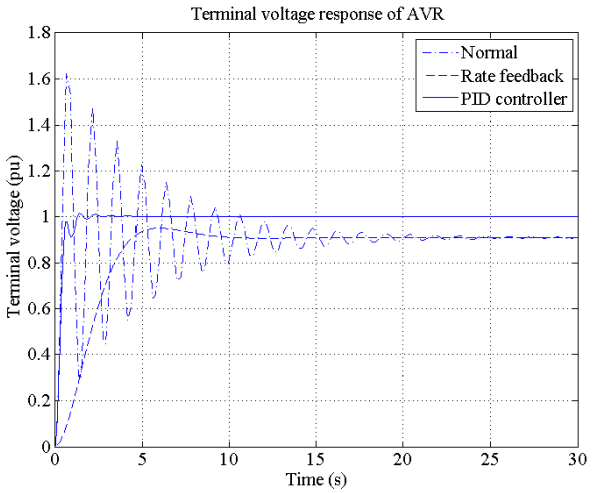
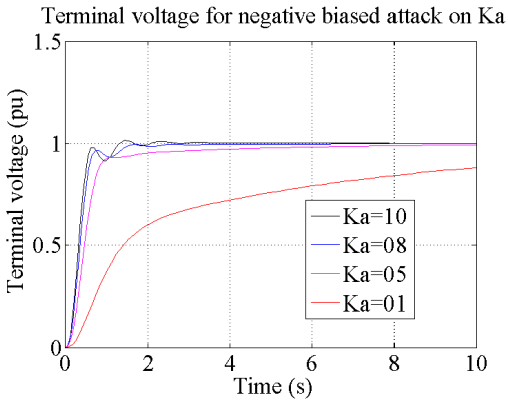
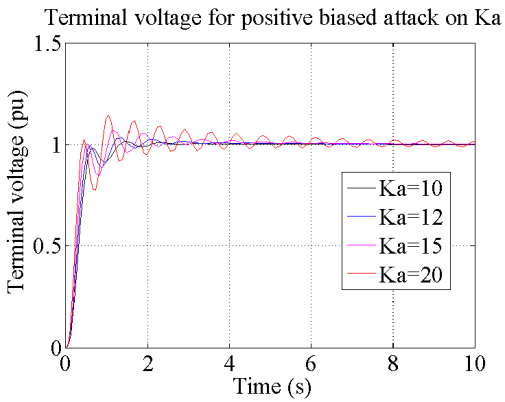
Fig. 2 shows response of normal AVR system. The major problem in this system is that it has oscillatory response for long period. Another problem in this system is its steady–state error.

To improve the response of simple AVR system rate feed-







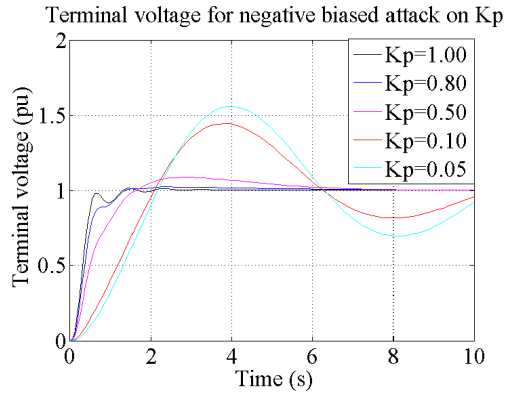


Fig. 6: Comparison of step responses of different AVR systems.

(g) Negative biased attack on K_d.

(h) Positive biased attack on K_d.

Fig. 7: Impacts of cyber–attack on PID controlled AVR.

back control can be implemented (see Fig. 3). Let's consider, gain of rate feedback controller is $K_F = 2$ and time constant $\tau_F = 0.04$. Though rate feedback control improves oscillatory response at the beginning of the response of simple AVR system, it does not eliminate steady–state error (see Fig. 4).

To solve these problems of normal AVR systems, PID controller is implemented. Three different control actions of PID controller eliminate steady–state error, reduce settling time and decrease oscillation as well as overshoot. Fig. 5 represents the block diagram of PID controlled AVR. The parameters of PID controller are $K_p = 1$, $K_i = 0.25$ and $K_d = 0.28$. Fig. 6 shows the comparison among normal, rate feedback and PID controlled AVR systems. It is observed that PID controlled AVR is proper choice for maintaining terminal voltage within permissible limit.

III. Vulnerabilities of PID controlled AVR

During cyber–attack, there is possibility that an attacker may attack an AVR system to disrupt voltage stability. Instability in terminal voltage may damage insulation of conductors as well as home appliances. So, it's important to identify the vulnerable parameters for ensuring proper protection for such an attack. In an AVR system, there are various parameters including parameters of PID controller. In a system, controller parameters are vulnerable during cyber–attack [15]. Again, the response of the AVR system is sensitive to proper choice of amplifier's gain (K_A). Hence, vulnerable parameters of a PID controlled AVR system are K_A, K_p, K_i and K_d. An attacker may change them separately or simultaneously. Again, the value of each parameter can be increased (positive biased attack) or decreased (negative biased attack) during a cyber–attack.

The impacts of cyber–attack on the vulnerable parameters are observed separately in Fig. 7. It is observed that negative biased attack has more impact than positive biased attack except for K_p, in which both types of attacks are severe.

IV. Indemnity for voltage disruption

A CSU is proposed in this paper as countermeasure against cyber–attack on AVR. It acts in two steps to ensure protection of vulnerable parameters in AVR. At first step, it monitors them to check occurrence of any disturbance. It compares current value of parameters with default data during monitoring. Default data for the system is kept in secure off–line data storage, so attacker can not cause any change in those parameters. In second step, it performs control action. If there is any attack to change those parameters, it modifies the signals using default data.

Fig. 8 represents protective model for AVR in single unit of power system. It takes two signals and two data as input. It has a feedback loop with amplifier's gain for protecting amplifier gain during an attack. The output is fed to amplifier after implementing control action, where application of control action depends on cyber–attack. Fig. 9 shows the result of implementing CSU in AVR.

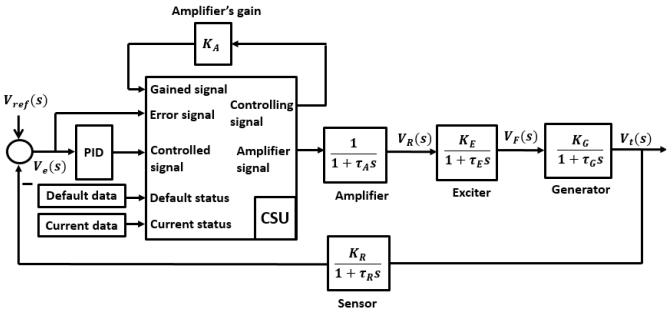

Fig. 8: CSU for AVR in single unit of power system.

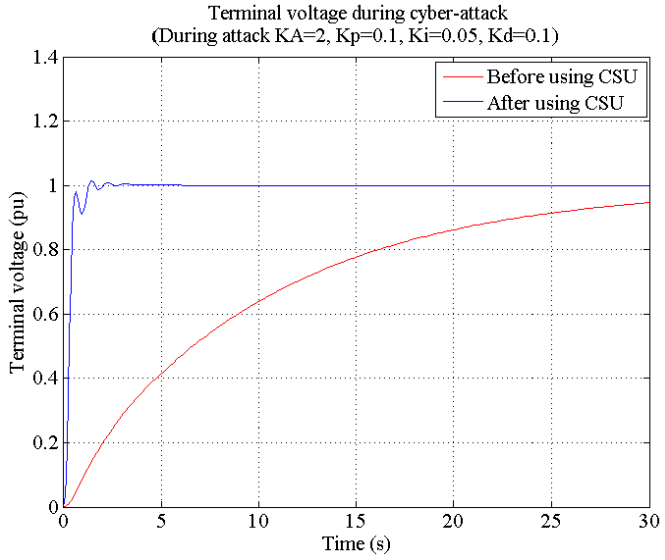

Fig. 9: Terminal voltage during cyber–attack in isolated power system (before and after using CSU).

V. Conclusion

In this work, impacts of cyber–attack on PID controlled AVR are analyzed. The values of vulnerable parameters have been changed manually during simulation for observing negative and positive biased attacks. A CSU based protective model of AVR is proposed as countermeasure for compensating voltage disturbance. The attacks, impacts of attacks and effectiveness of CSU as a countermeasure have been simulated using MATLAB Simulink. However, the proposed model is designed for a single unit of power system. In future work, protective model will be designed for interconnected system. Again, there is scope for designing a CSU for providing protection for AGC and AVR simultaneously.

***Abstract*— Electric Vehicles are opening a new field of engineering research which is very innovative and promising due to increasing consumer swiftly. As like other developed countries, Bangladesh is also experiencing with the use of battery electric vehicles like easy bike, auto rickshaw and electric bike. However, the charging stations are not sufficient and thus the electric vehicle owner recharges the batteries from the residential connection. Due to the huge electricity consumption throughout the country, the power sector has been fallen into higher system loss and failed to earn profit from this sector. In this paper, fuzzy logic based energy management algorithm is developed for electric vehicle charging station in Bangladesh. The fuzzy optimization techniques provide different charging rate for different conditions. It will save energy and makes electric vehicle business profitable to the owner.**

Keywords—Electric Vehicle, Electric Vehicle Charging Station, Fuzzy logic, Charging rate

I. INTRODUCTION

The worldwide awareness about environmental issues and reduction of fossil fuel moves the transport industry into clean and eco-friendly transportation like electric vehicles. Electric vehicles (EV) are running in three typical modes such as- Hybrid electric vehicle (HEV), Plug-in-Hybrid Electric Vehicle (PHEV), and Battery Electric Vehicle (BEV). Among of these vehicles BEV is widely used in Bangladesh which is driven by an electric motor that takes the power from battery. BEV has required no fossil fuel and provides less emission than HEVs and PHEVs [1].

In Bangladesh, mass EV penetration require large amount of power and creates a huge pressure on the power grid, distribution networks [2]. A study showed that, more than 0.5 million electric vehicles are running in Bangladesh and these ingest 450 MW electric power daily from the national grid [3]. This huge power demand creates a serious problem with the existing demand. Charging of EV requires high power and large time but their range is not satisfactory. In addition, there is no sufficient charging station in Bangladesh. Thus, the EV owner has to charge their batteries from residential connection illegally which becomes a cause of system loss in the power sector. Batteries are charged through a charger from the ac power. The charger is a non-linear equipment which hampers the power quality through production of harmonics, voltage fluctuation etc. When large number of chargers is connected with the distribution networks, the power quality problem arises [4-5]. To solve the above problems regarding EV charging, it is necessary in Bangladesh to develop sufficient charging infrastructure, their charging coordination scheme and charging policy [6].

Several researches were performed on fuzzy logic based electric vehicle charging station for controlling power demand and setting priority level for EV charging [7-9]. However, in this paper, the charging station connected with grid is considered and fuzzy logic optimization principle is applied for determining charging rate at different conditions. The power demanded by EV, time of charging (off peak/ peak hour) and duration of charging are assumed as input of mamdani fuzzy logic tool in MATLAB where charging rate is taken as output variable. Finally a comparison will be shown among fuzzy based charging station with conventional charging station.

II. ELECTRIC VEHICLE CHARGING STATION IN BANGLADESH

In Bangladesh, Electric vehicle charging stations are not sufficient. There are two types of charging stations exists- i.e. public and private charging stations. Government has established few charging stations in different cities of Bangladesh but maximum charging stations are private. These private charging stations have taken a higher charging rate.

In city areas where the electric vehicle parking is not possible for every owner, they can park it during night time & lunch time in private stations. Charging stations categorizes according to the capacity, number of charging points and charging time & cost. With the appropriate use of charging stations in Bangladesh, government can earn additional revenue and also it will increase the opportunity for decreasing unemployment. According to the technology used, charging station may be classified as follows. Such as- grid based charging station and renewable solar based charging station. The charging stations provide full charging of battery by BDT.120-150. Daily load profile for an EVCS located in Gazipur is displayed in fig. 1.

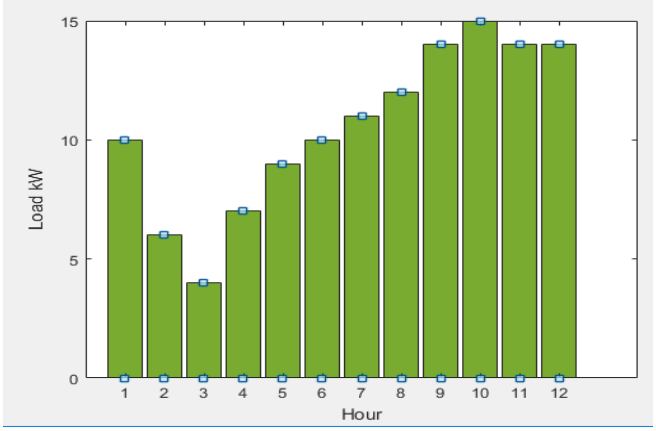

Fig.1: Daily load profile of an EVCS located in Gazipur, Bangladesh.

III. Modeling of Electric Vehicle Charging Station

Rising popularity of electric vehicles due to several positive impacts is admirable but its detrimental impacts on the grid power quality cannot be neglected. EVCS consists of the following parts basically- transformer, rectifier and converter etc. A model of EVCS is shown in fig. 2 below.

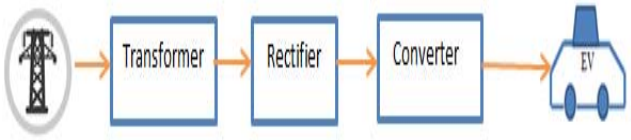

Fig. 2: Electric Vehicle connected with utility grid.

The voltage level is stepping down by the transformer for distribution purposes. Rectifier transforms AC electricity into DC and the DC-DC converter controls the DC power supplied to the EV battery. Power demanded by an EVCS can be determined as the equation (1) below.

$$P_{EVCS} = \frac{P_{EV} * N_i * F_{O.L}}{\cos\theta}; \qquad (1)$$

Where P_{EV} is the individual maximum power absorbed by an EV, N_i is the number of slot for EV connection and $F_{O.L}$ is the overload factor and $\cos\theta$ is the power factor [10]. In case of EV battery, minimum SOC has taken as 30% and maximum SOC is taken as 70%.

A. Power Demand

Electric Vehicle battery takes charge from the power distribution system. The increased power demand affects the stability of the system due to non-linearity. The power demand by an EV can be expressed as in equation (2).

$$P_{EV} = \frac{B.C*(SOC_{\max} - SOC_{\min})}{D_t - A_t}; \qquad (2)$$

Where B.C is the battery capacity, D_t and A_t are the departure and arrival time of EV respectively [11]. Battery SOC is a factor whether the EV takes high or small power. The gross power demand of the EVs is the summation of individual power demand of all EVs which likely signifies as in equation (3).

$$P_{Gross} = \sum_{N=1}^{N} P_{EV}; \qquad (3)$$

B. Duration of Charging

Higher charging time for electric vehicle battery is a great problem for EV penetration. The difference between EV arrival and departure time at EVCS is called duration of charging. In Bangladesh, level 2 AC charging is mostly used which takes large time to recharge batteries approximately 6-8 hours. The charging duration can be useful for calculating charging rate. Actually, in Bangladesh charging stations are insufficient and can provide simultaneous charging for only 30-50 EVs. Thus, maintaining charging duration is necessary. Duration of charging can be expressed as equation (4).

$$T_D = T_{departure} - T_{arrival} - T_{waiting}; \qquad (4)$$

C. Time/period of charging

Electric vehicle charging affects the power network by consuming huge energy. If the electric vehicle charging is performed on peak hour, it will surely provide a negative impact on the power system. Otherwise, electric vehicle charging at off-peak hour can be beneficial for the power system and also for the consumers. In Bangladesh, off-peak period is between 11 pm to 5 pm and peak hours are between 5 pm to 11 pm. Due to having less power demand in the off-peak hour, the charging rate will be lesser than the peak hour charging rate. In the proposed fuzzy based EVCS, the charging rate for peak hour is taken greater than the off-peak hour.

$$T_C = \begin{matrix} T_{off-peak}; & 11pm \rightarrow 5pm \\ T_{peak}; & 5pm \rightarrow 11pm \end{matrix} \qquad (5)$$

IV. Optimization Algorithm for EVCS

The main objective of the optimization algorithm is to minimize charging rate with proper utilization of electricty supply. The objective function of the proposed model is as follows:

$$Minimize\{C_{charging}\} \qquad (2)$$

This objective function works under few constraints as folows:

$$SOC_{\min} \le SOC_i \le SOC_{\max};$$

$$P_S \le P_i(t) \le P_D;$$

$$t_1 \le t \le t_2;$$

The supplied power, P_s depends only on the availability of power supply. This is also a cause of varying electrcity price in the proposed EVCS. The power demand of the EV depends on the SOC and battery capacity. In this model, the minimum SOC is taken as 20% where maximum SOC is 80%. The supplied available power should be less than or eqaul to the power demand of the EVCS. The duration of charging is the time to recharge the batteries which is shown in equation (4). The period of charging should be in between t_1 and t_2. Minimum duration of charging, t_1 is assumed as 3 hours whereas maximum charging time, t_2 is taken as 10 hours.

Power demanded by the EVs can be determined using equation (2). The overall charging cost is the function of the four input parameters such as- power demand, period and duration of charging. Thus, it can be represented by equation given below.

$$F_C = \int_{t=t_1}^{t_2} P_D(i,t) r(t) dt \qquad (5)$$

Where r(t) is the actual charging rate for an EV. Charging time varies from t_1 to t_2. If t is equal to the T_C, then r(t) will be maximum. Also, if the power generation is smaller within the proposed EVCS, the extra demand will be fulfilled by the utility grid. In that case the price will be highest. The definite integral of the r(t) is constant over the time between t_1 and t_2.

V. FUZZY LOGIC BASED EVCS

Mamdani type fuzzy inference model is used in this proposed EVCS for obtaining optimized charging rate at various conditions. Centroid based defuzzification technique is employed in this modeling. Power demanded by EVs, time of charging and duration of charging are the input parameters of fuzzy model and charging rate is the output parameter. Fig. 3 demonstrates a Mamdani fuzzy system having three input variable and an output variable.

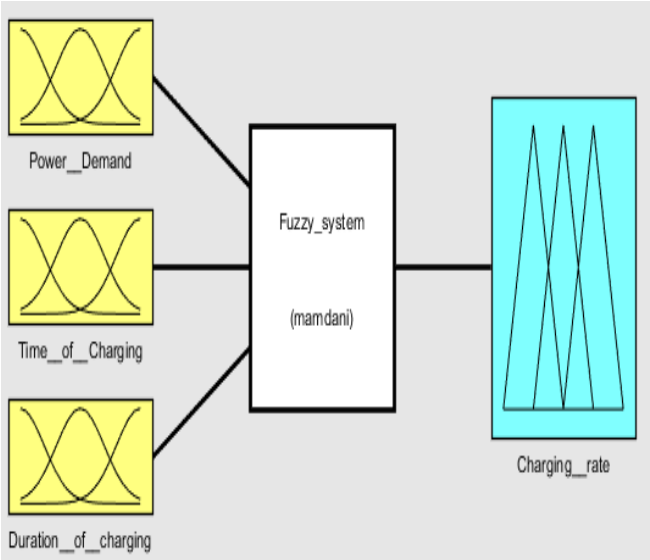

Fig.3: Fuzzy optimization model

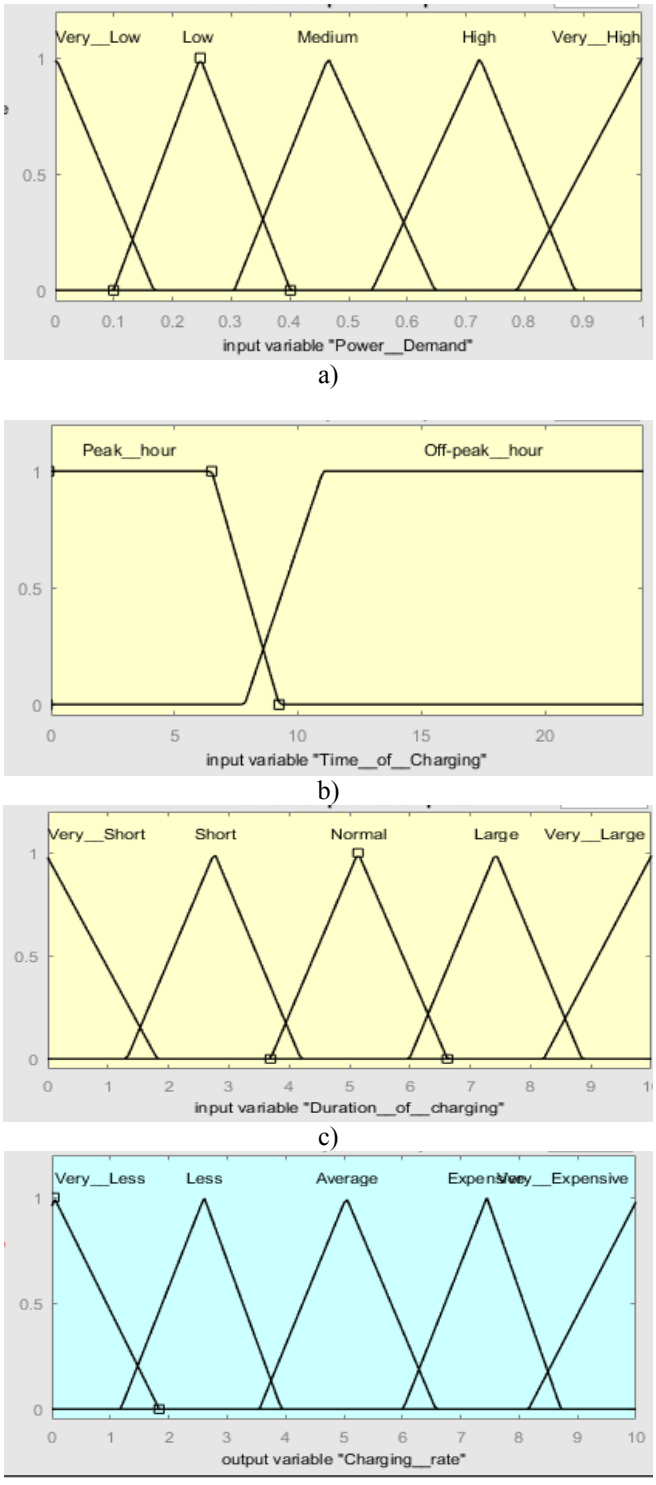
A. Input and output parameters

Power demanded by an EV depends on the battery capacity and SOC. In this model, the membership functions of "Power_Demand" are as Very_Low, Low, Medium, High and very_High. In bangladesh, peak hour is defined as 5:00 PM to 11: 00 PM and off-peak hour is the time between 11:00 PM to 5:00 PM. For this reason, in this proposed model membership functions of the "Time_ of_ Charging"are peak_hour and off-peak_hour. Electric vehicles in Bangladesh mainly recharge their batteries in night time. But few of them are charged at day time also. Normally the easy bike and auto-rickshaw battery takes 8-10 hours for full charging. But the EVs come at charging station with above the minimum SOC, requires less time to recharge. Thus, the "Duration_ of_ charging" has membership functions as Very_short, Short, Normal, Large and Very_Large.

Charging rate is the output variable which is used in designing fuzzy system. It has membership functions declared as Very_less, less, Average, Expensive and Very _ Expensive. The input and output parameters with the membership functions are shown in fig. 4 below.



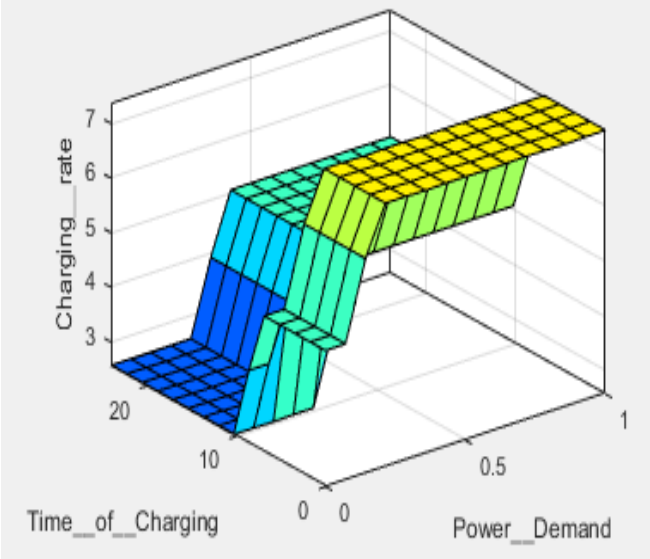


Fig. 4 a) b) c) d): Input & output parameters of Fuzzy with membership functions.

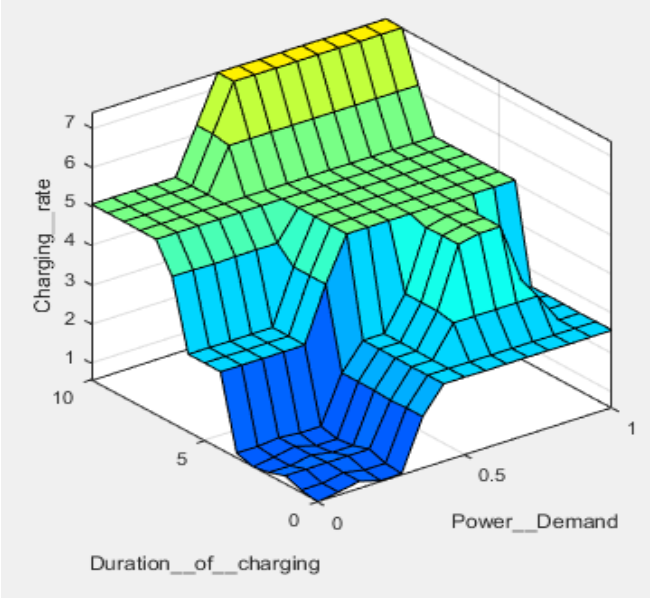
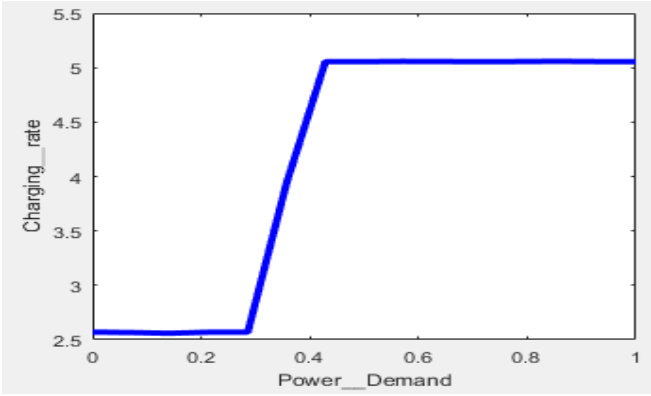
VI. RESULT AND DISCUSSION



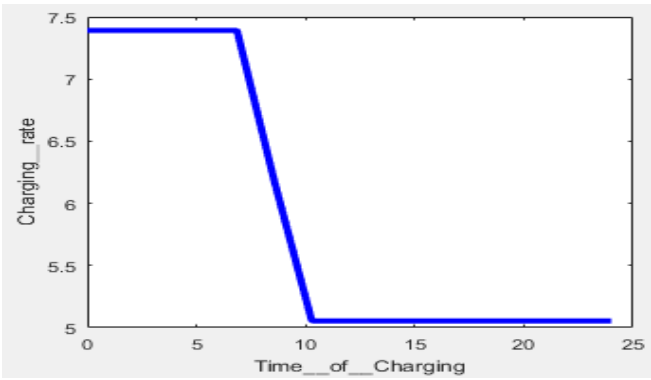
Electric Vehicle Charging Station optimization for minimizing charging cost is the main purpose of this research. In the present energy scenario of Bangladesh, charging electric vehicles leads to a huge consumption with increasing system loss. EV owners are also in a big trouble

for being less number of charging stations throughout the country. On the other hand, charging cost is very high when the electric vehicles are charged from the commercial line. Due to solve these problems with fuzzy optimization technique is employed in this research.

Fuzzy "if-then" rules based strategy is used in this optimization system. The membership functions are defined according to the data for the current battery electric vehicles of Bangladesh. The surface view of the charging rate, power demand, time of charging and duration of charging is shown in fig. 5 (a) & (b).

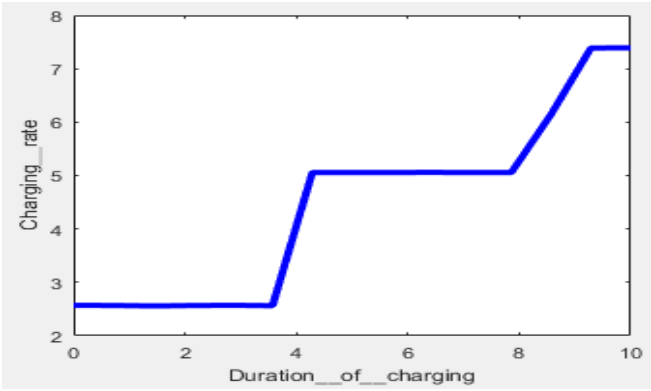


a)



b)

Fig. 5 a) b): Surface view of charging rate, power demand time of charging and duration of charging.



The variation of charging rate with power demand, time of charging and duration of charging are expressed in fig. 6 (a), (b) & (c).

a)

b)

c)

Fig. 6: Variation of charging rate with power demand (a), time of charging (b) and duration of charging (c)

The conventional EVCS takes on average BDT. 120 - 150 for charging an EV. In this proposed method, the charging cost is optimized which is shown in fig. 7. Conventional charging station has charging rate per kWh BDT. 7.70 whereas the fuzzy logic based EVCS offers BDT. 7.95 peak hour conditions and BDT.5.90 for off-peak hour conditions.

Using such optimization technique, EV owner can save extra cost for charging electric vehicles. It will reduce the system loss of power sector and reduce the extra burden on the utility grid by proper scheduling of EV charging coordination. This type of optimization will encourage the EV owner to recharge their batteries at scheduled period.

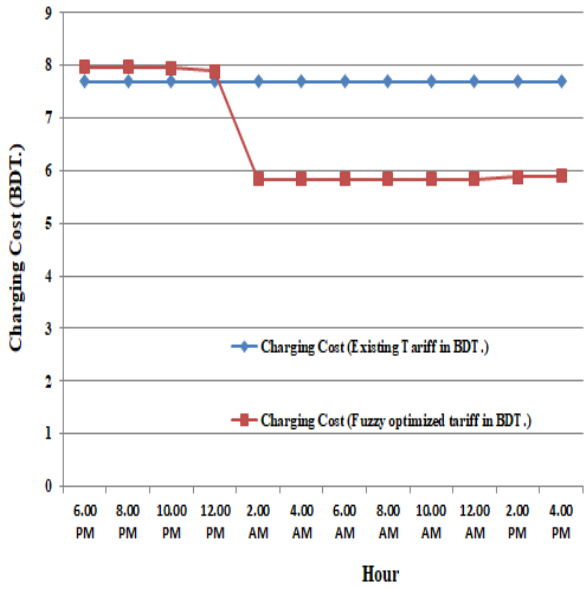


Fig. 7: Comparison of charging rate by fuzzy logic system with conventional electricity price.

VII. CONCLUSION

Electric vehicle penetration in Bangladesh is largely affected by the factors such as- lack of sufficient charging stations, high charging cost and low range. Rapid proliferation of electric vehicle consumes a large amount of electric power and the EV owner recharges their batteries from residence which leads to increase in the system loss. To minimize the charging cost with respect to power demand, charging period and charging duration, this fuzzy based EVCS model is proposed. During peak hour electricity rate is higher than the off-peak period irrespective of load connected in the charging station. However, in the proposed charging station, the EV owner can save the cost by choosing proper schedule. In case of low power demand of an EV, the charging rate is lower and higher for large power demand in the proposed charging station but in the existing system it is not possible. This type of charging station not only save the consumer income but also increase the chance of earning more revenue by choosing proper electricity charging rate.

***Abstract*— This paper proposes the design and simulation of a Fuzzy Logic based PID controller for DC motor speed control. The speed of a DC motor depends on armature voltage, field current and torque. In this paper, the armature voltage is changed in order to have the required speed output. The armature voltage is firstly controlled by a simple proportional controller and then controlled by PID constants and tuned by a Fuzzy Logic Controller (FLC). The FLC tunes the values of PID parameters based on the fuzzy rules fed into it and gives a satisfactory output wave shape for wide range of motor speed variation which is tested in MATLAB-Simulink environment achieving improved voltage regulation. The proposed closed loop implementation maintains constant output voltage despite changes in input voltage and significantly reduces overshoot thereby improving the efficiency of the motor. The output of this investigation has the potential to contribute in a significant way in electric vehicles, industry, communication and renewable energy sectors.**

Keywords—Dc Motor; Speed Control; Fuzzy Logic Controller (FLC); overshoot; PID

I. INTRODUCTION

DC drives are used extensively because of their simplicity, high starting torque, ease of application, high reliabilities, flexibilities and favorable cost. When it comes to power conversion, a DC-DC converter plays a significant role in widespread applications in cellular phones, laptop computers, LED Drivers, maximizing energy harvest for photovoltaic systems and for wind turbines, electric vehicles, hydro power plants and many more [1-4]. This widespread application demands that the converter should have good efficiency, less Total Harmonic Distortion (THD) and improved Power Factor (PF) at the load side. Moreover, reducing size and cost of the device and increasing availability are also some of major concerns in designing power converters for which researchers are thriving in recent years [5-9].

A high performance motor drive system must have good dynamic speed command tracking and load regulating response to carry out different tasks. In these applications, the motor should be precisely controlled to give the desired performance [10]. The regulated voltage sources used for DC motor speed control switching devices of power electronics such as MOSFET, IGBT and GTO [11]. However, the non-linearity arises due to armature current limitation, change in loads and drive inertia [12].

In addition, the parameters of the PID controller have to be fine-tuned which is difficult to model in a non-linear system. Hence to obtain better speed control, the conventional PID controllers combined with intelligent techniques such as Fuzzy logic are widely employed. Fuzzy logic controller deals with problems having uncertainties and use membership functions with values lying between 0 and 1, and uses rules to optimize the system performances [13]. This process is made particularly easy by adaptive techniques like ANFIS (Adaptive Neuro-Fuzzy Inference Systems), which are available in the Fuzzy Logic Toolbox [14]. In a DC-DC converter it is always desirable that a constant output voltage is achieved despite changes in the source voltage, the load current and variations in element values of the converter circuit [15-16]. Several control techniques have been proposed to ensure stability as well as fast transient response namely - Fuzz Logic controller [17], Artificial Neural Network (ANN) [18], PID controller [19] and PI controller [20].

In this paper voltage regulation of DC Motor is achieved employing PID controller which is tuned using trial and error method to find appropriate values for the proportional, integral and derivative gains, thereby improving converter performance. Section II of this paper deals with the modeling of conventional DC Motor followed by a brief idea about PID Controller in Section III. Section IV depicts the proposed self-tuned fuzzy logic controller and finally the simulation and results are presented by comparing the speed control with the proposed fuzzy rule based controller with PID controller in section V. The proposed circuit parameters, simulation and experimental results demonstrate the effectiveness and feasibility of the proposed scheme.

II. MATHEMATICAL MODELING OF DC MOTOR

DC Machines are of three kinds as well- Separately excited, Shunt excited & Series excited. Motor speed can be varied by controlling armature voltage, field current and torque demand.

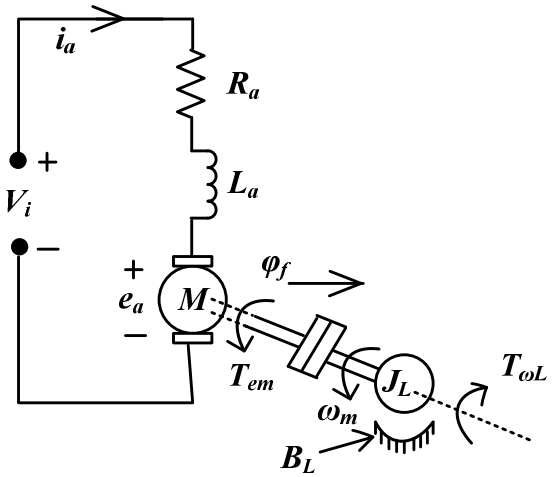

Fig. 1. Schematic Diagram of Electromechanical System

The schematic diagram of the electromechanical system is shown in Fig. 1. The corresponding parameters of the system are as follows:

V_i	Input voltage
i_a	Armature current
e_a	Back emf
R_a	Armature resistance
L_a	Armature inductance
T	Torque
J_L	Moment of inertia
B_L	Friction coefficient of motor
ω_m	Angular velocity of motor
K_b	Back emf Constant
K_m	Motor Torque Constant

The mathematical modeling of the electrical system and mechanical system are carried out by developing the following equations:

i. Electrical Modeling :

$$V_i(t) = R_a i_a(t) + L_a \frac{di_a(t)}{dt} + e_a(t) \tag{1}$$

$$\frac{di_a(t)}{dt} = \frac{1}{L_a}[V_i(t) - R_a i_a(t) - e_a(t)] \tag{2}$$

Therefore,

$$i_a(t) = \int [\frac{1}{L_a}\{V_i(t) - R_a i_a(t) - e_a(t)\}]dt \tag{3}$$

where,

$$e_a(t) = K_b \omega_m(t) \tag{4}$$

ii. Mechanical modeling :

$$T_{em}(t) = K_m i_a(t) \tag{5}$$

$$T_{em}(t) = J_L \frac{d\omega_m(t)}{dt} + B_L \omega_m(t) + T_{\omega L}(t) \tag{6}$$

$$\frac{d\omega_m(t)}{dt} = \frac{1}{J_L}[T_{em}(t) - B_L \omega_m(t) - T_{\omega L}(t)] \tag{7}$$

Therefore,

$$\omega_m(t) = \int [\frac{1}{J_L}\{T_{em}(t) - B_L \omega_m(t) - T_{\omega L}(t)\}]dt \tag{8}$$

III. Implementation of Conventional PID Controller in Simulink

One of the simplest and most widely used controllers for decades is the PID controller. PID stands for proportional (P), integral (I) and derivative (D) controller. Fig. 2 shows the block diagram of a typical PID controller.

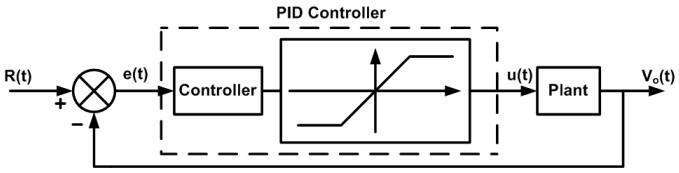

Fig. 2. Conventional PID control Structure [21]

The system under study is the plant to which necessary excitation is provided thereby achieving overall closed loop control effectively. PID controller can be expressed as –

$$C(s) = K_P + \frac{K_I}{s} + K_D s \tag{9}$$

Where, K_P, K_I and K_D are proportional, integral and derivative gains respectively. The signal e(t) as shown in Fig. 2 represents the tracking error obtained from the difference between the reference signal which serves as the input R(t) and the actual output signal $V_o(t)$. The tracking error is fed on to the PID controller which computes the derivative and integral of the signal provided. Simulink block diagram is evident in Fig. 3.

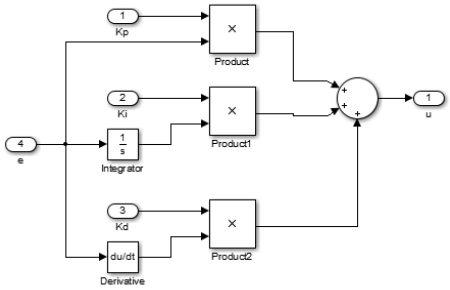

Fig. 3: Simulink Block diagram of PID Controller

Time domain representation of the signal u(t) fed to the plant is given below:

$$u(t) = K_P e(t) + K_I \int e(t)dt + K_D \frac{de(t)}{dt} \tag{10}$$

The plant on receiving the signal u(t) will generate a modified output $V_o(t)$ which will be again compared to the reference signal until the desired level is reached thereby forming a close loop system. Effect of proportional, integral and derivative control on close loop system is summarized in Table I [22].

TABLE I. EFFECT OF PID ON CLOSE LOOP SYSTEM

	Rise Time	Overshoot	Settling Time	Steady State Error
Proportional	Decrease	Increase	Small Change	Decrease
Integral	Decrease	Increase	Increase	Eliminate
Derivative	Small Change	Decrease	Decrease	Small Change

The overall system is implemented in Simulink which is evident from Fig. 4.

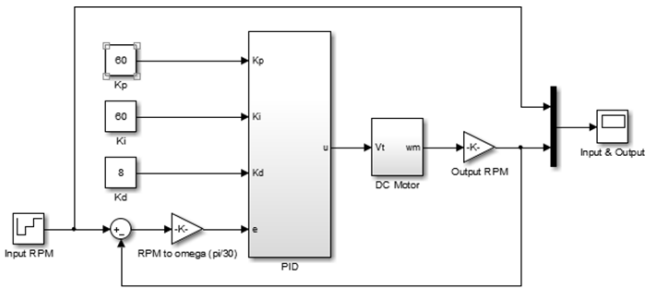

Fig. 4: Implementation of overall system in Simulink

IV. PROPOSED FUZZY LOGIC CONTROLLER

After implementing the overall system for conventional PID controller, the fuzzy controller is studied and employed in order to obtain better performance. Inputs which are fed to the Fuzzy Logic based PID Controller are speed error e(t) and change in speed error or rate de(t) which can be presented as:

$$e(t) = \omega_r(t) - \omega_a(t)$$

$$de(t) = e(t) - e(t-1)$$

PID parameters are auto-tuned using fuzzy control rules which is shown in Fig. 5. Incorporating a PID controller with the converter will improve the dynamic response and reduce the steady-state error.

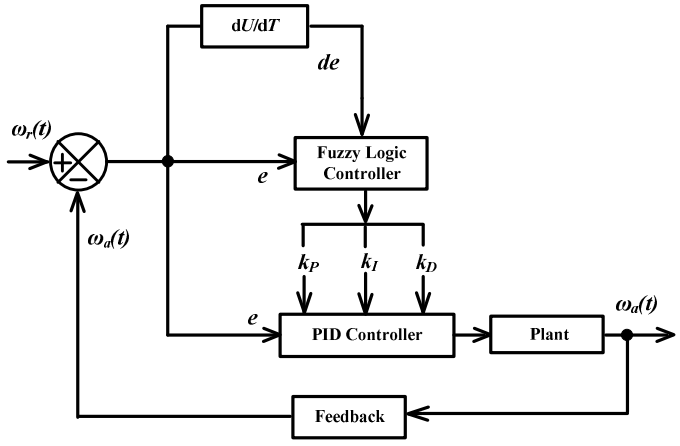

Fig. 5. Overall Block Diagram of Proposed Fuzzy Logic Based PID Controller.

The derivative controller (K_D) ameliorates the transient response and the integral controller (K_I) will reduce the steady state error of the system. The proposed system maintains an output of 200V when the input is in the range of 90V-110V which makes it quite feasible to apply in different industrial purposes.

Design of membership functions:

The parameters are expressed in the same format as they are written in the Membership Function Editor of the Fuzzy Logic Toolbox in MATLAB. All the membership functions of the input variables (speed error and change in speed error) are triangular in shape.

A. Fuzzy sets of speed error (e) variable:

Fuzzy Sets	Description	Parameters
Negative Large (NL)	Large speed difference in negative direction	[-20 -20 40]
Negative Small (NS)	Small speed difference in negative direction	[10 40 100]
Zero (ZE)	Speed difference is zero	[40 70 100]
Positive Small (PS)	Small speed difference in positive direction	[40 100 130]
Positive Large (PL)	Large speed difference in positive direction	[100 160 160]

B. Fuzzy sets of change in speed error (de) variable

Fuzzy Sets	Description	Parameters
Negative Large (NL)	Large speed difference in negative direction	[-1300 -1300 -800]
Negative Small (NS)	Small speed difference in negative direction	[-1050 -800 -300]
Zero (ZE)	Speed difference is zero	[-800 -550 -300]
Positive Small (PS)	Small speed difference in positive direction	[-800 -300 -50]
Positive Large (PL)	Large speed difference in positive direction	[-300 200 200]

C. Membership function of proportional gain K_P

Fuzzy Sets	Parameters
Positive Very Small (PVS)	[0 0 3.614 16.47]
Positive Small (PS)	[1.957 8.352 13.77 26.64]
Positive Medium Small (PMS)	[11.81 18.2 23.56 36.2]
Positive Medium (PM)	[21.8 28.2 31.8 38.2]
Positive Medium Large (PML)	[23.52 36.4 41.8 48.2]
Positive Large (PL)	[33.8 46.44 51.8 58.2]
Positive Very Large (PVL)	[43.68 56.4 60 60]

D. Membership function of integral gain K_I

Fuzzy Sets	Parameters
Positive Very Small (PVS)	[0 0 3.644 16.6]
Positive Small (PS)	[1.799 8.196 13.61 26.48]
Positive Medium Small (PMS)	[11.8 18.2 23.6 36.48]
Positive Medium (PM)	[21.8 28.2 31.8 38.2]
Positive Medium Large (PML)	[23.8 36.44 41.8 48.24]
Positive Large (PL)	[33.68 46.44 51.84 58.2]
Positive Very Large (PVL)	[43.68 56.4 60 60]

E. Membership function of derivative gain K_D

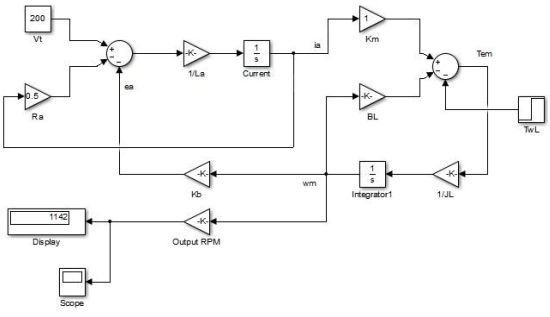
V. Result and Simulation

Simulations are carried out in MATLAB-Simulink environment. The parameters used for this simulation are given below:

TABLE II. Simulation Parameters

Parameter	Value
Armature resistance	0.5Ω
Armature Voltage	200 V
Armature inductance	0.02 H
Mechanical inertia	0.1 Kg.m^2
Friction Coefficient	0.008 N-m/rad/sec
Back emf constant	1.25 V/rad/sec
Rated Speed	3000 r.p.m
Motor torque constant	1 N-m/A



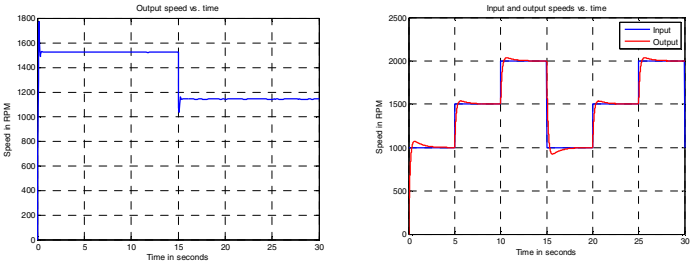


Fig. 6. Simulink Block Diagram of simple DC motor

Simulink block diagram of simple DC motor is shown in Fig. 6 and the Output speed vs. time curve is evident in Fig. 7(a). Then conventional PID controller is deployed to the system and the result is presented in Fig. 7(b).

(a) (b)

Fig. 7. (a) Speed vs. Time curve for DC motor (b) Input-Output Speed vs. Time curve for Conventional PID Controller

Initially motor runs at no-load condition. A load torque of 100 N-m is added after 15 seconds from start and remains till end of simulation. MATLAB Simulink model of Fuzzy Logic based PID controller is given in Fig. 8. Hence, speed vs. time curve is observed and shown in Fig. 9 which depicts that output follows input in a far better way with respect to conventional PID controller.

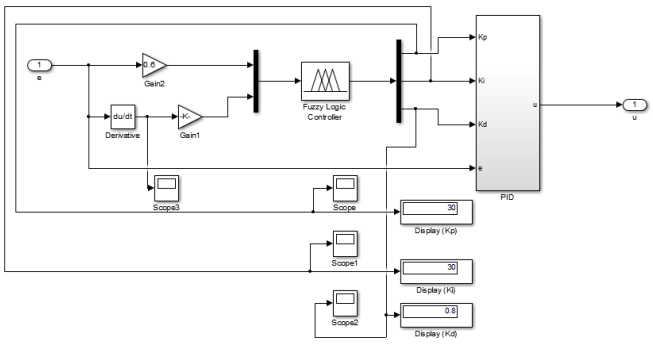

Fig. 8. MATLAB-Simulink model of fuzzy logic controller.

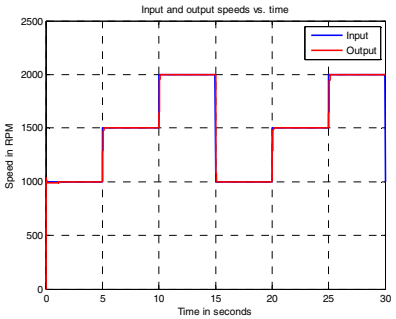

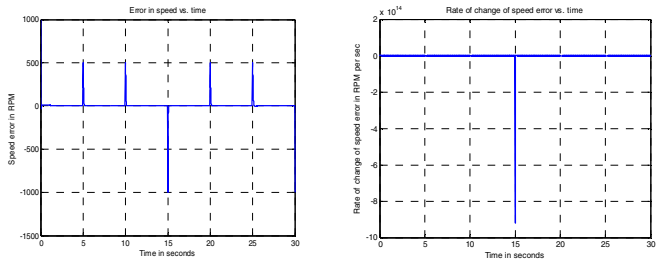

Fig. 9. Speed-time characteristics of DC motor controlled by self-tuned fuzzy PID controller.

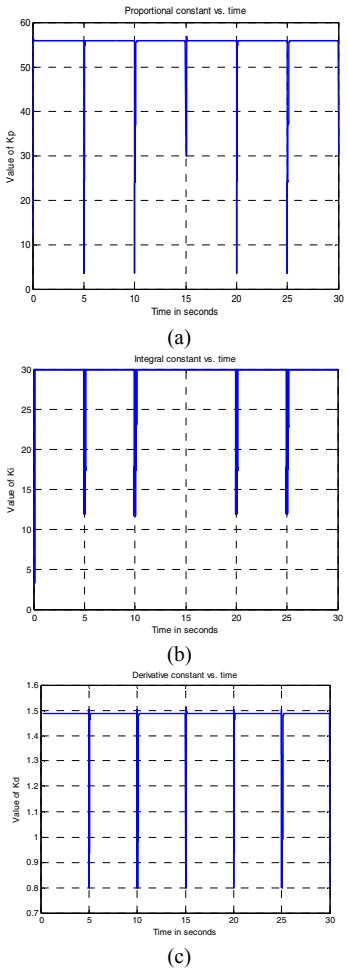


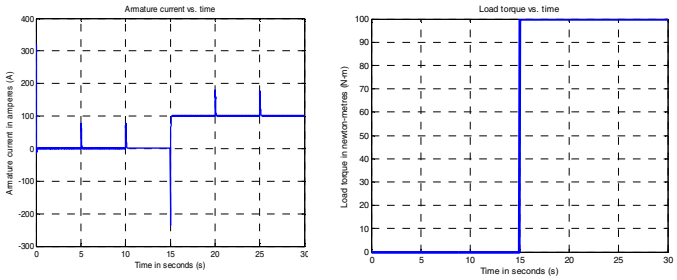
The same speeds that were fed into the controller during simulation of PID controlled DC motor as input are used here, i.e., 1000 r.p.m., 1500 r.p.m. and 2000 r.p.m. as a staircase function with sample time of 5 seconds. The simulation is run for 30 seconds, where the motor runs at no-load condition for the first 15 seconds, and at a load of 100 N-m from 15 seconds to the end of simulation. Now, error in speed vs. time, rate of change of error vs. time is shown in Fig. 10 (a) and (b). After

that, proportional, integral and derivative constant vs. time curve is sown in Fig. 11.

(a) (b)

Fig. 10. (a) Error in speed vs. time, (b) rate of change of error vs. time

(a)



(b)

(c)

Fig. 11. (a) Proportional (b) Integral and (c) Derivative Constant vs. Time Curve

When simulation is started, high armature current flows as the motor just got started from rest. As the motor reaches steady speed, the armature current falls down to a very small value. This happens very abruptly as the rise time of the motor from rest to steady speed is extremely small. The armature current only increases at the instances when the output speed changes. This is shown by the positive spikes in Fig. 12. At 15 seconds, the speed of the motor decreases sharply.

Hence, the armature current flows in the opposite direction by a large amount. This is shown by the negative spike in Fig. 12. At the same time, a load torque is added to the motor. The current immediately increases in order for the motor to take the load, and retains a value much higher than no load condition.

(a) (b)

Fig. 12. Variation of (a) armature current (b) load torque vs. time

Rise times and fall times, Percentage maximum overshoots and undershoot, settling times and steady state errors of the output speed of DC motor controlled by proposed Fuzzy Logic based PID controller are tabulated in Table III, IV, V and VI respectively.

TABLE III. RISE TIME/FALL TIME BY SPEED VARIATION FOR UNLOADED AND LOADED CONDITION

Load condition	*Speed variation (r.p.m.)*	*Rise time/fall time (seconds)*
Unloaded	0 – 1000	0.0404
	1000 – 1500	0.0866
	1500 – 2000	0.0863
Loaded	2000 – 1000	0.0559
	1000 – 1500	0.0852
	1500 – 2000	0.0866

TABLE IV. PERCENTAGE OF MAXIMUM OVERSHOOT/UNDERSHOOT BY SPEED VARIATION FOR UNLOADED AND LOADED CONDITION

Load condition	*Speed variation (r.p.m.)*	*Percentage maximum overshoot/undershoot*
Unloaded	0 – 1000	3.55442
	1000 – 1500	0.03333
	1500 – 2000	0.07000
Loaded	2000 – 1000	0.04325
	1000 – 1500	0.07137
	1500 – 2000	0.06978

TABLE V. SETTLING TIME BY SPEED VARIATION FOR UNLOADED AND LOADED CONDITION

Load condition	*Speed variation (r.p.m.)*	*Settling time (seconds)*
Unloaded	0 – 1000	0.2307
	1000 – 1500	0.1050
	1500 – 2000	0.1008
Loaded	2000 – 1000	0.1520
	1000 – 1500	0.1069
	1500 – 2000	0.1016

TABLE VI. STEADY STATE ERROR BY SPEED VARIATION FOR UNLOADED AND LOADED CONDITION

Load condition	*Speed variation (r.p.m.)*	*Steady state error*
Unloaded	0 – 1000	0.71870
	1000 – 1500	-0.01823
	1500 – 2000	-0.03354
Loaded	2000 – 1000	0.01240
	1000 – 1500	-0.12005
	1500 - 2000	-0.11092

VI. CONCLUSION

The overall analysis illustrates that Fuzzy Logic based PID controller has very low rise time, fall time, overshoot, settling time and steady state error when employed in a DC motor under different load conditions. Both transient and steady-state responses of the system are quite satisfactory. Simulations at both unloaded and loaded conditions show the adaptability of the controller and consistency of the output response. The technique developed in this paper can be investigated for separately excited, series and shunt DC motor drives, and also different types of AC motor drives so that more robust and compact system can be developed.

***Abstract*— This paper presents a systematic approach to design an optimal controller by using linear quadratic regulation (LQR) technique for single phase Full Bridge Voltage Source Converter (FB-VSC) for distributed and Renewable energy application. Traditionally, a Proportional (P) or Proportional-Integral (PI) controller is commonly used. These controllers are not robust enough to deal the converter and system uncertainties (For example, changing converter or filter parameter and disturbance in the input or output terminal of the converter). This paper presents 1) a systematic design method for both conventional PI and proposed optimal controller based on state space approach; and 2) a comparative study between these two controllers. Equivalent MATLAB Simulink simulation model for both controllers are developed to investigate their performance at various possible uncertainties. The proposed optimal controller exhibits more robustness and flexibility compared to the PI controller.**

Keywords*— *Voltage Source Converter (VSC), Linear Quadratic Regulation (LQR), PI controller, Optimal Controller, Distributed energy, and Renewable energy.

I. INTRODUCTION

The demand of electrical energy production is increasing day by day with the increasing population and it is difficult to meet this increasing demand through the existing means of power generation. Furthermore, most of our existing power generation is depleting energy source and causes environmental degradation [1]. To meet this rising power demand and to prevent the environmental degradation, expanded distributed and renewable energy resources need to be integrated into the existing utility grid system [2].

With the wide range of technological development, the installed capacity of distributed generation (DG) is increasing at a very faster rate [3, 4]. The DG technology includes solar photovoltaic (PV), wind turbines, fuel cells and battery energy storage (BES). Among these DG technologies, solar PV is becoming progressively more attractive and suitable in many countries because of the environmental and regional benefits [5]. Large- and small-scale DG units are generally connected to the utility grid at sub-transmission voltage level and at distribution voltage level respectively through a common DC bus [6, 7]. To regulate the common DC bus voltage properly a VSC is used between the DG unit and the common DC bus voltage [8]. This commonly used converter system is known as two-stage topology [9]. The first stage converter performs the power extraction and regulates the common DC bus voltage to provide a suitable voltage level for the second stage, whereas the second stage converter generates and injects stable ac power to the utility grid at a low harmonic level [10]. In the first stage of VSC converter, a close loop P or PI controller-based voltage or current controlling technique is widely used to regulate the power and voltage properly for the second stage [11]. The existing PI controller designs depend on the exact system parameters and assume that the system parameters are constant over the whole operation range and they do not perform satisfactorily against system uncertainties and disturbances.

Due to the load and temperature variation, the unmodeled dynamics such as resistance of the converter and filter elements can be changed over the time and usage, which is known as the converter parameter uncertainty. Intermittent nature of renewable energy resources (for instance, a sudden change of sunlight in solar PV and wind speed in wind turbine) can initiate a rapid disconnection of DG units. Furthermore, any unwanted fault in the utility grid can affect the dc bus voltage. These kinds of uncertainties can change the input or output voltage level of first stage converter, which is called as system uncertainty. To obtain benefits from the integration of wide-scale DG units to existing utility grids, it is expected that the first stage VSC will be robust enough to handle these converter and system uncertainties [12]. However, the conventionally used PI controller is very sensitive to the slight change of system parameters.

The purpose of this paper is to develop an efficient and systematic method to design the optimal controller and its gain to address the aforementioned controller issues. To this end, this paper first presents systematic design method for PI controller, then the optimal controller by using state-space approach. At the end, this paper shows the difference between the two controller's performance at various uncertainties.

II. CONTROL MODEL OF VSC

Voltage Source Converter (VSC) is an essential part of a variety of power electronic system and application including motor drive, integration of distributed, and renewable energy resources. Fig.1 shows a single-phase pulse-width modulation (PWM) full-bridge voltage-source converter (FB-VSC) with DC-side voltage of V_{dc}. Its output is connected to another DC supply of V_g through an inductor L. The inherent resistors of the inductor, of the line, and of the conducting-state of switches are aggregated and denoted

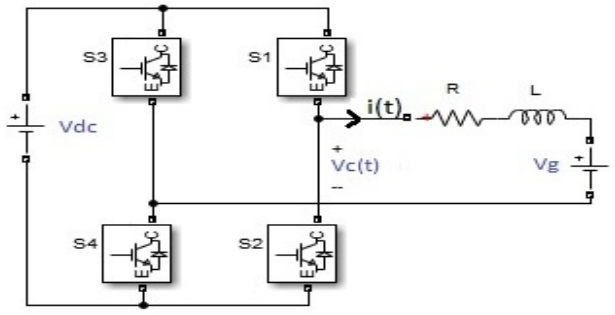

Fig. 1. Single phase FB-VSC.

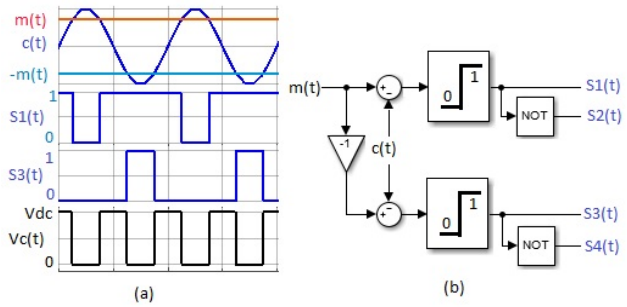

Fig. 2. Unipolar PWM for single phase FB-VSC

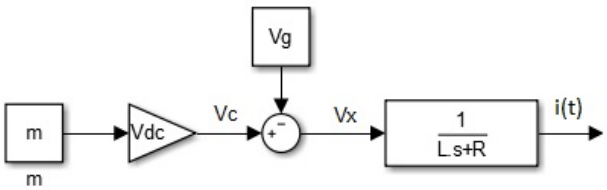

Fig. 3. Control-Average model of FB-VSC

By *R*. $V_c(t)$ is the converter output voltage and *i(t)* denotes the converter output current as well as line current. The differential equation of this FB-VSC can be expressed as

$$L\frac{di(t)}{dt} + Ri(t) = V_c(t) - V_g \qquad (1)$$

A unipolar PWM scheme is shown in Fig. 2, where *m(t)* and *c(t)* are modulation and carrier signal respectively produce the gating signals (S_1, S_2, S_3, S_4) for the IGBT's. The converter output voltage $V_c(t)$ is generated by the gate signals can be expressed as

$$V_c(t) = V_{dc}[S_1(t) - S_3(t)]$$

If switching duty cycle is D, then $S_1 = D$ and $S_3 = 1\text{-}D$

$$\bar{V}_c = V_{dc}(2D - 1) = mV_{dc} \qquad (2)$$

(2D-1) = m is Modulation index. From equation (1)

$$LsI(s) + RI(s) = V_c(s) - V_g \text{ [s is Laplace operator]}$$

$$I(s)(Ls + R) = V_x(s)$$

$$\text{Where, } V_x(s) = V_c(s) - V_g \qquad (3)$$

The open loop transfer function of the VSC converter is

$$G(s) = \frac{I(s)}{V_x(s)} = \frac{1}{Ls+R} \qquad (4)$$

From equation (2), (3), and (4), the control /average model of FB-VSC can be derived as shown in fig. 3.

III. Conventional PI Controller for FB-VSC

The open loop VSC control model is highly sensetive to a very small change of converter's input (V_{dc}) and output (V_g) terminal voltage, converter paramenters, and external disturbance. This characteristic is not desirbale at all for any kind of sensetive system for example, HVDC grid system, motor drive, PV connected grid system etc. Conventionally, to make this open loop control system robust, a close loop feedback control system with a P or PI controller is widely used [13]. Fig. 4, shows the simplified diagram of close loop feedback control FB-VSC with a PI controller. A current limiter is used to limit the reference current during grid low voltage transient fault. To solve the starting problem of VSC, the soft starter technique is used. The open loop transfer function of the PI controller is

$$G_{PI}(s) = \frac{K(s+z)}{s}$$

Here, z is the position of zero. $z = \frac{R}{L}$ (5)

Fig. 5 shows the close loop transfer function T(s) of the control system. The Close loop transfer function equation can be derived as:

$$T(s) = \frac{\frac{KV_{dc}}{Ls+R}}{1 + \frac{KV_{dc}}{Ls+R}} = \frac{KV_{dc}}{Ls + (R + KV_{dc})}$$

Close loop pole is $-\frac{R+KV_{dc}}{L}$. Assume, time constant = τ .

$$\tau = \frac{L}{R + KV_{dc}}$$

$$K = \frac{1}{V_{dc}}\left(\frac{L}{\tau} - R\right) \qquad (6)$$

For a proper system response, the maximum speed or the time constant of the system must be at least several times larger than the switching frequency (f_s). i.e $\tau > [\beta (1/f_s)]$, β should be equal or greater than 5 (Rule of thumb). This condition can be summarized as:

$$K < \frac{1}{V_{dc}\{(\beta / f_s L) - (1/R)\}}$$

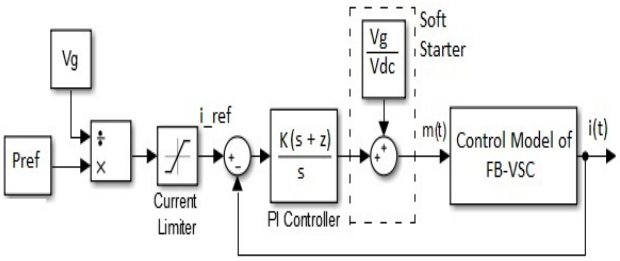

Fig. 4. FB-VSC with a PI controller.

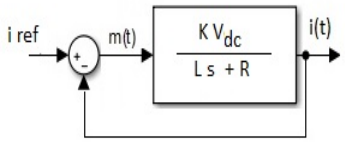

Fig. 5. Close loop Transfer function of FB-VSC with PI controller.

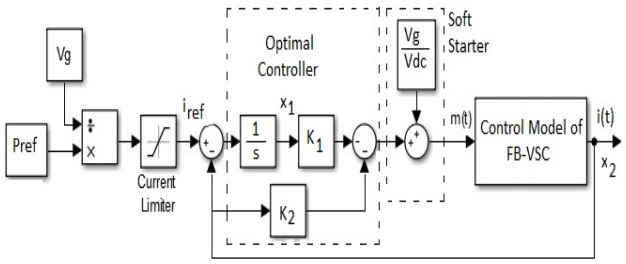

Fig. 6. FB-VSC with an optimal controller.

IV. Proposed Optimal Controller for FB-VSC

The optimal controller is designed by using state space full state feedback control approach. Fig. 6 shows the simplified diagram of close loop feedback control FB-VSC with an optimal controller.

A. State space model of proposed control structure

From fig. 6, two state variables of the control system are $x_1 = \int e$ (e=tracking error signal) and $x_2 = i(t)$ = converter output current.

$$x_2 = \frac{u V_{dc}}{Ls + R} \quad \text{or} \quad Lsx_2 + Rx_2 = uV_{dc}$$

[Where, feedback control signal $u = -k_1 x_1 - k_2 x_2$]

Derivatives of state variable $x_1 and\ x_2$ / (state equations of the system)

$$\dot{x_1} = e = i_{ref} - x_2 \tag{7}$$

$$\dot{x_2} = -\frac{R}{L}x_2 + \frac{uV_{dc}}{L} \tag{8}$$

To remove external input signals from the state equations and to convert the tracking problem to a regulation problem, apply $\Delta = \frac{d}{dt}$ transformation to both sides of equation (7 and 8) and then map **x to z=Δ(x).**

$$z_1 = \dot{x_1} \quad \text{and} \quad z_2 = \dot{x_2}$$

The control signal $v = \dot{u} = -k_1\dot{x_1} - k_2\dot{x_2} = -k_1\dot{z_1} - k_2\dot{z_2}$

The new state representation becomes

$$\dot{\boldsymbol{z}} = \boldsymbol{Az} + \boldsymbol{Bv} \tag{8}$$

Where, z_1 and z_2 are state variables, A is system matrix, B is input matrix, and v is the control signal. The New sate equations can be derived as: (assuming I_{ref}= constant)

$$\dot{z_1} = -\dot{x_2} = -z_2 \tag{9}$$

$$\dot{z_2} == -\frac{R}{L}z_2 + \frac{vV_{dc}}{L} \tag{10}$$

From equation (9 and 10), system matrix **A** and input matrix **B** can be expressed as:

$$A = \begin{pmatrix} 0 & -1 \\ 0 & -R/L \end{pmatrix} \quad B = \begin{pmatrix} 0 \\ V_{dc}/L \end{pmatrix}$$

Now LQR technique is applied to equation (8) to obtain the optimal controller's gains (k_1 and k_2).

B. Linear Quadratic Regulator (LQR) technique

LQR is a very useful and well-known concept in the optimal control theory. If a linear system has the state-space equation $\dot{\boldsymbol{z}} = \boldsymbol{Az} + \boldsymbol{Bv}$**,** then LQR is able to provide the full state feedback gains **k** in the control law $v = -kz$ which can minimize the following quadratic cost function:

$$J(v) = \int_0^\infty z^T Q z + v^T R v \tag{10}$$

In the cost function, v is the control signal, z is the system's space vector, Q is a positive semi-definite matrix, R is a positive definite matrix, and T stands for vector transposition [14]. The solution to finite-time LQR is obtained from a Differential Riccati Equation (DRE). The solution of the equation (6) is $K = R^{-1}B^T F$ can be obtained from the algebraic Riccati equation [13].

$$A^T F + FA + Q - FBR^{-1}B^T F = 0$$

Computational tools like MATLAB can be used to find the solution. These gains can provide a phase margin of greater than 60° to the close loop, which can make a system relatively good robustness to uncertainty and unmodeled dynamics.

For this FB-VSC system, **Q, R,** and **z** can be selected as:

$$Q = \begin{pmatrix} q1 & 0 \\ 0 & q2 \end{pmatrix} \quad R = 1 \quad Z = \begin{pmatrix} e \\ i \end{pmatrix}$$

Then the quadratic cost function can be written as:

$$J = \int_0^\infty (q_1 e^2 + q_2 i^2 + v^2)dt$$

By selecting q_1 and q_2 directly impact the tracking error (e) and the derivative of output current i(t). MATLAB control toolbox can be used to design Q, increase q_1 from an initial positive value and set all other coefficient to zero. Once q_1 reaches a definite desirable value representing a sufficient distance of the dominant pole from the imaginary axis, fix it to that value and then increase q_2 by same process. Bode diagram, system response, and close loop poles locations are observed during this process.

V. Simulation and Results

In this section, simulation of FB-VSC with PI controller and optimal controller are presented. Numerical Values of Table I are selected for the inverter with a simple L output filter. Fig. 7 shows the circuit diagram of FB-VSC. For both control system, same arrangement will be used, only different controller will be implemented in the controller block (Shown in the fig. 7).

TABLE I
SYSTEM PARAMETERS

Dc Link voltage at input side (V_{dc})	600 V
DC voltage at output side (V_g)	400 V
L Filter parameter (L)	700 uH
Total resistance (R)	0.005 ohm
Switching frequency (f_s)	10 KHz
Inverter Power rating (S)	640 KVA
Time constant (t)	5 ms

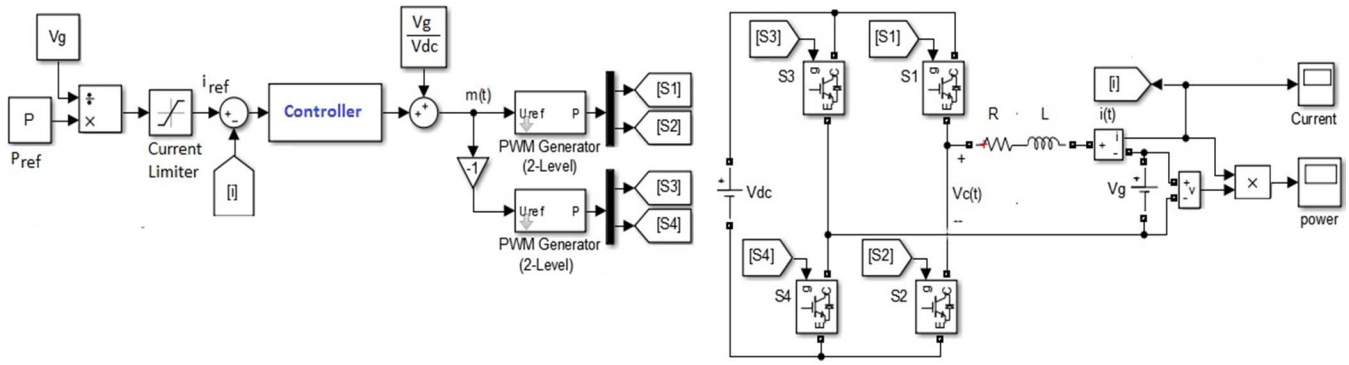

Fig. 7. Circuit arrangement of FB-VSC.

i) Open loop operation:

For a given power P,
The converter output current, $I = P/V_g = 640KW/400V = 1600A$.
The converter Voltage, $V_c = V_g + RI = (400 + 0.005*1600) = 408V$
The modulating signal, $m = V_c/V_{dc} = 408/600 = 0.68$.
And the duty cycle, $D = (m+1)/2 = 0.84$.

Simulation scenario (1):

Gating signal is applied at t=0 s, V_g jumps up 4% at t=1s, and V_{dc} jumps up 1% at t=2s.

Simulation scenario (2):

The value R is increased by 50%, 75%.

Fig. 8 & 9 show the robustness of the controller to the system and converter uncertainties. If V_g changes slightly, the direction of power flow changes. If V_{dc} and R change a little, inverter current changes by a large amount. And the system takes about 0.5 s to settle.

ii) FB-VSC with feedback loop using PI controller:

A PI controller (Designed in section III) is applied in the FB-VSC simulation circuit shown in fig. 7. Assume time constant τ =5ms. Then the value of z and k is calculated from equation (5) & (6) respectively.

$$z = \frac{R}{L} = \frac{0.005}{0.0007} = 7.143$$

$$K = \frac{1}{V_{dc}}\left(\frac{L}{\tau} - R\right) = \frac{1}{600}\left(\frac{0.0007}{0.005} - 0.005\right) = 0.000225$$

Simulation scenario (1):

i) Gating signal is applied at t=0 s. V_g jumps up 3% at t=0.05s, and V_{dc} jumps up 1% at t=0.07s.
ii) The value R is increased by 50% and100%.

Simulation scenario (2):

i) Reference power changes (P) from 640 KW to 600 KW at sec 0.05 s.

Fig.10 shows that if V_{dc}, V_g, and R change even by a very small value, the converter current (I) changes significantly. From Fig.11 it is also observed that when the reference power (P) changes from 640KW to 600KW at t = 0.05s, it takes approximately 0.02 s to track this slight change. From these observations, it is obvious that the PI controller is not robust enough to eleminate system uncertenities and disturbnce.

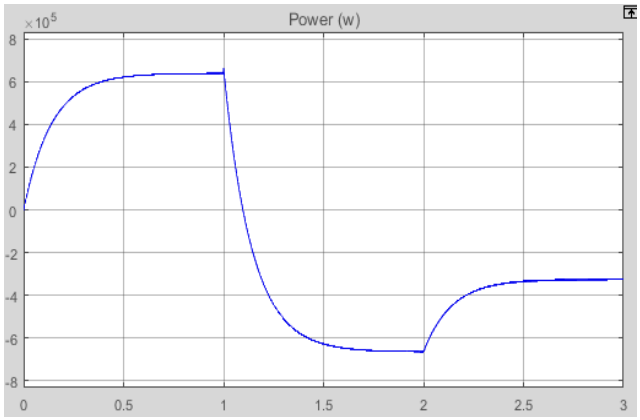

Fig. 8. Output Power of open loop FB-VSC.

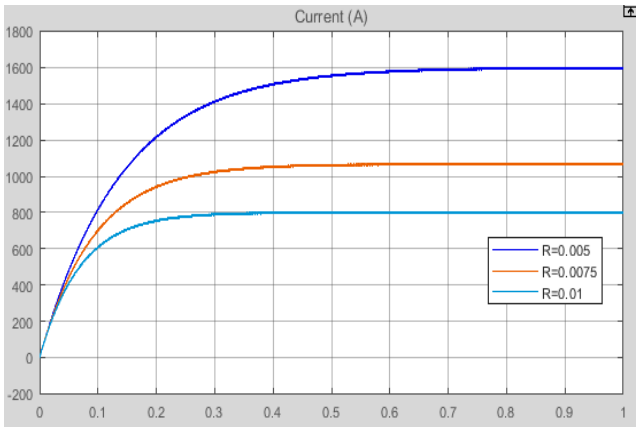

Fig. 9. Output Current of open loop FB-VSC.

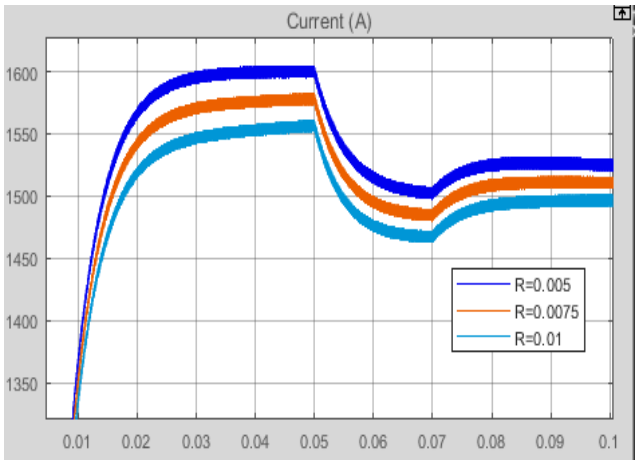

Fig. 10 Output Current of FB-VSC with PI controller (Zoomed)

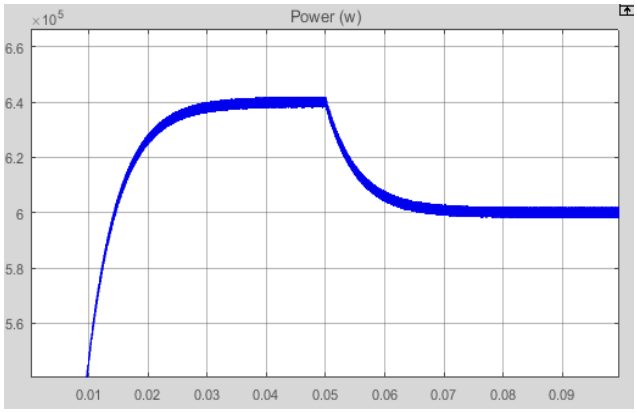

Fig. 11 Output power of FB-VSC with PI controller (Zoomed)

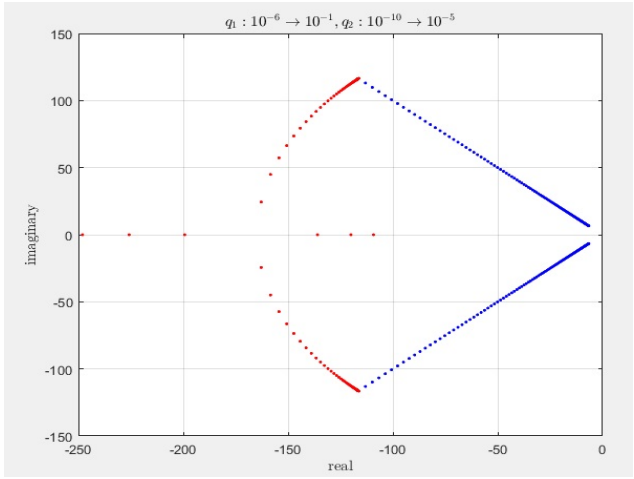

Fig. 12. root locus of close loop poles.

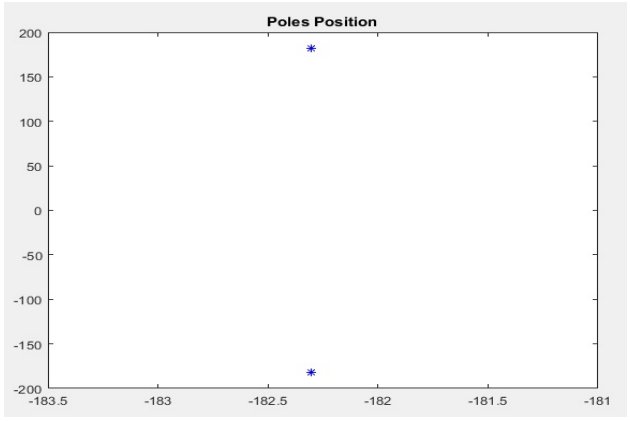

Fig. 13. Close loop pole position for k_1=-0.7071 & k_2=0.0036.

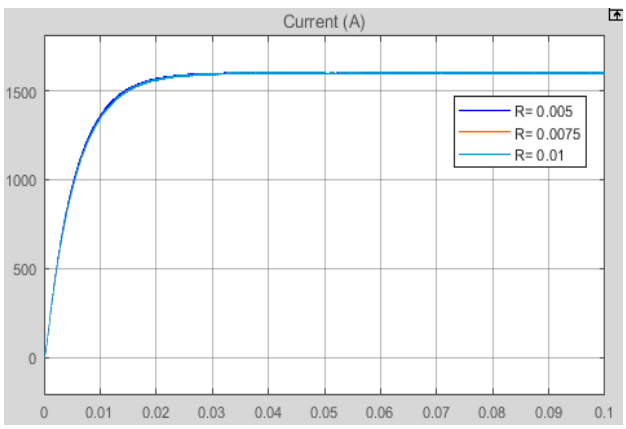

Fig. 14 Output current of FB-VSC with optimal controller (Zoomed)

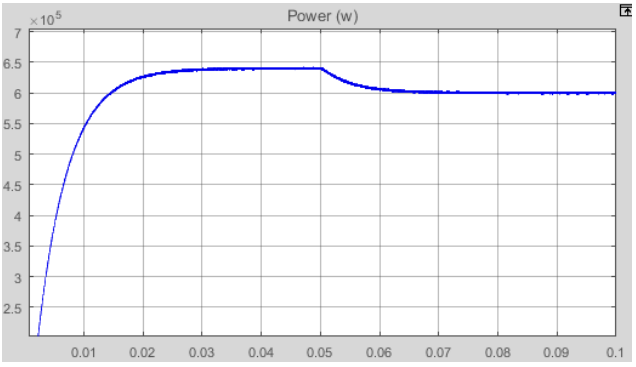

Fig. 15 Output power of FB-VSC with optimal controller (Zoomed)

iii) FB-VSC with feedback loop using optimal controller:

An optimal controller (designed in section IV) is applied in the FB-VSC simulation circuit shown in Fig.7. The value of k_1 and k_2 are obtained by using LQR technique. Calculate **A** and **B** using given parameter

$$A = \begin{pmatrix} 0 & -1 \\ 0 & -7.143 \end{pmatrix} \quad B = \begin{pmatrix} 0 \\ 1714285.714 \end{pmatrix}$$

$$Q = \begin{pmatrix} q_1 & 0 \\ 0 & q_2 \end{pmatrix} \quad Z = \begin{pmatrix} e \\ i \end{pmatrix} \; and \; R = 1$$

In this case, q_1 is varied from 10^{-5} to 10^{-1} and q_2 varied from 10^{-10} to 10^{-5}. To meet the time constant τ = 5ms, q_1 and q_2 are selected as $5e^{-1}$ and $2e^{-8}$ respectively. Fig.11 shows the root locus of close loop poles. Then k_1 and k_2 are obtained by using MATLAB command **lqr(A,B,Q,1).**

$$k_1 = -0.7071 \text{ and } k_2 = 0.0036$$

Simulation scenario (1):

i) Gating signal is applied at t=0 s. V_g jumps up 3% at t=0.05s, and V_{dc} jumps up 1% at t=0.07s.
ii) The value R is increased by 50% and100%.

Simulation scenario (2):

i) Reference power (P) changes from 640 KW to 600 KW at sec 0.05 s.

Fig.13 shows that in spite of changing V_{dc}, V_g, and R by the same value, the converter output current remains same. And from fig.11 it is also observed that when the reference power (P) changes from 640KW to 600KW at t=0.05 s, it takes only 0.015 s to track the change (less than 0.02 s takes by PI controller). So from these study, it is evident that the optimal controller is more robust to cancel various system uncertenities and disturbnce. Optimal controller also exhibits faster dynamics compare to PI controller.

VI. Conclusion

A Systematic design procedure and a new controller structure of single-phase full bridge VSC for renewable and distributed energy system have been addressed in this paper. The proposed controller has designed using the optimal control technique. A comparative study between this proposed optimal controller and conventional PI controller has also presented in this paper. The proposed optimal controller shows more robustness than PI controller to deal with external disturbance and system uncertainties.

Simulation results confirm effectiveness of the proposed optimal controller. In the future work, this proposed controller will be implemented in a prototype system.

***Abstract*—Multilevel inverter for industrial application has gained tremendous popularity in recent years. That's why an urge to develop simpler topologies and control techniques has drawn the attention of the researcher community. The flying capacitor multilevel inverter (FCMLI) is one such topology. FCMLI is an attractive alternative for medium voltage applications as it does not need complex transformers to obtain the dc-link voltage and also present good robustness characteristics. Different controlling techniques can be applied for modulation purpose in FCML inverters i.e. Pulse Width Modulation, Space Vector Modulation and Model Predictive Control. The standard procedure of predictive control is basically building a model of the system to predict the future values of the controlled variables. This information is utilized by the controller to achieve the optimal actuation, according to a predefined optimization criterion. This paper proposes the implementation of Finite Control Set Model Predictive Control with Space Vector technique applied to 7-level Flying Capacitor Multilevel Inverter. Our method controls output currents and voltages which allows one to increase the number of output voltage levels and reduce harmonic contents. It also ensure that output current contain minimum amount of harmonic. The feasibility of the proposed method operating with different loads and transient conditions has been verified by MATLAB/Simulink.**

Keywords—model predictive control, flying capacitor multilevel inverter, space vector, harmonic content

I. INTRODUCTION

Multilevel voltage source inverters has emerged as a new variety of power converter options for high power applications [1]. The multilevel voltage source inverters typically synthesize the staircase voltage wave from several levels of DC capacitor voltages. One of the major drawbacks of the multilevel inverters is it's inability to balance the voltage between different levels. The techniques to overcome the problem typically involve voltage clamping or capacitor charge controlling. There are multiple ways of achieving voltage balance in multilevel converters. The most popular multilevel converter topologies are the cascaded H-bridge converter [2], the modular multilevel converter [3], the neutral point clamped converter [4], and the flying capacitor Multilevel Inverter(FCMLI) [5].

The FCMLI is such a topology for high voltage applications that doesn't rely on any series connection of the power switches. It is a symmetric topology. It has some advantages over other types of converters like Diode Clamped Multilevel Inverter, Cascaded H-Bridge Multilevel Inverter. One of its significant advantages is that one can increase the number of voltage levels by simply adding basic cells in the load end of each leg. The prime challenge of implementing FCMLI is to maintain voltage balance on the different capacitors. To deal with the problem redundant switching states are used in each leg of the inverter with the help of adequate modulation scheme. Different connections of the flying capacitor is used to obtain different voltage levels of an FCMLI. It is necessary to ensure that all the flying capacitors ultimately reach a stable and constant voltage, so that the net charge variation become zero . Normally, FCMLI is implemented using Space Vector Modulation or Phase Disposition Pulse Width Modulation (PDPWM) techniques [6]-[7]. These techniques have good performance in controlling the three phase output voltage and reducing the harmonic content. But the output current has relatively high harmonic content (around 2 to 5 %). Also, in PDPWM technique the output current has a significant dc component in first few cycles. To deal with this problem we use Finite Control Set Model Predictive Control (FCS-MPC) in our FCMLI design to have smooth sinusoidal current and staircase voltage wave at load side with less harmonic.

FCS-MPC [8] (also known as direct MPC [9]) is considered to be the best predictive control for power inverters. In this method, the predictive control strategies precisely treat the power switches as control input of the system. In FCS-MPC a finite set of switch combinations is possible as power switches can have two particular states, 1 or 0. Therefore, a finite number of predictions can be obtained for the different electrical variables. The optimal solution is achieved by evaluating the cost function for each possible switching combination at each sampling interval. In this paper we use space vector technique to find the optimum voltage vector that will minimize the cost function (mainly, the difference between reference current and predicted current) in every time interval. Then the optimal switching combination is implemented in the inverter. As this method strictly ensures that the output current follows the predefined reference current, the output current is perfectly sinusoidal with less harmonic. The output current also has average value zero with no dc component. FCS-MPC can also deal with more complex target by including them in the cost function, e.g. reducing the common mode voltage [10] and switching loses [11]. Considering the performance, FCS-MPC allows one to achieve a fast transient response when load change or reference change occur compared to other modulation schemes. Also, this predictive technique allows the inverter to avoid any unwanted overcurrent condition,by adding safety limits for the electrical variables as constraints [12].

II. FLYING CAPACITOR MULTILEVEL INVERTER

The Flying Capacitor Multilevel Inverter (FCMLI) has been presented by Meynard and Foch [5]. It is a very efficient multilevel topology for medium voltage application because unlike cascade multicell converters these inverters do not rely on any isolated dc sources and, hence, big multi-secondary transformers.

An *m*-level FCMLI has *m*– 1 stages, where each stage is controlled with a switching function (s_j). The *j*th stage of a FCMLI consists of complementary switches with (*m*– *j*) capacitors connected in series. In real application, these switches are high speed semiconductor switches like MOSFET (Metal Oxide Semiconductor Field Effect Transistor), Thyristor or IGBT (Insulated Gate Bipolar Transistor) [13]-[14]. For generalized topology the voltage across each capacitor (V_c) maintains the same value. So, for an *m*-level converter,

$$V_c = \frac{V_{dc}}{m-1} \tag{1}$$

The generated leg voltage V_{aN} due to the collective action of the switching functions of each stage is given by

$$V_{aN} = \frac{V_{dc}}{m-1}\sum_{j=1}^{m-1} s_j \tag{2}$$

An *m*-level FCMC has (*m*– 1)(*m*– 2)/2 flying capacitors in each leg of the inverter with (*m*– 1) capacitors on the DC bus. These capacitors are named as flying capacitor as they are floating with respect to earth's potential and not connected to the ground. The number of capacitors in each stage can be reduced if the flying capacitors are rated for different voltages. Then, the (*m*– *j*) capacitors of each stage can be replaced by only one capacitor, and each leg will be consisting of only (*m*– 1) capacitors. In fig. 1 one leg of a seven level converter is shown where one capacitor is used in per stage. Here the ratio of voltage in different capacitors

$$v_{c_{6a}} : v_{c_{5a}} : v_{c_{4a}} : v_{c_{3a}} : v_{c_{2a}} : v_{c_{1a}} = 6:5:4:3:2:1 \tag{3}$$

FCMLI has many redundant states for which the output voltages are same. These redundant states play a vital role to maintain the average voltage on each flying capacitor. This condition ensures that the overcharge or undercharge in one state is removed or regained in the redundant state. In order to maintain constant average voltage on C_j ($j \in \{1,2,3,4,5,6\}$) by using those redundant states, it is necessary that the time span the capacitor is being charged and the time span capacitor is being discharged in one cycle should be same which ensures no net charge (ΔQC_j) along one cycle. So, the following criterion must be satisfied along a switching cycle T_c, in steady state:

$$\Delta Q_{c_j} = \int_{t_c} I_{c_j}.dt = 0 \tag{4}$$

To ensure the above relationship it is essential to know the direction of current flow and the voltage magnitude across the capacitor to understand whether it is charging or discharging.

III. FINITE CONTROL SET MODEL PREDICTIVE CONTROL

Model Predictive Control (MPC) is widely used control technique for various power inverters [15]-[17]. In this technique the model of system is used to accurately predict the future behavior of the controlled variables. The time horizon is divided into several interval and each interval, the optimum solution of controlled variables for next interval or

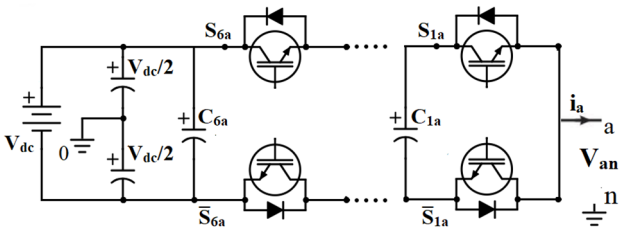

Fig. 1. One leg of a 7-level FCMLI

intervals is predicted using the value of controlled variable in present interval. A cost function is developed using the system model and the cost function is calculated for the predicted values of the variables to be controlled. Prediction of the future value of these variables is calculated for each possible switching state and then the state that minimizes the cost function is selected to be used in next time interval. In FCS-MPC (Finite Control Set Model Predictive Control) the number of combinations of controlled variables is a finite value and from this finite number of combinations the most preferable combination is found and implemented in next interval.

The control strategies we followed in this paper to implement FCS-MPC are

- Building an inverter model and its possible switching states
- Building a model of load for prediction
- Defining a cost function and finding appropriate switching state to minimize it

A. Inverter Model

The inverter used in this paper is a 7-level Flying Capacitor Inverter. It has six stages in each leg and each stage has two complementary switches with capacitor connected across them. The switching states and corresponding leg voltage is shown in Table I. We can see that 0 state can be achieved by two different combination. To deal with this without incorporating this constraint in cost function we measured the current flowing through the c_{3a} capacitor (the capacitor at third stage) $i_{c_{3a}}$ and voltage across the capacitor $v_{c_{3a}}$ and take appropriate action according to Table II. where, V_{ref} is the reference voltage need to be maintained across capacitor.

We know in balanced three phase connection three phase line current and three phase line to neutral voltages are balanced. So, we can write

$$i_a + i_b + i_c = 0 \tag{5}$$

Table I. SWITCHING COMBINATION

.

S_{6a}	S_{5a}	S_{4a}	S_{3a}	S_{2a}	S_{1a}	V_{aN}
1	1	1	1	1	1	$V_{dc}/2$
1	1	1	1	1	0	$V_{dc}/3$
1	1	1	1	0	0	$V_{dc}/6$
1	1	1	0	0	0	0
0	0	0	1	1	1	0
0	0	0	0	1	1	- $V_{dc}/6$
0	0	0	0	0	1	- $V_{dc}/3$
0	0	0	0	0	0	- $V_{dc}/2$

Table II. CONTORLLING CAPACITOR VOLTAGE

System State	***Switching state for one leg***
if ($i_{c_{3a}} \geq 0$) and ($v_{c_{3a}} \geq V_{ref}$) or if ($i_{c_{3a}} < 0$) and ($v_{c_{3a}} < V_{ref}$)	**S**= [0,0,0,1,1,1]
if ($i_{c_{3a}} \geq 0$) and ($v_{c_{3a}} < V_{ref}$) or if ($i_{c_{3a}} < 0$) and ($v_{c_{3a}} \geq V_{ref}$)	**S**= [1,1,1,0,0,0]

and also

$$V_{aN} + V_{bN} + V_{cN} = 0 \tag{6}$$

Now in this balanced condition as the quantities are not independent, the three phase components of a three phase quantity are determined by two components and therefore, can be described by a plane vector [18]. This is known as space vector. So, the three phase current can be converted into current vector and three phase voltage can be converted into voltage vector. In this paper, we used this approach to predict the future voltage and current of the inverter which enables us to avoid computational burden of three phase quantity. If the real and imaginary component of current vector is i_α and i_β, then

$$\begin{bmatrix} i_\alpha \\ i_\beta \end{bmatrix} = \frac{2}{3}\begin{bmatrix} 1 & -\frac{1}{2} & -\frac{1}{2} \\ 0 & \frac{\sqrt{3}}{2} & -\frac{\sqrt{3}}{2} \end{bmatrix}\begin{bmatrix} i_a \\ i_b \\ i_c \end{bmatrix} \tag{7}$$

B. Load Model:

The load we used in our simulation is a typical RL branch. If the voltage vector applied in the RL branch is **v,** the load current vector is **i** and then the dynamic operation of the load can be described by the differential equation

$$\mathbf{v} = R\mathbf{i} + L\frac{d\mathbf{i}}{dt} \tag{8}$$

We used discrete time model to predict the future value of current in different time interval. Equation (8) is discretized to implement FCS-MPC so that we can predicted the value of current in different interval of time horizon. The sampling time for the discretization process is expressed as T_s. At any sampling instant *n*th the discrete time model of the load is utilized to predict the future value of load current from applied voltages and measured currents. Different discretization principle can be implemented to obtain a suitable discrete time model for calculating future values. In this paper we used forward Euler approximation to replace $\frac{d\mathbf{i}}{dt}$ term by following equation,

$$\frac{d\mathbf{i}}{dt} \approx \frac{\mathbf{i}(n+1)-\mathbf{i}(n)}{T_s} \tag{9}$$

By using this approximation, we can predict the value of current vector of future interval *n+1* by using the value at *n*th interval. Then the predicted value of future current can be written as,

$$\mathbf{i^p}(n+1) = \left(1 - \frac{RT_s}{L}\right)\mathbf{i}(n) + \frac{T_s}{L}\mathbf{v}(n) \tag{10}$$

Where $\mathbf{i^p}$ is the predicted current vector and **v** is the applied voltage vector.

C. Design of cost function

The cost function is designed to minimize the difference between the measured load current and the predefined reference current. The expression of cost function of designed system is,

$$c = \left|i_\alpha^r(n+1) - i_\alpha^p(n+1)\right| + \left|i_\beta^r(n+1) - i_\beta^p(n+1)\right| \tag{11}$$

Here, $i_\alpha^p(n+1)$ and $i_\beta^p(n+1)$ are real and imaginary component of the predicted current vector and $i_\alpha^r(n+1)$ and $i_\beta^r(n+1)$ are real and imaginary component of reference current vector at $(n+1)$th instant for the applied voltage vector. To reduce complexity, we ignore the change of reference current in one time interval. So, we consider that

$$\mathbf{i^r}(n+1) = \mathbf{i^r}(n) \tag{12}$$

In each interval equation (11) is evaluated for each voltage vector and the voltage vector generates minimum error is applied in next time interval with its corresponding switching combination

IV. SIMULATION RESULT

The effectiveness of the proposed design is confirmed by doing several simulations in Matlab (Simulink) environment. The circuit parameters used for this simulation is given in Table III and Table IV. The reference current is predicted as 1.9A. The prediction is done by considering the fact that by applying a DC bus voltage of Vdc, we are able to get highest phase voltage of (2/3)*Vdc. We have applied 533V as DC bus voltage and consequently we have got highest phase voltage 355V in output. If the output voltage was a pure sine wave (with 355V peak value) then the peak value of output current would be 2.1A for the RL load of 10 ohm and 500 mH (in 50 Hz system). But as our output voltage is not a pure

sine wave, the suitable value for predicting the peak output current is below 2.1A. By using trial and error we find 1.9A is the best value for predicting reference current magnitude In Fig. 2 the simulated value of Output Load Current, Line to Line voltage and Phase voltage are shown. From the figure we can see that initially the graphs are inconsistent due to transient effect of RL load. But the problem is overcome in first half cycle. Again, the output current has no dc component after first cycle which solve the problem other techniques where the output current has significant dc component. Fig.3 shows the harmonic content of current and voltage. This figure indicates that the harmonic content is almost zero (.27%) for output current. This is one of the important features of this method. As our technique ensures that the output current follows the reference current, the harmonic content is greatly reduced. The harmonic content of Line voltage and Phase voltage is high, but these values are much lower for 7-Level FCML compared to a 5-Level FCMLI which values are shown in Fig. 4 and Fig. 5. and Table V. This design can also efficiently react on any sudden reference change like change in reference current or sudden load change which is another benefit of this topology. Like in Fig. 6 at t = 50 ms the reference current I_{ref} is changed from 1.9A to 1.33A. The Output Load Current, Line to Line voltage and Phase voltage quickly cope with the changed reference with little discrepancy.

V. CONCLUSION

This paper presented an analysis on 7-level Flying Capacitor Multilevel Inverter using Model Predictive Control technique. It shows that we can ensure better output with less harmonic distortion if we increase the voltage level and design the system with appropriate parameter. It also have very good transient response. But the most significant characteristics of Model Predictive Control is that it can reduce the dc component of output current to zero with almost perfect sinusoidal current of minimum harmonic content. This method can be developed by adding more level or by using fixed switching frequency for every MOSFET which will further reduce the harmonic content of Line to Line voltage and Phase voltage.

***Abstract*— In modern times, the design and optimization of different control systems for servo control of a hard disk drive (HDD) is popular interdisciplinary research area. Nowadays, dual-stage actuator system is widely used in HDD servo system, where voice coil motor (VCM) actuator and piezo-electric micro actuator are used as the primary actuator and secondary actuator, respectively. In this paper, different combinations of PI, PD, and PID are employed for primary and secondary actuators. The tuning method is applied on these combinations to obtain the best performance. After a rigorous comparative analysis, this paper proposes the optimized method among these different combinations by analyzing and comparing the results obtained through MATLAB/Simulink simulation.**

Keywords—hard disk drive (HDD); voice coil motor (VCM); piezo-electric (PZT); actuator;

I. INTRODUCTION

A hard disk drive (HDD), a very popular storage system used in computers and data-processing, is a magnetic storage device to record and recover digital information in magnetic disks. The disks are coated with magnetic materials and rotated at a specific speed. Information bits are recorded in circular rounds, known as tracks, on the disks. The read/write heads are installed in a slider and the slider is attached to the tip of an actuator arm. This actuator arm drives the read/write head in the horizontal direction over the disk surfaces and the motion of this head is controlled by head positioning servomechanism. This servomechanism has two primary actions in the disk drive systems; one is track seeking and another one is track following [1]. In a dual-stage HDD shown in Fig. 1, the mechanical and eletromechanical parts of the servo system consist of the VCM, the suspension, piezoelectric micro-actuator made from Lead-Zirconate-Titanate (PZT), and the slider. The magnetic read/write (R/W) head is fabricated with the slider [2]. Early age HDDs use only one actuator, a VCM actuator that plays a vital role to move the R/W head. To achieve the high precision positioning control, the dual-stage actuator system has been emerged recently. As a result, the data capacity of HDDs can be increased with the availability of increased servo bandwidth [3]. Different control techniques are designed for dual-stage system by many researchers over the previous years. Optimization and simplification of these control approaches is a growing demanding research work in order to obtain a suitable controller for the dual-stage system to make it acceptable for the mass production. Dual-stage HDD servo system is a dual-input single-output (DISO) system[4]-[5] and for designing a servo controller for this DISO system diverse methods are already designed and optimized that have been described in the revealed articles [6]-[9]. For dual-stage controller, there are three popular configurations: (a) parallel loop configuration, (b) master-slave configuration, and (c) decoupled master-slave configuration [10].

Fig. 1. A Hard Disk Drive.

This paper represents the design and comparative analysis of performances of PI, PD and PID controllers in different combinations as the controllers for primary VCM actuator and secondary PZT micro-actuator in dual-stage HDD servo system. By using MATLAB and Simulink simulation, the open-loop bandwidth, gain margin, phase margin, rise time, settling time, and percentage overshoot of each combination are obtained and then compared to achieve the optimized performance.

II. PLANT MODEL

Dual-input single-output (DISO) system of a HDD servo system shown in Fig. 2 uses two actuators- one is VCM actuator as primary and another one is PZT as secondary actuator. Control signals from the controllers are applied to the actuators and system's combined output is the displacement of the R/W head. In the dual-stage HDD servo system, bandwidth of the system increases which thereby increases the positioning speed than the single-stage actuation system.

A. VCM Model

Voice coil motor actuator is mathematically modeled as a double-integrator model which can be expressed as the following form [6]:

$$G_V(s) = \frac{K_V}{s^2} \times \sum_{i=1}^{N_V} H_{ri} \quad (1)$$

where K_V is the gain, N_V is the total number of mechanical resonant modes of VCM actuator. Each resonant mode is represented by three parameters (A_i, ω_{ri} and ζ_i) as follows:

$$H_{ri} = \frac{A_i}{s^2 + 2\zeta_i \omega_{ri} s + \omega_{ri}^2}$$

VCM model used in this work has the frequency response shown in the Fig. 3 with four mechanical resonant modes. These resonant modes decrease the performance of the HDD servo system since this force the designer to reduce the system bandwidth in order to keep the system stable. So effect of these resonant modes should be compensated by using resonance compensator.

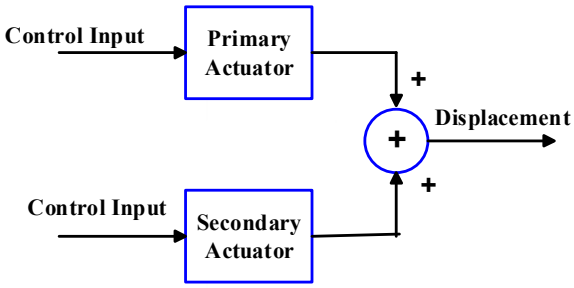

Fig. 2. Dual-Input Single-Output (DISO) system in HDD.

B. PZT Model

The secondary actuator PZT can be modeled in the following mathematical form [6]:

$$G_P(s) = K_P \times \sum_{j=1}^{N_P} R_j \quad (2)$$

where K_P is the gain, N_P is the number of the mechanical resonant modes of secondary actuator where each resonant mode can be expressed as,

$$R_j = \frac{a_i}{s^2 + 2\zeta_j \omega_{pj} s + \omega_{pj}^2}$$

The frequency response of secondary PZT actuator is shown in Fig. 4. Here, we deal with five mechanical resonant modes in the frequency response to further analysis. These resonant modes are also detrimental for the response of the plant output.

III. DUAL-INPUT SINGLE-OUTPUT CONTROLLER

A common design detailed description for controlling servo mechanism of dual-stage HDD is summarized in Table I. Due to the conflicting features of inertia, bandwidth and range of motion on both primary and secondary, our controller must be designed perfectly for these two actuators [10].

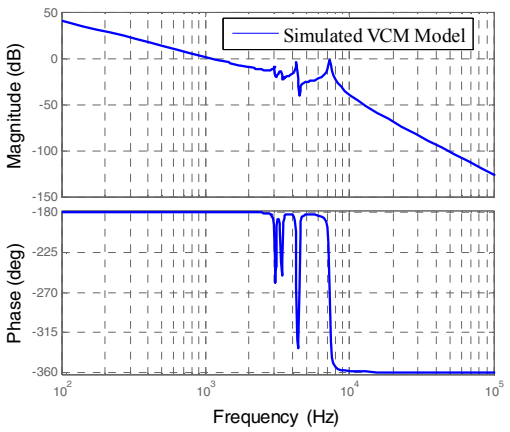

Fig. 3. Frequency response of VCM model.

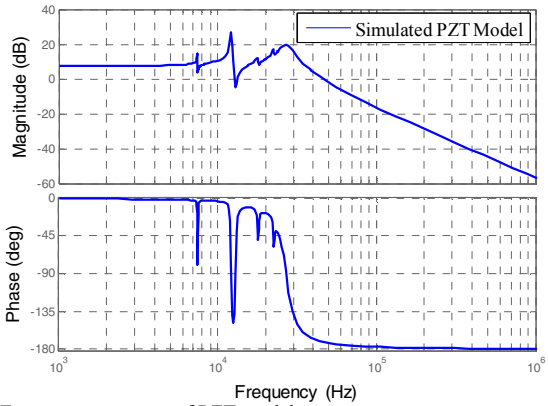

Fig. 4. Frequency response of PZT model.

TABLE I. DETAILED DESCRIPTION FOR A TYPICAL DUAL-STAGE CONTROLLER

Parameters	Required value
Open-loop bandwidth f_o :	>2000 Hz
Phase margin :	>40 degree
Gain margin :	>6 dB
Rise time :	<0.2 ms
Overshoot :	<20%

Fig. 5 shows the decoupled master-slave (DMS) controller architecture. In this configuration, the output of secondary controller is feed to input of the primary controller by adding with error signal. For this configuration, the transfer function

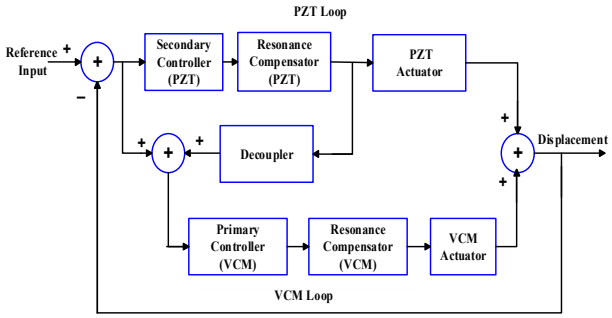

Fig. 5. Decoupled master-slave control architecture for dual-stage HDD.

of open-loop $L_{DMS}(s)$, closed-loop $T_{DMS}(s)$ and sensitivity $S_{DMS}(s)$ can be expressed as:

$$L_{DMS}(s) = (1 + C_M P_M) C_V P_V + C_M P_M,$$

$$T_{DMS}(s) = \frac{C_V P_V + C_M P_M + C_V P_V C_M P_M}{(1 + C_V P_V)(1 + C_M P_M)},$$

$$S_{DMS}(s) = \frac{1}{1 + C_V P_V} \frac{1}{1 + C_M P_M},$$

Where, C_V is the primary controller (VCM controller), C_M is the secondary controller (Micro actuator or PZT controller), P_V is the primary actuator (VCM actuator) and P_M is the secondary actuator (PZT actuator).

A. SIMULATION RESULTS

All the simulations of dual stage servo system are done by using MATLAB/Simulink. Fig. 6 shows the relation of output response among three configurations where PI controller used as primary controller and PI, PD, PID controller used as secondary controller respectively. In Fig. 6, using PI-PD controller, it is observed that, the steady-state error was not completely removed. On the other hand steady-state error can remove completely using both PI-PI and PI-PID.

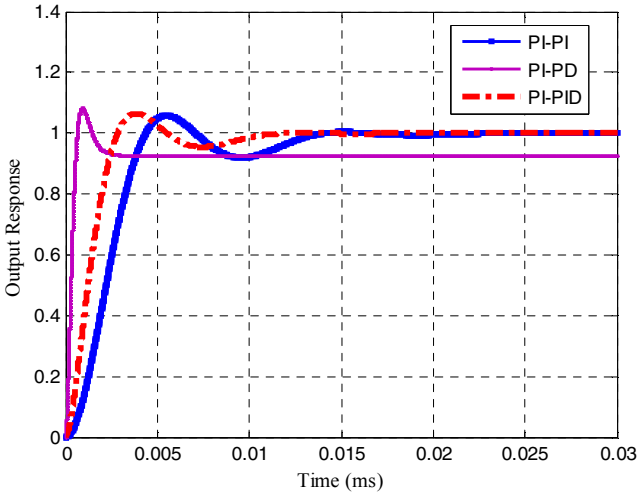

Fig. 6. Output Response of dual-stage controller where PI as primary controller.

Fig. 7 represents the comparison of output responses among the three configurations where PD controller is used as primary controller and PI, PD, PID controller are used as secondary controller individually. In Fig. 7, using PD-PD controller, it is observed that, the steady-state error was not completely removed. On the other hand steady-state error can remove completely using both PD-PI and PD-PID.

Fig. 8 shows the relation of output responses among three configurations where PID controller used as primary controller and PI, PD, PID controller used as secondary controller respectively. In Fig. 8, using PID-PD controller, it is observed that, the steady-state error was not completely removed. On the other hand steady-state error can remove completely using both PID-PI and PID-PID.

Fig. 9 and Fig. 10 presents the open-loop and closed-loop frequency response respectively where PI, PD and PID used as secondary controller. The rise time, settling time, percentage overshoot, open-loop bandwidth, phase margin and gain margin obtained from the output response and open-loop frequency response of different combination that are mentioned in Table III. PI, PD or PID controller in the primary loop results-in approximately same performance. However different types of controller in the secondary loop given different output responses. This can be observed from Fig. 6, Fig. 7, Fig. 8 and Table III.

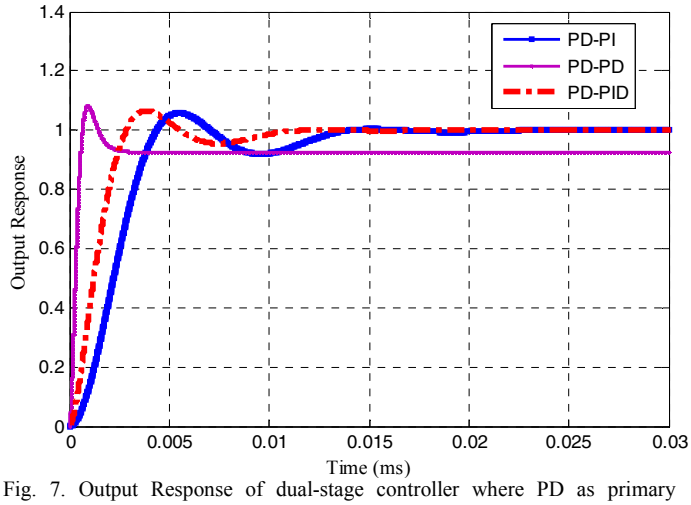

Fig. 7. Output Response of dual-stage controller where PD as primary controller.

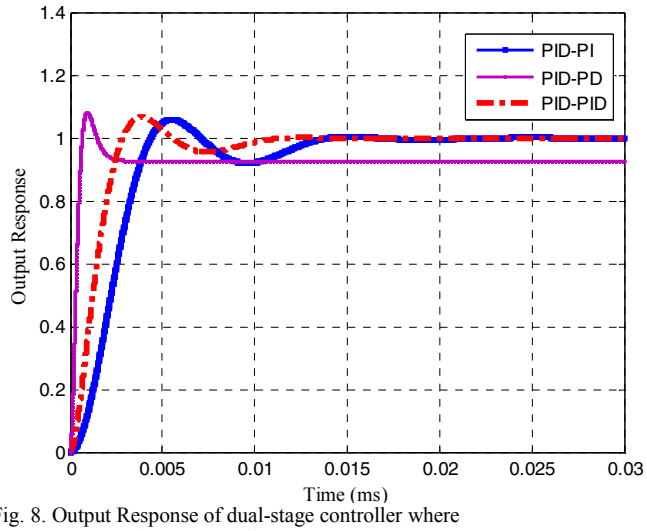

Fig. 8. Output Response of dual-stage controller where PID as primary controller.

Fig. 11 presents the error signal of three different configurations, where PI, PD and PID are used as the secondary controller individually. The standard deviation is calculated to determine the percentage improvement of each configuration (shown in Table II). It is observed that when PD

controller is used in secondary stage, 65.27% and 53.29% error can be improved than PI and PID controller. From the Table III it can be concluded that, PD controller in a secondary actuator controller has the best performance than others. It is observed from Table III, the bandwidth is comparatively high when PD used in secondary stage than that for other two controllers and phase margin is same.

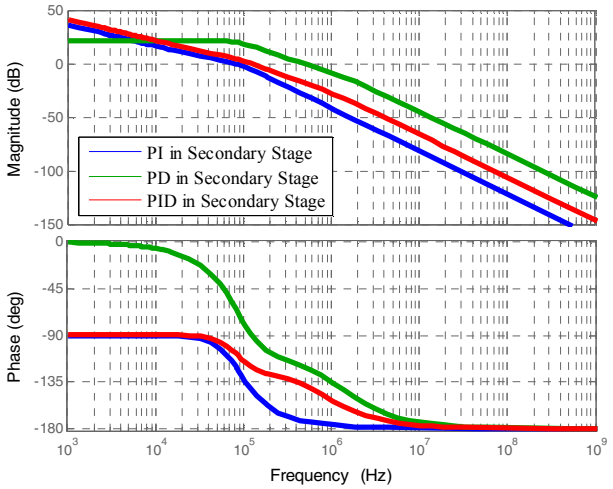

Fig. 9. Open loop frequency of different configuration.

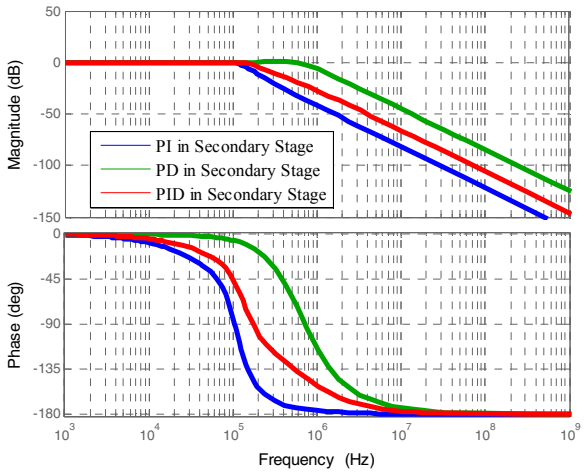

Fig. 10. Close loop frequency of different configuration.

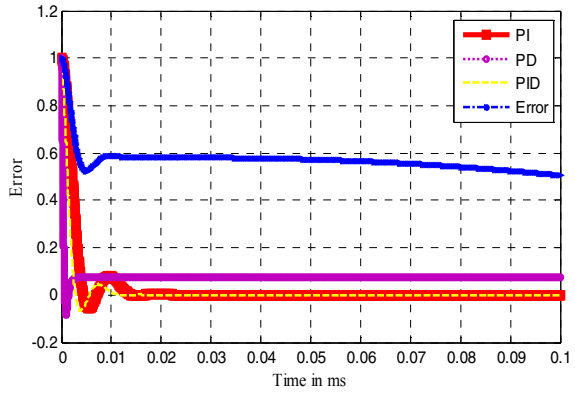

Fig. 11. Error signal.

TABLE II: STANDARD DEVIATION CALCULATION

Sl. No	Controller used as secondary	Standard deviation
01	PI	0.1267
02	PD	0.0440
03	PID	0.0942

TABLE III: SUMMARY OF RISE TIME, SETTLING TIME, PERCENTAGE OVERSHOOT, OPEN-LOOP BNADWIDTH, PHASE MARGIN AND GAIN MARGIN OF DIFFERENT CONFIGURATION

Sl. No.	Controller	Rise Time (µS)	Settling Time (µS)	%OS	Open-loop bandwidth f_0 (kHz)	Phase margin (Degree)	Gain margin (dB)
01	PI-PI	3.704	12.7	5.80	81.1	60	84.7
02	PI-PD	0.491	2.024	16.96	483	60	101
03	PI-PID	2.336	9.589	6.50	122	60	109
04	PD-PI	3.704	12.7	5.80	81.1	60	84.7
05	PD-PD	0.491	2.024	16.96	483	60	101
06	PD-PID	2.336	9.589	6.50	122	60	109
07	PID-PI	3.704	12.7	5.80	81.1	60	84.7
08	PID-PD	0.491	2.024	16.96	483	60	101
09	PID-PID	2.336	9.589	6.50	122	60	109

IV. CONCLUSION

The simulation results show the comparison among the different combination of PID controller used in HDD servosystem. When PD controller used in secondary stage, it shows the better and optimized performance than others. For this configuration we observed the rise time is 0.491 µs, settling time is 2.024 µs, open-loop bandwidth is 483 kHz, phase margin is 60 degree but percentage overshoot is 16.96% that is better than others and gain margin is 101 which is smaller than PID controller. Therefore, we can conclude that the PI-PD, PD-PD and PID-PD combinations can be the suitable controller configuration for the dual-stage servo system if the resonance is compensated properly.

Intelligent Speed Control of DC Motor using ANFIS D Controller

Tanjim Tarannum
Khulna University of Engineering and Technology,
Khulna-9203, Bangladesh.
tanjim729@gmail.com

***Abstract*—The main objective of this paper is to present the speed controlling method of a separately excited DC motor with Adaptive Neuro Fuzzy Inference System (ANFIS) based derivative controller. Efficient control of speed of DC motor has been achieved using by reducing the overshoot, undershoot, peak to peak ripple and steady state error by the proposed approach. A derivative controller has also been used to validate the performance improvement by comparison between the two methods. From the assessment, it clearly shows that, the suggested ANFIS D controller provides better performance including overshoot, undershoot, peak to peak ripple and steady state error the reduction and hence improving the speed control technique of separately excited DC motor.**

Keywords— Speed Control, DC Motor, ANFIS D controller, Derivative controller.

I. INTRODUCTION

The conversion of energy is done by electrical machines which are of different types. DC motor is a kind of electrical machine that takes electrical input and converts it into mechanical energy. Electric motors are mainly categorized into two types: direct current (DC) and alternating current (AC) motors. DC motors are utilized in thousands of regular devices used by in our daily life [1]. A DC motor as the name indicates is a motor initiated usually by direct current and is converted into mechanical energy according to the requirement. DC motors are ruling the world due to their extensive use in modern technologies and in almost every industry such as to operate steel rolling mills, electric screw drivers, sewing machines, hard disk drives, air compressors, reciprocating machine etc.[2]. Due to wide range of application, the speed control of DC motor is very important. The speed of DC motor stands various unexpected events such as overshoot, undershoot, peak to peak ripple, steady state error, delay in rise time and settling time, which need to be settled down for which controllers are used. The controllers can be proportional, proportional-integral (PI), proportional derivative (PD), proportional integral derivative (PID), artificial neural network based, Fuzzy Logic based, ANFIS based or any combination of these [3].

Many advancement has been done in Fuzzy PID as well as Fuzzy PI controller which provides better speed performance to the DC motor with more complex design pattern. Fuzzy D controller provides better performance to prevent the overshoot, undershoot, preshoot, ripple and steady state to a considerable amount [3]. In this paper, the FZ-D controller performance has been modified using ANFIS scheme, which enhances its performance over FZ-D controller in the case of overshoot, undershoot, steady state error and peak to peak ripple voltage. ANFIS is the combination of fuzzy logic and neural network. Neural network is supervised learning algorithms which uses a prior experience dataset for predicting future values. In fuzzy logic, the speed control signal of DC motor is generated from the rule base. This rule base is drawn on past experience data which is random. This means that controller's output is also random which may prevent optimal result. But if we use ANFIS, it can make the selection of the rule base more adaptive to the load condition on DC motor[4]. Thus a more robust speed controlling technique of DC motor is proposed in this paper.

II. METHODOLOGY

In this paper, we evaluated the improved method of speed control of a separately excited DC motor by making use of the ANFIS scheme in derivative type controller. This improvement has been ensured by the reduction in rise time, settling time and steady state error provided by the proposed controller. For the evaluation process, we used a step input as the dc input to a motor. We chose error speed and derivative of error speed as the input of ANFIS controller which are multiplexed to provide the input and the output of the controller is a voltage. The output voltage of the controller is added or subtracted to the error voltage depending on the polarity of output voltage of ANFIS controller, which is then applied to the plant. This is done to keep the control variable i.e. speed at a constant value. The same thing is done for Fuzzy logic controller except the fact that controller is provided with Mamdani type Fuzzy inference system with rules while Sugeno type inference system is used for ANFIS controller with training data. The whole process is presented in Fig 1.

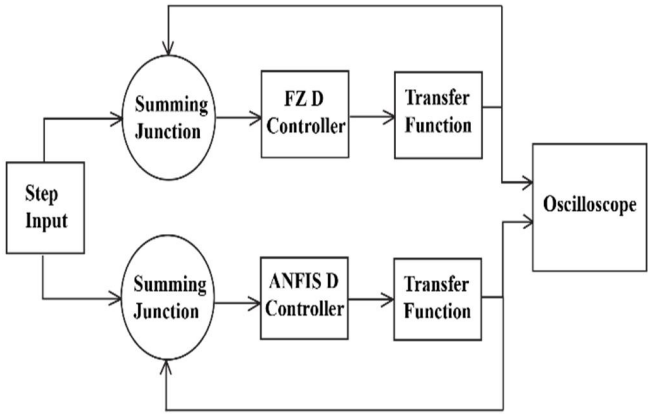

Fig 1. A block diagram employing FZ D and ANFIS D controller.

III. MATHEMATICAL MODELLING

A.Plant Model

DC motor stands a popular actuator in control system engineering. It provides rotational displacement in the direction prescribed by Fleming's left-hand rule and also the translational motion combined with wheels to deliver speed as a mechanical output. Fig 2 represents the equivalent circuit of a DC motor.

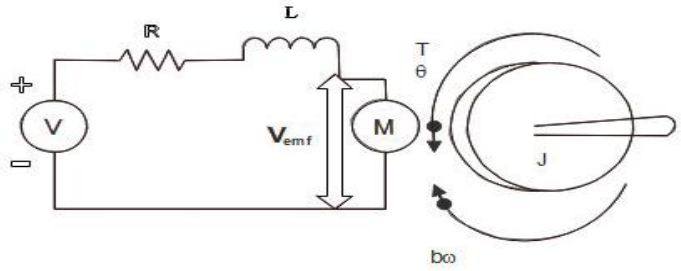

Fig 2. Equivalent circuit of DC motor

Here, V, R and L denotes source voltage (V), electrical resistance(Ω) and inductance(H) of armature circuit and J, b, T,θ, ω, i, V_{emf} denotes moment of inertia of the rotor (kgm), viscous friction coefficient (Nms/rad), motor torque (Nm), angular displacement (rad), output rotating speed (rad/s), armature current (A) and back emf (V) respectively. The mathematical expression of back emf and torque is provided via (1) and (2) respectively.

$$V_{emf}=K_e\omega \quad (1)$$

$$T=K_tI \quad (2)$$

Here, K_e and K_t denotes motor constant armature constant which are essentially equal in SI unit. Equation (1) points out that the back emf is proportional to the output rotating speed and (2) implies that the motor torque is proportional to the armature current. By Newton's law and Kirchhoff's law we obtain (3) and (4).

$$J\frac{d^2\theta}{dt^2}+b\frac{d\theta}{dt}=KI \quad (3)$$

$$L\frac{di}{dt}+Ri=V-K\frac{d\theta}{dt} \quad (4)$$

Here, K indicates electromotive force constant (Nm/A). Using Laplace transform on (3) and (4), (5) and (6) are achieved, and from (5) and (6) the transfer function of the DC motor is presented in (7) is being calculated. Lastly, to obtain its transfer function the value of system parameters of a DC motor is made use of.

$$Js^2\theta(s)+bs\theta(s)=KI(s) \quad (5)$$

$$LsI(s)+RI(s)=V(s)-Ks\theta(s) \quad (6)$$

$$G(s)=\frac{\theta(s)}{V(s)}=\frac{K}{(Ls+R)(Js+b)+K^2} \quad (7)$$

To ensure proper acclimatization of the controlled variable feedback is inveterately fed from the output. To avoid complexity, voltage mode unity feedback control loop is preferred to others.

The DC motor with the parameter is listed below in the table I [1].

TABLE I. VALUES OF DC MOTOR PARAMETERS

Parameter	Value
Armature resistance, R	11.2 Ω
Armature Inductance, L	0.1215H
Rotor inertia, J	0.02215 kgm
Viscous friction coefficient, b	0.002953Nms/rad
Torque constant, K_t	1.28 Nm/A
Back emf constant, K_b	1.28s/rad

B.D Controller Design

The PID is constituted with three different parameters connected in parallel namely the proportional, the integral, and the derivative. The proportional parameter is employed to meliorate the amendatory expedient to the coexisting error of a stable system but it fails to control an unstable system, and steady-state error takes place for the gain stands unchanged for varying frequencies. The integral parameter depreciates the steady state error to zero by constellating the former errors but fails in the regard for loop stability adding a pole at the origin. The derivative parameter presages the coming error and reacts akin to diminish it but fails to deal with constant errors. For a PID controller a weighting mechanism is handy to condition the outcome of the parameters. Equation (8) points the mathematical formula for designing a PID controller [3].

$$U(s)=[K_p+sK_d+\frac{K_i}{s}]E(s) \quad (8)$$

Here, U(S), K_p, K_d, K_i and E(S) denotes controlled variable, proportional gain, derivative gain, integral gain and error value respectively. The error value shows the deviation of the desired input from the actual output.

For a D controller, the equation would be,

$$U(s)=[sK_d]E(s) \quad (9)$$

Basing on rise time, preshoot, overshoot, undershoot, peak to peak ripple, and steady-state error the system performance is being assessed. The controllers can function solo or in conjunction with others. Should the count of parameters in a controller exceeds one, they are linked in parallel.

C.Fuzzy Logic Controller Design

Fuzzy logic allows the inclusion of partial truth to modify two valued logic which then becomes a modification to classical control theory that is more robust and immense [5]. It outreaches the binary logic incorporating the human ideology. It accounts all feasible values encompassing and within "yes" and "no". The fuzzy system consists of four main components;

fuzzification module, knowledge base, inference engine, and defuzzification module. Data is injected into the fuzzification module, and fuzzy sets are formed. In the knowledge base section required rules are put employing "If-Then" rules in general. Inference engine operates on data from fuzzification module based on the depiction of rules. Lastly, defuzzification module appropriates the fuzzy sets to traditional or crisp set.

To design the proposed FZ-D controller, "Fuzzy Logic Controller" block from MATLAB/Simulink is made use of. Input variables "Error" and "ChangeError", along with one output variable "Voltage", are defined through three suitable membership functions each. Utilizing Fuzzy Inference System (FIS) editor in MATLAB/Simulink the design procedure of the fuzzy logic controller, the definition of input and output variables, along the setup of the fuzzy operator, fuzzification module, inference engine, and defuzzification module are executed. The default Mamdani inference and aggregation method is used. A graphic view of the FIS editor.

Every input and output variable defined has seven membership functions; "BN", "MN", "SN", "Zero", "SP", "MP" and "BP". The befitting confines of the variables and apt parameters for the membership functions are picked. Values of the range and the parameters. We defined forty-nine rules making use of If-Then format to design the fuzzy logic controller. The input variables and the entire fuzzy set are respectively the input and output of the rule. Using Rule viewer, we displayed a road map of the fuzzy inference process.

D.ANFIS Controller Design

ANN provides strong learning capabilities by numerical training data while Fuzzy based system ensures better interpretation with the integration of expert level knowledge. The hybridization of these two, is assumed to include advantages of both of the systems. Hence ANFIS scheme comes as a new tool [2]. To improve its performance, the properties of fuzzy logic is tied in this ANFIS technique, by approximating a non-linear system through setting IF-THEN rules [4]. Using a given input/output data set, ANFIS establishes a Fuzzy Inference System (FIS), where the membership function for input and output are adjusted by a back-propagation algorithm or its combination with a least square method called the hybrid method [7, 8].

The ANFIS Editor Graphical User Interface of *MATLAB* window has four areas to support training-

- Load, Plot and Clear the Data
- Generate or Load the Initial FIS Structure
- Train the Fuzzy Inference System
- Validate the Trained Fuzzy Inference System [6]

In the proposed method, we took seven membership function for the two inputs "E" and "CE" which denotes speed error and change of speed error respectively. We chose Gaussian type membership function for the two inputs and there are 7 membership function in each of the inputs which forms 49 conditions for output combining the membership function of the two inputs. The membership function for the two inputs are shown in Fig 3 and Fig 4.

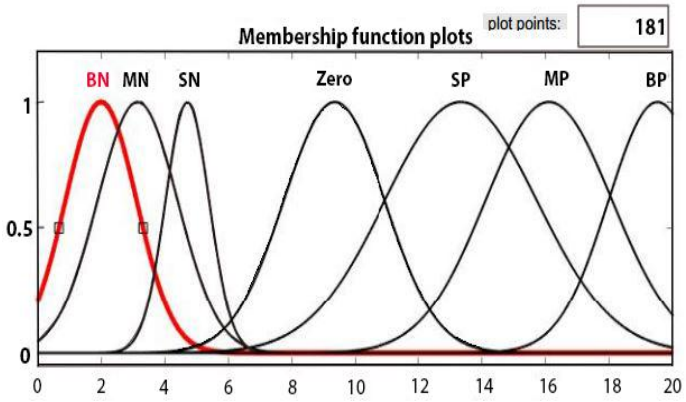

Fig 3. Membership functions of input "E"

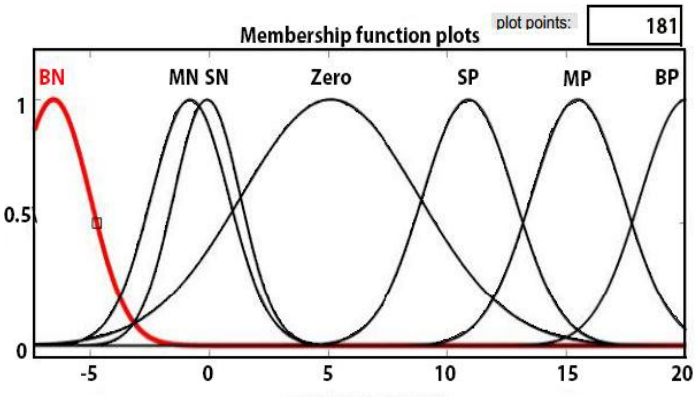

Fig 4. Membership functions of input "CE"

As the Fuzzy Inference system is Sugeno type, the output of each if-then rule a constant which is shown in Fig 5.

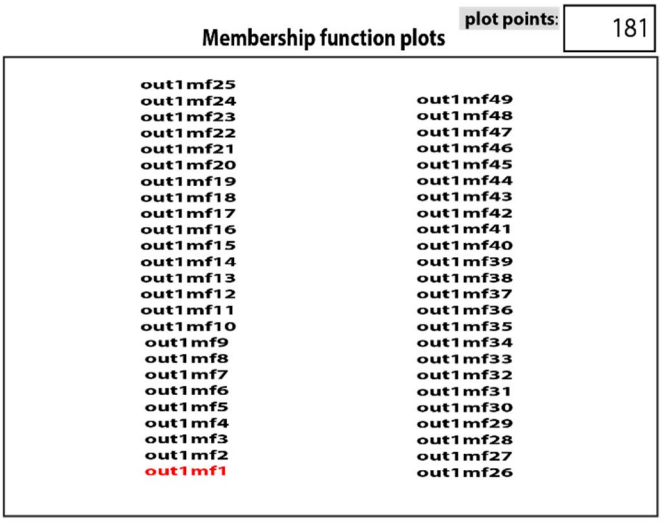

Fig 5. Membership functions of output.

In ANFIS, appropriate training data for inputs and outputs are provided which trains the ANFIS controller to perform in desired manner.

According to the input and output training data, the rules for ANFIS controller is created from the training. The rule base for training data is shown in table II.

TABLE II. RULES FOR ADAPTIVE NEURO FUZZY BASED D CONTROLLER

CE / E	BN	MN	NS	Zero	PS	PM	PB
BN	BN	BN	BN	BN	MN	SN	Zero
MN	BN	BN	BN	MN	SN	Zero	SP
SN	BN	BN	MN	SN	Zero	SP	MP
Zero	BN	MN	SN	Zero	SP	MP	BP
SP	MN	SN	Zero	SP	MP	BP	BP
MP	SN	Zero	SP	MP	BP	BP	BP
BP	Zero	SP	MP	BP	BP	BP	BP

The abbreviations for the membership function stand for

1) BN = Big Negative
2) MN = Medium Negative
3) SN = Small Negative
4) Zero
5) SP = Small Positive
6) MP = Medium Positive
7) BP = Big Positive

IV. SIMULATION

In this section, we evaluated the performance of FZ-D controller and ANFIS-D controller to ascertain the comparative study and performance improvement regarding the rise time, settling time, overshoot and steady state error. A step input is provided to the system which is eventually fed to the D-controller for both Fuzzy and ANFIS. The output of the controller is combined with the error signal to provide an input to dc motor which substantially performs the control mechanism. Thus the speed of DC motor is controlled. The schematics for the proposed speed control mechanism of DC motor is shown in Fig 6.

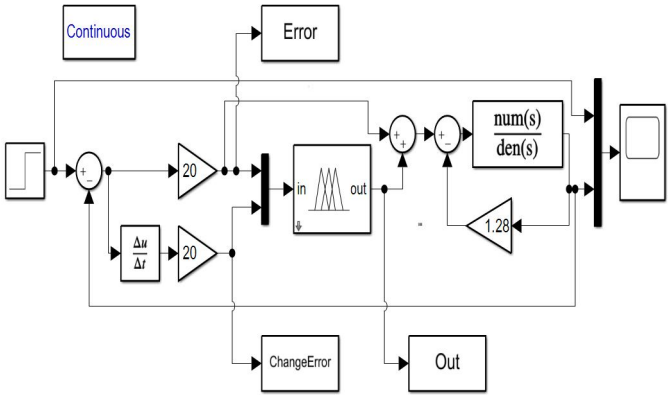

Fig 6. Schematics of speed control of DC motor using FZ D controller.

We have evaluated the performance characteristics for FZ-D controller which is shown in Fig 7.

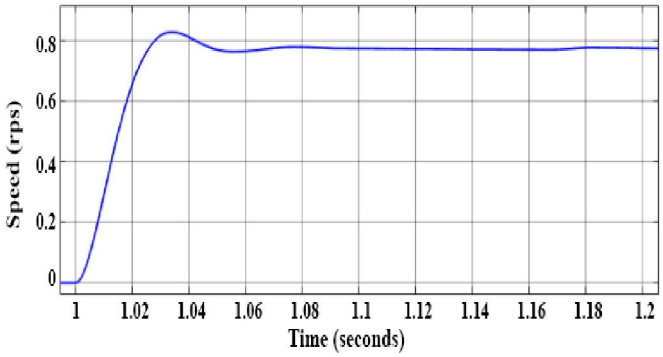

Fig 7. Speed of DC motor for FZ-D controller.

From the data, we have found the that the rise time, preshoot, overshoot, undershoot, peak to peak ripple and steady state error are 17.080ms, 0.513%, 6.989%, 1.972%, 8.273e-01 and 0.463% respectively.

We did similar work for ANFIS-D controller which is shown in Fig 8 to visualize the improvement of performance which is shown in Fig 9.

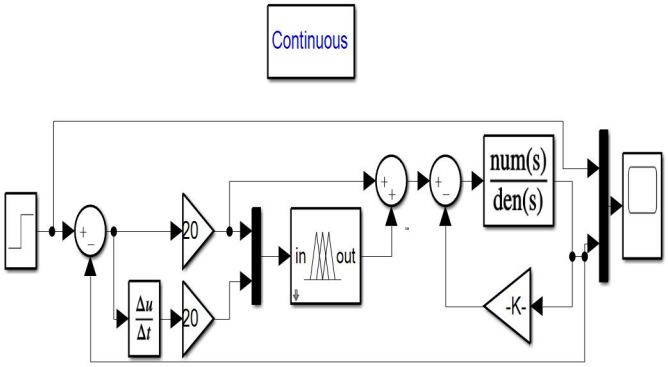

Fig 8. Schematics of speed control of DC motor using ANFIS D controller.

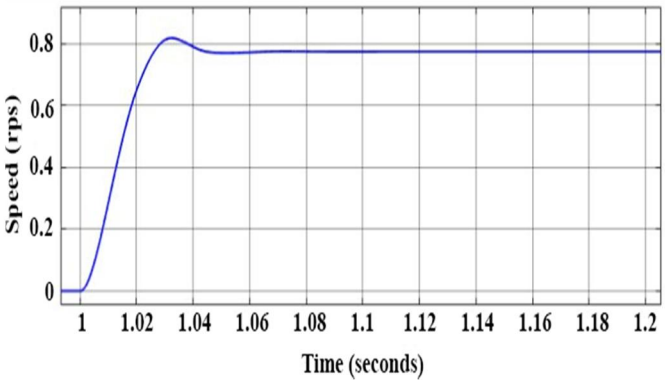

Fig 9. Speed of DC motor for ANFIS D controller.

The rise time, preshoot, overshoot, undershoot and peak to peak ripple and steady state error found in this case are 17.269ms, 0.532%, 5.851%, 1.926%, 8.183e-01 and 0.402% respectively.

V. Outcomes

The result obtained from the simulation has been tabulated in table III. From the comparative evaluation between the data obtained from FZ-D controller and ANFIS-D controller, we demonstrated that, the overshoot, undershoot, peak to peak ripple and steady state error has been reduced in case of ANFIS-D controller that ascertains its better performance compared to FZ-D controller. The negligible increase of rise time and preshoot in ANFIS-D controller has been compensated by its capability to reduce other demerits to a considerable amount.

TABLE III. Speed Controlling Performances of Different Controllers

Controller	FZ-D	ANFIS-D
Rise time	17.080ms	17.269ms
Preshoot	0.513%	0.532%
Overshoot	6.989%	5.851%
Undershoot	1.972%	1.926%
Steady State Error	0.463%	0.402%
Peak to Peak Ripple	8.273e-01	8.183e-01

VI. Conclusion

The main target of this paper is to ensure efficient speed control mechanism for DC motor which suffers from certain unwanted phenomenon. To serve this purpose, FZ-D controller has been modified by ANFIS scheme which has managed to improve its performance in manifold ways. The proposed ANFIS-D controller has caused the increase of rise time and preshoot to a small extent. In spite of these drawbacks, the proposed ANFIS-D controller has managed to reduce the overshoot, undershoot, peak to peak ripple and steady state error successfully and thus it serves the purpose of the proposed method discussed in this paper.

***Abstract* — In this paper, a new design of bridgeless single phase AC-DC buck boost converter has been proposed to enhance the overall performance of AC-DC converter. Use of single switch and bridgeless topology makes the proposed converter a suitable choice than other conventional AC-DC converters. The conventional AC-DC converters with bridge configuration supply a pulsating ripple signal to the input of the converter circuit which creates lots of disturbance in the overall power system. Due to absence of bridge rectifier such problems do not arise in the proposed converter and it has also reduced using high value filtering element in the input side. Comparisons are shown between proposed and conventional converters. Comparison analysis makes it clear that proposed AC-DC converter performed better than conventional converters. The circuit performances were observed based on software circuit simulation using PSIM 9.1.1.400 professional environments.**

Keywords— AC-DC Buck Boost Converter, Bridgeless Topology, THD, PFC

I. INTRODUCTION

The power quality of the AC system is a vital importance due to the increasing number of newly designed AC-DC converters. Conventional single phase AC-DC converters having full wave rectifiers in bridge configuration always suffer from high total harmonic distortion in the input current and low input power factor. Large input filter like inductor and capacitor can improve THD but power factor still remains low and practical feasibility of such converters is too poor [1, 2]. This problem can be solved by using switch mode regulators. Lots of research works have been done to improve these drawbacks. All techniques are targeting to achieve more precise results [3-7]. Researchers are using different method to improve overall power quality of AC-DC converter. All new methods are providing some advantages than the existing methods [8-11]. Newer research works are going in this field to bring new techniques too. One of the techniques is active PFC [12].

Active filtering requires smaller sized filter than passive filtering, but a DC-DC converter is required after it. The DC-DC converters use unidirectional switch for the switching purpose [13]. In conventional AC-DC converter the bridge rectifier converts AC to uncontrolled DC and the DC-DC converter provides controlled and regulated DC output [14].

In this paper a new design of bridgeless buck boost converter is proposed with high performance. Section II of the papers are discussed about principle of operation of the proposed converter, in section III deals with all the simulation result of the proposed converter circuit. The proposed circuit is advantageous for two reasons. The first is the use of a single switch composed of a unidirectional switch and proper positioning of diodes. The second is the input current switching. The second technique confirms high constant frequency switching of input AC which is almost in phase with input AC voltage without using any feedback control scheme [15-18]. This technique provides smooth input current by using a small filter. It would also results improved power factor with high efficiency.

II. PRINCIPLE OF OPERATION

Fig. 1 below depicts the circuit configuration of a conventional AC-DC buck boost converter.

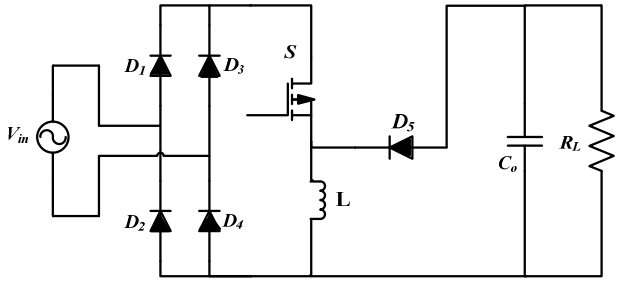

Fig. 1 Conventional AC-DC Buck Boost Converter

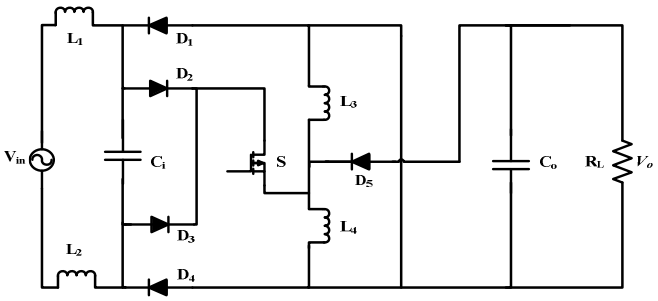

Fig. 2 Proposed Converter Circuit

In conventional buck boost AC-DC converter input resistance of inductor has sudden variety of input current. In the event that the switch S is ON, the inductor takes the energy from the input and it stored the energy of magnetic energy. When switch S is close it releases the energy. The capacitor of the output circuit is accepted as high adequate than the time constant of a RC circuit is high on the output. Primarily inductor L_1 is working as a source of current.

The circuit diagram of the proposed AC-DC converter is given in Fig. 1. This converter has thirteen components; five diodes (D_1, D_2, D_3, D_4 & D_5), two capacitors (C_i & C_o), four inductors (L_1, L_2, L_3 & L_4), one switch S and one load resistor R_L. The supply is given by AC input voltage and

from there can get DC output voltage. The proposed AC-DC buck boost converter can be operated in two conditions–

(i) Continuous conduction mode (CCM)
(ii) Discontinuous conduction mode (DCM)

Switch ON mode for positive half cycle:

When switch S is turned ON for positive half cycle, diode D_1, D_3 & D_5 are turned OFF, because of reverse biased and diode D_2 & D_4 are turned ON due to forward biased condition. In the positive half cycle, the flow of current creates a loop shows in Fig. 2(a).

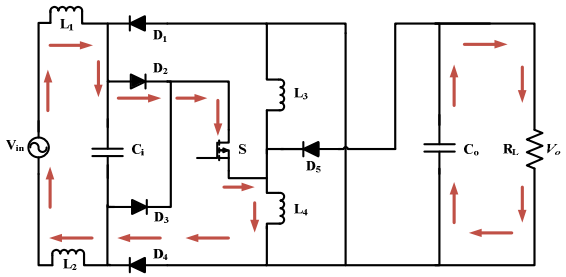

Fig. 2(a) Switch ON Mode (positive half cycle)

In this loop, the AC source V_{in} flows through the diode L_1, D_2 & switch S; connected with the circuit and the inductors L_3, diode D_4 & inductor L_2 for the time duration DT, also current flows to output capacitor C_o & load resistor R_L; from there can get output.

Switch OFF mode for positive half cycle:

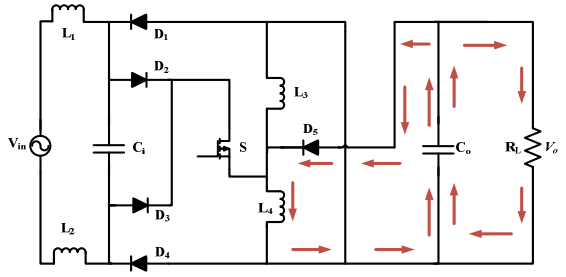

Fig. 2(b) Switch OFF Mode (positive half cycle)

When switch S is turned OFF for positive half cycle, diode D_1, D_2, D_3 & D_4 are turned OFF because of reverse biased. Inductor L_4 released the energy & inductor L_4, output capacitor C_o & diode D_5creates a loop, also current flows to output capacitor C_o & load resistor R_L for the time duration (1-D)T which shows in Fig. 2(b).

Switch ON mode for negative half cycle:

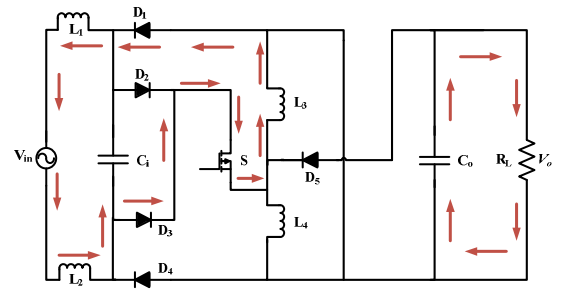

Fig. 2(c) Switch ON Mode (negative half cycle)

When switch S is turned ON in Fig. 2(c) for negative half cycle, diode D_4 & D_5 are turned OFF because of reverse biased and diodeD_1, D_2 & D_4 are turned ON due to forward biased. In the negative half cycle, the flow of current creates a loop. In this loop, the AC source V_{in} flows through the inductor L_2, diode D_3 & switch S; connected with the circuit and the inductor L_3 diode D_1 & inductor L_1 for the time duration DT, also current flows to output capacitor C_o and load resistor R_L; can get output value.

Switch OFF mode for negative half cycle:

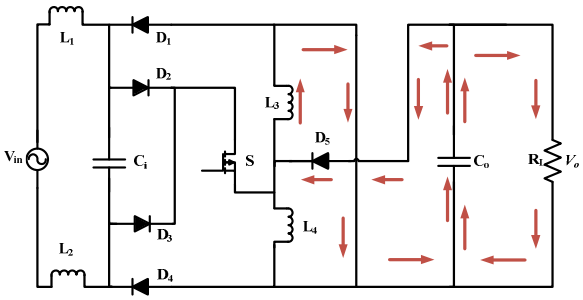

Fig. 2(d) Switch OFF Mode (negative half cycle)

When switch S is turned OFF for negative half cycle, diode D_1, D_2, D_3 & D_4 are turned OFF, because of reverse biased. During this time, Inductor L_3 realized the energy and inductor L_3, output capacitor C_o & diode D_5 creates a loop, also current flows to output capacitor C_o & load resistor R_L; shown in Fig. 2(d).

III. Simulation and Result

The simulation of the two conventional and proposed converter were performed using PSIM 9.1.1 professional version environment and also with Matlab simulink.

A. Values of elements of proposed and conventional circuits:

Simulation results for the proposed and conventional converters are given below to justify the practicability of the proposed circuit. Following values have been used for both of the proposed and conventional converters are given below in Table I.

Table I
Values of the elements used both in proposed and conventional circuit

Parameter	Symbol	Value
Input voltage	V_{in}	220 V, 50 Hz
Switching frequency	F_s	5 kHz
Inductor	L_1 , L_2	9 mH
Inductor	L_3 , L_4	1.5 mH
Capacitor	C_i	5 µF
Capacitor	C_o	220 µF
Load resistor	R_L	10 Ω

B. Open Loop Simulation Result:

For circuit simulation we used PSIM Professional Version 9.1.1.400. After drawing the circuit we used volt probe and current probe both in input and output circuit to view the input and output waveform. Then we set the simulation duration for 0.5 sec and ran it. We observed input voltage versus current and output voltage versus current waveform. PSIM software automatically calculates the power factor and power for voltage versus current both in input and output side. Simulation results of the proposed and conventional circuit in open loop operation are given in Table II.

Table II
Performance Analysis of Proposed and Conventional CUK Converter under Power Factor and Efficiency

Duty Cycle	Conventional AC-DC Buck Boost Converter		Proposed AC-DC Buck Boost Converter	
	Power Factor	Efficiency (%)	Power Factor	Efficiency (%)
0.1	0.29	80.51	0.67	94.57
0.2	0.40	91.11	0.90	98.50
0.3	0.49	95.19	0.96	99.18
0.4	0.58	97.28	0.96	99.22
0.5	0.66	98.41	0.87	98.95
0.6	0.74	98.95	0.73	98.48
0.7	0.74	99.01	0.50	97.42
0.8	0.80	98.78	0.25	94.95
0.9	0.85	96.93	0.09	85.96

Comparison analysis for the power factor and efficiency of the proposed and conventional circuit is given by the bar diagram in Fig. 3 and Fig. 4 respectively whereas Fig.5 shows the THD comparison. From graphical comparison it is visible that proposed circuit is showing better performance in all parameters in duty cycle variation. The conventional and proposed AC-DC converters are not performing well in extremely high and low duty cycle due to non-ideal characteristics MOSFET switch.

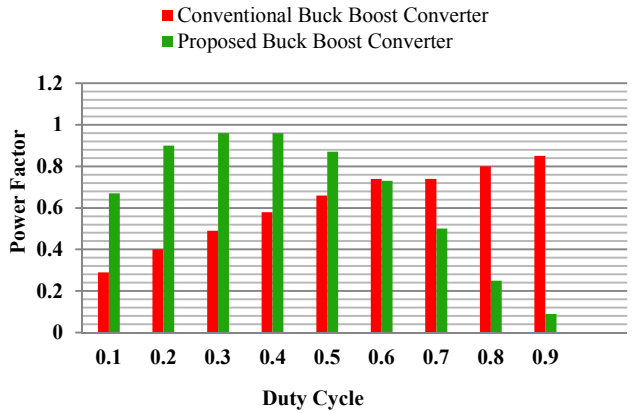

Fig. 3 Comparison of the Performance of Power Factor between Conventional and Proposed Converter with Duty Cycle Variation

Moreover, Table III shows the comparative analysis of the AC-DC buck converter for THD under duty cycle variation.

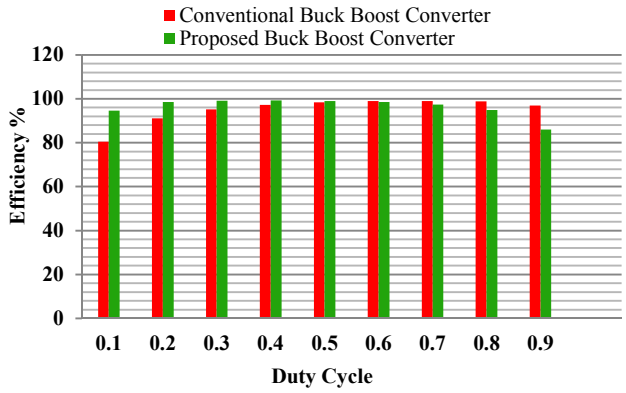

Fig. 4 Comparison of the Performance of Efficiency between Conventional and Proposed Converters with Duty Cycle

Both proposed and conventional AC-DC buck boost converters kept fixed at 5 kHz for switching frequency and the load variation is fixed at 10 Ω throughout the duty cycle 0.1 to 0.9. It is clear from the bar diagram of Fig. 4 that the efficiency of the proposed AC-DC buck boost converter is much better for maximum the range of efficiency than conventional AC-DC buck boost converter.

Table III
Performance analysis of proposed and conventional cuk converter under duty cycle and THD

Duty Cycle	THD	
	Conventional AC-DC Buck Boost Converter	Proposed AC-DC Buck Boost Converter
0.1	0.29	0.22
0.2	2.20	0.32
0.3	1.70	0.28
0.4	1.38	0.18
0.5	1.11	0.06
0.6	0.89	0.04
0.7	0.72	0.02
0.8	0.70	0.009
0.9	0.61	0.007

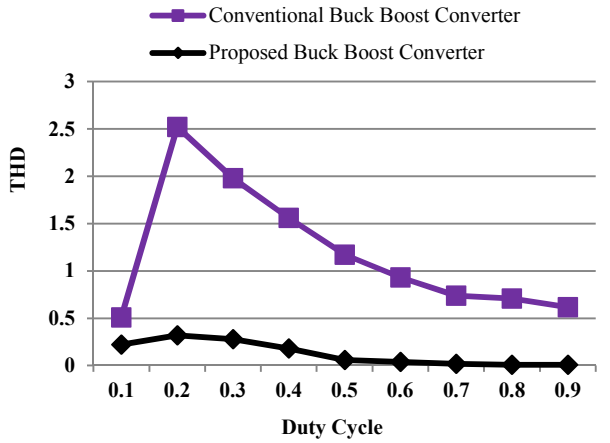

Fig. 5 THD comparison of Conventional and Proposed AC-DC Buck Boost Converters, throughout the Duty Cycle of 0.1 to 0.9

Furthermore, Fig. 6 shows the input current and voltage waveform of the proposed AC-DC buck boost converter, it is clear from the given wave diagram that the input voltage and current are not having any phase difference that means the power factor is almost unity at 40 to 50 percent of duty cycle variation which is mentioned in comparison Table II.

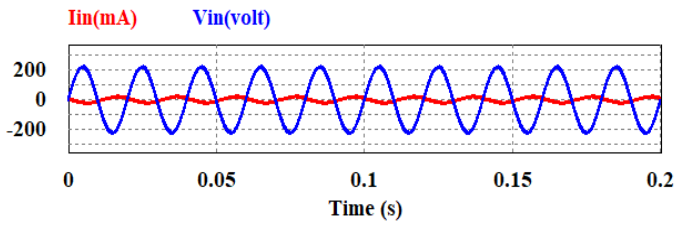

Fig. 6 Input Current and Voltage Waveform of Proposed AC-DC Converter

In the wave diagram the blue wave is representing the input voltage where the rms value of the voltage is 155 V whereas the red one is representing the input current holding the rms value of 14 mA.

IV. CONCLUSION

The proposed circuit significantly improves the performance of all parameter. It is evident from the performance analysis the proposed buck boost Converter without feedback controller scheme outperforms all the other converter circuits based on the individual simulation results and achieves superior power quality not only in terms of power factor and efficiency, but also the input current THD value has been brought to 0.02 which is within IEEE prescribed limit. The proposed Buck Boost converter circuit offer 99% conversion efficiency Thus, this converter circuit holds promise for future which can be practically realized through hardware implementations.

***Abstract*—This paper presents a new 36-pulse star connected diode rectifier. It takes intimate sinusoidal currents from utility with the elimination of lower than 35th order harmonics. The proposed rectifier consists of a parallel four-star 12-pulse diode rectifier and two passive injection circuits at DC links. This passive injection circuit can triple the number of pulses of parallel four-star 12 pulse rectifier system. The primary side of specially tapped interphase transformer (STIT) with two diodes constitutes the first injection circuit while the secondary winding of the STIT with a single phase full-wave rectifier (SPFR) constitutes the second passive injection circuit. This rectifier is compatible for large current rating application such as electroplating, plasma torches, dc arc furnaces etc. The simplicity of the proposed rectifier scheme makes it more economical compared to other existing designs of same performance. The proposed rectifier is analyzed and simulated in MATLAB environment. The simulation result presented in this paper confirms the IEEE-519 standards requirements at varying loads.**

Keywords—specially tapped interphase transformer (STIT), single phase full-wave rectifier (SPFR), total harmonic distortion (THD), passive injection circuit.

I. INTRODUCTION

Star rectifier is used for low voltage and high current applications that require minimum voltage drop due to source impedance, leakage reactance, source impedance and devices used in the path of load current. The star rectifiers have one device in the path of load current and preferred in large current rating applications such as induction heating, electrochemical processes, plasma torches, dc arc furnaces etc [1]. Unfortunately, rectifier affects the power quality by injecting harmonics into AC mains and can not meet IEEE-519 standard requirements [2]. Harmonics increase error of the measuring instruments, increase the losses, disrupt control systems, affect the torque of the motors, interfere with communication systems, degrade the operating characteristics of the protective devices and may cause undesirable resonances. To minimize the unwanted effects of harmonic distortion, IEEE Std. 519-1992 suggests that an individual harmonic distortion of voltage to be less than 3% of the fundamental component and the total harmonic distortion (THD) to be less than 5% of the fundamental component.

Passive filters and active filters have been used in the rectifiers to reduce the input line current harmonics [3]-[4]. But passive filter is bulky and susceptible to load switching transients while active filter suffers from complexity and high cost. Multi-pulse rectifiers are reliable for input line current harmonics mitigation. 12-pulse, 18-pulse and 24-pulse star rectifiers can not meet the IEEE-519 standard requirements [5]. More than 24-pulse rectifiers are required to meet the IEEE-519 standard requirements [6]-[7]. But these rectifiers require complex phase shifting transformer and increase complexity. In [8]-[9], active injection techniques have been proposed for rectifier. Active injection technique can reduce the input line current harmonic but it can not improve the output power quality.

One way of reducing the input line current harmonics and increasing the pulse number of the rectifier simultaneously without increasing significant complexity of the rectifier circuit is through the use of passive injection technique at the DC link [10]-[12]. In [10], pulse tripling technique has been proposed for parallel 12-pulse diode bridge rectifier and it can meet the IEEE-519 standard requirements. In [11], pulse doubling technique has been proposed for parallel four-star 12-pulse diode rectifier but it fails to meet the IEEE-519 standard requirements. In [12], a passive harmonic reduction method has been proposed for the double-star 6-pulse diode rectifier which fails to meet the IEEE-519 standard requirements.

This paper presents a new 36-pulse star connected diode rectifier that is based on the passive injection technique at DC link. In the proposed rectifier, STIT and its auxiliary circuits constitute the two passive injection circuits. When tap position and turns ratio of the STIT is designed optimally, the proposed rectifier operates as a 36-pulse rectifier. It eliminates 5th, 7th, 11th, 13th, 17th, 19th, 23rd, 24th, 29th and 31th order harmonics from utility line currents**.** After using passive injection circuits, THD of input line current is about 4.82%.

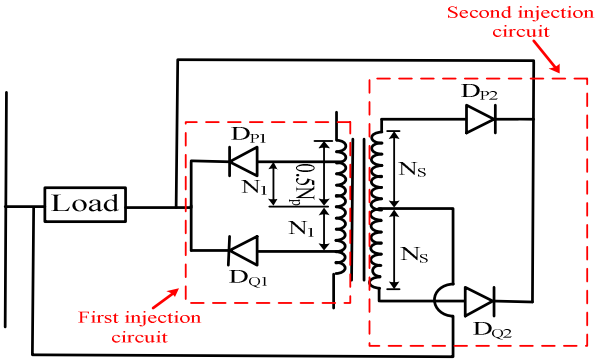

Fig. 1: Passive injection circuit.

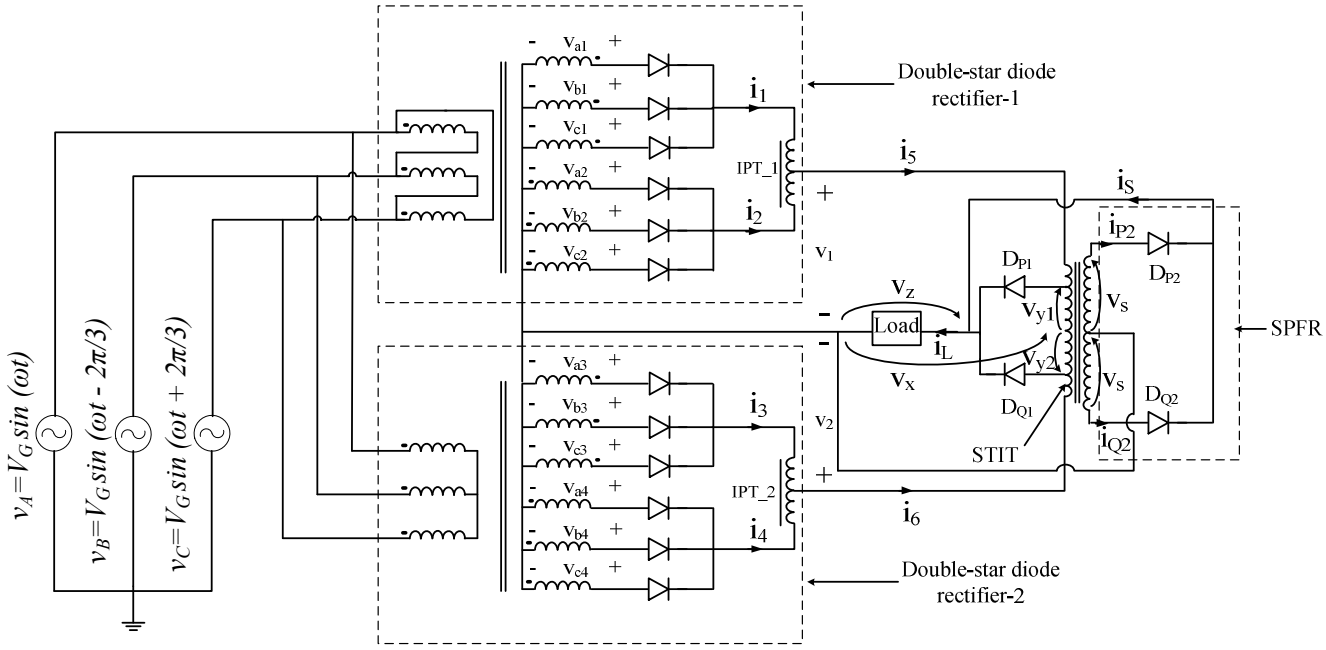

Fig. 2: Proposed 36-pulse star rectifier

II. Proposed 36-Pulse Scheme

A. Circuit Configuration

Fig. 2 shows the proposed 36-pulse uncontrolled star rectifier. It is similar to the conventional parallel four-star 12-pulse rectifier with the addition of two passive injection circuits at dc link. The proposed rectifier configuration uses delta-wye-wye and wye-wye-wye connected transformer for phase shifting from three-phase source to feed four three-phase star rectifier. The primary winding of the STIT and two diodes D_{P1} and D_{Q1} constitute the first injection circuit which is shown in Fig. 1. The primary winding of the STIT has two tap which are connected to the load through diodes D_{P1} and D_{Q1}. Taps on the primary winding of STIT are chosen such position that proposed rectifier produces asymmetrical 24-pulse output voltage across the load without second passive injection circuit which is shown in Fig. 4(d). The center-tapped secondary winding of the STIT with two diodes D_{P2} and D_{Q2} constitute the SPFR which is the second passive injection circuit. Output terminals of the SPFR are connected in parallel to the load such that the harmonic power drawn is being fed back to load thus improving the energy conversion efficiency. This second passive injection circuit extends asymmetrical 24-pulse operation to 36-pulse operation. Interphase transformers (IPT) are used in the proposed rectifier circuit to ensure the parallel operation of the star rectifier.

Following assumptions are taken into consideration.

N_p= Number of turns in primary winding of the STIT.

N_s=Number of turns in secondary winding of the STIT.

N_1=Number of turns between midpoint and tapped points of primary winding of the STIT.

m = Turns ratio = $\frac{N_s}{N_p}$

k = Tap ratio = $\frac{N_1}{N_p}$

t:1:1 = Turns ratio of the $\Delta - Y - Y$ transformer.

t: $\sqrt{3}$: $\sqrt{3}$ = Turns ratio of the $Y - Y - Y$ transformer.

B. Circuit Operation

Assume that load voltage is v_z, voltage across the primary winding of the STIT is v_m, voltage across the secondary winding is v_s and load current is i_L. According to relation among v_z, v_m and v_s, the proposed rectifier has four operation modes. Fig. 3 shows the operation modes of the proposed rectifier.

P1-Mode: Whenever $v_m > 0$ and $v_s < v_z$, the proposed rectifier operates under P1-mode which is shown in Fig. 3(a). In this mode diode D_{P1} is forward-biased and diode D_{Q1}, D_{P2} and D_{Q2} are reversed-biased. SPFR does not work and the output current i_{P2} and i_{Q2} are equal to zero. Double-star diode rectifier-1 and double-star diode rectifier-2 conduct and supply current i_5 and i_6 to the load respectively. Diode D_{P1} carries load current i_L. The MMF relationship of the STIT for the P1-mode is

$$i_5(0.5 - k)N_p = i_6(0.5 + k)N_p \quad (1)$$

Output current of the rectifier is

$$i_L = i_5 + i_6 \quad (2)$$

From (1) and (2), the output currents of two double-star rectifiers are obtained as

$$\begin{cases} i_5 = (0.5 + k)i_L \\ i_6 = (0.5 - k)i_L \end{cases} \quad (3)$$

Current of individual star rectifier is

$$\begin{cases} i_1 = i_2 = \frac{i_5}{2} \\ i_3 = i_4 = \frac{i_6}{2} \end{cases} \quad (4)$$

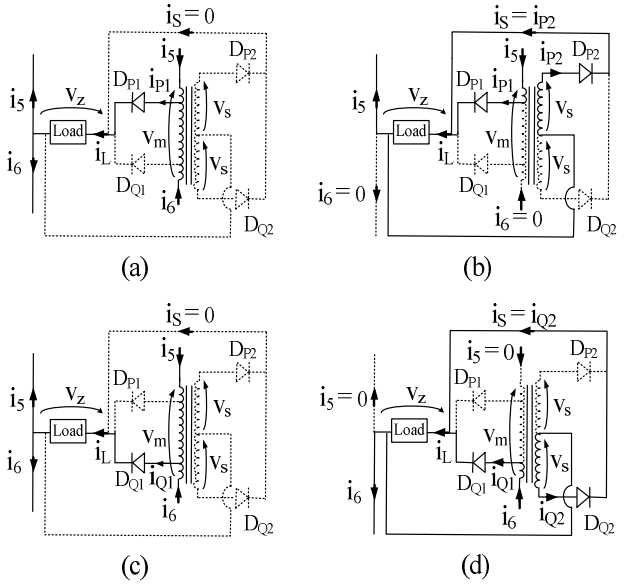

Fig. 3: (a) P1-mode (b) P2-mode (c) Q1-mode (d) Q2-mode.

P2- Mode: Whenever $v_m > 0$ and $v_s > v_z$, the proposed rectifier operates under P2-mode which is shown in Fig. 3(b). In this mode diode D_{P1} and D_{P2} are forward-biased and diode D_{Q1} and D_{Q2} are reversed-biased. SPFR works and current i_{P2} is injected to the load. The double-star diode rectifier-1 conducts and the double-star diode rectifier-2 does not conduct. Diode D_{P1} and D_{P2} carry load current i_L and relation among i_5, i_{P2}, i_S and i_L is

$$i_5 + i_{P2} = i_5 + i_S = i_L \tag{5}$$

The MMF relationship of the STIT for the P2-mode is

$$i_5\left(0.5N_p - kN_p\right) = i_{P2}N_s \tag{6}$$

From (5) and (6), the currents i_5, i_{P2}, and i_S are obtained as

$$\begin{cases} i_5 = \frac{m}{0.5-k+m} i_L \\ i_{P2} = i_S = \frac{0.5-k}{0.5-k+m} i_L \end{cases} \tag{7}$$

Current of individual star rectifier is

$$\begin{cases} i_1 = i_2 = \dfrac{i_5}{2} \\ i_3 = i_4 = 0 \end{cases} \tag{8}$$

Q1-Mode: Whenever $v_m < 0$ and $|- v_s| < v_z$, the proposed rectifier operated under Q1-mode which is shown in Fig. 3(c). In this mode diode D_{Q1} is forward-biased and diode D_{P1}, D_{P2} and D_{Q2} are reversed-biased. SPFR does not work and the output current i_{P2} and i_{Q2} are equal to zero. Double-star diode rectifier-1 and double-star diode rectifier-2 conduct and supply current i_5 and i_6 to the load respectively. Diode D_{Q1} carries load current i_L. The MMF relationship of the STIT for the Q1-mode is

$$i_5(0.5 + k)N_p = i_6(0.5 - k)N_p \tag{9}$$

Output current of the rectifier is

$$i_L = i_5 + i_6 \tag{10}$$

From (9) and (10), the output currents of the two double-star rectifier diode rectifiers are obtained as

$$\begin{cases} i_5 = (0.5 - k)i_L \\ i_6 = (0.5 + k)i_L \end{cases} \tag{11}$$

Current of individual star rectifier is

$$\begin{cases} i_1 = i_2 = \frac{i_5}{2} \\ i_3 = i_4 = \frac{i_6}{2} \end{cases} \tag{12}$$

Q2-Mode: Whenever $v_m < 0$ and $|- v_s| > v_z$, the proposed rectifier operates under Q2-mode which is shown in Fig. 3(d). In this mode diode D_{Q1} and D_{Q2} are forward-biased and diode D_{P1} and D_{P2} are reversed-biased. SPFR works and current i_{Q2} is injected to the load. The double-star diode rectifier-1 does not conduct and the double-star diode rectifier-2 conducts and supply current i_6 to the load. Diode D_{Q1} and D_{Q2} carry load current i_L and relation among i_6, i_{Q2}, i_S and i_L is

$$i_6 + i_{Q2} = i_6 + i_S = i_L \tag{13}$$

The MMF relationship of the STIT for the Q2-mode is

$$i_6\left(0.5N_p - kN_p\right) = i_{Q2}N_s \tag{14}$$

From (13) and (14), the currents i_6, i_{Q2} and i_S are obtained as

$$\begin{cases} i_6 = \frac{m}{0.5-k+m} i_L \\ i_{Q2} = i_S = \frac{0.5-k}{0.5-k+m} i_L \end{cases} \tag{15}$$

Current of individual star rectifier is

$$\begin{cases} i_1 = i_2 = 0 \\ i_3 = i_4 = \frac{i_6}{2} \end{cases} \tag{16}$$

III. Optimal Tap Ratio And Optimal Turns Ratio

A. Optimal Tap Ratio of the STIT

To find the optimal tap of the STIT, assume that second passive injection circuit is not connected to the proposed system and proposed rectifier produces asymmetrical 24-pulse output voltage across the load which is shown in Fig. 4(d). Consider that voltage across double-star rectifier-1 is v_1, voltage across double-star rectifier-2 is v_2, voltage across primary winding of STIT is v_m and variable voltage $\overrightarrow{V_y}$ is established between the taps point and the center point of the primary winding of the STIT. Variable voltage $\overrightarrow{V_x}$ is added to $\overrightarrow{V_y}$ and produces asymmetrical 24-pulses output voltage ($\overrightarrow{V_z}$). These voltage wave shapes are shown in the Fig. 4 and relations among them are

$$v_m = v_1 - v_2 \tag{17}$$

$$v_x = \frac{v_1 + v_2}{2} \tag{18}$$

$$v_y = v_{y1} = \frac{N_1}{N_p} v_m \text{ ,When diode } D_{P1} \text{ conducts} \tag{19}$$

$$v_z = v_{z1} = v_x + v_{y1}, \text{ When diode } D_{P1} \text{ conducts} \tag{20}$$

$$v_y = v_{y2} = -\frac{N_1}{N_p} v_m \text{ , When diode } D_{Q1} \text{ conducts} \tag{21}$$

$$v_z = v_{z2} = v_x + v_{y2}, \text{ When diode } D_{Q1} \text{ conducts} \tag{22}$$

$$\overrightarrow{V_z} = \overrightarrow{V_x} + \overrightarrow{V_y} \tag{23}$$

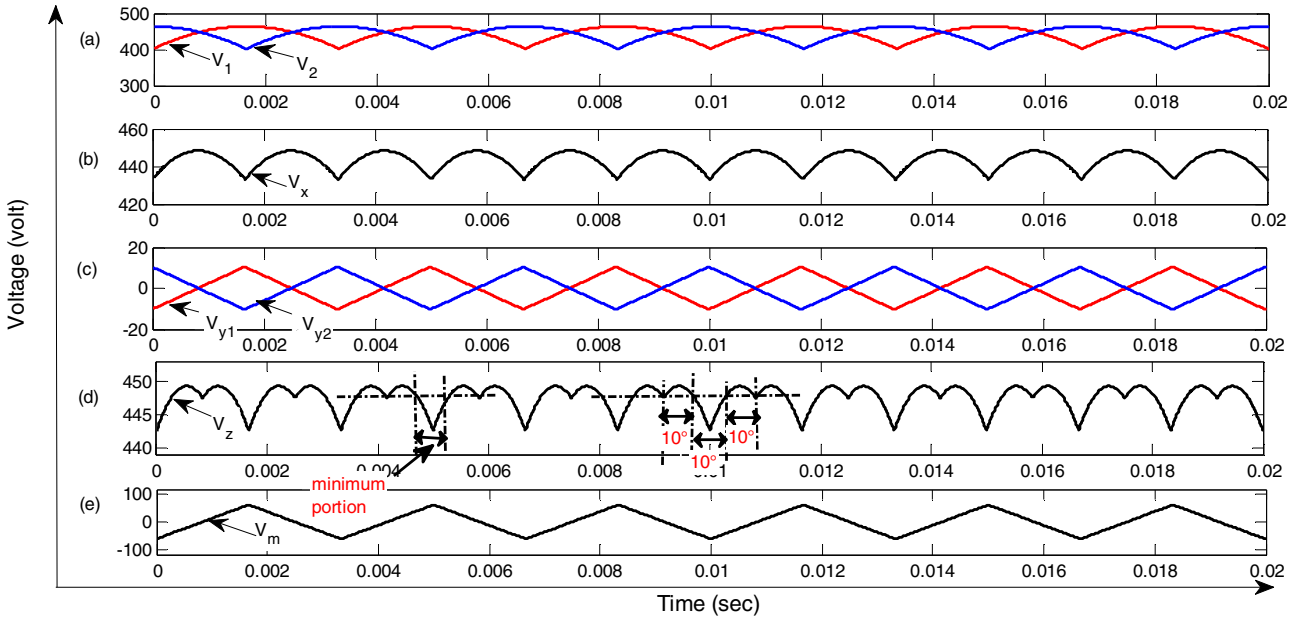

Fig. 4: Waveforms of (a) Output voltage of the rectifier-1 and rectifier-2 (b) Voltage v_x (c) Voltages v_{y1} and v_{y2} (d) Voltage v_z (e) Voltage v_m.

Tap ratio of the STIT is chosen such value that the output voltage v_z can be divided into 36 portions per power supply cycle and conduction period of each portion is 10° which is shown in the Fig. 4(d). The phasor diagram of Fig. 5 presents the relationship between voltage waveforms contained in Fig. 4. The following expression can be written from the Fig. 5.

$$\frac{N_1}{N_p} = \frac{V_y}{V_m} = \frac{V_1 cos\frac{\theta}{2}\, tan\frac{\theta}{6}}{2\, V_1\, sin\frac{\theta}{2}} \tag{24}$$

Output voltages of the two double-star 12-pulse rectifier are displaced by $30°$. Optimal tap ratio is obtained by substituting $\theta = 30°$ in (24).

$$k = \frac{N_1}{N_p} = 0.163 \tag{25}$$

B. Optimal Turns Ratio of the STIT

Output voltage of the double-star diode rectifier-1 and the double-star diode rectifier-2 without second passive injection circuit can be expressed as

$$v_1 = \frac{max(v_{a1}, v_{b1}, v_{c1}) + max(v_{a2}, v_{b2}, v_{c2})}{2} \tag{26}$$

$$v_2 = \frac{max(v_{a3}, v_{b3}, v_{c3}) + max(v_{a4}, v_{b4}, v_{c4})}{2} \tag{27}$$

Where v_{a1}, v_{b1}, v_{c1}, v_{a2}, v_{b2} and v_{c2} are the secondary side phase voltages of the $\Delta - Y - Y$ transformer and v_{a3}, v_{b3}, v_{c3}, v_{a4}, v_{b4}, v_{c4} are the secondary side phase voltages of the $Y - Y - Y$ transformer. The voltage across the load can be represent by the following expression

$$v_z = v_x + 0.163\,|v_m| \tag{28}$$

Expression of the voltages v_m and v_x are obtained by substituting (26) and (27) into (17) and (18). Expression of the voltages v_m and v_x are

$$v_m = \begin{cases} -\frac{3(\sqrt{6}-\sqrt{2})\,V_G}{4t}\, cos\left(\omega t + \frac{5\pi}{12}\right), & \omega t \,\epsilon \left[0, \frac{\pi}{6}\right] \\ \frac{3(\sqrt{6}-\sqrt{2})\,V_G}{4t}\, cos\left(\omega t + \frac{\pi}{4}\right), & \omega t \,\epsilon \left[\frac{\pi}{6}, \frac{\pi}{3}\right] \end{cases} \tag{29}$$

$$v_x = \begin{cases} \frac{3(\sqrt{6}+\sqrt{2})\,V_G}{8t}\, sin\left(\omega t + \frac{5\pi}{12}\right), & \omega t \,\epsilon \left[0, \frac{\pi}{6}\right] \\ \frac{3(\sqrt{6}+\sqrt{2})\,V_G}{8t}\, sin\left(\omega t + \frac{\pi}{4}\right), & \omega t \,\epsilon \left[\frac{\pi}{6}, \frac{\pi}{3}\right] \end{cases} \tag{30}$$

Now considering that second passive injection circuit is connected to the proposed rectifier system. The second passive injection circuit injects the harmonic current into the load in the 'minimum portion' of the asymmetrical 24-pulse output voltage which is shown in Fig. 4(d). The maximum amount of injected current by SPFR in P2-mode or Q2-mode must be equal to the maximum load current in P1-mode or Q1-mode minus the maximum current supplied by double-star rectifier-1 or double-star rectifier-2 in P2-mode or Q2-mode respectively. When the SPFR works, proposed rectifier operates in P2-mode or Q2-mode and only one double-star rectifier supplies the load current. In Q2-mode, the current i_6 is supplied by the rectifier-2 and expression of i_6 is

$$i_6 = \frac{P}{v_2} \tag{31}$$

Where P is the KVA rating of the $\Delta - Y - Y$ and $Y - Y - Y$ transformer. Assume that proposed rectifier operate under rated load condition. The expression of i_6 is obtained by substituting (27) into (31).

$$i_6 = \frac{Pt}{1.5\, V_G cos\, \omega t} \quad \omega t \,\epsilon\, [0, \frac{\pi}{36}] \tag{32}$$

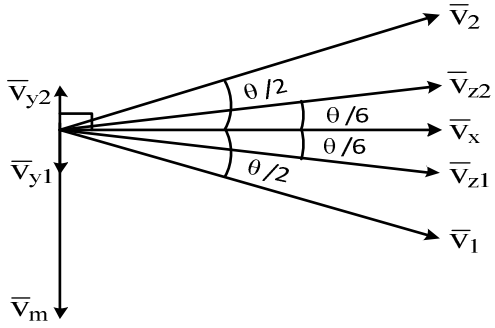

Fig. 5: Phasor diagram.

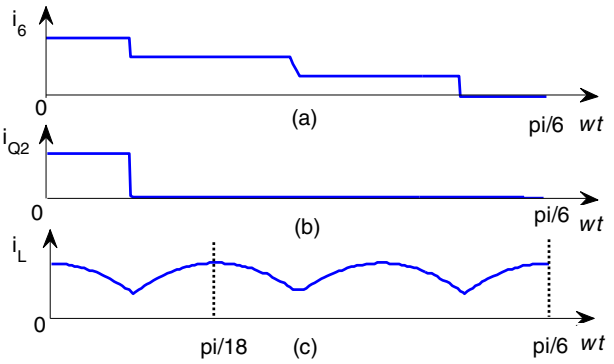

Fig. 6: Waveforms of (a) Current i_6 (b) Current i_{Q2} and (c) Current i_L.

Where V_G is amplitude of input phase voltages. Fig. 6(a) shows the maximum value of current i_6 is obtained at $\omega t = 0$ and expression is

$$i_{6max} = \frac{Pt}{1.5V_G} \tag{33}$$

The load current i_L in P1-mode and Q1-mode is

$$i_L = \frac{P}{v_z} \tag{34}$$

Fig. 6(c) shows that the maximum value of load current i_L is obtained in Q1-mode at $\omega t = \frac{\pi}{18}$ and expression is obtained by substituting (28) to (30) into (34). The maximum value of load current in P1-mode and Q1-mode is

$$i_{Lmax} = \frac{Pt}{1.4544\,V_G} \tag{35}$$

The maximum value of current should be injected by the SPFR in P2-mode and Q2-mode is

$$i_{Q2max} = i_{Lmax} - i_{6max} = \left(\frac{Pt}{1.4544\,V_G} - \frac{Pt}{1.5V_G}\right) \tag{36}$$

The optimal turns ratio is obtained by substituting (33) and (36) into (14) and this value is

$$m = \frac{N_s}{N_p} = 10.75 \tag{37}$$

IV. Simulation

MATLAB software is used for simulation to verify the theoretical analysis of the proposed rectifier. Following specifications are taken into consideration for simulation purpose.

TABLE I. SYSTEM SPECIFICATION

Parameter	Value
Input line-to-line voltage (rms)	400 V
Frequency	50 Hz
Turns ratio of the $\Delta - Y - Y$ transformer	1 : 1 : 1
Turns ratio of the $Y - Y - Y$ transformer	1: √3 : √3
Turns ratio of the STIT	1 : 10.75
Rated output power	50 KW

V. Results

Fig. 7 and Fig. 8 illustrate input line current and spectrum of the input line current respectively. It is concluded that input current has 36 steps approximately per cycle and THD of input line current is about 4.82% under rated load condition. When passive injection circuits are not used in the four-star diode rectifier, THD of the input line current is about 15.11%. TABLE II shows comparison of the input line current THD of the proposed rectifier and conventional four-star 12-pulse diode rectifier. It is concluded from the table that THD of the input line current is within the IEEE-519 standard requirements for wide load variation condition. Fig. 9 shows output voltage which contains 36 pulses per cycle of input voltage. The waveforms of current i_{P1} and i_{Q1} that flow through the diodes D_{P1} and D_{Q1} are reported in Fig. 10 (a) and 10 (b) respectively. Fig. 11(a) and 11(b) show the waveforms of current i_{P2} and i_{Q2} that flow through the diodes D_{P2} and D_{Q2} respectively. The graphical representation of output current of double-star rectifier-1 and double-star rectifier-2 are presented in Fig. 12(a) and 12(b) respectively.

TABLE II. PERFORMACE COMPARISON

% Rated Load	THD of the Input Line Current for Proposed Rectifier (%)	THD of the Input Line Current for Conventional 12-Pulse Star Rectifier (%)
30	4.97	14.70
40	4.94	14.81
50	4.88	14.90
60	4.83	14.96
70	4.83	15.02
80	4.82	15.07
90	4.82	15.07
100	4.82	15.11

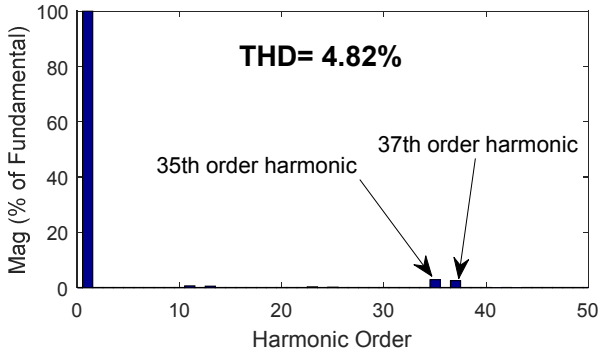

Fig. 8: Spectrum of input line current.

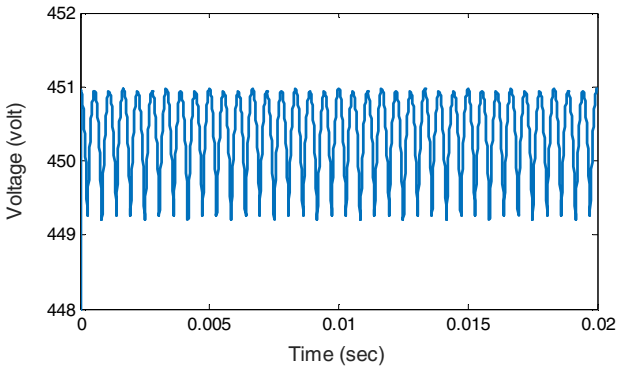

Fig. 9: Waveforms of output voltage.

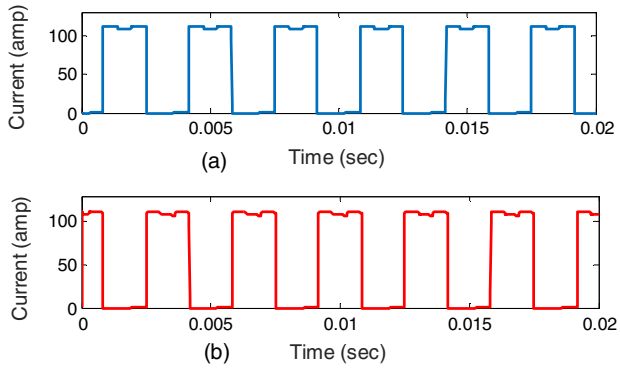

Fig.10: Waveforms of (a) Current i_{P1} (b) Current i_{Q1} of first injection circuit.

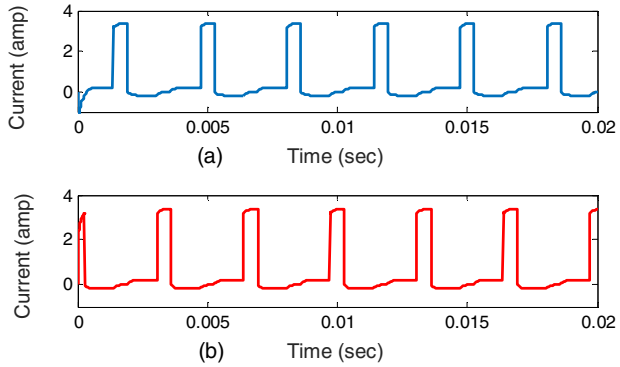

Fig. 11: Waveforms of (a) Current i_{P2} (b) Current i_{Q2} of second injection circuit.

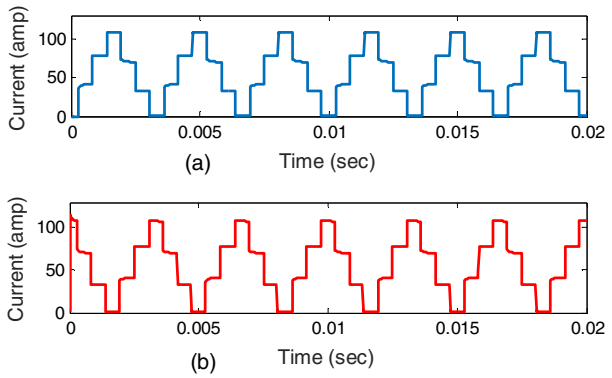

Fig. 12: Waveforms of (a) Current i_5 of double-star rectifier-1 (b) Current i_6 double-star rectifier-2.

VI. CONLUSION

In order to extend four-star 12-pulse rectifier operation to 36-pulse rectifier operation, passive injection method is introduced and presented in this paper. The proposed rectifier has been designed, analyzed and simulated in MATLAB environment. After using this method, the THD of the input line current is about 4.82% which is within the IEEE-519 standard requirements. The load voltage contains 36 symmetrical pulses and input line current contains 36 steps per cycle of power supply. The proposed rectifier works satisfactorily under wide load variation condition and preserves pulse tripling technique when STIT designed optimally. It suppresses lower than 35th order harmonics from input line currents. We will design a laboratory prototype in the next research.

***Abstract*—The rapid growing battery-powered and plug-in hybrid electric vehicles will have a significant impact on power networks due to their zero carbon emission and mass deployment. DC motors, AC induction motors, and Brushless Direct Current (BLDC) motors are used worldwide in electric vehicles for years. Among them, BLDC motors are one of the electrical drives that are continually gaining popularity in motion control applications due to their high efficiency, good dynamic response and low maintenance. Unlike DC motors and Induction motors, BLDC motors need a controller as the motors run in 3 phase but take DC input. The controller converts DC power to 3 phase AC power suitable for the motor. This paper describes the design and development of a BLDC motor controller and its performance comparison with the existing BLDC motor controller imported from abroad. The controller circuit is simulated in Proteus software and the PCB is designed in ARES.**

Keywords*— *Electric vehicle, BLDC motor controller, No-load test, Performance comparison.

I. INTRODUCTION

In the urban area of Bangladesh, according to BRTA (Bangladesh Road Transport Authority), over 332,000 registered motorcycles were on the road in 2016 and now it has almost doubled [1]. The reason behind this massive increment is because motorcycle overcomes the traffic easily; it is much cheaper than four-wheelers and consumes less fuel. Both males and females will feel comfortable riding these electric tricycles/e-bikes as they are very easy to ride and there is no need to maintain balance like in cycles or bikes. They are the best solution for green transportation due to their zero greenhouse gas emissions. The vehicles run using electrical energy that is stored in a battery bank and requires a motor controller to control speed and some other functions.

Fig.1. A typical electric tricycle

The market of these e-bikes is getting vast in size day by day but yet there are no companies or facilities to manufacture or develop e-bikes and its controller locally. It is high time to design, develop and manufacture local electric vehicle and their motor controller which will be suitable for the ambient condition of Bangladesh.

For these E-bikes, BLDC motor is preferred over traditional DC brushed motors or AC induction motors [2]. They are more reliable and can be used in poor environmental conditions as the BLDC motor have no chance of sparking, unlike brushed DC motors, making them better suited to environments with volatile chemicals and fuels [3]. DC motors have been used in the industries for many years, due to precise control capability and high efficiency. Since the late 1980's new design concept of permanent magnet brushless direct current (BLDC) motors are gaining grounds in electrical vehicle sector.

These electric vehicles run using electrical energy that is stored in a 48V/60V/72V battery bank. This system voltage mainly depends on the BLDC motors and its controller. The BLDC motors are typically permanent magnet synchronous motors; they are well driven by dc voltage and have a trapezoidal back-EMF. They have a computation that is done mainly by electronics application [4].

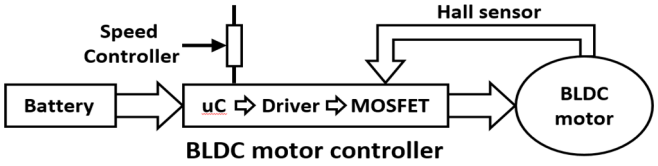

Fig.2. The functional block diagram of the electric tricycle

The paper will focus on designing and developing a BLDC motor controller and its performance comparison with the existing BLDC motor controller. The basic principle will be according to the block diagram of Fig.2. The controller will work according to the signals obtained from the BLDC motor's inbuilt hall sensors. This controller will invert the DC power from the battery to 3 phase AC power that will run the motor. The controller will be able to control the rotor speed and also the rotating direction. Lead acid batteries will be used in the battery bank.

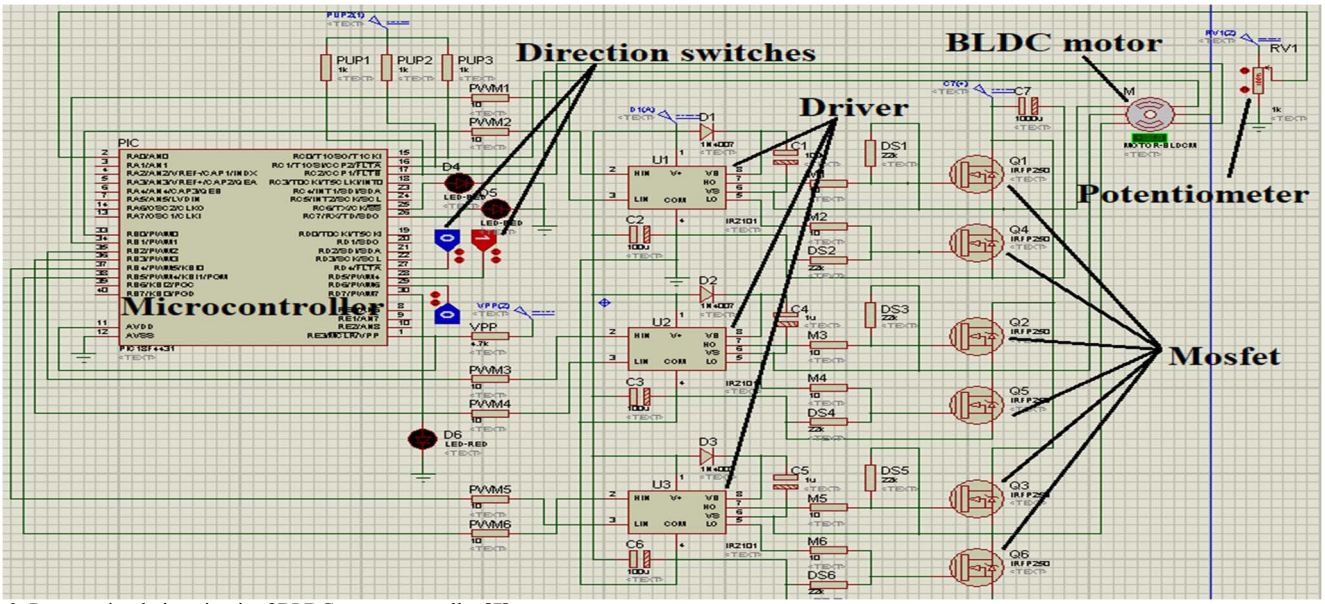

Fig.3. Proteus simulation circuit of BLDC motor controller [7]

II. Simulation of The Proposed BLDC Controller

Simulation of the BLDC motor controller is carried out by using Proteus ISIS Simulator software (Fig.3). Total 6 PWM signals of 20 KHz are generated by using PIC18f4431 microcontroller (PWM0 to PWM5, Pin B0 to B5). The duty cycle of the PWM signals is controlled by a reference input ADC signal (through potentiometer) into the microcontroller. A voltage divider circuit is then used to obtain the reference in the microcontroller to generate PWM signals and to control its duty cycle, output current and rotor speed [6]. Then 3 dual channels MOSFET driver (IR2101) is used to drive the MOSFETs with PWM signals. These drivers also initiate the dead time to the switches. Six IRFP250N N channel MOSFETs are used as switches to create the full bridge motor driver circuit.

The code was written in CCS PIC C compiler in C language for this project. The main task was to generate 6 different PWM signals according to different hall sensor combination. Six different combinations of hall sensors were taken as input in 3 analog pins (C0, C1, C2) of the PIC18F4413 microcontroller.

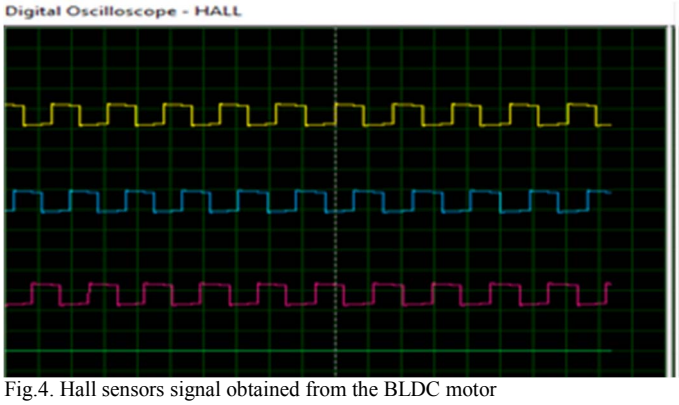

Fig.4. Hall sensors signal obtained from the BLDC motor

Hall sensors or optical sensors are used in BLDC motors to detect the position of the rotor (Fig.3). But it can be driven also without any position detection by sensors [5] using back-emf signals. The terminal voltages on the stator windings of each phase are controlled by the power electronic switches (MOSFETs). Each phase of the motor will connect with DC power source through two switches, one switch with positive terminal and other switch with negative terminal. To control terminal voltage of the three phases of the motor, 6 MOSFETs are used in this BLDC motor controller. After successfully circuit design in simulation software, desired output was achieved in 3 phases of the motor (Fig.5).

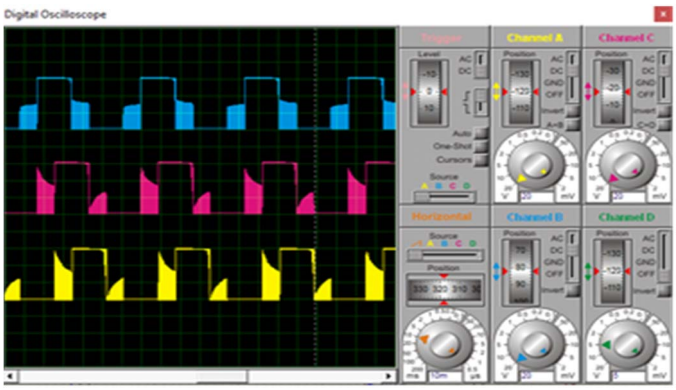

Fig.5. Three phase output waveform of the motor controller

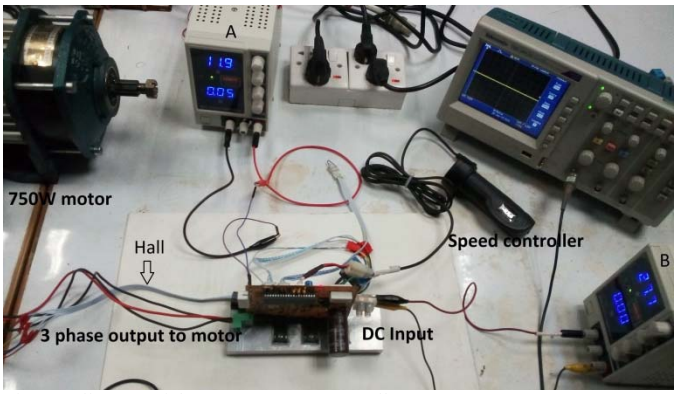
III. System Development and Testing

Almost all power-electronics products have become microprocessor controlled in recent years. The main advantage of using a microcontroller is that it reduces the complex control hardware where the control functions can be changed as many times as it is required without extra

hardware implementation. Furthermore, it offers the possibility of improved reliability and flexibility.

After successful simulation, a PCB (printed circuit board) of the BLDC motor controller was made. The PCB was double-sided so components were placed on both sides. The microcontroller was placed on top side of the PCB which produces 6 distinctive PWM signals to drive the power converter full bridge circuit through a MOSFET driver circuit. The power converter is actually a three-phase power semiconductor bridge.



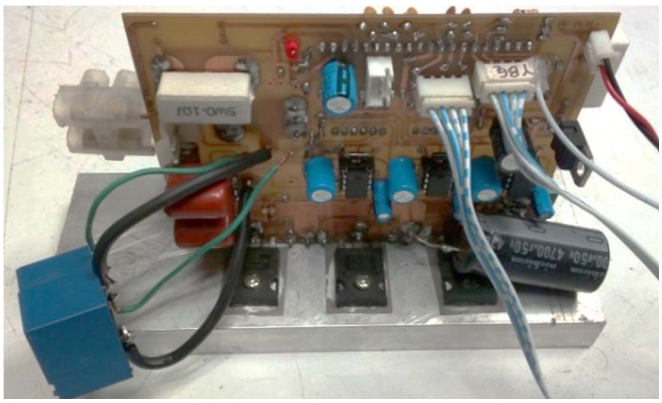


Fig.6. Full setup of the BLDC motor controller

This driver provides amplified gate signals at the same duty cycle to drive one high side and one low side MOSFET at a time. The bootstrap circuit is used to complete the driver circuit and amplify the signal coming from the microcontroller. The main function of the power converter is to transform power from the DC power to 3 phase AC power so the motor can convert electrical energy to mechanical energy. This converter can takes 48V to 60V DC power as input and gives a special kind of 3 phase AC power output (10V amplitude) to the motor according to the 3 Hall sensor's references. The complete setup can be seen in Fig.7 where the controller takes power from Lab bench power supply (A & B) and runs the motor according (upper left corner). The speed of the motor is controlled by using a throttle. This converter runs in 12V DC. The motor used in this project was 750W but the converter was designed to handle up-to 1000W of power. To meet up the criteria and availability, a components selection was done to get the possible optimized result.

Fig.7. The prototype of the developed BLDC motor controller

IV. Results and Discussions

Once developed, the controller was tested using a 750W BLDC motor. The input of the controller was 48V DC which consists of 4 * 12V, 100Ah lead acid batteries. At full speed current consumed by the controller was 3A [Table 2]. The motor was well driven by the controller for hours and the motor running sound was quite low. Heat generation of the MOSFETs was tolerable so no extra cooling system was required. The three outputs or phase signals of the controller were considerably smooth and noise free (Fig.8).

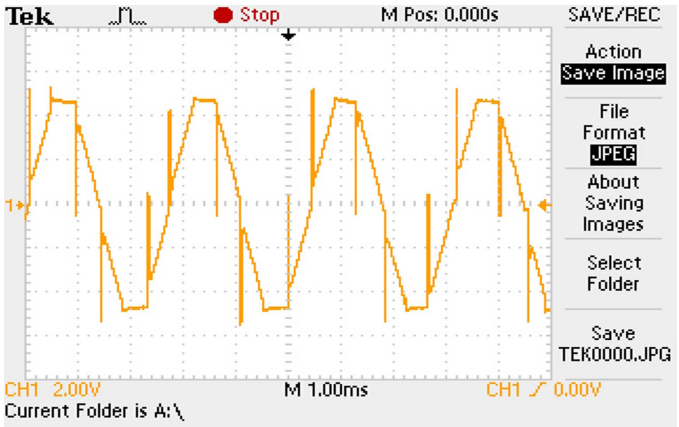

Fig.8. One of the three phases of the developed controller

Table 1 shows the experimental data obtained from the Existing BLDC motor controller for running 750W BLDC motor with no load.

TABLE 1. EXPERIMENTAL DATA OF THE EXISTING CONTROLLER

Speed	Input voltage (V)	Input current (A)	Input Power (W)

Existing BLDC motor controller	Developed BLDC motor controller
Frequency: 16KHz	Frequency: 17KHz
Period: 62.5 us	Period: 59us
Input voltage: 48V	Input voltage: 48V
Input current: 3.4A	Input current: 3A
Input power: 163.2W	Input power: 144W

V. CONCLUSION

In this paper, a detailed description of the design and development of a more efficient and lightweight BLDC motor controller for electric bike/electric tricycle has been presented. The controller tested and experimented successfully. The experimental data of the no load test shows an excellent performance of the locally developed BLDC motor controller over the existing BLDC motor controller. The developed motor controller consumes less power compared to the existing motor controller and makes less noise. The developed motor controller has an improved performance over existing controller due to proper selection of the filtering component and for using high frequency switching. Future work of this project is to implement this motor controller in an electric vehicle.

***Abstract*— The use of fossil fuels in generating energy is not only depleting these fixed resources at a higher pace but also has enormous negative impact on the environment. In this scenario, using renewable energy to design hybrid generation systems is both cost optimizing and environment-friendly. This paper carries a detailed study of a renewable energy-based electrification scheme for a Rohingya Relocation Center, an isolated island named Bhasan Char with sensitivity analysis of the proposed system. Using HOMER (Hybrid Optimization Model for Electric Renewables), a hybrid system is designed which contains a combination of the wind turbine, solar PV modules, microturbine generators, converter, and battery. The focus of this study is to achieve low NPC (net present cost) and low LCOE (Levelized cost of energy) with reduced carbon emissions.**

***Keywords*—** *wind energy, PV modules, hybrid system, microturbine generator, etc.*

I. INTRODUCTION

Energy plays a vital role in our day to day activities and is a crucial tool to meet up the future challenges of human civilization. Electricity is a preferred form of energy for its numerous advantages and applications. Currently, an estimated 16 percent of the world's population that is 1.2 billion people have very little or no access to electricity [1]. Shocking comparability in this number is the urban-rural ratio of energy use, more than 80 percent of victims of energy-poverty live in rural areas. About 65% of the total population of Bangladesh lives in rural areas[2]. The fact is that Bangladesh faces a deficit in adequate electricity generation capacity and grid-connected electricity distribution for the whole country[3]. For this reason, off-grid generation schemes utilizing various forms of renewable energy sources has become a recent trend to minimize the energy crisis. There is no rebutting of the fact that both developed and developing countries are looking forward to the novel and advanced types of energy solutions for their economic sustainability. Bangladesh has set a target to achieve 10% of total energy from renewable resources by 2020. However, the achievement from these forms of energy is only 3.5% until 2015 [4]. So, it is imperative in the context of our country to design and implement microgrids incorporating renewable energy resources on a broader scale. The advantage of the microgrid is that it fulfills the requirement of improved quality and reliability more economically and efficiently. This advantage can be used as a solution to provide electricity in isolated islands like Bhasan Char (a Rohingya relocation center). Some studies have been conducted previously for areas like St. Martin's island [5], Nijhum Dwip [6], Sandip-para [7] and also for Bangladesh as a whole [8]. However, this is the first initiative of a detailed study on Bhasan Char. A comprehensive load calculation is done based on the information collected from different sources.

In our study, HOMER has been used for finding the best hybrid electric system for Bhasan Char with low NPC (net present cost) and low COE (cost of energy). HOMER is the most frequently used software tools by the researchers worldwide than other similar software like HYBRID2, SOMES, Dymola, iHOGA, HOGA, RETScreen, etc. [9] [10].

II. JUSTIFICATION OF SITE SELECTION

Bhasan Char, previously known as Char Piya and Thengar Char, is an island in Hatiya Upazila, Chittagong district (Coordinates: 22.3872° N, 91.4145° E). The island is 30 km away from the mainland. It has become a place for national and international interest because the government of Bangladesh has decided to move the Rohingya refugees to this isolated island. Nearly 700,000 of Rohingya Muslims have crossed the Rakhine state, Myanmar since the end of August 2017. They joined about 300,000 Rohingya already staying in Bangladesh, one of the world's most crowded nations, who had fled the previous spell of brutality. The government has decided to turn this island into a home for 100,000 Rohingyas to reduce the pressure on Cox' Bazar [11] [12]. As such, the design and implementation of a suitable energy system which will provide low NPC and low LCOE have become the recent challenge for national and international bodies. Our study provides an appropriate hybrid system with sensitivity analysis to show the pathway in handling this challenge.

Fig. 1: Google earth top view of Bhasan Char (Char Piya)

III. LOAD ESTIMATION

To calculate the load we categorized the whole load into three main parts:

i) Primary Load 1
ii) Primary Load 2
iii) Deferrable Load

The total load distribution scenario is presented in table 1. Primary load 1 is mainly a household load. Mobile tower, police station, medical center, school, etc. are considered in primary load 2.

Load varies in different seasons in Bangladesh. For simplicity, we have divided them into two main categories, i.e. summer and winter. Scaled monthly average load graph is shown in figure 1 and 2 for primary load 1 and primary load 2 respectively. The deferrable load is considered fixed throughout the year. In our study, the deferrable load is 2.79 kWh/day. The overall average annual load is 814.8 kWh/day whereas peak load is 106.45 kW.

TABLE I. ESTIMATED LOAD SCENARIO FOR THE HYBRID SYSTEM

Category	Load Type	Sample considered of load type	Description of loads
Primary load 1	Household	100	3 CFL bulbs (20W each), 2 fans (40W each), 1 socket for mobile charge
Primary load 2	Mobile tower	1	Total 5 kW
	School	1	15 CFL bulbs (20W each), 15 Fans (40W each), 10 Computers (100W each)
	Shop	1	2 CFL bulbs (20w each), 1 Fan (40W), 1 refrigerator (200W)

IV. RENEWABLE ENERGY RESOURCE

The main renewable energy source in our selected site is Solar and Wind. The area is shiny and has promising wind speed in some of the months of the year.

A. Solar Energy:

Monthly solar irradiation data of Bhasan Char has been taken from NASA website. The average daily radiation is found to be 4.606 kWh/m^2/d with an average annual clearance index of 0.498. The maximum solar irradiation is found in February, April and May.

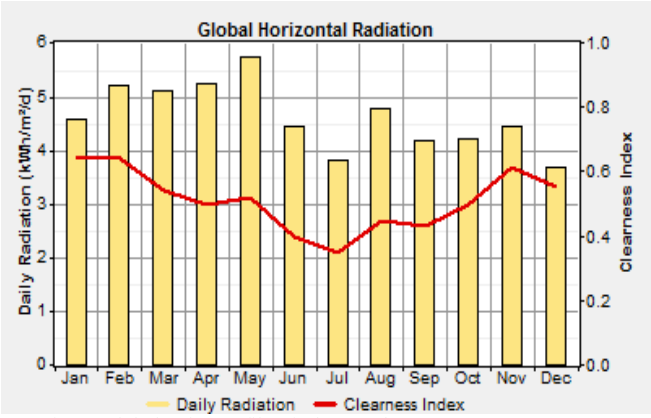

Fig. 4: Global Solar profile of Bhasan Char

B. Wind Resource

The average annual wind speed of Bhasan Char is 5.231 m/s which is quite promising. Wind speed is found maximum on the site at April, June, July, and August.

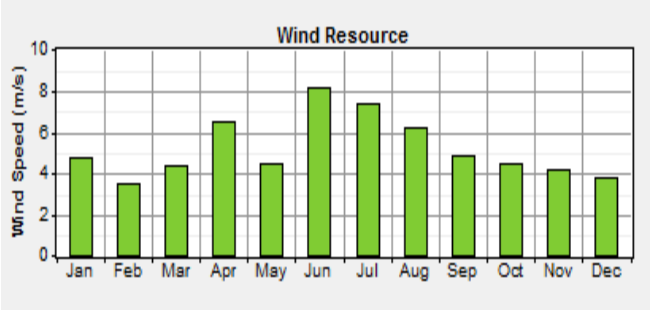

Fig. 5: Monthly wind resource of Bhasan Char

TABLE II. MONTHLY SOLAR AND WIND DATA FOR BHASAN CHAR

Month	Clearness index	Daily Radiation (kWh/m²/d)	Wind Speed (m/s)
January	0.648	4.560	4.750
February	0.643	5.210	3.500
March	0.542	5.100	4.360
April	0.500	5.230	6.490
May	0.521	5.730	4.510
June	0.399	4.440	8.140
July	0.345	3.810	7.380
August	0.445	4.770	6.220
September	0.428	4.170	4.900
October	0.496	4.200	4.470
November	0.611	4.430	4.200
December	0.551	3.680	3.770
Average	**0.498**	**4.606**	**5.231**

V. COMPONENTS OF THE HYBRID SYSTEM

Main components of this hybrid energy system are the wind turbine, PV panel, microturbine generator, converter and battery as shown in figure 6. To design the system, HOMER needs different parameters such as the number of units used, capital cost, replacement cost, operation and maintenance (O&M) cost of the system, lifetime and other parameters.

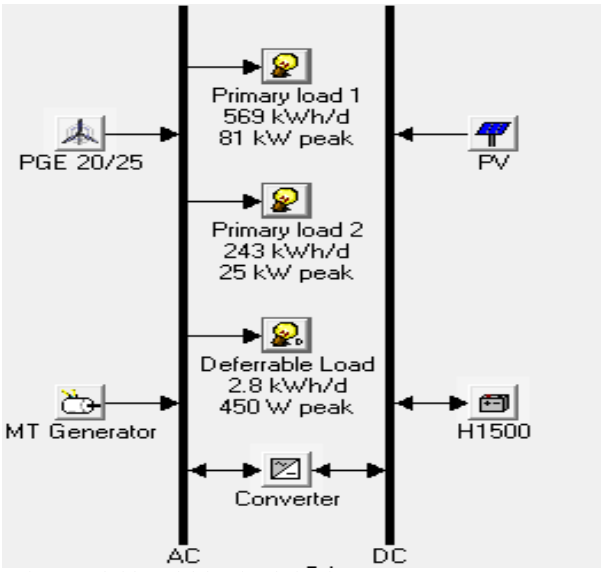

Fig. 6: Hybrid model for simulation in HOMER

A. Wind Turbine:

For the hybrid system, we used the PGE 20/25 wind turbine that has a rated capacity of 25 kW. It has rated wind speed of 12 m/sec and lifetime considered is 20 years.

TABLE III. PARAMETERS CONSIDERED FOR WIND TURBINE (PGE 20/25)

Parameter	Unit	Value
Power (rated)	kW	25
Starting Wind speed	m/sec	4
Rated Wind speed	m/sec	12
Cut off Wind speed	m/sec	25
Lifetime	Years	20
Capital Cost	BDT/turbine	9000000
Replacement Cost	BDT/turbine	7000000
O&M cost	BDT/year	20000

B. Solar PV modules

For solar modules, the capital cost is considered 1 lac BDT for one kW and replacement cost is 80 thousand BDT. Lifetime is 25 years.

TABLE IV. PARAMETERS CONSIDERED FOR PV MODULE

Parameter	Unit	Value
Capital Cost	BDT/kW	100000
Replacement Cost	BDT/kW	80000
O&M cost	BDT/kW/year	5000
Lifetime	Years	25
Derating factor	Percentage	92
Ground Reflectance	Percentage	20

C. Microturbine (MT) Generator

The fuel used in the MT generator was LNG. Bangladesh has started importing LNG in 2018 [13], and the price is as low as 33 BDT per cubic meter. Adding transportation and other costs, the LNG price is considered 35 BDT. In the sensitivity analysis, the LNG price is varied from 35 to 45 BDT. A 30 kW MT generator was considered in the system.

TABLE V. PARAMETERS CONSIDERED FOR MICROTURBINE GENERATOR

Parameter	Unit	Value
Capital Cost	BDT/kW	73333
Replacement Cost	BDT/kW	60000
O&M cost	BDT/hr (30kW)	30
Operational Lifetime	Hours	45000
Minimum load ratio	Percentage	20
Fuel Price (LNG)	BDT/m³	35
Lower Heating Value of fuel	MJ/kg	45
Fuel Density	Kg/m³	0.41

D. Converter:

For the purpose of converting AC-DC or DC-AC, the hybrid system needs converters.

TABLE VI. PARAMETERS CONSIDERED FOR CONVERTER

Parameter	Unit	Value
Capital Cost	BDT/W	15
Replacement Cost	BDT/W	10
Lifetime	Years	10
Efficiency	Percentage	90

E. Battery:

To store energy produced by PV panels, battery model of Hoppecke 12 OPzS 1500 are used. It is vented lead-acid, tubular-plate, deep-cycle battery with a nominal capacity of 1500 Ah.

TABLE VII. PARAMETERS CONSIDERED FOR BATTERY

Parameter	Unit	Value
Nominal Voltage	Volt	2
Maximum Charge current	A	306
Nominal Capacity	Ah	1500
Minimum Battery life	Years	10
Capital Cost	BDT/battery	100000
Replacement Cost	BDT/battery	87500
O&M cost	BDT/Year	50

VI. Optimization Results and Discussion

The Hybrid system comprising of MT generator, PV and wind is simulated using HOMER for an optimized system. HOMER shows the result of the optimized system in descending order with parameters such as Net present cost (NPC) and Cost of Energy (COE) are considered for economic analysis and hybrid system grading.

After setting suitable system control parameters and constraints, the simulation is carried out. In our simulation of MT-PV-Wind system, the optimized result is shown in fig. 7 with minimum COE of 16.88 BDT/kWh and minimum NPC of 82,089,760 BDT. 60 kW of PV, 2 wind turbine and 30 kW microturbine generator is found to be the most cost-effective and economically feasible solution. The unmet load is only 91 kWh/yr and capacity shortage is 0.1%.

PV (kW)	PGE25	Label (kW)	H1500	Conv. (kW)	Initial Capital	Operating Cost ($/yr)	Total NPC	COE ($/kWh)	Ren. Frac.	LNG (m3)	Label (hrs)	Batt. Lf. (yr)

Fig. 7: Optimized result of hybrid system simulated in HOMER **(NB: all currency values are in BDT, not in USD)**

This optimized system has renewable fraction around 68% and primary energy saving 75%. Production of electricity of each component is shown in table 8. Monthly average electricity production is shown in fig. 8. During June and July, wind turbine is supplying most of the electricity to the system as wind speed is higher in that time of the year.

The hybrid system in this study shows very less emission of pollutants as the renewable fraction is higher. CO_2 emission is found to be 60,290 kg/yr whereas CO is 351 kg/yr.

TABLE VIII. POWER GENERATION DATA OF PV-MT-WIND

Production	kWh/yr	Percentage (%)
PV panels	100,375	27.25
Wind Turbine	148,678	40.36
MT generator	119,290	32.38
Total	**368,343**	**100**

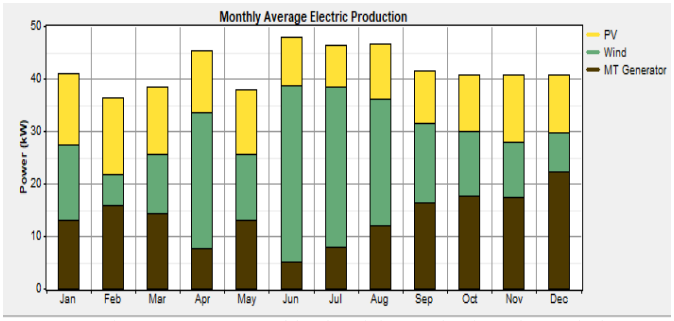

Fig. 8: Average monthly electricity production of PV-wind-MT

The result found in our study is compared with other relevant works, and it is very promising in both technical and economic perspectives. The optimized scheme in our study is PV-MT-Wind that has COE of 16.886 BDT. Some of the previous work [7] [14] [5] in this field of hybrid system had COE more than this.

VII. Sensitivity Analysis

Variation of wind speed, solar irradiation and price of LNG are considered for sensitivity study of the hybrid system. Fig. 10 shows sensitivity results in terms of LNG price and solar irradiance and fig. 9 shows the results in terms of LNG price and wind speed. In both cases, Levelized COE is superimposed and the maximum annual capacity shortage is 0%.

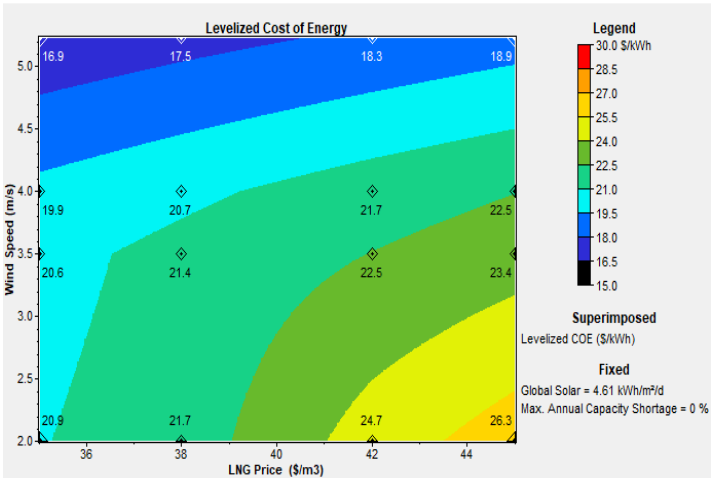

Fig. 9: Variation of LCOE in terms of LNG price and wind speed with fixed global solar o 4.61 kWh/m^2/d

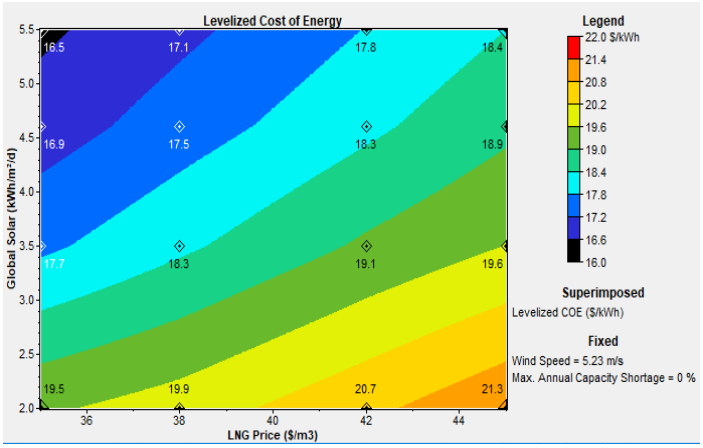

Fig. 10: Variation of LCOE in terms of LNG price and solar irradiation with a fixed wind speed of 5.23 m/s

It can be seen from fig 8 and 9; the LCOE is minimum when LNG price is minimum, 35 BDT. As wind speed and global solar is increased, the COE starts to decrease. If LNG price is increased COE also increases with fixed wind and solar profile.

The sensitivity analysis for optimal system type for fixed global solar of 4.61 kWh/m^2/d and a maximum annual capacity shortage of 0% is shown fig. 10. PV-MT system is feasible in terms of LCOE if the wind speed is below 3.3 m/s for any price of LNG. However, when the wind speed increases beyond this value, PV-MT-Wind system is economically more feasible.

Emission of CO_2, CO and other pollutants are less in the proposed system. The variation of this pollutants with other parameters can be seen from fig. 12. Wind-PV-MT system has lower carbon-di-oxide pollution than PV-MT system as the renewable fraction is high in the former system. Again for PV-MT system, CO_2 emission grows with the rise of fuel price. But for PV-MT-Wind system, CO_2 emission reduces with LNG price.

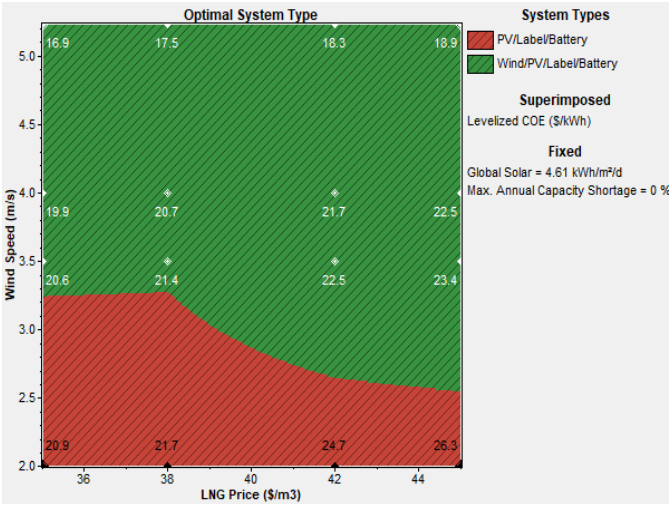

Fig. 11: Optimal system type in terms of LNG price and wind speed with a fixed global solar of 4.61 kWh/m^2/d

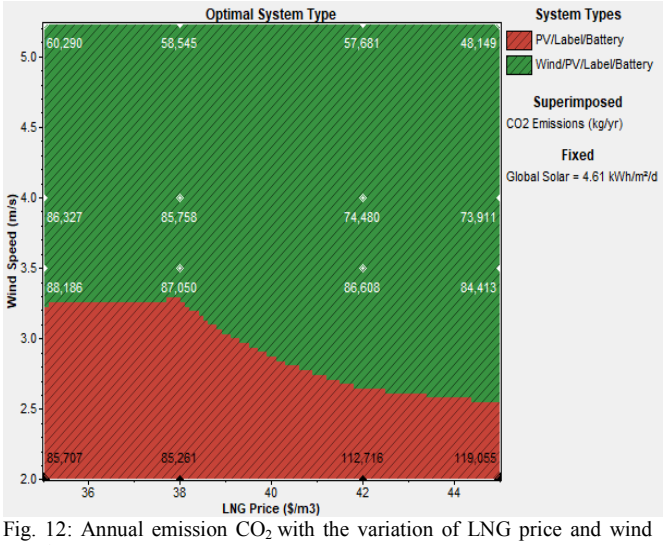

Fig. 12: Annual emission CO_2 with the variation of LNG price and wind speed

VIII. Conclusion

Hybrid systems are very important for electrification in areas like Bhasan Char that are far away from the mainland. This study of wind turbine, PV module and microturbine generator has found its optimized scheme with 60 kW from solar, 50 kW from wind and 30 kW from MT generator. A high fraction of renewable sources (around 67%) means the proposed scheme has fewer pollutants and thus more environment-friendly. LCOE is found to be less than 17 BDT per unit for the estimated load of 814 kWh/day. Similar studies of hybrid systems can be undertaken for other areas of Bangladesh to mitigate electricity problem and also to find alternative clean energy.

***Abstract*—This paper represents a metering system which will measure the power factor of a load and frequency of a main-line and plot a real-time AC power triangle in MATLAB environment. The system uses Arduino as a controller. It reads the load voltage, current, their phase difference, and main-line frequency. A preliminary circuit arrangement, including a potential transformer (PT), a current transformer (CT), comparator and logic gate transforms the high value of voltage and current to the Arduino readable form. A serial communication between the Arduino and the MATLAB is done for plotting the power triangle. The simulation and experimental results are compared with the real data observed in the oscilloscope and frequency counter.**

***Index Terms*—Power triangle, MATLAB, high differential comparator, X-OR gate, power factor, Proteus and Arduino.**

I. Introduction

Electrical energy is the popular form of energy because of its easy transportation and reasonable cost. The cost of electrical energy increases due to power losses in transformer, transmission line and loads. Most of the loads are inductive where the current waveforms lagging the voltage. It consumes the reactive power which causes the real power to be less than the apparent power. The lower value of real power produces the poor power factor that can be used to measure the efficiency affecting by the phase lag [1]. A load with less power factor draws more current from the power line which is responsible for more losses.

The power factor directly relates to the system efficiency and performance. A large amount of load current results in lower voltage regulation of the system and provides a large joule loss in the power lines [2]. The lower voltage level generates heat in the motor windings that reduces the lifetime, reliability and performance of the machine. The reduced system performance and efficiency generates poor value of power factor that results in increasing utility charge. The economic returns of the power factor can be easily noticeable in the lower utility charges. Another visible benefit of power factor is the released system capacity, decreasing line losses and improved voltage regulation. Though having lots of benefits of power factor, the power factor measuring device is not available with the range of consumers. The system introduces in this paper measures the power factor and plots a power diagram for further analysis.

Fig.1 shows the basic block diagram of the proposed system. The system first converts the high value of load voltage and current to the proportional lower value. The conversion is done by using a PT of 20:1 trans ratio and a CT of 1:24 turns ratio. The output of CT and PT is fed into a comparator circuit designed with lm311 IC for detecting the zero crossing. Its strobe terminal operation and low voltage handling capacity makes it possible to respond to the lower value of CT output. As a result, no additional amplifier circuit is needed between CT and comparator circuit. An X-OR gate is used in the proposed system for detecting the lagging time pulse and phase delay between the voltage and current. A precision full wave rectifier is used to convert AC to DC voltage and current. The output from rectifier is passed through the Arduino and measures the equivalent voltage and current. Arduino sends the data to the MATLAB through serial communication, and then the Matlab calculates active, reactive, and apparent power and plots a power triangle. The MATLAB also calculates the required capacitance value to improve the poor power factor to unity.

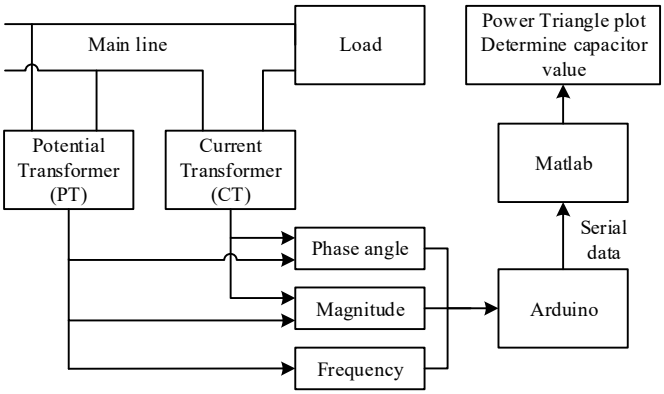

Fig. 1: Basic block diagram of the proposed system

In the previous literature, experts research on the field of power factor measurement. In [3] a system is demonstrated which is used for measuring and correcting the power factor (PF). The required capacitance is switched in or out by solid state relay and continuously monitors the PF. This system can not be used as a portable power factor meter. A PF measuring system based on Arduino is shown in [4] where the active power is calculated by taking the instantaneous value of voltage and current. It needs a high sampling rate. The higher sampling rate may cause sampling error, which affects the accuracy of measurement.

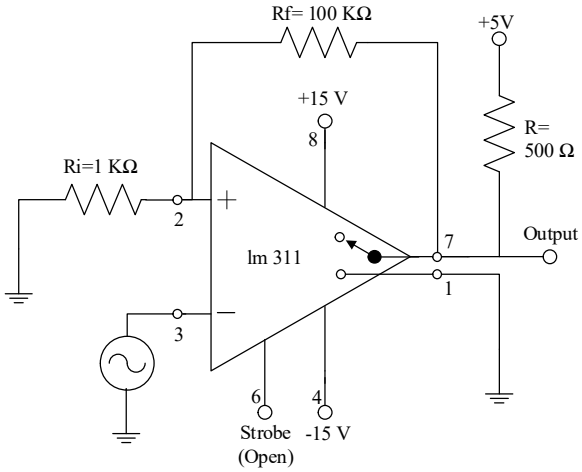

Fig. 2: A high speed differential comparator circuit using Lm 311

An ARM® microcontroller based approach for monitoring the power factor is introduced in [5]. This approach provides much accuracy. The drawback of this approach is its high implementation cost. In [6] power factor control unit based on Arduino is presented where a fixed line frequency is assumed. Moreover, the power line frequency may vary within a small range. The variation of frequency may affect the calculation of the power factor.

Motivated by above difficulties, this paper presents a smart power factor metering system for measuring the PF and frequency of a main-line. The proposed system is able to eliminate the error due to rounding the frequency like 50Hz. The advantage of proposed system includes the use of high-speed differential comparator lm311 which limits the use of the preamplifier circuit and reduces the cost of metering system. The aim of this work is to ensure the accurate PF by ploting a power triangle in the MATLAB environment. The power triangle is used to find the accurate PF by comparing the amount of power used in the load and consumed power from the transmission line.

The rest of this paper is organized as follows. Section II explains the theoretical background of this system. In section III the procedure of measuring power factor is described. The method of calculating voltage is expressed in section IV. The current measurement procedure is shown in section V. Section VI manifests the way of frequency measurement. The evaluation of the experimental results is illustrated in section VII. The conclusion of this paper is given in section VIII.

II. Theoritical Background

The power factor of the circuit $\cos(\phi)$ is measured by taking the phase difference ϕ between the voltage and current in an AC circuit. When the circuit is inductive, the current lags behind the voltage and the power factor is mentioned to as lagging. Most of the residential loads are inductive in nature and therefore have low lagging power factor. The power factor can also be calculated in terms of power drawn by the AC circuit. The ratio of active power to the apparent power is referred to as power factor. The relation between the active, reactive and apparent power is shown in Fig. 3 and discussed in (1), (2) & (3) as follows:

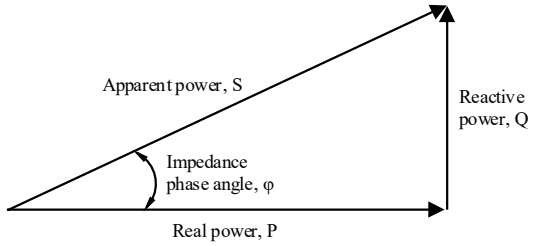

Fig. 3: Relation between the active, reactive and apparent power

$$P = V * I * \cos(\phi) \quad (1)$$

$$Q = \sqrt{S^2 - P^2} \quad (2)$$

$$S = V * I \quad (3)$$

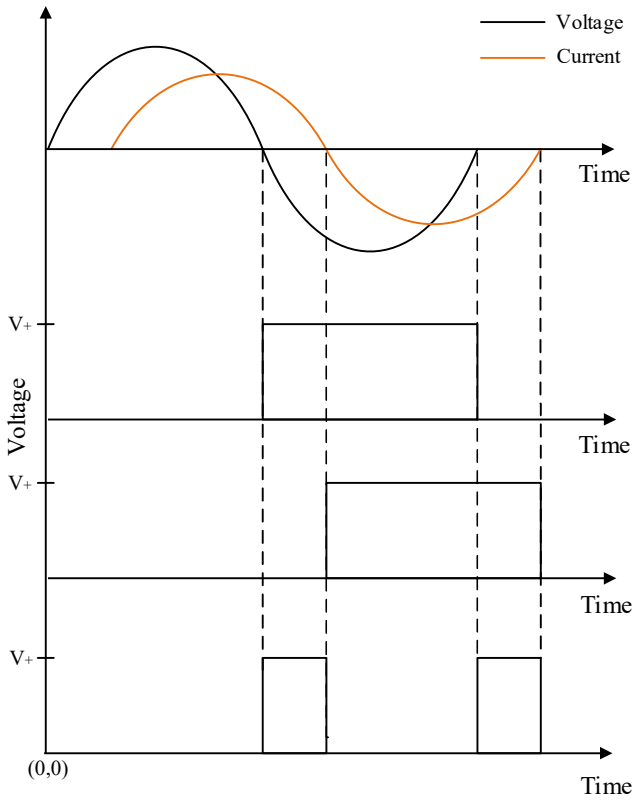

Fig. 4: A phase angle generation from the time delay between the voltage and current

For measuring the phase angle, the sinusoidal output from CT and PT are fed into two different comparator circuit. Lm 311 is chosen to make a comparator circuit shown in Fig. 2 because of its strobe terminal operation and faster response time of 165 nS [7]. The result from strobe terminal acts like a switching output and connecting between a voltage source V_+ and ground. When the strobe switch is open, the lm311 operates normally and gives the positive output voltage V_+ for negative values of the input signal and 0 V for the positive values as reported in Fig. 4.

A Proteus simulation result with the input and output wave shape of comparator circuit is presented in Fig. 5. Here the sinusoidal output of channel A shows the input wave shape and channel B shows the output of the comparator circuit. From Fig. 5, it is observed that the comparator generates an

output of +5 volt for every negative value and returns 0 volts for the positive value of input wave. The switching outputs are passed through the X-OR gate to detect the time delay between the voltage and current. This logic gate detects the inequality between two pulses and generates another pulse. The results obtained from the X-OR gate is reported in Fig. 6. The on time of this pulse denotes the time delay between the voltage and current.

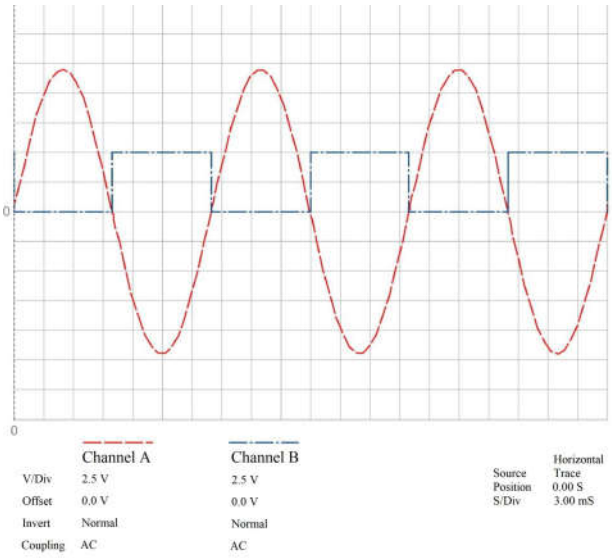

Fig. 5: A simulation result of comparator output

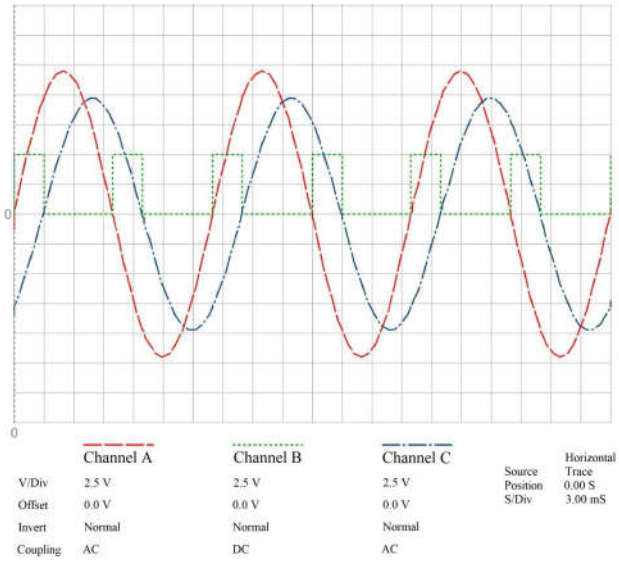

Fig. 6: A simulation result of X-OR gate output

III. Power Factor Measurement

This section presents the brief discussion of the power factor measurement by using phase difference between the voltage and current of an inductive load. The phase difference is obtained by measuring the time delay with the help of Arduino board. After measuring the time delay, the phase difference between the voltage and the current is measured. The relation between the time delay and the phase difference is described by the following equations:

$$\phi_D = 2 * 180 * f * T_D * 10^{-6} \quad (4)$$

$$\phi_R = \frac{\pi}{180}\phi_D \quad (5)$$

Here,
ϕ_D = Phase difference in degrees
T_D = Time delay in μS
f = Frequency in Hz
ϕ_R = Phase difference in radians

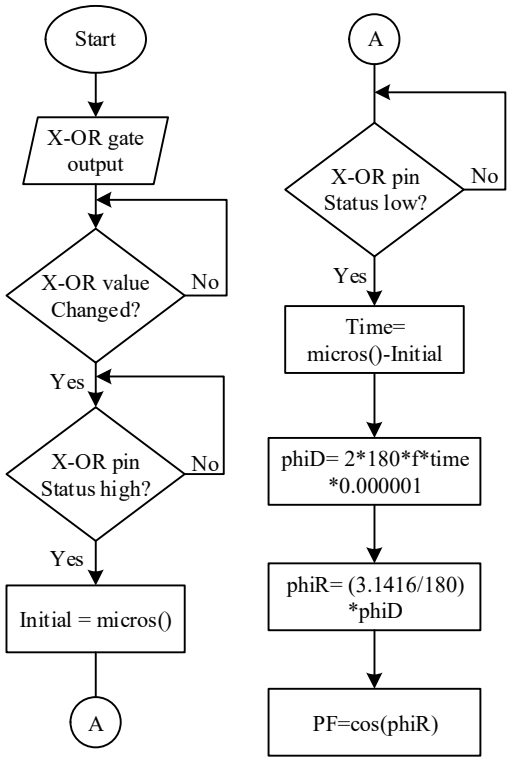

Fig. 7: A flow chart of power factor measurement

A flow chart of the programme for measuring the power factor is shown in Fig. 7. The time delay between the voltage and the current is measured using the pulseIn() function of Arduino. The process of the pulseIn() function is that it waits until the rising edge of X-OR output is detected. While detecting the signal from low to high, it stocks the time in its memory using the function micros(). After that, a recursive function is called which call itself again and again until detecting the falling edge. If the signal goes low, it deducts the current time from the starting time. This process returns the on-time duration of the pulse. Based on this on-time duration, the power factor is then evaluated using (4) and (5). After that, taking the cosine of the phase angle and returns the power factor. The obtained power factor is then put in (1) and calculates the required active power for the load. From (1), it is seen that the load voltage and current also needs to be measured in order to calculate the active power. The proposed system is able to measure the load voltage and current. The measurement process of load voltage and current is discussed in the next section.

IV. Voltage Measurement

For measuring the voltage across the load, the output from the potential transformer is given to a rectifier circuit. A precision full wave rectifier circuit as shown in Fig. 8 is chosen for the rectification purpose.

The rectifier circuit excludes the additional voltage drop across the diode and rectifies low value of AC signal by adding the large gain of OP-Amp. A voltage divider is employed to

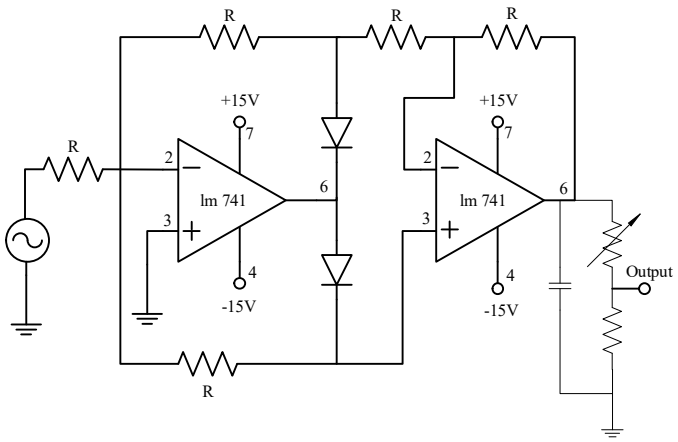

Fig. 8: A precision circuit diagram of full wave rectifier

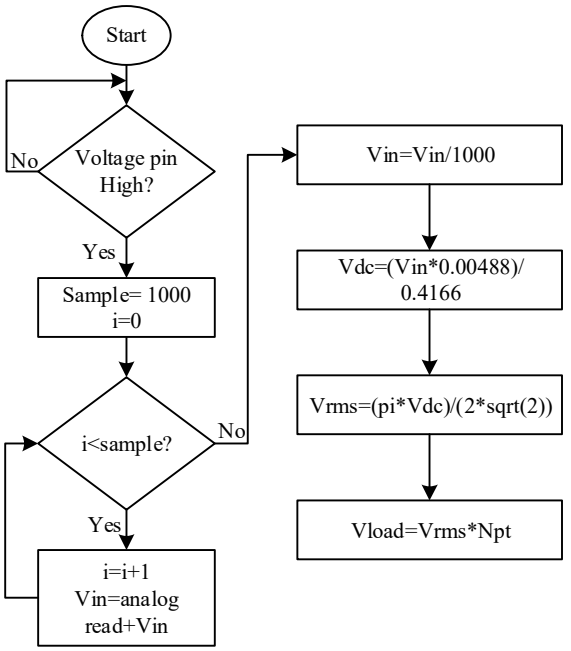

Fig. 9: A flow chart of load voltage measurement

convert the high value of DC signal into Arduino compatible form. The ratio of Arduino input to the total DC voltage is 0.4166 used for the proposed system. As the Arduino uses 10-bit ADC, it gives 0-1023 (1024 steps) for a 0-5V input. After using this step, the Arduino calculates the load voltage by using the following equations:

$$V_{DC} = \frac{ADC\,reading \times 0.00488}{0.4166} \tag{6}$$

$$V_{RMS} = \frac{\pi \times V_{DC}}{2\sqrt{2}} \tag{7}$$

$$V_{load} = V_{RMS} \times N_{PT} \tag{8}$$

Here,
V_{DC} = Rectified DC voltage
V_{RMS} = RMS value of AC voltage at PT secondary
V_{load} = Load voltage
N_{PT} = Transformer ratio of PT

A flow chart of the programme for AC voltage measurement is reported in Fig. 9. For measuring the AC Voltage, Arduino waits for the voltage pin to go high. When the voltage pin goes high, the programme starts sampling for 1000 times. This is done by using a "for" loop. Inside the "for" loop, the programme samples the analog input from the rectifier circuit and stocks it into the memory. When the " for" loop is executed, the average value is computed by summing all the sampled data and dividing it by 1000. After completing this step, the load voltage is calculated by using (6)-(8).

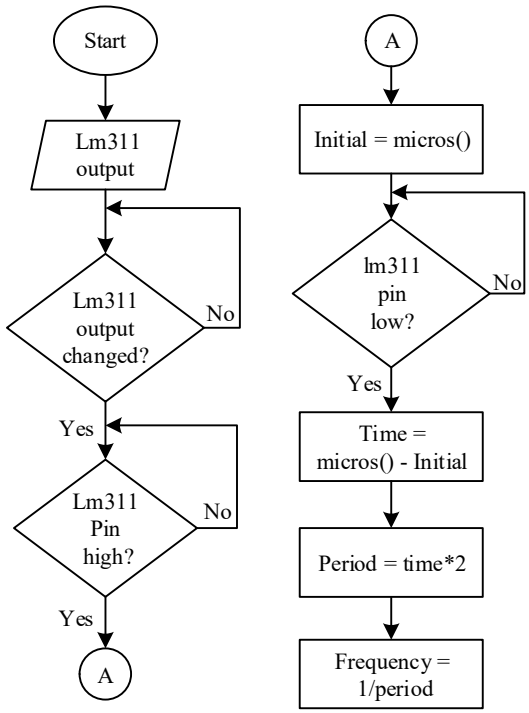

Fig. 10: A flow chart of frequency measurement

V. Current Measurement

A current transformer (CT) of 1:24 turns ratio is used to obtain the high value of load current. As the output of CT is a current signal, it converts the current signal into a voltage signal. The required conversion is done by adding a 100-ohm resistance at the secondary windings of the CT. The converted signal is applied to the full wave rectifier circuit. Arduino reads the voltage in the similar way used in voltage measurement and calculates load current by using the following equations:

$$V_{DC} = \frac{ADC\,reading \times 0.00488}{0.4166} \tag{9}$$

$$V_{RMS} = \frac{\pi \times V_{DC}}{2\sqrt{2}} \tag{10}$$

$$I_{RMS} = \frac{V_{RMS}}{100} \tag{11}$$

$$I_{load} = I_{RMS} \times N_{CT} \tag{12}$$

Here,
I_{RMS} = RMS value of AC current at CT secondary
I_{load} = Load current
N_{CT} = Transformer ratio of CT

VI. Frequency Measurement

The transmission line frequency is not exactly 50Hz in an ideal case. It may vary between 49Hz to 51Hz. Thus, for better accuracy, the measurement of frequency is needed rather than assume it. The output of the comparator circuit is directly fed to the Arduino. Arduino then measures the on-time duration

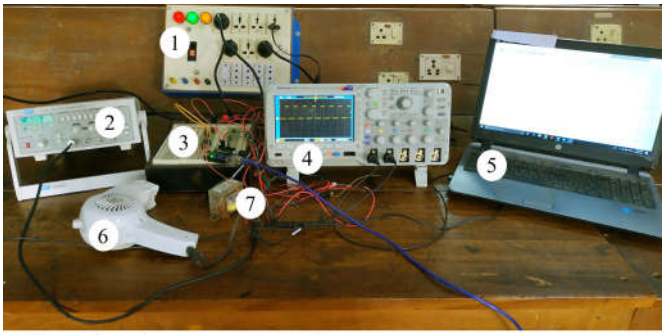
of the pulse output from the comparator circuit using pulseIn() function. The time period of the original sinusoidal signal is twice the on-time duration of that pulse. This duration is then converted into frequency using the below equations:

$$T = t_{on} \times 2 \tag{13}$$

$$f = \frac{1}{T} \tag{14}$$

Here,
t_{on} = On time duration of comparator pulse output
T = Time period
f = frequency

Fig. 11: Frequency measure using frequency counter



A flow chart of the frequency measurement is shown in Fig. 10. The flow chart is similar as the power factor measurement except that the input of the programme is given from the output of the comparator. After measuring the on time of the comparator output as discussed in the power factor measurement section the frequency is then calculated from the equation (13) and (14). The actual measured frequency of power line is presented in Fig. 11.

VII. Experimental Setup and Performance Analysis

This section presents the experimental setup for measuring the power factor as shown in Fig. 12. The setup consists of a power board, frequency counter, computer, oscilloscope, potential transformer and load. A 200W hair drier is used as an inductive load which contains a motor that shows dynamic behavior along with the time. The function of frequency counter is to measure the actual frequency of main line. A computer is used for plotting the power triangle curve with the help of MATLAB that provides the support of analyzing of power factor. The wave shape of voltage, current, and time difference are observed in an oscilloscope. The performance of proposed system is evaluated by comparing its output and the measuring instrumental output.

A. AC power measured by the measuring device

The power factor, frequency, and the AC power are first measured from the instrumental data. The performance of the proposed system with an inductive load is verified in Fig. 13 and Fig. 14. Here, the channel-1 (yellow wave) presents the voltage wave and channel-2 (blue wave) presents the current wave. From Fig. 14, it is seen that the time delay between voltage and current is 2.96 ms. The frequency counter gives the accurate line frequency value of 50.41 Hz as shown in Fig. 11 and the phase difference between voltage and current is 53.716° obtained from (4). After collecting the instrumental data and finishing some calculations, the system reaches the following parameters presented on table I.

1) Power board
2) Frequency counter
3) Project board
4) Oscilloscope
5) Computer
6) Hair drier
7) Potential transformer

Fig. 12: Experimental set up of the system

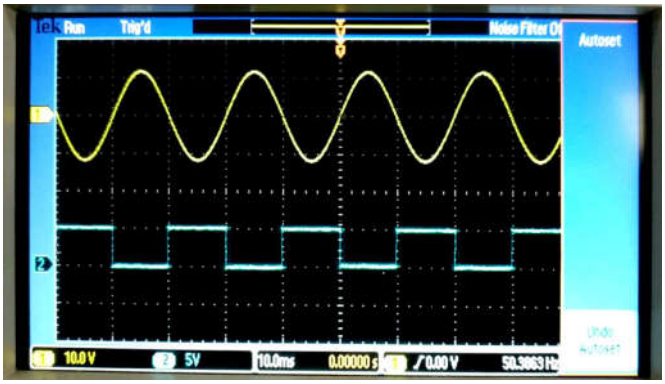


Fig. 13: A generation of pulse wave using high differential comparator

Fig. 14: An experimental output of the proposed system

TABLE I: Parameters measured from the instrumental data

Parameter	Measured value
Power factor	0.598
V_{load}	200 V
I_{load}	1.08 A
Active power	129.17 W
Apparent power	216 VA
Reactive power	173.12 Var

B. AC power measured by the system

The results of the system are displayed on the computer screen. After calculating the AC power, MATLAB plots a power triangle which is shown in Fig. 15. Here, The green, blue and the red line presents the active, apparent and reactive power respectively. The other calculated parameter is displayed

on the MATLAB command window. In table II the measured value of the parameters are shown.

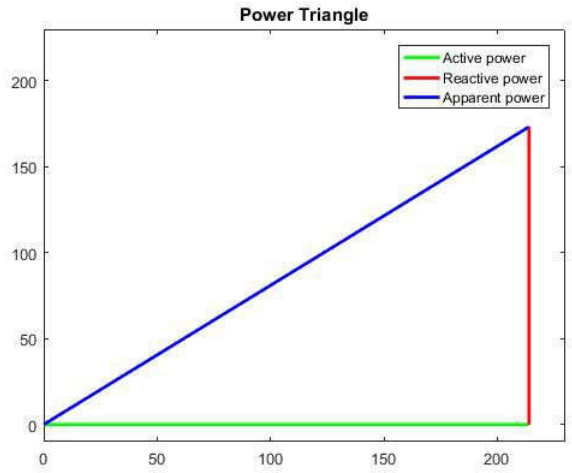

Fig. 15: A triangle power curve using MATLAB

TABLE II: Parameters measured by the system

Parameter	Measured value
Power factor	0.590
Active power	126.25 W
Apparent power	213.90 VA
Reactive power	173.23 Var

After comparing the results, it is observed that the proposed system is able to ensure the required power needed to the load. The proposed system also meets the accurate utility charge within the reasonable range by calculating the appropriate power factor.

VIII. CONCLUSION

A design of high differential strobe terminal based smart power factor metering system is presented in this paper for measuring the power factor of an inductive load. This is done by measuring the load voltage, current and time delay between the voltage and current. In many cases, the variation of line frequency limits the calculation of accurate power factor that may result in higher utility charges. The proposed metering system is able to measure the accurate line frequency and find out the appropriate power factor corresponding to the load. The experimental results are used to proof the validation of proposed system. The obtained result confirms the high effectiveness of proposed system.

***Abstract*— Frequency adjustment and protection of a wind turbine due to wind gust is a salient aspect of the grid-tied wind farm. Both of them require conserving system stability. This paper presents an investigation of the converter based frequency adjusting method and wind turbine protection. A grid-tied wind farm model using the Doubly Fed Induction Generator in MATLAB is used. To regulate the active power output, synchronization between wind speed and wind turbine speed is adjusted. Thus, wind farm operated at grid frequency and maximize turbine output. The control strategy of the converter based frequency synchronization of a grid-tied wind farm also includes protection subsystem. The protection system executed by receiving information from the logical block implemented in the wind farm model. It provides wind turbine protection by terminating wind turbine from a grid in abnormal wind conditions. Simulation result validates the analysis and control methods.**

Keywords—Grid-tied wind farm, DFIG (doubly fed induction generator), frequency regulation, wind turbine protection.

I. INTRODUCTION

A huge amount of electricity is required to meet up the growth of electricity demand due to the industrial revolution and modern civilization. The conventional power generation sources such as thermal, nuclear power, hydroelectric, geothermal are used throughout the world. Most of these power plants create harmful effects on the environment. All though we can't avoid these power plants totally, nonetheless it is possible to minimize those energy usages. Optimal generation mix from different sources is considered to be one of the key elements for economic growth of a country [1]-[3]. The worldwide energy policy concerned with the utilization of renewable energy resource [4], [5]. By combining the traditional energy and renewable resources, an optimized, low-cost and environment-friendly power systems can be planned. Among renewable, the wind energy's share sharply rises, and it's growing penetration demands for flexible supply resources and various options [7].

At the present time, wind energy harvesting technology by using wind turbine improves significantly than in the past. Yet the integration of wind power in the exciting power system creates a few technical challenges, power quality issues are prime among them. The term "power quality" means the stability of the voltage, the stability of frequency and the non-existence of various forms of electrical commotion (e.g. fluctuation or harmonic distortion) in the power grid [8], [16]. Combining wind generators with the existing power system could lead to many disturbances like voltage fluctuations, harmonics, flickers and frequency instability [9]. The interconnection of a large number of wind turbines to the grid creates huge trouble to the stability of power system [10], and the uncertainty associated with the uncontrolled wind system is disparaging to the power system operation as well as a control mechanism.

The remainder of the paper is prepared as follows: Section II presents the problem associated with grid-integrated with the wind power system. Frequency adjustment technique is explained in Section III. Section IV provides the intelligent converter control mechanism followed by a protection mechanism in Section V. The simulation results for several plausible scenarios are shown in Section VI. Finally, concluding notes are delivered in Section VII.

II. PROBLEM WITH GRID CONNECTED WIND SYSTEM

Among various renewable sources, wind energy is the speedily expanding energy source, which is regarded as the promotable future of renewable energy [16]. By the end of 2018, the comprehensive capacity of all wind farms installed across the world reached 600 GW, according to a report of the world wind energy association. The rate of extension in the installation of wind-power generation capacity has increased fairly, steadily over the years. So addressing the problem associated with the wind generation system is the real challenge for modeling of a grid-tied wind farm.

When the wind turbine assists a large proportion of the grid load, an irregular change in wind speed can cause voltage inequality, frequency fluctuation and flicker effects on the healthy operation. When a squall of wind hits a wind turbine blade, the blades struggle to speed up because the synchronous generator is locked to the speed of the power grid. In this situation, a huge amount of forces is developed in the gearbox, hub and generator to synchronous turbine shaft with power grid frequency. But it causes damage to the whole coupling mechanism. On the other hand, uncontrolled wind speed causes frequency fluctuation and damage of the structure for a grid-tied wind turbine system. This causes instability in the power system.

III. FREQUENCY ADJUSTMENT TECHNIQUES FOR WIND ENERGY CONVERSION SYSTEM

A grid linked wind farm system always tries to keep the system frequency close to 60/50 Hz. When generation and demand unbalance because of variable wind speed, the

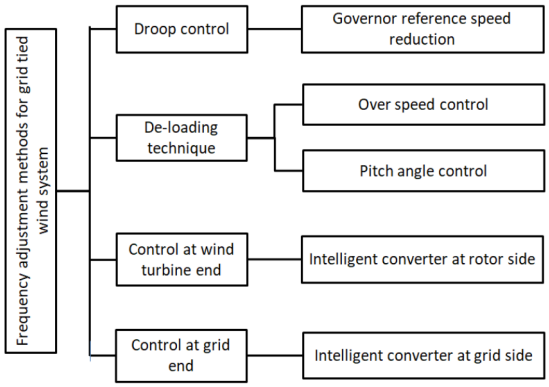

Fig. 1 Frequency tuning methods for a grid-integrated wind power.

system operating frequency starts to decrease based on system inertia and unbalanced power, according to the swing equation of power system stability given in (1) [13].

$$\frac{df}{dt} = \frac{f_0}{2H_{sys}S_G}(P_m - P_e) \quad (1)$$

Where,$\frac{df}{dt}$ denotes the rate of frequency change, $f_0$is the system frequency, H_{sys}stands for the overall system inertia parameter,S_G indicates the rated power of the machine. The terms P_m and P_e are refers respectively to the mechanical power and electrical power [13]. [14].

In order to minimize the negative impact of wind power penetration on system frequency, various inertia and frequency control techniques imply for wind energy conversion system [15], [16]. Fig. 1 elaborates the techniques which apply to adjust the frequency of a grid tied wind power system.

IV. INTELLIGENT CONVERTER FOR FREQUENCY ADJUSTMENT

With the speed change of wind, if the turbine, which converting wind power into electricity allowed to speed up immediately, the stress can be lower on the turbine. Themechanical power from wind gust can be transformed to usable electricity. Most of the wind turbine intended to operate at its standard speed to maintain synchronization of frequency between wind farms and the grid [20]. The frequency of a system linearly increases with the decrease of active power and vivaversa. Any deviation between grid frequency and wind turbine frequency can minimize by active power control of both sides.

A doubly fed induction generator (DFIG) with insulated gate bipolar transistors (IGBTs) based four-quadrant ac-to-ac converter is the best solution for a grid-tied wind turbine system. Fig. 2 presents a model of grid-tied wind farm.Doubly fed electrical generators operate similarly like an AC electrical generator, but the added feature of a DFIG is it can run at speeds to some extentoverhead or lower than its synchronous speed. The converter at rotor side and grid side of a doubly fed induction generator (DFIG) based wind turbine basically regulate the active power which eventually adjusts frequency variation of a grid-tied wind farm [21] – [24]. The four-quadrant converter in the rotor circuit of a DFIG enables decoupled control of active and reactive power of the generator.Fig. 3 illustrates the view of the converter

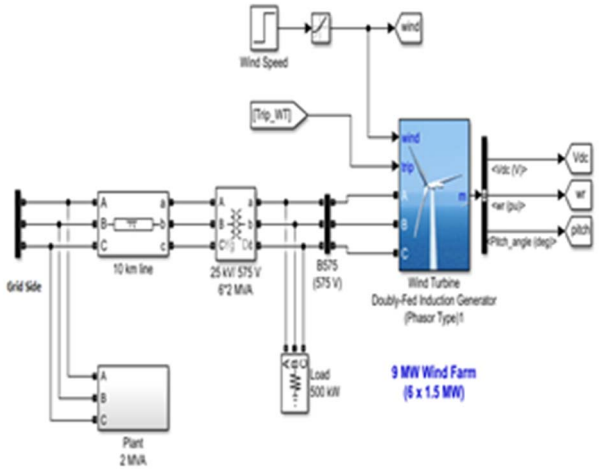

Fig. 2 Grid connected wind farm Simulink model.

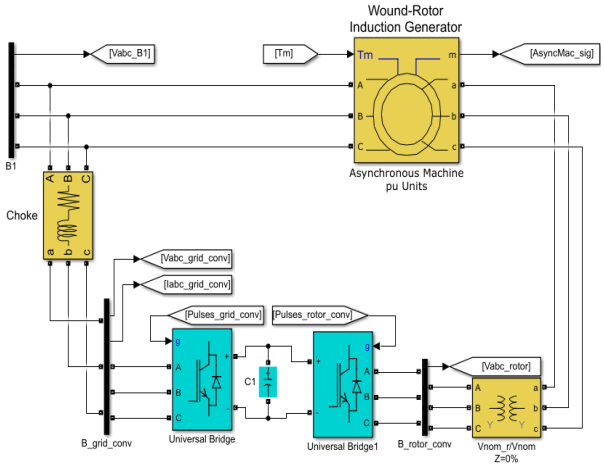

Fig. 3 Doubly Fed Induction generator (DFIG).

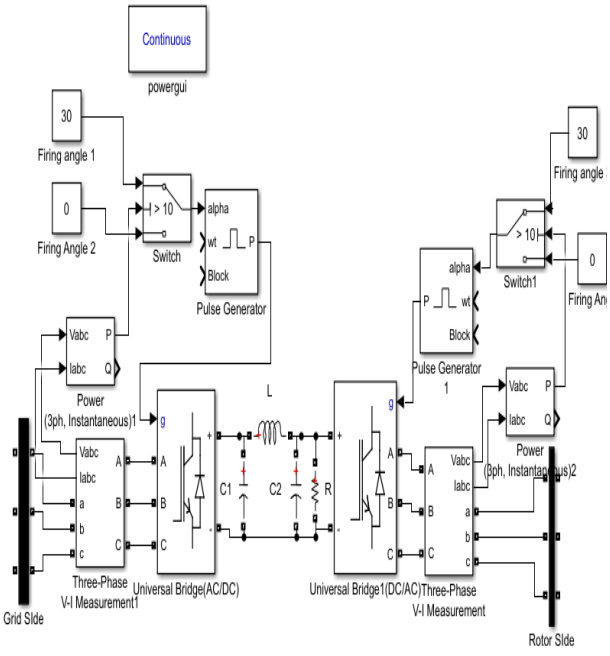

Fig. 4 Back to Back converter (AC/DC/AC) circuit

controlled Doubly Fed Induction Generator (DFIG) [25].The converter associated with DFIG is divided into two components: the grid-side converter (C_{grid}) and the rotor-side converter (C_{rotor}). Fig. 4 shows a converter circuit for controlling both the grid side and rotor side active power.

C_{grid} and C_{rotor} are force commutated Voltage-Sourced Converters that employ power electronic devices (Power MOSFET, IGBTs) to synthesize an AC voltage from a DC voltage [26], [27]. The DC side capacitor acts as the DC voltage source. The coupling inductor, L employs to connect $C_{grid}$to the grid. The brush helps to connect the three phase stator winding to the grid directly and slip ring applies to associate $C_{rotor}$with rotor winding [28].

The induction generator converts the power captured by the wind turbine into electrical power and transmitted to the grid.In Doubly fedInduction generators instead of the field winding is fed by a DC voltage and a stator winding where generates electricity; there are two individual three-phase windings, one stationary and one rotating [29]. One winding is directly connected to the grid and generates 3-phase AC power at the synchronous grid frequency. The other winding generally is known as field winding or rotor winding is connected to 3-phase AC power via a converter to create variable frequency [30]. This input power is adjusted in frequency and phase to compensate for changes in the speed of the turbine. The converter of the rotor side creates the desired magnetic field by controlling its current. The rate of rotation of the output magnetic field is the sum or difference of the rotor rate of rotation and the electric rate of rotation. If the desired frequency 50 Hz, but the shaft of the wind turbine is rotating at 49 Hz, the converter can drive the winding on the rotor with 1 Hz and the output frequency of the generated electricity will be 50 Hz.

In this way, the output frequency will always be in sync whatever the wind turbine speed is. By controlling the rotor currents precisely, the induction machine output power can be controlled. The frequency synchronizes efficiently with the grid frequency while the speed of wind varies [19]. The relationship between stator power and voltage with rotor current shows in (2), (3), (4) and (5) given by [20].

$$P_g = P_s + P_r = -\frac{V_s E_{eq}}{X_{eq}} \sin(\theta - \delta) \quad (2)$$

$$Q_g = Q_s = -\frac{V_s E_{eq}}{X_{eq}} \cos(\theta - \delta) - \frac{V_s^2}{X_{eq}} \quad (3)$$

$$V_s = j\omega_s L_s I_s + V_b \quad (4)$$

$$V_b = j\omega_s L_m I_R' \quad (5)$$

Where

P_s = Stator active Power
P_r = Rotor active power
P_g = Active power of grid
Q_g = Reactive power of grid
Q_s = Stator reactive power
δ = Blade Pitch Angle
V_s = The voltage of the stator
V_b = The back-EMF voltage induced in the stator by rotor current, I_R.
X_{eq}, E_{eq}= Impedance and voltage of DFIG equivalent circuit respectively
L_s,X_s&L_m=stator Inductance and Mutual Inductance

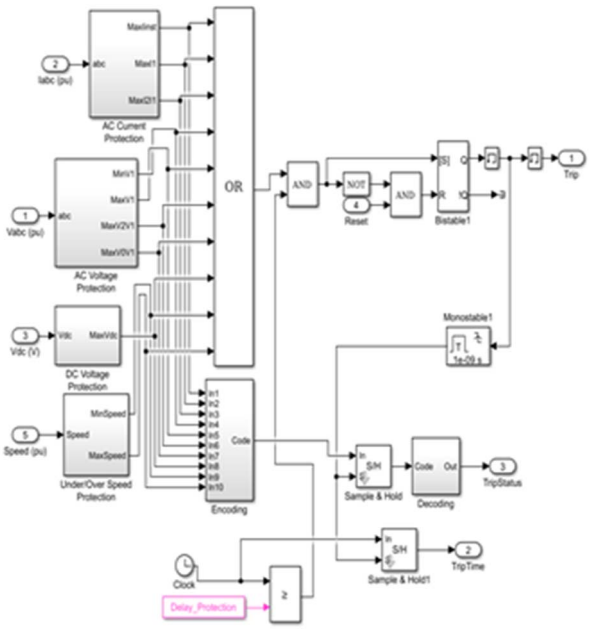

Fig. 5 Logical unit for wind turbine protection.

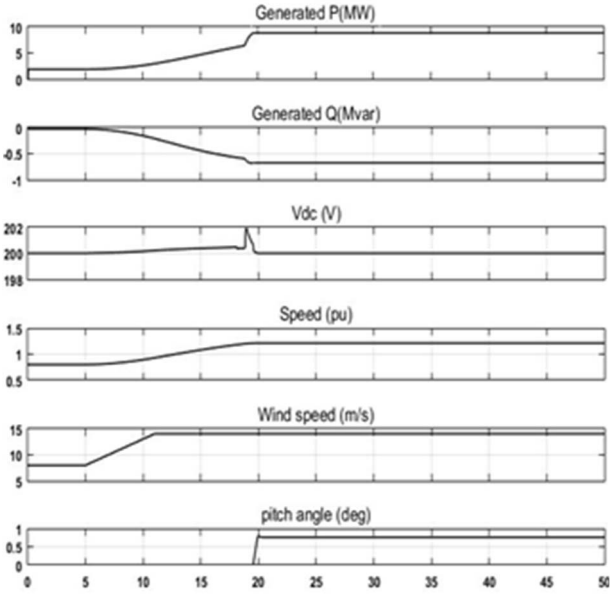

Fig. 6 Turbine response curve for maximum predefined wind speed 15 m/s.

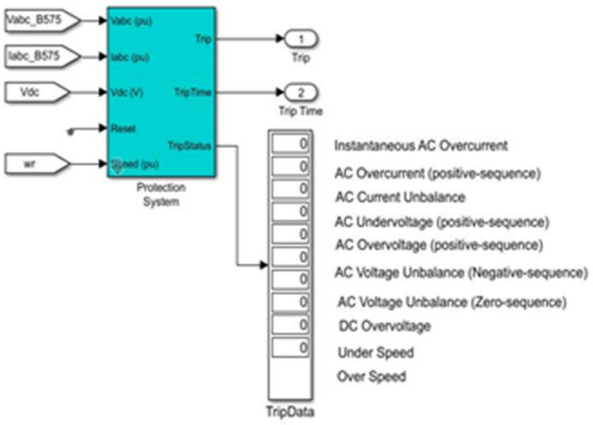

Fig. 7 Wind turbine protection module data (trip status) for maximum predefined wind speed 15 m/s.

The control system induces the voltage control command signals V_{gc} and V_r for C_{grid} and C_{rotor}respectively. By changing the firing angle of power electronics switch, the universal converter can control the power generated from the wind turbine, the reactive power, the DC bus voltage or the voltage at the grid point.

A. Rotor side converter

The rotor-side converter presented in Fig. 4 controls the voltage (or reactive power) and the wind turbine output power. The output power is controlled on the basis of a tracking characteristic which provides a pre-defined power-speed information and maintains the rated output frequency.

B. Grid side control system

The converter of the grid side shown in Fig. 4 regulates the DC bus capacitor voltage. In conclusion, the wind farm empowered a grid converter to produce or dissolve reactive power to adjust the frequency.

V. WIND TURBINE PROTECTION

A trip input is used to provide protection for the wind turbine in an abnormal condition. Fig. 5 indicates a logical unit for wind turbine protection. The block reaches a conclusion about disconnecting wind turbine from the grid on the basis of specific inputs at unexpected conditions.

When any specific input level crosses its reference level, the logical output will be high, both the grid and rotor side are decoupled the wind generator.

VI. SIMULATION RESULT ANALYSIS

The steady state and dynamic performance of a wind farm using The Doubly Fed Induction Generator in MATLAB Simulink R2017a is analysed. The wind farm consists of six 1.5 MW wind turbines. The farm transmits power to a 120 kV grid through a 30 km long 25 kV feeder under 25 kV distribution systems. A 2300V, 2 MVA plant consisting of a motor load (1.68 MW induction motor at 0.93 PF and 500 kW load) is also connected on the 575 V bus of the wind farm.

A. Wind turbine response to a change in wind speed

Initially, wind speed has kept hold at 8 m/s, and then at t=5 Sec., wind speed accelerates to 14 m/s. Waveforms for a squall of Wind (which is in Voltage Regulation Mode) is illustrated in fig 6 where a frequency adjusting converter associate for a grid-connected wind farm. At t=5 Sec., the active power generated from the wind farm elevates smoothly (together with the turbine speed) to reach its rated value of 9 MW in approximately 15 Sec. Over that time period the turbine speed raises from 0.8 pu to 1.21 pu.

At the beginning, the pitch angle of the turbine blades is set to zero degrees. If the wind speed reaches beyond its rated maximum value, the pitch angle is changed from 0 deg to 0.76 deg to limit the mechanical power. Fig. 6 conveys that the pitch angle remains in its initial value zero up to maximum wind speed.

If the wind speed reaches beyond is a predefined maximum value, pitch angle increase with the increase of wind speed to divert the turbine blade out of the wind gust with turbine speed to adjust the system frequency to its

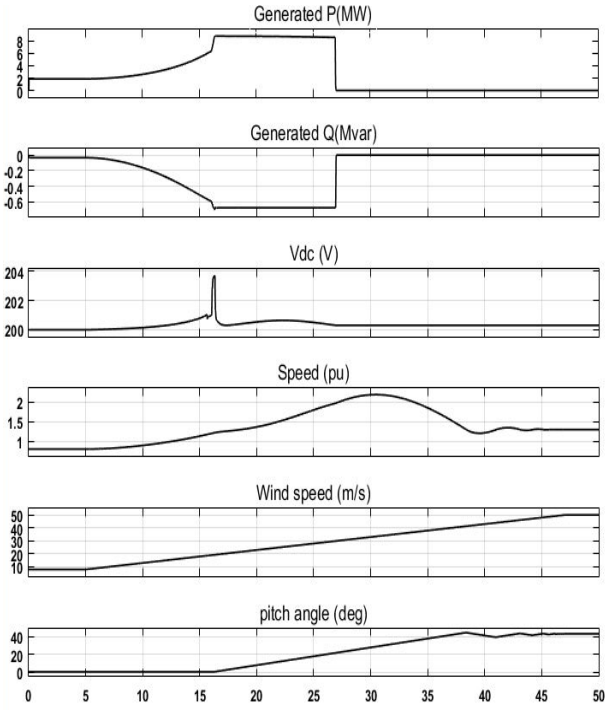

Fig. 8 Turbine response curve for wind speed 50 m/s.

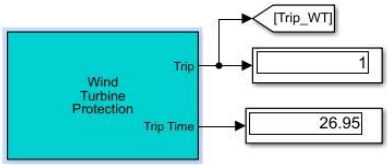

Fig. 9 Wind turbine protection module data (trip time) for over speed wind.

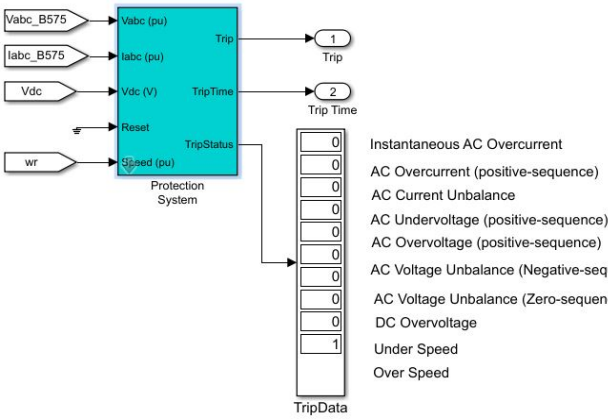

Fig. 10 Wind turbine protection module data (trip input) for over speed wind.

constant value.All the trip status is zero shown in the trip module (Fig. 7) as the wind turbine is operating in between its maximum level.

Fig. 8 implies that the pitch angle of the turbine changes rapidly with the change of wind speed. This is done so to keep the rotor blades at the desirable angle to maximize output in all wind speeds. Blades are angled to protect the wind turbine from wind gust or over speed wind. Fig. 8 also

implies the fact that the power generated from wind turbines is zero when wind speed is over than predefined maximum speed. At that moment trip circuit activated and disconnects the wind farm from the connecting grid.

Fig. 9 and Fig. 10 shows when wind speed (50 m/s) is over than predefined maximum speed (15 m/s), the trip input is high in the wind turbine protection module. The wind turbine trips at 26.95 Sec when the wind speed reached over than maximum speed.

VII. CONCLUSION

In concern to the energy demands and environmental prospect, wind energy is considered as one of the best and clean solutions. But the integration of wind energy in the exciting grid introduces few factors of uncertainty. Interaction of feedback control, intelligent power electronic based controller could improvise frequency adjustment mechanism as well as system instability by ensuring system protection. The analytical study of this paper emphasizes on the fact that a well-designed interfacing of power electronics based converter with grid-tied wind farm can effectively and efficiently synchronize frequency between the power system grid and wind farm by controlling active power and the pitch angle. Also a smart logic control block can protect the coupling structure of grid-tied wind farm in unanticipated wind speed condition. The limitation of this paper is that the other feature of the trip module is not included in the discussion.

Abstract – This paper implies and demonstrates a unique Smart Autonomous power and switch controlled Led Street Lighting System for Bangladesh. As we live in the age of globalization where streetlights are very much important for a city infrastructure in the crowded regions, the autonomous power and switching of these streetlights can have a huge impact in our electricity usage and minimize the wastage of electricity. Usually street light is needed at the time of sunset until the sunrise, but during peak hours (time 17:00 pm to 20:00 pm), the electricity demand is higher than electricity supply from the National Grid for many under developing countries including Bangladesh as this is the high time of excessive usage of Home Loads like Television, Air-Cooler etc. Proposed herein is a design and practically implementation of a smart autonomous power and switch controlled street light system by using stored solar energy during peak hours and light dependent resistor based energy efficient automatic Streetlight switching rather than the conventional switching operations. Besides temperature sensor and Real time clock (RTC) are being attached to display the updated time and temperature to the nearby passengers of the vehicles and walkers of the street sides. Thus, proper implementation of the proposed system will be able to be a medium for an energy efficient circuit, national grid's power scarcity minimizer and free cost of energy and high reliability.

***Index Terms* - Relay operation, Light Dependent Resistor (LDR), LED Street light, Temperature sensor, Real Time Clock, ARDUINO UNO.**

I. INTRODUCTION

In this modern globalization, Power Scarcity Minimization is the biggest challenge and responsibility whereas natural coals and fossil fuels are at empty line. Lighting is one of the biggest power consumption load and most expensive burden for the under developing countries like our Bangladesh. Recent studies shows that one of the most expensive and vital responsibilities of a city which accounts almost 10% to 38% of the dissipation on electricity [1]. A critical and crucial duty of public officials is Street lighting which has a strategic impact on the stability of social and economy for under developing and developing countries. 8 to 10% of the whole lighting occurs outdoor lighting including traffic lights, street lights and vehicle parking lights [2].

Some of the developing and under developing countries have several outdoor lighting studies,for example, India's central public officials have found the estimation in 2010-2011 of power consumption for public lighting to be about 6.7 TWh annually [3]. Indonesia's officials found on average 15 to 30% consumption occurs for street lighting [4]. Whereas, Libya's street lights causes about 50% power dissipation of the total lighting consumption [5].

In Bangladesh the total road length is mentioned as 4,21,117 km in Local Government Engineering Department (LGED) sites.[6-7] The data shows a diversity of 3,69,999.95 km of rural roads, 30,000 km city roads and 21,118 km of Highways. As a result, approximately 60 to 80 lac street lights are needed to be lighten up the streets of Bangladesh every day. Until now 200-250 watt Pressure Sodium Vapor Lamp (HPSV) are being vastly used in the street of Bangladesh where around 5.475 TWh-7.120 TWh electric energy is needed in every year which is 3.67% to 4.8% of total generation [8] This implies almost 23% to 39% of the total lighting consumption of this street lights considering as per wattage and one light per 100 m road length.

TABLE 1: COMPARISON BETWEEN HPSV AND LED LAMP

Lamp Type	Wattage (W)	Efficiency (lm/W)	Life Span (Hours)
HPSV	**215-250**	**50-150**	**15000**
LED	**15**	**70-160**	**50000**

To get such assumptions the annual Cost of Street lighting is calculated using equation (1) where C is the total annual cost, W is the wattage, H refers the daily working hours, P is the price of electricity in KWh, N is the number of Street lamps.

$$C = (W \times H \times P \times 65)/1000 \quad (1)$$

Power Savings is calculated by equation (2) where S is the Power saving variable in percentage, U1 is the previous lamp's energy dissipation, U2 is the lamp's energy dissipation.

$$S = ((U_1 - U_2)/U_1) \times 100\% \quad (2)$$

Annual Energy Consumption is calculated through equation 3 where E is the annual energy dissipation,

$$E = (W \times H \times 365 \times N)/1000 \quad (3)$$

Battery Requirement (AH) to be calculated by equation (4) where T is battery back up hour, V_b is Battery voltage and Pf is power factor of the source.

$$A_H = (W \times T)/(V_b \times P_f) \quad (4)$$

Minimum charging current required for Battery I is measured by equation (5) where Ta is active Solar Radiation Hours,

$$I = \frac{A_H}{T_a} \quad (5)$$

Required Panel Watt-Peak Wp is measured by equation. (6) as follows:

$$W_p = (W \times T)/T_a \quad (6)$$

Required Solar Panel wattage as Ws is measured by equation (7) where η_s is the efficiency of the System and P_v is the efficiency of the Photovoltaic Solar Panel,

$$W_s = W_p/(\eta_s \times P_v) \quad (7)$$

On the other hand, If LED 60 Watt Street Lights are being used instead of HPSV, 1.314 TWh to 1.71 TWh electric energy will be needed in every year which is 0.88% to 1.15% of total generation power and 13 to 29% of the total lighting dissipation. The two comparisons represents a 4.161 TWh-5.41 TWh energy saving (and 76%) in every year just by using LED instead of HPSV lights. So a crucial conclusion can be provided by the data that for the current scenario of Bangladesh, the usage of LED lights can be the best solution for the street lighting because of the highest energy saving and efficiency.

II. Proposed Design and Hardware Architecture

Improper lighting is dangerous for public transportation where as traditional lighting infrastructures of streets can be mostly improper with huge financial and energy drain. Fortunately, there's a proper, smarter and cost-effectively designed street lighting infrastructure proposed in this paper with a very simple circuit and several feasibilities that will operate automatically on the street lighting on/off with relay coupled. It enhances well enough to find out objects nearby.

TABLE 2. Utilized Components for the Design

Component's Name	Specification
Arduino Uno	Version R3, 5watt, 7-12 volt
LM35	3 pin, 5volt, 10 mv/°C
LDR	1.8 kΩ - 4.5kΩ, 600 nm
RTC	DS1307
5V Relay Module	10 A, Active low
Small LED Strip	60 watt
Battery	12 V
Potentiometer	10KΩ
Resistor	10KΩ
Breadboard	
80 watt Solar Panel	
Charge Controller	
DC Adapter	230 V AC to 12 V
LCD Display	16×2

This circuitry and hardware is very easy to operate and it permits low power dissipation as very few numbers of components have been used.

A. Arduino Uno

Arduino Uno R3 is an ATmega328 AVR based microcontroller board which offers DIP (dual-inline-package) and removable IC with 20 digital i/o (Input/Output) pins. Out of them 6 pins can provide PWM outputs and another 6 pins can have analog inputs. Programs using C++ language provided by IDE platform can easily be loaded into it. The programs can be loaded Computer USB hub. Arduino has an openly extensive supportive community, which is a open source platform for everybody. So it is very easy for the embedded electronics based projects to get started working.

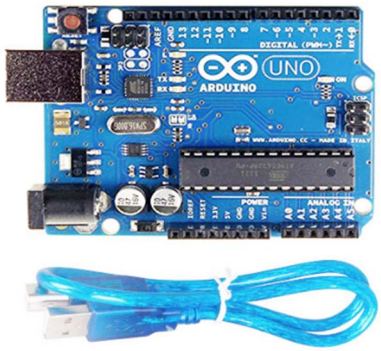

Figure 1: Arduino Uno R3 [9]

It has 16 MHz resonator and 16k flash memory. It consumes too little power and it has the feasibility to use pins for any projects. Sensors can be interfaced with this micro-controller. Data from the sensors can be read easily through ADC (Analog to Digital Conversion) method and based on that data, i/o pins can be controlled as required to any projects. Those pins can be worked as digital signal producer. Whenever the signal is high it means 5V has been provided on the selected pins by the micro-controller or, data has been sent to the output devices. Whenever the signal is low it means the pin is connected with the ground and data can be received. [9]

B. Temperature Sensor-LM35

It is a temperature sensor which is used to measure temperature. It has 3-pin, middle pin works as an output which changes depending on the temperature changes. For every 10MV change in output it indicates 1° C change in temperature.

C. Light Dependent Resistor (LDR)

LDR is a light intensity based sensor whose sensitivity changes depending on the light intensity poured on it. When the increasing strengthen light falls on LDR, the resistance of LDR decreases, and the vice versa.

In darkness when there is not enough light to see anything, the resistance of LDR shows the range of resistance in mega ohms, and when presence of light or in brightness increment occurs then the resistance decreases and shown by few hundred ohms. Based on that resistances variation light intensity measurements are done and decisions are made based on those measurements.

D. Relay Module

Relay is an Electro-Mechanical switch which takes digital or logical signals from various micro-controllers, ICs or chips like Arduino, 8086, AVR, ARM, PIC, DSP, PLC, MSP430, TTL etc. It can be Multichannel and different voltage and current rated. In our case, 5v, 10A 2-Channel active low Relay interfacing was done with the micro-controller board Arduino Uno R3. These relays are used to control any kinds of high current electrical appliances and equipment with safety. These

relays can be controlled through directly with 3.3V or 5V logic output signals from any microcontroller.

E. Real Time Clock (RTC) Module

Real Time Clock (RTC) which is a clock module can provide local time from local time zone. One of the modules of RTC is DS1307 which has 8 pins with an I2C capabilities. The DS1307 consumes very low-power time clock with calendar with SRAM of 56 bytes battery backup. The module provides time as seconds, minutes, hours, and date as day, month, year from local qualified data. Each month's end date is smartly adjusted, for those special months which are less than 31 days. RTC has an integrated circuits (ICs) and it can be easily supervised of timing just like a clock. In addition, it can operate date just like a year calendar. The main feasibility of RTC is that it has a setup of battery backup which helps the module running though there is no power provided externally. As a result, it can keep and continue the clock/calendar. There are many applications of RTC module like integrated and embedded in several systems for example mother boards of computers.

F. Implemented Resistors

Resistor is the most basic passive electrical component with two unidentified terminals that is applied to manage and limit the flow of current in any closed circuit. Current which flows through a resistor is directly proportional to the appearing voltage drops across the resistor. Resistors are of two types –
i) Fixed Resistor – having a fixed resistance value.
ii) Variable Resistor – whose resistance can be varied or changed for example a variable resistor of 8K can be used for the value of resistance from 0 to 8 KΩ
In the proposed design a 10KΩ resistor has been used.

III. FRAMEWORK

In the proposed circuit, Arduino Uno R3 microcontroller has been implemented as the brain of the hardware, which actually reads data from the sensors and takes proper decision based on that data. Arduino reads data from any sensor's voltage which is digitally converted from analog Signal and give an output as numerical format depending which the micro-controller is programmed to take decision independently. Based on those decisions Arduino is programmed to make its output pin high or low.

The very next task of the hardware was done by the Relay which has been used as an active low operational device hereby. This means if any grounding point can be provided then the relay coil will be operational by completing the relay circuit with the combination of magnetic field and mechanical contact. The circuit has two relay operations hereby as there are two power sources which are Battery and national grid.

Additionally, RTC is used to provide time from local time zone and simple interfacing with Arduino Uno. LM 35 temperature sensor is used to read atmosphere temperature and give the projection of daylight. Meanwhile, LCD display has been used to represent the local time and daily temperature to the passerby.

A. Proposed Design

The proposed Smart automatic power and switch control Led Street Light system can be divided in four main parts: The working principal of each part has been described hereby.

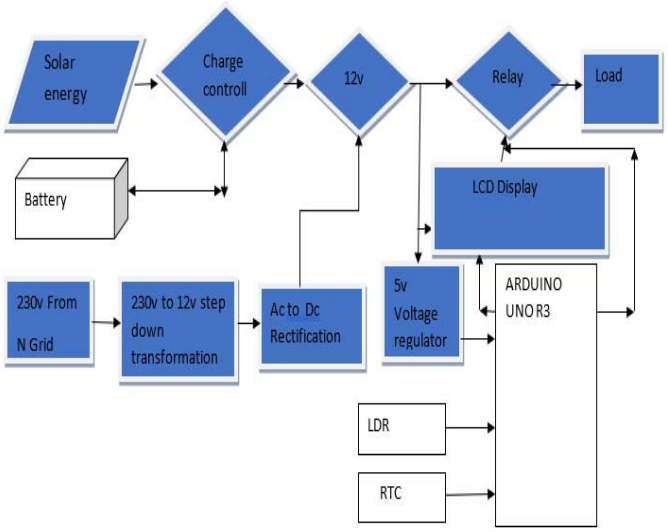

Figure 2: The block diagram of the proposed System

B. Battery and Solar panel setup

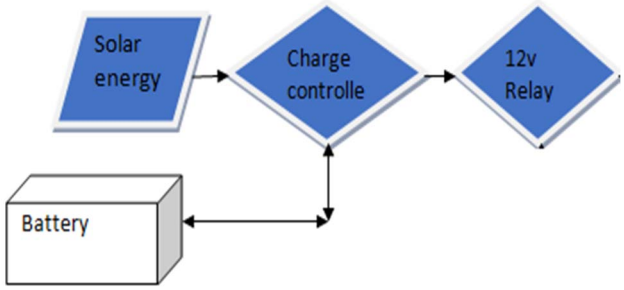

Figure 3: The block diagram of the battery and solar panel setup

During day time the electricity is produced by solar panel then the electricity is stored in battery by the charge controller after that the stored energy active the 12v relay and work as source as well.

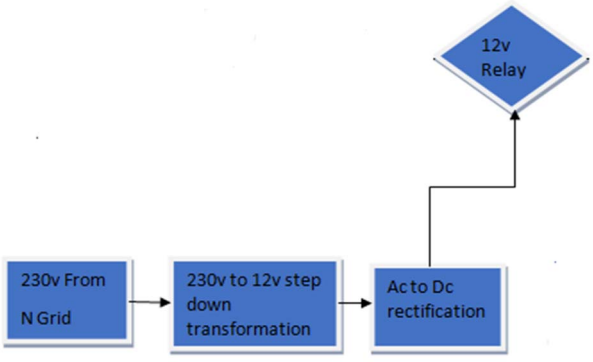

Figure 4: The block diagram of the grid and relay setup

C. *National Grid Connection*

The conventional street light has electricity connectivity which is connected with National grid, then converts 230v AC to 12v AC after that modify 12v AC to 12v DC using rectifier and filter circuit, However the 12v DC always work as backup power, when the battery power is finished then 12v DC will work automatically by the help of relay .Here12v dc relay is used to permit which source will be used, that means output of the relay will act as 12v DC source constantly.

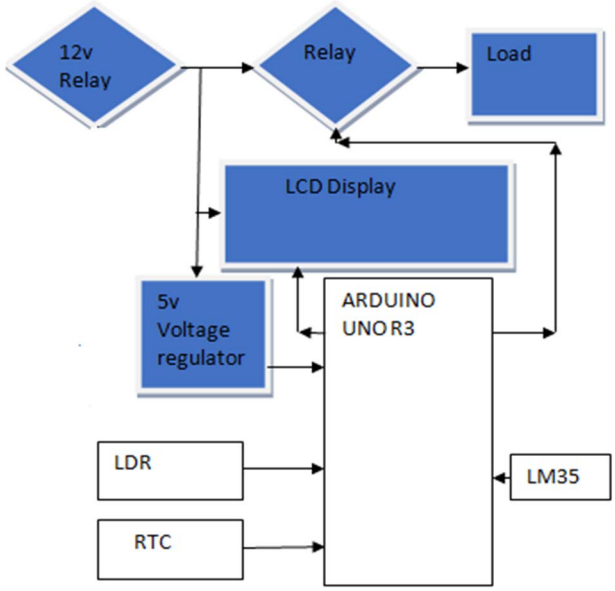

Figure 5: The block diagram of process of voltage regulator

Here, the output of the Relay is considered as the source of the rest of circuit, which is 12V DC. As we know, ARDUINO or Microcontroller needs fixed 5v supply power for long time service that's why we use 7805 voltage regulator to get fixed 5v power for ARDUINO and other appliances.

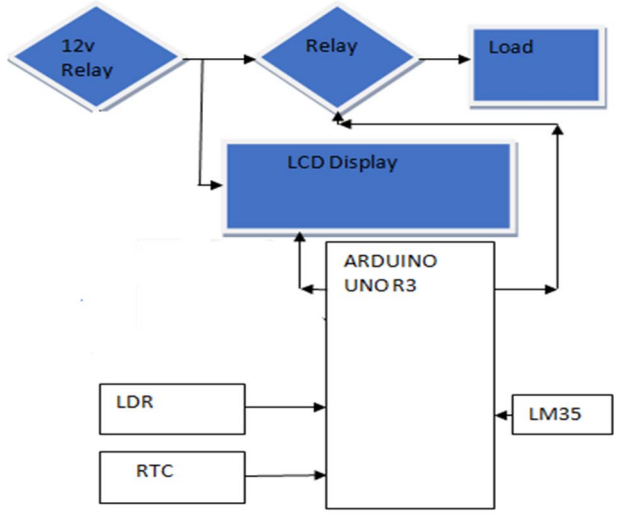

Figure 6: The block diagram of central circuit

ARDUNO Board used as the brain of entire part of street lights. The Light Dependent Resistor (LDR) can sense daylight and dark and send analog signals to the ARDUNO Board, according to ARDUINO processed LDR data the 5v relay will operate switching ON or OFF the load automatically. Temperature sensor senses Current temperature and produce analog also the Real Time Clock (RTC) produce analog signal as well.

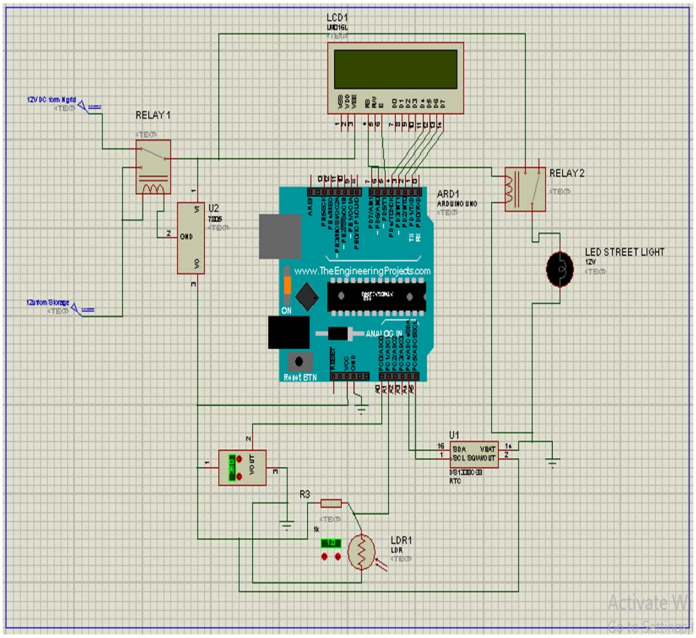

Figure 7: Proteus design of the Smart automatic power and switch control LED Street Light.

According Temperature sensor and RTC data the display will show current time and temperature which helps the people who are traveling or walking on the road.

D. *Experimental Work*

In This project the main focused was on Practical implementation of a cost efficient and highly reliable automatic power and switch control streetlight control system where used two sources of power and display will show local time and temperature. The main difficulty of Current conventional streetlight use only one source either from national grid or storage energy which charge up from solar panel and old switching system is wastage of power.

The project aims are to fabricate and Practical installation a highly reliable Smart automatic power and switch control Led Streetlight system which has two types of sources to reduce energy crisis during peak hours. Usually street lights are needed after sunset to sunrise using either energy directly from national grid or directly stored energy form solar panel (where needed higher rated solar panel and Battery for 6
Hours backup)

Figure 8: Practical installation of the proposed project.

The solar panel converts solar energy to electrical energy presence of sunlight then the electricity is stored in battery by the charge controller after that the stored energy activated the 12v relay and worked as the source as well.

The conventional street light has electricity connectivity which is connected with National grid which converts 230V AC to 12V AC and modifies 12V AC to 12V DC using rectifier and filter circuit. However, the 12V DC always works as a backup power, After peak hours or when the battery power is finished it will shifted automatically by the Relay operation to alternative source which is 12V DC converted energy from national grid. Here12v dc relay is used to permit which source will be used, that means output of the relay will act as 12v DC source constantly.

ARDUNO Uno Board has been used as the brain of entire controlling circuit of streetlights. Here the output of Relay conducted as source of the rest of circuit, which is 12V DC. The control circuit requires fixed 5v DC to operate, that's why we use 7805 voltage regulator to get fixed 5v Dc power for ARDUINO and other appliances.

The present streetlight systems has enormous amount of power wastage due to conventional switching operation. The Light Dependent Resistor (LDR) used to sense daylight, dark and send analog signals to the ARDUNO Board. The Analog signals from the LDR are processed in Analog to digital converter (ADC) of the Microcontroller, A code Written in C language and the program is dumped into the microcontroller, according to LDR data the microcontroller generates signals to activate or deactivate the relay for switching ON or OFF the streetlight automatically. This system is efficient automatic switching control.

Temperature sensor senses Current temperature and produce analog also the Real Time Clock (RTC) produce analog signal as well. The Signals send to the ARDUNO Board. According Temperature sensor and RTC data the display will show current time and temperature which helps the people who are traveling or walking on the road.

IV. Result Analysis

The Smart automatic power and switch control Led Street Lights Are necessary in today's life for safety issues and eliminate unexpected accidents during night. Providing street light is important and more expensive of any city. Usually street lights are needed after sunset to sunrise using either energy directly from national grid or directly stored energy form solar panel (where needed higher rated solar panel and Battery for 12 hours backup)

It is being known that during peak hours (time 5pm to 10pm) the electricity demand is higher than electricity supply of many countries for instance, Bangladesh. This project is designed for two types of sources; these are stored energy from solar panel and energy from national grid. During peak hours the street lights will run by stored energy from solar panel and after peak hours it will shifted automatically by Relay operation to alternative source which is DC converted energy from national grid. As a result this system can reduce energy crisis during peak hours also utilize power of national grid by street lights after peak hours (because after peak hour energy is less). However the solar panel and Battery size will reduce using this idea.

From the proposed design the annual Consumption of Energy is found to be 131.4 KWh through equation03 where W=60 watt LED Bulb, H=6 hours for a single lamp during the pick hour when demand is high. This amount of energy is provided by our system which is from the solar energy. Battery Requirement is found as 30 AH by equ-4 where T=6 hours, Vb=12 volt and Pf =1 as dc power source.

Charging current (minimum) required for 30 AH Battery I is calculated as 4.29 Amps. by equation 5 where considering Ta =7 Hours

Required Solar Panel Peak wattage Wp is measured as 51.5 watt by equ. (06) and Rated Solar Panel wattage, Ws is found 80.5 watt by equ. (07) where considering ηs =80% and ηpv=80%

Power Savings of national grid by our system is calculated through equ-02 where U1 =213.6 KWh and U2 =131.4 KWh. We found 38.5% power savings and minimization of pick demand may occur just because of our proposed hardware And 76% power savings can be done just using the LED light.

Annual Cost minimization for a single Street lighting is calculated through equation (1) and found that worth of 1314 BDT can be saved through our system [P=10 BDT in pick hours in KWh].

In large scale for example 1 lac street light, 13.14 GWh energy demand can be minimized and around worth of 130 million BDT can be retained just for using free solar energy.

A. Cost Analysis

The costing is done for single Street lighting System. In large scale installation the costing would be 70 to 80 percent less.

Single Street Lighting system's initial installation cost can be retrieved in 6 years approximately through the service we are getting from it.

TABLE 3 : COST EVALUATION OF THE PROPOSED SYSTEM

Sl	Equipment name	Price (per unit) BDT	Net Price BDT
1	Solar panel (80 watt)	50	4000
2	Battery 30AH	3000	3000
3	Hardware(Arduino Uno R3, LDR,LM35)	600	600
4	Led street lamp (60 Watt)	300	300
5	RTC Module	100	100
Total costing			8000

Table 2 shows how much we have to invest to produce the system where a power generation small unit also present. On the other hand convention system only consumes power where National Grid is the only power provider and no alternative power generation can be done through it.

B. Findings

The whole analysis and findings are summarized in a table would be helpful to make comparison between our system and the previous system. [10] The table 4 shows a summarized view of the findings of the system where it shows 38% demand minimizing capability of it. In this modern era, where power is a very serious issue this percentage can have a huge impact in the economical and infrastructure of the country. One of the alternative solution of resolving the electricity crisis is by implementing solar plants which gives energy free of cost except plant installation cost which is very less comparing with other power plant.

TABLE 4: COMPARISON BETWEEN CONVENTIONAL AND OUR PROPOSED STREET ELECTRIFICATION

Technology	Annual Energy Consumption		Demand Minimizing of National Grid	Energy Savings
	National Grid	Solar powered Battery		
Previous and Conventional Street lighting system	100%	0%	0%	0%
Our Proposed Street Lighting System	40%	60%	38.5%	76%

Table 4 shows how much Energy burden on National Grid can be reduced and energy savings can be done through our proposal in practically over conventional street lighting system. Above comparison and benefits shows that our system will be very handful for our motherland Bangladesh. Both people and government will be benefited highly which shows that Our Street lighting system is the best option for our Bangladesh. Not only that there are some features which makes our project proposal more useful and those feature can be operated with Zero Cost.

VI. CONCLUSION

As being a part of the resident of developing country, some necessary initiatives should be taken as soon as possible to solve the most challenging fact of power crisis of this country. In this aspect the proposed Smart Autonomous Power and Switch Controlled Led Street Lighting system will be the first initiative to overcome the situation. Our Government and Officials of Electrification Board of Bangladesh should think about the present situation of Power generation and be cautious about using the electricity for any purposes. As it has been represented here that the system is helpful and enormously beneficial for the power crisis, it can be implemented practically with further advancement to make it applicable in the Street Lighting Sector by which power crisis of our motherland can be slightly solved by minimizing the power loss and applying the renewable solar energy in this sector.

***Abstract*—The potential of wind energy in Bangladesh is not so good but has reasonable prospect if modern technology and optimum design of air foils and blades can be used. Coastal regions of Bangladesh including Cox's Bazar, Chittagong, Teknaf, Patenga, Mongla, and Kutubdia, are most suitable points of harnessing wind energy. Although the velocity of wind in these regions is not perfect for harnessing energy from a big sized wind turbine rather it is quite capable to generate electricity from small sized turbine in an efficient way. Vertical axis wind turbine (VAWT) is perfectly appropriate for extracting the maximum power from wind in such low wind speed area. NACA foil is mainly prioritized to build this type of small sized VAWT system because of the low maintained mechanism. The small-sized VAWT system needs more analyzed wind data to work in an optimized condition. The positions and efficiency of the turbine system are highly dependent on the blade lift and drag coefficient because of random wind flow directions. Counting all these points, this paper examines the wind data available in these areas, and describes the design of a vertical axis wind turbine (VAWT) suitable for small sized electricity generation system in an efficient way by optimizing turbine blades and its foil mechanism.**

Keywords—Vertical Axis Wind Turbine; Power Generation; Coastal areas; Blade design; Windpower

I. INTRODUCTION

The electricity generation is increasing rapidly due to it's high demand [1]. Currently, the energy is produced mostly from fossil fuel as its main sources. The use of these non-renewable fuel sources has genuine harmful effects on surrounds. An abnormal amount of fossil fuel uses can cause several environmental damages like ozone layer exhaustion, acid rain, climate change and so on [2]. It is obvious that fossil fuel is decreasing over the period due to excessive use to generate power. To slow the decreasing rate of fossil fuel and make environment more reclamation, renewable energy is the only alternative solution except nuclear energy which has great negative impact and risk for the livable environment. Currently, many countries adopted renewable energy as their primary electricity generation sources over fossil or nuclear because of less or negligible effect on the environment. Besides the renewable sources are quite available and affordable. There is no cost in raw renewable energy sources.

Also, harnessing wind energy across all over the globe is increasing due to raw energy availability and use of a higher grade of optimized technology. Most of the European countries are adopted this energy expansion over other regions of the globe because of huge availability of wind in these areas.

The situation in Bangladesh is quite different where most of the power generation system is fully depended on conventional fuel sources and alternate energy development is not making that much impact over this. But the development in the solar system is really appreciable in renewable sector although the expansion is not fully satisfactory yet [3]. Currently, different approaches are taking place to improve this solar energy and make it more handy and mainstream. To increase renewable energy generation in this country the only focus on the solar system is not quite enough. Finding the availability of other sources like wind, geothermal, tidal, hydro, biomass, etc. and harnessing energy from these sources are relatively challenging [4]. Few small-sized winds or biomass projects are taking place although most of them are only showcasing the structure and lies on idea of the projects, and many of them are not in working conditions. The main reason behind this kind of wasting technology and resources is the lack of adequate analysis and modification of the technology suitable for Bangladeshi weather and environment. In the context of Bangladesh, the wind has a great prospect. Maybe the available wind energy is not capable to harness a huge amount of electricity but it is quite capable to generate in a micro amount in an efficient way [1, 5, 6]. Currently, the annual average wind velocity in Bangladesh is 2 m/s which is quite low to develop the huge size wind turbines all over the country [5, 6]. But the coastal regions and some hilly areas of Bangladesh has a reasonably good average wind speed to demonstrate the wind energy harnessing in an effective way [1]. The availability of electricity is not regular in these hilly or coastal regions. Hence proper utilization of wind energy can make an off grid or on grid network suitable for home, small business model, several types of commercial enterprises and so on [7]. Proper installation of a bunch of wind turbine can also use for harvesting crops, pumping drinking water which can significantly reduce the use of diesel generator [2]. Still different NGO and government do not show proper interest for harvesting this energy due to the absence of appropriate information about wind velocity, mechanism, weather adjustment, and its future opportunities to expand with latest available technology [1, 5]. Hence the available wind velocity is not adequate for normal or high-speed turbine system, only low-speed turbine system is more efficient over the existing available model.

Counting all these obstacles, the focus of this research work is to examine the actual wind prospect in the coastal region of Bangladesh to determine the available energy and analyze of airfoils to develop a vertical axis wind turbine (VAWT) perfectly suited for low-speed wind to extract the available energy with the maximum efficiency. In low-speed small size power generation, VAWT is much smaller and work efficiently over horizontal axis wind turbine (HAWT). The analysis of air foils of the turbine blade is done using QBlade software which is specially design for existing and new type blade foils analysis made by Hermann Föttinger Institute of TU Berlin.

II. Wind Prospects in Coastal Region of Bangladesh

Currently the electricity generation in Bangladeshi grid is quite high but most of them are directly or indirectly depend on fossil fuel [2], although most of the coastal areas are not grid connected. The geographical position of Bangladesh is one of the biggest advantages over other small countries because of comparatively large coastal regions. Figure 1 shows the coastal area geographically where the scope between 20°34'- 26°38'N and the longitude between 88°01-92°4E [2]. Strong wind flows are fairly available in the southern part of Bangladesh where 724 km longest coastline is located with 200 km long hilly areas [6]. The average wind velocity in these areas are recorded 5 m/s or greater at a height of 20-30 meter which has decent potential to feed small-sized wind turbine [6, 8, 9]. Although some projects like Kutubdia island and Muhuri dam has been established long ago but all of them are out of order because of lack of proper knowledge about wind prospect and maintenance. Bangladesh government along with several NGOs do some research earlier where it shows clearly that to generate electricity now in a small amount, the desired wind velocity is available from late March till the beginning of October and the maximum peak will be in June-July [1, 6]. Besides coastal areas, many waterfront areas, for instance, Teknaf, Patenga, Cox's Bazar, Chittagong, Hatiya, Mongla, and Kutubdia can also potentially stable to generate wind energy because of availability good wind velocity [10]. The average wind velocity in these areas are recorded to be precise around 3.5 m/s [10, 11].

III. Analysis of Wind Velocity at Coastal Regions

To find out the optimum energy generation in coastal regions of Bangladesh, at first it is needed to analyze the wind velocity, air density on that areas and maximum power calculation for the desired system carefully.

A. Wind Data Analysis

It is quite important to measure the minimum, maximum and the average wind velocity on that particular area where the wind turbine system is supposed to be installed. Table I shows the monthly measured average wind velocity of some coastal regions targeted for wind turbine installation. The wind velocity is measured at a height of 20 meters from the ground [11]. The average yearly maximum wind velocity has been recorded 5.52 m/s and the yearly average minimum wind speed is 2.44m/s where May and July can be considered as the most prospective months and November to January can be considered as the least prospective month for wind power extraction. This indicates a good amount of wind energy can be harvested and utilized during the monsoon period in the coastal regions of Bangladesh [7].

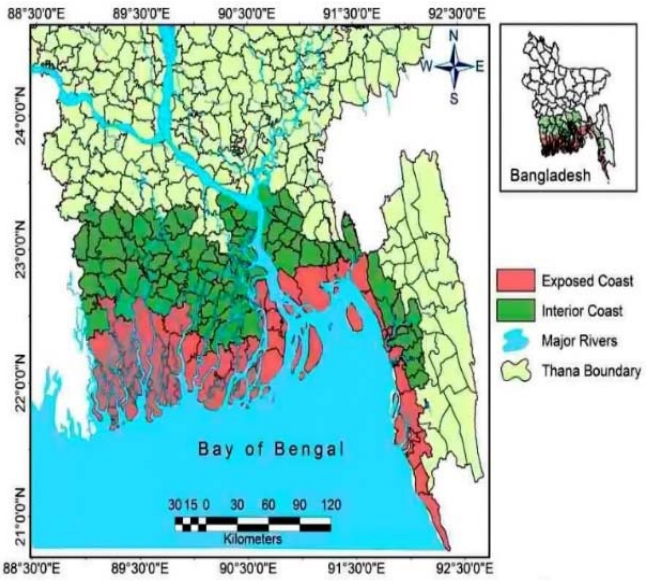

Fig. 1. Wind Prospective Coastal Regions in Bangladesh

B. Wind Velocity Calculation

The wind shear exponent can be used to determine the velocity of wind, v at a reference height, h_{ref} and wind velocity at practice height, h [11–14] as equation (1) and plotted in Fig.2.

$$v = v_0 \left(\frac{h}{h_{ref}}\right)^{\alpha} \quad (1)$$

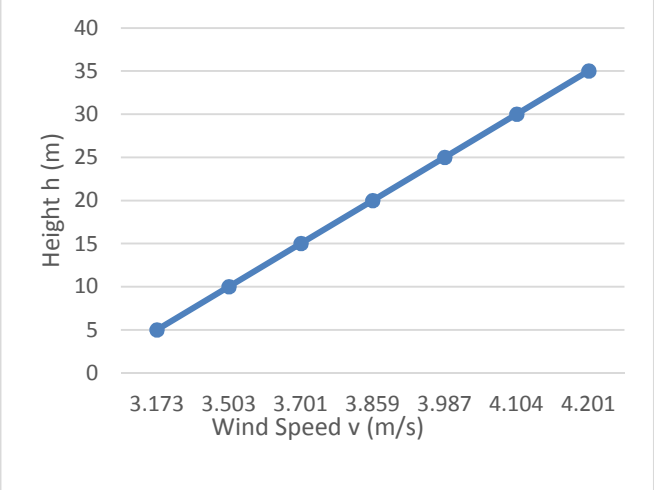

Fig. 2. Height from ground vs. wind speed

C. The Density of the Air Factor

The density of the air, ρ is the mass per unit volume of Earth's atmosphere. Power extraction from a wind's kinetic energy significantly depends on various factors such as air moisture and air density. Here the density of the air has been considered since it has a great impacts during power extraction. Within a settled atmospheric pressure, a list of the density of the air at various temperature is given in Table II [15]. In this research work ρ =1.16 kg/m^3 is considered as the average coastal temperature is 30℃ in Bangladesh.

Table I. Wind Speed (m/s) at a height of 20m in Various Coastal Areas of Bangladesh

Locations	Monthly wind velocity (m/s)												Yearly Maximum	Yearly Minimum	Yearly Average
	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec			
Chittagong	3.65	2.87	4.94	5.02	5.52	6.88	7.08	6.85	4.63	2.81	3.38	2.21	7.08	2.21	4.66
Cox's Bazar	3.76	3.86	4.53	5.56	3.84	4.13	3.84	3.96	3.21	3.27	2.58	3.27	5.61	2.58	3.82
Teknaf	3.71	4.01	4.39	4.02	3.33	3.88	3.85	2.71	2.43	2.21	1.58	1.77	4.38	1.58	3.16
Hatiya	3.05	2.64	4.18	3.98	4.83	6.48	5.76	2.63	2.97	2.78	3.07	2.58	5.76	2.58	3.73

Kutubdia	1.78	1.82	2.34	2.74	2.78	3.66	3.62	3.15	2.12	1.46	1.18	1.28	3.66	1.18	2.32
Mongla	1.06	1.25	1.76	2.52	2.93	2.64	2.47	2.36	1.84	1.26	1.03	1.02	2.93	1.02	1.85

D. Calculation of Maximum Available Power

The kinetic energy available in the wind cannot be converted more than 59% into the mechanical energy as stated in Betz law where practically the power extraction is usually calculated less than 45% [11]. By considering VAWT's rotor blades swept area, $A = rl$, the velocity of air = v, length of the VAWT blade = l of the density of the air = ρ and the theoretical Betz limit C_p=0.59, the output power, P (maximum) availability can be calculated by,

$$P_{available\ (max)} = \frac{1}{2}\rho A v^3 C_P \qquad (2)$$

By considering the average wind velocity from the height 5m to 15m, v= 3.437 ms^{-1} as calculated in section III.B, length of the blade, l= 10m, the radius of a swept area by blades, r = 3m, the total swept area can be calculated, $A = 30\text{m}^2$, air density, ρ = 1.16 kg/m^3 as measured in Table II, Betz coefficient, C_p = 0.59 (theoretical) and considering Betz coefficient, C_p = 0.35 (practical), the maximum output power availability for the proposed low-speed vertical axis wind turbine (VAWT) can be found using the equation (2) as

$$P_{available\ (Max)} = \frac{1}{2}\rho A v^3 C_P$$
$$= \frac{1}{2} \times 1.165 \times 30 \times 3.437^3 \times 0.59$$
$$\approx 480W\ (theoretical)$$
$$P_{available\ (Max)} = \frac{1}{2}\rho A v^3 C_P$$
$$= \frac{1}{2} \times 1.165 \times 30 \times 3.437^3 \times 0.35$$
$$\approx 270W\ (practical)$$

Table II. Air density vs. Temperature

Temperature, T (℃)	Air Density, ρ (Kg/m^3)
35	1.143
30	1.165
25	1.184
20	1.204
15	1.226
10	1.247
5	1.269
0	1.292

IV. Design of Blades for a 250W VAWT

A. Calculation of Blade Radius

In consideration of the average wind velocity as calculated in section III.B (from height 5m to 15m), v = 3.437 ms^{-1}, desired output power, $P_{desired\ (Max)}$= 250W, density of air at 30℃ temperature, ρ = 1.165 kg/m^3 (as measured in Table II), and considering the Betz coefficient, C_p ≈0.35 (practical), the blade radius, r can be determined using eq.(1) as

$$r = \sqrt{\frac{2P_{available\ (max)}}{\rho v^3 C_P \pi}}$$
$$= \sqrt{\frac{2 \times 250}{1.165 \times (3.437)^3 \times 0.35 \times 3.1416}}$$
$$\approx 3.0\text{m}$$

B. Selection of Air Foil

There are lots of NACA airfoil models available right now. For low-speed small size VAWT system, numerous studies suggested that NACA 0021 is one of the lightest weights, robust, efficient and shapeable air foil. As the blade length covers 2/3rd of the entire pole which is 15m in length and the velocity of wind is under 5 ms^{-1}, weight is the primary reason to select NACA 0021 airfoil as for the research. Another important goal is to reduce the cost as the NACA 0021 air foil is one of the low costs and commercially available airfoils which is suitable for small size low-speed blade. With a wide operational range, this airfoil performs at its best with an optimum efficiency [15, 16]. Selection of the air foil in the Qblade simulation software with 21% thickness and 100 measurement points are shown in Fig. 3. The operational points and air foil pressure point analysis of the blade (NACA 0021) are shown in Fig. 4 where the angle of incidence α = 18 (as simulated).

Although blades of VAWT generally operates in high inflow angle range, due to the limitation of the simulation software used in this study, the airfoil's inflow angle range is limited to take from -25° to +25° as shown in Figs. 5-8 where the curve shows the coefficient of lift vs. coefficient of drag behavior, lift coefficient vs. pitching moment coefficient analysis and incidence angle vs. pitching moment coefficient

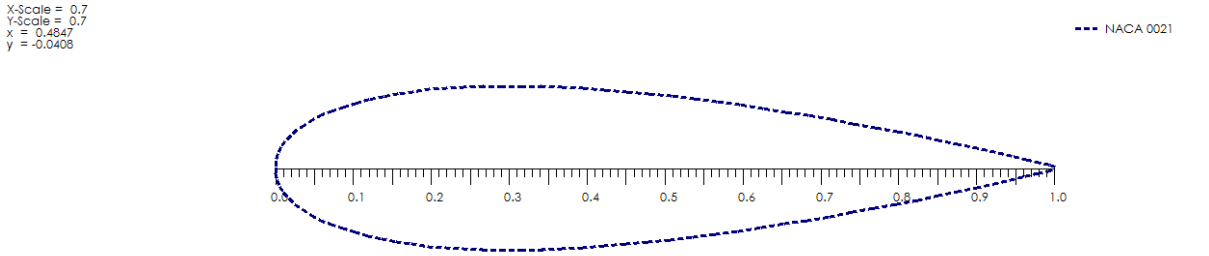

Fig. 3. NACA 0021 Airfoil Selection

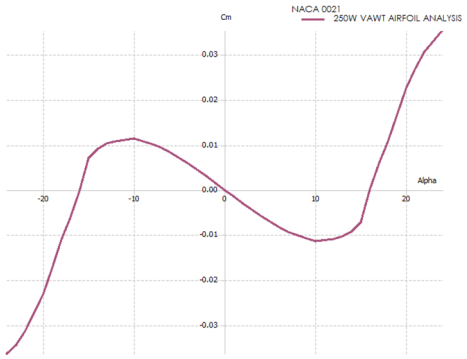

Fig. 7. NACA 0021 Incidence angle, α vs. Pitching moment coefficient, C_m (inflow angle -25° to +25°)

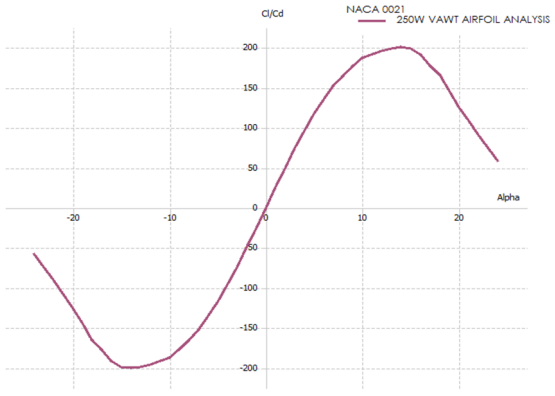

Fig. 8. NACA 0021 Glide ratio C_l/C_d vs. Incidence angle, α (inflow angle -25° to +25°)

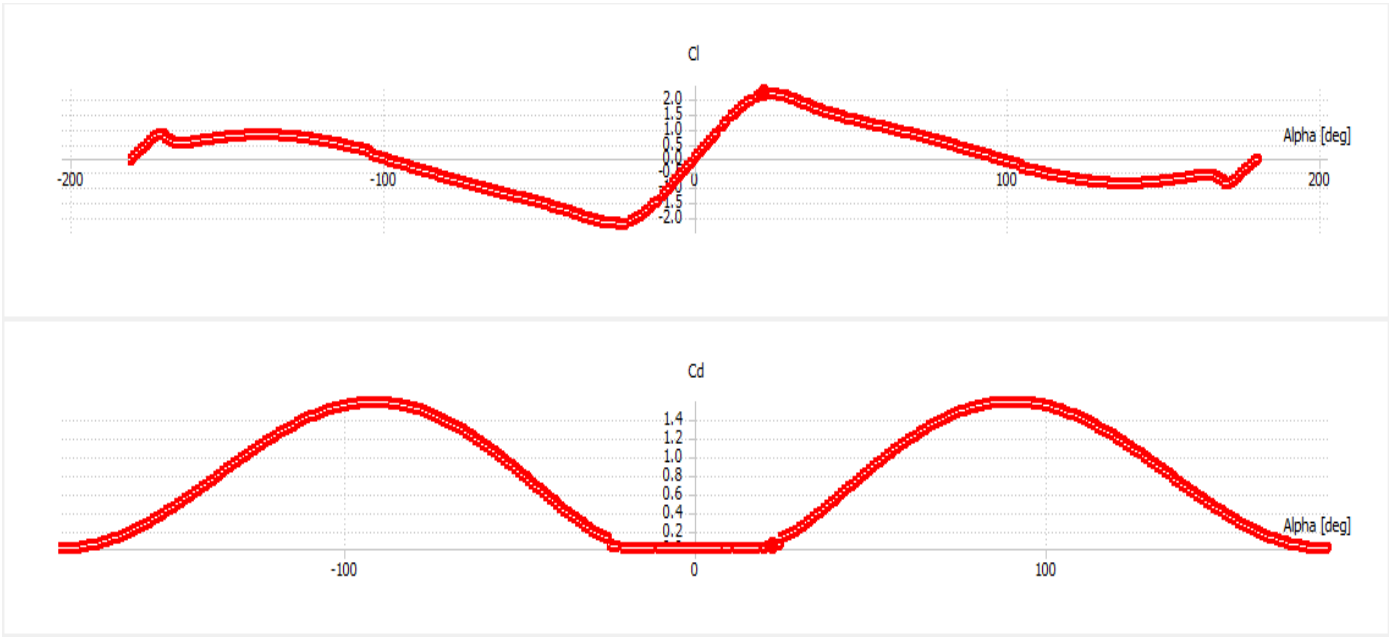

Fig. 9. 360 Polar extrapolations of NACA 0021 airfoil responses

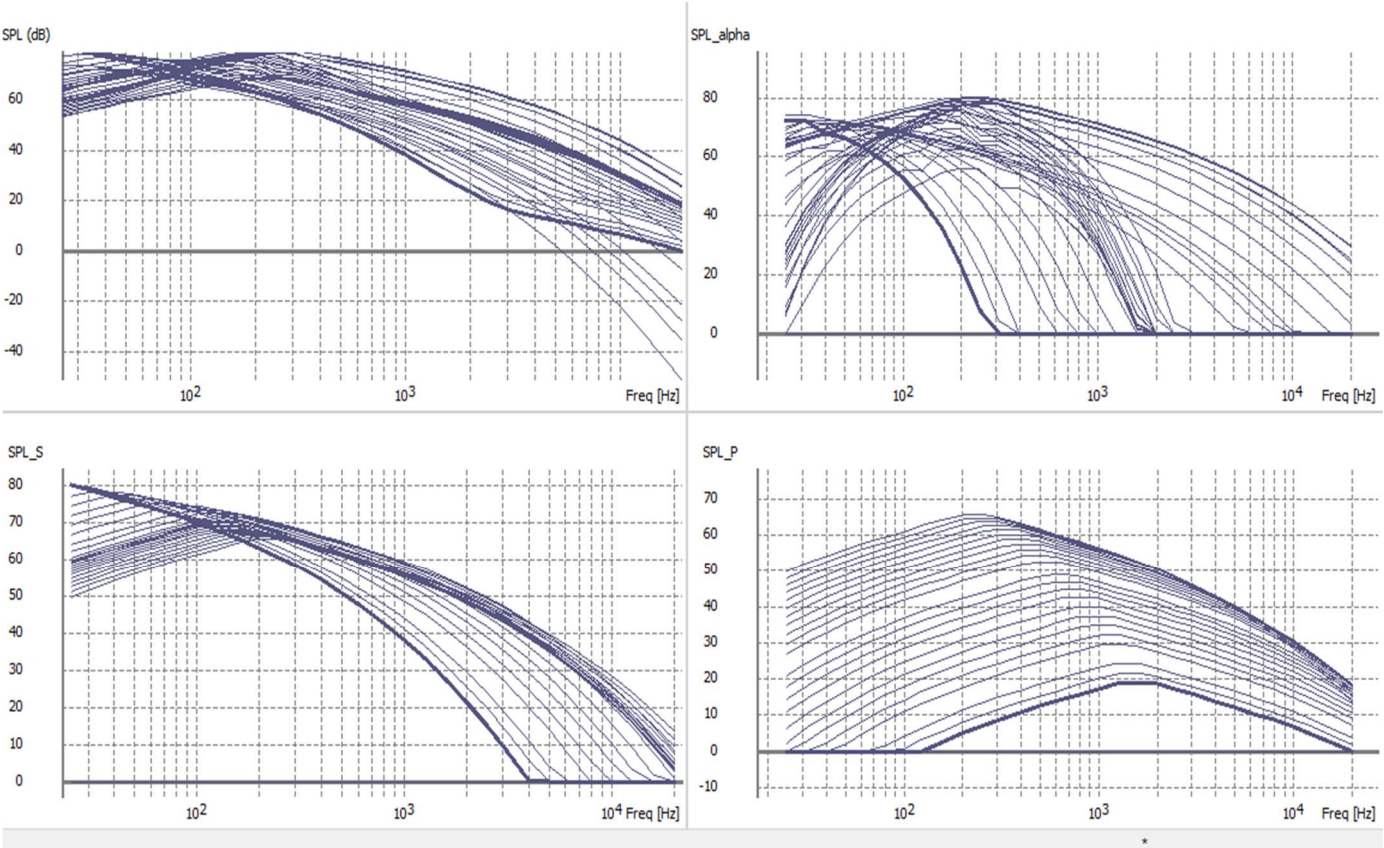

Fig. 10. Noise simulation of NACA 0021 at all operational points

with Glide ratio vs. Incidence angle, respectively. To minimize the limitation, an extrapolation of 360° of the inflow angle has been executed within the Qblade in order to converge in practice and to achieve an error-free analysis as shown in Fig.9, where angle of incidence = α , coefficient of lift = C_l, lift = L, coefficient of drag = C_d , drag = D and pitching moment coefficient = C_m.

A simulation of possible noise and interferences at different operational points are made within the Qblade as shown in Fig.10. For the purpose of this research, NACA 0021 Airfoil analysis was made to understand the blade element momentum theory. To find out the response of the selected airfoil drag, lift, the angle of incidence, glide ratio and other coefficients were analyzed. The 250W low-speed VAWT's designed blades with single blade view and rotor view using NACA 0021 air foils at different points of the blades are shown in Figs. 11 and 12, respectively, which will be used to install the wind power system in the proposed location.

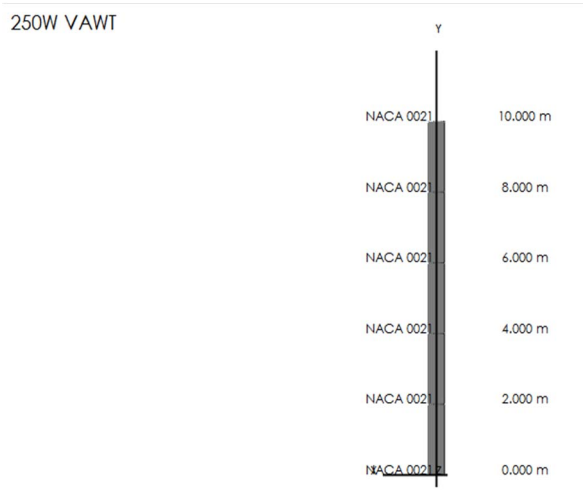

Fig. 11. Design of the Blade

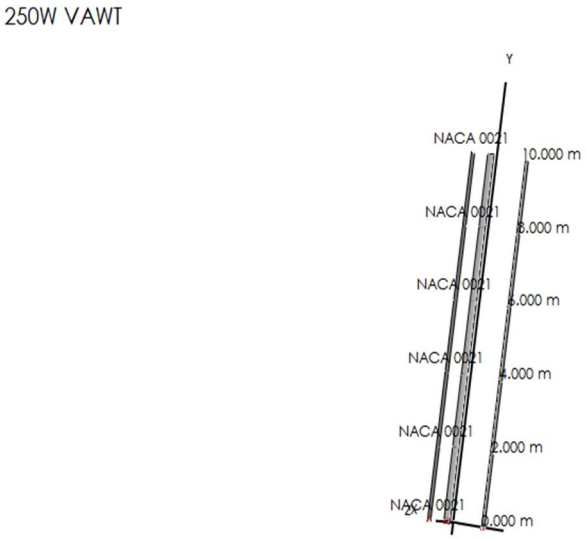

Fig. 12. 3-Blades rotor view

V. CONCLUSION

In this research work, the theoretical and statistical analysis have been studied for a small-sized low-speed vertical axis wind turbine perfectly suitable for the areas where wind velocity is quite low like coastal region of Bangladesh using NACA 0021 airfoil. The pole heights of the VAWT is keeping optimum to build at a low cost and can extract the efficient energy from available wind. In a small scale, the vertical axis turbine makes smaller in diameter and protect all the system quite well than horizontal axis turbine. That's why the VAWT is used here for low wind flow rate. Single airfoil can make this blade more robust and maintenance free. This type of small system is good for power solution for thousands of people living in these areas which can significantly reduce the pressure on fossil fuel and can have some contribution to growing electricity demand.

sajjatulislam@ciu.edu.bd

Abstract—**One of the worst epidemics in the history of mankind is the deadly disease known as cancer. There are several types of cancer and the one that is more commonly heard of these days is leukemia. There are two types of leukemia – acute myeloid leukemia (AML) and acute lymphocytic leukemia (ALL) – and the purpose of this study is to take into account the gene expression data of several people and predict what type of leukemia they have by using three machine learning algorithms, XGBoost, Random Forest Classification and Artificial Neural Networks. The dataset's dimensionality was reduced using principal component analysis (PCA) before using the algorithms on them.**

Keywords— **genetics, leukemia, cancer, machine learning, xgboost, neural networks, pca, random forest**

I. INTRODUCTION

Death and destruction have been in the history of humankind ever since its inception. Wars and conflicts have taken many lives while via atrocious means and it is perhaps no different now. However, war and conflicts are not the only aspects sweeping humankind as diseases have taken a prominent place in the society. One of the deadliest among them is cancer. This is a disease that has taken a lot of lives and is continuing its surge by clasping people in its claws. According to the World Cancer Research Fund [8], approximately 17 million people have been afflicted with cancer in 2018, out of which approximately 437000 cases were of leukemia, which constitutes of 2.6% of all cancer. Researchers are desperately trying to eradicate this abomination and this is where machine learning could come in handy.

The first step to solve a problem is to be aware that the problem exists. In other words, knowing the type of cancer a person has as soon as possible can help the rejuvenation process take place faster. With the advancement of technology, humankind has been able to store gargantuan amount of data. With this data, researchers can use Machine Learning algorithms to find patterns and then predict something before anything else can. The process used in this study is also similar as the main idea is to take the genetic expression data and use it to find out the type of leukemia a patient has via supervised learning. At first, the dataset that consists of 7129 independent attributes was narrowed down using principal component analysis and then XGBoost, Artificial Neural Networks and Random Forest Classification was used in order to correctly classify the type of leukemia that a specific person has.

This study can be confined and indexed down to five sections. While the next section – II – constitutes of the literature review in this field, Section III defines the system used for the purpose of this study. The experimental design is expounded in Section IV and the results are offered in Section V before finishing off by giving a conclusion in Section VI.

II. RELATED WORKS

Cancer forecast is one of the most investigated subjects around the earth because of its unmatched prominence. In [1], the researches reveal that ALL have a distinguishing gene expression outline that is stable with an early hematopoietic antecedent articulating select individual HOX genes and multilineage markers. They also added that clustering algorithms reveal that lymphoblastic leukemia with MLL translocations can evidently be alienated from conventional acute lymphoblastic and acute myelogenous leukemia. The researchers in [2], meanwhile, predicted malignancy with 98.14% on Wisconsin's Breast cancer dataset with the use of numerous if-then rules and J48 classifier. In the following study [3], Bellaachia et al. proved that C4.5 was the best at accurately predicting cancer whilst having variables like race, marital status, age, tumour size and so on. The 86.7% accuracy of C4.5 beat the other two techniques, Naïve Bayes and Neural Networks.

The researchers in [4] executed a detailed study of numerous exploration papers and associated a surfeit of data mining techniques to settle that data mining is very beneficial for forecasting the probabilities of breast cancer as it delivers respectable accuracy rates. For [5], the authors discovered that Naïve Bayes was the best technique to predict lung cancer as it could thoroughly identify the variables. The other techniques they used were if-then rules, Neural Networks and Decision Trees. In [6], Decision Tree came out victorious when it came to predicting the malignancy of a tumour. They used various mining techniques but Decision Tree gave the highest accuracy of 93.62%. For the agricultural research in [7], Dey et al. used four mining techniques and a equation of their own to forecast the harvest of rice in Bangladesh. At the end of the study, they found out that their non-linear modified regression equation produced the best results overall.

III. LEUKEMIA TYPE RECOGNITION SYSTEM (LTRS)

A. Data preprocessing

The system with which the analysis was done is encapsulated in the Figure 3.1 below.

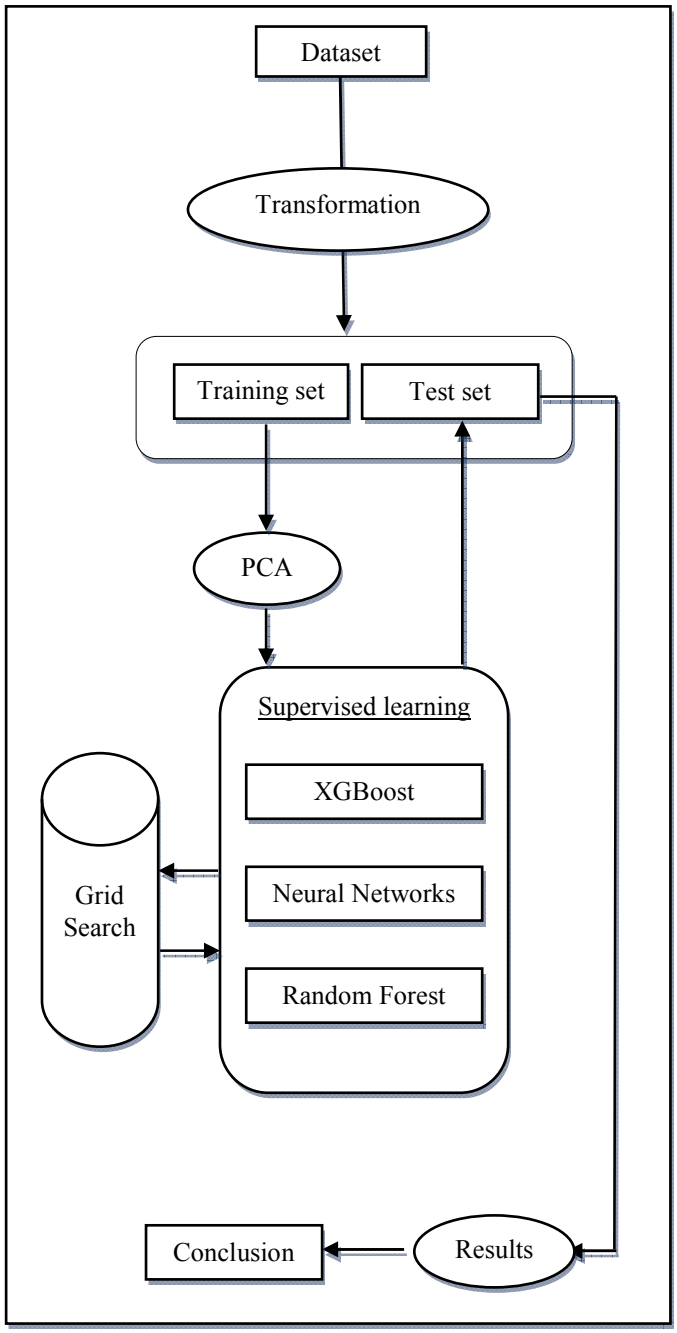

Figure 3.1: Leukemia Type Recognition System (LTRS)

To further elaborate, the dataset containing the genetic expression had to be transformed at first for the purpose of the study. After that, they were split into two: training set and test set. With the use of Principal Component Analysis (PCA), the dimension of the independent variables in both the training and test set was reduced to just 6 components from a whopping 7129. PCA is an unsupervised dimensionality reduction technique. The goal of PCA is to identify the patterns in the independent variables of the dataset and then detect the correlation between them. The idea behind PCA is to find the direction of maximum variance in a high dimensional data – such as this dataset – and then project it into a smaller dimensional subspace whilst also keeping most of the information provided by the dataset. PCA can be defined by the following steps:

1. Standardising the dataset
2. Obtaining the eigenvalues and eigenvectors from the correlation matrix or just perform Singular Vector Decomposition
3. Sorting the eigenvalues in descending order while selecting the k eigenvectors that relate to the biggest eigenvalues, where k is the number of dimensions of the new subspace
4. From the chosen k eigenvectors, construct a projection matrix, W
5. The final step concludes the transformation of the original dataset, X, using the projection matrix W as a means to obtain the k-dimensional subspace Y.

After reducing the dimension of the large dataset, the training set was passed on for supervised learning with the use of three Machine Learning algorithms: XGBoost, Artificial Neural Networks and Random Forest Classification. They are classification algorithms and were chosen because of the fact that the output is binary (which suits classification more) and that the computational requirement to run these aren't very high. Most importantly, for a dataset like this, classification algorithms give better accuracy.

B. Extreme Gradient Boosting (XGBoost)

Extreme Gradient Boosting, or simply known as XGBoost, is among the most powerful gradient boosting algorithms created for the purpose of not only speeding up the execution but also improve the performance of the model. It has become renowned in Kaggle for its competition-winning ability. The principle idea behind XGBoost is to combine many 'weak learners' trees to form a strong learner that performs better and much faster than the others. The number of boosted trees to fit in this model was set at 40 while the booster used was gblinear.

C. Artificial Neural Networks

Scientists have been trying to make systems that can work like the human brain. Artificial Neural Network (ANN) is basically an attempt simulate the working methodology of the brain. The brain consists of many neurons that send and receive signals, allowing humans to make a decision accordingly. The idea behind ANN is similar as there are layers of neurons connected to each other to make a network. Some networks are feed-forward, which means that it only moves in the forward direction but the one used is back-propagated, wherein the error between the test result and the

actual result is sent back to the network as means to adjust the weights and reduce the error rate in the following cycle. This is the oversimplified idea of ANN.

Delving deeper, Neural Networks can consist of many layers between the input layer and the output layer. When the input layers are fed with the data, it passes it to "hidden" layer in the middle, whose neurons then add a weight to the information received from the input layer. Every neuron adds up the input it receives and only "fires up" if the sum of it is more than the threshold value. The threshold here is, simply, decided by the activation function and for this study, the activation function used for the hidden layers is Rectified Linear Unit. It is one the most popular functions in Neural Networks and can be represented as follows:

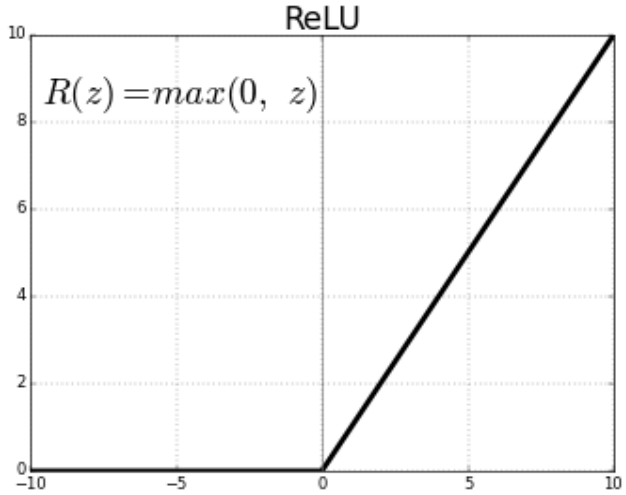

Figure 3.2: Rectified Linear Unit activation function [9]

For the output layer, another activation function was used. Since the output has only two types – acute myeloid leukemia (AML) and acute lymphocytic leukemia (ALL) – the sigmoid activation function was used as the output for this function is constrained to either 0 or 1.

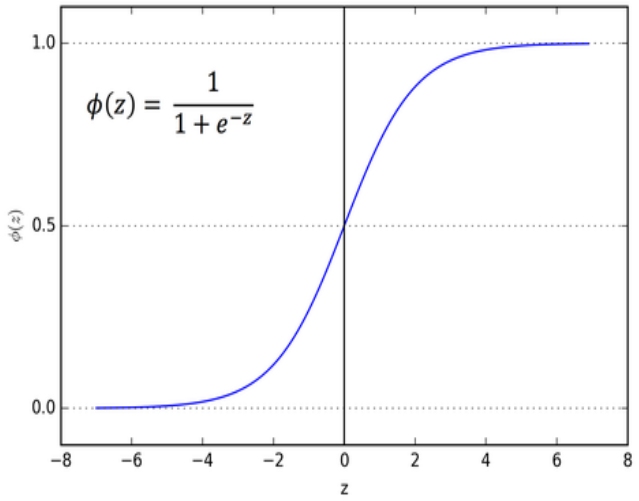

Figure 3.3: Sigmoid activation function [10]

After that, the output is cross-checked with the real result and if there are errors, the feedback is given to the network. This is basically back-propagation since after being made aware of the feedback, the hidden layers adjust the weights as a means to reduce the error rate in the next epoch. An epoch is simply the cycle from the moment the data enters to the input layer(s) to the moment an output comes about. For this study, an epoch of 100 was chosen. Since PCA reduced the dimensionality to 6 components, the input layer for this ANN had 6 neurons. Furthermore, three hidden layers with 6 neurons each was chosen as it gave the best results.

D. Random Forest Classification

Random Forest Regression basically chooses some data points in the dataset and builds a decision tree associated to those points. After that, multiple decision trees are built to cover the entire dataset. Once it is done, a new data point's category is chosen by a voting system, wherein the trees will predict where the new point belongs and the category that gets the most votes will have the new point. This procedure can be narrowed down to four steps:

1. Select random data points, K, from the training set
2. Build a decision tree based on those selected K data points
3. Choose the number of trees, N, to be built and repeat steps 1 and 2
4. To predict which category a new data point belongs to, assign the new data point to the category that gets the most votes from the decision trees

For this study, the number of trees used for Random Forest Classification was set at 10 with minimum sample leaves per node kept at two and minimum sample split at 0.1.

E. Grid Search

After training the algorithms with the data, the best hyper-parameters were selected using Grid Search. Hyper-parameters are parameters whose values can be chosen by the user. For instance, the number of trees in Random Forest Classification is a hyper-parameter. Parameter tuning optimizes the model to such an extent that the accuracy of the prediction increased. To find out the best hyper-parameter values, Grid Search was done on the dataset corresponding to the classifier (or learner) to find the best parameter values for that specific classifier. For instance, to find out the optimal hyper-parameter values for Random Forest Classification, once the Random Forest classifier was trained with the training set, the classifier along with the training set was passed onto Grid Search, which then scans the data to find the optimal hyper-parameter values corresponding to the Random Forest classifier. This is how the hyper-parameter values for Random Forest Classification, ANN and XGBoost was found out. After that, those values were implemented on the classifiers and they were once again trained on the training set.

F. Evaluation

The results were then obtained by running the trained learners on the test set and evaluated using Accuracy, Precision, Recall and F1 score. For the context of this study, where the objective is to predict the type of cancer, Accuracy and modified F1 score are given the highest priority. They are calculated as follows:

1. Accuracy = (True AML + True ALL)/Total data points
2. AML Precision = True AML/(True AML+False AML)
3. AML Recall = True AML/(True AML+False ALL)
4. AML F1 score = 2 * (AML Precision * AML Recall)/(AML Precision + AML Recall)
5. ALL Recall = True ALL/(True ALL+ False AML)
6. ALL Precision = True ALL/(True ALL + False ALL)
7. ALL F1 score = 2 * (ALL Precision * ALL Recall)/(ALL Precision + ALL Recall)

Here, Accuracy is mainly the ratio of the correct predictions over the total data points in the dataset. AML Precision, meanwhile, is the measure of how accurate a model is when it makes AML predictions and ALL Precision is the measure of how accurate the model is when it makes ALL predictions. AML Recall is how good a model is at correctly predicting the AML instances and ALL Recall is how good the model is at correctly predicting ALL instances. Finally, AML F1 score is the accuracy based on AML Precision and AML Recall while ALL F1 score is the accuracy based on the ALL Precision and ALL Recall

IV. Experimental Design

A. The dataset and modifications made

The dataset was taken from Kaggle [11] and it has the genetic expression of 72 people, where each person consisted of 7129 genes. As mentioned in section III, the dataset had to be modified. The reason being, the dataset had gene expression for 72 people but with the independent variables in the rows instead of the columns. There was also a categorical variable named Call after each independent variable and it was removed because it was deemed as unnecessary. The dataset was transposed with the independent variables taking the columns. The dataset consists of the measurements relating to ALL and AML samples from the bone marrow and peripheral blood.

Table 4.1: Sample of dataset before preprocessing

Gene Description	Gene Accession Number	1	call	…

As mentioned earlier, the dataset, in its raw format, had the independent variables as rows. The 'call' variable was removed entirely since it was redundant. The header Gene Description and Gene Accession Number were dropped but their values were kept. These values are the types of genes and there are 7129 of them.

Table 4.2: Sample of dataset after preprocessing

1	-214	-153	…(other 7127 gene values)
2	-139	-73	…(other 7127 gene values)
3	-76	-49	…(other 7127 gene values)

Here, the values correspond to the patient as in 1 is patient number 1 and the values in its row are the genetic values relating to it, of which there are 7129 values.

There are two target variables – ALL and AML – where AML stands for *acute myeloid leukemia* and ALL means *acute lymphocytic leukemia.* Since having both of these variables would lead to a trap, a single dummy variable was taken where 0 meant that the said patient had ALL while patients with AML were given the value of 1. The dataset was split into training and test set with a split ratio of 0.65 for training set and 0.35 for test set, which means 26 data points were assigned for the test set and 46 for the training set.

B. Tools used and calculations made

Python, along with libraries such as scikit, numpy, pandas, tensorflow, keras and so on, was the only tool used to conduct this research. The calculations made were corresponding to the test set and the results were evaluated against the actual values. If the prediction was 0, then the person is thought to be afflicted by ALL and if 1, then AML was the type of leukemia in that person. These results were represented on a confusion matrix in in order to calculate the False AML, False ALL, True AML and True ALL, which, in turn, was used to calculate the Accuracy, AML Precision, AML Recall, ALL Precision, ALL Recall and F1 score.

V. Results and Discussion

After the trained learners were run on the test set, the resulting output, as expected, assisted in evaluating the methods used in this study. Keeping in mind the fact that a result of 1 means that the specific person is predicted to have AML type leukemia and a result of 0 means that a person is predicted to have ALL type of leukemia, the confusion matrix for the three algorithms are as follows:\

Table 5.1: Confusion matrix for XGBoost

	Predicted ALL	Predicted AML
Actual ALL	14	0
Actual AML	2	10

Table 5.2: Confusion matrix for ANN

	Predicted ALL	Predicted AML
Actual ALL	14	0
Actual AML	2	10

Table 5.3: Confusion matrix for Random Forest

	Predicted ALL	Predicted AML
Actual ALL	14	0
Actual AML	5	7

From the confusion matrices in Table 5.1, 5.2 and 5.3, the Accuracy, Precision, Recall and F1`Score were calculated and the resulting graphs obtained were as follows.

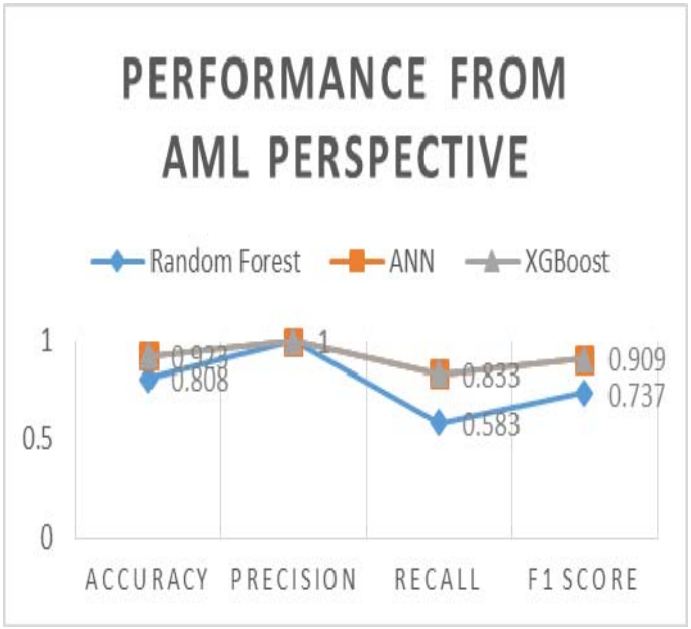

Figure 5.1: Performance from AML perspective

From Figure 5.1, it can be seen that ANN and XGBoost have the exact same results and are far superior to Random Forest when it comes to predicting the AML type leukemia. The Precision of 1 for all three learners simply means that when the model predicts that the type of leukemia is AML, it is correct every time. However, the Recall value for ANN and XGBoost mean that the model can predict whether a person has AML with 83% correctness.

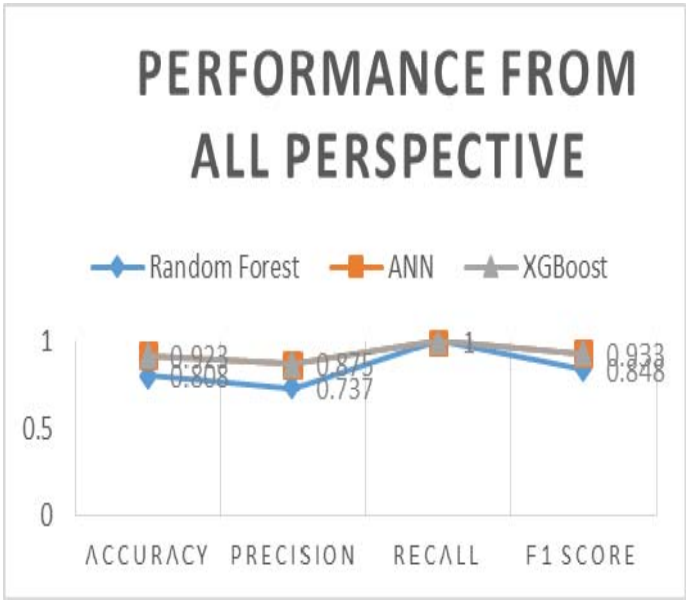

Figure 5.2: Performance from ALL perspective

In Figure 5.2, as expected, ANN and XGBoost fare better than Random Forest but it should be noted that the latter is actually performing better while predicting ALL than it was in Figure 5.1. Random Forest in AML prediction had an F1 Score of 0.737 while in Figure 5.2 is at 0.848. Indeed, even XGBoost and ANN have a higher F1 score while predicting ALL when compared to predicting AML. The Recall value of 1 for all three learners mean that the model can predict whether a person has ALL with 100% correctness. The Precision value, meanwhile, suggests that if the model predicts that a person is afflicted by ALL, then it is right 87.5% of the time for ANN and XGBoost and 73.7% with Random Forest. The accuracy, for obvious reasons, stays the same from both perspectives.

VI. Conclusion

From section V, Results and Discussions, it could be safely concluded that the model used here does a good job at predicting the type of leukemia a patient has, especially when it comes to forecasting ALL type leukemia. With just two incorrect outcomes, out of a possible 26 (0.923 * 26 = 24), in XGBoost and ANN it is very difficult to better the model presented here. In fact, comparing this with other studies, A.C Tan et al [12] got a predictive accuracy of 91.18% while T. Li et al [13] did slightly better at 93%. Furthermore, A.B. Olshen et al secured similar results as their study [14] also had only two incorrect outcomes out of a possible 34.

The use of PCA to decrease the dimensionality of the dataset not only made the computation faster but also gave better results since when the dimensionality wasn't reduced at all, the results were far poorer, which is why they weren't included here. Similarly, the use of Grid Search allowed the discovery of the best possible hyper-parameters associated to the learners used, which, in turn, helped the model produce better results. Without tuning the parameters, the results were some way off to what was found when the parameters were

tuned. Finally, the power of Neural Networks and XGBoost became apparent here as even a great ensemble algorithm like Random Forest fell pale in comparison to the former two. However, considering everything from computational time and predictive power, XGBoost edges out even Neural Networks as it was much faster to simulate than Artificial Neural Networks.

***Abstract*—Maximum power point tracking using artificial neural network model has been implemented. Maximum Power point tracking is used to track the maximum power from a PV panel under different conditions. This model is tested for a variety of irradiance from the light source. The proposed ANN-based algorithm does not have any sensor for prediction purpose. In order to cope with real life maximum disturbance, it is tested under non-linear time domain and non-linear condition state as well. That shows noteworthy performance in estimating maximum power point (MPP). It has the competency to predict irradiance and maximum power point(MPP) with a very tiny amount of error using two series neural networks. Simulation results and experimental studies manifest that proposed sensorless ANN-based model has a minor amount of undesired oscillations and much more effective in tacking maximum power under swiftly changing condition.**

Index Terms*—Maximum power point trackers, photovoltaic systems, ANN algorithm, irradiance, sensor, I–V curve, DC/DC converter.

I. Introduction

Global warming is being commented over the past years. Day by day we are forwarding in a path that needs electricity by anyhow. Many methods have developed for energy generation and carry them out. Most out of them use fossil fuel for generation purposes, which has the ultimate result of decreasing the amount of fossil fuel from limited sources and increasing pollution and adverse effect. However, we need energy sources that do not affect the environment. Renewable energy sources can be a good option to meet the demand for todays electricity famished world. The renewable energy sources (RES) have a little impact comparing to other energy sources like fossil fuel. Solar power is one of the widely used energy sources with a negligible amount of adverse effect on the environment [1]. All other criteria for a clean planet need to be considered. Solar power is available for most of the time when energy demand is high. The solar power generation technique is described as a photovoltaic (PV) system, which has a remarkable performance among other renewable energy sources. Over past years, many MPPT techniques [2], [3] have been proposed and implemented by researchers; such as fuzzy logic method [4], incremental conductance method, and artificial neural network method. Among them, fuzzy and artificial neural networks are getting much more response because of their robustness and accuracy [5]. Increase in output energy is 45.2% for using MPPT in the sunny environment [6]. Our main focus would be given to the implementation of Artificial neural network and maximum power point tracking under different unfavorable conditions. Selecting the efficiency depends on the method and accuracy of tracking MPP. The PV system shows a non-linear Current and Voltage characteristic under different conditions like irradiance and temperature, which depends on selecting the maximum power point. Therefore, tracking and determination of MPP have a tremendous effect on the efficiency [7]. MPPT ensures the maximum possible power to deliver from the solar cell, and even it may happen in low light. Modern MPPT system has approximately 93% to 97% efficiency in the conversion. Comparing with traditional MPPT technique, it is concluded that ANN based technique has a swift response to MPP tracking and more accuracy under different environmental conditions [8]. Perturbation and observation technique is a widely used method for MPPT, but the MPP tracking performance is not much responsive, and it results in undesired oscillation, which has consequences of disturbance in tracking operating point [9]. Artificial Neural networks can be used to overcome such MPPT problem [10]. ANN can handle non-linear equation and few data loss effectively [11], [12]. Very reasonable and low-cost ANN based MPPT techniques take voltage, and current as input [13]which has multistage output because of two series of the neuron network. Our proposed technique composed of two cascaded ANN, first one for irradiance prediction and the second one is for MPP, thus required training sets have been minimized. The complexity of the PV grid integration is increasing day by day and also been reported by industries frequently [14]. As PV arrays, Voltage and current are used for the input; no other sensor is used, which decreases the possibility of being complex. This presented technique has the specialty of calculating irradiance and MPP with a nominal amount of error using Neural network (NN) based algorithm. For any changes in irradiation, it can estimate the new MPP, which ensure better

efficiency and better performance. The simulation results and experimental studies indicate the positive outcome of this algorithm. This paper has five major parts. Introduction part is discussed in the first section. PV model and different behavior are presented in the second part. In the third section maximum power point tracking strategy is discussed, proposed model simulation results are shown in the fourth part. Finally, in the fifth section, the conclusion part is discussed.

II. Solar PV Model

The fundamental part of a PV model is the photovoltaic cell. Current is proportional to irradiation. Thus, depending on different condition solar irradiation varies with time, which has consequences of output power variation. The mathematical expression for I(V) curve of a PV model is given by the following expression.

$$I_{pv} = i_{pv} - I_0 \left[e^{\frac{(V_{pv}+I_{pv}R_s)}{\eta N_s V_t}} - 1 \right] - \frac{V_{pv} + I_{pv}R_s}{R_{sh}} \quad (1)$$

$$V_t = \frac{K_b T}{e} \quad (2)$$

Where I_{pv} denotes output current of the Solar cell, V_{pv} is Output voltage, V_t is the thermal Voltage, I_0 is reverse saturation current and K_b is Boltzmann's constant.

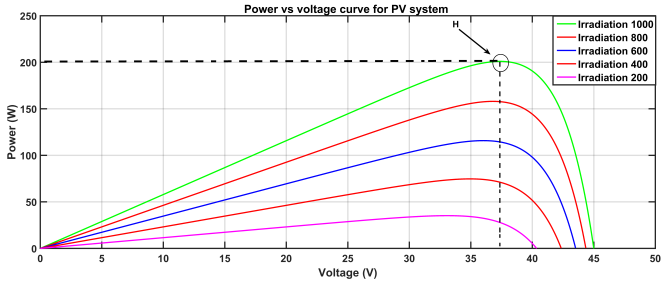

Fig. 1. Power vs voltage curve for PV system

Effect of different irradiation for the PV system can be easily observed in Fig. 2. For this experiment we have taken (1000-800-600-400-200) W/m2 as our primary irradiation levels, that is shown in both Fig. 1 and Fig. 2. Under different irradiation level, the variation of current and voltage is shown in Fig. 2.

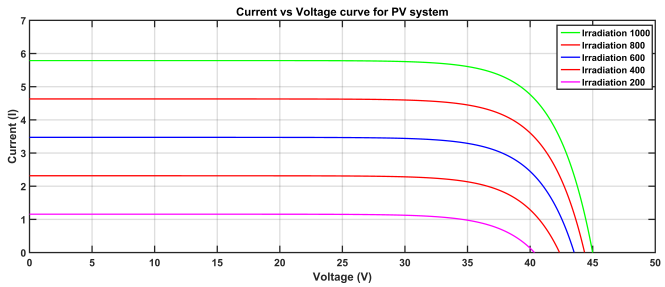

Fig. 2. Current vs Voltage curve for PV system

III. ANN Based MPPT Algorithm

As discussed before, MPP depends on climatic conditions. Because it is directly dependent on irradiation, and different climatic conditions give rise to different irradiation. This basic concept is demonstrated clearly in Fig. 3. It shows how MPP is obtained from our proposed model. After data extraction from MATLAB, those are used for neural network training. Thus different layer will be created. ANN1 predicts the irradiation and ANN2 will provide MPP. Any significant change in irradiation results in MPP variation. For distribution, DC-DC buck-boost converter is used.

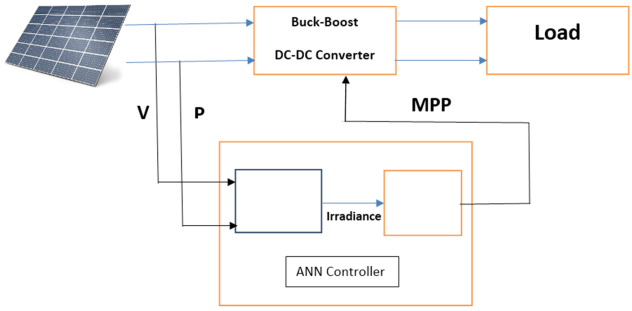

Fig. 3. ANN based MPPT for PV system

In Fig.1, (H) represents the maximum power for its corresponding voltage level V* and current level I*. The artificial neural network is used for the internal measurement of current, voltage and MPP. Different types of algorithms are used to train the ANN. Among them, feed forward back propagation is very popular. Location selection, stock market prediction, distinct pattern recognition can be carried out efficiently with this propagation method. Feed-forward backpropagation algorithm is chosen because of its high-performance rate. This type of network has a massive number of virtual way to carry out information as per networks need, and this information can move forward or backward direction. This propagation network uses a gradient-descent search technique to minimize the error for the network. In the following Fig. 4, a basic feed forward back propagation steps are shown.

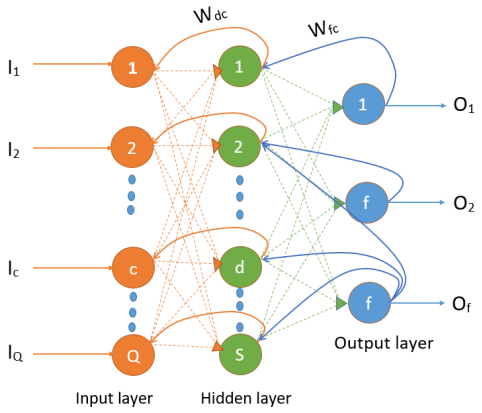

Fig. 4. Feed forward back propagation layers

$$u_c = \sum_{d=-1}^{n} I_d W_{cd} \tag{3}$$

$$V_f = \frac{1}{1 + e^{(-u_c)}} \tag{4}$$

Expression (5) stands for the actual output.

$$O_c = \frac{1}{1 + e^{(-s_c)}} \tag{5}$$

Difference between our targeted output square and actual output square is denoted as the sum of squared error, which would be expressed as (6).

$$E = \frac{1}{2} \sum_{m-1}^{M} E_m = \frac{1}{2} \sum_{m=1}^{M} \sum_{c=1}^{1} (t_c^m - O_c^m)^2 \tag{6}$$

Weights are updated from the minimization of error function using gradient descent method. Continuously those weights are updated. For c^{th} neuron, d^{th} weight update equation would be expressed as (7).

$$W_{cd}(t+1) = W_{cd}(t) + \eta \left(\frac{\partial E_m}{\partial W_{cd}(t)} \right) \tag{7}$$

Where η denotes the learning rate, $W_{cd}(t)$ denotes the old weight, $W_{cd}(t+1)$ for the new weight.

IV. Results and Discussion

For this proposed ANN-based model, two series networks are used, and those are tested under different conditions. Using MATLAB software this model was trained. Validation performance is shown in Fig. 5.

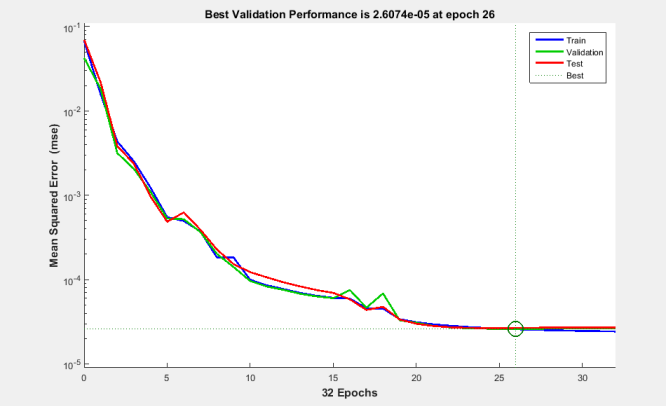

Fig. 5. Validation performance for the proposed system

Where the solid blue line represents training set, green line for validation, a red line for testing the trained model. Best validation performance is indicated, which is at epoch 26. Epoch is iteration that indicates one forward path and one backward path of all our training data (represented by a blue line). To adjust the weight of the neural network, a training set is used. The validation set is used to minimize over-fitting. It's not adjusting the weight of the network and data sets. Testing set is used for testing the final solution of the neural network which ensures the actual predictive power of the network. Here two layers and ten neurons are taken. Tan-sigmoid function is used. During training state, a regression curve is found, which is shown in Fig. 6.

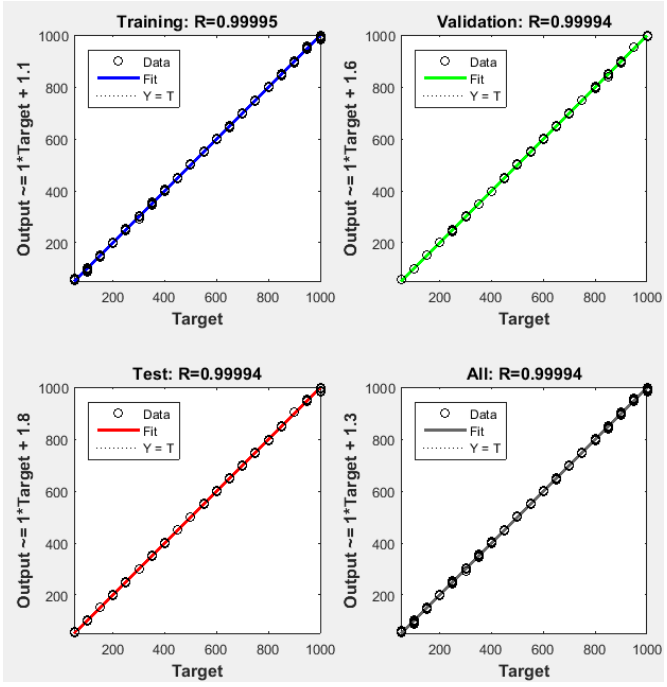

Fig. 6. Regression analysis graph for the proposed model

In Fig. 6, it is simply demonstrated about training performance. This regression performance is generated from MATLAB internal logic, and it gives an idea of whether the training was good enough or not. From Fig. 6, it can be mentioned that our proposed model has performed better in this training stage as values are close to the unit. For training R= 0.99995, for validation R= 0.99994 and value for overall performance is R=0.99994. Thus solid lines are following dotted data very accurately. To avoid any kinds of misrepresentation, this analysis was tested for several times and confirmed.

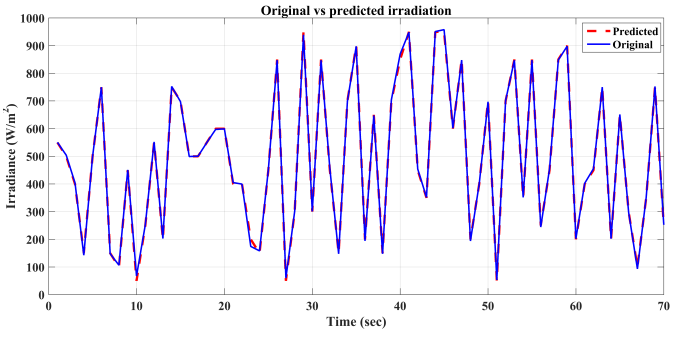

Fig. 7. Original vs predicted irradiation

Among two series networks, the first network estimates the

irradiance which is shown in Fig 7. Blue solid line represents the given irradiation, and red dotted line stands for predicted irradiation. Predicted irradiance is following the original one very closely which results in a tiny amount of error. This error is the difference between original irradiation and predicted irradiation which is shown in Fig. 8.

Table 1: Comparision between MATLAB estimation and given data

Serial No	Given data	Estimated data	Error
01	550	548.5773	1.4227
02	750	750.7156	-0.7156
03	150	150.5157	-0.5157
04	250	253.8099	-3.8099
05	100	102.9519	-2.9519

For ANN1 network, up to 1000 W/m2 irradiation was taken into consideration. Which can be seen from Fig. 7. From table 1, we can get an idea of error volume. All of those data are taken from the above mentioned Fig. 7.

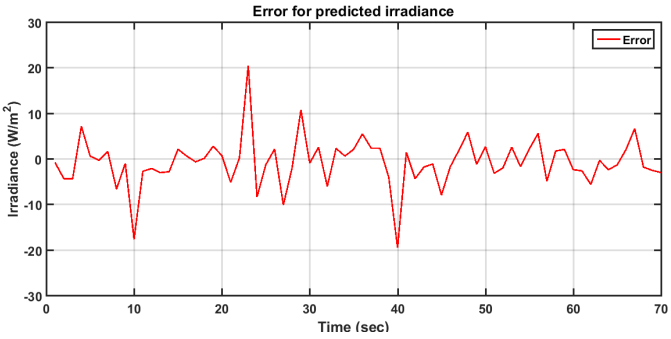

Fig. 8. Error for predicted irradiance

In Fig. 8, simulation result shows the maximum error is about 20. Which is 2% of the maximum irradiation taken into account. Thus the proposed project shows how accurately it can estimate a suitable irradiance for the next (ANN) network. For significant changes in any condition, it has the ability to get better estimation with low error portion. Next ANN2 network works for maximum power point estimation. Which will be in series with the previous network ANN1. In Fig. 3, it is clearly shown that the output of ANN1 is used as an input of ANN2. Therefore, this proposed model can estimate MPP more accurately.

Fig. 9 demonstrates how the estimated MPP is following the given (original) MPP with a low error portion. Hence, it suggests the proficiency of the model. It can be mentioned from the previously stated graphs that error rate depends on the range of original value, where the range is a difference between the maximum and the minimum of the value. Fig. 9 exhibits that estimated MPP almost overlaps the original MPP that leads to a small variance from the ideal value. Difference between those two arrays is simulated which represents an error graph, showed for MPP estimation. In Fig. 10 that is clearly illustrated.

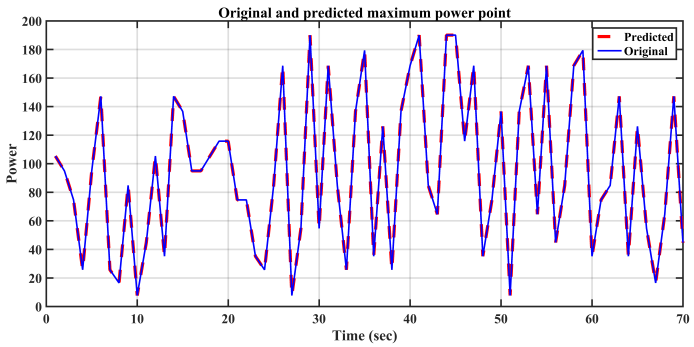

Fig. 9. Original vs predicted maximum power point

Table 2: Comparision between MATLAB estimation and given data

Serial No	Given data	Estimated data	Error
01	54.7055	54.6699	0.0356
02	35.2267	35.2245	0.0022
03	84.8565	84.8326	0.0239
04	95.004	95.0429	-0.0389
05	147.2778	147.2814	-0.0036

From table 2, we can clearly see how precise those estimations are. Here all of those data are chosen from before mentioned Fig. 9.

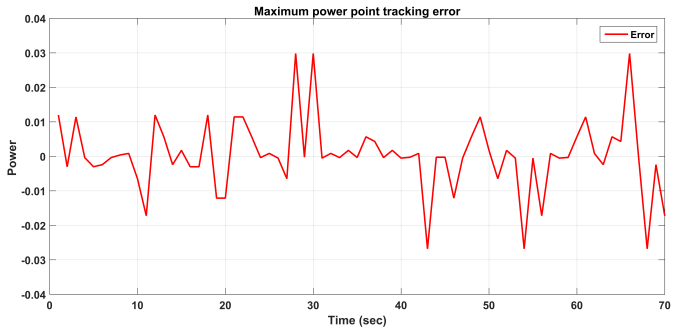

Fig. 10. Maximum power point tracking error

It can be mentioned from Fig. 10 that maximum error for MPP estimation is about 0.03, which is almost negligible. Hence, our proposed ANN-based maximum power point tracking system can function effectively.

V. Conclusion

In this paper, Sensor-Less solar irradiance estimation and maximum power point tracking algorithm is proposed to enhance the efficiency of Maximum power point extraction. Our proposed ANN-based algorithm does not need any sensor to track MPP. The simulation and experimental results of the presented algorithm are compared with traditional results, and that demonstrates the proposed algorithm has better performance

than conventional MPPT method. It exhibits swift response and accurate estimation of irradiance and MPP while tested under unfavorable and non-linear condition. The proposed model has little amount of error which implies the prosperity of this research.

***Abstract*—Among the various reason behind Non-technical losses in smart grid, losses due to electricity theft have become major apprehension in power system industries. A significant amount of consumption of electricity in a fraudulent manner decrease the supply quality, increase generation load and the real consumers have to pay excessive electricity bill that finally affects in overall economic condition. The advance metering infrastructure (AMI) has the ability to monitor the consumption detail of every consumer, record the consumption pattern, billing them as well as find any types of abnormalities. The communication capabilities of smart grid have facilitated the utilities to store their consumers' consumption patterns. With this database it is possible to formulate a theft detection model by machine learning algorithm by analyzing the recorded data of smart meter. In this paper, Support vector machine (SVM), one of the prominent machine learning classifiers applied with principle component analysis to train the data collected from smart meter and calculate the prediction accuracy with the test data. Here the principle component analysis reduces the dimension of the data to make the further processing less complex. After that, by using grid-search method the best-suited meta-parameters for SVM has been selected where the almost 90% accuracy rate is achieved. The classification results with respect to different meta-parameters of SVM (regularization parameter C and γ) have presented. Moreover, the obtained result specifies that the applied techniques possesses higher accuracy and less false positive rate for real time consequences.**

***Index Terms*—Classification techniques, electricity theft, grid search method, principle component analysis (PCA), smart grid, support vector machine (SVM).**

I. Introduction

In the last few years, the new idea of a smart grid (SG) became a critical issue in the contemporary world and has attracted cumulative attention of energy users', policy makers and engineers. The combined electricity network of computers and power system infrastructure which monitor and manage energy use as well as can incorporate the nature and activities of all consumers connected to it intelligently is known as Smart Grid. The grid is a collection of digital systems and rejuvenation of current electrical system which extends customers' and electrical companies' ability to observe, control, and foretell energy usage [1]. The overall process is designed to efficiently deliver sustainable, economical, and secure electricity supplies and reduce loss due to energy wastage [2].

Among various technologies, the key technical areas used in smart grid operation are integrated communications, advanced components, sensing and measurement, innovative control methods and finally, improved interfaces and decision support. To execute the operation of Smart grid through these technologies, some basic components like electric power generators, electric power substations, transmission and distribution lines, controllers, collector nodes, smart meters, and distribution and transmission control centers have been implemented [2].

Among the devices use in smart grid, smart meter is one of the most important devices. It provides two way communication between subscribers and utilities to exchange informations such as voltage, current, phase angle, real time energy consumption data and control information [3]. The combination of the unique meter identifier of smart meter, the electricity consumption value, the data timestamp provides the smart meters' data which helps the utilities to optimize end users' bill and also help to control the power transmission and consumption rate.

Though many countries have already started the implementation of smart grid system, the power utilities suffered a dramatic economic loss due to some technical and non-technical issues. The main reason of technical loss (TL) due to the internal electrical resistance and affected components like transformers, generators, and transmission lines [4].

On the other hand Non-technical losses (NTL), also known as Transmission and Distribution losses can be estimated with various types of techniques. Fraud due to the electricity theft, errors and delay in meter reading and billing, irregular bill submission, power stealing by any means, faulty energy meters or un-metered supply and ignored unpaid bills are the main reasons of NTL. The energy supplied to the consumers by stealing of power does not measured by the energy meter which makes a variation between the energy supplied through the meters and the registered amount of energy by the meters [1].

Undoubtedly, electricity is a key input for the development for many underdeveloped and developed countries as many production processes solely depend on it. Because of the NTLs significant damage in economies which results loss of profit and revenue of utility companies as well as reduces the consistency and steadiness of electric power grid. Among the causes of NTL, electricity theft poses a serious concern for the power system utilities as they have to accept excessive loses due to electricity theft. The real time fraud detection

and current action is the only way to get rid from this. By analyzing of all customers data on grid, the detection of illegal consumption is possible. As the SG has been implemented many countries and the ICT field becomes more advance, various methods have been already proposed to identify and restrict the electricity theft. Most of the current methods focus on detecting fraudulent consumers at distribution phase with limited set of parameters. Keeping these issues in mind, this paper focuses on presenting a framework to measure the accuracy of machine learning model to detect electricity theft. The rest of the paper is organized as follows. Section 2 summarizes a brief literature review. Section 3 presents the methodology that contains brief description of Support Vector Machine (SVM), Principle Component analysis and the overall working procedure. While section 4 provides the experiment results generated using SVM classification. In the end, Section 5 presents the conclusions of this paper.

II. Previous work

The NTL, especially electrical theft poses a serious concern in the power system domain because of its huge amount of economic losses. In the recent times, many researcher s got involved to develop and propose several techniques through an extensive and fecund research to detect as well as minimize electricity theft. Energy theft detection system (ETD) can be categorized into three major groups, as state, game theory and classification based [5]. The state based detection was proposed in [6]–[8] by using improved sensors and the devices to improve the accuracy of ETD and reduce the false positive rate. Due to the higher cost of equipment and software, this model is quite difficult to implement.

On the other hand, because of the expansion of internet and emergent concern of cyber-attacks, the ICT can play a vital role to avoid electrical theft [9]. To make data computation, transmission, and storage protected, Wei et al. [10], [11] proposed a security frame work by using Markle Hass tree concept. The security threats can be linked with the metering infrastructure which is discussed in [12], and various countermeasures as suggested tackling them to ensure data confidentiality, integrity, and availability in smart grid.

Monitoring of consumers' load profile by data from electric meter was one of the effective suggested criteria to find fraudulent customers. Nagi et al. [13] applied data mining method by calculating the average daily consumptions of end users over a two-year period by finding the abrupt changes in load profile. Angelos et al. [14] computed average consumption, maximum consumption, standers deviation, sum of the inspection remarks and the average consumption of neighborhood were selected from six months usages profile and detect the abnormalities in data pattern.

In the field of theft detection, the support vector machine has been widely used technique in recent times. The SVM has been applied to detect anomalies on manually collected data by Joker et al. [15]. Based on the irregularities in data frame, [16] presented a SVM based approach to detect fraud consumers. To make the detection more effective, a model of ANN incorporate with SVM has been proposed by Depru et al. [17]. Not only this, Nagi et al. [18] implemented fuzzy logic with SVM to improve the overall performance. An improved coding technique was proposed and both SVM and a rule-engine based algorithm were applied on encoded data to improve efficiency in [19]. Moreover, different techniques such as one-class SVM, optimum path forest and C4.5 decision tree has been combined by Martino et al. [20] to achieve higher accuracy.

III. Methodology

This work classified normal and theft electricity data based on supervised learning technique. The overall working flow is described in Fig. 1.

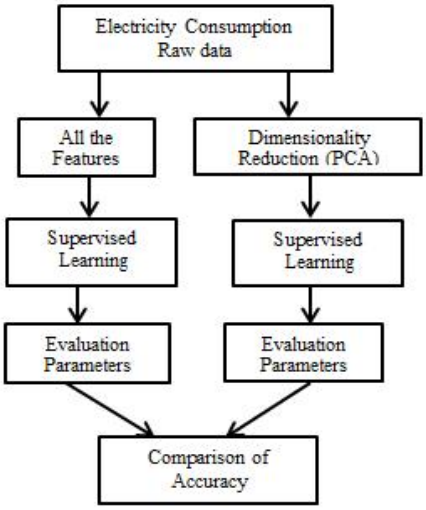

Fig. 1. Proposed framework for comparing accuracy

A. Support Vector Machine

Support Vector Machine (SVM) is powerful and widely used learning algorithm used for both supervised classification or regression tasks. In this work SVM is used for theft classification. SVM classifies labeled data by using a separating hyperplane as depicted in Fig.1 [21].

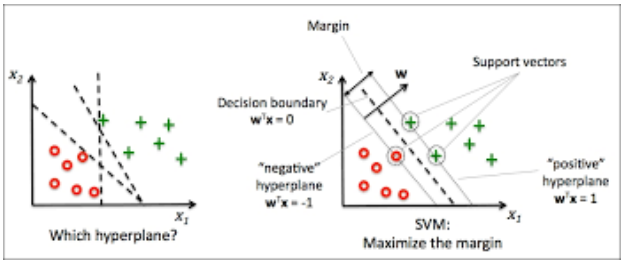

Fig. 2. Concept of Support Vector Machine [21]

The figure depicts a visualization of simple classification involving only two class which are linearly separable. Here

the positive and the negative hyperplanes can be formulated as follows:

$$w_0 + w^T x_{pos} = +1 \quad (1)$$

$$w_0 + w^T x_{neg} = -1 \quad (2)$$

Subtracting these two equations would results the following equation:

$$\frac{w^T(x_{pos} - x_{neg})}{\|w\|} = \frac{2}{\|w\|} \quad (3)$$

The left side of equation 3 represents the margin between positive and negative hyperplanes. The goal of SVM is to maximize this margin. For more complex data points which are not linearly separable as shown in Figure 2, SVM uses kernel method to create hyperplanes. The kernel method utilizes a mapping function , to transform the original features into a higher dimensional space where it is possible to separate them by linear hyperplanes which is also shown in Figure 2.

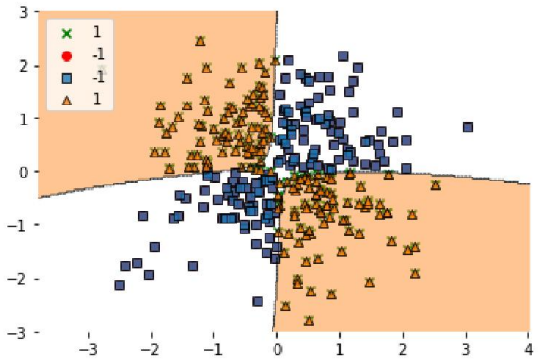

Fig. 3. Support vector Machine for linearly inseparable

Performance of SVM classifier can be optimized by selecting some tuning parameters one is the regularization parameter or C parameter. In simple terms this parameter defines the amount of misclassification in training data. A higher value of C will create small margin hyperplanes which will try to classify all training data correctly. Whereas, smaller value of C will produce hyperplanes with larger margin but doing so it will allow some outliers or misclassified points in training data. This is depicted in Figure 3. Higher value of C can lead to overfitting the training data.

Gamma is another tuning parameter of svm that is used for rbf kernel. Higher the value of gamma the tighter the hyperplane boundary. Large gamma leads to high bias and low variance models, and vice-versa. A classifier with high gamma value might have a high generalization error on test data. Figure 4 displays how change in gamma value changes the decision regions.

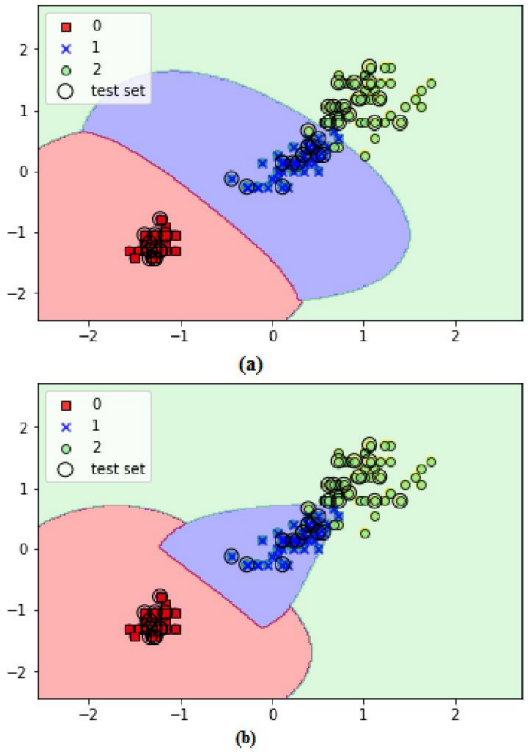

Fig. 4. Decision regions for (a) C = 1 (b) C = 1000

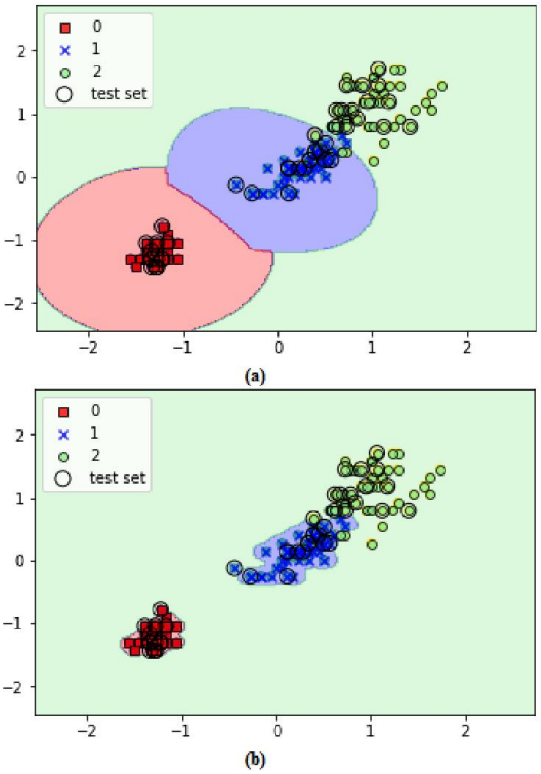

Fig. 5. Decision regions for (a) gamma = 1 (b) gamma = 1000

B. Principle Component Analysis

A huge number of features for each training instance are involved in any machine learning problem, which makes the training awfully slow and also creates over fitting problem. It is mandatory to reduce the number of features/dimensions to enhance the model's performance and facilitates to find out an optimal solution for any respective machine learning problem. A well-known method for this task is Principal Component Analysis (PCA), that aims is to reduce the dimensionality of data set contains many variable interrelated with each other, by keeping the variation present in the data set. It is statistical method that uses an orthogonal transformation to transform a set of interpretations of possibly correlated variables into another set of linearly uncorrelated variable values named principle components. The data set must be scaled on which the PCA techniques will be applied. To implement PCA on a data set, first the data has to be normalized, after that the value of covariance matrix, eigenvalues and eigenvectors needs to calculate. At the next step from the data we have to choose components and form a feature vector for next step. By forming principal components with all the calculative values this process comes to an end.

C. Data Acquisition

The data we used in this paper includes approximately 10,000 users daily real electricity consumption data over the year of 2015 which represents in time series. The dataset is released by State Grid Corporation of China. The dataset is available at (http://www.sgcc.com.cn/). The information in this data set includes customers consumption signature in daily basis.

D. Data Preprocessing

The data contains almost 10,000 users' data over one year. The real world data contains very inconsistent data, there was some missing data as well as the value of some data was too high or immeasurable. To reduce this problem, data preprocessing is applied, which is one of the important parts in data mining techniques. In this process, to reduce noise we have to apply statistical method and converted the data to normal consumption values.

E. Data Normalization

For further processing, the load data needs to be represented using a normalized scale for the SVM classifier [22], [23]. Though we have the data for 365 days, the daily average kWh consumption feature data is normalized as follows:

$$\mathrm{N} = \frac{\mathrm{L} - \min(\mathrm{L})}{\max(\mathrm{L}) - \min(\mathrm{L})} \tag{4}$$

where L represents the current kWh consumption of the customer, and min(L) and max(L) represent the minimum and maximum values over 1 year consumption feature set. The load profiles of customers is found with each load profile being represented by the 365 normalized daily average kWh consumption features.

F. Choice of Appropriate kernels

Karnel can be defined as the set of mathematical functions which is used to set SVM algorithm. The main aim of kernel function is to take data as input and transform it in any required form. Based on the mathematical interpretation, the functions can be various types , such as linear, nonlinear, polynomial, radial basis function (RBF), and sigmoid. To find the best result, one have to choose the best result that fits the respective problem [24].

G. Choice of Modeling Parameters

The selection of two SVM model parameter (C, γ) are plays a vital role to calculate accuracy of classification problem. Thus, selecting the perfect values for for these parameters is an important task. A lot of practical approaches, asymptotical optimization [25], cross-validation (CV), and grid search [26] are available for selecting and optimizing parameters.

H. Train and Test the classifier

Once the selection of kernel and modeling parameters has been defined, the data needs to be divide into training and test sets. The SVM classifier is trained first with the training data and then new test data is classifying based on the trained classification model. Depending on these factors, the data is evaluated and the related results of this classification are described in the next section.

I. Data Compression

Principal component analysis (PCA) is used to reduce problems related to high dimensional and co linearity of any high volume data set, while retaining the variability of the data set. PCA is a classical statistical method for transforming attributes of a data set into a new set of uncorrelated attributes but keep the data type unchanged. Generally, with this initial PCA step, a significant progress in the performance of machine learning methods can be achieved. [27].

J. Grid Search method

Grid search is a search mechanism based on deined subset of hyper-parameter space. By defining minimal value, maximal value, and number of steps, the hyper-parameters are specified [28]. Grid search optimizes the SVM parameters (C, γ, degree) as a performance matrix. To identify good hyper-parameter combination is the main objective, so the classifier can predict test data accuracy more appropriately.

IV. Results and Discussions

To apply SVM classifier, we need to preprocess the data to convert it into SVM compatible format. The next step is to data normalization which is used to standardized the data using sample mean and standard deviation for each feature for optimal performance. After that, we split the data set into training and test data. First, we extract the accuracy rate with respect to number of samples without applying PCA. The training sample accuracy is quite high for the number of sample 0 to 2500.

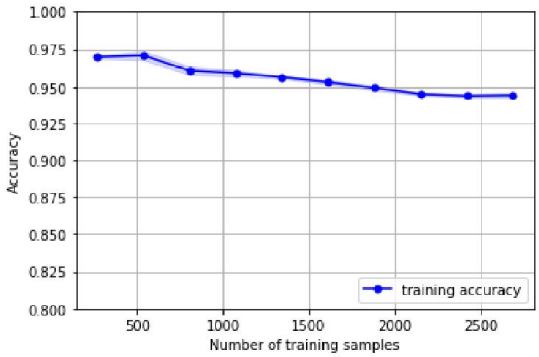

Fig. 6. Learning Curve for the data set

PCA acts as a key component for increasing accuracy for high dimension data. As we have to work with almost 9700×366 dimension data, apply PCA will reduce computational complexity. After that, we have to choose an appropriate kernel with the modeling parameter. In this work, RBF kernel with modeling parameters C and gamma (γ) are taken. For a range of C and gamma (γ),the training data and test data accuracy has been illustrated.

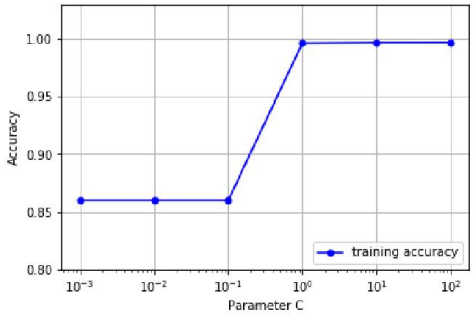

Fig. 7. Validation Curve for Parameter C

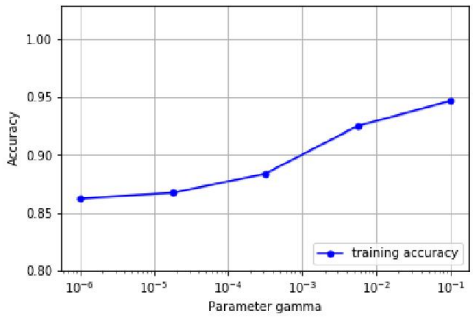

Fig. 8. Validation Curve for Parameter gamma

The confusion matrix of this data set for applying SVM is given in Fig. 9. From this matrix we get true positive(TP), false positive (FP), true negative (TN) and false negative (FN) values, where the ratio of misclassyfied data is quite low for both cases of SVM, with or without PCA [29], [30].

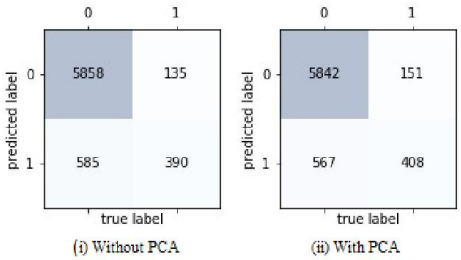

Fig. 9. Confusion matrix

The SVM is trained on the basis of parameters C and gamma (γ). Three different ratio of training and test data as 60-40, 70-30 and 80-20 has been taken in order to test the accuracy, that is given in Table I. The highest accuracy we achieved is 90%.

TABLE I
RESULT FOR DIFFERENT RATION OF TRAINING AND TEST DATA

Training date/Test data	Precision	Recall	f1-score	Accuracy
60/40	0.89	0.90	0.89	89%
70/30	0.89	0.90	0.89	90%
80/20	0.89	0.90	0.89	90%

Principal component analysis along with SVM improves the accuracy of machine learning model in the classification for any high dimensional data set [27]. In this work, we have in total 365 components to analysis. Because of applying PCA, we achieve the maximum accuracy (90%) with 50 components only, which finally reduce the complexity of overall model.

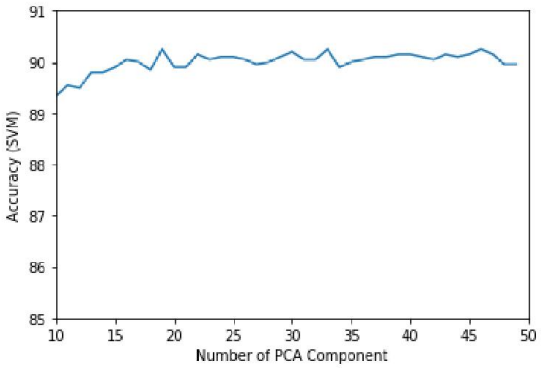

Fig. 10. Accuracy calculation for PCA components

Finally, the grid search method has applied on SVC to estimate the optimum classification by optimizing the kernel and other meta-parameters (C and γ). For this study, a range of values for both parameters has taken into account to detect the optimum value. Finally, it is found that the optimal parameters C = 100 and γ = 0.001 for RBF kernel where the accuracy is approximately 90%.

The dataset used in this work is relatively new and until now only two research works have been performed on this dataset. Multi-scale DenseNet is investigated in [5] and other used convolutional neural network [31]. In this work shallow machine learning algorithm is used. We have used different performance matric (accuracy) whereas the authors of the previous works used AUC curve. As the performance metric is different, so, it is not possible to compare our result with the other ones. In future, other algorithms and similar performance metrics can be investigated for comparison.

V. Conclusion

Electrical theft leads to huge losses to the utilities in the power sector. The illegal use of electricity through tapping by consumers is the main reason behind this. To identify the malevolent consumers and find the accuracy of smart meter data with Support Vector Machine (SVM) has been presented in this paper. The consumption data provides as the input of the SVM classifier to train the collected data set first. Then classifier applied to classify the customers as normal or fraud. The experimental results obtained show that the by choosing the optimal meta-parameters of SVM effectively by grid search method can increase accuracy of the system. The optimal value of C is 100 and gamma is 0.001. The SVM classifier identifies fraudulent consumers with an accuracy of 90% and false positive rate as low as almost 9%.

***Abstract*— Most of the appliances that we used in our everyday life are electronic devices, i.e. TV, Air Conditioner, Refrigerator, etc. Excessive voltage, current, temperature, etc. can harm the devices and in extreme cases, the devices can be completely damaged. We proposed a system to monitor the electrical behaviors of the devices in real-time. The system is trained with an unlabeled dataset and capable of identifying outliers. We have used a clustering technique, i.e. Density-Based Spatial Clustering of Applications with Noise (DBSCAN) to learn the label of a dataset and then apply machine learning algorithms, i.e. Support Vector Machine (SVM) and Decision Tree to predict the label of the new data. From the prediction, the system determines whether the device is operating in safe mode or not. In this work, we have achieved the accuracy of 98.61% in detecting outliers using SVM with 'rbf' kernel. Hence, if the device operates beyond safe mode, we can shut down the device.**

Keywords—Outlier; Outlier Detection; Clustering; Density-based Clustering; DBSCAN; Support Vector Machine; Decision Tree.

I. INTRODUCTION

People depend on the use of electronic devices in their everyday life. Most of the cases, the end users cannot identify the poor performance of the device and can only understand the weak performance when the device isn't working any longer. Hence, we need to find a way to protect these devices.

An outlier is an observation point or a set of observation points that have different properties and are inconsistent with other observations [1]. They are generated by any kind of disturbances in the system. Hence, outliers indicate the erroneous condition of the system. Outliers detection techniques try to find unusual patterns in the system. There are various approaches like distance-based approaches, depth-based approaches, density-based approaches, deviation-based approaches, etc. to detect outliers in the system [2].

In this work, a density-based approach, i.e. DBSCAN is used to detect outlier. DBSCAN is a hierarchical clustering method and can determine the number of clusters automatically. Moreover, DBSCAN can successfully identify arbitrary shaped cluster. This work describes an advanced system which can monitor the electrical characteristics of the device and identify disturbances like overvoltage, flicker, etc. This work considers these disturbances as the outlier and proposes an effective way to detect it. Then, supervised learning algorithms, i.e., SVM, Decision Tree are used for training a model to predict a new sample. Hence, we can decide whether the new sample data is an outlier or not.

The remaining part of the paper is organized as follows: Section II demonstrated the related works that have been done in this field. The proposed methodology with some theoretical explanations is investigated in Section III. The result is illustrated in details with some performance measures in Section IV. The conclusion of the paper is drawn in Section V.

II. RELATED WORK

For a system, outlier or anomaly may come at any time and can cause significant harm to the system. In case of protecting the system, we need to detect the outliers. In recent years, outlier detection has drawn considerable attention in the research community. For identifying outliers in feature spaces, Eskin et al. [3] proposed a system using different machine learning techniques. These techniques include one class SVM, K-nearest neighbor, and cluster-based estimation. They used these algorithms to identify the points that are in the sparse areas. Among the three algorithms, they obtained the detection rate of 98% and a false positive rate of 10% for SVM over the KDD Cup 1999 Data. Ester et al. [4] investigated the effectiveness of DBSCAN. They concluded that DBSCAN is good at detecting outlier and discovering a cluster of arbitrary shape. Their experiment on SEQUOIA 2000 benchmark data shows that DBSCAN outperforms the well-known algorithm CLARANS (Clustering Large Applications based on RANdomized Search) by a factor of at least 100 regarding efficiency.

For unsupervised anomaly detection, Kingsly Leung and Christopher Leckie [5] presented fpMAFIA, a new density-based and grid-based clustering algorithm over the 1999 KDD Cup data set. Their results indicate that their new approach fpMAFIA able to achieve a high detection rate while it suffers from a high false positive rate compared to the other methods. Bakar et al. [6] experimented different techniques like linear regression, control chart and Manhattan distance to detect outliers. Their experimental results demonstrate that the control chart technique gives reliable results in detecting outliers than linear regression. Ramaswamy et al. [7] demonstrated a profoundly efficient partition-based algorithm for discovering outliers. Their algorithm first partitions the input data set into disjoint subsets and as soon as it concludes that they do not include outliers then, the algorithm prunes entire partitions. Breunig et al. [8] talked about LOF (Local Outlier Factor). According to them, each object has its own LOF. The factor depends on how isolated the object is regarding its surrounding neighbors. Their outcome shows that the approach is very assuring in recognizing significant local outliers.

Arning et al. [9] presented a linear algorithm to detect deviation in data. Their investigation reveals that the effectiveness of the algorithm mainly depends on the

dissimilarity function. A dissimilarity function catches how different is a new data from the data items seen previously. For distinguishing outliers, Jiang et al. [10] suggested a two-phase clustering technique. In the first phase, they used a modified k-means algorithm. In the second phase, they applied an OFP (Outlier Finding Process) for finding outliers in the clusters that are generated by phase one. Hawkins et al. [11] suggested a Replicator Neural Networks (RNN) based outlier detection approach. An RNN is trained on sampled dataset so that it can predict the new data. This approach identifies cluster labels which are used to interpret the generated outliers.

III. The Proposed Methodology for Outlier Detection

The primary objective of the work is to determine the outliers of the electronic devices. Fig. 1 illustrates the detailed design of the proposed methodology. The main steps of the methodology include dataset preparation, preprocessing, DBSCAN clustering to detect the outliers and learn the label of the outlier and normal data, from that labeled dataset, predict new samples using Support Vector Machine (SVM) and Decision Tree.

A. Dataset Preparation

Ohm's law illustrates the relationship between current, voltage, and resistance. It informs us that the current i, passing through a circuit is directly proportional to the voltage v, and inversely proportional to the resistance r.

$$i = v/r \tag{1}$$

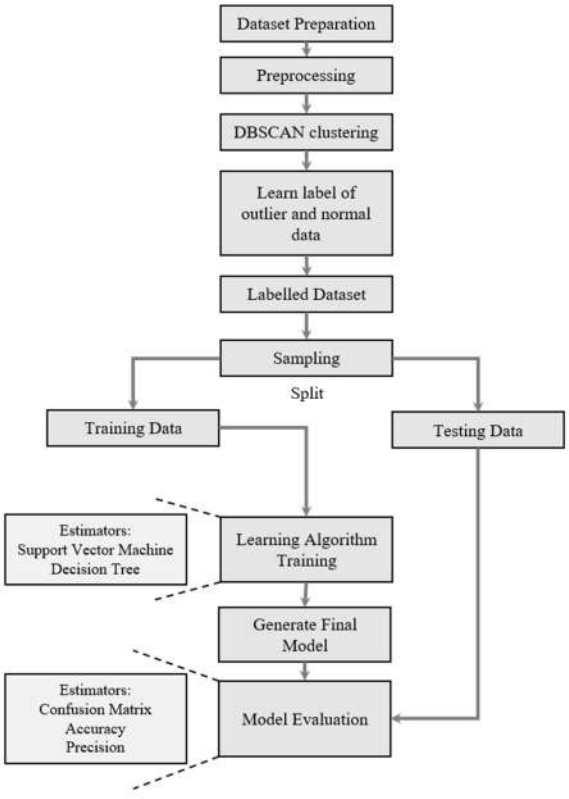

Fig. 1. Proposed methodology of the system.

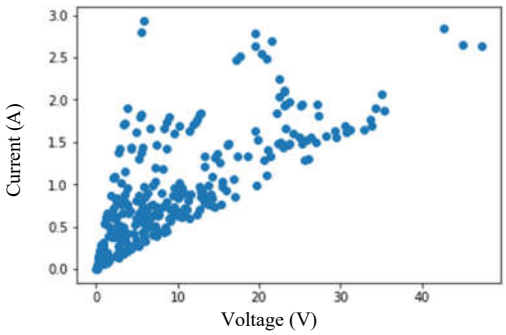

Fig. 2. The generated dataset for the system.

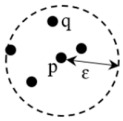
A synthetic dataset is prepared for the work. For preparing the dataset, we have used the (1) and randomly generate v and r and then calculate the corresponding i. The dataset contains two features, i.e., voltage (v) and current (i). Fig. 2 illustrates the generated dataset.

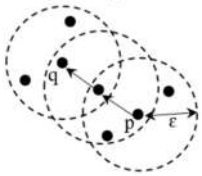
B. Preprocessing

The real-world data can be noisy and sometimes there are missing values in the dataset. The amount of noise and the number of missing values mainly depend on how we collect the data. A large amount of the datasets that are used to solve a machine learning problem need to be handled carefully [12]. For preprocessing, we have used z-score normalization. We get the rescaled features after using the standardization i.e. normalization. Standardizing the features is vital for our dataset as the dataset has measurements on different units. The z-score of a sample x is estimated as:



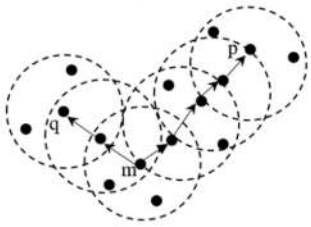
$$z = (x-\mu)/\sigma \tag{2}$$

where μ denotes the mean of the training samples, and σ denotes the standard deviation of the training samples.



C. Clustering and Learning the label of the dataset

Clustering is mainly used for grouping objects that have the same kind of properties [13]. There are many techniques for clustering objects depending on dataset's perspective. In this work, DBSCAN is applied for clustering purpose. DBSCAN discovers neighbors, i.e. the member of the same cluster by using two parameters, i.e. MinPts and radius ε. The formation of a cluster depends on the notions of directly density-reachability, density-reachability and density-connectivity of points [14]. A cluster can be formed as the maximal set of 'density connected points' in the feature space.



Let, consider two points p, q. From Fig. 3 it can be inferred that, q is directly density-reachable from p regarding ε if and only if q is in p's ε-neighborhood. q is density reachable from p regarding ε if there is a series of points p_1, …, p_n in such a way that $p_1 = p$, $p_n = q$ and for each i= 2, . . ., n it is true that p_i is directly density-reachable from p_{i-1} regarding ε. q is density connected from p regarding ε if and only if there is a point m such that q is density reachable from m and p is also density reachable from m [15].

(a) q is directly density reachable from p

(b) q is density reachable from p

(c) q is density connected from p

Fig. 3. The concepts of directly density reachability, density reachability and density connectedness of points.

DBSCAN defines different classes of points as followings

- Core point
- Border point
- Outlier

Let, u be another new point. u can be a core point if its neighborhood defined by radius ε contains at least or more points than the number of points defined by parameter MinPts. u can be a border point if it a member of a cluster and its ε neighborhood contain less points than MinPts but u is still density reachable by other points in that cluster. u will be an outlier if it is not a core point and at the same time not a border point. Fig. 4 represents the notion of core point, border point, and outlier. Hence, it can be realized that, all the points inside the same cluster are respectively density connected and if a point is density reachable from any member point of that cluster the point is also a member of that cluster as well.

We have used DBSCAN in our dataset. It finds the number of clusters automatically and also finds the outlier. It also returns the labels of the calculated clusters and outlier. Hence, we learn the label and use a predictive learning algorithm, i.e. SVM (Support Vector Machine) and Decision Tree to predict the label of the newly arrived data.

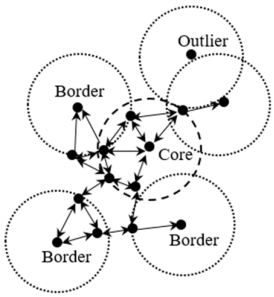


Fig. 4. The concept of core point, border point and outlier.

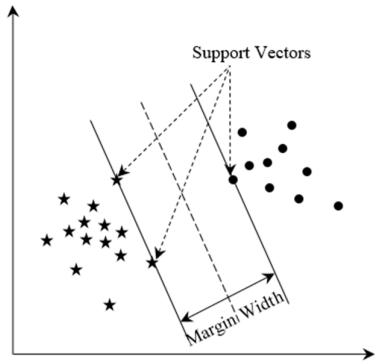

Fig. 5. Support vector points and margin width of hyperplane of SVM.

D. Prediction of outlier

Support Vector Machine (SVM) is a supervised learning algorithm in machine learning which is used for the classification problem. The main ideology behind the concept of SVM is finding the optimal hyperplane that confidently separates different classes [16].

The closest points to the hyperplane consist the support vector points. The distance between the support vector points and the hyperplane is called the margin. Fig. 5 shows support vector points and margin width of hyperplane for SVM. The support vector points play an important role for finding the hyperplane that maximizes margin width. All other points are irrelevant for finding the hyperplane.

Let, n be the number of dimensions. Thus, the equation of the hyperplane can be given as the following

$$\begin{aligned} y &= w_0 + w_1x_1 + w_2x_2 + w_3x_3 + \ldots \\ &= w_0 + \sum_{i=1}^{n} w_ix_i \\ &= w_0 + w^TX \\ &= b + w^TX \end{aligned} \tag{3}$$

where y is the outcome, b is the biased term ($b = w_0$), x_i are the attribute values. The weights w_i will be learned by the algorithm. In (3) w_i are the parameters that will determine the hyperplane [17].

Decision Tree is a very popular algorithm for classification in machine learning. To develop a tree, we need to choose features and conditions for splitting along with stopping criteria [18]. For classification, different split point is considered using a cost function. The split is selected that has the lowest cost. Gini score is considered as a cost function for classification.

$$G = sum(p_k * (1 - p_k)) \tag{4}$$

Here, p_k is the proportion of same class inputs present in a particular group. Gini score decides whether a split is good or not by estimating how mixed the response classes are in the groups formed by the split. When a group contains all the member from the same class then p_k is either 0 or 1 and $G = 0$. The performance of Decision Tree can be increased by pruning. It involves removing the branch that has less important features.

As we already generate label using DBSCAN, we train the dataset using SVM and Decision Tree. For model evaluation confusion matrix, accuracy and precision are used. Confusion matrix is used to decide the performance of a classification model. Accuracy, precision evaluates the

output quality of the classifier. Confusion matrix is formed using T_P, T_N, F_P, F_N. where,

T_P = *True Positive*
T_N = *True Negative*
F_P = *False Positive*
F_N = *False Negative*

For calculating accuracy (*Acc*) and precision (*Prec*), the following formulas are used.

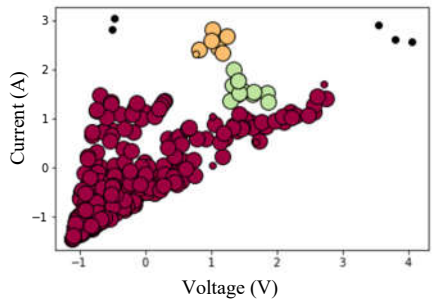
$$Accuracy\ (Acc) = \frac{T_P + T_N}{T_P + T_N + F_P + F_N} \quad (5)$$

$$Precision\ (Prec) = \frac{T_P}{T_P + F_P} \quad (6)$$

IV. Result Analysis

The system is implemented in the python environment using 'scikit-learn' which is a machine learning library. The synthetic dataset that we generated by using (1), it is not possible to directly apply a supervised learning algorithm on the dataset as it has no label. We standardize the features of the dataset by using (2). Then, we apply DBSCAN on the dataset with MinPts = 3, radius ε = 0.3 and choose Euclidean metric for the DBSCAN to perform its clustering.

Fig. 6 illustrates the result of applying DBSCAN on the dataset. Here, the black points represent the outlier. All the other colored points are members of different normal classes. In addition, Fig. 6 also shows that there are three normal classes (class 0, class 1 and class 2). After performing DBSCAN on the dataset, we get the label of the normal data as well as the outlier. Now, as we know the label of the dataset, we apply supervised learning algorithms i.e. SVM and Decision Tree. Fig. 7 depicts the result of applying SVM and Decision Tree on the labeled dataset.



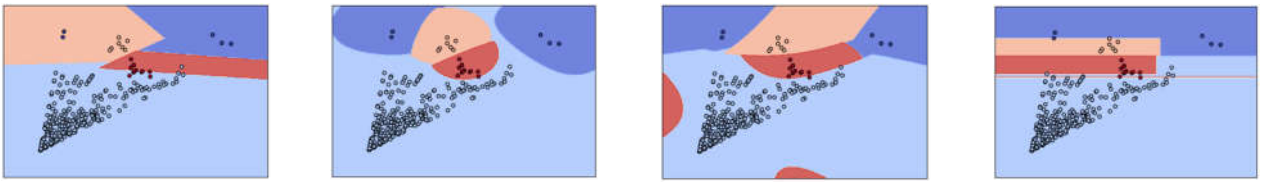


Fig. 6. Result of using DBSCAN (MinPts = 3, radius ε = 0.3, metric = 'euclidean') on the dataset.

Here, SVM and Decision Tree are used as classifier. For SVM, three different kernels i.e. linear, radial basis function ('rbf') and polynomial ('poly') are used. Different kernels are used to see which kernel can perform better. We used confusion matrix, accuracy and precision to evaluate the models. Table I and Table II represent the normalized confusion matrix for SVM and Decision Tree respectively. SVM with linear kernel predicts 50% of the outliers correctly and predict 50% as class 1.

All the other classifiers correctly predict the outlier. As our main concern is predicting the outlier, if a classifier predicts class 0 as class 1 or class 1 as class 2 it will cause no harm to the system.

The accuracy and precision are calculated using the (5) and (6) respectively. Fig. 8 illustrates the measure of accuracy and precision for training and testing phase of different classifiers. Table III contains the summary of accuracy and precision of different models. It shows that, in testing phase SVM with 'rbf' kernel has the highest accuracy and precision i.e. 98.61% and 99.60% respectively. Decision Tree classifier also performs well in the testing phase with the accuracy of 97.22% and precision of 94.59%.

(a) SVM (kernel = 'linear') (b) SVM (kernel = 'rbf', gamma = 0.5) (c) SVM (kernel = 'poly', degree = 3) (d) Decision Tree

Fig. 7. Result of applying different classifier on the labeled dataset (different colors represent different classes).

TABLE I. NORMALIZED CONFUSION MATRIX FOR SVM

	SVM (kernel = 'linear')				**SVM (kernel = 'rbf', gamma = 0.5)**				**SVM (kernel = 'poly', degree = 3)**			
	outlier	class 0	class 1	class 2	outlier	class 0	class 1	class 2	outlier	class 0	class 1	class 2
outlier	0.50	0.00	0.50	0.00	1.00	0.00	0.00	0.00	1.00	0.00	0.00	0.00
class 0	0.00	0.98	0.00	0.02	0.00	1.00	0.00	0.00	0.00	0.98	0.00	0.02
class 1	0.00	0.00	1.00	0.00	0.00	0.00	1.00	0.00	0.00	0.00	1.00	0.00
class 2	0.00	0.80	0.00	0.20	0.00	0.20	0.00	0.80	0.00	0.20	0.00	0.80

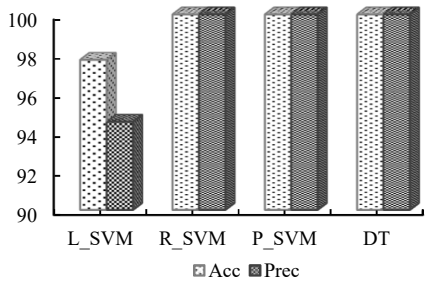

TABLE II. NORMALIZED CONFUSION MATRIX FOR DECISION TREE

	Decision Tree			
	outlier	class 0	class 1	class 2
outlier	1.00	0.00	0.00	0.00
class 0	0.00	0.98	0.00	0.02
class 1	0.00	0.00	1.00	0.00
class 2	0.00	0.00	0.20	0.80

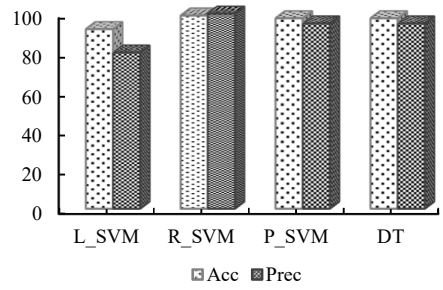

TABLE III. PERFORMANCE MEASURE INDICES OF OUTLIER DETECTION SYSTEM

Algorithm	**Kernel**	**Training Phase**		**Testing Phase**	
		Acc (%)	***Prec (%)***	***Acc (%)***	***Prec (%)***
SVM	Linear	97.68	94.51	91.67	79.71
	RBF	100	100	98.61	99.60
	Polynomial	100	100	97.22	94.59
Decision Tree	-	100	100	97.22	94.59

From Table III it is evident that if we compare the different models that have been employed on the system, SVM with 'rbf' kernel performs admirably in both training and testing phase with respect to other models.

(a) Training Phase

(b) Testing Phase

Fig. 8. Accuracy and precision for training and testing phase of different classifiers where L_SVM, R_SVM, P_SVM, DT represent SVM (kernel = 'linear'), SVM (kernel = 'rbf'), SVM (kernel = 'poly'), and Decision Tree respectively.

V. CONCLUSIONS

Protecting electronic devices from damage is very important as most of the devices are expensive. In this work, we focused on developing a system that not only detects outlier but also predicts whether a new current, voltage pair is an outlier or not. For outlier detection, a density-based clustering approach DBSCAN is used which can detect any arbitrary shaped cluster. Then, we develop models based on SVM and Decision Tree. We also provide a detailed performance measure for SVM with different kernels and Decision Tree. In the testing phase, SVM with 'rbf' kernel ends up with the highest accuracy of 98.61%. The performance shows that the proposed system will be quite helpful in protecting electronic devices.

***Abstract*—**Wireless capsule endoscopy (WCE) becoming a very useful device for detecting diseases in the human digestive tract. Using WCE Physicians diagnose the different abnormalities such as ulcer, bleeding, polyps, chronic diarrhea, small intestinal cancer/tumor and Crohn's disease in the digestive tract in invasive way. Researchers are working for the development and improvement of the performance of WCE using software to detect these diseases at a high rate of advancement automatically. This paper proposes an advance methodology for automatically discovering ulcers in the image converted from WCE video footage. The method applied for numerous frames of capsule endoscopic images with logistic regression classifier in HSV color space and found effectiveness for the physicians. We obtained the result of 87.70% accuracy and 94.00% sensitivity which provides the evidence of the accuracy of this automated computer aided system.

Keywords— CE images, Color threshold, GI tract, HSV Color space, Logistic regression classifier, Ulcer detection, Wireless capsule endoscopy.

I. INTRODUCTION

Throughout the world, a lot of people are affected by the diseases related with gastrointestinal tract specially stomach, small intestine, large intestine. In Bangladesh 27.8% people die in intestine infectious diseases [1]. In the United States, around 1.6 million Americans are now enduring from inflammatory bowel disease (IBD) and since 2011 increase to around 200,000. Each year about 70,000 new IBD are diagnosing. Among this 80,000 are children who are affected by Crohn's disease (CD) or ulcerative colitis (UC) [2]. IBD is now rising globally [3]. To cure the diseases of GI tract it is needed to detect as soon as possible. So now researchers are trying to upgrade the technique of detecting these types of disease. In this way there have used some medical diagnose system such as ultrasound, X-ray, CT scan, endoscopy, endoscopy biopsies etc. But these technologies have drawbacks and side effects for which researchers are working to discover such technique which will be the best technique and without any side effect. At last capsule endoscopy has been introduced which is painless during the procedure, easily swallowed and sedation free. At this technique a capsule shaped device containing a CMOS camera, a radio transmitter, a battery and light sources is swallowed by the patients with water like pill. This passes through the GI tract and taking caption and transmits via radio transmitter to the receiver [4]. The accruing video footage will be converted into images. These images will be processed by software for detecting the abnormalities. The abnormality for this paper is ulcer.

The WCE system consists of 3 components: (1) a capsule endoscope; (2) a sensing system with sensing pads or a sensing belt to piece together to the patient, a data recorder and a bat-terry cell; and (3) a personal computer with exclusive software for image inspection and explication. All 3 systems include handheld viewers that allow real time review of images during WCE examinations [4]. In WCE system, Different sensors are attached to the different position of abdomen and waist. A data recorder will be attached to the sensors. These sensors allow the capsule to wirelessly transmit images. Then the patient swallows the capsule with a glass of water. The capsule passes through the digestive tract and takes images. And then transmit wirelessly which is received by the receiver and stored in data recorder. The internal and experimental overview of the wireless capsule endoscopy are shown in the figure 1. Capsule endoscopy device, Internal construction of CE device, Image receiver, Attachment of sensors in human body at different positions and Real time viewer are respectively shown in the figure 1(b). By using real time viewer, the condition of imaging of the digestive tract is observed. The process continues approximately eight hours until the battery life of the capsule. There recorded approximately 50,000 images. The capsule is disposable and passes naturally within 24 – 72 hours.

Fig. 1. (a) Internal Structure of CE and (b) Imaging methods of CE

A. Related Work

Firstly, software was designed for detecting bleeding region whose sensitivity and specificity were only 21.5% and 41.8% [5]. Then a feature extractor is designed for detecting the abnormalities such as bleeding, ulcer and polyp named MPEG-7 visual descriptor [6]. According to [7] bleeding and ulcer has detected from of capsule endoscopy images which signify chromaticity moment using HSI (Hue-Saturation-Intensity) color space. In [8] statistical feature-based bleeding detection from capsule endoscopy video. In [9] bleeding detection is obtained by histogram from indexed images in capsule endoscopy videos. Curve let based local binary pattern in textural features for detecting ulcer regions from normal regions [10]. In [11] texture and color-based image segmentation and pathology detection in capsule endoscopy videos have proposed. In [12] A Color Coherence Vector (CCV) based feature is introduced for

identifying ulcer images of capsule endoscopy videos. In [4] histogram bin method for ulcer detection in capsule endoscopy was proposed.

In this paper a method is proposed using HSV color space with logistic regression classifier. At first convert the video footage into image frame. After that, enhance the image which highlights the key information. Then, color threshold is applied at HSV color space to get only the ulcer portion. After this, the images are converted into binary image, adjust intensity and sharpen the image and filter is used for removing the non-ulcer portion from the ulcer selection. Then, several features are extracted from the ulcer portion. Using these features, classifier is applied and tested on publicly available CE

II. OUR PROPOSED METHOD

The method we have used for ulcer detection is very much easy and ensured the high performance of the procedure. By using color threshold on the CE images, normal portion has been removed and separated the abnormal portion from the ideal portion which is regarded as ulcer for this paper. Normally, ulcer portion occupies small area on the ulcer image frame. Then the algorithm is only applied on that particular portion of the image frame for which the calculation is not complicated. The working chain of our proposed method is shown in Figure 2.

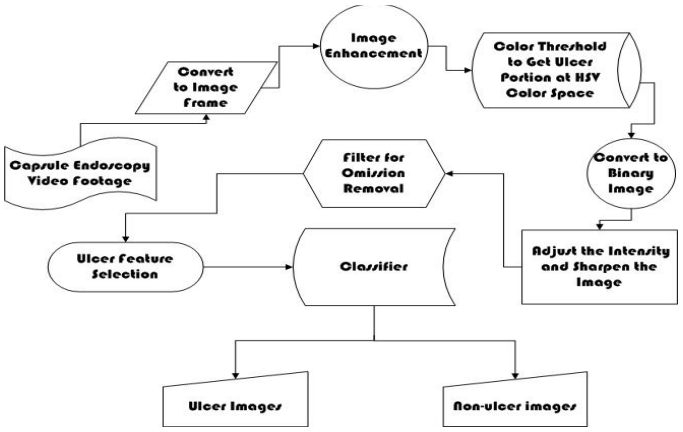

Fig. 2. Flow diagram of the proposed method

A. Video Footage to Image Frame

The initial process of this research work is to convert the acquiring video footage from wireless capsule endoscopy into image frame according to frame rate specified by the capsule specification for further processing such as image enhancement, image segmentation, feature extraction and classification. For this particular experiment, we have used capsule endoscopy of PillCam®SB whose frame rate per second is 2 and battery life is 8 hours which stored a huge amount of data for analyzing. From this huge data, we have used 220 color images from 8 capsule endoscopy videos which are available in [13].

B. Image Enhancement

Image enhancement is the method of adjusting digital images in order to make more suitable images for display or further image analysis. It removes noise, brighten an image, makes easier to identify, and sharpen as well. This is the initial step for preprocessing. The main purpose of the step is to remove noise and secondary information, enhance the contrast and high lighting the key information of an image. It also improves the quality of supervision [14]. For the image enhancement process, histogram equalization method has been employed in this paper.

C. HSV Color Threshold

Color threshold has been applied for removing the unwanted portion the images that fall within a specified color range and detect the objects of consistent color values. For this paper, the unwanted information of image is non-ulcer portion and detected object or information is ulcer. In this particular experiment, we applied color threshold in HSV color space. In the case of HSV color space, it contains the value the values of Hue, Saturation and Brightness at a particular range which only select approximately the ulcer portion from the CE images. By selecting these values **of** three channels in HSV color space we have obtained the ulcer pixels that have shown in Figure 3. This figure also displays the Hue, Saturation and Brightness value histograms which have been selected.

Fig. 3. Color threshold in HSV color space

D. Convert to Binary Images

After acquiring the color threshold images, we converted those into binary images which regard the pre-preparation for further calculation or feature extraction. Color threshold image converted to binary image has been shown in Figure 4.

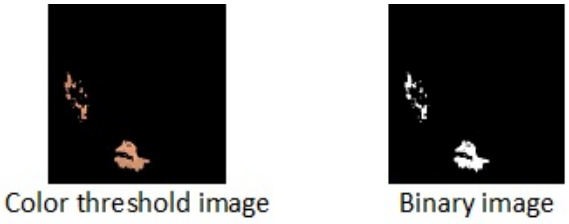

Fig. 4. Color threshold image converted to binary image

E. Filter for Omission Removal

The N-D filtering of multidimensional images has been applied that compares with a required value and truncates elements that exceed the range of the given prototype and rounds fractional values. This filter eliminates the non-ulcer portion from the pure ulcer portion which is the main requirement.

F. Convert to Binary Images

In this method, ulcer features of the capsule endoscopy images have been calculated by using mean of hue, saturation, brightness value and standard deviation of the pure ulcer portion. The image frames which contain any ulcer portion will have a particular numerical value. But image frames without any ulcer portion will contain zero numerical value. Some sample has shown in Table I.

TABLE I
Sample of ulcer and non-ulcer image features

	Mean Hue	Mean Saturation	Mean Value	Mean Std. Deviation
Ulcer	0.000308133512948861	0.00301234398048923	0.00433409447763483	0.000803345356704952
Ulcer	0.000753306172406202	0.00663013986873620	0.00979742910347761	0.001444624 87951517
Ulcer	0.000974931012444869	0.00869841504836054	0.01213699 04162840	0.002144505 84794773
Non-ulcer	0	0	0	0
Non-ulcer	0	0	0	0
Non-ulcer	0	0	0	0

G. Logistic Regression Classifier

For classifying ulcer and non-ulcer images logistic regression classifier has been used. It is a **classification** technique for different pattern recognition from the field of statistics. Logistics is the directory of the flow of sample between the point of origin and the point of haul. In this method of classification, the extracting four types of feature are measurement variables. The values of the nominal variable are "Ulcer" and "Non-ulcer" for this paper. To obtain the performance results 5-fold cross validation technique has been taken. After classification of these data ulcer and non-ulcer images will be separated.

III. Result and Discussion

The performance of logistic regression classifier in CE images is measured by accuracy, specificity and sensitivity which are extensively used to evaluate performances of classification. Here are definitions of them: In [10] definitions have been given:

$$\text{Accuracy} = \frac{Quantity\ of\ actula\ prediction}{Total\ sample\ data} \quad (1)$$

$$\text{Sensitivity} = \frac{Quantity\ of\ actula\ successful\ positive\ prediction}{Number\ of\ actula\ positives} \quad (2)$$

$$\text{Specificity} = \frac{Quantity\ of\ actula\ negative\ prediction}{Number\ of\ actula\ negatives} \quad (3)$$

Number of correct predictions is the sum of ulcer and non-ulcer images prediction is correct. Number of correct positive predictions is the number of ulcer images prediction is correct. Number of correct negative predictions is the number of non-ulcer images prediction is correct. The logistic regression classifier results obtained from the testing phase are summarized in Table II.

The Table III shows the correlation between different existing method. In addition, the table shows the evidence of higher efficiency of proposed method than the mentioned existing methods like CWC in which chromaticity is created [7], LBP which uses curvelet transformation [10], DCT-LAC in which lacunarity index is calculate to collect texture information [15] and histogram in which color plane is used [4].

TABLE II
Results obtained using logistic regression classifier for ulcer detection

Parameters	Values
Accuracy	87.70 ± 0.40%
Sensitivity	96.50±0.50%
Specificity	76.50±0.50%

TABLE III
Ulcer detection performance comparison with other existing method

Methods	Accuracy	Sensitivity	Specificity
CWC [7]	74.35%	78.46%	70.24%
LBP [10]	83.92%	86.28%	81.56%
DCT-LAC [15]	86.54%	84.51%	88.56%
Histogram bin [4]	87.27%	88.64%	85.75%
Proposed method	**87.70%**	**94.00%**	**75.00%**

IV. Conclusion

This paper proposed a method using color threshold of HSV color masking for selecting the ulcer portion in CE images that achieved from the video footage of WCE. After selecting the ulcer portion in CE images features are extracted only from the ulcer portion. Analysis of ulcer features values has been successfully prepared for providing the logistic regression classifier that offers the best separation of ulcer and non-ulcer images. The method has applied for numerous frames of capsule endoscopic images and found effectiveness. The result has obtained 87.70% accuracy and 94.00% sensitivity which proof that the proposed method is more accurate.

The results especially accuracy and specificity encourage that the method can be enhanced in the future by adding more image data base, statistical and texture features descriptor of other color spaces too.

***Abstract*— This paper proposes a model of sentiment analysis of various features of different companies' mobile phones and their overall rating. Before buying a phone, customers usually look for reviews to decide which phone to buy. The model proposed in this paper provides an optimal solution for the customer for making this decision more efficiently. In this model, each feature of a mobile phone is rated based on public opinion and an overall rating for each phone is provided. Amazon is one of the largest Internet retailers, which makes way for most public reviews on their products. These reviews are collected as a form of an open source platform and used as the dataset in this model. The gathered data is pre-processed and then separated into two different sets – Training Set and Testing Set which are used to train and test the supervised machine learning algorithms for classification. Fifteen most common features of the mobile phones based on public reviews are selected from the training data set and used as the feature set in this model. Different algorithms which include Naïve Bayes, Support Vector Machine, Logistic Regression, and Stochastic Gradient Descent algorithms are used in this model and the comparison of their performance is shown. This model provides a rating of each feature and an average rating of the mobile phone based on sentiment polarity. Thus, this research work can assist potential customers to choose the best product based on the opinion of the other users.**

Keywords—Sentiment Analysis; Machine Learning; Natural Language Processing

I. INTRODUCTION

Mobile phones have been one of the most essential components for us during the last decade. From Brick Phone to iPhone, technological advancement is seen in the sector of telecommunication. At present, mobile phones have different features according to the customer's choice and need. Among thousands of companies, offering their technology to the customers, choosing the appropriate phone for an individual has become an issue. Thus, the decision-making process becomes more challenging in recent times. In this research, a model is proposed which generates a rating of particular features and overall features, based on public reviews of different features or specification of a mobile phone. The ratings will let consumers compare their need and satisfaction and thus choose a suitable mobile phone. There are many websites, YouTube channels and also individuals on Social Media who reviews mobile phones. Professional reviewers are appointed by different companies to act as a marketing policy of the company.

However, very few reviewers are authentic and independent of their opinions. Such reviewing criteria benefits the mobile manufacturer companies to convince the customer about their product. This has major drawbacks from the consumer's point of view. However, lacking's in the software or hardware part of the product such as power consumption, battery lifetime, operating systems or operation time and many information get skipped for the sake of the company's marketing strategy. Thus, these reviews are not helpful in terms of customers point of view. Secondly, a mobile phone's technical features such as Chipset, GPU, CPU, OS's contribution to a mobile phone system are not often understood to an average user. Thus, a potential buyer cannot get suitable information that he desires about a mobile phone from the reviewers. Thirdly, the reviewer's point of explanation of a device does not match the expectation of the customer. A customer's prime concern may be about the camera while a reviewer will be emphasizing on other technical features of the device. This indicates the absence of a platform where customers can get the rating of their desired features. Additionally, a professional review never reflects the actual state of a device. Generally, reviewers don't review the device after using it for a long time, rather they do their reviews based on a test-use which doesn't always contemplate the actual experience of that particular device. Therefore, the customer's opinion about a mobile phone and its features are more reliable and authentic. This is why comparing ratings of public opinions about mobile phone to buy one is better rather than relying on professional reviews. Author's in this research also focused on public reviews rather than the professional reviewer's opinion.

The rest of the paper is organized as follows. In Section II, background study and related works have been presented. In Section III, the working principle has been explained. Furthermore, in Section IV, the result of the work has been

discussed. And finally, in Section V, the conclusion of the paper with future work has been presented.

II. Background Study

Sentiment analysis is an emerging area of research in natural language processing (NLP). In recent years, this field has gained much interest as the social context changed a lot. The internet-based economy made sentiment analysis more essential. As the number of consumers' review increases, the need for analyzing these reviews automatically is also increasing which can help today's business to significantly improve as digital marketing has become a genuine marketing concept. As a result, not only researchers but also entrepreneurs are becoming interested in sentiment analysis [1].

Sentiment analysis is a machine learning method which can be used to classify and analyze peoples' sentiments, emotions, opinion, etc. Review of online product which is expressed in terms of text, star rating, and thumbs up and down can be analyzed using sentiment analysis which can significantly help to improve certain products or services [2]. With the aid of negative prefixes, words like adjectives and adverbs are able to carry the opposite sentiment. So, in this research, the authors used the negation phrase identification algorithm to find such words and analyzed the reviews.

In some researches, twitter data is used for sentiment analysis. Similarly, in the research conducted by Rane and Kumar, the authors have classified twitter data for US airline service analysis where firstly the tweets are pre-processed to obtain a vector using deep learning concept (Doc2vec) for phrase-level analysis. And then using 7 different classification technique, the analysis is carried out. Based on the accuracy of the result, a comparison among different classification technique is given in this research paper [3]. Opinions can also be extracted based on the product's features using several techniques. In this research paper, the authors suggested a system that automatically expands opinion lexicon and based on dependency relations, the product's features are extracted. And to find this dependency relation between features and opinions, StrandfordCoreNLP dependency parser is used and then an algorithm based on double propagation is used to extract feature and opinions [4]. With the aid of Vader lexicon, polarities of extracted opinions are defined.

The author Xing Fang and Justin Zhan in their research work describe that when sentiment sentences are extracted, it contains at least one positive or negative word. Tokenization is done to separate the sentences into words and Parts-of-speech (POS) tagging is done. From the original dataset, the tokens and their scores are extracted which are known as features. So, to classify these features, they transformed into vectors [5]. Furthermore, in another paper, the authors used unsupervised learning on large twitter corpora to obtain a word embedding which uses latent contextual semantic relationships and co-occurrence statistical characteristics between words in tweets [6]. Together with n-grams features and word sentiment polarity score features, these words embedding form a sentiment feature set of tweets and this feature set is combined into a deep convolution neural network for training and predicting sentiment classification labels. This model shows a significant amount of accuracy in their result.

However, authors Roshna Rafeek and R. Remya, in their research work stated that context-dependent opinion words are challenging for sentiment analysis because of their polarity changes according to the context in which they are used. So, to overcome this challenge, they have proposed a system that uses (aspect, opinion) pairs and logistic regression (LR) model. In this model, to acquire (aspect, opinion) pairs, syntactic rules are used and for classifying the sentiment words into positive class and negative class, the LR model is used [7]. In this research paper, the authors proposed an approach for sentiment analysis using Python and its library NLTK (Natural Language Toolkit). Python, which is simple yet powerful, high level, interpreted and dynamic programming language, is very useful for processing natural language using its own library NLTK that helps to build programs and classify data. Data can be trained and different numerous classifiers can be tested using NLTK. Additionally, using NLTK, results, and patterns can be graphically represented.

In another research, the authors described different supervised machine learning approaches for sentiment analysis [8]. Various algorithms are used and their advantages and disadvantages are stated. There are two broad categories which are Lexicon based approach and machine learning approach. In their research work, they have used three algorithms. These algorithms are naïve Bayes, support vector machine and maximum entropy. According to their result, naïve Bayes algorithm provided better accuracy than the other two [9].

III. Working Principle

Sentiment analysis is a very useful tool in the modern technological era where people are frequently sharing their thoughts in microblogging social sites. Analyzing sentiments help human beings to take a decision in case of socio-economic and business aspects. In this research, we used natural language processing along with machine learning algorithms to find out the sentiment of a review. Furthermore, they also intended to find the best accuracy of the sentiment. We used different machine learning algorithms, such as Naïve Bayes Classifier, Linear Regression, Support Vector Classifier, Stochastic Gradient Descent Classifier and Random forest for analyzing sentiments. A block diagram is given below to show the proposed model of sentiment analysis,

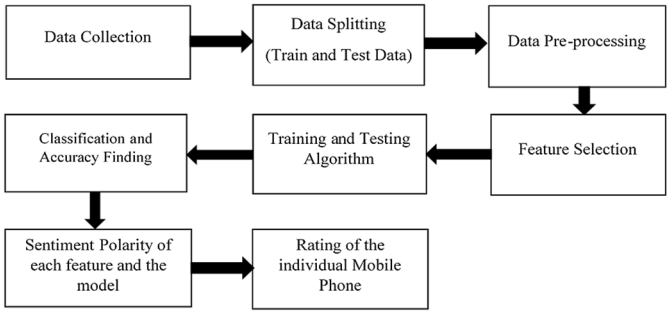

Fig. 1. Block diagram of the proposed model.

A. Data

Dataset is the most important factor in any kind of machine learning and sentiment analysis process. In the research of sentiment analysis, the most technical and one of the toughest tasks is to find out the proper dataset applicable to the model. As the aim is to find out the proper review and rating of a mobile set, we generalized searching criteria for datasets with proper reviews along with mobile set company or model name. We used Amazon's unlocked mobile phone review's dataset which was collected from an online open source platform named Kaggle. There were four hundred thousand data in the dataset. The dataset had six columns, which were 'product name', 'company name', 'review', 'rating', 'rating votes'. Three of the columns consists of textual data and the rest is numerical data. 'Product Name' column represented the model of the mobile phone whereas the 'Company Name' had the name of the company. The review column consists of reviews provided by users. These reviews are mixtures of different sentence type. Rating column is the rating of each review given by users at Amazon.

B. Text-Preprocessing

Data preprocessing is the process of cleaning the data to an extent where the machine learning algorithm will understand the content of the data. Overall the data pre-processing deals with finding the inaccurate, irrelevant and incomplete data and removing or minimizing the data. Pre-processing is a very important step in terms of textual data. This pre-processing task is done using NLTK (Natural Language Tool Kit) which is an open source language tool for textual data mining. There are several steps of text pre-processing, which are,

i. Tokenization
ii. Normalization
iii. Noise removal

Tokenization is a step which splits longer strings of text into smaller pieces or tokens. Larger chunks of text can be tokenized into sentences and sentences can be tokenized into words, etc. Further processing is generally performed after a piece of text has been appropriately tokenized. Tokenization is also referred to as text segmentation or lexical analysis. Sometimes segmentation is used to refer to the breakdown of a large chunk of text into pieces larger than words (e.g. paragraphs or sentences), while tokenization is reserved for the breakdown process which results exclusively in words.

Before further processing, the text needs to be normalized. Normalization generally refers to a series of related tasks meant to put all text on a level playing field: converting all text to the same case, upper or lower case, removing punctuation, converting numbers to their word equivalents, and so on. Normalization puts all words on equal footing and allows processing to proceed uniformly. Normalizing text can mean performing a number of tasks, but for our model, we approached normalization in three distinct steps, Stemming, Lemmatization, and POS tagging.

Stemming is the process of eliminating affixes (suffixed, prefixes, infixes, and circumfixes) from a word in order to obtain a word stem. Lemmatization is related to stemming, differing in that lemmatization is able to capture canonical forms based on a word's lemma. For example, stemming the word "cacti", "geese", "rocks" would fail to return its citation form (another word for lemma); however, lemmatization would result, "cactus", "goose", "rock". POS tagging is also a part of text pre-processing and used for detecting the parts of speech of the words in a sentence. For selecting the adjective of a sentence, we have to use this process in sentiment analysis.

C. Feature selection of a mobile phone

The model concentrates on finding out the most frequently reviewed specifications of the mobile phone, so the selection process plays a key role in the working methodology. Mobile phones have multiple features like Camera, RAM, Storage, Battery, Display, Operating system, etc. Firstly, a list of the specifications was created. As a single feature may have several names, we created NLTK synonyms for the features or specifications and stored all the strings in a single array. The features which appear mostly in the dataset are taken into account and matched with the feature set we created. We selected in total 15 features, mostly consisting of nouns which define the specification of any mobile phone.

D. Classification

We have used multiple algorithms for training the dataset. The amount of train data was increased gradually to see the accuracy of the algorithms. Classification is the task of choosing the correct class label for a given input. In the basic classification tasks, each input is considered in isolation from all other input, and the set of the labels is defined in advance. Mentioned earlier, we are using the built-in libraries to do all the classification process. To be specific, the following algorithms are used in the classification process,

- Naïve Bayes (NB), Multinomial Naïve Bayes (MNB), Bernoulli Naïve Bayes (BNB)
- Support Vector Classifier, NuSVC, and Linear SVC
- Logistic Regression and Linear Regression
- Stochastic Gradient Descent (SGD) Classifier
- Random Forest

Machine learning algorithms are used to classify the sentences based on their polarity. However, the purpose of the research is to find out the best algorithm for sentiment analysis based on the accuracy of classification. The details of the algorithms are given below,

1) Naïve Bayes Classifier: A Naive Bayes classifier is an algorithm that uses Bayes' theorem to classify data. Naive Bayes classifiers assume strong, or naive, independence between attributes of data points. The classifier uses probability theory to classify. The main key insight of Bayes' theorem is that the probability of an event can be adjusted as new data is introduced. A Naïve Bayes classifier is called naïve because it assumes that all attributes of a data point under consideration are independent of each other [10]. A Naïve Bayes model is easy to build and it has no complicated iterative parameters estimation which makes it particularly useful for very large datasets.

2) Linear Regression: In machine learning and statistics linear regression is very useful for classifying a large set of datasets. The model attempts to model the relationship between two variables by fitting a linear equation to observed data. One variable is considered as a dependent variable whilst the other variable is considered as an explanatory variable. Linear regression has the equation,

$$Y = a + bX \tag{1}$$

Here, X is the explanatory variable and Y is the dependent variable, the slope of the line is 'b' and 'a' intercepts. We determined the relationship between variables of interest and attempted to fit the linear model for the observed data.

3) Support Vector Machine: Support Vector Machine (SVM) is a supervised machine learning algorithm which can be used for both classification or regression challenges. However, it is mostly used for text classification [11]. In the algorithm, each data will be plot as a point in n-dimensional space with the value of each feature. n is the number of features. Then classification is done to find the hyperplane to differentiate two classes very well. Normally this model draws lines to separate the groups according to patterns.

4) SGD Classifier: Stochastic Gradient Descent also known as SGD classifier is a very efficient approach to discriminative learning of linear classifiers under convex loss functions such as (linear) Support Vector Machines and Logistic Regression. For large scale learning, this algorithm is very efficient. Moreover, this algorithm is very successful in text classification as well as natural language processing.

5) Random Forest Classifier: Random forests, also known as random decision forests, are a popular ensemble method that can be used to build predictive models for both classification and regression problems. It is a flexible, easy to use machine learning algorithm that produces, even without hyper-parameter tuning, a great result most of the time. It is also one of the most used algorithms because it's simplicity and the fact that it can be used for both classification and regression tasks [13]. As its name, it creates a forest and makes it somehow random. The 'forest' it builds, is an ensemble of Decision Trees, most of the time trained with the "bagging" method. The general idea of the bagging method is that a combination of learning models increases the overall result. Simply random forests build multiple decision trees and merge them to get more accurate and stable predictions. There are three main choices to be made when constructing a random tree. These are (1) the method for splitting the leaf's, (2) the type of predictor to use in each leaf, and (3) the method for injecting randomness into the trees.

The classification algorithms are to classify the dataset which consists of features and finds out the accuracy of the algorithms. The classification is done in a various number of sets starting from 1000. We have to find out the accuracy of the different algorithm by gradually increasing the number of sets. However, to get the best accuracy it is vital to increase the number of sets. For this research, classification started from 1000 up to 12000 because the larger the set number the more computer power is needed for classification.

IV. Result and Discussion

In the proposed system, the Python programming language is used for implementation. To measure the accuracy of the algorithm we used an evaluation equation. Accuracy is the performance evaluation parameter and it is calculated by the number of correctly selected positive and negative words divide by the total number of words present in the corpus. The formula is given below,

$$Accuracy = \frac{\sum TruePositibve + \sum TrueNegative}{\sum TotalNumberofWords} \tag{2}$$

Here, true positive is the number of tweets recognized as positive and true negative is the number of tweets recognized as negative.

As high computing power is needed for finding the best accuracy by classifying large data sets, we classified a selected set for classification. Figure 2 demonstrates a graphical representation of the classifiers and the accuracy obtained by using the number of sets. Matplotlib, a python plotting library was used for plotting the data.

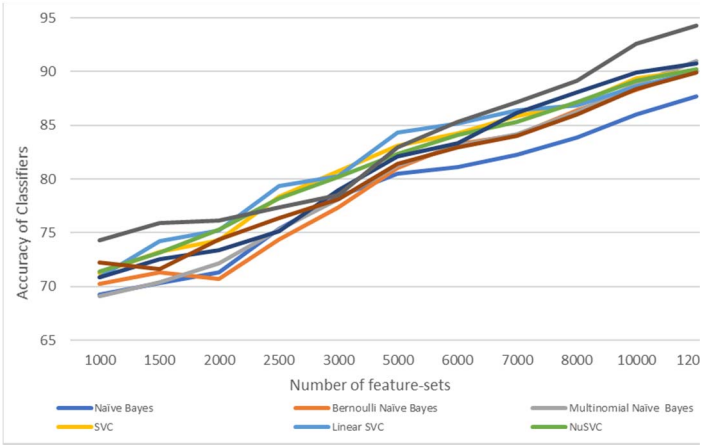

Fig. 2. Machine Learning Algorithms Accuracy

It clearly indicated the high accuracy whenever the number of sets is increased. The line chart shows the superiority of the Random forest algorithm as it shows the highest accuracy of around 92% with 12000 sets.

In this research data selection, data pre-processing, and specification or feature selection of mobile phones, training algorithms, classifying algorithms are done. Python and Scikit-learn which is a machine learning library of python and NLTK which is a language processing tool widely used for the sentiment analysis and text polarity measurement are used for the research. However, we have applied all the classifiers individually to get the best accuracy but for the best outcome from sentiment analysis, it is recommended by many researchers that a combination of multiple supervised algorithms will be better. This combined classifier provides the best possible result for the pre-processed data. As mentioned earlier, we have separated all the sentences of the review text according to the specification or feature of the mobile. As an example, if there is a review mentioning multiple features of the phones followed by their review, the sentence is picked and applied sentiment analysis on that sentence. In figure 3 selection of sentence, the process is shown in a pictorial view.

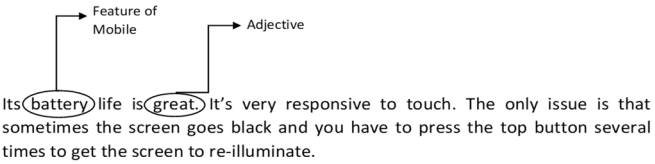

Fig. 3. Selection of Adjective and Specification (feature)

After the selection of text, we specifically applied sentiment analysis with NLTK in the adjectives or the words which can determine polarity. As an example, "Nokia is the brand that can be used in telephone, good price, excellent team, was a gift to my daughter and she liked it, easy to use and very affordable price, I recommend it." this review has one big sentence with a lot of features or specification and their classification, the result shows polarity positive and the confidence level 98.56%.

The last step of the research is to provide a rating of the mobile phone according to the review and polarity. In the previous step, we found out the polarity of each feature and the score of the polarity which starts from 0 to 100. However, there is a threshold value in sentiment score, which determines the accuracy of the sentiment analysis. We set the threshold value to 30 so whenever the score is less than 30 the sentiment analysis will indicate it as a bad sentiment.

To rate the mobile we used a special parameter. As in sentiment analysis, the polarity of each word along with the polarity percentage is shown, we used the polarity percentage and converted that numerical value into the 0-5 range. This gives an individual rating of each feature. However, to find out the rating of the product or mobile phone, the average rating of each feature is calculated which shows the rating of the desired mobile phone.

$$Average\ \ rating = \sum_i^n \frac{ratingofeachfeature}{n} \qquad (3)$$

In figure 4 the result of the example is shown, which consists of the final result of sentiment analysis.

```
C:\Users\LENOVO\Thesis\Scripts\python.exe C:/Users/LENOVO/PycharmProjects/Thesis/New.py
Review Sentence
Nokia is the brand that we can rely on, good price, excellent durability.
 I gifted my daughter and sheliked it, very affordable and long battery life
Sentiment Analysis -->
Positive
Confidence Level: 98.99

Specification/Feature based result -->

Noun --> Adjective --> Polarity

Price --> Good --> Positive
Durability --> Excellent --> Positive
Battery --> Longlife --> Positive

Process finished with exit code 0
```

Fig. 4. The final result of Sentiment analysis

The framework applied in this research seems very convenient in terms of mobile selection for customers. This methodology will help the customers to evaluate any mobile phone based on public rating. Moreover, this model also determines the rating of a mobile phone by calculating the mean value of all ratings of that particular device. However, from this research, we compiled some comparisons between different devices. Figure 5 represents the ratings of different mobile devices.

Fig. 5. Rating comparison between different models

V. CONCLUSION

In today's world, uses of sentiment analysis can play a significant role to understand people's opinion automatically and use that to improve certain product or service efficiently. This can be a field of interest for both researchers and entrepreneurs. In this research, analyzing the sentiment of the customer's review of mobile phones which is collected from Amazon and rate them according to their features. Naïve Bayes, Support Vector Machine, Logistic Regression, Stochastic Descent algorithm are used in this model and accuracy of their performance are compared which showed that SVC and Random forest perform better with greater accuracy. Using multiple algorithms helped to understand which algorithm is more suitable for this system. Ratings of the product are given based on the average polarity obtained which can help the customer to know about certain products or services and take decisions accordingly. From this research work, it is found that, the cleaner the data, the better the accuracy of the result. In the future, this model can be implemented as a web application so that while a customer is willing to buy a certain product, they can easily make a decision just by looking at the ratings.

We want to improve the algorithms that are used in this research. In the future, the goal is to apply unsupervised machine learning in the model, such as the neural network. We are looking forward to making the decision-making process easier when it comes to selecting mobile phones for users. We believe that this model will be user-friendly and accurate enough for users to use this on a regular basis for judging mobile phones and save their time from looking at different sites to find good reviews.

***Abstract*—Content-based image retrieval is an application of retrieving similar images of a query image. In this paper, global and local features are used to describe the content of an image. Color, texture and shape features are used as global features and SURF, FAST and BRISK are used as local features to retrieve similar images from the database. Different similarity checking methods are also tested to find the best approach. Combined approach using global features (obtained by using modified gray-level co-occurrence matrix) and local features (obtained by using SURF and color moments) produce better accuracy than some existing methods. Here, local features are obtained around the blob points detected by SURF detector. SURF descriptor and color moments which are calculated within a region of size 6*s* (*s* is the scale of the image at which the blob point is detected) around the detected blob points are used for extracting local features. Color moments are used because SURF only works on grayscale images. Thus, local color information is achieved. This combination of global and local features result in better performance in term of accuracy compared to some current methods.**

***Index Terms*—image matching, image processing, unsupervised, feature extraction, feature matching, SURF**

I. Introduction

For the last few years, similar image retrieval systems from large image database have been growing rapidly. Content-based image retrieval (CBIR) is a system which retrieves similar images of a query image from a image database without any help of caption, description of images.

During similar image retrieval, all retrieved images are not actually similar to the query image. This is because different objects can have same color, texture or shape. It is hard to differentiate objects with same color and texture. Yet, there is no universally applicable algorithm that can understand image as human does [1].

Similarity between two images is determined by checking the similarity of the contents of the two images, e.g., textures, colors, shapes etc. Feature extraction and feature matching are the two main processes of a CBIR system [2].

Any single technique usually can not extract features from an image by considering all aspects such as scale, rotation etc. There are also many good and bad aspects of similarity checking methods during similar image retrieval. No similarity checking method is perfect for matching all kinds of features. Objective of this work is to develop an efficient CBIR system which can retrieve similar images according to the query image by using the best combination of feature extraction and similarity checking methods.

II. Related Works

A CBIR system using color features (combined HSV, auto correlogram and color moments) and texture features (gabor wavelet) is proposed in [3]. It gets overall accuracy of 89.47% using a set of images as training images from a class and other images of the same class as test images. In case of another set of training images and test images it gets overall accuracy of 87.89%. In [4], color and texture features are used. Color Moments and Wavelet Packet Entropy are applied for extracting color and texture features respectively. Then, the correlation between those components of query image and images of the database are computed. The mostly correlated images with the query image are retrieved. This method shows better accuracy than the method in [3] for most of the cases by using 50 images of a class as training images and other 50 images of the same class as test images for all classes of WANG database [6], [7]. In [5], speeded-up robust features (SURF) is combined with the color features (color moments) which are calculated for a 5×5 fixed region around the SURF interest point for the RGB channel. It uses the KD-tree with the best bin first search algorithm to match the similarity between the features of the images. COIL-100 object database is used in this work which contains 72 views for 100 objects acquired by rotating the object under study about the vertical axis. This proposed method achieves 88% of average precision for 15 categories of 1080 images of COIL-100 database. A CBIR approach using SURF and fast retina keypoint (FREAK) is

proposed in [23]. This work is invariant to rotation and scale. But no color information is used in this approach since SURF and FREAK do not give color information. It uses Euclidean distance to measure the similarity between the query image and images of the dataset. Another CBIR approach based on visual words fusion of SIFT (scale invariant feature transform) and LIOP (local intensity order pattern) is proposed in [24]. This approach also uses Euclidean distance for retrieving similar images of the query image.

III. Feature Extraction

Generally, there are two kinds of features to describe the content of an image, global and local features [8]. Global features contain information of the whole image. On the other hand, local features are calculated from a local region of an image.

A. Global Feature Extraction

Generally, global features include color, texture and shape features. Color space is defined as a model for representing color in terms of intensity values [9]. There are several ways to extract color features such as, color histogram, color moments [10], color autocorrelogram [11], color layout descriptor (CLD) [12] etc. Texture is a property of image region rather than just pixel value like color [13]. There are many ways to extract texture features, such as using gray-level co-occurrence matrix (GLCM), wavelet moment, wavelet entropy [4] etc. Shape feature represents contours and shapes of objects in the image. There are many ways to extract shape features [14], such as, Hu's moment invariants [15].

1) Gray-Level Co-Occurrence Matrix (GLCM): Co-occurrence matrix describes the spatial relationships among pixels in a grayscale image. Gray-level co-occurrence matrix (GLCM) extracts texture features from an image by calculating the number of occurrence of pair of adjacent pixels with same intensity value. Similarity of pixels is calculated considering the horizontal, vertical or diagonal relation between the adjacent pixels.

B. Local Feature Detection and Extraction

Local features can be points, edges or small image patches [16]. Local feature detection means finding a pixel or a set of pixels from an image which are different with respect to color, texture from their neighbor pixels. These are called interest points. Local feature extraction means computing features around the detected interest points. Some feature detectors and descriptors are: Speeded-Up Robust Features (SURF) [17], Features from Accelerated Segment Test (FAST) [18], Binary Robust Invariant Scalable Keypoints (BRISK) [19] etc.

1) Speeded-Up Robust Features (SURF): The Speeded up robust features (SURF) is a scale and rotation-invariant blob-like interest point detector and descriptor which is computationally very fast [17]. To improve the speed of summing intensity values of an area of an image, SURF uses integral images. SURF descriptor extracts a distribution of haar-wavelet responses around the detected interest point [17].

Integral image is used for calculating the sum of intensities of a region of an image using only four memory look ups. The entry of an integral image $I_{\sum}(X)$ at a location $X = (x, y)^T$ is

$$I_{\sum}(x) = \sum_{i=0}^{i \le x} \sum_{j=0}^{j \le y} I(i,\ j). \tag{1}$$

However the region size is, calculation time for finding the sum of pixel values is independent [17].

SURF detector detects interest points (blob points) using Hessian matrix. The point where the determinant is maximum is considered as an interest point [17]. The Hessian matrix $\mathcal{H}(\mathrm{X},\ \sigma)$ for a pixel $X = (x, y)$ in an image I at scale σ is defined as follows:

$$\mathcal{H}(X, \sigma) = \begin{bmatrix} \mathrm{L_{xx}}(\mathrm{X},\ \sigma) & \mathrm{L_{xy}}(\mathrm{X},\ \sigma) \\ \mathrm{L_{xy}}(\mathrm{X},\ \sigma) & \mathrm{L_{yy}}(\mathrm{X},\ \sigma) \end{bmatrix}, \tag{2}$$

where $L_{xx}(\mathrm{X},\ \sigma) = \frac{\partial}{\partial x^2} g(\sigma)$, which is the convolution of the Gaussian second order derivative at pixel X, and similarly for $L_{xy}(\mathrm{X},\ \sigma)$ and $L_{yy}(\mathrm{X},\ \sigma)$. SURF approximates second order Gaussian derivatives with box filters [17]. The determinant of the Hessian matrix is calculated as:

$$det(\mathcal{H}_{approx}) = D_{xx}D_{yy} - (wD_{xy})^2, \tag{3}$$

where D_{xx}, D_{yy} and D_{xy} are the box filters for approximating Gaussian second order partial derivative in x, y and xy direction respectively. Here, w is kept constant at 0.9 [17]. As SURF is scale-invariant, it detects interest points at different scales. A fixed number of scales are defined for each octave by repeatedly smoothing the image with a Gaussian. In SURF, scale space is determined by increasing the box filter size. As an example, for the third octave, the filter sizes are 27-by-27, 51-by-51, 75-by-75, ... The initial scale is $s = 1.2$ which is the output of the 9×9 filter [17].

During local feature extraction, a circular region is taken around the interest point of size $6s$, where s is the scale at which interest point is detected. Haar-wavelet responses are calculated in both vertical and horizontal directions within the circular region. The dominant orientation is taken in the direction where the two summed responses are longest [17]. A squared window of size $20s$ is taken around the interest point. The window is oriented along the dominant orientation. To extract the features, for each 4×4 square of the window, the wavelet responses are computed from 5×5 samples [17]. For each 5×5 region, a four-dimensional feature vector is calculated.

$$V = (\sum d_x, \sum d_y, \sum |d_x|, \sum |d_y|), \tag{4}$$

where d_x is the haar-wavelet response in horizontal direction and d_y is the haar-wavelet response in vertical direction [17]. This results in a feature vector of length 64 for all subregions within the window.

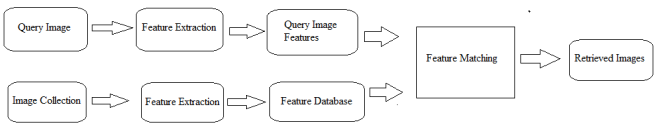

Fig. 1. The proposed CBIR system.

IV. Feature Matching

There are several ways of measuring distance between features of a query image and an image from a database. These are: euclidean distance (L2), standard euclidean distance, canberra distance, mahalanobis distance, city block/manhattan distance, relative manhattan distance (L1), minkowski distance, chebyshev/chessboard distance, cosine distance, correlation, spearman, relative deviation, fast approximate nearest neighbor search using multiple randomized kd-trees and hierarchical k-means tree [20]. Among them fast approximate nearest neighbor search is ideal for matching local features.

A. Fast Approximate Nearest Neighbor Search using Multiple Randomized Kd-trees and Hierarchical K-means Tree

An automatic process is proposed in [20] for selecting algorithm between multiple randomized kd-trees and hierarchical k-means tree for finding approximate nearest neighbor. One of these two algorithms gives the best performance depending on the dataset and desired precision.

Let, X is a high-dimensional feature vector and d_1 is a dimension of X which has largest variance. At the first stage of creating a normal kd-tree, X is split in d_1 dimension. Similarly, for each level of the tree, X is split in d_i dimension, where d_i dimension shows the largest variance. On the other hand, randomized kd-tree is built by splitting X in d_j dimension, where d_j is chosen randomly from first 5 dimensions which show largest variance [20]. The randomized kd-tree is created k times depending on the search time and tree build time. Each of the k trees is created on the rotated dataset [21]. By searching the kd-tree, similar features are found.

During creation of hierarchical k-means tree, X is split into K regions using k-means clustering for each level of the tree. This process is repeated for each regions until the number of points of a region become less than K. By searching the hierarchical k-means tree in a best-bin-first manner, similar features are found [20].

V. The Proposed System

The proposed CBIR system is shown in Fig. 1. To retrieve similar images, the feature vectors are extracted from the given query image. Similarities between the feature vectors of the query image and the feature vectors of the database images are then calculated. The retrieved images are the images with features that match with that of the query image in term of similarity.

Different combinations of feature extraction and matching techniques are investigated to find the best approach.

A. Algorithms for Feature Extraction

1) Color Feature Extraction Using Color Moments: In the proposed method, first, two color moments, mean and standard deviation are used. To do this, color moments are computed for each channel of RGB image. Thus, total 6 color moments are obtained for each image.

2) Texture Feature Extraction Using Gray-Level Co-Occurrence Matrix (GLCM): The RGB image is converted to the gray scale intensity image. Then the range of intensity values of the image are changed from 0 - 255 to 0 - 7. The GLCM is created by calculating how many times a pixel with value *i* occurs horizontally adjacent to a pixel with the value *j*. Thus, a feature vector of size (8×8) is obtained. The feature vector is simplified by resizing it to (1×64) size. Another GLCM is also obtained by calculating how many times a pixel with value *i* occurs vertically adjacent to a pixel with the value *j*. Finally, combining the 2 results, feature vector of size (1×128) is obtained. This is referred as 'modified GLCM' in this context.

3) Shape Feature Extraction Using Hu Moment Invariants: In this work, the seven Hu moment invariants are used as shape features. The Hu moment invariants are described in [15]. These seven moments are combined to make a vector of size 1×7.

4) Local Feature Detection Using SURF: At first, RGB image is converted to the gray scale intensity image. Then local feature (blob) is detected using SURF detector based on the hessian matrix as described in section III-B1. Strongest feature threshold = 500.0, number of octave = 3, number of scale levels per octave = 4 are used during SURF point detection. The number of points detected, location of the detected points, scale at which the interest points were detected, strength of detected feature, sign of the laplacian and orientation of the detected feature (specified as an angle, in radians) from the SURF points are obtained during the detection process.

5) Local Feature Extraction Using SURF: SURF algorithm derives the descriptors from pixels surrounding an interest point as described in section III-B1. The interest points can be detected using SURF, FAST or BRISK detector. Each interest point determines the center location of a neighborhood for extracting local features. If n is the number of detected interest points, then SURF descriptor extracts features of size ($n \times 64$).

B. Algorithms for Feature Matching

If F_q is the feature vector of query image and F_d is the feature vectors of the database images, then the similarity between the F_q and F_d can be computed using any similarity checking methods as described in section IV. Similarity checking methods give the distance between two feature vectors. The distance output is sorted in ascending order and the images for which the distance shows minimum value output, the corresponding images are retrieved as similar images of the query image.

1) Global Feature Matching: Euclidean distance (L2), standard euclidean distance, mahalanobis distance, city block/manhattan distance, relative manhattan distance (L1),

minkowski distance, chebyshev/chessboard distance, cosine distance, correlation, spearman and relative deviation are used for checking similarity between the global features of query image and database images.

2) Local Feature Matching: Generally, the local feature vectors are higher dimensional, large and SURF, FAST and BRISK give different number of interest points for different images. For this reason, feature matching process can be tedious. To solve this problem, an efficient approximate nearest neighbor search [20] which selects the best algorithm, between multiple randomized kd-tree and hierarchical k-means tree, based on the desired search precision, is used for local feature matching (described in section IV-A). In this approximate nearest neighbor search process, search precision 70% is chosen, meaning that 70% returned neighbors are exact nearest neighbors and 30% are just approximations. If two feature vectors are f1 and f2, then multiple features in f1 can match to one feature in f2. In this case, the best match is kept. Distance between a query point and a node of the tree is measured using sum of squared differences. After the completion of the nearest neighbor search, matching features and the distances between those features, from the two feature vectors of the images, are obtained. This nearest neighbor search is done separately between each images of the database and the query image to form a new vector:

$$f_i = \begin{matrix}[number\ of\ matching\ features\ with\ the\ query\ image,\\ sum\ of\ distances\ of\ the\ matching\ features],\end{matrix} \quad (5)$$

for each images of the database (In case of WANG database, i = 1,...,999, except the query image itself). Let, number of matching features with the query image = n and sum of distances of the matching features = d. Now the database images are sorted according to two criteria: (I) n in descending order (II) d in ascending order when $n_i = n_j$, where i and j are two different images. Here, n is much bigger number than d. So, at first, n and d are obtained by comparing query image with itself which gives, f_0 = [number of matching features (a large number), 0]. Then f_0 is compared with the vector mentioned in (5) using cityblock distance for each images of the database except the query image. The cityblock distances are sorted in ascending order. Thus, sorted similar images of the query image are obtained according to the two criteria.

VI. Experimental Results

WANG database [6], [7] is used for testing. It contains 1000 images of 10 classes, each class having 100 images. The 10 classes are African people, beaches, buildings, buses, dinosaurs, elephants, flowers, horses, mountains and food. The 10 classes are used for relevance measurement [22]. For a query image, all images from the same class of the query image are similar to that image.

To evaluate the performance of each method, the accuracy of each method is calculated. Here, accuracy is the ratio of the number of similar images retrieved to the total number of images retrieved expressed in percentage [22]. For example, if number of retrieved image for a query image is 20 and 14 of them are similar images, then the accuracy is 70%.

$$\text{Accuracy} = \frac{Number\ of\ relevant\ images}{Total\ number\ of\ images\ retrieved} \times 100, \quad (6)$$

where total number of images retrieved = number of similar images + number of dissimilar images.

In this work, accuracy is calculated by considering 20 retrieved images for each query image. Here, each of the 1000 images of WANG database is considered as query image. Thus, total number of image retrieved = (1000 $\times$ 20) = 20000.

Since this work is unsupervised, no supervised classification method is used. If the query image is from class 1 then the class 1 is the positive class and the classes except the class 1 is the negative class jointly. Therefore, the top 100 retrieved images for the query image are the images which are predicted as the members of the positive class. Because, each class has 100 images. Since the number of retrieved images which are predicted as the members of the positive class is always same, the accuracy, precision and recall values are always same. For example, top 100 images are retrieved for a query image of class 1. Among the 100 images, if 70 images are actually from class 1 then the number of true positives are 70, other 30 images are false positives and number of false negatives is also 30. So, the accuracy, precision and recall all are 70%. For this reason, precision and recall are not used here to measure the performances.

Table I shows the accuracies for each of the above described global feature extraction techniques (the one feature matching technique is included in the table which gives the best accuracy for a global feature extractor). From Table I, it is observed that, among the color feature extractors, the best accuracy is obtained using color histogram which is **60.62%** using the relative manhattan (L1) distance. Among the texture feature extractors, the best accuracy is obtained using modified GLCM which is **57.06%** using the relative manhattan (L1) distance. The best color and texture feature extractors color histogram and modified GLCM are combined and thus, a better accuracy of **63.32%** is obtained using relative manhattan (L1) distance. Then the best color and texture feature extractors are combined with the shape feature extractor invariant moment which gives accuracy of **63.32%** using the relative manhattan distance (L1). To decrease the computational expense, invariant moment is omitted as it is not upgrading the accuracy. Table I also contains the accuracy of the combinations which are used in [4]. Combination of color histogram and modified GLCM outperform them.

Table II shows the accuracies for each of the local feature detector and extractor method as described in section III-B (fast approximate nearest neighbor search [20] is used for similarity checking of local features). From Table II it is observed that, the best accuracy is obtained using the SURF detector and SURF descriptor which is **37.86%**. It is less than the accuracy achieved in [5], where SURF alone gives **65.47%** average precision. In [5], COIL-100 image database is used. On the other hand, here WANG image database is used where

TABLE I
ACCURACY OF ALL GLOBAL FEATURE EXTRACTION METHODS

Feature extraction technique	Feature matching technique	Accuracy	Feature extraction technique	Feature matching technique	Accuracy
Color Histogram	Relative Manhattan (L1)	60.62%	Wavelet Moment	Standard Euclidean	35.06%
Color Moments	Mahalanobis	57.45%	Wavelet Entropy	Mahalanobis	53.70%
Color Autocorrelogram	Relative Manhattan (L1)	23.02%	Color histogram + modified GLCM	Relative Manhattan (L1)	63.32%
Color layout descriptor (CLD)	Euclidean (L2)	52.25%	Color histogram + modified GLCM + Invariant moments	Relative Manhattan (L1)	63.32%
GLCM	Relative Manhattan (L1)	52.83%	Color Moments + Wavelet Entropy [4]	Standard Euclidean	55.77%
Modified GLCM	Relative Manhattan (L1)	57.06%			

there are 10 classes of images of different things and in each class each image is actually different images of similar things. But in COIL-100 database, each class contains same image repeatedly by just rotating it. So, images of WANG database are far more random than images in COIL-100 database. As a result, accuracy is much lower in case of WANG database.

TABLE II
ACCURACY OF ALL LOCAL FEATURE EXTRACTION METHODS.

Method Name	Accuracy
FAST detector + SURF descriptor	32.34%
BRISK detector + SURF descriptor	27.41%
SURF detector + SURF descriptor	37.86%

The second best color feature extractor color moments are also calculated within a region around the detected blob points by SURF. Color moments are calculated for a region of size 6s (orientation is also computed within a circular neighborhood of radius 6s around the blob point during the computation of SURF descriptor) around the blob points (where s is the scale at which the blob point is detected by SURF detector). So, now feature vector size is (n$\times$(64+6)) where n is the number of detected blob points by SURF. This method increases accuracy of SURF from **37.86%** to **57.34%**. The best color feature extractor color histogram is not used here, because the feature size would be (n$\times$(64+768)), which is very large.

Now SURF detector and descriptor and the best color and texture feature extractor global color histogram and modified GLCM are combined and thus, the accuracy of **63.56%** is obtained. In this case, similar images of the query image are obtained by sorting the sum of cityblock and L1 distances in ascending order. Here, the cityblock and L1 distances are obtained during matching of SURF descriptors (described in section V-B2) and during matching of color histogram and modified GLCM respectively.

If SURF detector and descriptor with color moments within the region of size 6s around the detected blob points and the best texture feature extractor global modified GLCM are combined, then the accuracy of **70.48%** is obtained. In this case, the cityblock distance obtained during matching of SURF descriptor with color moments (described in section V-B2) and L1 distance of modified GLCM are added and after sorting them in ascending order, similar images of the query image are obtained.

If SURF detector and descriptor with color moments within the region of size 6s around the detected blob points and the best color and texture feature extractor global color histogram and modified GLCM are combined, then the accuracy of **68.61%** is obtained. In this case, the cityblock distance obtained during matching of SURF descriptor with color moments and L1 distance of color histogram and modified GLCM are added and after sorting them in ascending order, similar images of the query image are obtained.

So, the best accuracy of **70.48%** is obtained by using SURF detector and descriptor with color moments within the region of size 6s around the detected blob points and global modified GLCM. Table III shows the accuracies of this method and other similar methods.

The performance of the method in this paper is compared with the method in [4] by showing an example.

TABLE III
COMPARISON OF THE APPROACHES IN THIS WORK AND SIMILAR WORKS.

Approach	Accuracy
CBIR using SURF and colour moments [5]	55.5%
CBIR using color moments and wavelet packet entropy [4]	50.13%
Feature matching technique: standard euclidean distance instead of correlation in the approach [4]	55.77%
Approach in this proposed work	70.48%

Fig. 2 and 3 show 20 most similar retrieved images for a query image by this proposed method and method in [4]. It is observed that, this proposed method retrieves all of the 20 images correctly. On the other hand, the method in [4] retrieves 18 images correctly.

From the experimental results it is observed that, the best result is obtained by combining global modified GLCM and

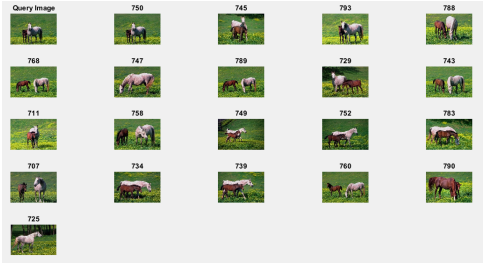

Fig. 2. Retrieved images for a query image by this proposed method.

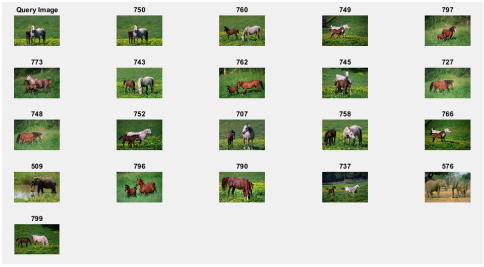

Fig. 3. Retrieved images for a query image by method in [4].

SURF detector and descriptor with color moments which are calculated within a region of size $6s$ (s = scale at which blob point is detected) around the detected blob points where L1 distance is used for matching modified GLCM features and efficient approximate nearest neighbor search [20] is used for matching SURF features with color moments. This approach gives better accuracy than the approaches in [4] and [5], where the approach in [4] gives better accuracy than the approach in [3].

VII. Conclusion

In this paper, various global and local feature extraction methods based image retrieval techniques are investigated. The performances of these feature extraction methods based on their similar image retrieval accuracies are calculated on WANG dataset of 1000 images. This approach uses combination of SURF detector and descriptor with color moments as local features and modified GLCM as global features. Color moments are calculated in the region around the SURF blob points which gives the local color information. Both local and global features are used because only local features are not suitable when the variety of images is large. As an example, bus and building both have many straight edges and corners. In this case, local feature detectors would detect lots of interest points on the edges and corners, which might make it difficult to differentiate between the two images. On the other hand, global features are biased towards the background of the images. As an example, if two images of horse and elephant both have natural background, then similar features are likely to be made by global feature extractors because it calculates features involving all pixels of image. Therefore, both global and local features are important in case of similar image retrieval from large image database. The future scopes of CBIR are very large. Detecting round, square, triangle objects and extracting their features might bring better performance.

***Abstract*— Recognition of handwritten characters from Bangla handwritten texts is of immense importance considering the complexity of the task. Researchers have explored the task of recognizing Bangla handwritten digits, but a few numbers of published works are available for Bangla Handwritten Character Recognition (BHCR). In this paper, we present a comparative overview of classification algorithms for BHCR, which may help the researcher to decide an appropriate classification algorithm for their work. We have created a new dataset of Bangla handwritten characters from 150 volunteers at different levels. We extracted around 2500 samples of Bangla characters which consist of Bangla Vowels only. Histogram adjustment and other image preprocessing techniques are applied in handwritten characters before their classification. We compare the performance of seven commonly used classification algorithms for BHCR in terms of Sensitivity, Miss Rate, Specificity, Precision, Fall-out, F-score, and Overall Accuracy. This result shows that among the seven algorithms, the best performance is provided by Artificial Neural Network (ANN). Logistic Regression performed well compared to others in terms of the sensitivity, specificity and error rate. This comparative overview will help scientists, especially the new researchers to give a quick start with Bangla handwritten character recognition.**

Keywords*— Handwritten character recognition, Pattern recognition, Histogram of Oriented Gradient (HOG)

I. INTRODUCTION

Bengali script is a writing system which originates from Indian Subcontinent for the Bengali language and with the Assamese alphabet. Bangla script is the second most popular script in the Indian subcontinent and mostly used for Bangla, Ahamia and Manipuri languages. Among these languages, Bangla is the national language of Bangladesh and is the fifth most popular language of the world [1]. Around 210 million people use Bangla as their speaking and writing purpose as a first or second language. Therefore, automatic recognition of Bangla characters has massive importance.

There are many applications of Bangla handwritten character recognition, such as, Bangla Optical Character Recognition (OCR), National ID number recognition system, automatic license plate recognition system for vehicle and parking lot management system, post office automation, online banking, writer identification, searching in historical manuscripts, and others[11] .

The Bengali script has a total of 50 characters consisting of 11 vowels and 39 consonants. Figure 1 depicts the vowels. This script is written from left to right, and there are no cases like uppercase or lowercase letters. Bangla character has a unique feature which is called MATRA- a distinctive horizontal line running along the tops of the letters that links them together. Also, the Bengali script is less blocky and presents a more curvy shape that facilitates classification.

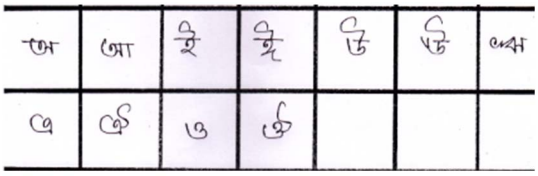

Fig. 1. Vowels in Bangla Script

BHCR is a classification task, which composes of several steps like handwritten image processing, feature extraction and applying classification algorithms. However, it is tough to determine which algorithm is the best compared to the others, as it depends on various factors, such as, classification accuracy, algorithm performance, computational resources and so on [4]. There is a trade-off between time complexity, resource constraints, and accuracy. For example, Artificial Neural Network (ANN) provides good result but takes much more time as compared to the others. Moreover, the accuracy of algorithms also depends on the quality and robustness of training dataset, the selection of the dataset used and different environmental settings. A sufficient number of training samples and their representativeness are critical for image classifications [5]. Kamavisdar, Pooja, et al. [6] described the advantages and disadvantages of classification algorithms like ANN, Support Vector Machine (SVM), Decision tree. However, they only described from the theoretical perspective and did not show any experimental results. Arun and Vidushi [7] compared different classification algorithms on multiclass dataset extracted from the multispectral satellite image. They

compared the result based on the average result of all classes and showed that KNN gives the best results over the others for satellite image. Although much of the previous research concerned explicitly with image classification, a comprehensive, up-to-date overview of BHCR is not available which inspired us to conduct a study on classification algorithms performance on BHCR.

II. Related work

Researchers have explored the area of recognition and classification of Bangla handwritten digit and character. Several machine learning algorithms for handwritten character recognition, such as Multilayer Perceptron, Support Vector Machine, Naïve Bayes, Bayes Net, Random Forest, J48 and Random Tree have been presented in the literature [8]. Most of these algorithms rendered a reasonably good result, but they do not focus on a wide range of evaluation matrices and visualizations of the results. Shyla Afroge et al. proposed a model which is based on Discrete Fréchet Distance for Bangla Optical Character Recognition which recognizes both characters and digits with 90-95% accuracy [9]. Some articles show that classic KNN provides excellent accuracy (95%) for BHCR [12]. Researchers also used Genetic algorithm (GA) to sample the optimal set of local regions of Bangla digits and then applied SVM classifier with popular optimization techniques like simulated annealing (SA) and hill climbing (HC) on the same data set to maximize recognition accuracies [13]. The geometric convex hull-based feature set for effective recognition of isolated handwritten Bangla basic characters and digits also maximize the success rate of 99.45% for Bangla handwritten digits [14].

Recently, ANN, especially deep learning along with Convolutional Neural Network used extensively in BHCR. Cheng-Lin Liua, Ching Y. Suenb worked with MLP neural network, modified quadratic discriminant function (MQDF), discriminative learning quadratic discriminant function (DLQDF), polynomial network classifier (PNC), class-specific feature polynomial classifier (CFPC), SVM classifiers and found that DLQDF, PNC, CFPC, SVM gave higher Accuracies than MLP and MQDF [15]. Deep Belief Network (DBN), CNN, CNN with dropout, CNN with dropout and Gaussian filters, and CNN with dropout and Gabor filters are also used in BHCR where CNN with dropout and Gabor features exceeds the state-of-the-art algorithms for HDBR with 98.78% accuracy [16]. Shopon et al. get even higher accuracy which is almost perfect (99.50%) using Convolutional neural networks (ConvNets) [17]. ConvNet used19,313 images from ISI handwritten character dataset for training and for testing, they used CMATERDB dataset. All of the approaches achieved good accuracy, but no comparative study is found in the literature which provides a clear idea on different classification algorithms performance evaluation. We have provided a comparative overview which provides a clear idea with different evaluation metrics and graphical visualizations.

III. METHODOLOGIES

BHCR is basically a multiclass classification problem. In Bangla script, there are total eleven vowels which are not case sensitive like English script. For multiclass classification, we have divided the whole task into several parts. The first part is feature extraction from the handwritten image and second part is implementing classification algorithms. This also includes post-processing and visualizations of the final results. Finally, we have assessed the accuracy of the whole system based on different evaluation metrics.

A. Feature Extraction

We have used Histogram of Oriented Gradient (HOG) for extracting the features from the image. HOG uses the histogram as distribution and directions of gradients which is called oriented gradients as the feature. Gradients are x and y derivatives of an image. HOG feature detector encodes local shape information from regions within an image. Figure 2 shows the gradients with direction. The first image is the original image and the second image is with the oriented gradient in red color. We have experimented with different cell size and find out that 4x4 provides reasonable results. We have got a total of 4356 features from HOG for each image which has been used as the input for the classification algorithms model.

Fig. 2. Feature Extraction from the image.

B. Classification algorithms

Classification is a subarea of artificial intelligence, which is used in many practical applications. In this article, different classification algorithms are discussed in the context of BHCR.

1) Feedforward Artificial Neural Network (ANN): Artificial neural network resembles the human brain system. Like the human brain, ANN is the collection of interconnected neurons which transfer information among them. Each connection of the neurons has numeric weights which will be updated based on adaptive learning. This weight is used to approximate function which uses inputs to estimate the output class. The multilayer perceptron is the most popular type of neural network in image classification [18]. Figure 3 depicts the used architecture of ANN in our system. However, it is challenging to decide the structure (no of hidden layers) in the network.

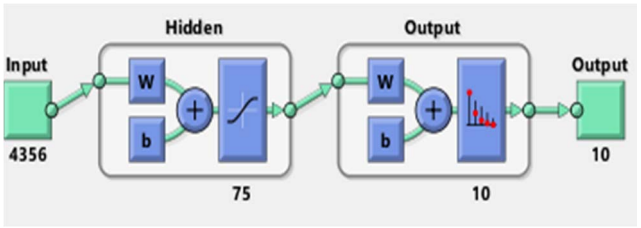

Fig. 3. Architecture of Applied ANN Model

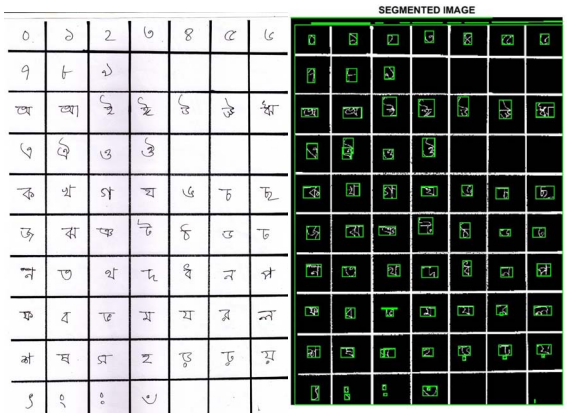
2) Decision Tree (DT): Decision Tree calculates class membership by iteratively dividing a dataset into uniform subsets. DT is a kind of hierarchical classifier which permits the acceptations and rejection of class labels at each intermediary stage or nodes. DT consists of 3 parts: dividing the nodes, find the terminal nodes or leaf and allocation of the class label to leaf. DT is simple, computationally efficient and non-parametric methods which do not require any extensive design and training. But DT becomes complex when various

value is undecided or class label are missing and when various outcomes are correlated.

3) Random Forest (RF): Random Forests (RF) or random decision forests are an ensemble learning method for classification, regression and other tasks. RF constitutes of multiple DT which are used for training purpose. RF output the mode or mean class of all classes predicted from the collection of DT[19,20]. The number of the decision tree that will be combined to form the forest can be determined through a hyper-parameter at most implementation. MATLAB has one function named 'TreeBagger' which performs as Random Forest classifier

*4) Linear Discriminant Analysis (LDA):*The classifiers that assign data into two or more groups and predict categorical or grouping variable by one or more predictive variable is called as discriminant classifiers. They follow a set of rules in which maximum likelihood used for classification linearly and nonlinearly. It uses the multivariate normal distribution of the data depending on whether it is linear or nonlinear. Discriminant analysis can be linear and quadratic. LDA has average classification accuracy but this method is poor in object recognition.

5) Support Vector Machine (SVM): SVM is a supervised learning algorithm which is used for classification and regression. For classification, SVM builds a hyperplane or set of hyperplanes in a high or infinite dimensional space. Largest distance to the nearest training data point of any class (functional margin) gives good separation in the hyperplane that results in a good classifier and lowers the generalization error of the classifier by removing overfitting problems. Performance of SVM depends on the selection of hyperplane and kernel parameter. But determination of the optimal parameter is a little bit difficult for multiclass classification which is normally nonlinearly separable.



6) Logistic Regression (LogReg): Logistic Regression is one of the most commonly used classification algorithms in machine learning and data science. Logistic regression mainly used for the binary classification task. But logistic regression can also be used with multiple class classification tasks. For multi-class classification, the one-vs-all paradigm is used in logistic regression. Fine tuning of learning parameters like alpha, number of iterations in gradient descent gives good results. At the same time, poor selection of these parameter gives poor results and the different implementations of the gradient descent algorithm affect the results of the algorithm.

7) K Nearest Neighbor(KNN): KNN is also a distance-based classification algorithm. KNN classify an object based on the information of closest or most similar data points in the feature space. KNN use distance measure to compare the distance or similarity between two data points i.e. the Euclidean distance, Manhattan distance, and City Block distance etc. KNN select the label of the test data based on the label of surrounding data points or neighbor. KNN is the simplest but widely used classification method that has been applied in many fields like big data, biology, satellite image classification, medical image classification etc.

IV. EXPERIMENTAL SETUP AND RESULTS

A. Data Collection and Description

We created a new dataset of Bangla Handwritten Characters. We experimented on 150 volunteers. We collected data in a plain white page and then extracted the individual characters. Sample of individual handwriting is given in figure 4(a).

(a) (b)

Fig. 4. (a) Collected Handwritten Sample (b) Object Detection Sample

After that, we segmented the characters from the individual handwritten image. First we detected the characters using object detection algorithm and then segmented the individual's characters. Sample is shown in figure 4(b).

Finally, image preprocessing technique has been applied to the character image. Then we divided the dataset at a ratio of 70% and 30% for training and testing set respectively. We preprocessed and resize all handwritten characters (vowels) images into a fixed size of 50x50 pixels. The dataset was pre-labeled according to their containing image class. We use this label in the training phase of our classification algorithms. After that, we use the test set to measure the performances of the classification algorithm

B. Evaluation Criteria

We evaluated the classification algorithm performance for individual class rather than overall measurement. This will help us and others to decide which classification algorithm will be useful for characters (vowels) recognition and provide an insight for individual handwritten characters (vowels). We provided both the confusion matrix and Receiver operating characteristic (ROC) curve for the mentioned 8 image classification algorithms.

On the confusion matrix plot, the rows or x-axes correspond to the predicted class (Output Class) and the columns or y-axes correspond to the true class (Target Class) [22]. The second plot shows the receiver operating characteristic (ROC) for each of the output class. The quality of classifiers checked by the receiver operating characteristic [23]. Figure 05-12 shows the confusion matrix and ROC curve of the classification algorithm performances on test data. It has been found that ANN performs best with an

overall accuracy of 93.8% (Figure 5) and then LR performs with an overall accuracy of 86.8% (Figure 10). Similarly, RF (Figure 6) and SVM (Figure 12) provides more than 79% accuracy. Whereas, LDA (Figure 8) provides more than 73.1% accurate result. But KNN (Figure 12) and DT (Figure 7) perform poorly which gives only 68.3% 66.6% accuracy for the given dataset.

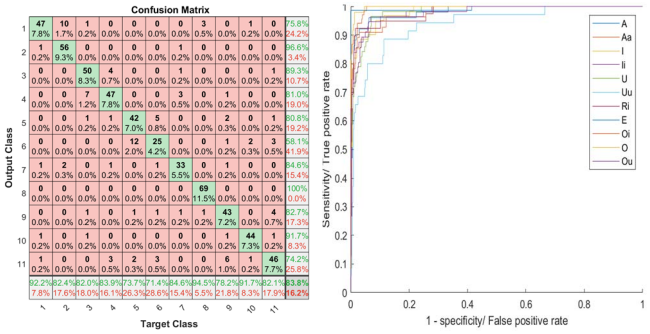


Fig. 5. Performance of ANN (Confusion Matrix and ROC curve)

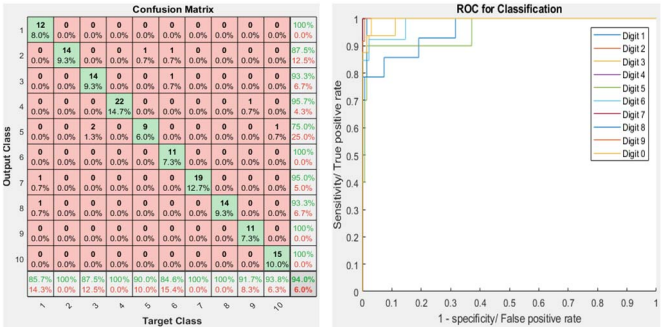

Fig. 10. Performance of LR (Confusion Matrix and ROC curve)

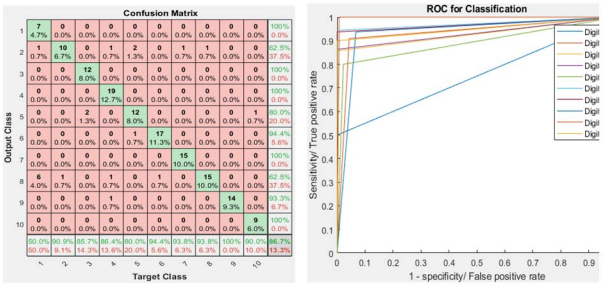

Fig. 11. Performance of NB (Confusion Matrix and ROC curve)

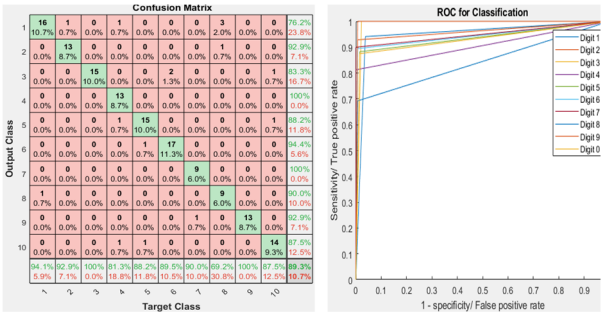

Fig. 12.Performance of KNN (Confusion Matrix and ROC curve)

As we measure class wise performance for individual characters (vowels) for each classification algorithms, we averaged the results of individual class or characters (vowels) to show an overview of the performance of whole classification algorithms. Table 1 summarizes the results. As expected ANN provides the best sensitivity, specificity, F score value.

TABLE I. COMPARISON OF AVERAGE PERFORMANCE OF INDIVIDUAL CHARACTERS (VOWELS) ON CLASSIFICATION ALGORITHMS

Algorithm	AS[a]	AMS[b]	ASP[c]	AP[d]	AF[e]	AFS[f]	AOA[g]
ANN	0.833	0.166	0.983	0.016	0.832	0.829	0.938
RF	0.857	0.142	0.986	0.013	0.858	0.856	0.865
DT	0.650	0.349	0.966	0.033	0.662	0.652	0.666

Finally, we graphically show the relative performance of different classification algorithm on the Bangla Handwritten characters (vowels) recognition. We have used the grouped bar graph which made it easy to understand the performance differences among different classification algorithms. X-axes of the bar graph represents grouped data to show the performance of individual characters (vowels). Y axes of the bar graph represents the metrics based on which the comparison is made. We have used total 08 metrics for understanding the difference in the performance of the classification algorithm. Error rate has been also measured Miss Rate (Type-II error). The result shown that ANN performs better and DT performs in a poor manner. In Figure 13, we showed Type-II error, performance on different classification algorithm with individual characters (vowels) performances. We got almost zero error for ANN but for DT the error is pretty high.

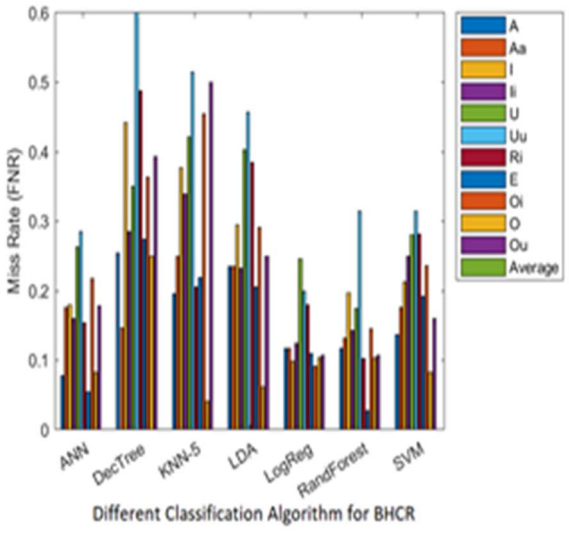

Fig. 13. ype-II error of discussed classification algorithms

V. DISCUSSION

We present a totally new dataset for Bangla handwritten characters. More than 150 students of Daffodil International University, a private university of Bangladesh has participated in the experiment with their verbal consent to use this data in research purpose. After that data set has been prepared for using in classification algorithm by thorough preprocessing described in the experiment section. Finally, Different supervised classification algorithms performance has been compared to find out the best classification algorithm. This result shows that among the seven algorithms, the best performance is provided by Artificial Neural Network (ANN). Among the old classic algorithm Logistic Regression performed surprisingly well compared to others. We consider each character as a class. For each class we measure the performance of the classification algorithm. Finally, we calculated the average performance of all classes (characters) for a single classification algorithm. ANN provides 93.8% average overall accuracy and logistic regression provides 86.8% average overall accuracy. Individual character performance has similar performance for all classification algorithms. For example vowel Uu (ঊ) and vowel U (ঊ) error rate is high in all classification algorithms. This will help ones to identify each character separately. Most of the algorithms presented in section-II do not focus on a wide range of evaluation matrices and visualizations of the results. Most of them used the metrics that provides the best result. We have shown 08 metrics. Moreover, we have shown graphical view of our outputs which enables one to capture the result easily.

VI. CONCLUSION

Our study has discussed the performance comparisons of mostly used classification algorithms for BHCR. We have found that Logistic Regression (86.8%) and ANN (93.8%) outperform all other classification algorithms. Besides, we have shown that individual handwritten characters (vowels) perform differently on the same classification algorithms. We considered only the supervised classification algorithms in the context of BHCR but did not consider the different approaches of classification like [4, 24, 25] which can be done in the future. In the future, we can extend our study on semi-supervised learning. We have also used only one feature extraction method to emphasize the performance of a classification algorithm on BHCR. In the future, multiple feature extraction method like zoning, template matching, deformable templates, unitary transforms etc can be used to show which feature extraction perform best. The performance of a different combination of feature extraction methods and classification algorithms can also be analyzed. We get the result after experimenting only on the vowels of Bengali alphabet. We can extend our works on consonant and especially on joint alphabet. Finally, this work can be extended to recognize Bangla handwritten text like handwritten letters, applications, exam scripts, different forms etc.

***Abstract*—The distinguishing characteristics belong to a person are personality traits, which is predicted from person's behavioral pattern. As most of the people provide lots of information knowingly or unknowingly into their writings, it is possible to extract personality traits from those texts. Individual personality traits detection from texts, yields enormous possibilities toward various applications named as forensic department, mental health diagnosis, etc. Meanwhile, deep learning algorithm performs fairly well in text personality detection; however, its performance may vary with activation functions. Hence, this paper proposed an empirical approach to find the best personality detection performance by comparing several activation functions named sigmoid, $tanh$, and leaky relu. Here, text documents were pre-processed and vectorized for input in convolutional neural network. The input size was multiple to length of word, sentence, documents, and feature vectors. Five personality traits named as EXT, NEU, AGR, CON, and OPN have been used for experimental analysis. The result showed that $tanh$ and leaky relu performs over sigmoid in all datasets. The average F1-score of sigmoid, $tanh$ and leaky relu showed 33.11%, 47.25%, and 49.07% respectively. However, F1-score of Leaky relu was high only for CON, $tanh$ showed better result for others datasets. The overall performance showed by $tanh$ is better than sigmoid and leaky relu for personality detection from texts.**

***Index Terms*—Personality Traits, Sentiment Analysis, Convolutional Neural network, Deep Learning, Text Analysis.**

I. Introduction

Personality traits are distinguishing quality or characteristics typically belong to a person. The way that an individual talk and write is reflect upon their personality. A persons thought pattern is built upon the behavioral, emotional, mental and motivational attributes which collectively called personality. According to J. Digman, personality is typically assessed along big five personality traits which are the results of (i) Extroversion (EXT): is the person outgoing, talkative, and energetic or reserved? (ii) Neuroticism (NEU): is the person sensitive and nervous versus secure and confident? (iii) Agreeableness (AGR): is the person trustworthy, straightforward, generous, and modest versus unreliable, complicated, meager, and boastful? (iv) Conscientiousness (CON): is the person efficient and organized versus sloppy and careless? and (v) Openness (OPN): is the person inventive and curious versus dogmatic and cautious? [1].

Individual's personality detection from texts yields enormous possibilities toward various practical applications. For example, companies can establish their strategies based on positive sentiment of the people towards their products. Forensic department can exploit personality traits to reduce the circle of suspects. In the context of mental health diagnosis, certain diagnoses correlate with certain personality traits. In human resource management, detection of personality traits can graph the thought pattern which affect one's suitability for certain jobs. To exploit personality traits in such different applications, detection of an individual's personality from texts is essential. However, manual text analysis for personality traits identification is not feasible in terms of time, cost, and accuracy. Therefore, automatic personality traits detection system is required to exploit its strength effectively.

To this end, researchers introduced few works for personality traits detection using textual content analysis, which is a established field of Natural Language Processing (NLP). In 1999, a personality trait analysis dataset has been developed experimenting 2,468 peoples [2]. On the other hand, a document-level feature set for personality detection has been developed considering 84 features such as linguistic inquiry, word count features, medical research council features, etc. [6]. Using large text corpus continuous vector representations of words has been developed to strengthen machine learning based textual analysis research work [3]. To take the advantages of deep learning in text analysis, several sentence classification techniques have been applied using convolutional neural network [7]. Recently, document modeling has been carried out using Convolutional Neural Network (CNN) feature extractor for personality detection [5].

The existing personality traits detection strategies exploited deep learning algorithms to improve classification accuracy. However, performances of different activation functions in deep learning based textual data classification are yet to be explored. To this end, this research proposed an empirical approach to find the best personality traits extraction framework. Where, textual data analysis performance of sigmoid, hyperbolic tangent (tanh), and leaky rectified linear unit (leaky relu) activation functions has been compared. This method classified five different personality traits named as EXT, NEU, AGR, CON, and OPN using exclusive five special CNN networks considering same architecture. Where, each network acts as a binary classifier for the respective traits to be positive or negative. In this framework, first text documents were pre-processed to remove unwanted characters. Then, n-gram feature vectors obtained by feeding pre-processed data as

input in convolutional filters. These feature vectors aggregated and concatenated with Mairesse features to represent each document. Also, emotional features containing sentences were filtered for classification accuracy improvement. Finally, the document vectors were used as input to neural network with one hidden layer.

The empirical results showed that $tanh$ and leaky relu performed better over sigmoid activation function. The average training performance of sigmoid, $tanh$ and leaky relu are 51.19%, 56.15%, and 57.07% respectively. Where, three function's average validation performance are 49.30%, 53.90%, 53.52% and test performance are 49.48%, 54.29%, 54.24%. On the other hand, average F1-score of sigmoid, $tanh$ and leaky relu functions are 33.11%, 47.25%, and 49.07% respectively. Even though, average F1-score is high for Leaky relu, this function outperformed only for CON personality trait. However, for all other personality traits named as EXT, NEU, AGR, and OPN $tanh$ over performed. In a nutshell, the overall performance of $tanh$ function is better than sigmoid and leaky relu in personality detection using texts.

The rest of this paper is organized as follows; Section II discussed the existing work related to this thesis. Section III and IV illustrated the proposed method and result analysis respectively. Finally section V concludes this paper with future research direction.

II. Related Works

Automatic personality detection from text is relatively new concept in the field of Natural Language Processing (NLP). There have been few works implemented on this domain using NLP algorithm which are discussed in this section.

There have been many theories regarding the structure of personality. How a personality should be classified was a bigger challenge in research community. However, in 1990, John M. Digman, a researcher from University of Hawaii, has published a journal which shaped a persons personality into five different categories [1]. After that, it becomes the most reliable unified theory for personality till date. According to J. Digman, personality comes as a five factor model. The first of those five factors is extraversion or introversion, which means, a person talkative or not, more outgoing or stays inside more etc. The second factor is, agreeableness and defined by a person's paranoid, friendly or unfriendly, social or not etc. As for the third factor, conscientiousness defined as the prudence, judgment of a person. The fourth factor, neuroticism is defined as the mental or emotional stability of a person. Final factor is openness, which involves a persons intellect, creativity etc.

Experimenting 2,468 peoples, Pennebaker et al. has developed a dataset that is used for personality trait analysis research work [2]. Each of them had given a task to write whatever comes in their mind in a very short period of time in a closed environment. So, when people do not have enough time to think they tend to write something that reflects upon their personality. After that they had developed a text analysis application Linguistic Inquiry and Word Count to get better insight from the collected data.

On the other hand, Francois Mairesse and his colleagues developed a document-level feature set for personality detection, consisting of 84 features [6]. It comprised the linguistic inquiry and word count features, medical research council features, utterance-type features, and prosodic features. Examples of the features included in this set are the word count, average number of words per sentence, total number of pronouns, past tense verbs, present tense verbs, future tense verbs, letters, phonemes, syllables, and assertions in the document.

Tomas Mikolov et. al proposed two model for computing continuous vector representations of words using large data sets [3]. The quality of resulting vector representations was measured using word similarity and results were compared with existing best techniques. In this study, they have proposed two approaches to define word embedding. One is Continuous Bag of Words (CBOW) model and another one is Continuous Skip Gram model. In continuous bag of words model, target word is predicted from the context whereas, in skip gram model, a context is predicted from a target word.

In 2014, Yoon Kim showed several sentence classification based on convolutional neural network [7]. This work trained a simple CNN model using one layer of convolution and Googles pre-trained word vectors. Initially, keeping word vectors static this research learned only other parameters of the model. This model achieves excellent results on multiple datasets with hyper-parameters tuning. Finally, this paper concluded that word vectors is a key element for deep learning applications in NLP. However, efficiency of this sentence classification model could be improved using multiple convolution layer and extensive hyper parameters tuning.

Majumder et. al. proposed a novel document modeling approach using convolutional neural network feature extractor [5]. In this study, sentences from the stream-of-consciousness essay dataset were fed as input in convolution filter to obtain the sentence model in the form of n-gram feature vectors. The individual essay was represented by aggregating the vectors of its sentences. Then the obtained vectors were concatenated with the mairesse features. For final classification, this document vector is being fed into a fully connected CNN, which act as a binary classifier that predicted the corresponding trait to be positive or negative.

The analysis of existing natural language processing approaches shows that different topic modeling strategies have been proposed for personality trait analysis such as personality classification, personality dataset development, CNN based n-gram feature extraction, etc. However, no guideline has been found yet to compare different deep learning activation functions such as sigmoid vs tanh or tanh vs leaky relu etc. in personality analysis.

III. METHODOLOGY

Document modeling framework to extract personality traits using Convolutional Neural Network (CNN) is proposed to improve classification accuracy. This approach classified five different personality traits named as EXT, NEU, AGR, CON, and OPN using exclusive five special CNN networks in same

architecture. Each network acts as a binary classifier for the respective traits to be positive or negative. In this architecture, sentences are preprocessed to remove unwanted characters then feed in convolutional filters to obtain sentence model as n-gram feature vectors. These feature vectors are aggregated and concatenated with Mairesse features to represent each document [6]. Emotional features containing sentences are filtered for result improvement. The processed document vector is used as input to neural network with one hidden layer in the final classification. The proposed method is broadly divided into following 2 steps.

- Step 1: Data Preprocessing
- Step 2: Classification

The details regarding the steps are elaborated in following sections and sub-sections.

A. Step 1: Data Preprocessing

Initially standard text preprocessing steps named as sentence splitting, tokenizing, stemming, and case-folding applied for text preparation. Preprocessed document used for document level feature extraction using convolutional filter and Mairesse baseline feature-set. Extracted features from non-neutral sentence considered for training and others were discarded to reduce noise as well as input size. This process was considerably affected on training time. The word level features extracted using word2vec algorithm for each word in documents as word vectors [8]. Theses word vectors used to represent words of each sentence in documents. Thus, variable length words became fixed-length word feature vectors. Those generated word vectors were used for input of CNN network.

B. Step 2: Classification

Deep CNN used as the classification network, where initial layer process the text in a hierarchical manner. Initially, words and sentenced are represented as fixed length feature vector and variable length word vectors. However, at some network layer, the variable length vectors of each sentence reduced to fixed length vectors. At that level, documents are represented as a variable number of such fixed length sentence embedding. Similarly, variable length document vector also reduced to fixed length document vector at deep network layer. Finally, this fixed length feature vectors are concatenated with document level features for final classification. The whole classification process using neural network model are divided into following six layers:

- Layer 1: Word Vectorization
- Layer 2: Convolution (sentence vectorization)
- Layer 3: 1-max pooling (document vectorization)
- Layer 4: Concatenation (document vectorization)
- Layer 5: Linear with tanh and leaky relu activation (classification)
- Layer 6: Two neuron softmax output (classification)

The functions of each layer is described in the following sections.

1) Layer 1: Input (Word Vectorization: The text document in dataset was preprocessed then vectorized to feed as input in CNN. The dataset is represented as a set of documents where each document is a sequence of sentences, each sentence is a sequence of words, and each word is a real valued word vector. Thus, the input layer is a four dimensional real values array named as document, sentence, word, and embedding. All the documents are padded to keep uniform size of sentences. Where, shorter documents and sentences are padded with dummy sentences and words respectively for uniformities.

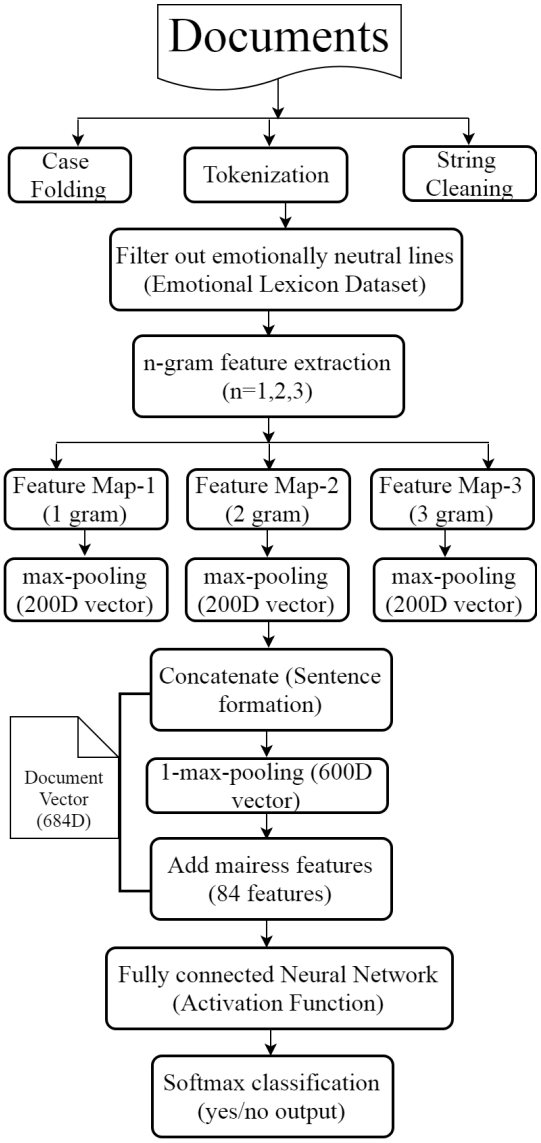

Fig. 1. Architectural overview of proposed system

2) Layer 2: Convolution (Sentence Vectorization): Convolutional filters with max pooling were applied used to extract n-gram features from each sentence; where n belongs to unigram, bigram and trigram. The size of convolutional filter is n-gram multiplied with length of word embedding on each sentence. A bias added with output filtering, which generated three feature maps for a given sentence. Then, max pooling

was applied on each feature map to further reduce sample dimension similar to n-gram feature dimension in convolution. The obtained feature vectors for unigram, bigram and trigram were concatenated to represent sentence vector. This process is applied to all sentences in the document.

3) Layer 3: Max Pooling (Document Vectorization): The sentence vectors obtained in previous step were concatenated to get document vectors, where dimension of each sentence vector is multiple of n-grams. If the document belongs to at least one feature, it considered for vectorization otherwise discarded. Thus featured documents converted to fixed size real valued vector. The maximum number of sentences across all documents was considered as the document vector size.

4) Layer 4: Concatenation (Document Vectorization): In this layer, document level features are added to document vector [6]. The considered features are words per sentences, type/token ratio, words captured, negations, negative emotions, anxiety, personal concerns, concreteness rating etc. Among those, 84 features are concatenated with document vector. The dimension of resultant vector changed to the summation of embedding word vector size and selected features size.

5) Layer 5: Non-linear with tanh and Leaky ReLU Activation (Classification): A fully connected two layer perceptron is used for activation in the final classification, where the layer size is r (real number). In this activation process, the document d is multiplied by a matrix W^{fc}. A bias B^{fc} is also added to it for calculating the document vector d^{fc}. Where, d, W, B, fc, denotes document, weight, bias value and fully connected network respectively. The dense layer output gives leads to linear value which affect on classification accuracy. Therefore, $tanh$ activation function used to ensure non linearity which improves classification result. Equation (1) denotes the $tanh$ activation function.

$$d^{fc} = tanh(dW^{fc} + B^{fc}) \tag{1}$$

where $tanh(x) = \frac{e^x - e^-x}{e^x + e^-x}$.

Another activation function Leaky Rectified Linear Unit (ReLU) also used to improve efficiency of the model. Equation (2) denotes this activation function.

$$d^{fc} = lrelu(dW^{fc} + B^{fc} \tag{2}$$

Where, $d^{fc} = 1(x < 0)(ax) + 1(x \geq 0)(x)$ and a is a small constant.

6) Layer 6: Two-Neuron Softmax Output (Classification): The two-neuron softmax function was used to measure probability of each document. The softmax produce either 0 or 1 as output result, this result indicates the class to which document belongs. Following vector was used for softmax probability determination.

$$x_{yes}, x_{no} = dW^{sm} + B^{sm} \tag{3}$$

Where, weight $W^{sm} \in R^{200\times2}$ and bias $B^{sm} \in R^2$. After that, the class probabilities calculated as,

$$P\frac{i}{network_{prs}} = \frac{exp(x_i)}{exp(x_{yes}} + exp(x_{no})for \quad i \in \{1, 0\} \tag{4}$$

In this research, the documents were reprocessed and vectorized to fed into CNN model. The N-gram feature extraction technique and max pooling were applied in this personality traits analysis framework. Finally, softmax classifier has been used to categorise each documents into five personality traits.

IV. Experimental Result

This section discusses the experiment of empirical approach for the proposed personality trait identification using convolutional neural network. The classification performance of used activation functions is compared with other significant activation functions. Details regarding the implementation setup of those functions are also provided in this section.

A. Environment Setup

The research work was performed on a single workstation having 3.6 GHz Intel Core i7 CPU and 32GB RAM running the Ubuntu 16.04 LTS version operating system. To implement this work python 2.7, python numerical computational library theano (version 0.7), and pandas 18.0 were installed.

B. Datasets

A popular collection of essays collectively called stream of consciousness has used for evaluation of proposed technique [2]. The dataset contains 2,468 random essays marked with the writer's personality traits which are, EXT, AGR, NEU, CON and OPN [2]. The rest of the datasets are subsidiary which were built upon these datasets. Mairesse listed a number of features based on these 2468 essays [6]. NRC emotion lexicon datasets has used to remove those words that are not emotionally significant [10]. Finally, Google's Pre trained Word Vectors and Phrases dataset has used to obtain word vectors of the essay dataset.

C. Stream of Consciousness Essays

This dataset is developed by James W. Pennebaker and his colleagues at University of Texas at Austin experimenting 2,468 people [2]. Each people of them had given a task to write whatever comes in their mind in a very short period of time in a strict environment. So, when people do not have enough time to think they will tend to write something that will reflect upon their personality. This was the main goal of this particular experiment.

D. NRC Emotion Lexicons

NRC word emotion lexicon aka EmoLex is a list of English words and their associations with eight basic emotions named as anger, fear, anticipation, trust, surprise, sadness, joy, and disgust with two sentiments (negative and positive) [10]. The annotations were manually given by crowdsourcing and this dataset consists of 14182 words that are identified to be emotionally charged or not.

E. Googles Pre-trained Word and Phrase Vectors

These are the pre-trained vectors trained on part of Google News dataset that contains about 100 billion words [8]. The model contains 300-dimensional vectors for 3 million words and phrases. The phrases were obtained using a simple data-driven approach that is skip-gram model of Word2Vec.

F. Mairesses Baseline Feature Set

Based on stream of consciousness essay dataset, Francois Mairesse and his colleagues have developed a document level feature set for personality detection that consists of 84 features [6]. Examples of the features included in this set are words per sentences, type/token ratio, words captured, words longer than 6 letters, prepositions, negative emotions, anxiety, etc.

G. Training

The dataset contains total 2,468 number of random essays among which 60%, 10%, and 30% data has taken for training, validation and testing respectively. Network parameters are randomly initialized and stochastic gradient descent with Adaleta update rules have used to adjust network parameters which reduced the negative log likelihood error [12]. Due to limitation of the hardware specifications the network is trained up to 6 epochs for each personality trait.

H. Experimental Data Preprocessing

The document preprocessing is important to remove unwanted text, symbols, and splitting documents into a list of words. This process consists of document tokenization, stop word removal, and word stemming. First, for tokenization, texts were splitted into sentences using period or question marks. Second, using apostrophe or white space character, sentences were splitted into words. Third, words were case-folded by reducing all letters to lowercase and ASCII characters also removed. The sentences longer than 150 words were splitted into sentence of 20 words.

After getting list of words, document level features extracted using Mairesses Baseline feature set [6]. The extracted document features used filtering out emotionally neutral words using NRC Emotion Lexicon dataset [11]. At last, word level features extracted, where Googles pre-trained vectors used to convert words into 300 dimensional vectors. The words assigned randomly to 300 coordinates with a uniform distribution from negative 0.25 to positive 0.25, when they are not found in the list.

I. Classification

This experiment has done with CNN and Mairesse setting, where a Multiple Layer Perceptron with one hidden layer is used for train the data. For final classification three activation functions namely Sigmoid Function, Hyperbolic Tangent Function (TanH), Leaky Rectified Linear Unit (Leaky RELU) have experimented.

J. Result Analysis

The prepared dataset is trained and tested to evaluate classifying accuracy of proposed model. The labeled data was used for training and individual written texts were used for testing. The experimental results of Personality Traits (PT) for different Activation Functions (AF) have shown in Table 1. The result includes training Performance (TrP), Value Performance (VP), Test Result (TR), and F-Score (F1).

TABLE I
EXPERIMENTAL RESULT FOR 2 AF

PT	AF	TrP	VP	Test P	F1(%)
EXT	Sigmoid	51.65%	56.50%	49.26%	33.00%
	Tanh	54.20%	56.50%	50.00%	39.40%
	Leaky ReLU	49.90%	44.09%	49.63%	35.02%
NEU	Sigmoid	50.65%	47.50%	47.40%	32.20%
	Tanh	57.75%	53.00%	58.14%	58.14%
	Leaky ReLU	56.60%	51.50%	55.20%	54.50%
AGR	Sigmoid	53.05%	53.50%	53.70%	35.00%
	Tanh	55.80%	50.50%	55.90%	46.16%
	Leaky ReLU	56.00%	49.50%	56.00%	45.70%
CON	Sigmoid	51.65%	46.50%	47.40%	32.16%
	Tanh	52.05%	47.00%	47.41%	32.76%
	Leaky ReLU	58.85%	55.50%	52.22%	52.11%
OPN	Sigmoid	48.95%	42.50%	49.63%	33.20%
	Tanh	60.95%	62.50%	60.00%	59.80%
	Leaky ReLU	64.00%	67.00%	58.15%	58.00%

From Table I, it is observed that overall performance of hyperbolic tangent function is better than sigmoid or Leaky ReLU. However, for some cases Leaky ReLU outperformed than other two functions. For example, agreeableness personality trait test result has found 56.00% for Leaky ReLU where 53.70% and 55.90% is for Sigmoid and $tanh$ respectively. Similarly, for Conscientiousness, test result has found 52.22% for Leaky ReLU where 47.40% and 47.41% is for Sigmoid and $tanh$ respectively.

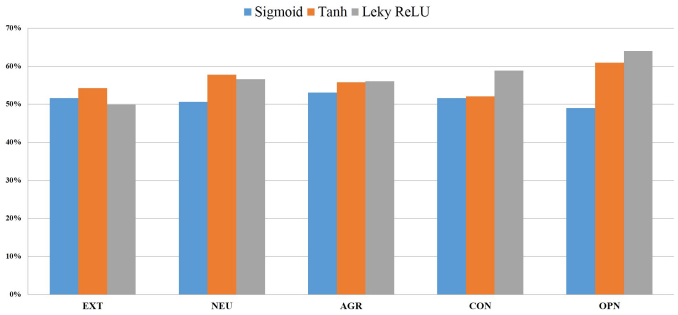

Fig. 2. Training Performance Comparison Chart

Figure 2, is showing a comparison chart for training performance using sigmoid, $tanh$ and leaky relu activation function. Tanh and leaky relu performed better for all the cases except for the extroversion trait where sigmoid performed better than leaky relu.

As for the test results shown in Figure 2, $tanh$ and leaky relu outperformed the sigmoid activation for all of the personality

traits. Moreover to this, $tanh$ is seems like the best performer amongh these three.

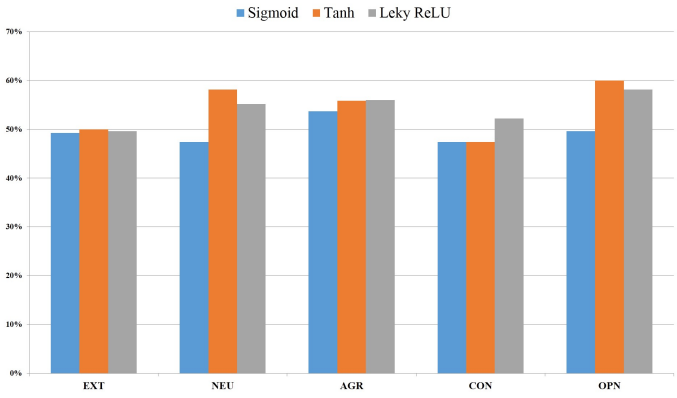

Fig. 3. Test Result Comparision Chart

Proposed model's classification accuracy was estimated with F1-Score to evaluate how accurately this model can classify unknown samples. F1 score is the weighted average of precision and recall considering both false positive and false negative. This score conveys the balance between precision and recall. In this strategy, the F1 score is calculated by equation (5).

$$F1 - score = 2 * (\frac{Precision * Recall}{Precision + Recall}) \tag{5}$$

In Table I and Figure 4, F1-score of sigmoid activation is very poor for all the personality traits whereas hyperbolic tangent and leaky relu performed better. Particularly, leaky relu outperformed on conscientiousness data set, however, $tanh$ performs better on all other datasets.

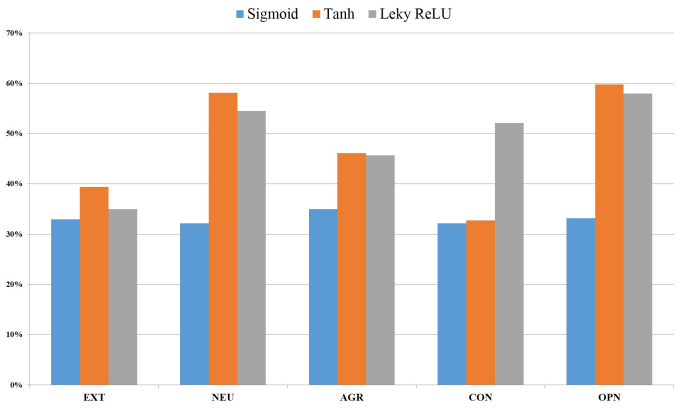

Fig. 4. F1-Score Comparison Chart

All the empirical results showed that leaky relu outperformed on conscientiousness data set only, where $tanh$ performs best over other datasets. Therefore, this research concluded that $tanh$ activation function is suitable for personality traits analysis.

V. CONCLUSION

This research proposed an empirical approach for finding the best personality traits detection approach using CNN model. The main contribution of this work is to compare personality traits detection performance of sigmoid, $tanh$ and leaky relu activation functions for selecting the best one. This method consists of data preprocessing, data filtering, feature extraction, and classification phases. First, the text documents have been preprocessed to remove any unwanted characters. Then, the processed data was vectorized using word2vec algorithm. The vectorized document was fed as input in CNN where features were extracted in hidden layers. Finally, deep CNN has used for classification, and soft max function is applied as output layer to find probability of each document.

Five personality traits named as EXT, NEU, AGR, CON, and OPN have been used for comparative experimental analysis. The comparison results showed $tanh$ and leaky relu performs over sigmoid in all personality traits datasets. The average F1-score of sigmoid, $tanh$ and leaky relu are 33.11%, 47.25%, and 49.07% respectively. However, F1-score of leaky relu was high only for CON dataset and for all other $tanh$ showed better results. In a nutshell, the overall performance of hyperbolic tangent function is better than sigmoid and leaky relu. Changing in the activation functions i.e. using $tanh$ and leaky relu showed surprising improvement at the both training accuracy and testing accuracy over the sigmoid function. Hence, it implies that, for text analysis using Convolutional Neural Network other activation functions may improve the result in a big scale. Incorporating RNN for personality traits will be the future research direction of this work.

***Abstract*—Cervical Cancer, being one of the most pressing issues now-a-days, needs to be addressed properly. With a view to achieving an accurate diagnosis method for Cervical Cancer by screening the risk factors, different machine learning approaches have been taken over time. But by analyzing the performances of most of state-of-the-art approaches, it was inferred that there is still room for improvement by developing a more accurate model. Hence, in this paper an approach using ensemble methods with SVM as the base classifier has been taken. The ensemble method with Bagging technique achieved an accuracy of 98.12% with very high precision, recall and f-measure value.**

***Index Terms*—Ensemble methods, Bagging, Machine learning, cervical cancer, risk factors**

I. Introduction

Cervical cancer has turned out to be a major concern around the world. According to the World Health Organization (WHO), it is the fourth most common cancer in women. Cervical cancer represents almost 7.9% of the total female cancer that occurred in 2012 [1]. It arises in the cervix cells in uterus and has the potential to invade other parts of the body [2]. A number of risk factors are associated with this type of cancer. It is very pivotal to make a prediction based on the risk factors for the detection of the disease. An early identification can play a crucial role in the treatment process. Proper medical care, after an early detection can increase the chances of survival to a great extent [1]. Different stages of Cervical Cancer has been shown in Fig 1.

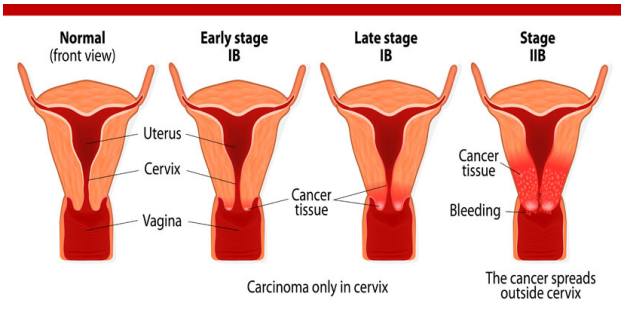

Fig. 1. Cervical Cancer [3]

In this study, different machine learning algorithms were carried out based on the risk factors in order to make a comparative analysis in the intervention of the disease. Four classification algorithms such as SVM, Decision tree, Multilayer Perceptron and K-nearest neighbors were used for the purpose in **WEKA** data mining tool. Classification accuracy was then improved by applying different ensemble methods. Bagging and boosting were performed on the data-set to acquire better accuracy.

The organization of the remaining paper is as follows - Earlier works related to cervical cancer is presented in Section II, Section III represents the overall methodology. Section IV shows the performances of the experiment done and Section V summarizes the results with a short discussion. Finally, Section VI concludes the paper with an overall discussion.

II. Literature Review

Cervical Cancer has been a red-flagged issue for a very long time now. Proper diagnosis of cervical cancer has become a very challenging and demanding domain of research. Various machine learning based attempts has been made in order to achieving a classification model with high accuracy for screening cervical cancer.

TABLE I
Literature Review

Author	Accuracy	Classifier
Kelwin et. al. (2017) [4]	68.30%	SVM
Hayder et. al. (2017) [5]	42.9%	Decision Tree
Wesabi et. al. (2018) [6]	97.5% 49.0% 88.2% 87.6%	Decision Tree Logistic Regression SVM KNN
Wen et. al. (2017) [7]	94.13% 94.03% 94.03%	SVM SVM-RFE SVM-PCA
Ramit et. al. (2017) [8]	94.92%	Random Forest
Fahri et. al. (2018) [9]	95.89% 95.89% 97.26%	kNN MLP Bayes Net

All the above mentioned papers in TABLE I have used the same dataset. Our empirical result is also based on the same dataset with 36 attributes containing the medical records of 858 patients. In [4], a transfer learning based approach has been taken. The authors proposed a strategy that facilitates target and source models to share the same coefficient signs for reducing the amount of labeled data from each expert/modality. In [5], a 3-staged cost sensitive classifier for cervical cancer screening was proposed. The classifier was a decision tree with cost selectivity and the model was evaluated with 10-fold cross validation.

In [6], diverse classification techniques on cervical cancer dataset have been applied. The result shows the advantage of feature selection approaches to the best predicting of cervical cancer disease. The results also showed that first sexual intercourse, age, hormonal contraceptives, number of pregnancies, smokes, and STDs:genital herpes are the main predictive features for cervical cancer. In [7] three SVM based approaches, namely - Simple SVM, SVM-RFE and SVM-PCA were introduced for cervical cancer classification. According to their result, SVM-PCA method was the most accurate method.

In [8] a penalty function was introduced to the already existing fitness function for Binary Firefly Algorithm. This addition radically reduced to an optimal subset which gained an increased classification accuracy compared to the traditional deep learning and information gain methods. In [9] a comparative study of the performance of popular classification algorithms like Multilayer Perceptron, BayesNet and k-Nearest Neighbor was done.

All the results from the aforementioned papers are presented in Table 1.

III. Methodology

The overall workflow had been divided into some major steps. Each and every steps are shown in Figure 2 and discussed in details afterwards.

A. Data Collection

The data-set used for the classification was collected from the UCI machine learning repository. This data-set was originally collected at 'Hospital Universitario de Caracas' in Caracas, Venezuela. The data-set comprises demographic information, habits, and historic medical records of 858 patients. Several patients decided not to answer some of the questions because of privacy concerns. So definitely there were some missing values present in the dataset which was handled in the later step.

The classifications were carried out on the medical information of 858 different patients with 36 features. Table I shows the information of the available attributes. Four attributes such as **Schiller**, **Hinselmann**, **Biopsy** and **Cytology** were selected as the class attributes for classification.

TABLE II
ATTRIBUTES [10]

Attribute Name	Type	Attribute Name	Type
Age	Integer	First sexual intercourse (age)	Integer
Number of sexual partners	Integer	STDs:molluscum contagiosum	Boolean
STDs:pelvic inflammatory disease	Boolean	STDs:genital herpes	Boolean
Number of pregnancies	Integer	STDs:AIDS	Boolean
Smokes	Boolean	Smokes (years)	Integer
Smokes (packs/year)	Integer	STDs:HPV	Boolean
STDs:HIV	Boolean	STDs:Hepatitis B	Boolean
Hormonal Contraceptives	Boolean	Hormonal Contraceptives (years)	Integer
STDs: Time since first diagnosis	Integer	STDs: Number of diagnosis	Integer
Intrauterine Devices (IUDs)	Boolean	STDs: Time since last diagnosis	Integer
IUDs (years)	Integer	Dx:Cancer	Boolean
Sexually Transmitted Diseases (STDs)	Boolean	Dx:CIN	Boolean
STDs:condylomatosis	Boolean	STDs:pelvic inflammatory Dx	Boolean
STDs (number)	Integer	Dx:HPV	Boolean
STDs:vaginal condylomatosis	Boolean	STDs:vulvo-perineal condylomatosis	Boolean
STDs:cervical condylomatosis	Boolean	STDs:syphilis	Boolean
Hinselmann	Boolean	**Biopsy**	Boolean
Schiller	Boolean	**Cytology**	Boolean

Each patient can be classified into four different classes at the same time since it is a multilabel and multiclass problem. The classifications were done on WEKA data mining tool. A cross-validation with 10 folds were conducted on the dataset to evaluate the performances of the different algorithms used for comparison.

B. Pre-processing

The dataset collected contained a lot of missing values. After analysis, it was seen that two attributes named ***STDs: Time since last diagnosis*** and ***STDs: Time since first diagnosis*** contained the highest number of missing data. So, they were removed from the dataset and classifications were done based on the other 34 attributes. The missing values of these 34 attributes were filled up by the median of the corresponding column in java.

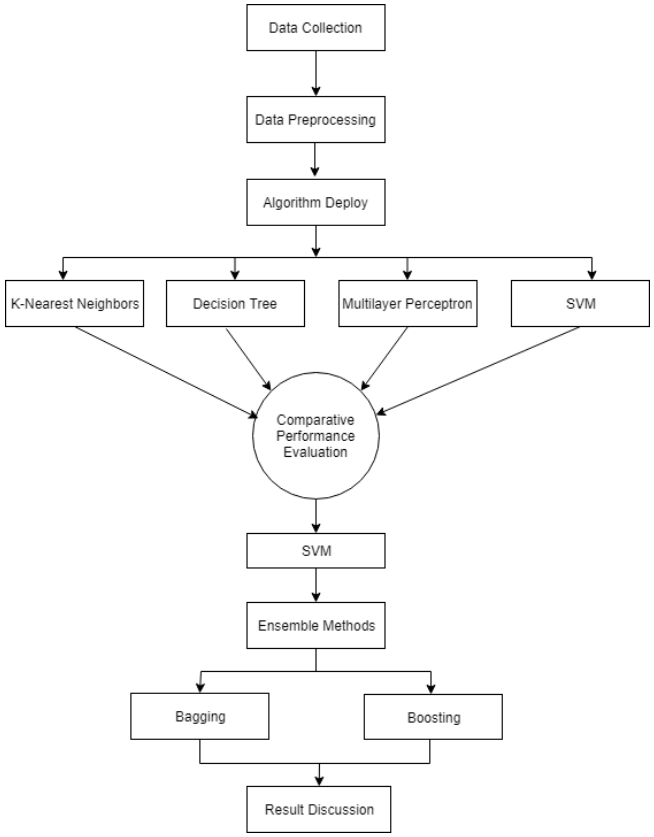

Fig. 2. Overall Work flow.

C. Classification Algorithms

Decision Tree:

Decision tree is a fast learning algorithm that enables us to classify and predict a target variable. It is a tree like structure in which every non-terminal nodes represent a condition and the terminal nodes contain class labels [5].

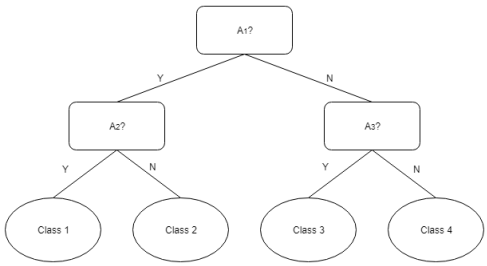

Fig. 3. Decision Tree Induction.

Multilayer Perceptron:

Multilayer Perceptron (MLP) is a type of neural network model that makes the use of supervised learning technique where the input sets are mapped into proper output sets. It consists of different layers of nodes in which one layer is connected to the next layer. An MLP typically has 3 types of layers, namely - Input Layer, Hidden Layer and Output Layer. Every node, other than the input nodes, is a processing unit called neuron that has a nonlinear activation function. In order to train the network, back propagation is typically used in this algorithm. [9]

SVM:

SUPPORT vector machine is a strong classifier for solving regression problems [11]. It has a very easy implementation. A hyperplane is chosen to separate all the points in the input variable with respect to their classes. Sequential Minimal Optimization (SMO) is one of the ways to solve the SVM problem. According to [12], SMO is fast and has good scaling properties.

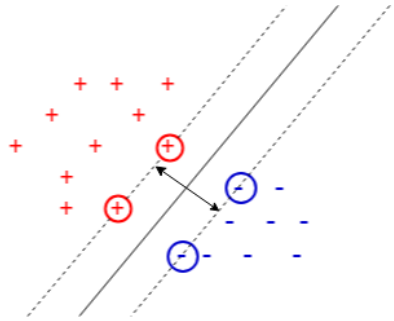

Fig. 4. Optimal hyperplane separating two classes.

K-Nearest Neighbor:

The k-NN is one of the supervised learning techniques for solving classification problems. One crucial point is that the features are to be determined in advance. According to this algorithm, the distance between the desired item to be classified and the previous items is determined and the nearest k class is taken. Identifying the number of neighbors is a very important optimization problem in this algorithm [9].

Ensemble Methods Ensemble methods are hybrid algorithms that combine different machine learning algorithms into one predictive model and decrease bias (boosting), variance (bagging) or improve predictions (stacking). Most ensemble methods use a single base learning algorithm to produce homogeneous base learners.

1) Boosting: Boosting is one of the ensemble methods which is used for improving the performances of a weak classifier. Sequential learning of the predictors is used here. Initially, the whole data set is used for learning. Subsequently, learning occurs through the training sets based on the previous performances. The weights of the misclassified instances are increased so that the possibility of appearing in the training set of the following predictor gets higher [13]

2) Bagging: Bagging is an ensemble methods which is used to improve unstable classification problems. If

the position of a training point changes marginally, weak classifiers can become unstable. Bagging can be applied to different classification algorithms. It is a very useful technique for large data sets in which detecting a good model is difficult due to the complexity and scale of the problem [13].

IV. Performance Evaluation

Performances were determined based on accuracy, precision, recall and f-measure. Table II shows the equations used for calculating the desired performance measures.

TABLE III
PERFORMANCE EVALUATION MATRIX [14]

Measure	Equation
Accuracy	$\frac{TP+TN}{TP+TN+FP+FN}$
Recall	$\frac{TP}{TP+FN}$
Precision	$\frac{TP}{TP+FP}$
F-Measure	$\frac{2X\,Recall X\,Precision}{Recall+Precision}$

Using 10 folds cross validation, different classification algorithms were conducted on the data-set to obtain the performance measures which is represented by the following graphs.

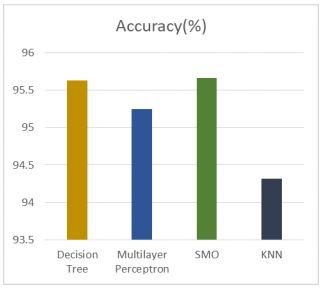

Fig. 5. Accuracy.

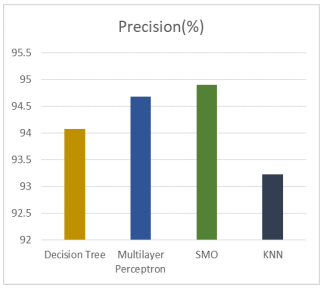

Fig. 6. Precision.

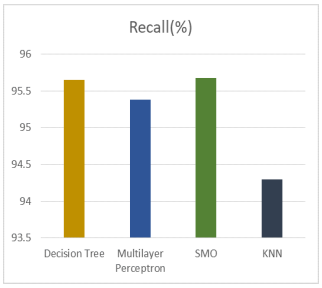

Fig. 7. Recall.

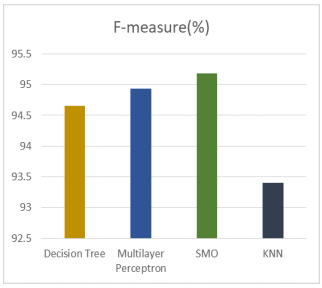

Fig. 8. F-measure.

After analyzing the results obtained, it is seen that SMO offers us the best performance. SMO is superior to all other classification algorithms used in respect of accuracy, precision, recall and f-measure. Two ensemble methods namely AdaBoostM1 and bagging were conducted using 10 fold cross validation and SMO as the classifier.

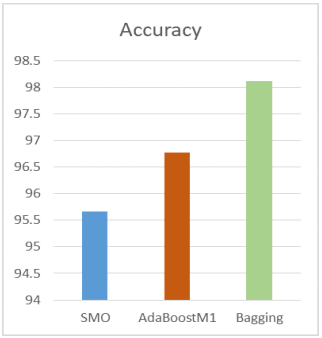

Fig. 9. Accuracy.

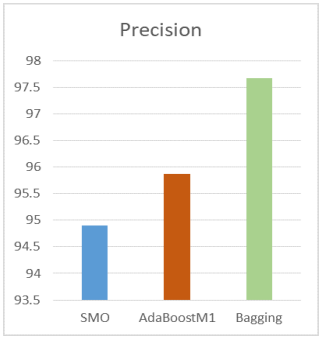

Fig. 10. Precision.

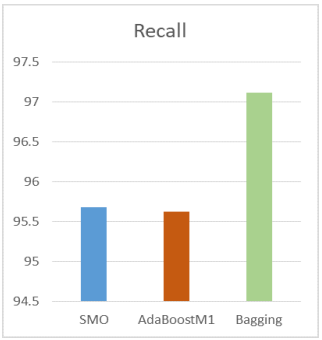

Fig. 11. Recall.

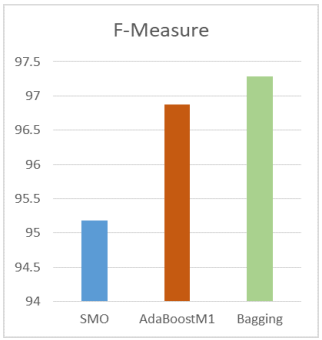

Fig. 12. F-measure.

V. Results and Discussion

Four classification algorithms were used in our study. After analyzing the performances, it was seen that SMO had a better performance than the others. So, SMO was selected as the base classifier and two ensemble methods namely AdaboostM1 and bagging were carried out to enhance the performance. AdaboostM1 had a slight increase in performance but bagging had the bigger impact.

Machine learning techniques aim to find a single model that best predicts our desired result. Instead of using a single model as the predictor, ensemble methods take into account different models and average those models to generate a final stable model.

Bagging is a powerful ensemble method which uses multiple models of the same algorithm. It reduces variance by building more advanced models of data sets. It takes different subsets from our training data sets randomly and then uses bootstrap as a subroutine of its learners. Bagging trains the learning models and then take the votes on their output. Thus, by reducing variance, it can reduce the overfitting problem leading to higher stability.

VI. Conclusion

Machine learning classification has received a great attention in the past days. Some of the popular classification algorithms were used in our study. The study was conducted among 858 patients having 36 different attributes. The performances were measured in respect of accuracy, precision, recall and f-measure. The algorithm with the best performance was selected and the ensemble methods were carried out on them to improve the overall accuracy. This accuracy can further be improved with nature inspired optimization algorithms and therefore will remain as a possible future extension for our work. Also, we could try out other non-ensemble based classification models to reach higher accuracy. Finally, this study turns out to be a very crucial one considering its health and social impact and research on this arena should be kept going on in a continued manner.

***Abstract*—Document categorization is a classic NLP task which includes allocating documents based on their content into one or more predefined classes. In this paper, we proposed a model using multilayer dense neural network with TF-IDF as feature selection technique in terms of Bangla text document categorization. The proposed system is distributed into three consecutive steps: i) preprocessing raw text data and extracting feature using TF-IDF, ii) designing the model architecture and fitting the model to train set, and iii) evaluating model performance on test set based on accuracy and F1 score. It is observed from experiments that the proposed method exhibits higher accuracy (84.58%) and F1 score (0.84) compared to the other well-known classification algorithms (Support Vector Machine, Multinomial Naive Bayes and so on) for Bangla text document classification.**

***Index Terms*—Document categorization, TF-IDF, Neural Network, Classification.**

I. Introduction

Document categorization is a classification task in natural language processing (NLP) with a variety of real-life applications that range from sentiment analysis to spam detection. In terms of document classification tasks, supervised classification algorithms have been a popular choice among NLP practitioners. [1], [2] Furthermore, neural networks(NN) with word embeddings have accomplished remarkable results regarding text classifications in recent times. [3] However, ample amount of studies has been implemented on English in contrast to Bengali. Bangla, also known as Bengali, is one of the most widely spoken language throughout the world. Hence, with the rapid growth of internet, almost every form of digital text documents such as blogposts, newspaper articles, social media posts are noticeably escalating all over the web. Consequently, the necessity of automated document categorisation has become a critical issue to address. Various methods of Bangla document classification have been proposed in recent studies. [4]–[7] In this paper, we designed a dense neural network model with TF-IDF as feature selection technique for Bangla text document categorization. However, a comparative analysis among our proposed model and other well-established methods can aid to the better comprehension of our model's applicability in terms of Bangla document categorization. In this paper, we designed total nine experiments with two different feature selection method (TF-IDF and word embeddings) for performance evaluation.

- Six classification models with TF-IDF: Logistic Regression (LR) , Stochastic Gradient Descent classifier(SGD), K-Nearest Neighbor (KNN), Decision Tree(DT), Support Vector Machine (SVM) and Multinomial Naive Bayes (MNB).We used Multinomial Naive Bayes (MNB) instead of Naive Bayes(NB) since study [8] suggests that MNB performs better than other Naive Bayes models.
- Two neural network models with word embedding layer: Dense NN (embed +NN) and Convolutional NN (embed +CNN).
- Our proposed model: one dense neural network model with TF-IDF(TF-IDF +NN)

The purpose of these experiments is to evaluate and compare the efficiency of our model and the other models in terms of document categorization. The rest of this paper is as organised as follows: section-II discusses about related early works. Section-III depicts the design and methodology of our study. In section-IV, experimental analysis is discussed. Section-V provides the concluding remark of this study.

II. Related works

Literacy review indicates that extensive research works are conducted on English document categorization. Well-known supervised algorithms have been implemented for English text document categorization tasks. [1], [2], [8], [9] TF-IDF has been commonly used for extracting feature from text data in considerable amount of studies. [10], [11] However, word embedding has shown to achieve outstanding results in recent years. In terms of Bangla document classification, several classifiers such as Stochastic Gradient Descent classifier (SGD), K-Nearest Neighbor (KNN), Naive Bayes (NB), Decision Tree (DT), Support Vector Machine (SVM) has been implemented with TF-IDF and chi-square as feature selection methods [4], [5], [7], [12].Word embeddings with Word2Vec model has shown to accomplish excellent result in document categorisation. [4], [6]

III. Methodology

In this section, the procedure of our designed experiments is described. This process is composed of three vital steps. Firstly, we preprocess raw text data and divide the entire

dataset into train set and test set. Secondly, classifier algorithms and neural networks are applied to test set. Finally, prediction is made on test data and models are evaluated. The details of these experiments are provided in the following subsections:

A. Data Preprocessing

We collected 1600 articles from two online Bangla newspaper known as ProthomAlo (http://www.prothom-alo.com) and BDnews24 (https://bdnews24.com) by parsing Bangla texts from these newspapers. 16 types of documents priorly labeled in the mentioned newspapers are obtained. These documents are arranged into 16 classes of each having 100 articles. Afterwards, this entire dataset is divided into two sets: train set containing 1120 articles and test set with 480 articles where each class has 70 training documents and 30 test documents. Our dataset is stratified as train set should contain data from all possible classes which is not certain in random sampling. Punctuation marks, english letters, mail addresses, html tags are removed from each raw document while tokenizing. Data set description is illutrated at table-I

TABLE I
DATA SET DESCRIPTION

Classes	Total documents	Train set	Test set
Commerce	100	70	30
Science	100	70	30
Art and Literature	100	70	30
Economy	100	70	30
Education	100	70	30
Entertainment	100	70	30
Immigrant	100	70	30
Kids	100	70	30
Lifestyle	100	70	30
Movie	100	70	30
National	100	70	30
Politics	100	70	30

Technology	100	70	30
World	100	70	30

For classifier algorithms, TF-IDF vectorizer is used to extract feature. Top 1500 features with the highest term frequency and document frequency less than 0.7 that appear in more than four documents is selected during the process.

For neural networks, 5000 words with the highest word frequencies in train set are selected for feature extraction where each word is mapped to an integer number (known as token). These tokens are used in convolutional neural network(CNN) as CNN works with sequential data and TF-IDF does not interpret neighbourhood among the words. However, for multilayer dense neural network, tokens are transformed into TF-IDF vectors and both TF-IDF and word vectors are utilised with two different architectures.

Maximum number of words in an article of the train set is 2037. To work with embedding layer, it is essential for each document to have the same length. For this purpose, each document size is fixed to 2000 words by padding and truncating as needed.

B. Model Fitting

a) Classifier algorithms: Six classifier algorithms(K-NN,DT,SVM,SGD,MNB,LR) have been used on train set for hyper parameter tuning and better model adeptness. For each model, grid search is applied on train set with different sets of parameters for hyper parameter tuning. Hyper-parameter optimisation for a model is a crucial task as the performance of a model can highly depend on it's hyper-parameters. Optimal parameters are determined based on the best score of 10 fold cross validation. During the process, train set is employed to fit each model with optimal set of parameters. The diagram for classifier models is illustrated in figure-1.

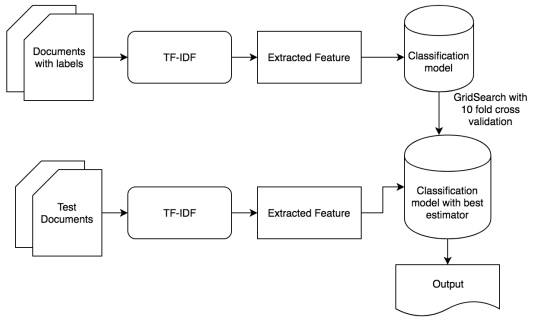

Fig. 1. Diagram for classifier models.

b) Neural Networks: In CNN model, we used embedding layer as a part of neural network in order to create word embeddings. This embedding layer learns word embeddings along with the model itself while being fitted on training data. An input document is provided as a sequence of N tokens (N=2000) to the model's embedding layer that transforms the tokens into n-dimensional word vectors (n=128). Subsequently, a one dimensional spatial dropout layer is added for regularisation in stead of dropout layer as suggested [13]. Next layer is a 1-D convolution layer followed by a GlobalMaxPool1D layer as pooling layer. Finally, a dense layer with 16 units and softmax as activation function is added as output layer.

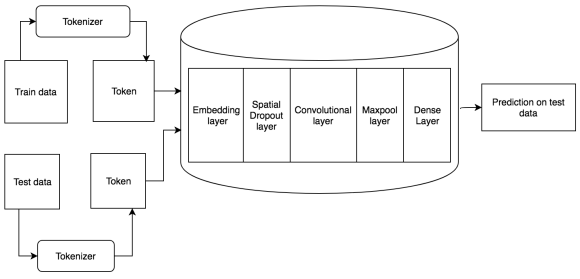

Fig. 2. Diagram for CNN with embedding layer.

In terms of dense NN, which contains embedding layer as the first layer, takes input as sequences like CNN. Next layer is a flatten layer that outputs a one dimensional tensor which

can be utilised by the following dense layer. Afterwards, a dropout layer is added. The output layer has the same structure as CNN.

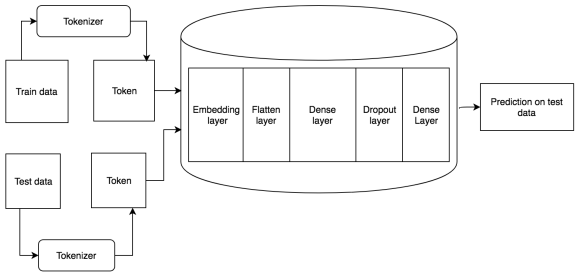

Fig. 3. Diagram for embedded Dense Neural Network

In terms of our proposed model which uses TF-IDF feature selection methods, first layer of this model is a dense layer which uses TF-IDF features as input. It is worth mentioning that this model does not include any flatten layer or spatial dropout layer due to the absence of embedding layer. Instead dropout layer is added after the first two dense layer to work as regularizer. The purpose of a dropout layer is to refine generalisation in performance by inhibiting strong correlation among activation functions. Finally, the output layer is a dense layer with 16 units and uses softmax as activation function. The diagrams of NN models are depicted in figure 2-4.

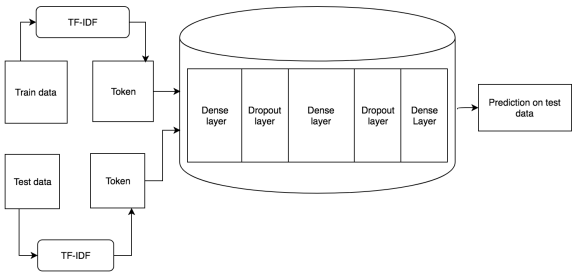

Fig. 4. Diagram for our proposed model: Dense NN with TF-IDF

C. Model evaluation

To evaluate the performance of our experimental models, we used accuracy and F1 score as performance measures. Test set is utilized for prediction on each fitted model of all 9 experiments. Predicted labels and true labels of test set are used to quantify accuracy and F1 score.

IV. Empirical analysis

a) Data collection and preprocessing: 1600 articles of 16 priorly labeled categories are parsed from two online Bangla newspaper (ProthomAlo, BDnews24) and grouped into 16 classes with 100 articles per class. The dataset is divided into train set and test set where test size parameter is 0.3. For TF-IDF used in classifier models, max df is 0.7 and min df is 4. For NN, we used keras.preprocessing.text.tokenizer tool for feature selection where number of maximum word is set to 5000. For NN models with embedding layer, we fixed the size of each article's word length to 2000 words by pre-padding or pre-truncating.

b) Experimental Setup: For classifier models, we used sets of parameters for hyper-parameter tuning. For DT, entropy criterion, maximum depth of 10 and minimum sample leaf 1 are selected as the best parameters through grid search with 10 fold cross validation. In SVM, Rbf kernel, C=10 and gamma value 0.1 are selected as the optimal parameters. Multinomial LR with newton-cg solver is chosen through grid-search. KNN with 15 neighbours, p value 2 and distance weight function is used for prediction. In terms of MNB, alpha value 0.1 is chosen. With regards to SGD, alpha value 0.0001 and log as loss function is selected through hyper parameter optimization. For neural network models, we used keras for all NN models and built them with sequential model which allows to create models layer-by-layer. For our proposed model, first dense layer has 128 node and relu as activation function. Second dense layer has 64 nodes with sigmoid activation function. After each dense layer, a dropout layer is added with value 0.5 as recommended [3]. For CNN and embed + Dense models, embedding layer takes 5000 word tokens as vocabulary and each token is represented in 128 dimensions (n=128) and maximum length of each token sequence is 2000. For CNN, Spatial dropout layer has been added with drop out value of 0.2. In 1 dimensional convolution layer, 256 different filters of kernel size 3 is added with relu activation function followed by a 1-D global max pool layer. For dense NN, flatten layer is added followed by the embedding layer. Next layer is a dense layer with 128 unit and sigmoid as activation function followed by a dropout layer of 0.5 to reduce overfitting. For all NN models, output layer is a dense layer with 16 units and softmax activation function. During model compilation, adam optimizer is used [14] and categorical cross entropy as loss function with accuracy and F1 score as metric. While fitting the model, validation split=0.3 and batch size=128 is used and all models are trained for 25 epochs.

c) Result: For all models, prediction on test dataset is conducted and confusion matrix is evaluated. Confusion matrix provides information about how many documents of a class on test set is correctly classified or misclassified. Afterwards, accuracy and F1 score is calculated from confusion matrix.The Confusion matrix of our proposed model is illustrated below in figure-5. Accuracy score and F1 score are depicted for all models in table -I.

From table-I, it is evident that our proposed model has the highest accuracy (84.580%) and F1 score (0.84). Afterwards, there is SGDclassifier and SVM with the same F1 score(0. 82) depicting slight difference in accuracy (82.290 % and 81.870 % respectively). LR and MNB performances are almost similar with accuracy 80.830% (LR) and 80.620% (MNB), and their F1 scores are 0.81 and 0.80 respectively. Next is KNN with F1 score of 0.76 which is slightly higher than the F1 score of CNN (0.75) and their accuracy is 74.375% and 75.0% respectively. Lastly, DenseNN + embedding and DT has lower

TABLE II
EVALUATION METRICS

Algorithms	F1 Score	Precision	Recall	Accuracy (%)
TF-IDF+DenseNN	0.84	0.86	0.85	84.580
SVM	0.82	0.82	0.82	81.870
SGD	0.82	0.83	0.82	82.890
LR	0.81	0.81	0.81	80.830
MNB	0.80	0.81	0.81	80.620
KNN	0.76	0.82	0.74	74.375
Embedding+CNN	0.75	0.76	0.75	75.000
Embedding+DenseNN	0.57	0.62	0.59	58.750
DT	0.53	0.59	0.52	51.670

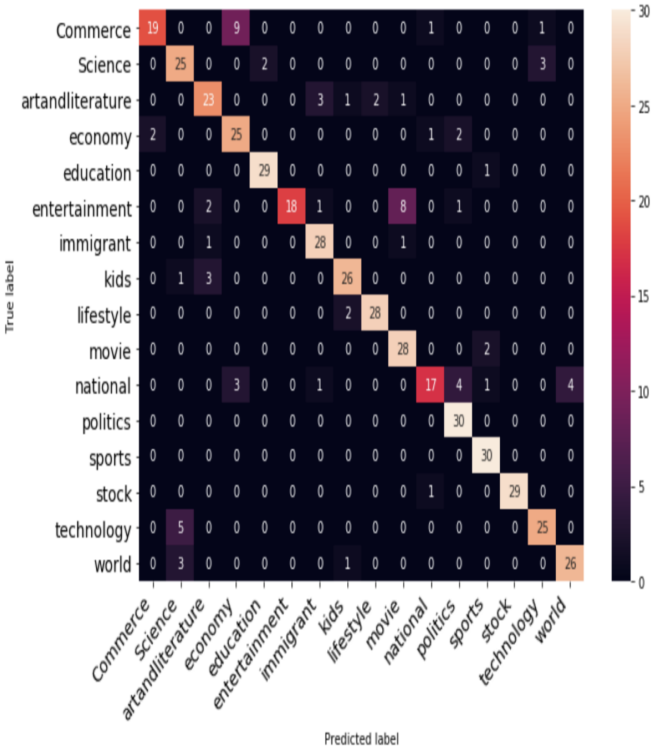

Fig. 5. Confusion matrix of our proposed model: TF-IDF+DenseNN

accuracy and F1 score than the other models where accuracy is 58.750% and 51.670% respectively and F1 score is 0.57 and 0.53 respectively.

V. CONCLUSION

In this paper, we represent a method to categorise Bangla text document by integrating TF-IDF feature selection technique with dense neural network. This paper concludes with the following verdicts:

- Our proposed system has accomplished higher accuracy (84.580%) and F1 score (0.84).
- Our proposed method which incorporates TF-IDF has superior performance than word embedding based NN models.

In future, the authors would like to implement hybrid approach with deep learning on larger datasets regarding Bangla text document categorization.

safialislam302@gmail.com

Abstract — **In the arena of software engineering, software defects prediction is one of the most attractive research topics. Here the main task is to predict if there is any bug in the software or not. For software testing, software defect detection is important for reducing the time and resources consumed. Accurate estimate of defect software prediction process enables effective discovery and identification of the defects. Such prediction methods are important for the big scale systems, where verification specialists need to focus their attention. In this paper, we proposed a method where the features are selected using Genetic Algorithm (GA). Secondly, make cluster of the selected features using Particle Swarm Optimization (PSO) and then train the model with different Neural Network (NN) methods such as: Feedforward Neural Network (FNN), Recurrent Neural Network (RNN), Artificial Neural Network (ANN), and Deep Neural Network (DNN) and finally calculate accuracy, sensitivity, specificity, precision, negative prediction value, F1 score, and Matthews correlation coefficient. We use five different datasets from NASA promise software engineering repository for our study. From our study, we get the best accuracy result using deep neural network. Experimental consequences show that proposed strategy is a decent technique to predict the software defects.**

Index Terms*— *Software Defect Prediction, Neural Network, Genetic Algorithm, Particle Swarm Optimization

I. INTRODUCTION

As software company grows in a number nowadays, the complexity and prediction of software defect plays an important role in the software industry. Build high-quality software, defect prediction plays an important role to consider the quality level of the software. Also, it helps for software testing and debugging. For large software, manually find the defects is very complex and time-consuming. Because there are several source files and many logic connections among those files. Quality of the software is very important and different issues which are related to testing software are becoming crucial when the defects are prediction. Code defects consider the key reasons for failures to build a software [1], so to improve consistency many companies like Google, employ code review and test the code to find bugs [2]. So, an automatic system is needed to find out the defect in a quick possible time [3]. This not only saves time but also ensure to build high-quality software. This type of system also gives information about the software like code complexity, time complexity. It helps the code reviewers to solve the defect in minimum time.

Software defect prediction is very challenging tasks in the software engineering sector. To detect the defect in manually a lot of manpower and times are needed. Also handle this huge data in manually is also very difficult. So, different types of computer-based automatic system are very effective to predict the defect in the software. In recent years, different methods have been proposed to detect a software contains any defect or not. The traditional approaches focus on designing structures of programs [4 – 6]. Then different machine learning techniques are proposed to build the models. Some of them use Neural Networks (NN) [7], Support Vector Machine [8], Transfer Learning [9] and etc. methods.

Artificial Neural Network (ANN) makes using the basic structure of the human brain, where the neurons receive input, process the input, and finally produce the output according to the processing steps. Feedforward Neural Network (FNN) is the first and simple type of ANN devised. Here the information moves only one direction i.e. forward. Here also have input state, one hidden layer, and output state like ANN. Recurrent Neural Network (RNN) is also a modification of ANN, where the connections of graphs between the nodes are temporary. RNN is used in two broad network classes of similar structure. Deep Neural Network (DNN) is a fast-growing method and it works like a human brain. Many studies work to prove that DNN provides a better outcome, decline the classification error rate and more robust to noise than other strategies.

In this paper, we proposed a method to predict the defect of software using Genetic Algorithm (GA) and Particle Swarm Optimization (PSO). GA is a method which impersonators the way biological evolution works. Mainly GA is an optimization algorithm but nowadays GA uses in different sectors in engineering. PSO is also one kind of optimization technique which is inspired by nature. In recent year it becomes very powerful and interesting search technique. It also modified to solve different engineering problems. In the proposed method, GA is used to select the features and PSO is used for clustering. Then the datasets are trained used four neural network techniques artificial neural network, feedforward neural network, recurrent neural network, and deep neural network. Then using the test set measure different performance measure parameters like accuracy, sensitivity, specificity, precision, negative prediction value, F1 score, and Matthews correlation coefficient.

Rest of the paper has been prepared as follows. Section II provides a short view of the researchers that have been done in this field. Section III provides the proposed methodology. Experimental outcomes of the proposed strategy are described in Section IV. Finally, Section V presents a brief conclusion of the paper.

II. Related works

X. Yang et al. [10] used deep learning methods to predict the defects. They use Deep Belief Network to extract the features from the initial set of linear features. Then they use Logistic Regression technique to classify the software contain any bug or not. S. Wang et al. [11] proposed a method to extract the features from the given set of data using deep learning algorithm and then applied Deep Belief Network to classify the defect and non-defect software.

T. Menzies et al. [12] focus on how the attributes are used for predicting defect rather than the attributes are used. They proved that this type of prediction is useful. They got 71% of mean probability detection and 25% of mean false alarms rates. Zhong et al. [13] make the cluster using k-means and Neural-Gas techniques. Neural-Gas method works better in the terms of mean squared error and the k-means method works much faster compare to other methods. N. Sharma et al [14] compare various algorithm for clustering the ISBSG and PROMISE dataset using WEKA. There are also some traditional statically methods [15 – 17] to predict the defect of software.

III. Methodology

This section discusses the proposed methodology for predicting the defect in the software. In this paper, we proposed a method using Genetic Algorithm (GA) and Particle Swarm Optimization (PSO) to predict the defect of software. We follow 5 steps, (1) Dataset Collection, (2) Feature selection, (3) Build Cluster, (4) Train the model, and (5) Performance measurement. Figure 1 describes the overall system for software defect. The following subsections explain all the steps in details.

A. Dataset Collection

We consider 5 different datasets to predict the defect of software. The dataset is taken from NASA promise software engineering repository [18] namely PC1, CM1, JM1, KC1, and KC2. There are no missing values and have 22 attributes in all the datasets. If the software contains defect then the final attributes were true or 1and have not any defect then the value was false or 0.

B. Feature Selection

Using Genetic Algorithm (GA) the features are selected for this paper. There are two operators namely crossover and mutation help to make a new population from the current population. Crossover exchanges a part of chromosomes to another chromosomes and mutation randomly change some allele values in the chromosome. GA calculate the fitness of every individual chromosome and chose the best fitness value for the next generation. The process of crossover and mutation are continuing until the requirement are not meet.

C. Build Cluster

To build cluster using Particle Swarm Optimization (PSO), a single particle represents the cluster centroid point. Each particle represents a clustering solution. Each particle maintains a matrix $X_i = (C_1, C_2, \ldots, C_i, \ldots C_k)$, where C_i in the *ith* cluster centroid vector and k is the number of clusters. Then randomly taken n centroid points. For each centroid point calculate the Euclidean distance, here the distance is considering the fitness value. For this paper we take the value of $n = 5$, i.e. for the given data, there are 5 clusters.

D. Train the Model

In the proposed method, we train the model 4 using different neural network methods: Feedforward Neural Network (FNN), Recurrent Neural Network (RNN), Artificial Neural Network (ANN), and Deep Neural Network (DNN). For training the dataset we divide the dataset into two parts. (1) train set and (2) test set. The ratio of divide the dataset in all the dataset is 75% for training and 25% for testing.

E. Performance Measurement

After the training the model, using the test set we measure some performance measurement parameters like Accuracy, Sensitivity, Specificity, Precision, Negative Prediction Value (NPV), F1 score, and Matthews Correlation Coefficient (MCC). In the confusion matrix, there are four classification performance indices are present. The indices are (1) True Positive (TP), (2) True Negative (TN), (3) False Positive (FP), and (4) False Negative (FN).

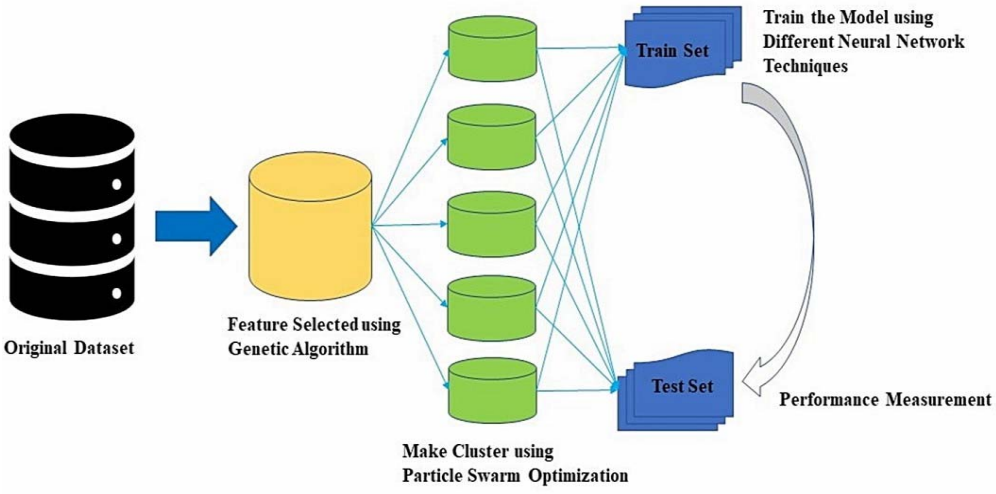

Figure 1. Full System for predicting software defect.

$$Accuracy = \frac{(TP+TN)}{(TP+TN+FN+FP)} \quad (1)$$

$$Sensitivity = \frac{TP}{(TP+FN)} \quad (2)$$

$$Specificity = \frac{TN}{(TN+FP)} \quad (3)$$

$$Precision = \frac{TP}{TP + FP} \quad (4)$$

$$Negative\ Predictive\ Value\ (NPV) = \frac{TN}{FN + TN} \quad (5)$$

$$F1\ Score = \frac{2TP}{(2TP+FP+FN)} \quad (6)$$

$$Matthews\ Correlation\ Coefficient\ (MCC) = \frac{(TP \times TN) - (FP \times FN)}{\sqrt{(TP+FP)(TP+FN)(TN+FP)(TN+FN)}} \quad (7)$$

IV. Result And Analysis

This section discusses the result and compares the performance with other existing methods.

A. Experimental Setup

All the experiment was implemented on Python 3.5.4. All the program was run on HP ProBook 450G laptop computer with configuration Intel® Core ™ i5-4200M, CPU @ 3.60 GHz, RAM 8 GB with Windows10.

B. Results Analysis

In this paper, first the features were selected using Genetic Algorithm (GA) from the given dataset. Then using Particle Swarm Optimization (PSO) made cluster. Finally train the model using different neural network techniques: Feedforward Neural Network (FNN), Recurrent Neural Network (RNN), Artificial Neural Network (ANN), and Deep Neural Network (DNN). We used five datasets namely: PC1, CM1, JM1, KC1, and KC2. All the datasets were partitioned into 10-fold cross-validation. The advantage of the cross-validation method was to observations for both training and testing, and each observation was used for the test set exactly once. The ratio of divide the dataset in all the cases was 75% for training and 25% for testing.

Using the confusion matrix accuracy, sensitivity, specificity, precision, negative predictive value, F1 score, and matthews correlation coefficient were measured. Results were shown in Table I, Table II, Table III, Table IV, and Table V for PC1, CM1, JM1, KC1, and KC2 dataset respectively. Best accuracy result found in Table I, Table II, Table III, Table IV, and Table V was 98.27%, 97.59%, 98.47%, 92.65%, and 91.54% respectively. All the cases deep neural network gave the best accuracy result. Other performance measurement parameters: sensitivity, specificity, precision, negative predictive value, F1 score, and matthews correlation coefficient were also shown in Table I, Table II, Table III, Table IV, and Table V. The result of matthews correlation coefficient was above 93% for JM1 dataset, which was very near to the best value of matthews correlation coefficient. Also, the F1 score was above 98% for PC1 and JM1 dataset, which was also near the best value 1.

C. Comparative Analysis

Table VI shows the comparative study to our model and other existing models. G. Abaei and A. Selamat [19] survey the software defect prediction using many techniques like decision tree, random forest, naïve bayes, neural network etc. methods. A. Chug and A. Dhall [20] using supervised and unsupervised algorithm to predict the defect software. They used simple k-means cluster, hierarchical cluster, and make density-based cluster to make clustered. M.M. R. Henein et al. [21] proposed a method namely cluster based under sampling. They used k-means algorithm to make cluster and artificial neural network to predict the model. A.A. Abdou and N.R. Darwish [22] use different machine learning techniques to predict the software defects.

V. CONCLUSIONS

Software defects prediction is an important task in the sector of software engineering. Early software defect prediction will help the developer to build the software in a short time. This paper proposed a new technique to predict defects in software. In the proposed method the features are selected using Genetic Algorithm and further using this data cluster are make using Particle Swarm Optimization. Finally used different neural network methods to predict the defects. To predict the defect, we use various dataset namely PC1, CM1, JM1, KC1, and KC2. From the experimental result, we see that deep neural network works better than the other methods. We get the accuracy of above 90% in all the dataset using deep neural network. Other three methods feedforward neural network, recurrent neural network, and artificial neural network also works well and give good accuracy. In the future, the same techniques will be applied to other sectors to solve different engineering problems.

***Abstract*— Cloud computing is a spirited topic in this epoch where IOT introducing the modern lifestyle. These embrace cost-effectiveness, time savings and actual arrangement of computing properties. Conversely, in Cloud Computing privacy and security is a big issue where there are many kinds of thread and attack are working rapidly. In the context, the best cryptographic method AES algorithm and AI-based method ANN have chosen to work for the enhancement of the security where cloud computing demands the highest priority. In this case, this paper is proposing the highly advanced two-step security layer for cloud computing. Primarily, AES provides for the first layer security of the first stratum. In the AES algorithm, the execution is dependent on the key size of the algorithm when the number of rounds to be accomplished. A MATLAB code is developed for plaintext encryption and ciphertext decryption. Experiments are conducted to measure execution times. ANN is a method of computation which is biologically stimulated. These only look like the parallel computation generated which are the basics of human learning by the biological neural network. Iris and Finger recognition is implemented using MATLAB through ANN. The paper demonstrated the great proficiency of the proposed system for the user purpose.**

Keywords— Cloud Computing Security, Artificial Neural Network, Advanced Encryption Standard, Iris Recognition, Fingerprint Recognition

I. INTRODUCTION

The world is more conscious about enriching the security issue. Cloud computing is the most burning topic to ensure the security of it. To do that many algorithms applied to the platform. Many of them are secured but not fast, many of them fast but not secured. So the research is continued till now on this security system. The proposed method of the paper is to increase both fast and secure algorithm.

In 1997, the National Institute of Standards and Technology decided to organize a competition to find out the successor of DES algorithm. Where the Rijndael algorithm (designed by Vincent Rijmen and Joan Daemen in 1977) had won the competition in April 2000 and would, later on, become the AES. The cryptographic community was assured the algorithm has been thoroughly tested and screened by the NIST to still be secure even 2030 [1].

AES (Advanced Encryption Standard) is the advanced, fast, latest and most secure system at the current time. The Fast Encryption system is too far to meet with the encryption time of conventional AES algorithm. Like as, most valuable research topic become the high-performance computing capability of graphics processing unit [2]. The security system used on the first layer of the proposed method is to encryption the traditional login system with a password. AES operates on a 4 × 4 column-major order matrix of bytes, designated by the state, although some versions of Rijndael have a larger block size and have extra columns in the state. Most AES calculations are done in a particular finite field.

The second layer is based on Iris recognition and Fingerprint based on biometric tools. Iris recognition is a preset method of biometric identification. It uses mathematical pattern-recognition techniques on images of one or both of the Irises of an entity's eyes. where, patterns are unique, stable, and can be understood from some distance. A biometric system is designed for automatic authentication over the special characteristic option of the human body. The most reliable and proficient Biometric system is Iris recognition. There are some parts; spherical Iris and pupil region, occluding eyelids and eyelashes and reflections of Iris are extremely automatic segmentation where the Hough transform and is capable to localize. [3]. So this will help the system to make more efficient to the best security system. In the method firstly the system will capture the Iris to register for the future login. In the second verification of login, there will the first option for verifying the identity.

On the other hand, if anyone is unable to do Iris scan, there is another option to verify is Biometric Fingerprint scanning. The Biometric authentication of the user provides some facility like as fast, precise, easy to use, trustworthy and economical where¬ this is conventional knowledge-based and token-based methods. [4]

II. RELATED WORKS

In this proposed work we introduce the security enhancement of user side access of cloud computing. There are well known and developed algorithms AES for the initial step to encrypt and decrypt password and another one is Artificial Neural Network (ANN) using for implementing the Fingerprint and Irish recognition.

In [5], proposed a method based on neural networks for detection and classification of underwater mines using sonar images is proposed. The paper shows the success of classification rate using neural networks.

Likewise, in [6] shows neural network system with supervised and unsupervised learning is used, so that the presentations among these are associated, shown same spectral data in input.

In Y. LeCun et al [7] they recognize handwrite using convolution neural network, which provides a good result. And another one is similarly P. Vincent [8], they proposed a method for show the advantage and stacked de-noising auto encoders model in handwriting recognition. Although there are a variety of deep structure models [9], they all gain very

good results in many fields, such as visual [10], natural language processing [11]and signal processing and so on. So we believe that the method based on depth neural network can also achieve good results for the fingerprint classification.

Bodade and Talbar [12] proposed a method for recognizing different kinds of iris images, spoofs and eyes on video. This paper shows 3 categories to spoof detection are the reflectance method, the pupil dynamics method and the frequency spectrum method. They achieve a mishmash of the methods is needed and shows some outcomes of iris images recognition.

Daugman approaches cosmetic contact lenses recognition [13]. This paper shows the working procedure for lenses where dot-matrix type technology is used for manufacturing. However, there are different types of approaches for manufacture the contact lenses and dot-matrix type lenses also can be failed as if they printed resolution of the iris sensor more than the camera resolution.

III. METHODOLOGY

Here, the paper will design to express the real-life strong method to secure cloud computing technology. This system will narrate in several sections includes encryption, the process of registration and verification with the provided database. This system is shown in some flowcharts and diagram.

A. Initial Encryption and Decryption:

The basic level of the providing of cloud computing security is designed with Advanced Encryption Security (AES). Which one is the existing conventional method for encryption and decryption work on the first layer of our proposed method? Password and Username will be stored in the database when the user will provide.

B. User Registration procedure:

The user will get in this process after completing the initial step. This layer is designed with 2 option where the biometric system Iris recognition and Fingerprint recognition will be worked for registration. The explanation and working procedure are briefly narrating with each step include Figure-1:

Step-1: The Encrypted password will be stored in the database. Successfully completing this, there will be 2 option to choose as a process of registration.

Option-1: The Neural Network algorithm will be applied to recognize the Iris. Here, our system will take some different position, a movement image of Iris. Which will be saved in the Database of the root user.

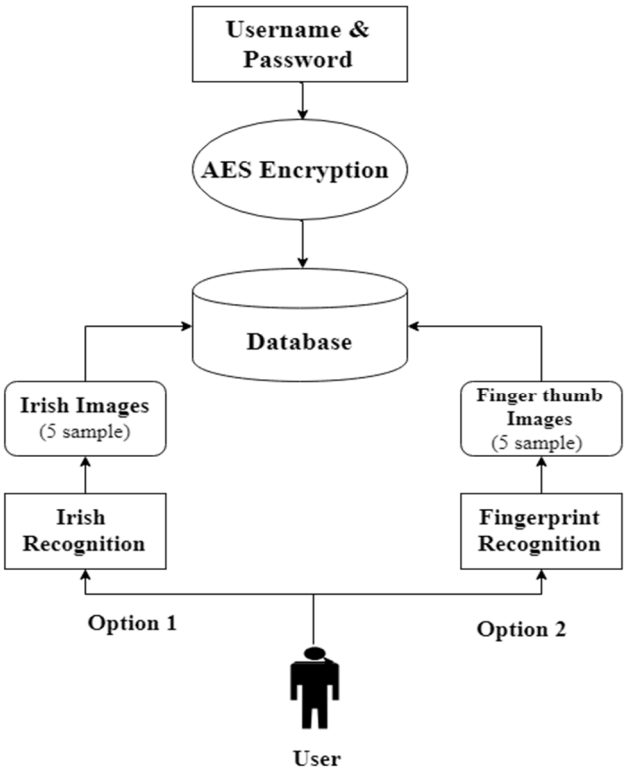

Figure-1: Registration Cycle

Option-2: The Neural Network algorithm will be applied for this option for the user registration. Where this process will take some sample of Finger to execute this method. This sample also saves in the database.

C. Data Matching:

Matching is the very crucial parts of the proposed model where the design requirements to verify with stored data from the database with the input data by comparing. This procedure will show in the figure and it will explain several steps.

Step-1: The username and password will be the first step of the Data-matching process where AES will be executed for encryption and decryption. The user will give his password and username which will be cross match through the Database. When the particular password verified with the database, the user gets access from the method and step-2 begins. But, if not verified with the database, then "Login Error" will be shown.

Step-2: When successfully complete the authentication, the user will able to get through the Biometric verification with one option out of two.

Option-1: This portion works on user Iris recognition where the user's Iris picture will be captured using the Digital camera. here, there are a number of pictures will be reserved. The Neural Network is applied as a pattern recognition with the database. If the Iris matched enough, then the user will get the confirmation to get access to "Login". On the other hand, if the algorithm gives a big number of false position rate on Iris. It will not verify which will indicate "Login Error".

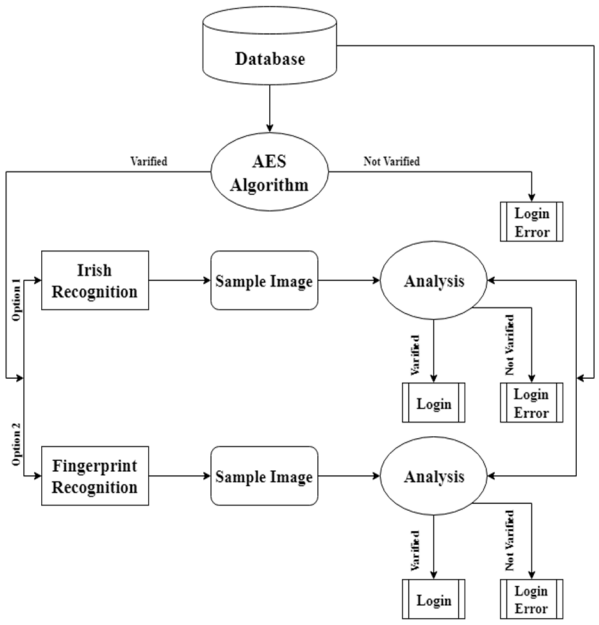

Figure-2: Data Matching process.

Option-2: This step is another Biometric step where the Neural Network algorithm will apply for the pattern recognition on the Fingerprint of the user. If the Iris matched enough, then the user will get the confirmation to get access to "Login". On the other hand, if the algorithm gives a big number of false position rate on Iris. It will not verify which will indicate "Login Error".

IV. Implementation

This part will represent the full proposed method where we designed a system where it will find out the user by using three cited the most secure option. These methods will be shown for AES, Neural Network for Iris recognition and Fingerprint recognition. Figure-1,2,3 defines how the implementation process is verified in the actual object.

A. Advance Security System (AES)

AES is a Symmetric Algorithm, which uses encryption and decryption a data or text by a similar key for both sender and receiver. This is the most proficient algorithm aimed at software application. [14]

AES algorithm is a Block cipher and works on a fixed-length set of bits. It proceeds an input block of 128 bits and yields a matching output block of the similar size. This system calls for a second input, which called a secret key. Moreover, AES has three different key sizes: 128, 192 and 256 bits. This time, Algorithm works on around function for 4 different byte-oriented layers through cipher and inverse cipher:

1) Byte substitution using a substitution table (Sbox)

2) Shifting rows of the State array by different offsets

3) Mixing the data within each column of the State array

4) Adding a Round Key to the State. AES algorithm uses this round function

for ten rounds, but the first and last round of the AES algorithm is differing from other rounds. That is depicted in figure 1 below. This template was designed for two affiliation

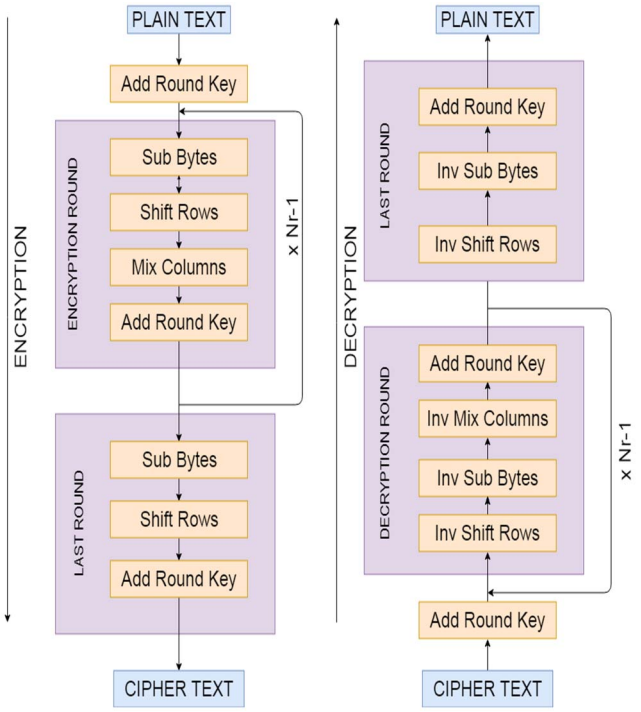

Figure-3: Advanced Encryption Standard (AES) working flowchart.

B. Neural Network

The artificial neural network works on neuron which is taken for input and changes it's some of the internal state names as Activation based on the input, besides create the output dependent on input and Activation. Basically, a directed weighted graph consists of the network which customs by linking that input of additional neurons to the neuron's output. The weights can be improved by a system known as learning that computes the activation and directed by a learning rule. [15]

ANN is capable of learning and it needs to be trained. This system runs on several strategies:

- Supervised Learning
- Unsupervised Learning
- Reinforcement Learning

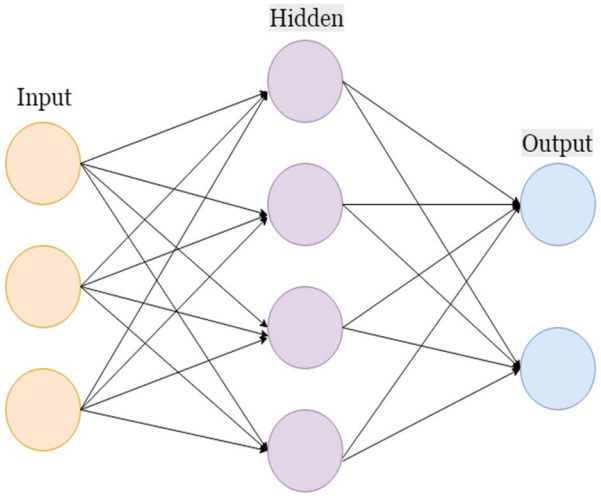

Figure-4: Working process of Artificial Neural Network.

Backpropagation: The backpropagation's weight updates operated by stochastic gradient descent over the equation:

$$\omega_{ij}(t+1) = \omega_{ij}(t) + \eta \frac{\partial C}{\partial \omega_{ij}} + \xi(t)$$

where,

η = the learning rate

C = the cost (loss) function

$\xi(t)$ = stochastic term.

The cost function dependent on influence and the activation. Influence is generated by supervised, reinforcement etc. Such as, if executing a function on a multi-class arrangement of the problem, cost function and common selection of activation are defining consistently, cross entropy function and softmax function. The softmax is shown as

$$\rho_j = \frac{\exp(x_j)}{\sum_j d_j \log(x_k)}$$

where ρ_j is the class probability (output of the unit j and signify the total input to units j and k of the same level correspondingly. [16]

C. Finger Recognition

The fingerprint is the most common and exclusive method in Biometric options which is transnationally known as a legal method to identify a person. The reproductions of the minute ridge which called as Dermal of the Finger. Ridges and Valleys are distinctive and unchangeable. [17] Finger ridge ending as a ridge point is established ends sharply. Ridge splits are mention as ridge point which is connected with the branch ridges. The minutiae location, attributes and time like a direction can be shown in a Fingerprint. There are 40 to 100 minutiae in a standard quality fingerprint sample, on the other hand, dozens of minutiae cannot identify the pattern of the fingerprint. [18]

Implementation of the Fingerprint verification system is broken down into four distinct stages as follows:

- Image acquisition.
- Edge detection.
- Comparison of images.
- Decision making.

D. Iris Recognition

Iris biometric technology was established by John Daugman [19]. Iris biometric is a texture of the Iris can be used as an underlying idea where the code is generated based on the image condition. Iris authentication becomes a progressively spirited research topic in the new era [20]. The exhausting of different types of contact lenses present defies for Iris biometric systems [21]. "Cosmetic contact lenses" used for the change Iris behavior of others in any way. Challenges to identify the image of eye uncovered with cosmetic contact lenses with the image of the similar eye covered with cosmetic contact lens outcome in an extremely wrong nonmatch rate [21]. That similarly imaginable, an attacker trying to imitate a specific user possibly will have cosmetic contact lenses completed to achieve the victim person's Iris grain. This is called "spoofing" of the Iris biometric system. The cornea is the outermost (anterior) layer of the eye. It is normally clear; this system provides some portions of the Iris sample. The aqueous humor is following layer of the cornea. normally clear; this system affords some percentages of the Iris sample. The following layer is Iris (and pupil). Where the quality of the Iris is imaged over the cornea and aqueous humor. [22]

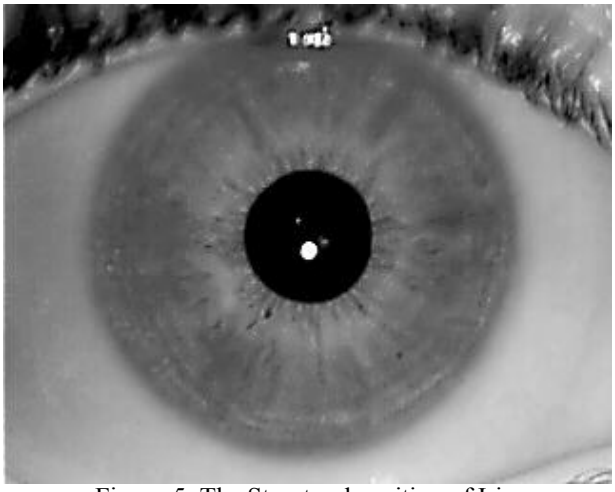

Figure-5: The Structural position of Iris.

Implementation of the Fingerprint verification system is broken down into four distinct stages as follows:

- Image acquisition.
- Edge detection.
- Comparison of images.
- Decision making.

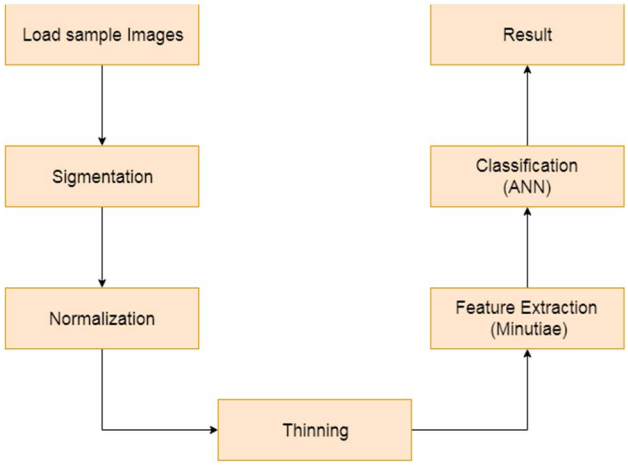

Figure-6: The Working procedure of Finger and Iris Recognition by using ANN.

In MATLAB the iteration is conducted by our own created tow dataset of separately Fingerprints and Irises. Here, we established the iteration is conducted by the sample image matrix binary values. Figure-7 depicts the whole procedure of Fingerprint and Iris recognition mechanism using Artificial Neural Network with some stepwise operations.

The Experimental dataset for the experiment is created our won using camera and fingerprint scanner. Our working station configuration is 7th gen core i3-7020u processor (3m cache,2.30 GHz); 4GB DDR4 RAM, 1TB HDD with

windows 10 setup. In the dataset, our data samples are in .png format images. We collected different peoples' data use for make the data set.

Following steps (1-4) establish how MATLAB works to recognize the user's iris and finger samples from the database. For the successful experiment, we have developed two personal datasets to effectively iris and fingerprint in MATLAB. These steps are provided for fingerprint recognitions where will be similar steps for iris recognition too.

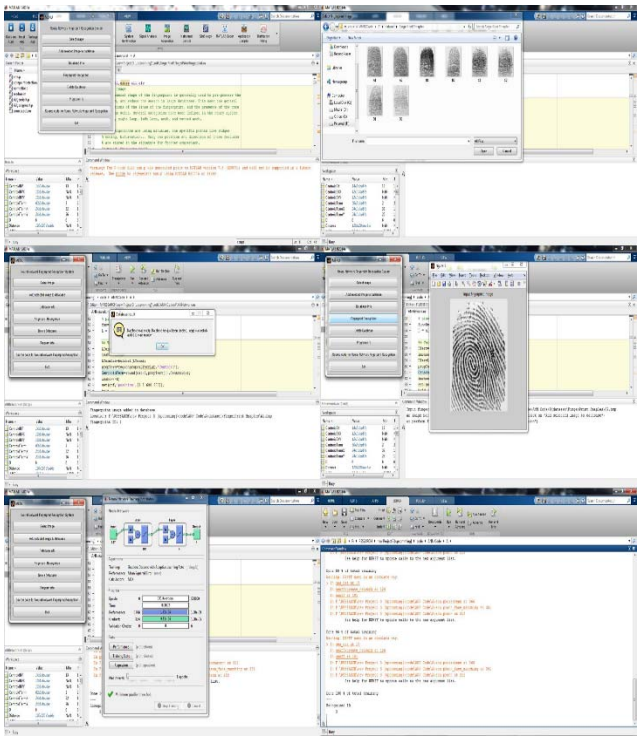

Figure-7: ANN implementation in MATLAB.

Step-1: Executing and administration the codes of ANN to add some samples for the experiment.

Step-2: All samples are in Bitmap (. bmp) image format for our farther steps. Extract and upload system of samples are followed by the database. Here, we provide four different samples for the dataset according to A1, A2; B1, B2; C1, C2; D1, D2.

Samples Name	Dataset Name
A1	1
B2	2
C1	3
D1	4
A2	5

Step-3: Comparing two samples, namely sample 1.bmp with sample 5.bmp, Then the result confirmations that mentioned samples are matched with Sample 1. So the resolution designates the matching of experiment samples.

Step-4: Whenever the samples didn't match, results show the unsuccessful matching results.

V. Experimental Results

In the starting, the proposed method is to implement the AES algorithm. AES has just two operations, encryption, and decryption of the password of each user. After that, the Neural Network toolbox in MATLAB is implemented, where Artificial Neural Network is created for Iris Recognition and biometric Fingerprint. A customized dataset with randomized value is used in case of an experiment and got a great output at the end of the experiment. The experiment is based on time and efficiency issue.

TABLE-1: 1st Layer Encryption, Decryption Analysis

	Iteration	Encryption Cycle (ms)	Decryption Cycle (ms)	Size (KB)
AES Algorithm (256bit)	01	160	110	363
	02	170	140	613
	03	220	180	944

Here, TABLE-1 is representing the result of encryption and decryption cycle of an AES 256 algorithm. Algorithms run for three iterations. For the encryption of AES algorithm gradually takes 160ms, 170ms and finally 220ms for according to 163kb, 313kb and 944kb where, decryption cycle gradually takes time 100ms, 140ms, and 180ms. Where this system provides feedback as a very speedy method.

TABLE-2: 2nd Layer Comparison Analysis

Steps	Iris Recognition (ms)	Finger Recognition (ms)	Size (KB)
Artificial Neural Network Encryption	1134	1465	2654
Artificial Neural Network Decryption	334	255	2654

In the 2nd layer, table-2 is representing the encryption and decryption cycle of the proposed method. Using AI, encryption takes 1134ms for 2654kb for Iris and 1465ms for fingerprint method. On the other hand, the decryption cycle takes 334ms for Iris and 255ms for Fingerprint matching.

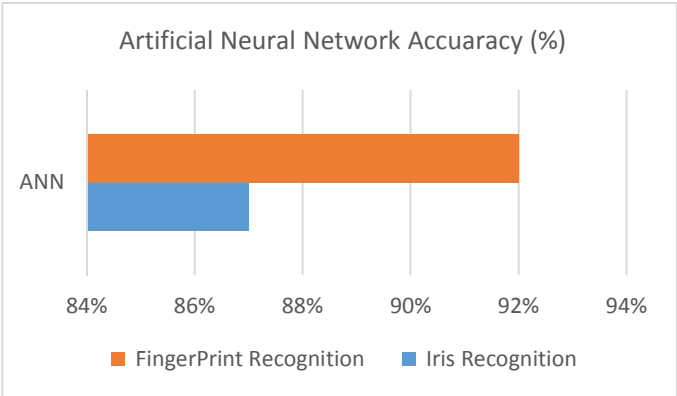

Figure-8: Accuracy Performance of ANN

Here, in the figure-8 shows the accuracy of the recognition is great. Thus the accuracy is showing that 87% accurate for Iris Recognition and for 92% for Fingerprint in biometric technology.

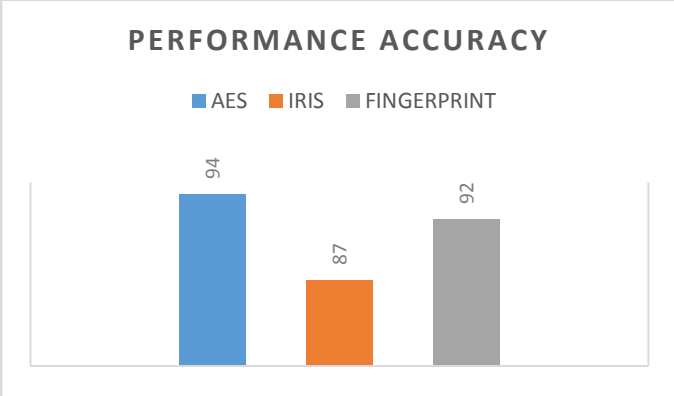

Figure-9: Accuracy Comparison Graph

According to Figure-9; Finally, the performance graph is showing the difference in the final result of the accuracy percentage of the result with the previous method comparison. And the graph surely shows that the proposed method is better working and reliable.

VI. Conclusions

In this paper, the importance of Cloud Computing security has been revealed strongly. Through the proposal method, the first layer AES algorithm provides high performance and accuracy. In the other hand, the second layer; Iris recognition or Fingerprint recognition through Artificial Neural Network will be responsible for the best accuracy of secure access for the user. This proposed procedure can accomplish the secure access of the most uses cloud computing interface for the client users..

Acknowledgment

In this Paper, we would like to acknowledge Mr. Md. Taslim Arefin, Head and Associate professor, Department of ETE, Faculty of Engineering, his project guide for his immense DIU Computer Lab support, genuine concern and invaluable advice that helped me to work on this topic.

I take this opportunity to thank my friends and colleagues for their technical help and moral support.

***Abstract*—Non Functional Requirements (NFR) describe a set of quality attributes required for a software such as security, reliability, performance, etc. Extracting and considering NFR from software requirement specification can help developers to deliver quality software which meets users expectations completely. Since, the functional and non-functional requirements are mixed together within the same SRS, it requires a lot of human effort for distinguishing them. This paper proposed automatic NFR classification approach for quality software development by combining machine learning feature extraction and classification techniques. An empirical study with seven machine learning algorithms and four feature selection approaches have been applied to automatically classify NFRs for finding out the best pair. The experiments were measured with statistical analysis including precision, recall, F1-score, and accuracy of the classification results through all the combinations of the techniques and algorithms. It is found that, SGD SVM classifier achieves best result where precision, recall, F1-score, and accuracy reported as 0.66, 0.61, 0.61, and 0.76 respectively. Additionally, TF-IDF (character level) feature extraction technique illustrated higher average score than others.**

***Index Terms*—Non Functional Requirements, Feature Extraction, Classification, Machine Learning, Text Analysis.**

I. Introduction

Software requirements specification is the most important artifacts producing step during the software development life cycle, which is composed of functional and non-functional requirements (NFR). Functional requirements specify software behavior directly listed by stakeholders, where, NFR describe how the software system will provide the means to perform functional tasks. However, the functional and NFRs are mixed together within the same paragraphs, and it becomes hard to detect manually. It is reported that neglecting NFRs leads to project failure or increase production cost [1].

Hence to develop quality software as well as reduce development cost, early NFRs detection is essential because it enables system level constraints to be considered and incorporated into early architectural designs. However, classifying requirements manually is not feasible in terms of required time, budget, and accuracy. To overcome these limitations, various approaches has been presented such as information retrieval based [1], linguistic knowledge based [2], CNN based [3], etc to classify software NFRs into different categories. In 2006, cleland et. al introduced NFRs classifying approach using information retrieval technique [1]. Where, hussain et. al presented a approach to classify text requirements as functional and non-functional using linguistic knowledge [2]. Using convolutional neural network, a method was proposed to classify text based non functional requirements [3]. In 2017, Matsumato et. al proposed a verification method to detect ambiguity, inconsistency, incompleteness, and redundancy of NFRs in software requirement specification [4]. On the other hand, Lu et. al proposed automatic requirements classification approach to classify app user reviews into functional, non-functional and others categories [5].

Although several machine learning methods are existed for automatic NFRs classification task, there is no extensive comparison among machine learning feature extraction, and classification techniques. Where, feature selection is an important task in machine learning to increase classification performance [10]. However, investigation of NFR classification accuracy combining different feature extraction techniques such as Bag of Words (BoW), Term Frequency-Inverse Document Frequency (TF-IDF), etc. with various classification algorithms named as Multinomial Naive Bayes (MNB), Gaussian Naive Bayes (GNB), Bernoulli Naive Bayes (BNB), K-Nearest Neighbors (KNN), Support Vector Machines (SVM), Stochastic Gradient Descent SVM (SGD SVM), and Decision Trees (Dtree) is a significant research direction.

Therefore, this paper proposed an empirical approach to automatic NFR classification technique combining four feature extraction methods with seven machine learning algorithms. The requirements dataset has been pre-processed to remove unnecessary characters which will be converted to feature vector using BoW, TF-IDF (character level), TF-IDF (word level), and TF-IDF (n-gram) techniques. Next, the MNB, GNB, BNB, KNN, SVM, SGD SVM, and DTree algorithms were applied for each type of feature vectors to train the classifier. Finally, based on different NFR classifying results the classification performance of each method has been evaluated. The PROMISE [6] software requirement dataset was used to investigate classification accuracy of considered techniques with several statistical analysis.

The investigated average results reported precision, recall,

and F1-score is higher for TF-IDF (character level). Where, SGD SVM showed best classification result compared to other algorithms. And reports average precision, recall, F1-score, and accuracy as 0.66, 0.61, 0.612, and 0.75 respectively. However, the Dtree achieves worst NFR classification performance for all cases, which reports 0.175, 0.17, 0.14, and 0.51 as precision, recall, F1-score, and accuracy respectively.

The rest of this paper is organized as follows; Section II discussed the existing work related to this thesis. Section III and IV illustrated the proposed method and result analysis respectively. Finally section V concludes this paper with future research direction.

II. Related Works

Software requirements are classified into functional and non-functional based on textual requirements analysis. Various requirements classification research has been investigated in the literature such as information retrieval based [1], linguistic knowledge based [2], multinomial naive bayes based [7], etc.. The approaches have been discussed in this section.

Cleland et. al introduced an approach for detecting and classifying non functional requirements using information retrieval technique in 2006 [1]. First, a set of indicator terms is identified for each NFR category, then additional requirements are classified. Indicator terms which is used to detect requirements were used as the basis of identification of different NFRs. A probabilistic weight for each potential indicator term is calculated from the requirements. This strategy requires less effort for NFR classification compared to semi-automated classification methods. However, this technique suffers for evaluating correctness of candidate NFRs manually.

In 2008, hussain et. al proposed a classification approach to classify text requirements into two categories named as functional and non-functional using linguistic knowledge [2]. The classifier works at sentence level as the characteristics of FR and NFR remain within the scope of sentences. The reported results were cross checked ten times over same data. The investigated results showed that the method improved classification performance significantly. However, more training and testing data could be introduced to improve classification performance.

Ju et. al proposed a method to classify non-functional requirements using convolutional neural network [3].The technique converts text data in low-dimensional vector space using Word2vec to vectorize requirement words in dataset. The average score of precision, recall, and f-measure has been used to evaluate proposed deep learning model. The reported results showed that CNN performs well for text based NFR classification task automatically. However, recurrent neural network could be incorporated to improved classification accuracy.

Matsumato et. al proposed a verification method using requirements frame model to detect ambiguity, inconsistency, incompleteness, and redundancy of NFRs in software requirement specification [4]. The investigation were focused on time-response and usability related requirements. In this experiment, the specific requirements were retrieved using respective keywords. Also multiline statements were converted to single sentence manually. However, such manual conversion is time consuming and error-prone.

Lu et. al proposed automatic requirements classification approach to classify app user reviews [5]. This approach combined BoW, TF-IDF, CHI^2 and AUR-BoW classification techniques with NB, J48, and Bagging algorithms to automatically classify user reviews. The classification technique was focused to four types of NFRs named as reliability, usability, portability, and performance. This research reported that in an automatic classification using unbalanced dataset performed worse when the size of certain types is obviously smaller. However, no solution has been provided for the mentioned unbalanced dataset problem.

Slankas et. al proposed a method called NFR locator and developed a tool to extract relevant NFRs from a wide variety of documents [7]. In this research, a word vector representation was used followed by the use of a multinomial naive bayes and k-nearest neighbor classifiers. After parsing document into an internal representation, classified sentences into specific NFR categories. The k-nearest neighbor classifier with a unique distance metric had outperformed in their experiments the optimal naive Bayes classifier.

Khan et. al investigated different existing methodologies for software requirement classification [8]. This research identifies co-relations between software architecture and NFRs in order to check their applicability in software development life cycle. The presented comparison results revealed that software architecture is important to address NFRs.

Kurtanovi et. al proposed a strategy to handle the imbalanced classes in the dataset and the classifiers were cross-validated using precision, recall, and F1 metrics [9]. The approach was automatically identified NFRs using supervised requirements. Where, four NFRs named as usability, security, operational, and performance were focused. After removing stop words and punctuations, BoW, bigrams, and trigrams techniques were applied for feature selection. The paper stated that part of speech tags are the most informative features. Experiments were conducted using SVM classifier algorithm.

The analysis of existing text classification approaches concluded that different strategies have been proposed for non-functional requirement analysis such as information retrieval based, linguistic knowledge based, CNN based, etc. However, no guideline has been found yet to select the best pair of feature extraction and machine learning for NFR classification by performance investigation of different feature extraction techniques and machine learning algorithms.

III. METHODOLOGY

This paper proposed technique for finding the best pair of feature extraction and machine learning approach on software requirement classification. This process considers NB, KNN, SVM, and D-tree machine learning algorithms and BoW and TF-IDF feature extraction technique for comparison. The software requirement classification performance of each algorithm is measured using different featured extraction methods named

as BoW, TF-IDF (character level), TF-IDF (word level), and N-gram. In this framework, text data has been pre-processed to remove unwanted texts, which then encoded with text encoding techniques. The encoded data has been trained and tested by NB, KNN, SVM, and Dtree algorithms. The whole process of this framework is divided into following four steps and depicted in Figure 1.

- Step 1: Data Preprocessing
- Step 2: Feature Extraction
- Step 3: Train Classifier
- Step 4: Classifying requirements

The details regarding the steps is elaborated in following sections and sub-sections.

A. Step 1: Data Pre-processing

The first step of this method is to cleaning and pre-processing dataset, which is composed of four sub-steps: (i) removing special characters, (ii) case-folding, (iii) removing stop words, and (iv) tokenization. Special characters and symbols are usually non-alphanumeric characters, which add extra noise to the experimental dataset. So, special characters has been removed using regular expression in order to remove noisy data. In English, words appear in upper-case or lower-case having similar meaning, hence, case-folding is applied for unique case consideration. On the other hand, Stop words usually refer to the most common words such as "a", "an", "the", which do not influence the semantics of a software requirement. The most uses natural language processing stop words corpus of nltk has been used in this framework. Finally, tokenization splits longer text into smaller piece or tokens. The requirements has been tokenized into sentences which then splitted into distinct words.

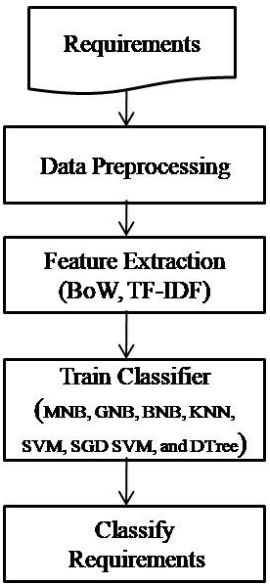

Fig. 1. Proposed Method Overview

B. Step 2: Feature Extraction

Textual feature extraction is a process of transforming list of essential words into a feature set that is usable by machine learning classifier. Textual dataset consists of documents which represents words, sentences or paragraphs of free flowing text and those are inherently unstructured i.e. no neatly formatted data columns. Therefore, extracting significant and meaningful features from text data is essential to building text classification machine learning model. In this step, textual data has been converted from free flowing text into some numeric representations to be understood by machine learning algorithms.

In this framework, a set of feature has been extracted from text data to automatically classify software requirements using machine learning algorithms. Initially this research went through the standards steps for text preprocessing. The feature extraction process from the preprocessed text are described in the following sections.

- **Bag of Words based feature:** Bag of Words (BoW) vector space representation model has been used as a first set of features for training machine learning algorithms. This vector space model represents unstructured text as numeric vectors, where it constructs a word presence feature set from all the words of an instance [5]. In this paper, requirements have been converted into numeric vectors such that each document is represented by one vector (row). As example, the following BoW model based document feature vectors was generated for the sentences of 'System shall be used by realtors', and 'System shall display Events'. The unique words in the corpus are 'The system shall be used by realtors display Events', therefore the vocabulary size will be of 9 words from total 12 words. The vector representation of this corpus is shown in table I.

TABLE I
BOW EXAMPLE

system	shall	be	used	by	realtors	display	Events
1	1	1	1	1	1	0	0
1	1	0	0	0	0	1	1

From the above table, it is clear that each column or dimension in the feature vectors represents a word from the corpus and each row represents one of corpus documents. The value in any cell, represents the number of times that word occurs in the specific documents which is represented by row. Therefore, if a corpus of documents consists of N unique words across all documents, it will have an N-dimensional vector for each of the documents.

- **Term frequency based features:** additionally to the BoW features, tf-idf scores associated with each term present in a given requirement has been used in this classification framework. The tf-idf term weighting technique assigns a higher score to rare words and a lower one to words occuring frequently across all requirements [5]. The tf-idf score calculation process is defined as following Equation (1):

$$tf - idf_{t,d} = tf_{t,d} \times idf_t = tf_{t,d} \times log(\frac{N}{df_t}) \quad (1)$$

where $tf_{t,d}$ is the frequency of word t in requirement document d while, idf_t is the inverse document frequency of terms occurring in various reviews. The three techniques of $tf - idf$ named as character level, word level and n-gram have been used in this paper.

After cleaning the requirements strings, above techniques were applied to extract textual features to train the classifiers.

C. Step 3: Train Classifier

Four classification techniques BoW, TF-IDF (character level), TF-IDF (word level), and TF-IDF (n-gram) has been used in above step to extract textual features, which act as the input of machine learning algorithms of training classifiers. The experimentation has been conducted using seven machine learning algorithms MNB, GNB, BNB, KNN, SVM, SGD SVM, and DTree. The multiple algorithms were applied for requirement classification to compare the performance.

D. Step 4: Classifying requirements

Each of the classifier trained in previous section will output for a given requirement whether is belongs to a category or not. For example, in order to classify requirement according to category PE (performance), the framework will return the list of requirements for which it received a positive answer. Also, the other documents will be classified accordingly.

The combination of four textual feature extraction method and seven machine learning algorithm has been applied in this software requirement classification framework. The textual data has been converted into vector representations to fed as input in machine learning algorithms.

IV. Evaluation

The experimental study, used requirement corpus and evaluated results are demonstrated in this section. Precision, recall, and F1-score have been measured to evaluate how well the model learn to classify software requirement. The labeled data was used for training and unlabeled text strings were used for testing. The experimental results of classification of NFR dataset for different machine learning algorithms are shown in Table II and Table III.

A. Environment Setup

The experimentation has been carried out on intel core i7, 32GB RAM and Ubuntu 16.06. Pandas, numpy, nltk, sklearn and matplotlib packages were used for loading the data preprocessing, and result evaluation.

TABLE III
Precision, Recall and F1-Score Comparison

Methods	Average Score			
	Precision	Recall	F1-Score	Accuracy
MNB	0.22	0.19	0.17	0.53
GNB	0.55	0.54	0.52	0.66
BNB	0.19	0.18	0.16	0.52
KNN	0.62	0.48	0.50	0.69
SVM	0.59	0.46	0.50	0.70
SGD SVM	0.66	0.61	0.61	0.76
Dtree	0.18	0.17	0.15	0.51

B. Datasets

The most popular PROMISE software requirement dataset has been used for experimental analysis [6]. It is a widely used dataset for software requirement classification research. It contains a set of labeled requirements in functional and nonfunctional (11 categories) requirements. The dataset is small in size which consists of 625 requirement sentences. In these sentences 255 are functional and 370 are non-functional requirements (NFRs). The NFR is labeled with eleven categories named as availability, legal, look and feel, maintainability, operational, performance, scalability, security, usability, fault tolerance, and portability. However, the dataset contains majority number of functional requirements which indicates class distribution is imbalanced.

C. Result Analysis

The prepared dataset is trained and tested to evaluate classifying accuracy of proposed model. The experimental results of non functional requirement classification using several feature extraction and machine learning algorithms have shown in Table II. Where, Table III demonstrated the average score of proposed seven machine learning algorithms.

Table II provides an overview of the experiment results obtained through the feature extraction techniques BoW, TF-IDF (character and word level, n-gram) combined with seven machine learning algorithms MNB, GNB, BNB, KNN, SVM, SGD SVM, and DTree, which show the weighted average precision, recall, and F1-score of the classification results.

From Table II performance comparison of different feature extraction methods with respect to different machine learning algorithms is displayed. It is observed that overall performance of TF-IDF (character level) feature extraction is better than other mentioned methods. However, for some cases BoW out performed than other two TF-IDF (word level and n-gram) feature extraction methods. The highest precision, recall, and F1-score is reported by SGD SVM technique for all feature extraction methods. However, SGD SVM best performs with TF-IDF (character level) which showed 0.70, 0.62, and 0.63 for precision, recall, and F1-score respectively. On the other hand, BNB with TF-IDF (N-gram) and MNB with TF-IDF (character level) performs worst, however, in Table III Dtree showed average lowest score as 0.18, 0.17, 0.15, and 0.51 for precision, recall, F1-score, and accuracy respectively.

In case of feature extraction techniques, this experiment showed almost same average score for BoW and TF-IDF (character level) which is shown in Table II. The average score of TF-IDF (character level) method shown as 0.45, 0.40 and 0.40 for precision, recall and F1-score respectively which is higher than TF-IDF (word level, and n-gram) feature extraction methods.

In Table III, the weighted average score has been reported, where, SGD SVM method showed highest score again for all cases. The SGD SVM achieves precision, recall, F1-score, and accuracy as 0.66, 0.61, 0.61, and 0.76 respectively. On the other hand, decision tree technique performs worst among

TABLE II
PRECISION, RECALL AND F1-SCORE COMPARISON

Encoding/ Algorithm	BoW			TF-IDF (Word level)			TF-IDF (n-gram)			TF-IDF (Character level)		
	Precision	Recall	F1-Score	Precision	Recall	F1-Score	Precision	Recall	F1-Score	Precision	Recall	F1-Score
MNB	0.47	0.43	0.40	0.13	0.13	0.11	0.22	0.12	0.1	0.04	0.09	0.06
GNB	0.58	0.54	0.55	0.59	0.51	0.53	0.54	0.68	0.57	0.5	0.41	0.43
BNB	0.15	0.13	0.12	0.15	0.13	0.12	0.04	0.09	0.06	0.4	0.35	0.35
KNN	0.49	0.29	0.28	0.64	0.55	0.58	0.68	0.48	0.52	0.65	0.58	0.59
SVM	0.65	0.58	0.60	0.63	0.53	0.56	0.41	0.22	0.25	0.66	0.52	0.57
SGD SVM	0.60	0.61	0.58	0.64	0.62	0.62	0.71	0.6	0.62	0.70	0.62	0.63
Dtree	0.23	0.20	0.18	0.23	0.21	0.19	0.13	0.1	0.07	0.11	0.18	0.14
Average	0.45	0.40	0.39	0.43	0.38	0.39	0.39	0.33	0.31	0.45	0.40	0.40

the seven algorithms, this method reports precision, recall, F1-score, and accuracy as 0.18, 0.17, 0.15, and 0.51 respectively. The KNN and SVM has shown moderate performance where, precision, recall, F1-score, and accuracy of KNN are 0.62, 0.48, 0.50, and 0.69 respectively. On the other hand, SVM reports 0.59, 0.46, and 0.50, 0.70 as precision, recall, F1-score, and accuracy respectively.

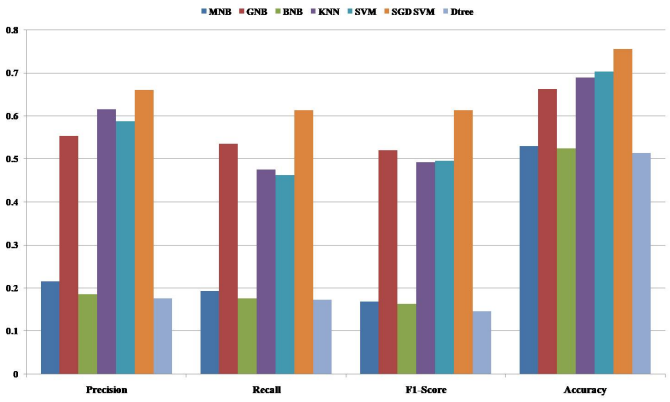

Fig. 2. Average Score Comparison

In Fig 2 the average results have been plotted, where SGD SVM method dominating other algorithms. However, BNB, MNB, and Dtree scored almost similar for textual NFRs classification. All the empirical results concluded that the pair of SGD SVM and TF-IDF (character level) performs best over other machine learning and feature detection pairs for non functional requirements classification. Functional requirement classification is beyond the scope of this research.

V. CONCLUSION

This NFR identifying framework focused on the investigation of various feature extraction and classification techniques classification performance. As feature extractor, BoW, and variation of TF-IDF techniques have been used. After getting, featured vectors from textual data, seven classifier algorithms named as MNB, GNB, BNB, KNN, SVM, SGD SVM, and DTree have been applied to classify requirements into different categories. For experimentation, standard PROMISE NFRs dataset have been used, where, all requirements are categorize into several categories. Among the requirement classifying algorithms, SGD SVM performed better than other algorithms, which reported average precision, recall, F1-score, and accuracy as 0.66, 0.61, 0.612, and 0.75 respectively. Where, decision tree performed worst which reports precision, recall, F1-score, and accuracy as 0.18, 0.17, 0.14, and 0.51 respectively. However, GNB and KNN achieved moderate score which is higher than DTree and lower than SGD SVM methods. On the other hand, TF-IDF (character level) feature extraction technique illustrated higher average score than others. This empirical research recommended TF-IDF (character level) for feature extraction with SGD SVM algorithm to predict best result in NFR classification.

Incorporating other significant machine learning feature extraction techniques such as Chi Squared, and classification algorithms such as bagging, boosting are the future research direction of this paper.

***Abstract* – The paper has presented about the experiment of design and development of automatic question answering system for Bangla language. The purpose of proposed answering system is to provide answer based on the keyword, lexical and semantic feature of a question. User gives a question for which answer has to be found from multiple documents. For measurement (time and quantity) related question the system gives specific answer otherwise the system retrieves relevant answers.**

Keywords – Question answering; keyword extraction; stemming; information retrieval; sentence ranking.

I. INTRODUCTION

In Question Answering (QA) system a user finds relevant answer of a question from unstructured document collection. QA is similar with Information Retrieval (IR) as minimum amount of information is retrieved which is enough to fulfill user demands [1].

Nowadays we need a system which will receive a question in natural language from user and find answers form given documents and provide relevant answers quickly to user. This study designed a QA system in NLP for Bangla language that allows a user to give question and provides relevant answers from a single or multiple documents. The originality of this paper is that the proposed system identifies the question type and for measurement (time and quantity) related question it provides relevant specific answer otherwise it retrieves relevant answers.

In this paper Section-II discusses the problems of QA system in Bangla language, section-III is about the implementation of the proposed system, section-IV analyses the evaluation of the system, section-V is the conclusion and finally references are given in section-VI.

II. PROBLEMS OF QUESTION ANSWERING SYSTEM IN BANGLA LANGUAGE

Question answering system in Bangla language faces many problems. Problems of it are following:

1) Automatic QA from unstructured documents is a difficult task as there is a probability that the source text may contain only one answer to any user's question [2].

2) Mapping questions to answers between question strings to answer strings using lexical, syntactic or semantic relationship is another difficult task [2].

3) The greater the answer redundancy in the text document, the more possibility to retrieve an answer in a simple relation to the user's question. Otherwise, we will need to solve the above issues facing NLP systems [2].

4) In Bangla language there is another challenge to identify the keyword or headword from the question as there is no specific rules in which place the *'wh'* word of the question will be appeared.

III. IMPLEMENTATION

The proposed system can be designed by merging the contents of all the documents, removing stop words, stemming of question and text documents, keyword extraction from question, N-grams formation from keywords for approximate matching, retrieving n-best answers and generating specific answers by question type and evaluation of performance and correctness. Details of the steps are following:

A. Removing Stop Words

In the proposed system necessary intelligence about conjunctions, pronouns, verbs and also inexhaustible words have to be provided for removing these stop words from the question as well as from the text documents.

B. Stemming

Intelligence about suffixes is also needed for stemming the words of the given question as well as the text document. Both the training sets of question as well as the documents have to be stemmed to find out the morphological stem of the words for approximate matching and retrieving information from source documents.

C. Keyword Extraction and N-grams formation from Keywords for Approximate Matching:

Keywords or headwords from the question have to be generated. In the proposed system one of the statistical approaches that is the word intermediate distance vector and its mean value was used to extract keyword from sentence [3].

N-grams have to be formed for effective approximate matching. Keywords generated from questions will be used to form n-grams (unigram/bigram/trigram), thus allowing the n-grams to be compared with other sequences for retrieving relevant information from the source text.

Table 1: Keyword Extraction Process. Here the keywords/Headwords are the root of the words.

Question	Keywords
বাংলাদেশে প্রথম কম্পিউটার কবে আসে?	Array ([0] => প্থম [1] => কম্পিউটা [2] => আস)
অ্যাবাকাস কবে আবিষ্কৃত হয়?	Array ([0] => অ্যাবাকাস [1] => আবিষ্কৃত)
জন নেপিয়ার (John Napier) এর অস্থি কি?	Array ([0] => নেপিয়া [1] => (John [2] => Napier) [3] => এ [4] => অস্থি [5] =>)
গটফ্রাইড ভন লিবনিজ কিভাবে যান্ত্রিক ক্যালকুলেটর আবিষ্কার করেন?	Array ([0] => গটফইড [1] => যান্ত্রিক [2] => ক্যালকুলেট [3] => আবিষ্কা [4] => কেন)
রিকোনিং যন্ত্র কি?	Array ([0] => যন্ত্র)
ডিফারেন্স ইন্জিন কি?	Array ([0] => ইন্জিন)

In Table 1, all the questions are set from a document related with computer collected from Wikipedia (Bangla). Here it's shown that keywords are extracted from the question. Here the keywords are stemmed to find out the morphological root of the word.

D. Lexical and Semantic Features:

In Bangla question ***"****wh-word" is* a vital lexical feature. An important role is played by the end marker. If the end marker is "|" then the given question is definition type [4].

In the proposed system, measurement unit is used as semantic feature. According to interrogative (*wh-type*) type and semantic feature answer will be retrieved.

Here, if the question type is time related কবে (kəbɛ)/ কখন (kəkhən) and quantity related কত (kət) then proposed system will give specific answer.

A document related with "Cox's Bazar" which is one of the tourist spot of Bangladesh and another document related with "Computer" have been collected from wikipedia(Bangla) and several questions given below have been set from these documents.

- **Question 1:** "কক্সবাজার থানা প্রথম কবে প্রতিষ্ঠিত হয়? (When Cox's Bazar Thana has been first established?)"
  Answer 1: "১৮৫৪ সাল" ("1854 year")
  Answer 2: "সাল এবং পৌসভা" ("Year and Municipality")
- **Question 2:** "কম্পিউটারে প্রথম বাংলা লেখা সম্ভব হয় কখন? (When Bangla writing was possible in Computer first?)"
  Answer 1: "১৯৮৭ সাল" ("1987 Year")
- **Question 3:** "বাংলাদেশে প্রথম কম্পিউটার আসে কত সালে ? (When Computer has first come in Bangladesh?)"
  Answer 1: "১৯৬৪ সাল" ("1964 Year")
  Answer 2: "১৯৭১ সাল" ("1971 Year")
  Answer 3: "১৯৮১ সাল" ("1981 Year")

In the first question the first answer is correct; the second answer here matches with the keywords of the question. In question 2, here only one answer is retrieved which is correct and in question 3 first answer is correct and other answers matches with the keywords of the question. In these answers every word is the root of the words itself.

E. Ranking the retrieved sentences

Retrieved sentences will be ranked by Textual Entailment Module (TE) [5] and best ranked retrieved information will be considered as answer.

IV. EVALUATION

Evaluation of the proposed system can be carried out by using the following formulas.

$$\text{Precision} = \frac{\text{Relevant Items Retreived}}{\text{Retreived Items}} \dots\dots \text{eq}^{(1)}$$

$$\text{Recall} = \frac{\text{Relevant Items Reteived}}{\text{Relevant Items}} \dots\dots\dots \text{eq}^{(2)}$$

$$\text{F Score} = 2 * \frac{(\text{Precision} * \text{Recall})}{\text{Precision} + \text{Recall}} \dots\dots\dots \text{eq}^{(3)}$$

For evaluation purpose several documents have been selected from Wikipedia. Approximate 500 questions have been set to test the performance and correctness. At first for every single question relevant items have been retrieved, retrieved items and total no of relevant answer for the question given by user have been identified. Thus for every single question precision and recall have been calculated using $\text{eq}^{(1)}$ and $\text{eq}^{(2)}$ respectively.

Then average precision and average recall have been calculated. With the value of average precision and average recall F Score/ F Measure has been calculated using $\text{eq}^{(3)}$.

After testing approximate 500 question average precision (0.35) average recall (0.65) have been obtained and the F score (0.45) is calculated based on average precision and averave recall. F score/ F measure reveals the system performance. The higher F score indicates that the system is more better.

Table 2: Process for Calculating Precision and Recall

Questions	Relevant Answers Retreived	Retreived Answers	Relevant Answers	Precision	Recall
কম্পিউটার শব্দের উতপত্তি কিভাবে?	1	2	1	0.5	1

In Table 2 process for calculating precision and recall has been shown. The first question in Table 2, this system has retreived two answers so here retrieved items=2. Among the two answers only one is relavent with the question and in the given document there is only one relevant answer as a result here relevant items retrieved=1 and relevant items=1. So for the first question using $eq^{(1)}$ and $eq^{(2)}$ precision (1/2=0.50) and recall (1/1=1.00) have been calculate. Like this way for every single question precision and recall have been calculated. Using the value of precision and recall average precision and average recall were calculated.

V. Conclusion

This paper has discussed a QA system from multiple documents. This study concludes the following:

- This approach is able to provide relavent answers of a user question for Bangla Language from multiple documents.
- Keywords of a question can be find out in this approach.
- This approach retreives relevant specific answers for time related and quantity related question.
- Precision, recall and F score of the system are 0.35, 0.65 and 0.45 respectively.
- If the document size is large then there is a possibilty that the system may retreive some less relevant information as total no of retrieved information increases.

In future the author of this paper would like to do the following tasks:

- There exists some more answer or information retreival system for some other languages like Chinese, English, Japanese [6][7][[8][9]. So this approach can be compared in future with other existing answer retreival approaches.
- Finding other question type by "*wh*" words and retreiving answers accordingly.
- If any relevant answers starts with pronoun then there is a chance that more relavant answers may exist in other sentences of the text. So finding out more relevant answers if any answers starts with pronoun.

***Abstract*— When it comes down to buying products from online shops, one of the key factor that influences a buyer are the reviews associated with a product. While buying people try to understand the quality and authenticity of the product by reading the previous user feedback. And sellers have started taking advantage of it. Putting fake and spam reviews to deceive the buyers is a common strategy mostly used by newcomers. But these reviews are important when it comes to deciding whether to buy a product or not. We propose a method to detect these fake reviews from Amazon Review Dataset. Rather than using traditional machine learning classifiers we have used boosting algorithms to improve the accuracy of the traditional approach. In this approach, a significant increase in accuracy has been achieved by boosting weak learners. Up to 93% accuracy has been achieved when tried to detect fake reviews where traditional machine learning algorithms achieve an accuracy of up to 89%.**

Keywords—fake review detection, boosting algorithm, spam detection, active learning.

I. INTRODUCTION

For every product sold on the internet and every buyer bought a product, around 60% of people post a review of that. As people are getting more connected to the internet, the style, medium of putting a review has changed. Nowadays people even make video reviews of a product to attract sellers and the industry is still growing where people promote products for compensation. But amongst all, there are people who write honest reviews to help others when it comes to making a decision about buying the product. Some sellers are taking this advantage by posting fake reviews to deceive the buyers.

Detecting these fake reviews are not a simple task when it comes down to handing over the responsibility to the computer. Some fake reviews are so skillfully written that even a human can't detect that let alone computers. And the freedom to write anything with no monitoring has made it more difficult to detect these deceptive reviews. These deceptive reviewers are mainly known as opinion spammers and their activities are known as opinion spamming [5]. In most of the cases, the new sellers are taking the chance of opinion spamming to grow the business quickly. Some websites are also paying review writers to write these fake reviews [6]. As a result, detecting these deceptive reviews are necessary to maintain the trust issue between the buyer and the seller.

There are many researchers who have proposed several techniques to detect review spam. But there are some difficulties which have made this task more complicated. One of them is the unavailability of the real-life enriched labeled dataset. Most of the datasets are based on the pseudo-fake reviews which are different from the real world data. It's a major drawback when it comes down to work with the real-life data depending on the pseudo-review dataset.

In this paper, we first create a labeled dataset from real life data with the help of active learning. This solves the drawback which was discussed previously and enables us to perform an experiment on the real-life data. Traditional machine learning classifiers have been used by many researchers. But it didn't have a significant impact when it comes down to accurately detecting the real-life fake reviews. So we have introduced boosting algorithms such as Extreme Gradient Boosting (XGBoost), Adaptive Boosting (AdaBoost) and the Gradient Boosting Machine (GBM) in fake review detection side by side with the traditional machine algorithms.

Our methodology is different from the previous work for the following aspects-

- **Real life custom labeled dataset:** The dataset used in this experiment were manually prepared and labeled. Because of the lack of gold standard real-life dataset we had to go through this phase. And drastically it has made a significant impact on the accuracy of our model. From a chunk of 100,000 reviews, collected from the authors of [3, 4]. Then from the chunk, fake reviews were collected based on the writers, writing pattern, the time difference between reviews, types of reviews for a product. A keyword-based search was also done to find out keywords in reviews such as 'Fake Review', 'Review exchange for product', 'Honest Review'. These key-word based search added more versatility to the dataset.
- **Supervised boosting approach:** Supervised boosting is a new approach which is not widely applied in spam detection as traditional machine learning algorithms. Amongst all other types of classifiers such as tree-based, boosting, regression, ensemble, and neural network, boosting is on the rise among researchers.

II. RELATED WORKS

Product reviews or consumer opinions are used in business as a guide for new customers. In e-commerce, product reviews written by customers can be beneficial. Positivity from the previous customer can bring new customers into the business. And it's one of the most vital things to generate revenue. Thus sellers always prefer a positive vibe of their product so that more customers get attracted. Throughout the process, some reviews come as opinion spam.

The term fake review was stated by the authors of [7] for the first time. In their research, they categorized it into different portions. The authors of [1] have used active learning to create a hybrid dataset from yelp and ott review dataset. Their proposed model performed very well on it. On the other hand, the authors of [8] and [9] explored time series and distributional analysis. From the crowdsourced fake review data Ott, Choi [9] focused on the fictitious opinions. In their model, they have used an n-grams based classifiers to detect the review spam. On the other hand, the authors of [10] proposed a novel approach of topic modeling using Latent Dirichlet Allocation. But the fixed number of topics was the main drawback when applied to the real-world dataset. Fei, Mukherjee [11] tried a different approach to ranking. They explored the burstiness in the reviews to detect the opinion spammers. The authors of [12] tried a graph relationship between the reviews and proposed a framework named FraudEagle. On an extended work [13], they collected the meta-data of the reviews to detect the review spammers.

Ren and Ji in [14] took the analysis one step further with the introduction of a convolutional neural network (CNN) and recurrent neural network. Their study showed that neural network based models have better generalization ability than discrete models. In [15], the authors proposed a heterogeneous graph model that finds the correlation between the reviews and the reviewers. This approach doesn't use the texts taken from the reviews. Therefore it only identifies the review spammer. In [16] the authors proposed a time series approach to detect the review spam. But the model suffered from a high computational problem during the scoring phase of the reviews.

III. DATASET & ACTIVE LEARNING

As stated before, a dataset with pseudo-reviews is available for analysis. But the problem with the dataset is that the model trained on this dataset didn't perform well on real-life test data. To solve the problem we created a hybrid dataset with the help of active learning. The active learning algorithm can interactively query the user or the information for the new data points to obtain the desired outputs and to reduce the cost of manual labeling of the dataset. A learner chooses a smaller set of examples to learn the concept. The main difference here with the normal supervised learning is that the learner learns from very small data samples than the one required for the normal supervised learning. We manually labeled 200 reviews as truthful reviews and another 200 as fake reviews. Then we fed these data to the learner to label the remaining 1600 data. For the remaining 1600 data, the model labeled 875 data samples as truthful reviews and leftover 725 reviews as fake reviews. So, we ended up with a dataset of 2000 samples where 1075 data samples were labeled as truthful reviews and 925 data samples were labeled as fake. Then this dataset was split into train, test and validation set. The algorithm of active learning is given below. The algorithm is quite same with authors proposed in [1].

Algorithm: Active learning process

```
INPUT:

initialTrain = The initial labeled training set;
initialTest = The initial labeled test set;
procData = unlabeled data;

OUTPUT:
finalTrain = hybrid training set;
//finalTrain    will    consist    intialTrainData    &
newLabeledData

1.    Load procData
2.    for all instances in procData
3.      create a sparse vector using the tf-idf vectorizer
4.       mat[] = sparse vector;
         //store s. Vector in a matrix
5.      feed mat[] to the CLASSIFIER
6.      accuracy = CLASSIFIER.accuracy
7.      if accuracy > 85% then
8.          finalTrain = (finalTrain U procData)
            //assert new labeled data
9.      else
10.       unlabData = DecisionFunction(procData instance)
11.       Manually label unlabData
```

Fig 1: Active Learning algorithm

IV. BOOSTING

The authors of [17] first came up with the concept of converting the weak learners into strong learner with higher accuracy. The work was then followed by the authors of [18] and [19] who made the boosting popular. They utilized it as a functional approximation of the logistic regression. This method of solving a problem is known as gradient boosting. This approach was slightly modified by the authors of [20] who fitted a subsample of the training set of the model without replacing it. This approach was based on the minimization of the loss function of the gradient and stochastic gradient descent in regression.

In [1], the authors introduced a hybrid ensemble approach to detect Amazon fake reviews. In their approach they have used active learning to create a labeled dataset first and then supervised learning with traditional classifiers such as Naïve Bayes, SVM, Decision Tree, Maximum Entropy and majority voting for classification were used. With n-gram features, their proposed model achieved an accuracy of 88%. Our proposed model extends their work to improve the performance with boosting. The extreme gradient boosting (XGBoost) is an end to end tree boosting algorithm which was proposed by the authors of [2]. The authors proposed it

as a novel sparsity-aware algorithm for sparse data and weighted quantile like a sketch for approximate tree learning. But the derivation of XGBoost follows from the existing idea of gradient boosting, originating a second order method from [Freidman at el]. The main factor of XGBoost is the leaf wise tree growth where the gradient boosting uses level wise tree growth. Recently XGBoost has become more popular because of winning kaggle competitions and outperforming classifiers and neural network models in some cases. 17 solutions out of 29 have used XGBoost and won the competition. 8 of the models solely used XGBoost while remaining models were ensembles of XGBoost and Neural Networks. Only some ensemble classifiers have outperformed well-tuned XGBoost. But they are very small in number according to [2]. Thus, this study and exploration of the previous work and kaggle winning solutions give us an overview that XGBoost can be explored with traditional approaches.

Our proposed method focuses more on XGBoost rather than other boosting approaches and classifiers that are commonly used. Different feature selection techniques were used to compare the performance of traditional classifiers and XGBoost. XGBoost performed brilliantly when compared with the previous work. Even with the default values of the hyperparameters described in [2], it beats the accuracy of fake review detection in a big margin. And finally, we ended up with a better result than the previous works.

V. METHODOLOGY

This section elaborates the experimental procedures that have been followed. We divide the whole methodology into 5 steps.

1. Collecting the unlabeled dataset.
2. Manually labeling some data and labeling remaining with Active Learning.
3. Preprocessing the dataset.
4. Feature selection.
5. Traditional and boosting approach to detect the review spam and comparison of results.

In previous researches, authors had their own way of preparing the dataset as gold standard data for amazon fake review detection is yet troublesome to find. That is where active learning played its role. Labeling all the data manually takes a huge effort, time and cost. To minimize these, we manually labeled some data with the help of experts and then using the active learning, labeled remaining dataset. Though it can't be claimed that our dataset is the gold standard but it is moderate enough for our research. From the dataset labeled by active learning, we picked some of the data and checked manually how active learning performed. Throughout the process, we labeled 1600 data with active learning and manually 400 data were labeled before. So we had 2000 labeled data where 1075 were labeled as truthful reviews and 925 reviews were detected as fake reviews. The dataset used here was collected from Amazon raw review data used by the authors of [3, 4]. It contains 142.8 million reviews and metadata spanning from 1996 – July 2016. The details of the dataset can be found at – http://jmcauley.ucsd.edu/data/amazon

After creating the dataset, in the second phase, we preprocess the dataset. The data we collected, needed a lot of preprocessing. The preprocessing part has not been discussed here as for the textual data standard preprocessing methods were followed such as removing stop words, stemming, lemmatizing etc. After preprocessing the dataset, it was split into 70%-10%-20% for training, validation, and testing. A small portion of the training set was used for validation.

In the feature selection phase, TF-IDF (Term frequency-Inverse document frequency) and Chi2 (Chi-Square) were used. TF-IDF increases the weight of uncommon words and decreases the weight of common word and results in creating a vector of features. On the other hand, Chi2 is a statistical approach that tries to find a relationship between every feature variable and the target variable. Features that are independent, gets discarded whereas dependent features get the most importance.

After the feature selection process traditional machine learning classifiers such as Decision Tree, Support Vector Machine, Stochastic Gradient Descent was trained and test data were used to check the accuracy. At the same time XGBoost and AdaBoost, GBM classifiers were trained and validated with training and validation sets and then accuracy was measured on the training set.

To understand the performance we took the accuracy, precision, recall and f1-score measurements. As said above, simulations were run based on different feature selection techniques, supervised approach with and without boosting, with default parameters and tuned hyperparameters. The results are discussed in the experiment section. The algorithm followed throughout the experiment is given below

Algorithm: Experimental Process

```
INPUT:

TrainData = The labeled training set (70%);
ValidationData = The validation dataset (10%)
TestData = Unlabeled dataset (20%)

OUTPUT:
Predictions = prediction from classifiers used.;
//ValidationData is used to validiate the classifier
predictions

1.    Load TrainData
2.    for all instances in TrainData
3.        create different sparse vector using the tf-idf
& chi2

4.       tf_idf_mat[] = sparse vector;
5.       Chi_2_mat[] = sparse vector;
6.       combined_mat[] = combine tf_idf_chi2_matrix
7.     for each feature matrix fed to the CLASSIFIER [DT,
SVM, SGD, XGB, ADB, GBM]
8.       train classifier
9.       accuracy, precision, recall = PREDICTION.metrics
10. RESULT COMPARISON
```

Fig 2: Experimental process Algorithm

VI. EXPERIMENT & RESULTS

In this part, we have discussed the details of the experimental procedure. As said above, using the active learning algorithm and manual labeling we created a dataset of 2000 reviews where 1075 were labeled as truthful reviews and the remaining 925 were labeled as fake reviews. We kept the size small to closely observe the performance. Before feeding this data into the classifiers, we need to select features from the data. In this case, tf-idf and chi2 were used individually. At first, we selected features with tf-idf and fed the data into traditional classifiers and boosting classifiers. In the second phase, we used chi2 as feature selection algorithm and followed the exact same procedure. At the third phase, we combined both to observe how all the classifiers perform. The boosting algorithms used here has several hyperparameters that can be tuned to achieve higher accuracy. Working with huge data can be time-consuming and costly when it comes to finding the best hyperparameter set. Choosing a smaller dataset of 2000 data has given us an advantage here. As for the traditional classifiers we have used

- Decision Tree (DT)
- Support Vector Machine (SVM)
- Stochastic Gradient Descent (SGD)

These traditional classifiers and boosting classifiers were simulated first before using Grid Search to find the best hyperparameter set. The results of the traditional classifiers with different feature selection technique are given below

Table 1: Performance of Traditional Classifiers on Tf-idf features

Classifiers	Feature Selection	DT	SVM	SGD
Accuracy	Tf-idf	0.824	0.833	**0.845**
Precision		0.810	0.845	**0.868**
Recall		0.804	0.860	**0.842**

The table above shows the performance metric for traditional classifiers with tf-idf. Tf-idf is one of the most popular feature selection technique used in natural language processing problems to select features. It can be seen that SGD achieves accuracy up to 84%. After observing performance with tf-idf feature selection performance with traditional classifiers, we then try chi2 features.

Table 2: Performance of Traditional Classifiers on Chi2 features

Classifiers	Feature Selection	DT	SVM	SGD
Accuracy	Chi2	0.846	0.857	**0.882**
Precision		0.829	0.875	**0.895**
Recall		0.839	0.872	**0.888**

Table 2 shows the performance of classifiers on chi2 features. From here we can say that the accuracy, precision, recall have improved. SGD achieved the highest among all up to 88% accuracy. Chi2 features have performed better than tf-idf features when fed into the target classifiers. After observing the accuracy of chi2 features, we combine both tf-idf and chi2 as part of our experiment to observe whether the metrics improve.

Table 3: Performance of Traditional Classifiers on combined tf-idf and chi2 features

Classifiers	Feature Selection	DT	SVM	SGD
Accuracy	Tf-idf + Chi2	0.842	0.868	**0.872**
Precision		0.813	0.845	**0.885**
Recall		0.798	0.879	**0.877**

From table 3, it can be observed that the combination of tf-idf and chi2 features didn't perform well. The overall accuracy was higher when only chi2 features were used. Here now on we have discussed the results of boosting algorithms with their default parameters and best parameter set found with Grid Search. The simulation procedure is the same as the traditional classification approach keeping the training data and feature selection techniques same for comparison purposes.

Table 4: Performance of Boosting Classifiers on Tf-idf features

Classifiers	Feature Selection	XGBoost	AdaBoost	GBM
Accuracy	Tf-idf	**0.932**	0.919	0.922
Precision		**0.947**	0.901	0.917
Recall		**0.911**	0.884	0.898

Boosting classifiers achieved a notable amount of higher accuracy than the traditional machine learning classifiers. These boosting classifiers ran on their default parameter values. XGBoost achieved up to 93% which is slightly higher than others with tf-idf features. In the table below the classifiers have the same configuration of parameters. Only the features were changed to chi2 to observe the performance.

Table 5: Performance of Boosting Classifiers on chi2 features

Classifiers	Feature Selection	XGBoost	AdaBoost	GBM
Accuracy	Chi2	**0.958**	0.942	0.952
Precision		**0.951**	0.911	0.939

Recall		**0.898**	0.887	0.906

As the traditional classifiers had slight improvement of accuracy in chi2 features from tf-idf features, boosting classifiers have also performed in the same way. Using chi2 features, evaluation metrics have slightly improved results. So combining tf-idf and chi2 features to observe the change in results.

Table 6: Performance of Boosting Classifiers on combined tf-idf and chi2 features

Classifiers	Feature Selection	XGBoost	AdaBoost	GBM
Accuracy	Tf-idf + Chi2	**0.937**	0.902	0.918
Precision		**0.932**	0.895	0.927
Recall		**0.909**	0.889	0.894

The combination of features causes the accuracy to be slightly reduced than only chi2 features. The accuracy achieved here is 93%. It can be said from the observations that all the classifiers performed well with chi2 features. The below figure demonstrates the overall highest accuracy achieved in the different experimental setup. It can be seen that XGB achieves the highest accuracy with Chi2 as a feature selection technique.

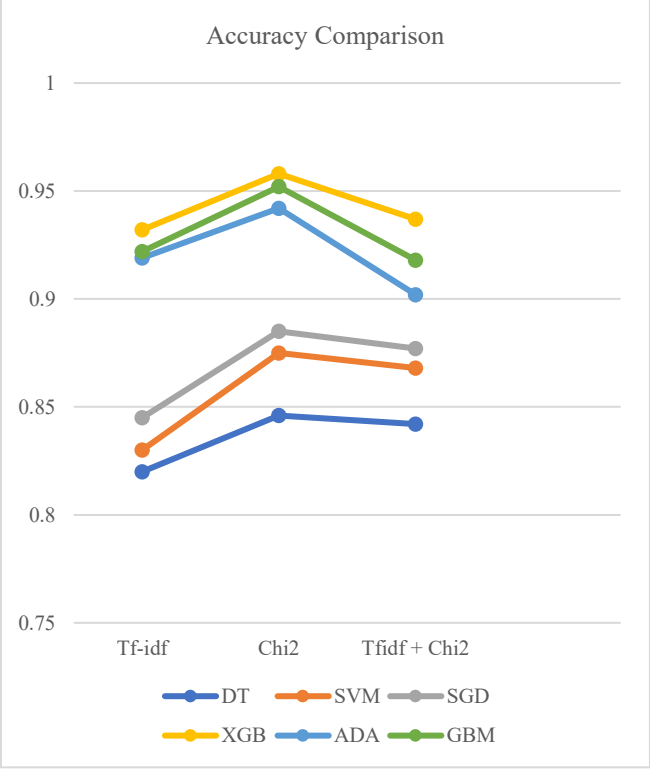

Fig 3: Accuracy Comparison

VII. CONCLUSION

As discussed earlier, we mentioned a lack of gold standard public dataset for analysis for which we had to introduce active learning. Manually labeling the data may increase the performance of the model. Using Extreme Gradient Boosting on fake review detection is still new and on the rise. There are many branches available to explore. As said, in our proposed method and experiments we didn't do deep hyperparameter tuning. Hyperparameter tuning is costly and time-consuming. Finding the best set of parameters can be very tricky. But with default parameters, it can be seen that XGBoost performed better achieving accuracy up to 95%. Finally, we hope to improve the dataset more and look forward to taking other aspects of the boosting algorithms to observe the change in results.

***Abstract*—The main concern of an educational institution is to enhance the performance of students. But dropping out of students is a large obstacle that creates bad impact in this purpose. For this reason, most of the educational institutions are conscious about reducing the rate of drop out students. To reduce the drop out students, firstly it is needed to identify the reasons behind the drop out students. In this paper to address the issue, different Decision Tree (DT) based methods as well as the boosted approaches have been used. Firstly, the features of the dataset have been sorted according to their importance based on Information Gain (IG). After the features being sorted, the dataset is partitioned into three categories: the all features, two-third of the features and one-third of the features. Thereafter the standard DTs and the boosted DTs are being experimented over the partitioned dataset to identify drop out students.**

***Index Terms*—Important features, information gain, decision tree, boosted decision tree, drop out.**

I. Introduction

Education facilitates our learning, knowledge and skill. Our mind and personality is completely changed because of education. It helps us to gain positive attitude. For every nation education is a key factor in its progress. For this purpose, many educational institutes give importance for completing graduation on time. But it is an enormous challenge for educational department to improve students graduation rate. The causes for not graduating on time is diverse; including economic problems, lack of motivation, and unexpected life changes can delay students graduation or cause them to drop out [1]. It is a lengthy process if we identify the students by observing students behavior. It needs huge man power. In this case, data mining techniques help us to identify drop out students.

Data mining is the process for discovering interesting patterns from huge amount of data [2]. It has both predictive and descriptive nature. Usually supervised learning approach has predictive nature. On the other hand, unsupervised learning has descriptive nature [3]. In supervised learning method we are given input instances with their class labels for training purposes. By analyzing the given data, we can predict the outcome for the test data. To identify drop out students, we have used some decision tree based method like J48, Random Tree (RT), Random Forest (RF), Logistic Model Tree (LMT), Decision Stump (DS) and Hoeffding Tree (HT).

For identifying drop out students, we have selected most important features by using information gain. The feature with highest gain value is considered as the most important feature. According to this gain value, we have sorted the features. After sorting the features, we have considered three categories of the dataset: all features, two-third of the features and one-third of the features. Then we have implemented the tree based methods to identify drop out students.

The leavings of the paper is systematized as follows: in section II, the related tasks by many researchers have been discussed. Important features are selected in section III. Different tree based methods have been described in section IV. In section V, a brief introduction to the datasets has been given. The evaluation criteria for performance analysis has been discussed in section VI. The performance of the tree based approaches are analyzed in section VII. And in section VIII, the conclusion of our work has been provided.

II. Related Work

Nowadays identification of drop out students is a major task. Because it strains the nation backward. Besides this, it attenuates the resource of an educational institutions. For this, researchers have tried to identify drop out students using several classification algorithms. In a recent work [4], the authors have implemented several classification algorithms (Naive Bayes, Neural Network, Support Vector Machine, Decision Tree and Random Forest) and tried to compare among them. They also have generated rules using Decision Tree. The authors of the paper [5] have reported on a large-scale study. They have used several classification algorithms such as Decision Tree, Decision Table, Logistic Regression, and Naive Bayes for identifying students of not meeting acceptable levels. In [6], the authors have tried to find out who, when and why are at risk of not graduating on time. Decision Tree, Logistic Regression, Stepwise Regression, and Cox Regression model have been used for their way of task. They have suggested predictors for prioritizing risk students. In another work [7], the authors have proposed a new threshold based method to identify drop out students and compared their method with some machine learning methods such as Logistic Regression, Naive Bayes and Support Vector Machine. In a work [8], the authors have compared different tree based

methods and have shown that each tree performs better for each condition. They have concluded that choice of parameter is important for knowledge discovery. The authors of paper [9] have compared REPTree and Decision Tree algorithms. They have shown that how pruning algorithm performs better. They have also focused on the influence of REPTree on the change of accuracy and complexity. In [10], the authors have compared among Random Forest, Logistic Model Tree (LMT) and Classification and Regression Tree (CART). They have shown that the performance of all the three methods are reasonably good. Among them Random Forest outperms than CART and LMT for prediction.

III. Feature Importance

To identify the drop out students, the mostly used features should be considered. In our way to work, Information Gain (IG) has been used to extract the most important features. It is based on Claude Shannon Entropy [11]. The feature with highest information gain is referred as the most important feature. The information gain can be calculated as eq. 1 [12]

$$IG(t) = -\Sigma_{i=1}^{|c|} P(c_i) log P(c_i) + P(t)P(c_i|t) log P(c_i|t) + P(1-t)P(c_i|(1-t)) log P(c_i|(1-t)) \quad (1)$$

where, c_i represents the i-th category, $P(c_i)$ is the probability of i-th category, P(t) is the probability appears in the documents, P(1-t) is the probability that doesn't appear in the documents, $P(c_i|t)$ is the conditional probability given that t is appeared, $P(c_i|(1-t))$ is the conditional probability given that t is not appeared.

Using the eq. 1, the most important features can be found out. Using these most important features and ignoring the less important features the dimensionality of the datasets can be reduced. This is to address as high dimensional data are the most important concerns in classification problem because of space and time complexity [13].

IV. Methodologies

A. J48

J48 is an modified version of ID3 and an implementation of C4.5 algorithm in WEKA. Depth-First strategy is used for growing this tree [8]. The algorithm considers all possible tests that can split the dataset. Here information gain is used as splitting criteria. The dataset selects an attribute with highest information gain. This algorithm can handle both discrete and continuous attributes. J48 algorithm also can handle missing values. After the tree is fully constructed, this algorithm performs pruning. Because of outliers pruning is a significant step to the result.

B. Random Tree

Random Tree (RT) is an ensemble learning algorithm that generates different learners. It is a supervised classifier. From different learner it employs a bagging idea to generate a tree. Every node is split using the best split among all variables in a standard tree. Random Tree is an ensemble of tree predictors called forest. The steps of the classification are as follows: the random trees classifier gets the input feature vector, classifies it with every tree in the forest, and outputs the class label that received the majority of "votes" [8]. Random Tree is a combination of two machine learning algorithms: single model tree and random forest. Single model trees are merged with random forest for creating Random Tree. In a single model tree every single leaf holds a linear model. Random Forests are used to enhance the performance of single model tree.

C. Random Forest

Random Forest (RF) is a supervised learning method. It is an ensemble learning method for classification, regression and other tasks. In the Random Forest algorithm, the more the number of trees in the forest, it gives higher accuracy. To create trees in the forest, we need not follow the information gain or gini index for splitting criteria. Trees are formed by randomly chosen features. Prediction is made by combining (majority vote for classification or averaging for regression) the predictions of the ensemble [8]. Random Forest classifier can handle missing values. As the number of trees in the forest becomes large, the generalization error for forests converges to a limit. The generalization error depends on the strength of the individual trees.

D. Logistic Model Tree

Logistic Model Tree (LMT) is a combination of two complementary classification methods: logistic regression and tree induction [14]. To generate an LMT, firstly it needs to build a standard classification tree, using C4.5 method. Afterwards, a logistic regression model is built at every node because every node is a 'candidate leaf' during pruning. In the logistic variant information gain is used as splitting criteria. Splits are either binary or multi way. The LogitBoost algorithm is used to form an LR model in every node. The tree is pruned using a CART algorithm. LMTs perform competitively with other classifiers while being easy to interpret. But the main drawback is the time needed to build them.

E. AdaBoost.M1

AdaBoost can be used to boost the performance of a weak learner. Freund and Schapire proposed a simple and natural extension of AdaBoost for k>2 classes, which is called AdaBoost.M1 [15]. It is an ensemble technique of classification. In this technique, learners are learned with weak learners fitting simple models to the data. After that analyze the data for errors. Boosting maintains a weight for each instance. The higher the weight, the more the classifier influence the learner [16]. When an input is misclassified by an assumption, its weight is increased so that next assumption is more likely to classify it correctly. It focuses to convert weak learners into strong one. By combining the whole set at the end, it converts weak learners into better performing model. The main disadvantage of AdaBoost.M1 is that it is unable to handle

weak hypothesis with error greater than 1/2. The algorithm of AdaBoost.M1 [17] is as follows:

Algorithm 1. AdaBoost.M1

Input: sequence of m examples $((x_1, y_1), ..., (x_m, y_m))$ with labels $y_i \epsilon Y = 1, ..., k$
weak learning algorithm **WeakLearn**

Output: the final hypothesis:
$h_{fin}(x) = arg\ max_{y \epsilon Y}\ \Sigma_{t:h_t(x)=y}\ log\frac{1}{\beta_t}$

Initialization :

1: $D_1(i) = 1/m$ for all i
2: **for** $i = 1$ to T **do**
3: Call WeakLearn, providing it with the distribution D_t
4: Get back a hypothesis $h_t = X \longrightarrow Y$
5: Calculate the error of $h_t : \epsilon_t = \Sigma_{i:h_t(x_i) \neq y_i}\ D_t(i)$. If $\epsilon_t > 1/2$, then set $T = t - 1$
6: **end for**
7: Set $\beta_t = \epsilon_t/(1 - \epsilon_t)$
8: Update D_t :

$$D_{t+1}(i) = \frac{D_t(i)}{Z_t} \times \begin{cases} \beta_t, & \text{if } h_t(x_i) = y_i \\ 1, & \text{otherwise.} \end{cases}$$

F. Decision Stump

Decision Stump (DS) is a prediction based machine learning algorithm. The algorithm is based on one-level decision tree [18]. Decision stump is a kind of decision tree in which only one rule is used. One internal node (Root node) is connected with only the terminal node. This algorithm predicts using only one input feature. So, it is also called 1-rules method.

G. Hoeffding Tree

Hoeffding tree (HT) induction uses information gain as splitting criteria [19]. It is an incremental decision tree induction method capable of learning from huge amount of data. In Hoeffding tree, Hoeffding bound is used because it holds the true distribution generating values, and depends only on the range of values, number of observations and desired confidence.

V. Dataset Description

The dataset "Student Performance Analysis" has been taken from the renowned UCI Machine Learning Repository [4]. This dataset contains 33 features such as: final grade, second period grade, first period grade, number of school absences, number of past class failures, going out with friends, wants to take higher education and so on. The dataset has 395 instances. The dataset is used to assess the performance of different tree based methods (J48, Boosted J48, Random Tree, Boosted Random Tree, Random Forest, Boosted Random Forest, LMT, Boosted LMT, Decision Stump, Boosted Decision Stump, Hoeffding Tree and Boosted Hoeffding Tree) for identifying drop out students. We have used WEKA for executing the methods.

VI. Evaluation Metrics

To assess the performance of our work, different metrics such as accuracy, precision [20], recall [20], F1-score [20] and ROC Area [21], PRC Area [22], MCC [22], Mean Absolute Error [22], Root Mean Squared Error [22] have been used.

A. Precision, Recall and F1 measure

$$Precision = \frac{TP}{TP + FP} \tag{2}$$

$$Recall = \frac{TP}{TP + FN} \tag{3}$$

$$F1measure = \frac{2 * Precision * Recall}{Precision + Recall} \tag{4}$$

where,TP = True Positive, means that the number of students who can continue study are correctly classified, FP = False Positive, means that number of drop out students are wrongly classified as the student who can continue studying. FN = False Negative, means that the number of students who can continue study are wrongly classified.

B. ROC Area

In a ROC curve, the true positive rate is plotted in function of the false positive rate. The accuracy of the test depends on how well the test separates the group. If the ROC Area is 1, then it represents perfect test and if the area is 0.5, then it is worthless.

C. PRC Area

In PRC curve, precision is plotted in function of recall. PRC is more useful when someone is only interested how the classifier is behaving in only one class. It is more informative than ROC when evaluating binary classifications on imbalanced data.

D. MCC

Matthews Correlation Coefficient (MCC) is used as a measure of the quality of binary classification. It considers true and false positives and negatives for measuring the correlation coefficient. It returns a value between -1 and +1. A +1 represents a perfect prediction, 0 represents no better than random prediction and -1 represents total disagreement between prediction and observation.

$$MCC = \frac{TP * TN - FP * FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}} \tag{5}$$

where, TN = True Negative, means that number of drop out students are correctly classified.

E. Mean Absolute Error

Mean absolute error (MAE) is used to measure how close the predictions are to the actual outcomes. The mean absolute error is an average of the absolute errors. The mean absolute error is calculated by

$$MAE = \frac{1}{n}\Sigma_{i=1}^{n}|f_i - y_i| = \frac{1}{n}\Sigma_{i=1}^{n}|e_i| \tag{6}$$

Where, f_i is the predicted value and y_i is the actual value.

F. Root Mean Squared Error

Root mean squared error (RMSE) represents the standard deviation of the differences between the predicted value and the actual value. It can be calculated as

$$RMSE = \sqrt{\frac{\Sigma_{t=1}^{n}(f_i - y_i)^2}{n}} \quad (7)$$

VII. Performance Analysis

At first, we have calculated information gain (IG) of the features. Feature with highest information gain is considered as most important feature. After calculating the information gain, features have been sorted according to their gain value. The feature with highest information gain is considered first and the rest of the features are considered in the same way. After sorting the features according to the IG value the dataset is divided into three different categories. We have used all features, two-third of the features with highest information gain and one-third of the features with highest information gain for this purpose. Then these three categories of dataset have been considered to analyze the performance of different tree based algorithm. The overall flow of our work is depicted in Fig 1.

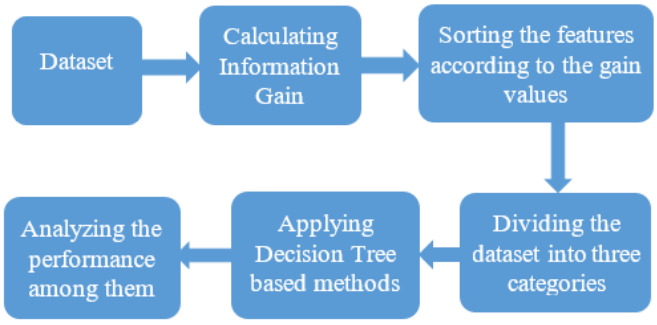

Fig. 1. Flow of the Work

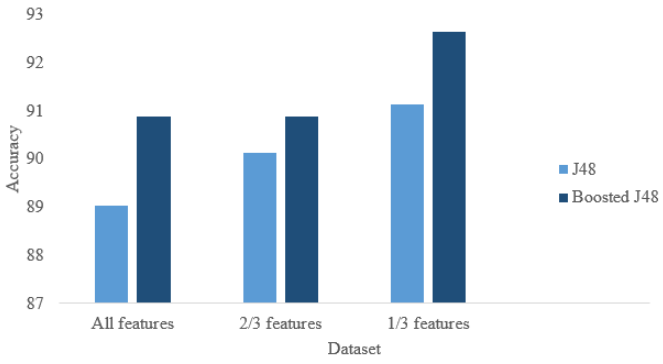

Fig. 2. Accuracy for J48 and Boosted J48

Accuracy for J48 and Boosted J48 are shown in Fig. 2. From this figure, it can be seen that Boosted J48 performs always better than J48. The performance for one third of the features is better than two third of the features and the performance for two third features is better than all features. Table I represents the comparative performance between J48 and Boosted J48.

TABLE I
Comparative analysis between J48 and Boosted J48

Evaluation Metrics	All features		2/3 features		1/3 features	
	J48	***Boosted J48***	***J48***	***Boosted J48***	***J48***	***Boosted J48***
Precision	0.895	0.909	0.901	0.908	0.911	0.926
Recall	0.896	0.909	0.901	0.909	0.911	0.927
F1 measure	0.896	0.909	0.901	0.908	0.911	0.926
ROC Area	0.878	0.964	0.876	0.957	0.926	0.972
PRC Area	0.867	0.960	0.869	0.951	0.912	0.973
MCC	0.727	0.762	0.741	0.759	0.767	0.808
MAE	0.115	0.091	0.113	0.089	0.096	0.074
RMSE	0.296	0.289	0.290	0.289	0.268	0.262
Time (sec)	0.02	0.11	0.02	0.06	0.01	0.05

From all the assessment criteria, it can be seen that Boosted J48 outperforms J48. Using one third features that means using most important features performance is better than other two cases.

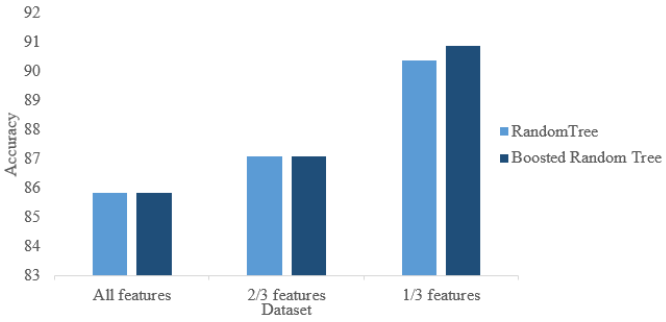

Fig. 3. Accuracy for Random Tree and Boosted Random Tree

Time (sec)	0.02	0.01	0.01	0	0	0

Fig. 3 shows that both Random Tree and Boosted Random Tree have equal accuracy for all features and two-third features. It can be also seen that, using most important features the result is outstanding than using all features. From Table II, it can be observed that Boosted Random Tree performs better than Random Tree.

Bar graph in Fig. 4 shows the accuracy comparison between Random Forest and Boosted Random Forest. Though

Time (sec)	0.09	0.09	0.06	0.08	0.06	0.08

performance of Boosted Random Forest is lower for one third features, it outperforms Random forest in a larger scale for two third features. Using different evaluation metrics we can also see the same results from Table III.

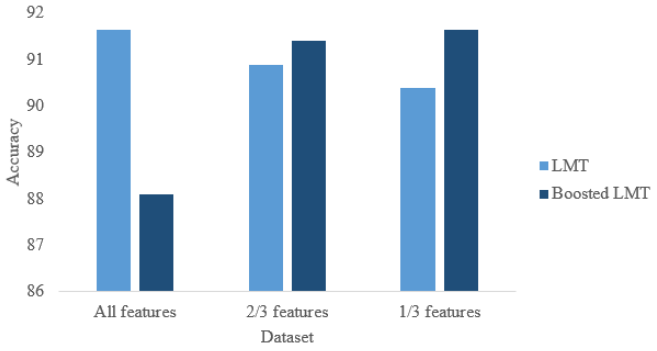

Fig. 5. Accuracy for LMT and Boosted LMT

The overall evaluation summary of both LMT and Boosted LMT is shown in Fig. 5 and Table IV. From these, it can be seen that Boosted LMT beats LMT for two-third features and one-third features. In case of Boosted decision tree performance using most important features exceeds the other cases.

From Fig. 6 and Table V, it can be seen that Boosted Decision Stump identifies drop out students more accurately than standard Decision Stump algorithm. Though the accuracy for standard Hoeffding Tree is better than Boosted Accuracy,

from Fig. 7 and Table VI it can be found that it performs better when we use most important features.

From the above it can be perceived that, Boosted trees outperform than standard trees. Because from a number of weak classifiers Boosted tree creates a strong classifier. Boosted algorithm builds a model from training data. After that it creates a second model that attempts to correct the error from first model. The method continues until the training set is predicted perfectly.

The performance is also higher for the most important features than using whole features. From all the tables, it can be seen that with the number of features are reducing the time taken for model building is also reducing. So, when only important features will be used, it will save time for building a model.

VIII. CONCLUSION

In this paper, different tree based methods are compared with their boosted approaches for identifying drop out students. For identifying drop out students important features are calculated. Features with highest gain value are considered as the most important features. To assess the performance of the methods, several evaluation criteria are used. J48, Random Tree, Random Forest, LMT, Decision Stump, Hoeffding Tree and their corresponding Boosted Trees are used for this purpose. Finally, it is observed that for most of the cases performance is higher for one third of the features, i.e., the most important features and Boosted DTs outperforms than the standard DTs. In future, a comparison with the recent tree based method such as XGBoost can be performed.

Abstract— **For evaluating student's performance, the existing methods are not so much fair and satisfiable. The ranges of marks used for grading here are sometimes blessing and sometimes not. A method is proposed to evaluate performance based on Fuzzy Inference System (FIS). This system considers the student's continuous assessment which includes the attendances, total times he/she is spent in class and marks obtained in class test. This method increases the fairness and excellency of a student's assessment than existing methods. In existing FIS for grading the continuous assessment of student is not fuzzified where only the final exam papers mark is fuzzified. But, the proposed system fuzzified both the continuous assessment and exam paper's mark which actually increase more precise justification of student performances.**

Keywords— Fuzzy Inference System, Expert System, Fuzzification, Defuzzification, Continuous Assessment.

I. INTRODUCTION

Student performance evaluation is one of the most important tasks in an educational institute. Proper evaluation method ensures fair evaluation what is highly desired and student grade should comply with performances. Student's performance depends on various factor such as attendance, class test, final exam etc. Considering, these factors final grade is calculated. In many universities only, number of class simply is considered for evaluating attendance. However, both number of class as well as time spent on class should be considered in the evaluation process, as class size is large in most of the universities in developing countries like Bangladesh and student sometimes do not attend the class of full time. For this purpose, a specialized hardware is used which scores number of class and time spent on the class.

Examinations are conducted in most of the universities, college and institutes of a subject in a subjective manner. In these examinations' students ask to write either short or detail answer which is indicated in the exam paper and depending on allotted time of that specific question. Usually, to solve 100 marks exam paper maximum 3 to 4 hours is given as a whole but time is not specified for each question, overall time management depends on students. Finally, performance is computed from their examination, class test, attendance etc. and each of these sections has a predefined weight.

Student educational performance is measured based on the results of examinations and usually expressed numerically or by later grades [1]. Conventional method compares student performance with predefined measurement criteria. Evaluation and measurement are vital parts of the educational process. Various methods are using for evaluating student performance.

A. Related Work

In 1965, fuzzy set theory was introduced by Lotfi A. Zadeh [2]. In recent years, it has been used extensively in a number of research fields including educational system to remove vagueness that conventional methods unable to solve properly. Echauz and Vachtsevanos in [3] proposed a system using fuzzy set theory for converting conventional result into later-grades. Law in [4] developed a fuzzy educational grading system structure model and proposed an algorithm to aggregate various test scores to generate a final single score of a student. It also discussed the method to build the membership functions of several linguistic values with different weights. Bai and Chen in [5] proposed a scheme to generate membership function of fuzzy rules automatically. Then this membership function used in fuzzy logic to obtain the marks of a student. It devised an unbiased and smooth scheme for evaluating students answer scripts. Then Biswas offered a method in [6] to evaluate student performance using fuzzy logic and fuzzy inference system. It took too much time to predict performance and there was chance to assign same grade for to different fuzzy marks. Later, Chen and Lee in [7] present a method which remove the limitation of the previous scheme by Biswas. Their method is faster enough and do not need any complicate matching operations.

Wilson et. al in [8] proposed a method using fuzzy set theory and genetic algorithm. Ramjeet and Vijendran in [9] consider student performance evaluation problem as a clustering problem where clusters (classes) are generated from student talent level and no. of cluster should be less than or equal to the predefined capacity. In [10] Arya et. al designed a dynamic model mainly for engineering students which take final exam marks as well as lab and project performance into account to devise final grade applying fuzzy model. Shilpa in [11] used fuzzy logic to measure a student performance considering vagueness of question paper along with accuracy rate, relative importance and complexity. Reference [12] represents a method by James using fuzzy expert system to evaluate student writing samples with high level of accuracy comparable to the best teacher graders. Ibrahim in [13] proposed an easy, transparent, fair, automatic method taking the difficulty, the importance and

the complexity of questions in account applying fuzzy inference system to provide student learning achievements. Wang and Chen in [14] presented a method for evaluating students' answer scripts using fuzzy numbers associated with degrees of confidence of the evaluator. Bardul proposed a method in [15] to evaluate the student's performance as an individual and as a group. This focus of this method is to evaluate student's answer sheet and group performance assessment of a student.

B. Basic Fuzzy Logic

Fuzzy logic was introduced by Prof. Lotif Zadeh to handle imprecision, vagueness and uncertainty of data. On the basis of working procedure, a fuzzy controller is similar to a traditional system. It takes inputs then carry out calculations and finally provide an output value. Fig. 1 illustrates the basic structure of a fuzzy system. Fuzzification is a process of converting crisp input values into fuzzy values using fuzzy membership functions. Defuzzification is the reverse process of fuzzification which converts this latter output into crisp values again.

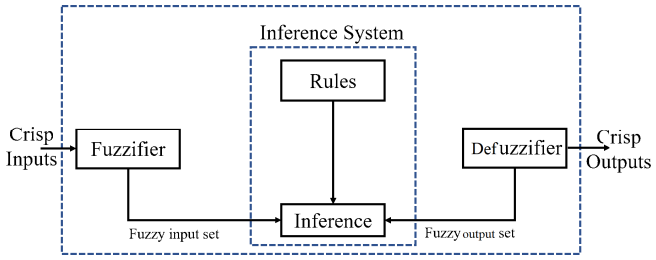

Fig. 1 Basic Fuzzy System

C. Motivation

Existing grading system is strict. This grading system has some predefined range of marks defined by University Grants Commission (UGC) of Bangladesh and a grade is awarded (e.g. A+, A, A-, B+, B, B-, C+, C, D, F etc.) equivalent to an integer interval such as 80-100 (A+), 75-(<80) (A), 70-(<75) (A-), 65-(<70)(B+), 60-(<65) (B), 55-(<60) (B-), 50-(<55) (C+), 45-(<50) (C), 40-(<45) (D), <40 (F) etc. The mark is simply obtained from different sections as a mean (class test, attendance, final exam etc). In this method same grade is awarded for a range of marks, for example if a student gets 80 and another student gets 100 percent of mark both of them will get the same grade A+, it is not fair. Therefore, an evaluation system is demanded which will provide fairness, transparency, objectivity, logical reasoning, and easy computer implementation.

Unlike existing grading system in fuzzy logic system every single mark is considered for calculating final grade as every mark has a degree of membership value in membership function. Although performance assessment process using fuzzy logic is intricate, it is flexible, whereas traditional grading system stick to fixed mathematical calculation.

D. Contribution

This paper proposes a fair method to evaluate student performance using fuzzy logic and fuzzy inference system. We summarize our contributions in this paper as follows:

- We consider number of classes as well as total time spent on the class. In credit system there is a direct relation between class time and credit. So, we have considered the total time spent on class for assessment.
- Continuous assessment (attendance, time spent on class and Class Test) and Final examination both are vital for measuring student performance. Our system considers both of these for assessing student's performance.
- Comparison between existing method and our proposed method has been done.

E. Organisation

This research paper forms as: section II which discusses the overall methodology how does the system work. Section III contains the performance analysis of students and results are compared with traditional method. In section IV, the conclusion of the research work is added.

II. METHODOLOGY

1 Proposed System for Evaluating Students Performance

In Bangladeshi Universities, for evaluating student's performance in each subject the mark is divided into two parts. So, our system consists of two parts. First part is student's continuous assessment which includes class test, attendance and total time spent in class. Second part is semester final examination's where exam paper is separated into two parts named Part-A and Part-B. The mark distribution for Part-A and Part-B is equal. The overall architecture of the proposed system is shown in Fig. 2.

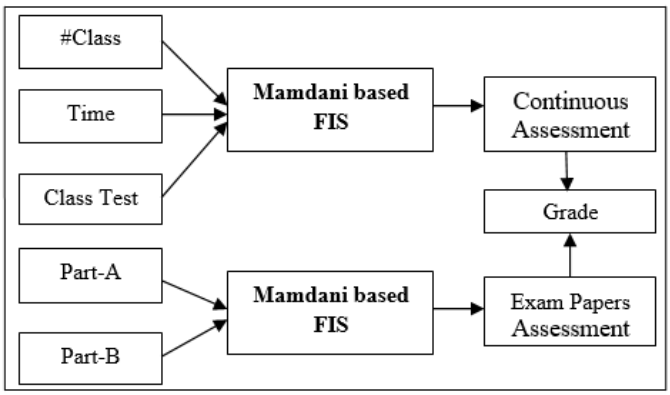

Fig. 2 Proposed System Architecture

1.1 Students Continuous Assessment System

In existing Student's Continuous Assessment System, the total no. of class and Class Test (CT) is considered which is not very much fair. But in our proposed system the total amount of time a student spent on class room is also considered which makes the assessment process more fair than existing system.

1.1.1 Fuzzification of Students Continuous Assessment

In this part, we have three linguistic input variables called Total number of class (#Class) and Total time spent in class (Time) and Class_Test. The linguistic values and interval for the variables are shown in the TABLE I, TABLE II AND TABLE III.

TABLE I: LINGUISTIC VALUES AND INTERVALS FOR INPUT VARIABLE "#CLASS"

Linguistic Values	Intervals
Few (F)	(0, 0, 0.20, 0.30)
Average (A)	(0.20, 0.30, 0.45, 0.55)
High (H)	(0.45, 0.55, 0.70, 0.80)
Very High (VH)	(0.70, 0.80, 1, 1)

TABLE II: LINGUISTIC VALUES AND INTERVALS FOR INPUT VARIABLE "TIME"

Linguistic Values	Intervals
Low (L)	(0,0, 0.20, 0.40)
Average (AV)	(0.20, 0.40, 0.60, 0.80)
Large (LG)	(0.60, 0.80, 1, 1)

TABLE III: LINGUISTIC VALUES AND INTERVALS FOR INPUT VARIABLE "CLASS_TEST"

Linguistic Values	Intervals
Very Low (VL)	(0,0,0.15,0.25)
Low (L)	(0.15, 0.25, 0.35, 0.45)
Average (A)	(0.35, 0.45, 0.55, 0.65)
High (H)	(0.55, 0.65, 0.75, 0.85)
Very High (VH)	(0.75, 0.85,1,1)

The trapezoidal membership function is used for all the input variables "#Class", "Time" and "Class_Test" as shown in Fig. 3, Fig. 4 and Fig. 5 respectively. The output variable for this part is assessment whose linguistic value is as same as input variable Class_Test shown in TABLE III and Fig. 5.

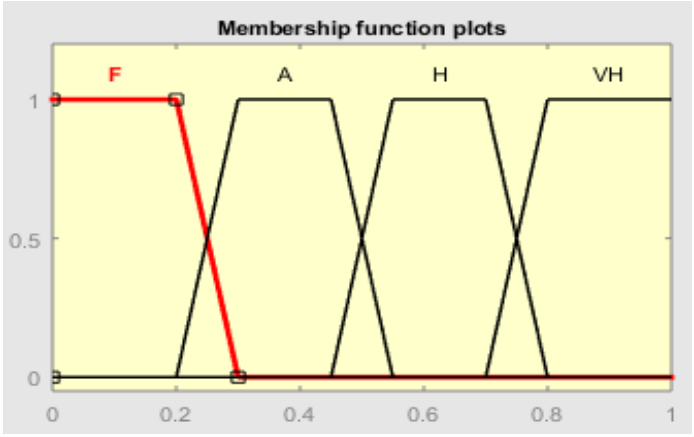

Fig. 3 Membership Function for #Class

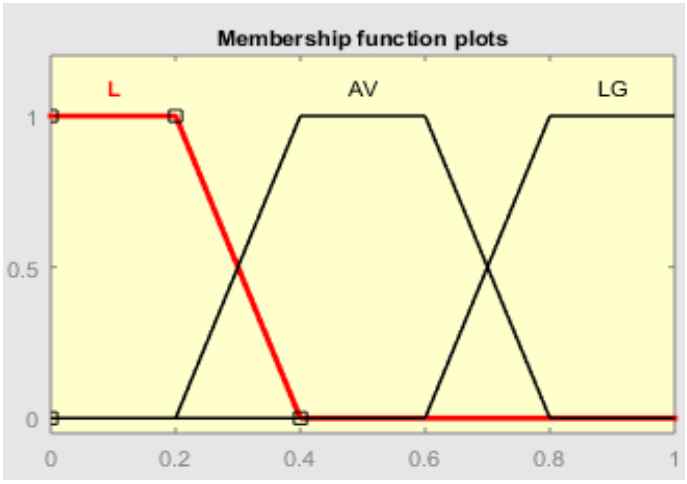

Fig. 4 Membership Function for Time

Fig. 5 Membership Function for Class_Test

1.1.2 Rules Evaluation for Assessment

The Fuzzy inference system uses the "IF Then Else" rules. For each of the input variables value the rules generated as follows.

1. If (#Class is F) and (Time is L) and (Class_Test is VL) then (Assessment is VL)
2. If (#Class is F) and (Time is L) and (Class_Test is LW) then (Assessment is VL)
3. If (#Class is F) and (Time is L) and (Class_Test is AG) then (Assessment is VL)
4. If (#Class is F) and (Time is L) and (Class_Test is HH) then (Assessment is L)
5. If (#Class is F) and (Time is L) and (Class_Test is VHH) then (Assessment is L)

……..

58. If (#Class is VH) and (Time is LG) and (Class_Test is AG) then (Assessment is H)
59. If (#Class is VH) and (Time is LG) and (Class_Test is HH) then (Assessment is VH)
60. If (#Class is VH) and (Time is LG) and (Class_Test is VHH) then (Assessment is VH)

The degree of membership value is generated by the trapezoidal membership function for each of the linguistic value of an input variable. In Fuzzy rules there are more than one value exists. So, a single value is need to choose. There are several ways to choose it. One is MIN rule and another one is MAX rule. The MIN rules select the minimum values among the degree of membership values which are ANDed by each other's. The MAX rules select the maximum values among the degree of membership values which are ORed by each other's.

1.1.3 Determining the Assessment Score

There are many others ways to calculate the final assessment score which is called defuzzification. In this paper we have used center of gravitation (COG) method or center of area calculating method.

1.2 Students Exam Papers Assessment System

1.2.1 Fuzzification of Student's Exam Papers

The answer script or the Exam paper is divided into two parts as Part-A and Part-B. So, in this part we have two linguistic input variables Part-A and Part-B. The linguistic value and interval for both of these variables are shown in TABLE IV.

TABLE IV: INPUT VARIABLE AND IT'S INTERVAL FOR "PART-A" AND "PART-B"

Linguistic Value	Interval
Very Low (VL)	(0,0, 0.02, 0.18)
Low (L)	(0.02,0.18,0.22,0.38)
Average(A)	(0.22,0.38,0.42,0.58)
High (H)	(0.42,0.58,0.62,0.78)
Very High (VH)	(0.62,0.78,0.82,0.98)
Very Very High (VHH)	(0.82,0.98,1,1)

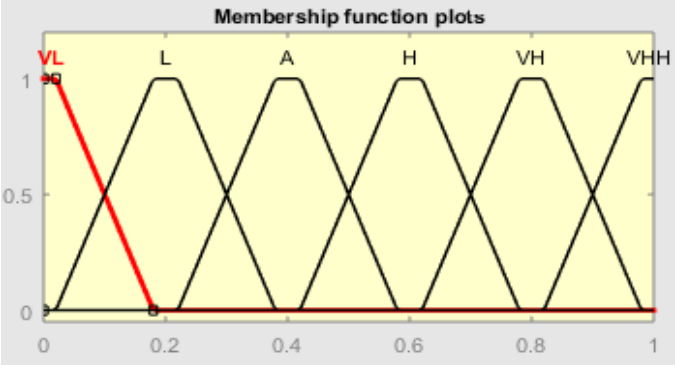

Fig. 6 Membership Function for Part-A and Part-B

Assessment is the output variable in this part whose linguistic variable and interval is same as input variable Part-A and Part-B as shown in TABLE IV and Fig. 6.

1.2.2 Rules for Performance of Two Variable

The same "IF Then Else" rules are used to measure the performance of student.

1. If (Part-A is VL) and (Part-B is VL) then (Performance is VL)
2. If (Part-A is VL) and (Part-B is L) then (Assessment is VL)
3. If (Part-A is VL) and (Part-B is A) then (Assessment is L)
4. If (Part-A is VL) and (Part-B is H) then (Assessment is L)
5. If (Part-A is VL) and (Part-B is VH) then (Assessment is A)

.....

31. If (Part-A is VHH) and (Part-B is VL) then (Assessment is A)
32. If (Part-A is VHH) and (Part-B is L) then (Assessment is H)
33. If (Part-A is VHH) and (Part-B is A) then (Assessment is VH)
34. If (Part-A is VHH) and (Part-B is H) then (Assessment is VH)
35. If (Part-A is VHH) and (Part-B is VH) then (Assessment is VHH)
36. If (Part-A is VHH) and (Part-B is VHH) then (Assessment is VHH)

The MIN and MAX rules are also used in this part for selecting only one value from several values.

1.2.3 Determining the Assessment Result

Same method (COG) is used for determining exam paper Assessment for a student which is used for determining the assessment score.

III. PERFORMANCE ANALYSIS

A. Dataset

Actually, our system is divided into two parts for evaluating student's performance for considering the student's continuous assessment related data and final exam paper data. In continuous assessment data, there are three fields named number of class, time spent in class and class test. For exam paper, also considered two fields named marks of exam papers Part-A and Part-B. The benchmark dataset is collected from Khulna University of Engineering & Technology (KUET), Khulna-9203, Bangladesh.

B. Result Analysis

For evaluating overall performance, we have used Mamdani type fuzzy inference engine which we have described briefly in methodology Section II. The performance of 15 out of 60 students in 5 individual subjects based on their benchmark dataset collected from Computer Science and Engineering Department, KUET is shown in TABLE V. Total number of class is considered 39 for each course and length of every class lecture is 50 minutes. So, total 50x39 = 1950 minutes (Time) a student can be spent in class. The final grade of an individual subject is calculated considering 30% marks in continuous assessment and 70% marks in exam papers evaluation. Then, the total marks obtained from continuous assessment and exam papers assessment is added to get the grade.

In Fig. 7 shows the assessment score is 0.9 for a student whose attendance is 94.9%, time spent in class is 96.8%. and class test is 96.67%. Similarly, Fig. 8 shows the Assessment

value is 0.8 for a student whose exam paper marks are 78.1% and 67.6% in Part-A and Part-B respectively.

TABLE V: ASSESSMENT OF STUDENT BY PROPOSED METHOD

SI No.	# Class	Time Spent on Class (Minute)	Class Test	Continuous Assessment	Part-A Mark	Part-B Mark	Exam Paper Assessment	Grade
1	37	1790	58	0.900	82	71	0.800	A+
2	28	660	60	0.888	52	67	0.636	A-
3	26	1000	40	0.700	59	54	0.566	B
4	25	1200	28	0.326	56	55	0.533	C
5	32	1400	10	0.338	49	76	0.667	B-
6	20	952	35	0.494	73	69	0.695	B
7	29	1400	18	0.444	58	57	0.557	C+
8	34	1400	55	0.900	62	63	0.600	B+
9	16	672	44	0.500	64	55	0.600	B-
10	15	500	33	0.300	48	57	0.547	C
11	12	444	23	0.176	73	66	0.695	C+
12	36	1303	39	0.813	69	73	0.695	A-
13	08	350	29	0.300	42	69	0.600	C+

15	20	1144	10	0.151	32	76	0.505	F

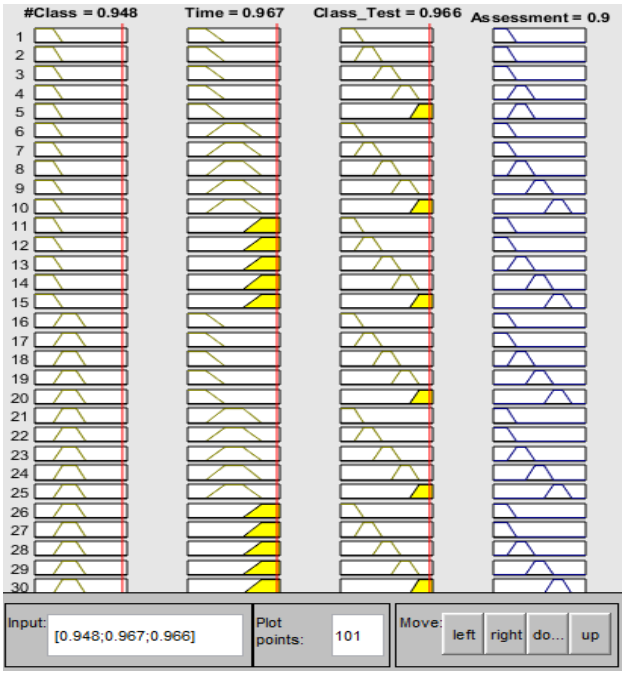

Fig. 7 Assessment Value for Student 1 Who was Presented 37 Class, spent 1890 Minutes in Class and Got 58 in Class Test.

C. *Comparison with Existing Method*

The comparing study between the existing system and the proposed fuzzy assessment system for the same 15 students out of 60 student's datasets for subject 1 is shown in TABLE VI. It shows, in the existing system the assessment score is always 0.00 for the students whose attendance is less than 60%.

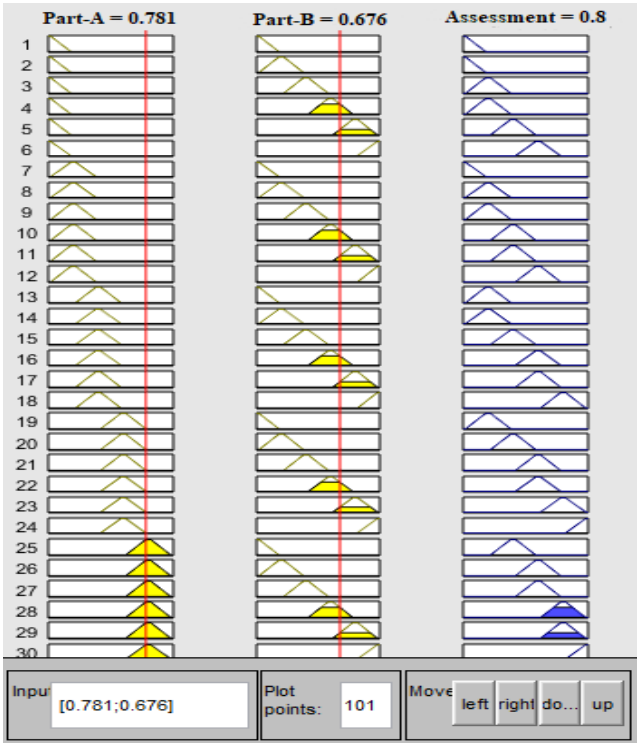

Fig. 8 Assessment Value for Exam papers Part-A and Part-B Based on Marks 82 and 71 Respectively.

TABLE VI: COMPARISON OF ASSESSMENT BETWEEN EXISTING METHOD AND PROPOSED METHOD

SI No.	Existing Method Continuous Assessment	Proposed Method Continuous Assessment	Existing Method Exam Paper Assessment	Proposed Method Exam Paper Assessment	Existing Method Grade	Proposed Method Grade
1	1.00	0.900	0.729	0.800	A+	A+
2	0.60	0.888	0.567	0.636	B+	A-
3	0.50	0.700	0.538	0.566	B-	B
4	0.40	0.326	0.529	0.533	C+	C
5	0.80	0.338	0.595	0.667	C+	B-
6	0.00	0.494	0.676	0.695	B-	B
7	0.60	0.444	0.548	0.557	C+	C+
8	0.90	0.900	0.595	0.600	B+	B+
9	0.00	0.500	0.567	0.600	C+	B-
10	0.00	0.300	0.500	0.547	C	C
11	0.00	0.176	0.662	0.695	C+	C+
12	1.00	0.813	0.676	0.695	A-	A-
13	0.00	0.300	0.529	0.600	C	C+
14	0.90	0.900	0.310	0.215	C	D
15	0.00	0.151	0.514	0.505	F	F

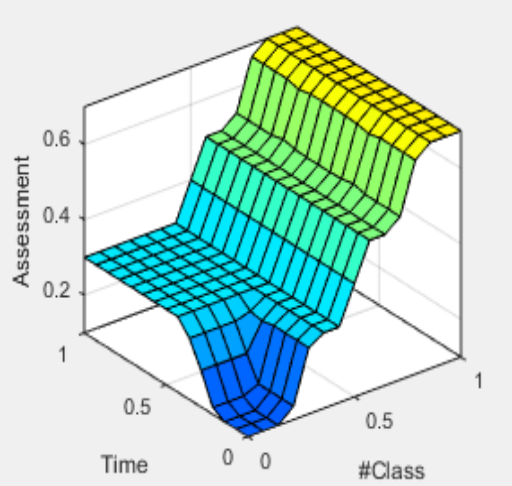

Fig. 9 Surface Viewer of Continuous Assessment.

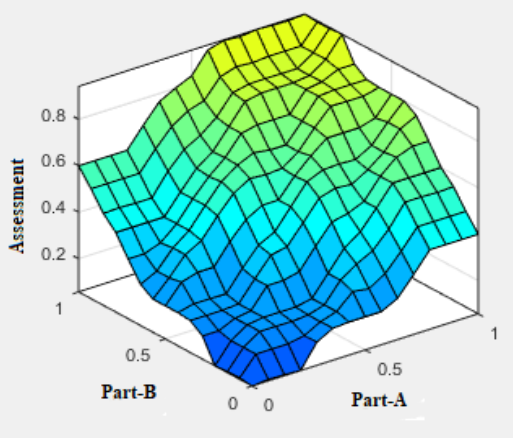

Fig. 10 Surface Viewer of Exam Papers Assessment.

TABLE VII: RESULT CHANGES BY EXISTING METHOD AND PROPOSED METHOD

Subject	# Total Students	Result Upgraded than Classical Method	Result Degraded than Classical Method	Total Changed
1	60	9	5	14
2	60	13	3	16
3	60	10	11	21
4	60	13	6	19
5	60	3	5	8

TABLE VII shows the changes in result for proposed method against existing method. Approximately, in average 16 students result is changed out of 60 in the proposed method but number of upgradation and degradation in results are varied subject to subject.

IV. CONCLUSION

A fair and unbiased performance evaluation system is needed for promoting education and to achieve learning outcome. Proposed method is very helpful in evaluating subjective types of answer paper. Our system considers many aspects of student's participation, not only grades got on exam marks in a formative way. Proposed system provides a smarter, fairer, transparent way to evaluate student performance. Proposed fuzzy logic centric evaluation method has greater flexibility with associated reliability and fairness while classical method uses a fixed mathematical rule. The method considers the aspect such as time spent on class making it more flexible and fairer than the conventional method which is clearly presented in the comparison TABLE VI. The system is implemented using Fuzzy Logic Toolbox by MATLAB.

***Abstract* - Digital technology has accelerated social networking and brought revolutionary changes. Facebook, YouTube and Twitter are the most popular platforms for social communication, marketing and information distribution. Unhappily, these networks have been invaded by spammers who misuse these online social networking platforms with misinformation, fake news, rumors, malicious links, unsolicited messages, comments etc. Therefore, spam detection in social networks has become a novel framework for distribution of information, sentiments, and news. Our research reflects the current experimental study on spam detection from different textual data. Extensive researches have been done on spam detection field from English texts or other languages. But detection of spam from malicious Bangla text content still needs a lot of attention. In this experimental research, we have used Multinomial Naïve Bayes (MNB) classifier, a supervised machine learning algorithm with feature extraction to detect spam from Bangla text at the sentence level. Our proposed system detects spam on the basis of the polarity of each sentence associated with it. Finally, our experiment shows that the model has an accuracy of 82.44% in detecting spam Bangla text content.**

Keywords— Bangla Text., Multinomial Naïve Bayes classifier, Spam Detection, Social media.

I. INTRODUCTION

Social networking sites are basically represented by Facebook, Twitter, YouTube, and many others. At present, people spend most of their time on social media instead of search engines. Celebrities, public figures, business icons create their social pages for interacting with their users and fans. Unfortunately, malicious behaviors on social media bring troubles to the users. The initial purpose of social networking sites was to facilitate the connection and message sharing. Therefore, people are heavily dependent on online interaction for communication.

The increasing number of users in social networks, along with the trust they inherently have in their virtual profile, makes a propitious environment for the spammers. In fact, reports clearly indicate that the volume of spam over the social network is dramatically increasing year by year [1]. It represents a challenging problem for traditional filtering methods since such messages or links are usually fairly short and normally rife with slangs, idioms, symbols and acronyms that make tokenization a difficult task. Even no strong authentication mechanism is provided by the social networking sites to find out the spammers. There is a crucial need in the society and industry for saving the image and maintaining a healthy environment in social media. Improved accuracy and consistency in text-mining techniques can help us overcome the current problems.

However, spam analysis of Bangla texts is still a new area and there is a scope for improvement. There are 250-300 million Bangla speakers worldwide [16]. With the development of information technology, these native Bangla speakers are now able to use Bangla text in the social networking sites and everyday huge amount of Bangla texts are generated online. As a result, it will be easier to check the polarity i.e. how much positive or negative the sentence is. After analyzing the text pattern, the sentence can be categorized according to the polarity it belongs to.

Most of the researches on Bangla text were performed using news corpus and blogs that were extracted by scrapping the websites [5] [6]. Another source of data is social media where the opinionated texts are shorter in length but are informal, full of grammatical and spelling errors, in mixed languages and characters.

In our approach, we have mainly researched on how we can identify spam from every new generated Bangla sentences. Our textual data were collected from popular Facebook groups and pages e.g. ‘’Sakib Al Hasan”, “Hero Alom”, “Prothom Alo” etc. and YouTube videos of the viral YouTube channel “Hero Alom OFFICIAL”. The spammers were also attracted by these groups and video posts for their unethical interactions. They put their malicious links or spam texts which degrades normal user’s experience. So, we have collected open source data from these platforms and applied Multinomial Naïve Bayes classifier algorithm for spam detection from Bangla texts.

II. RELATED WORK

The increasing popularity and the vast amount of information residing on social network attracts researchers to study issue faced by the social network user community. A large proportion of work has been done on various problems e.g. spam detection and filtering, community detection, and information diffusion. Spam emails are classified [2] using four different classification techniques (Naive Bayes, SMO, J48, and random forest). The evaluation showed that random forest has the highest weighted precision, the highest weighted recall, the highest accuracy, and the highest weighted F-measure of 95.50%. A semi-supervised spam detection framework named S^3D was proposed in [3]. S^3D employs four lightweight detectors to detect spam tweets in

real time. In [4], authors proposed a spam detection approach for Twitter based on sentiments using five classifiers i.e. Naive Bayes, Random Forest, Support Vector Machine (SVM), J48 and Random Forest. Multinomial Naive Bayes has been used in [5] based on features selection method (Mutual Information) for sentiment analysis on both Bangla and English dataset. The experimental result shows that the accuracy of English dataset differs from the Bangla dataset of the proposed approach. A lexicon based backtracking approach was proposed to detect emotion from Bengali text [6]. Two basic emotion, 'happiness' and 'sadness' are considered to detect emotion from Bengali text and the experimental result shows that the proposed system can produce an accuracy of 77.16%. Houshmand Shirani-Mehr [7] applied several machine learning algorithm on an SMS spam dataset from UCI Machine learning repository where the evaluation showed that 10-fold cross-validation showed the best accuracy in their work. A new supervised machine learning approach has been introduced in [8] to detect spam accounts in social networks through their behavioral characteristics. They collected messages crawling from Sina Weibo and then selected three categories of features extracted from message contents, social interactions, and user profile properties and applied the ELM based spam accounts detection algorithm. To improve the performance of detecting spam SMS, a new content-based feature was implemented in [9]. The effectiveness of the proposed features is validated using several classification methods and the results demonstrate that the proposed system can improve the performance of SMS spam detection. Moreover, authors in [10] proposed a scalable and online social media spam detection system for social network security. For dealing with the scalability and real-time detection challenges, they implemented GAD clustering algorithm for large scale clustering and integrated it with the designed active learning algorithm. Another approach is presented in [11] who explored the four supervised learning Methods, namely Decision Tree, KNN, Naïve Bays, and Support Vector Machine (SVM) for categorization of Bangla web documents. An experiment has been adopted in [12] which emulates incremental training of personalized spam filters. Several classification algorithms were applied in [13] e.g. Logistic Regression, Boosted Tree and SVM to classify sentiment (Negative or Positive) of Bengali newspaper headline and Support Vector Machine (SVM) performs better having higher accuracy. In [14], a text processing approach for semantic analysis and context detection is proposed. They evaluated their approach with a public, real and non-encoded dataset along with several established machine learning methods which can enhance instant messaging and SMS spam filtering.

III. RESEARCH METHODOLOGY

It is mandatory to prepare a convenient dataset for training and testing before applying a classification algorithm. Pre-processing and features extraction of Bangla documents are also prerequisite for the construction of a model for efficacious classification. Figure 1 illustrates the overall system of the classification process.

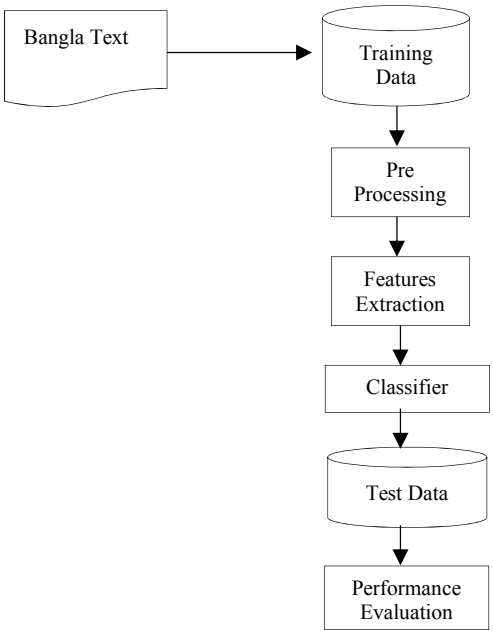

Figure 1. Proposed system of the classification process

A. *Proposed Dataset*

As no dataset is available for research purpose in terms of Bangla language, we have used some comment extractor tools e.g. "socialfy", "ytcomments" etc. to extract data from social platforms e.g. Facebook and YouTube. These social networking platforms have higher interactions of the users and vast amount of contents are posted every single day. We have accessed only public data from random users. Our proposed dataset consists of a wide variety of 1965 instances including 646 spam and 1319 ham. The percentage in dataset is given in the following table.

TABLE I. THE DISTRIBUTION OF HAM AND SPAM IN DATASET

Instances	**Percentage in Dataset**
Spam(1)	32.87
Ham(0)	67.13

B. *Pre-Processing*

A proper representation of words within the text document is important to achieve satisfactory classification performance. To train our model, it requires tagged data. We have formatted our dataset into two columns i.e. One is "Text" that contains actual text data and the other is "Status" that contains value 0 or 1. Spam text was labeled as "1", and non-spam was labeled as "0". It's recommended to apply a classification algorithm on cleaned corpus instead of noisy corpus. The noisy corpus includes insignificant things within the text e.g. misspelling, numerical values, emoticon, stop words e.g. ',', '!', '?', '.', '.', '~', '||', 'ı' etc. They degrade the processing which provides a low accuracy rate. Elimination of these entities from corpus will enhance the accuracy. For example – emoticon like ":-P", ":-D" etc. are meaningful while sentiment analysis but may not be meaningful while

other classification. After elimination of all the punctuation marks, numerical values, and emoticons, we have a clean dataset to fit into a classification algorithm.

C. Feature Extraction

After the pre-processing phase, we have to extract features from these words prior to applying the algorithm. Different statistical approaches can be used to extract features from this text corpus e.g. Count Vectorizer, TF-IDF (term frequency–inverse document frequency) vectorizer etc. Count vectorizer only counts the frequency of each word. We used TF-IDF vectorizer to extract the features from the document because it provides a way to score the importance of word based on how frequently they appear across multiple documents.

- If a word appears frequently within a document, give that word higher score.
- If a word appears frequently across multiple documents, that means it's not unique identifiers, give that lower score.

That is how, a common word e.g. "আমি", "তুমি", "ও", "এবং" that frequently appears across many documents, will be scaled down and word that appears frequently within a single document, will be scaled up. This will lead towards a better classification performance. The weight for a term 'i' in terms of TF-IDF is given by

$$W_i = \frac{(\mathrm{TF_i} \times \log(\mathrm{N}/\mathrm{n_i}))}{\sqrt{\sum_{i=1}^{n} (\mathrm{TF_i} \times \log(\mathrm{N}/\mathrm{n_i}))^2}}$$

Where N= total number of documents and n_i= document frequency of term 'i'.

D. Training

In this section, the processed data are split into a testing-set and a training-set. The 80/20 split is chosen. This research implements the algorithm called Naive Bayes Classifier which is widely used for spam detection. When dealing with text, it's very common to treat each unique word as a feature and since the typical person's vocabulary consist of numerous thousands of words, it produces a huge number of features. The simplicity of the algorithm and the capability of handling a large number of features makes Naïve Bayes Classifier a strong performer for classifying texts. It becomes a huge challenge regarding which variant of Naïve Bayes should be applied. It has been shown experimentally in [15] that Multinomial Naïve Bayes performs better than the Bernoulli Naïve Bayes and Gaussian naive Bayes in case of text classification. Multinomial naive Bayes treats features as event probabilities. Multinomial Naïve Bayes classifier are applied on the proposed dataset.

IV. EXPERIMENTAL RESULTS

After training, using training dataset, it's time to test our dataset using test set that is unknown to our model. From results, Multinomial Naive Bayes yields an overall accuracy of 82.44%. The confusion matrix is shown as follows in the following table.

TABLE II. CONFUSION MATRIX

	Predicted Ham	Predicted Spam
Actual Ham	269	11
Actual Spam	58	55

Test results after performing the tests have been pictured in the following figures.

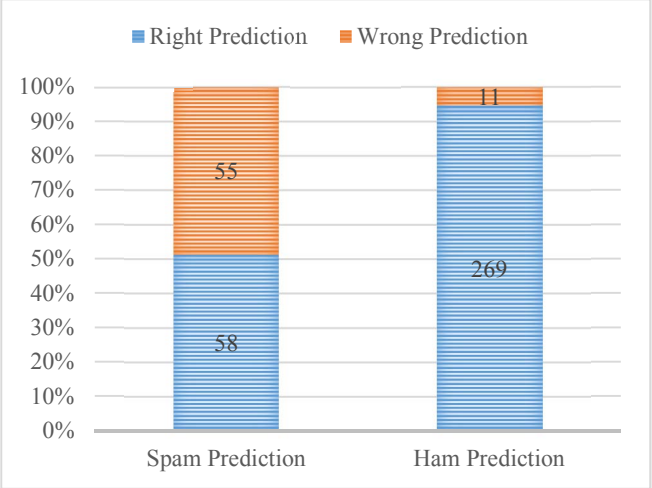

Figure 1. Confusion Matrix in Bar Chart

This chart shows the performance of the classifier in case of both spam and ham prediction. The accuracy of the ham prediction is higher than the spam prediction as the corpus has more ham compared to spam. So, the overall accuracy is satisfactory.

Error, Precision, Recall, F1 Score, AUC (Area Under Curve) are shown in the following table.

TABLE III. PERFORMANCE MEASURE

Precision	0.825
Recall	0.824
F-Score	0.808
Error	17.56
AUC (Area Under Curve)	0.72

In the testing phase, precision: 0.825 determines that 82.5% of positive prediction is actually correct. The recall: 0.824 indicates that 82.4% of actual positive was predicted correctly. F-score; the weighted average of precision and recall is 0.808.

The ROC is shown in the following figure.

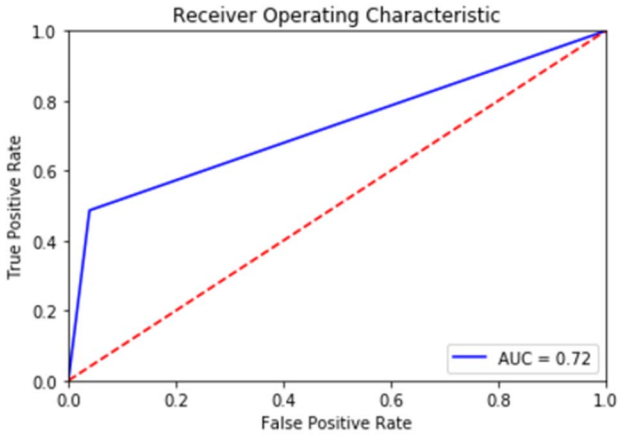

Figure 4. The ROC (Receiver Operating Characteristics) Curve.

V. CONCLUSION AND FUTURE WORK

During the last few decades, text classification has received an incredible attention from people because it helps to classify spam data and threats. Therefore, a lot of work has been done in this domain to find the finest classifier for text classification. Our text classification method helps us to detect exact expression that majority people think about. Among different approaches, we used Multinomial Naïve Bayes classification algorithm to extract semantic information from textual data for detecting spam. After extensive pre-processing, Multinomial Naïve Bayes was applied and it turned out to be 82.44 % successful in classifying malicious Bangla text content at the sentence level.

Besides, we also acknowledge that our corpus doesn't have sufficient lexicons and the mechanisms of feature extraction may be low in future. As every day, new data are generated through social media, a collection of sentences having new patterns is necessary to enrich the corpus. Further research on using combined-classifiers may increase the accuracy rate in future. Moreover, a stemmer may be added to reduce the size of the corpus and improve model performance.

***Abstract*— This paper demonstrates question classification for Bengali language questions which is the first step towards developing a closed domain based Bengali factoid question answering system. Question classification is an influential step towards a question answering system on which the performance of the whole system depends. We have used machine learning algorithms Stochastic Gradient Descent(SGD), Decision Tree(DT), Support Vector Machine(SVM) and Naive Bayes(NB) for the question classification process where Support Vector Machine(SVM) with linear kernel performs the best providing the accuracy 90.6% over five coarse-grained categories.**

***Index Terms*— Question Classification, Bengali Question Classification, Question Answering System, Factoid Question Answering System, Answer Type.**

I. INTRODUCTION

Bengali is the eighth most spoken language in the world. In Bangladesh Bengali is spoken as the primary language and is the second most commonly spoken language in India. About 242 million native and 261 million people in total all over the world speak in Bengali. But still compared to English the work in computational linguistic with Bengali language is yet very low. There is no automated question answering system in Bengali which will reply to our queries by processing the Bengali Language. Towards developing a question answering system question classification is an important first step [1].

Question classification is the process of classifying questions to predefined classes where the classes reflect the answer type of the respective questions. For example for the question "Where was Rabindranath Tagore born?", the task of question classification is to add the label "Location" to this question as the expected answer is of "Location" type.

A question answering system provides the most pertinent answer to a question asked in natural language which is to be found from a large set of documents. As the number of documents from which the answer is to be extracted is huge, it is difficult to find the most relevant one. But question classification makes the task easier as knowing the expected answer type of a question reduces the search space by a considerable amount [2]. Therefore a well performing question classifier algorithm makes the path easy to an efficient question answering system.

II. RELATED WORKS

A lot of work have been done and are also being done on question classification for different language questions. Besides there are also works on question features and question type taxonomy which is the set of classes to which the questions are to be classified. In QA system there are basically two different ways for the question classification process which are rule-based approach and machine learning approach. There are also researches where hybrid approaches have been used which integrates both the rule-based approach and the machine learning based approach [3][4].

The early approaches to question classification were mostly rule-based where many handcrafted rules were used for classifying the questions to their expected answer type. MULDER, a QA system determines the type of the question just by looking into the question's interrogative pronoun [5]. Author's used the object of the verb in the question to determine the type. 276 handcrafted rules were written by Authors Hermjakob et al., 2001 for question classification where there were 122 classes for the questions to be classified in [6].

In the machine learning approach features are extracted from the questions to classify them. Author's Zhang et. al., 2003 experimented question classification with five machine learning algorithms: Nearest Neighbors (NN), Naïve Bayes (NB), Decision Tree (DT), Sparse Network of Winnows (SNoW), and Support Vector Machines (SVM) using two kinds of features: bag-of-words and bag-of-ngrams where SVM outperforms the other four methods giving the highest accuracy 87.4% for both the features [7]. Another machine learning based approach was made by author's Hacioglu et. al., 2003 using Support Vector Machines and Error Correcting Codes which provides with highest accuracy 82% [8]. A question classification system based on Sparse

Network of Winnows (SNoW) architecture was developed by author's Li et. al., 2002 [9]. A collection of semantic and syntactic features were used for the system and it shows an accuracy of 91.0% on general coarse-grained question types and 84.20% on more specific fine-grained types.

Although the task of question classification is difficult in Bengali, there have been some works done. Author's Banerjee et. al., 2012 have studied suitable lexical, syntactic and semantic features to classify Bengali questions and used machine learning classifiers Naïve Bayes (NB), Kernel Naïve Bayes (KNB), Rule Induction and Decision Tree where the highest accuracy 87.63% was provided by Decision Tree [1]. Bengali question classification using Support Vector Machine(SVM) with hybrid feature extraction method was done by a team which provides an accuracy of 89.14% [10]. Word/Phrase based answer type classification for Bengali question answering system has been done by Islam et. al., 2016 [11]. Authors used stochastic gradient descent (SGD) classifier method and bi-gram and stop words for feature extraction. The system based on stochastic gradient descent (SGD) classifier provides average precision 0.95562 for coarse and 0.87646 for finer classes.

III. CORPUS CONSTRUCTION & ANALYSIS

Dataset is an important issue towards developing a question answering system. As we are working on a closed domain based Bengali factoid question answering system on the domain Shahjalal University of Science & Technology (SUST) we could not get any prepared dataset for our work. So we had to manually prepare our questions. This data collection task was one of the challenging tasks as we had no resource available. Table I shows some sample question from our corpus.

TABLE I
Sample factoid questions on SUST

Sample Question
সাস্টে সব মিলিয়ে সিট সংখ্যা কত?
শাহজালাল বিজ্ঞান ও প্রযুক্তি বিশ্ববিদ্যালয়ে অনুষদ কয়টি?
সাস্টের বর্তমান উপাচার্যের নাম কি?
শাবিপ্রবিতে একাডেমিক কার্যক্রম বছরে কয়টি সেমিস্টারে হয়?
সাস্টে কয়টি বিভাগ রয়েছে?

We used different sources for our data collection part. We used various sources for building question dataset such as crowd sourcing, social media, manual generation etc. But among them, we collected most of the data from crowd sourcing. We collected questions from the students of Shahjalal University of Science & Technology as well as from the official website of SUST where we got the frequently asked questions by the candidates. We also prepared questions from different documents, articles and news on SUST. Table III shows the statistics of our question database.

TABLE II
Sources of Question Database

Type	Source	Amount of Data
Crowd Sourcing	2nd Year students, Dept of CSE,SUST	11300
Social Media Data Crawling	Facebook Group: SUST Admission Aid, SUST Admission Help etc.	1055
Manual Generation	Authors	3000

TABLE III
Statistics of Question Database

Attribute	Description
Question type	Factoid
Total number of questions	15355
Avg. words carried by a question	6
Avg. characters carried by a word	5

IV. METHODOLOGY

A. Answer Type Taxonomy

Because we are working on the domain Shahjalal University of Science & Technology we defined five coarse-grained classes related to SUST for the question classification process. The questions are classified in these five categories. Table IV shows the category details and table V shows some sample tagged question in our corpus.

TABLE IV
Question Categories

Class Name	Short form	Description
Administration	ADS	Questions that require administrative information as answer are of ADS type
Admission	ADM	Questions that require admission related information as answer are of ADM type
Academic	ACD	Questions that require academic information as answer are of ACD type
Campus	CAM	Questions that require campus related information are of CAM type
Miscellaneous	MISC	Questions that require information other than the above four types as answer are of MISC type

TABLE V
Sample Tagged Question

Question	Label
সাস্টে মোট কতজনকে ভর্তি পরীক্ষার সুযোগ দেওয়া হয়	ADM
সিএসই বিভাগ হতে স্কলারশিপ পাওয়া যায় কি	ACD
সাস্ট মানে কি	MISC
প্রতিবর্ষে কি আলাদা পরীক্ষা ফি দিতে হয়	ADS
সাস্টের আয়তন কত	CAM

Our question dataset contains 15355 Bengali questions in total related to SUST. Among them most of them are of administration type which is they require administrative information. Figure 1 reflects the percentage of questions in each of the five categories that we defined for our system.

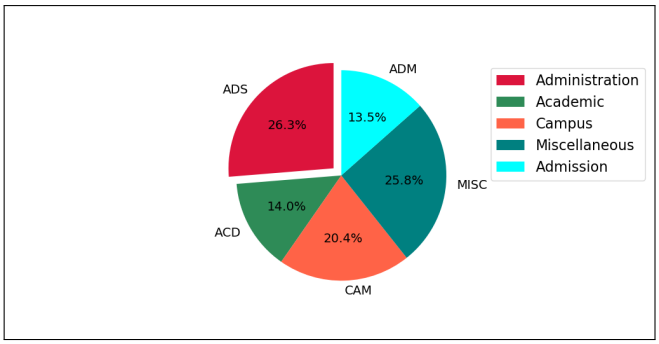

Fig. 1. Percentage of Questions in each category

B. Feature Extraction

The selection of features is an important part for the question classification process and all classification tasks.There are many features that are used for detecting the answer type of a question. Some of the features that are used frequently are lexical features, named entities, parts-of-speech tags, wh-words, semantic features etc. We used the following features for our question classification process:

1) Word level n-gram: A question Q can be written as the following expression.

$$Q_k = W_1, W_1, W_3, ..., W_n$$

where Q_k is any question and $W_1, W_1, W_3, ..., W_n$ represents consecutive words of that question. This successive words or n-gram is important for question classification process as questions of same class is likely to share word n-grams.

For our classification process for feature extraction we experimented with both bi-gram and tri-gram method where tri-gram provides better results than bi-gram.

2) Similar words: Another feature that we have used are words that carry the same meaning. We have mapped a word to words that carry the same meaning. This mapping makes it easy to determine the questions of the same meaning.

TABLE VI
Sample Similar Words

Similar Words
লাইব্রেরী, গ্রন্থাগার, পাঠাগার
ভিসি , উপাচার্য , ভাইস-চান্সেলর
⋮
শাবি, শাবিপ্রবি, শাহজালাল বিশ্ববিদ্যালয়, শাহজালাল বিজ্ঞান ও প্রযুক্তি বিশ্ববিদ্যালয় , সাস্ট

C. Classification Algorithms

We have done the question classification using machine learning based approaches. We used four machine learning algorithms Stochastic Gradient Descent(SGD), Decision Tree(DT), Support Vector Machine(SVM) and Naive Bayes(NB) where Support Vector Machine(SVM) outperforms the other three classifiers. The Stochastic Gradient Descent(SGD) classifier also shows better performance over our dataset.

D. Performance Metric

In general to evaluate the performance of a question classifier the accuracy measure is used. Accuracy is the number of correct predictions made by a model over all kinds of predictions made. Some other measures are precision, recall, f1 score which are also used for performance evaluation. We used the accuracy measure to evaluate our experiments. The accuracy is measured by the formula

$$Accuracy = \frac{TP + TN}{P + N}$$

where,

P = total number of positive samples

N = total number of negative samples

TP (True Positive) = number of cases when the actual class of the sample is true and the predicted is also true

TN (True Negative) = number of cases when the actual class of the data point is false and the predicted is also false

V. EXPERIMENTS & RESULT ANALYSIS

For the training purpose of the question classification stage we had to manually classify the questions of our dataset to predefined classes. We have used 75% of the question dataset for the training purpose and 25% for testing.

In our experiment we have used both bi-gram and tri-gram along with the feature similarity or similar words for feature extraction. We used the classifier algorithms Stochastic Gradient Descent(SGD), Decision Tree(DT), Support Vector Machine(SVM) and Naive Bayes(NB) for the question classification process where in both the cases Support Vector Machine(SVM) with linear kernel performs the best. As Support Vector Machine methodology works by pairing with kernel trick, so using fine tune of the kernel we probably have a better result. Again, we have used only five classes and that is one of the key reasons of showing better accuracy according to this work [7]. Though our classes are different but we have worked on a single domain which also holds a significance in accuracy.

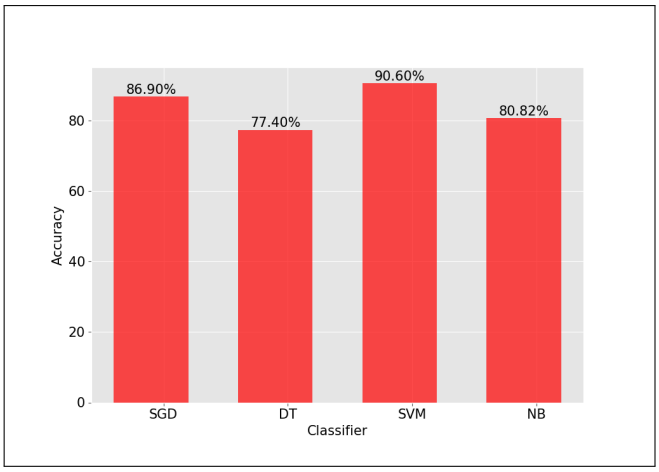

Fig. 2. Best performance for different classifier

We have experimented Support Vector Machine(SVM) with linear, rbf, sigmoid and polynomial kernels where linear kernel provides the best performance.

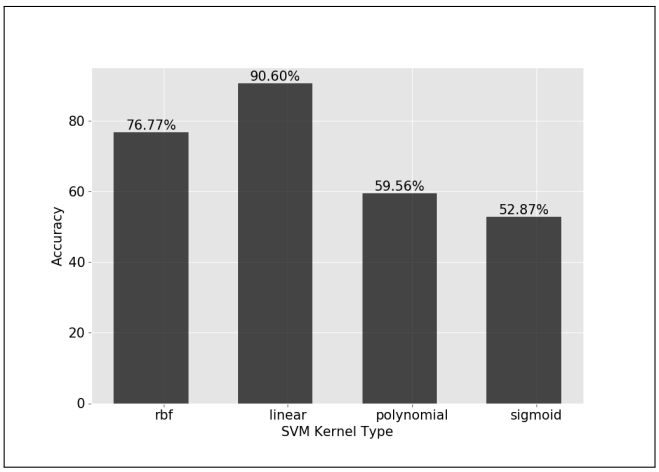

Fig. 3. Best performance for different SVM kernels

We have experimented with both bi-gram and tri-gram for feature extraction and for all the classifiers that we used for question classification process tri-gram gives better accuracy than bi-gram. The following graph shows the comparison between bi-gram and tri-gram for the classifiers.

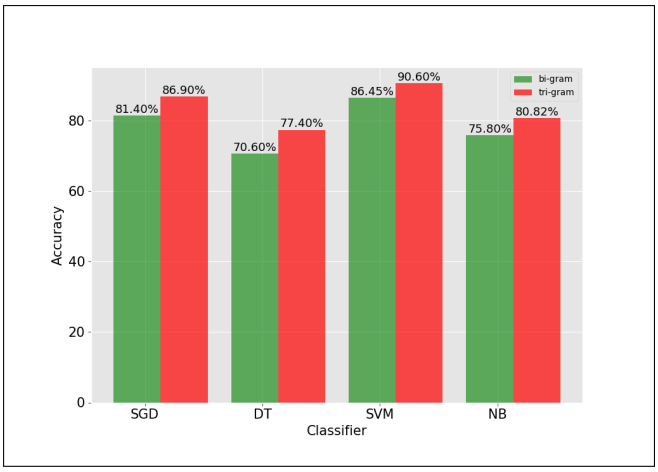

Fig. 4. Performance comparison for different classifier using bi-gram and tri-gram

VI. CONCLUSION

In this paper we have presented an approach for question classification towards building a factoid question answering system for Bengali language on a closed domain. We have built a corpus consisting of 15355 questions on the domain Shahjalal University of Science & Technology and used machine learning classifiers for the classification process over our dataset. As for Bengali language no standard dataset is yet available this can be helpful for the researchers in this field. Natural language processing(NLP) tools like named entity recognizer(NER) can help to enhance the performance of the classification process as the question classification phase plays a vital role in the performance of answer extraction in question answering system.

So far we have done the work for factoid questions only. We have future plans to work for complex and descriptive questions also and also want to implement more techniques to enhance the performance of the classification process.

***Abstract*—Support Vector Machine (SVM) is one of the most popular supervised learning methods for its better performances over diversified applications. SVM constructs a maximum-margin hyperplane and predicts the class of a new incoming data point based on that hyperplane. However, the hyperplane may not give a reliable decision in some cases specially when the training data is imprecise and noisy. To improve this situation, we propose an evidence based binary SVM classifier (EbSVM) where we first identify the sources of information (SoI) and propose a method to generate mass value from these SoIs. Finally, we combine these mass values using DS theory of evidence. An experiment over six benchmark datasets illustrates that EbSVM significantly performs better than the existing state-of-the-art methods.**

***Index Terms*—SVM, Belief, Evidential, Mass value**

I. Introduction

Machine learning is an area of artificial intelligence that mainly focuses on data analysis and interpretation of data to enable learning, reasoning and decision making. In machine learning, supervised learning approaches are commonly used for classification and categorization of data. A significant amount of research on supervised learning has been conducted to obtain an accurate classification. Many supervised learning algorithms such as K-Nearest Neighbors (KNN) [1], Decision Tree (DT) [2], Support Vector Machine (SVM) [3] and Naive Bayes (NB) [4] have been developed in this regard.

One of the simplest but most successful method is NB classifier. But for small amount data, it often assumes equi-probable priors and may fail in many cases. On the other hand, classifiers like KNN, DT and SVM do not assume any priors. Performances of all of these classifiers degrade when samples are located in highly overlapping area or the samples are noisy. To deal with these situations, various theories, such as fuzzy set theory [5], [6], imprecise probability theory [7], Dempster-Shafer (DS) theory of evidence [8], possibility theory [9], are used to build learning algorithms. Among them, DS theory of evidence is very popular. Different aspects of uncertainty are clearly distinguished by DS theory of evidence. As it is difficult to classify uncertain and imprecise data correctly to specific classes, DS theory of evidence allows one to assign mass values for meta classes for datapoints. Decisions are made using these mass values. DS theory of evidence is briefly described in section II-B.

SVM is considered to be one of the most successful and theoretically sound supervised learning methods. A brief descriptions on SVM is given in section II-A. A binary SVM classifies new datapoints based on which side of a hyperplane the datapoint is located. SVM finds the hyperplane that reduces the classification error, while having a maximum margin between the classes. However, SVM does not assign class-wise probability of that datapoint. Providing probabilistic outputs is necessary when they are used as a part of an overall decision making process. In [10], Platt presents a method (PSVM) which estimates probabilistic outputs for SVM. To estimate the probabilistic outputs, all the training points are projected on the kernel space and the perpendicular distance for each training point from the hyperplane is measured. Then a logistic regression is performed on these distances to extract probabilities. The class probability of a new input pattern x_i is thus calculated using (1).

$$\Pr(y = 1|x_i) = \frac{1}{1 + \exp(Af(x_i) + B)} \tag{1}$$

where, A and B are estimated by minimizing the negative log-likelihood function of the training data, $f(x)$ is the perpendicular distance of x from the maximum margin hyperplane, and $y \in \{1, -1\}$. Based on the distance from the hyperplane, a single probability is obtained in this case. As an extension to this classical probabilistic calibration method, an evidential calibration of binary SVM (EcSVM) is proposed [11]. In EcSVM, instead of estimating class membership probabilities, a mass function is estimated. This method better represents the uncertainty using the calibration procedure when less training data are available.

However, the aforementioned calibration methods do not take into account the density of the datapoints on either side of the hyperplane and the closeness of these datapoints to the test datapoint. For example, in Fig. 1, there are two test points named x_p and x_q, and situated in the same side of the separating hyperplane. So, SVM classifies both points as Class-1. Again as the distances to the hyperplane for both points are same, PSVM will assign the same probability to these two points. However, from Fig. 1 we observe that, x_p is more closer to the data points of Class-2 than the points of Class-1, whereas x_q is more closer to the data points of Class-1. Therefore, intuitively x_q should obtain higher probability (or mass value in the evidential case) for belonging to Class-1 than x_p. We need to consider this case and find a way so that

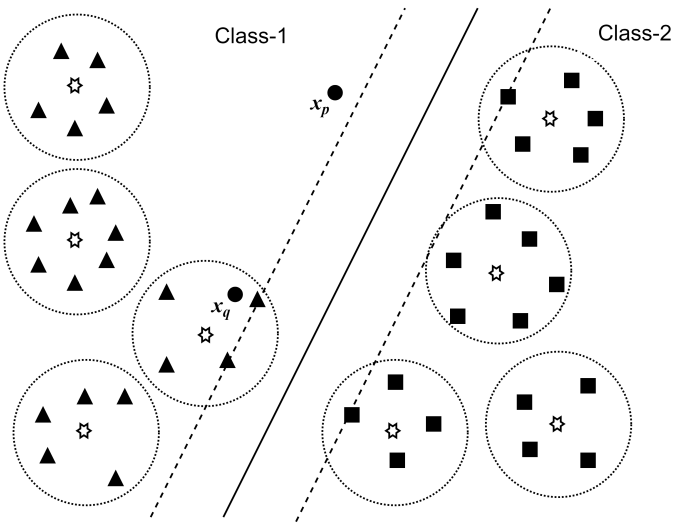

Fig. 1. Overview of plotting data points of binary classes where ▲ represents points belonging to Class-1, ■ represents points belonging to Class-2, • represents the test points, dotted lines represent the marginal hyperplane, the solid line represents the separating hyperplane of SVM.

x_q will be more probable for Class-1 than x_p which satisfies the intuition.

In recent years, many approaches using DS theory of evidence have been developed to estimate mass values [12]–[15]. In this paper, we propose a mechanism of generating mass values based on the different source of information (SoIs) provided by the SVM which also satisfies our above mentioned intuitions. These multiple evidences from these SoIs may provide more reliable estimates of the mass value. Our main contributions in this paper are as follows:

- Firstly, we propose a method to find multiple SoIs from the information provided by SVM.
- Secondly, we propose the mechanism of combining the evidences provided by SoIs to generate the mass value.
- Thirdly, we propose evidential SVM for binary classification and examine its performance on benchmark datasets.

The rest of the paper is organized as follows. In section II, we give an overview of the methods that are required to understand our proposed method. Our proposed method is discussed in section III. In section IV, we present experiments that we performed to validate the performance of our proposed method. Finally, we conclude and discuss our future work in section V.

II. Preliminaries

To understand our approach, the knowledge about SVM, DS theory of evidence, and K-means clustering is important and these methods are briefly discussed here.

A. Support Vector Machine

Let, consider a binary classification problem with features $X = \{x_1, x_2, ..., x_n\}$ and labels $\theta = \{\theta_1, \theta_2, ..., \theta_n\}$. A training set of n data points can be derived as $\{(x_i, \theta_i)\}$ where $x_i \in \mathbb{R}^l$ (l-dimensional feature vectors) and $\theta_i \in \{1, -1\}$ (for $i = 1, 2, ..., n$). SVM finds the maximum-margin *hyperplane* that separates the group of points into two classes [3]. The hyperplane can be described using (2).

$$\sum_{i=1}^{n} \alpha_i \theta_i \kappa(x, x_i) + b = 0 \tag{2}$$

where, α_i ($0 \leq \alpha_i \leq C$ for $i = 1, 2, ..., n$ and C represents the trade-off between margin and misclassification error) are positive constants, $\kappa(x, x_i)$ is a symmetric positive definite kernel function and b is bias.

For linear SVM, $\kappa(x, x_i) = x_i^T x$ is used. So, the weight vector, w, can be expressed as $w = \sum_{i=1}^{n} \alpha_i \theta_i x_i$ and the hyperplane for (2) can be represented by (3).

$$w^T x + b = 0 \tag{3}$$

A decision function, $f(x) = \text{sgn}(w^T x + b)$, is a scalar function of an input feature vector, x. A new incoming feature vector will be classified according to the sign of the decision function that can be described using (4).

$$f(x) = \begin{cases} -1 & \text{if } w^T x + b < 0 \\ 1 & \text{otherwise.} \end{cases} \tag{4}$$

B. DS Theory of evidence

Let, Θ is a finite set, which is called the *frame of discernment* [8]. It is assumed that, Θ is a set of mutually exclusive and collectively exhaustive hypotheses. A number in the range [0, 1] is used to indicate the belief in a hypothesis based on a piece of evidence. This belief is the degree to which the evidence supports the hypothesis. The power set of Θ is 2^Θ. A basic belief assignment (BBA) is a function $m : 2^\Theta \rightarrow [0, 1]$ which satisfies the following properties:

$$m(\emptyset) = 0 \tag{5}$$

$$\sum_{A \subseteq \Theta} m(A) = 1 \tag{6}$$

where, $m(A)$ is the quantity, which can be called mass value, represents the belief reflecting how strongly A is supported. The mass value assigned to Θ is called the degree of ignorance and the subsets A of Θ with non-zero mass values are called the focal elements.

Several pieces of evidence can be characterized by different BBAs. These different BBAs can be combined using Dempster's rule of combination. The Dempster's rule of combination from two BBAs $m_1(.)$ and $m_2(.)$ can be expressed using (7).

$$m(A) = \frac{\sum_{B \cap C = A} m_1(B) m_2(C)}{1 - K} \quad A \neq \emptyset \tag{7}$$

where, $A, B, C \in 2^{\Theta}$ and $K = \sum_{B \cap C = \emptyset} m_1(B) m_2(C)$ which is the degree of conflict.

The lower and upper probabilities of A usually interpret as belief $Bel(A)$ and the plausibility $Pl(A)$ [8]. These are two common evidential measures which are mathematically defined in (8) and (9).

$$Bel(A) = \sum_{B \subseteq A} m(B) \tag{8}$$

$$Pl(A) = \sum_{A \cap B \neq \emptyset} m(B) \tag{9}$$

C. K-means clustering

K-means clustering is a process that puts n training data points in an l-dimensional space into K clusters [16], [17]. Each of the clusters can be parameterized by its mean (mc). The algorithm consists of two steps namely *assignment step* and *mean update step*. At first, the means of K clusters are initialized with random values. In the *assignment step*, each training data point is assigned to the nearest cluster mean. In the *mean update step*, the cluster means are adjusted by the data points that the clusters contain. The two steps will be continued until all the cluster means remain unchanged after *mean update step*.

III. Evidential SVM for binary classification

EbSVM consists of three steps. First, SoIs are identified and mass values are generated from the SoIs. Then, classification decisions are made using the Bel function. These steps are described in the following subsections and presented in algorithms 1 and 2.

A. Source of Information Generation

SVM gives us support vectors (sv), a weight vector (w) and a bias (b). This weight vector and the bias are used to represent the separating hyperplane. Moreover, we can find two sets of support vectors (sv_+, sv_-) from sv on the basis of two marginal hyperplanes. Data points of a particular class are found in one side of the hyperplane. However, misclassified data points may remain on the other side. To obtain SoIs, we first eliminate these misclassified points. This process is defined in function $ClassifyPoints$ (line 10-25) of Algorithm 1. Applying this function, we get two sets of training data (X_{train+}, X_{train-}).

Another source of information is the clusters of data on either side of the hyperplane. It is usually observed that the density of the data for each class on the either side of the separating hyperplane are not equal. Moreover, there may be several highly dense areas on the either side of the maximum margin hyperplane. We plan to use the distance to high density clusters as SoIs. To capture these dense areas, we apply K-means clustering on X_{train+} and X_{train-} individually. Each cluster from each of the training sets are represented by S_+ and S_- in line 7 of Algorithm 1. In the following discussion, we use the notation S_{ji} for the i-th cluster of the j-th class (θ_j). Note that, for binary classification $\theta_j \in \{+, -\}$.

Algorithm 1: Source of Information Generation

input : Training Data (X_{train}), Training Data Labels (Y_{train}), Regularization Parameter (C), number of clusters (q)

output: List of Positive Support Vectors (sv_+, sv_-), List of cluster means (mc_+, mc_-), Mean distance of Clusters (mcd_+, mcd_-)

1 $svmModel \leftarrow$ Build SVM model with X_{train}, Y_{train}, C
2 $sv \leftarrow$ Get list of support vectors from $svmModel$
3 $w \leftarrow$ Get weight vector from $svmModel$
4 $b \leftarrow$ Get bias or intercept from $svmModel$
5 $(sv_+, sv_-) \leftarrow ClassifyPoints(sv, \emptyset, w, b)$
6 $(X_{train+}, X_{train-}) \leftarrow ClassifyPoints(X_{train}, Y_{train}, w, b)$
7 $(S_+, S_-) \leftarrow$ Apply K-means clustering over X_{train+}, X_{train-} where k=q
8 $(mc_+, mc_-) \leftarrow$ Get cluster means from S_+, S_-
9 $(mcd_+, mcd_-) \leftarrow$ Calculate average distance from cluster mean (mc_+, mc_-) to the points belonging respective cluster using (10)
10 **function** `ClassifyPoints`(X, Y, w, b) **:**
11 Initialize List pts_+ and pts_-
12 **forall** $i \in 1, ...X.length()$ **do**
13 $x = X[i]$
14 $y_{pt} \leftarrow$ Calculate decision using (4)
15 **if** ($Y \neq \emptyset$ *and* $Y_i \neq y_{pt}$) **then**
16 **continue**
17 **end**
18 **if** ($y_{pt} \neq +1$) **then**
19 Insert x to pts_-
20 **else**
21 Insert x to pts_+
22 **end**
23 **end**
24 **return** pts_+, pts_-
25 **end**

We can find two important properties such as cluster mean (mc_{ji}) and density (mcd_{ji}) for each cluster i in class θ_j. Calculation of mean is described in section II. Cluster density is defined by (10). It is easy to see that a smaller value of mcd indicates a denser cluster.

$$mcd_{ji} = \frac{\sum_{x_m \in S_{ji}} |x_m - mc_{ji}|}{\sum_{x_m \in S_{ji}} 1} \tag{10}$$

The process of using these SoIs to generate mass value is described in the next subsection.

B. Mass value Generation

Algorithm 2 presents the mass value generation process. To generate mass value we consider two intuitions. First, a data

Algorithm 2: Mass value Calculation & Decision Making

input : Test data (x_p), number of nearest clusters (k)
output: Predicted class label (Y)

1 $t_+ \leftarrow min$ (all distances from sv_+ to x_p)
2 $t_- \leftarrow min$ (all distances from sv_- to x_p)
3 $smc_+, smcd_+ \leftarrow$ Sort cluster means (mc_+) and avg. distance from cluster mean to the points belonging respective cluster (mcd_+) on the basis of distance from cluster mean and x_p
4 $smc_-, smcd_- \leftarrow$ Sort cluster means (mc_-) and avg. distance from cluster mean to the points belonging respective cluster (mcd_-) on the basis of distance from cluster mean and x_p
5 Initialize a list m of mass values
6 **forall** $i \in \{1, ...k\}$ **do**
7 $d \leftarrow$ Calculate distance from x_p to smc_{+i}
8 $m_{2i-1} \leftarrow$ Generate mass values from using (11), (12), (13), (14) where $t_j = t_+$ and $mcd_{ji} = smcd_{+i}$
9 $d \leftarrow$ Calculate distance from x_p to smc_{-i}
10 $m_{2i} \leftarrow$ Generate mass values from using (11), (12), (13), (14) where $t_j = t_-$ and $mcd_{ji} = smcd_{-i}$
11 **end**
12 $M \leftarrow$ Combine mass values from m using (7)
13 Calculate belief of singleton classes using (8)
14 $Y \leftarrow$ Calculate decision using (15)

point will be more probable to class θ_i than class θ_j when the distances from the k nearest cluster means of class θ_i are less than the distances from the k nearest cluster means of class θ_j. Second, a data point will be more likely to be assigned in class θ_i than class θ_j when the distance from nearest support vector of class θ_i is less than that of class θ_j.

The algorithm 2 proceeds as follows: as new test datapoint x_p arrives, we first find the k nearest clusters ($k \leq q$) from either side of the separating hyperplane. The k nearest clusters of both sides are considered as SoIs. The clusters we have generated in the previous subsection provide us mc_{ji} and mcd_{ji} which will help to generate mass value satisfying the first intuition. Now, suppose that, t_i is the distance of the test data point from the nearest support vector of class θ_i. According to the second intuition, if t_i is less than t_j, then the data point will be more likely to be assigned in class θ_i. Now in line 8 and 10 of algorithm 2, the mass values assigned by cluster S_{ji} computed using (11), (12) and (13) are added to a list m.

$$m(\{\theta_j\}) = \alpha * \Psi_{ji}(d, t_j) \tag{11}$$

$$m(A) = 0 \quad \forall A \in 2^{\Theta} \setminus \{\Theta, \{\theta_j\}\} \tag{12}$$

$$m(\Theta) = 1 - m(\{\theta_j\}) \tag{13}$$

where, $0 < \alpha < 1$ and d represents the distance between the cluster mean mc_{ji}) and the given data point (x_p). In our method, we use function (14) that satisfies the two aforementioned intuitions.

$$\Psi_{ji}(d, t_j) = \exp\left(\frac{-d^2 * t_j}{mcd_{ji}}\right) \tag{14}$$

According to (14), a larger mass value is assigned to θ_j, if x_p is close to both the center of cluster i and nearest sv of class θ_j.

C. Decision Making

For *Decision Making* process, we will combine the mass values from all SoIs using DS theory of evidence. For decision making, we can use belief, plausibility or combined mass value. We assign the given data point to class θ_j when θ_j has the maximum belief value among the singleton classes. The belief and combined mass value are identical for singleton classes. The decision function can be derived in (15).

$$Y = arg \max_{\theta_j} Bel(\theta_j) \tag{15}$$

where $\theta_j \in \Theta$ and θ_j is singleton class.

D. Illustrative Example

Consider the training dataset with 30 datapoints with two features as given in Table I. Fig. 2 presents the dataset and the SoIs to find mass values.

TABLE I
SAMPLE TRAINING DATA FOR EXAMPLE

Training Point	Label	Training Point	Label
(-1.328, 0.035)	-1	(0.408, 1.508)	+1
(-1.051, 0.792)	-1	(1.103, 0.245)	+1
(-1.282, 0.329)	-1	(1.450, 0.792)	+1
(-1.143, 0.456)	-1	(1.566, 0.456)	+1
(-1.259, 0.666)	-1	(1.219, 0.330)	+1
(-1.375, -1.017)	-1	(0.755, -0.386)	+1
(-1.282, -1.311)	-1	(0.871, -1.017)	+1
(-1.236, -1.143)	-1	(1.010, -0.470)	+1
(-1.143, -1.437)	-1	(1.172, -0.470)	+1
(-1.027, -1.227)	-1	(1.265, -0.638)	+1
(-0.194, -0.062)	-1	(0.177, 1.886)	+1
(0.015, -0.933)	-1	(0.640, 1.718)	+1
(-0.448, -0.848)	-1	(0.871, 1.297)	+1
(-0.356, -1.059)	-1	(0.756, 1.129)	+1
(-0.448 -1.101)	-1	(0.293, 1.507)	+1

After applying SVM model (linear kernel with $C = 10$) over the training data, we find a maximum margin hyperplane and list of support vectors sv_+, sv_-.

$sv_+ = \{(0.177, 1.886), (0.871, -1.017)\}$
$sv_- = \{(-0.194, -0.062), (0.015, -0.933)\}$

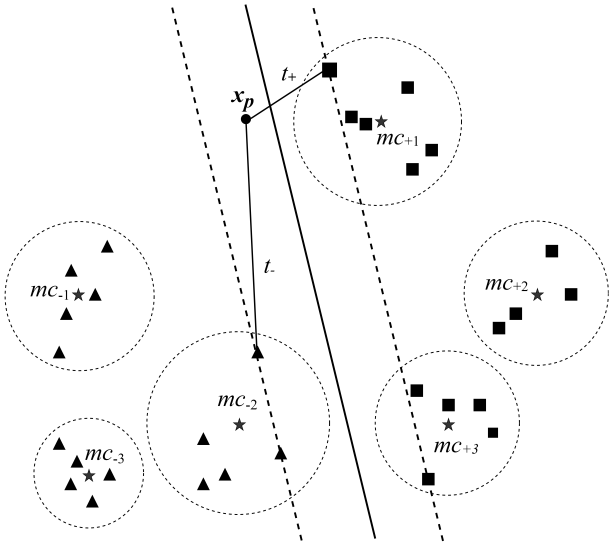

Fig. 2. An illustrative example of plotting data points of binary class problem where ▲ represents point belonging to Class {-1}, ■ represents point belonging to Class {+1}, ● represents test point, solid line represents the separating hyperplane of SVM and marginal hyperplane.

We create 3 clusters in the each side of the hyperplane. mc_+, mc_- represents the cluster means and mcd_+, mcd_- represents the average distance of all the points belonging that cluster from the cluster mean.

$mc_+ = \{(0.524, 1.508), (1.335, 0.456), (1.015, -0.596)\}$

$mc_- = \{(-1.21, 0.46), (-0.286, -0.8), (-1.21, -1.23)\}$

$mcd_+ = \{0.325199, 0.267903, 0.272036\}$

$mcd_- = \{0.247776, 0.370238, 0.173745\}$

When a new test point $x_p = (-0.323, 1.5)$ has come, we find one nearest cluster from each side of the hyperplane and generate mass values from these sources. The mass values from the two sources and combination of the mass values are shown in Table II.

TABLE II
BASIC BELIEF ASSIGNMENT FROM DIFFERENT SOURCE OF INFORMATION

Source	m({+1})	m({-1})	m({+1, -1})
1	0.23572	0.0	0.76428
2	0.0	0.0000006	0.999994
Combined	0.23572	0.000005	0.7642755

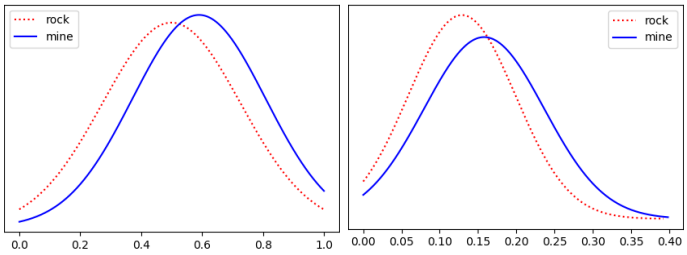
After we have calculated the belief of each singleton class, we get the following values.

$Bel(\{+1\}) = 0.23572$

$Bel(\{-1\}) = 0.000005$

When we apply decision function described in (15), we find a decision that is $Y = \{+1\}$. The test point will belong to class {+1}.

TABLE III
PROPERTIES OF DATASETS USED IN OUR EXPERIMENTS



Dataset	Number of instances	Number of features
Ionosphere	351	34
Madelon	2600	500
Musk	473	165
Parkinsons	195	23
Pima	786	8
Sonar	208	60

IV. EXPERIMENTAL RESULTS AND DISCUSSION

The dataset description, implementation details and a comparison of EbSVM with the state-of-the-art methods along with discussion are given in the following subsections.

A. Dataset Description

Six benchmark datasets are collected from UCI machine learning repository [18]. The characteristics of the datasets are illustrated in Table III. The features of these datasets are real and most of the cases, they are imprecise. For example, if we look at the Sonar dataset, most of the cases, the data distribution of the features are overlapping which are shown in Fig. 3. Features having these characteristics are difficult to classify.

(a) (b)

Fig. 3. Data distribution of Rock and Mine class with respect to (a) feature 20 and (b) feature 8 in $Sonar$ dataset

B. Implementation Details

The performances of EbSVM are compared to that of SVM, EcSVM, PSVM. In our experiment, we standarize the features of the chosen datasets using z standarization (mean is 0 and variance is 1). For all methods in the experiment, we use linear kernel and $C = 1.0$ as generalization parameter. The value of k, q, α are set in this experiment at 3, 15, 0.95 for EbSVM respectively. The average of 10-fold stratified cross validation are used as a performance metric and are reported for all the methods. The standard accuracy measure is used in this experiment. We have also performed paired t-test (at 5% level of significance) to show whether a method shows significantly better compared to other methods in terms of accuracies.

C. Result and Discussion

TABLE IV
COMPARISON OF EBSVM AND THREE OTHER METHODS

Dataset	SVM	EcSVM	PSVM	EbSVM
Ionosphere	86.35	86.61	87.48	**89.18**
Madelon	55.88*	55.80*	55.62*	**62.38**
Musk	87.77	**88.38**	87.13	**88.38**
Parkinsons	83.73*	86.26	84.75	**87.84**
Pima	77.21	**77.35**	77.21	76.43
Sonar	72.68*	73.10*	73.59*	**83.28**
Win/Tie/Loss	5/0/1	4/1/1	5/0/1	-
Sig. Win/Loss	3/0	2/0	2/0	-

* represents that EbSVM wins significantly against that method

In Table IV, accuracies of SVM, EcSVM, PSVM and EbSVM over the selected datasets are shown. We bold face the accuracies of the method which performs better than that of other methods. Besides this, accuracies are marked with asterisk(*) when EbSVM performs significantly better than that method. The second last line of Table IV summarizes Win/Tie/Loss of different methods. Here, Win means EbSVM performs better than that of other method, Tie means EbSVM performs as same as that method and Loss means EbSVM performs worse than that method.

From Table IV, it is clearly observed that, EbSVM outperforms the other state-of-the-art methods. For example, EbSVM wins five times and losses onoy lne time while comparing with SVM. It means that EbSVM obtains better accuracies for five datasets than SVM and worse accuracy for one dataset. In comparison with EcSVM, the average accuracy is same for Musk dataset. From last line of Table IV, we observe that EbSVM performs significantly better for three datasets than SVM, and EbSVM doesn't perform worse at all.

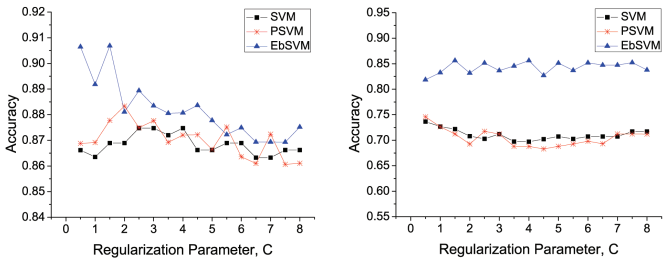


Fig. 4. Influence of regularization parameter, C on accuracy. (a) on $Ionosphere$ dataset; (b) on $Sonar$ dataset

It is easily understandable that, regularization parameter, C can play an influence over accuracy of these classifiers. The influences of choosing this parameter is shown in Fig. 4 for two different datasets namely $Ionosphere$ and $Sonar$. From Fig. 4, it is observable that, EbSVM reasonably performs better compared to SVM and PSVM for different values of C.

V. CONCLUSION

In this work, we present an approach of calculating mass values using SVM. These mass values are used to generate final decision. The solution is intuitive and performs better than the existing state-of-the-art methods over six datasets. However, one important limitation is that the mass value generation process proposed in this paper is defined in ad-hoc manner. A future research direction is to justify this mass value generation process. An extension of EbSVM to multi-class problem can also be considered in future.

***Abstract*—Recently, determining the customer impression is considered one of the prominent factors on the success of the restaurant businesses. Due to the rapid growth of digital contents related to restaurant or foods in the web, people are more inclined on reviews before going to any restaurant so the significance of customer review is inevitable. In order to selects a restaurant customer needs to check thousands of feedback's to understand the restaurant quality or services. Therefore, classification of a significant amount of reviews into a sentimental category is required to attain meaningful insights so that the customer can choose restaurants based on their preferences. This classification can be done by sentiment analysis. This paper proposes a system that can classify customer reviews into positive and negative classes based on their sentimental feedback. We have tested the proposed system with 1000 restaurant reviews text written in Bengali. The experimental result shows that the proposed the system can classify restaurant reviews with 80.48% accuracy using multinomial Naïve Bayes.**

***Keywords*—Bangla language processing, Sentiment analysis, Customer reviews, Machine learning.**

I. Introduction

The amount of people has increased significantly who are taking their foods or meals in restaurants due to rise their financial capability, miscellaneous food habits and improved lifestyle. Therefore, restaurant business have achieved remarkable popularity in recent years. Due to the rapid growth of Internet contents, customers has affinity to check the reviews of a restaurant before visit it. Thus, reviewing a restaurant from text comments become a common scenario.

The key objective of this paper is to build a supervised learning model to categorize the customer's feedback's in terms of positive and negative sentiments which are written in Bengali sentences. Any restaurant with plenty of positive reviews can attain a symbol of faith, ensure quality of foods and services among the customers. Conversely, it is very difficult to attract new customers as well as retain existing customers by a restaurant without positive reviews or feedback. Usually, more positive reviews conveys trustworthiness to customers. Thus, people appreciate the experience of the consumer and consent to others and the review on a restaurant is the only way to comprehend others opinion on the restaurant. Opinions collected from users experiences regarding specific criteria of a restaurant like food quality, environment and service quality, straightforwardly make an impact on the future customer decisions. Likewise, negative reviews often yield disinclination on the customer choices. Therefore, restaurants needs to take into account the customer's feedback for future improvements and attracts much attention of customers. This might totally unusual to check every customer reviews one by one as it requires ample amount of money and innumerable manpower to lead such a surveys. Taking consideration the rapid growth of visitors and users requirements, this imposes a concealment for a system that can understand the attitude of a reviewer comments written in various social media communities or blogs. In that case, a term sentiment analysis come uppermost that aim is to uncover how customer sense about a certain foods.

The sentiment analysis is used to attain a grasp of sentimental note behind the person's reviews. It is also known as opinion mining and it determines whether the sentiment of a person comment is positive, neutral or negative based on their writing. Many researches in sentiment analysis have been done in many languages like Chinese [1][2], Vietnamese [3], Arabic [4], Thai [5], Myanmar [6] and Bengali [7]. Research on Bengali text based opinion mining of restaurant reviews is in rudimentary stage still now. This paper presents an automated system for sentiment analysis of Bengali text for restaurant reviews to classify an opinion into two classes: positive or negative sentiment. Three machine learning algorithms such as decision tree, random forest and multinomial naïve Bayes classifier are implemented to classify the sentiment from Bengali review text.

II. Literature Review

The sentiment analysis of customer reviews has become one of the interested research area. Some of the research work by noted scholars on restaurant reviews on different languages are studied and discussed below. Aye et.al developed a lexicon-based sentiment analysis model in Myanmar text. On their work, the customer reviews on food and restaurant quality was the prime insight for the sentiment analysis. The sentiment classification was done by using a sentiment dictionary which contains a list of sentiment words. Their system successfully distinguished data for the reviews on Myanmar Language at

96% overall accuracy over 500 customers reviews on food and restaurant domain [6].

Kaviya et.al developed a sentiment analysis model where the rating system of a restaurant was done depending upon the user reviews. Their system splits user comments to find sentiment keywords and associates the comment with a sentiment rank. The reviews were categorized into positive and negative class and an overall rating was assigned to the restaurant. The Yelp dataset was taken for the testing of their developed system.

Perera et.al adopted an aspect-based opinion mining for restaurant reviews. The aspect-based mining finds a sentence aspect and the opinion of the users comments on these aspects to make a positive and negative review. SentiWordNet a lexical dictionary was used to determine the positive and negative polarity value for each opinion word. Dependency parser was used for the opinion word extraction. The evaluation of their developed system was done on both manually and systematically. From the comparison of the two approaches they found that their developed system provided a satisfactory accuracy of 70% [8].

Doan et.al developed a sentiment analysis model for customers reviews where a variant of online random forests was taken to perform the analysis. Their proposed model was an ensemble of tree-based classifiers and a portion of the restaurant reviews from the Yelp dataset was taken for the sentiment analysis. For the experiment, they set up an ensemble learning model for 100 trees using Online Random Forests (ORF) and incremental random forest (proposed approach) (iRF). Their model has longer run time than iNB because incremental learning was adopted in their design that induces trees instance by instance [9].

Sarkar et.al developed a Bangla sentiment analysis model where Bengali tweet dataset released for SAIL contest 2015 was used for classification. They used Multinomial Naïve Bayes and SVM classifiers for the classification of sentiment polarity expressed in tweets. N-gram and SentiWordnet features were used as their feature set.Their devleloped model showed that SVM classifier trained with unigram and SentiWordNet features performs best on Bengali tweet dataset [10]. Gan et.al designed a model for restaurant rating based on sentiment analysis. In their work, in addition to food, ambience and service, the overall rating of the restaurant also focuses on the pricing and special contexts but there was no emphasizing done on the scores [11]. Lak et.al developed a model to compare sentiment analysis results with star ratings in three different domains [12]. Xing Fang et.al developed a system for sentiment analysis of product reviews which used the sentiment polarity categorization process. They selected naïve bayesian, support vector machine and random forest classification methods for categorization. For the sentiment polarity classification a sentiment score formula was taken to generate the feature vector for a sentiment and based on this score they performed the sentiment polarity categorization [13]. Lada Banic et. al designed a hotel review mining system using natural language processing and machine learning. Number of negative and positive terms or phrases are used for the generation of cumulative information on the level of final evaluation. A grade from 1 to 5 in which 1 and 5 is referred as bad and excellent respectively was assigned in final evaluation[14]. Singla et.al done sentiment analysis on unstructured data of Mobile phone reviews. They used decision tree, naïve Bayes, SVM, and cross validation for the purpose of classification. Among these classification models they concluded that svm provides highest accuracy in opinion mining of product reviews [15].

III. Dataset Accumulation

Success of any machine learning system heavily depends on the dataset used to train that system. But unfortunately, it is really difficult to build a corpus which contains a large amount of Bangla text reviews on restaurant because there is lack of resources in Bengali language as well as researchers do not publish their dataset. For the purpose of research, Bengali benchmark dataset is not yet published. So an English benchmark dataset have taken [12] and translated into Bengali to build the corpus. Fig.1 shows sample positive and negative restaurant reviews.

	Sample Reviews	Sentiment
English	Preferably hot and spicy chicken fry. Excellent environment and hospitality. I'll give it a rating in the top restaurant in Dhaka.	Positive
Corresponding Bengali	গরম এবং মসলাযুক্ত চিকেন ফ্রাইটা পছন্দনীয়। চমৎকার পরিবেশ এবং আতিথেয়তা। আমি এটিকে ঢাকায় শীর্ষস্থানীয় রেস্তোরাঁর মধ্যে রেটিং দিব।	
English	The grill was cold, the bread was dry and strong, the stock was old ... very bad food ... frustrating ...	Negative
Corresponding Bengali	গ্রিলটা ঠান্ডা ছিল, রুটিও শুকনো এবং শক্ত ছিল, স্টকটা পুরাতন ছিল ... খুবই খারাপ মানের খাবার ... হতাশ...	

Fig. 1. Dataset Sample

Besides, different public pages [16], groups [17][18][19] of Facebook are used to collect data. As most part of the dataset collected manually some negligible inconsistencies may occur in it. Collected text documents are used to train the system which will be used for further classification of reviews. Dataset statistics is summarized in Table I.

TABLE I: Data Summary

	Training set	Testing set
Number of documents	800	200
Number of sentences	2559	628
Number of words	8236	2497
Total unique words	1069	358

IV. Proposed System Framework

Fig. 2 shows an abstract view of proposed system. Different statistical machine learning techniques are used to train the system. The overall framework is divided into three phases: training set preparation, feature extraction and classification respectively.

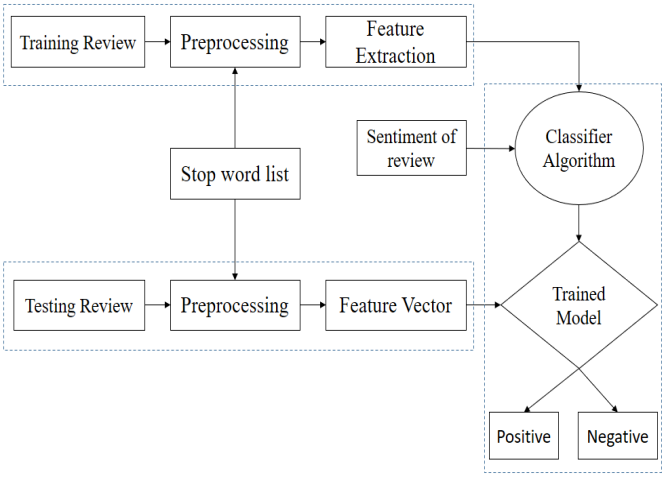

Fig. 2. Proposed System Framework

A. *Training Set Preparation*

Training set $R = \{r_1, r_2, r_3, ..., r_n\}$ consists of n training reviews. Each review either contains positive of negative sentiment where C_p and C_n are used to denote positive and negative class respectively. A review r_i with l words is represented by a word vector $W[] = \{w_1, w_2, w_3, ..., w_l\}$. All reviews are preprocessed to remove inconsistencies from dataset. Punctuation's are also removed in this step. Table II represents word vector$W[i]$ of a random review r_i.

TABLE II: Word vector of a review

r_i	w_1	w_2	w_3	...	w_l

A list $S[] = \{s_1, s_2, s_3, ..., s_t\}$ with t stopwords have been developed to remove the words w_i which has no contribution in deciding whether a review r_i conveys positive (C_p) or negative (C_n) sentiment. Stop words $s_1, s_2, s_3, ..., s_t$ are removed from a review by finding the match from stop word list $S[]$. Conjunctions, prepositions, interjections, pronouns, suffixes and prefixes are considered as stop words.

	Type	Example
s_1	pronoun	সে
s_2	conjunction	এবং
s_3	preposition	থেকে
...	...	...
s_r	interjection	সাবাশ

Fig. 3. Sample stop words

B. *Feature Extraction*

A vocabulary of Bengali words is created by tokenizing reviews of the corpus. "$tfidf$" : the term frequency-inverse document frequency statistic is used as features of the proposed model. Our used "$tfidf$" statistic is,

$$tfidf(w, r) = tf(w, r) \log \frac{N}{|\{r \epsilon R : w \epsilon r\}|} \quad (1)$$

Here,
$tfidf(w, r)$ = value of word w in review r,
$tf(w, r)$ = frequency of word w in review r,
N = total number of reviews,
$|\{r \epsilon R : w \epsilon r\}|$ = number of reviews containing w.

TABLE III: A small fragment of feature matrix

r \ c	w_1	w_2	w_3	w_4	...	w_v
r_1	0.21	0.13	0.20	0.16	...	0.10
r_2	0.18	0.36	0.17	0.21	...	0.31
r_3	0.17	0.13	0.14	0.15	...	0.19
r_4	0.24	0.40	0.48	0.47	...	0.41
...	...	...	...	...	...	...
r_u	0.25	0.32	0.46	0.71	...	0.48

Table III shows the feature matrix of proposed system. Features $(F[][])$ of the reviews are represented by a two dimensional$(U \times V)$ feature matrix. Here, rows represent the reviews $r_1, r_2, r_3, ..., r_u$ and columns represents unique words $w_1, w_2, w_3, ..., w_v$ respectively. Each cell of the feature matrix $(F[][])$ represent the "$tfidf$" value of word w_v occurs in a specific review r_i. Each row represents the feature vectors $F[1], F[2], F[3], ..., F[n]$ for the reviews $r_1, r_2, r_3, ..., r_n$ of the corpus.

C. *Classification*

As, the goal of the proposed system is to classify the reviews thus classification is the most significant part of the system. Extracted features from the reviews are used to train the proposed model that could classifies reviews into positive and negative sentiment. Mainly, the proposed system is implemented by using multinomial naïve bayes.

Multinomial naïve bayes [20] performs really well when multiple occurrences of the words have significant impact in the classification problem. It can be defined by bayes theorem where all the variables $V_1, V_2, V_3, ..., V_n$ in a given class C are conditionally independent with each other given C. Using bayes rule for a text review (R) and class (C),

$$P(R|T) = \frac{P(R|C)P(C)}{P(R)} \quad (2)$$

Final equation,

$$C_{MAP} = argmax P(R_1, R_2, ..., R_n|C)P(C) \quad (3)$$

A **decision tree** [21] has external and internal nodes. Decision classes are represented by external nodes and internal nodes correspond to attribute which are used for making decision. Entropy calculation is used to build a decision tree,

$$E(S) = \sum_{c \epsilon X} P(C)E(C) \tag{4}$$

Random forest is mainly collection of decision trees with some differences. Decision trees make predictions by formulating some set of rules but in random forest algorithm decision trees are built by selecting features randomly and finally acquired results are averaged. But for real time predictions a large number of trees can make this algorithm slow and ineffective.

Trained classifier model is tested with a test set, $TR = \{tr_1, tr_2, tr_3, ..., tr_x\}$ with x test documents. Feature extraction method is used to extract features $(F[][] = F[1], F[2], ..., F[x])$ from the test set TR. Proposed model use these features to classify a review tr_i as positive(C_p) or negative (C_n).

V. Evaluation Measures

A number of statistical and graphical measures have been adopted for evaluating the performance of the proposed system. Statistical measures such as confusion matrix, precision, recall, f_1 score and graphical measures such as precision-recall curve, receiver operating characteristics (ROC) curve have used for the measurement.

- A **confusion matrix** is used for evaluating the performance of a classification model. As the proposed system is designed for binary classification, thus the confusion matrix of the system must have two columns and two rows. This matrix indicates the number of true positives, false positives, true negatives and false negatives.
  - True Positive (TP): Reviews that conveys positive sentiment and also classified as positive.
  - True Negative (TN): Reviews that conveys negative sentiment and also classified as negative.
  - False Negative (FN): Reviews that conveys positive sentiment but classified as negative.
  - False Positive (FP): Reviews that conveys negative sentiment but classified as positive.

  This rates are used to calculate other evaluation measures.
- **Precision** refers as positive predictive value. Precision can be obtained form the following equation.

$$Precision = \frac{TP}{FP + TP} \tag{5}$$

  If precision is high then the algorithm is doing well.
- **Recall** is the ratio of correctly classified positive reviews to the total number of positive reviews. Recall can be obtained from the following equation.

$$Recall = \frac{TP}{TP + FN} \tag{6}$$

  High value of precision and Recall are vital for a model.
- f_1**-score** of algorithms need to be calculated for choose a particular learning algorithm between several algorithms. f_1-score can be obtained from the following equation,

$$f_1 - score = \frac{2 * precision * recall}{precision + recall} \tag{7}$$

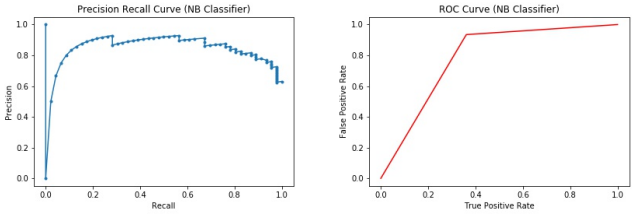
VI. Results and Analysis

Proposed model has been tested with random forest, decision tree and multinomial naïve bayes algorithms. K-fold cross validation has been used to test the performance of the system. Table IV presents a comparison of performance of this algorithms for different values of K.

TABLE IV: Performance Comparison

K-value	Classifier	Precision	Recall	f_1 score	Accuracy
5-fold	Random Forest	0.75	0.76	0.75	75.51
	Decision Tree	0.71	0.70	0.71	70.40
	Proposed	0.81	0.80	0.79	79.59
6-fold	Random Forest	0.79	0.78	0.77	78.04
	Decision Tree	0.70	0.70	0.70	69.51
	Proposed	0.82	0.80	0.80	**80.48**
7-fold	Random Forest	0.70	0.70	0.70	70.00
	Decision Tree	0.71	0.72	0.71	71.42
	Proposed	0.80	0.79	0.78	78.57

Same number of training and test reviews used for all algorithms. Table IV shows that multinomial naïve byes with "tfidf" feature outperforms other algorithms for every fold size K. Different value of K has been used for finding the optimum value of K which gives maximum accuracy. Initially, 2-fold cross validation has been selected and then by increasing the value of k we observed that after a certain value of K the accuracy become turns down. The reason is that, the increasing the number of folding size will decrease the number of testing data in the individual fold that effects the accuracy. From this discussion it can be concluded that, proposed system gets maximum accuracy of 80.48% for 6-fold cross validation.

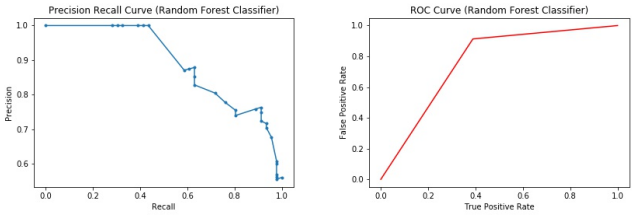


Precision, recall and f_1-score of each class can be presented by a classification report. This report helps for further analysis of an algorithm. In table V classification report of proposed algorithm is presented.

Classification report shows value of f_1-score is 0.74 and 0.84 for positive and negative class respectively. That means proposed system can correctly classify 74% of negative and 84% of positive reviews correctly. For the further evaluation

TABLE V: Classification Report (Proposed algorithm)

Class (C)	Precision	Recall	f_1-score	Support
Negative (C_n)	0.88	0.64	0.74	87
Positive (C_p)	0.77	0.93	0.84	113
avg./total	0.82	0.80	0.80	200



of proposed model graphical measures such as precision-recall curve and receiver operating characteristics curve have been used. Fig. 4 to Fig. 6 show these measures for the tested algorithms.

(a) precision-recall **(b)** ROC

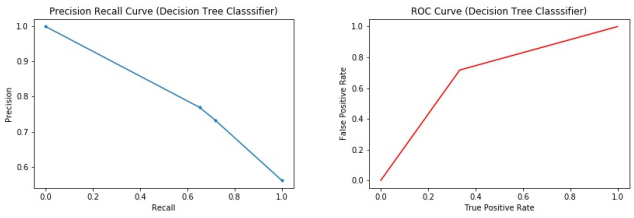


Fig. 4. Result of Multinomial Naïve Bayes

Fig. indicates the precision value of the multinomial naïve bayes is increasing for a certain margin of recall value. Fig. 5(a) and Fig. 6(a) show increase in recall make an adverse effect in precision.

(a) precision-recall **(b)** ROC

Fig. 5. Result of Random Forest

(a) precision-recall **(b)** ROC

Fig. 6. Result of Decision Tree

Fig. 4(b), 5(b) and 6(c) show that true positive rate linearly increase for certain value of false positive rate after that rate of increase becomes almost constant. The trade-off between

Sample Text = > এরাবিয়ান মাস্টারের অভ্যন্তরীণ সজ্জাটা অনন্য। এদের খাবার সুস্বাদু এবং একটু মসলাযুক্ত .. তাদের কর্মীরা খুব বন্ধুত্বপূর্ণ।
System output: Positive
Desired output: Positive

Sample Text = > অপূর্ব খাবার, গ্রেট সার্ভিস... !!
System output: Positive
Desired output: Positive

Sample Text = > আমার জীবনের খাওয়া সবচেয়ে খারাপ খাবার। পুরো টাকাটাই গোল্লায় গেল।
System output: Negative
Desired output: Negative

Sample Text = > পিজার স্বাদটা খুবই জঘণ্য ছিল।
System output: Negative
Desired output: Negative

Sample Text = > খাবারের পরিমাণ কম কিন্তু দাম খুব বেশী। খাবারটা আন্তর্জাতিক মানের নয় কিন্তু স্থানটা ভাল ছিল।
System output: Negative
Desired output: Neutral

Fig. 7. Sample Output

the true positive rate and the positive predicted value is summarized by precision-recall curve and receiver operating characteristics curve summarizes the trade-off between the true and false positive rate for different probability thresholds. Fig. 7 shows some sample restaurant reviews classified by the proposed system.

VII. Conclusion

In this paper a sentiment analysis scheme is presented for restaurant reviews on Bangla language. In this work, different machine learning algorithms have been employed to classify the underlying sentiment of the customer reviews for Bangla text. Besides this, an accuracy comparison of the used models has also been showed where multinomial naïve bayes obtained maximum 80.48% accuracy for 6-fold cross validation among all other used algorithms such as Random forest and Decision Tree. Sentiment analysis has become very effective for the restaurant owners as it can helps owner by providing an essence that what customers think about his restaurant. For sentiment analysis of restaurant reviews many works have been done in English. On the contrary, very few works are done in Bengali. This work is a little effort to compensate the deficiency. In future, more powerful algorithms can be used to find the semantic connection between words of a text that would help us to provide sentiment accurately for more sentiment category. To achieve this goal, increasing the size of dataset would be our prime concern.

Abstract: This study reports a novel approach for biometric gait pattern classification using Extreme Learning Machine (ELM) algorithm. Clinical gait analysis can be used for early detection of gait abnormality in brain or neurological disorder subjects. In many cases gait abnormality cannot be detected through visual observation alone, but becomes apparent only in a quantitative analysis of subject's gait. This can also help us understand the neuro-muscular mechanics associated with brain disorders. Human gait is also of profound interest to the research community in the field of biometric identification and bipedal robot locomotion due to its uniqueness and efficiency. This paper explores multi-class gait classification using four machine learning methods (KNN, SVM, ELM, MLP) and evaluates their performance for multi class gait classification. The proposed method achieves very good results. TheELM is used first time in to analyses the neuromuscular of patients suffering from multiple sclerosis and stroke

Keywords: Extreme Learning Machine (ELM), Biometric identification, Gait classification, Bipedal walk, Multiple sclerosis, Stroke gait, Clinical gait analysis, Cerebral palsy, Crouch gait, Anthropomorphic robot.

I. INTRODUCTION

Human gait is a complex locomotion for forward propulsion of center of gravity of the human body. It is achieved through a process of continuous learning as a child interacts with his environment [1]. It is highly nonlinear and complex due to varying configuration during different sub phases of human gait [2]. The human walk is designed as 8 discrete sub phases [3] with continuous behavior and researchers have started considering it as hybrid system [4]. Fig.1 shows the 8 different phases of bipedal walk. It is inherently unstable and nonlinear due to high degrees of non-linearity, high dimensionality, under actuation (in swing phase) and over actuation (in stance phase) [5]. Human gait is also unobtrusive compared to other biometric identifiers such as fingerprint [6]. Many Researchers have used human gait for purposes such as biometric identification, understanding the problem of elderly people, to understand the biomechanics of human walk, artificial limb development and bipedal walk [7] [8].

As on today, due to its inherent complexities, bipedal robots are not efficient to work outside laboratory environment i.e. unstructured environments designed for humans and are controlled as fully-actuated system, which is not energy efficient [9]. Among various types of humanoid locomotion, bipedal walking is the most natural, energy efficient and interesting, since bipedal robots have more potential to move in rugged terrains or complex environments, where wheeled or tracked robots cannot operate. On the other hand, bipedal robots are less stable and prone to falling down. To meet this challenge, over the years, many solutions have been proposed [10].

Gait can be studied as non-linear time series of kinematic trajectories [11],[12]. The analysis involves the investigating sensory motor interaction and understanding the biomechanics of locomotors system [13]. Gait classification allocates walking patterns into groups that can be identified and differentiated from one another based on a set of defined variables or features. We believe the problem being addressed so far using conventional mechanics based model and automated control theory can effectively be addressed using data driven computational theory. Throughout this work we tried to validate this hypothesis using machine learning techniques including ELM for patients suffering from multiple sclerosis and stroke. The ELM is used first time in to analyses the neuromuscular of patients suffering from multiple sclerosis and stroke

The paper is organized as follows. Section II is about methodology. Section III introduces ELM and briefly describes other machine learning approaches used in this study. Section IV discusses performance evaluation and results achieved by different machine learning algorithms. Section V is about Conclusion and Future work.

II. METHODOLOGY

A. The Proposed System:

Proposed system consists of eight phases which is shown in the Fig.1. They are gait data collection, gait data detection, trajectories smoothing, feature extraction, feature selection and classification using ML algorithms [14]. Figure 2 depicts a systematic approach for proposed gait recognition process.

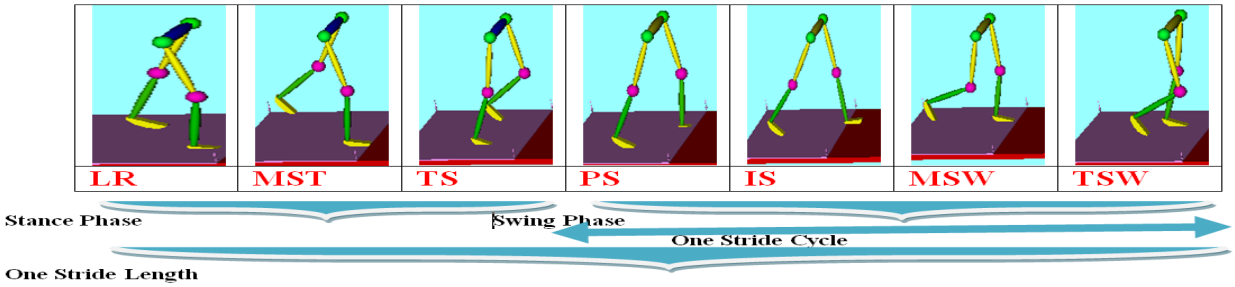

Fig.1. Breakdown of Human Gait into different Discrete Sub Phases

Fig.2. Proposed Architecture of the System

The Gait is divided into 2 phases, namely stance phase and swing phase. The swing phase is critical since only one leg needs to carry the entire body load. We consider it as discrete phase and the configuration during this phase will be over actuation. The swing phase can be considered as continuous phase as well. The configuration is under actuation during this phase.The Percentage-wise distribution of gait time series as following:

Stance phase:

1. Initial Contact– IC[0-2%]
2. Loading Response– LR[2-10%]
3. Mid Stance– MS[10-30%]
4. Terminal Stance– TS[30-50%]

Swing phase:

5. Pre Swing– PS[50-60%]
6. Initial Swing– IS[60-73%]
7. Mid Swing - MS[73-87%]
8. Terminal Swing – TS[87-100%]

B. Data Collection:

For class Multiple sclerosis and Stroke gait, data was collected and recorded using accelerometer for capturing acceleration in all the three planes for the 6 joints (left hip, right hip, left knee, right knee, left ankle, right ankle).This was later converted into joint angles using inverse kinematic solution [17].

C. Data Smoothing:

To remove unwanted noise from the data collected through accelerometers, we have cubic spline interpolation.

D. Dimension Reduction:

After data smoothing, we employed PCA (Principle Component Analysis) and IFA(Incremental Feature Analysis) to compute covariance between different features incrementally.

E. Feature selection:

After analyzing covariance between different set of features, we then proceed to select set of 6 features out of 10, which have highest covariance. This not only reduces the chance of over fitting, but also leads to improved generalization and classification accuracy as discussed in [15],[16].Table-1 below shows all the 10 kinematic features. F1-F6 represents the selected features.

Table1: List of 10 kinematic features

Feature Category	Feature Name
F1	Left Ankle
F2	Right Ankle
F3	Left Knee
F4	Right Knee
F5	Left Hip
F6	Right Hip
F7	CoP*
F8	CoG*
F9	GRF*
F10	Velocity

III. ALGORITHMS:

A. Extreme Learning Machines(ELM)

ELM was proposed by Huang [18], [19]. It is different from MLP and SVM. MLP used to consider many hidden layer neuron and considered whole networks as a black box. ELM theories show that hidden neurons do not need tuning because its hidden nodes parameters (c_i ,a_i) are randomly assigned [20]. For N arbitrary distinct samples $(x_k, t_k) \in R^n \times R^m$, the single ELM classifier with N hidden nodes becomes a linear system as,

$$\sum_{i=1}^{N} \beta_i G(x_k;\ c_i;\ a_i) = t_k, k = 1, \ldots \ldots . N. \quad (1)$$

where $c_i \in Rn$ and $a_i \in R$ are the learning parameters of hidden nodes and randomly assigned weight β_i connecting the ith hidden node to the output node, xk are the training examples, t_k is the target output for k = 1, ..., N, and G (x_k ; c_i ; a_i) is the

output of the i^{th} hidden node with respect to the input xk. The output weights can be described in matrix form as

$$\beta = \left[\beta_1^T \ldots . \beta_N^T\right]_{mxN}^T \quad (2)$$

Equation (1) can be rewritten as:

$$H\beta = T \quad (3)$$

Where H (c_1…….c_N, a1 ……, x_1, ….., x_N) =

$$\begin{bmatrix} G(x_1; c_1, a_1) & \ldots & G(x_1; c_N, a_N) \\ \vdots & \ddots & \vdots \\ G(x_N; c_1, a_1) & \ldots & G(x_N; c_N, a_N) \end{bmatrix}_{NxN} \quad (4)$$

$$T = \left[t_1^T \ldots t_N^T\right]_{mxN}^T (5)$$

The weights β can be obtained using equation 6 by taking the least-square solution:

$$\hat{\beta} = H^{\dagger}T \quad (6)$$

Here, H† is the Moore-Penrose generalized inverse [21] and H is the output matrix of the hidden layer. The ELM used to implement the multi-class classification using a network architecture which has output nodes equal to the number of pattern in the classes. The network output can be written as O = $(O_1; O_2; \ldots O_n)^T$. For each training example say x, the target output tg is coded into n bits: $(tg_1; \text{--- } tg_n)^T$ .For a pattern of class k, only the target output t_k is "1" and the rest is "-1"

B. MLP, SVM and KNN Classifiers:

Multi-layer perceptron (MLP) is the simplest neural network architecture which is used most frequently. It has configuration flexibility, good representational capabilities and programmable algorithms. The Complexity of neural network depends of no. of hidden layer and no. of neurons. The best model of neural network is derived by trial and error. The major challenge of neural network is to decide the no. of hidden layer and no. of neurons, as there is no as such mechanism of optimal selection of neurons and hidden layers. Most MLP are based on gradient descent techniques that require iterative tuning which makes MLP extremely slow and the algorithm can also converge to local minima and provide sub optimal results.

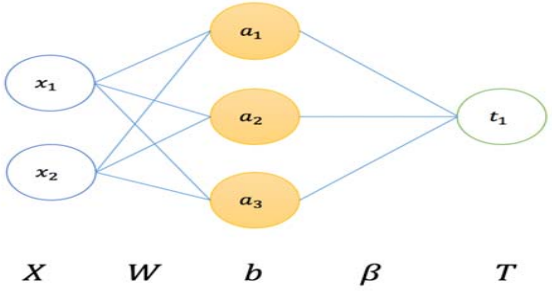

Fig.3. SLFNarchitecture of ELM

The objective of next classifiers SVM is to find the optimal decision boundary with maximum margin between classes in higher dimension feature space. It used to map the lower dimension data into higher dimension feature space using kernel function. The kernel function used to take linear time for this transformation. It converts the nonlinearly separable data into linearly separable data in high dimension feature space. Using SVM, an optimal separating hyper plane in the higher dimensional feature space can be computed by using kernel functions in the input space. In this study, we have used a Support Vector Machine classifier based on LibSVM. It uses a RBF(Radial Basis Function) kernel.

KNN used to match the similarity measure to classify the new class. It is simple algorithm. It is a simple non-parametric technique for classification. When the new testing data is fed, KNN computes the distance between the query data and training samples. Based on the defined threshold, number-k, k samples with least distances are selected and the class with more samples in the boundary is the result.

IV. Results and Discussions

Our experiments were conducted on a Windows 10 machine with a 2.50-GHz 7200U i5 CPU and 8.0-GB RAM. To find the best parameters for each of the classifiers, a grid search was run exhaustively with 10-fold cross validation to reduce variation associated with randomness of data shuffling and arrive at mean scores. KNN, SVM and MLP were implemented using scikit-learn python module. The best set of parameters was found to be as under. Table 2 represents the best set of parameters for MLP.

Table2: Set of Parameter for MLP

Hidden Layer Neurons	50

To evaluate results we computed confusion matrix, precision, recall, f1 score for each of the four classifiers and calculated overall classification accuracy. Overall accuracy is simply number of correct predictions divided by total number of predictions. F1 score is the harmonic mean of precision and recall. Additionally, we also recorded time taken for each classifier to train and predict labels on testing set. All performance measures were generated using scikit-learn python module. In order to eliminate high variation from results we have employed a 10-fold cross validation.

The data set consists of 5 classes namely,(Normal, Crouch1,Crouch2) obtained from OpenSim [22], Multiple sclerosis and Stroke. Data for classes Multiple sclerosis and Stroke were collected clinically capturing the same kinematic features as in the first three classes. Subjects didn't suffer from any other medical condition besides the said diseases. There are, a total of 945 samples across all 5 classes with their individual numbers given under 'support' column in the classification report tables. Crouch gait is a common movement abnormality among children with cerebral palsy, decreases walking efficiency due to the increased knee and hip flexion during the stance phase of gait [23][24].Crouch gait is of four types, out of which we have included type 1 and type 2 for classification. Table 6 and 7 represents the confusion matrix and classification report for ELM.

Table 6: ELM Confusion Matrix

	Normal	Crouch1	Crouch2	MS	Stroke
Normal	202	0	0	0	0
Crouch1	0	54	19	0	0
Crouch2	0	25	45	0	0
MS	0	0	1	299	0
Stroke	0	9	7	0	284

Table 7: Classification Report using ELM

	Precision	Recall	F1-score	Support
Normal	1.00	1.00	1.00	202
Crouch1	0.61	0.74	0.67	73
Crouch2	0.62	0.64	0.63	70
MS	1.00	1.00	1.00	300
Stroke	1.00	0.95	0.97	300

The Overall classification accuracy using ELM is 93.54%. Table 8 and 9 represents the confusion matrix and classification report for MLP.

Table 8: MLP Confusion matrix

	Normal	Crouch1	Crouch2	MS	Stroke
Normal	197	2	3	0	0
Crouch1	0	26	47	0	0

MS	1.00	1.00	1.00	300
Stroke	1.00	1.00	1.00	300

The Overall classification accuracy=85.92% using KNN. Table 12 and 13 represents the confusion matrix and classification report for SVM.

Table 12: SVM Confusion matrix:

	Normal	Crouch1	Crouch2	MS	Stroke
Normal	202	0	0	0	0
Crouch1	0	53	20	0	0
Crouch2	0	15	55	0	0
MS	0	0	0	300	0
Stroke	0	0	0	0	300

Table13: Classification Report using SVM

	Precision	Recall	F1-score	Support
Normal	1.00	1.00	1.00	202
Crouch1	0.78	0.73	0.75	73
Crouch2	0.73	0.79	0.76	70
MS	1.00	1.00	1.00	300
Stroke	1.00	1.00	1.00	300

We have achieved the overall classification accuracy 96.29% using SVM.

Comparative analysis

We have used three figures as shown below to bring out a comparative analysis of the four classifiers. From figure-4 we can see that although numerically the poorest performing classifier-KNN, achieves a good overall accuracy of 85.92%, but it's classification is very poor in the case of Crouch 1 and Crouch2.MLP too, fails to have a decent f1 score in the same two classes, while SVM and ELM have evidently performed well across all 5 classes. The overall accuracy comparison is provided by figure-5.Interestingly, although KNN is the fastest of all four algorithms, it's also the least accurate, while ELM, despite having a far more complex Neural network of 370 neurons against MLP's 50, predicts labels in less than $1/10^{th}$ the time.

VI. CONCLUSION

This paper presented the performance of ELM based classifiers with other machine learning classifiers named SVM, MLP and KNN for multi class gait classification. The paper has used kinematic features. The results show that ELM performs very good classification accuracy compare to other classifiers. The ELM has achieved the 93.54% overall classification accuracy. As the performance of machine learning algorithms dependent on the selected feature and parameter used, to improve the performance the paper has implemented increment feature analysis technique for kinematics features selection and various parameters is adjusted. In the future one could experiment with dynamic and kinematic features as this study was limited to kinematic gait characteristics alone.

A Performance Improved Kretschmann Configuration Based Surface Plasmon Resonance (SPR) Sensor

Tauhidul Haque * and Hasan Khaled Rouf †
Department of Electrical & Electronic Engineering
University of Chittagong
Chittagong-4331, Bangladesh
E-mail : * tauhidtuhin670@gmail.com, † hasan.rouf@cu.ac.bd

***Abstract*— A surface plasmon resonance (SPR) sensor has been designed having improved sensor performance by taking the advantage of higher sensitivity of silver (Ag). Integration of a titanium (Ti) layer in the sensor configuration improves the adherence of metal on prism glass. Inclusions of an air gap also increase the sensor performance. Addition of a thin dielectric layer of indium phosphide (InP) enables surface plasmons (SPs) to spread along it and support a guided mode. Thereafter SPR sensor performances are measured with different performance parameters including sensitivity factor or sensitivity, full width at half maximum (FWHM) value, detection accuracy and quality factor. Numerical simulation has been carried out by using finite difference time domain (FDTD) method to study the reflectance curve and also metallic film optimization has been performed. In a comparative study between proposed SPR sensor and Kretschmann configuration, the proposed sensor provides better sensitivity of 70.65^0/RIU and higher quality factor of 365.9 RIU^{-1} which is 2.4 times higher than the Kretschmann configuration.**

Keywords—surface plasmon; SPR sensor; sensitivity; quality factor; Kretschmann configuration; FDTD.

I. INTRODUCTION

Surface plasmon resonance (SPR) is a charge density oscillation wave arising from the interaction of light with free electrons at metal - dielectric interface. At specific resonance wavelength or resonance angle of incident light, the photons energy is transferred to surface plasmon (SP) when the wave vector of incident light and SP are matched. The resulting SPs are excited and produce a surface plasmon wave (SPW) which is considered as electromagnetic surface waves. This wave propagates along the interface and decay exponentially with distance normal to the interface [1]. Generally, SPW propagation constant is always higher than the incident optical wave propagation constant. Therefore, to excite SP it is necessary to be enhanced photon momentum of the incident light beam to the level of SP momentum. Conventionally, prism coupling is used for optical excitation of SPs by attenuated total reflection (ATR) method which was demonstrated by Kretschmann. In this case a light is totally reflected at prism - metal interface by generating an evanescent wave when it intends to pass through the prism. This evanescent wave penetrates through the metallic layer and propagates with the propagation constant of $k_x = n_p(2\pi/\lambda)sin\theta$, where, n_p is the refractive index of the prism and λ and θ are wavelength and angle of incident light, respectively. The propagation constant k_x can be adjusted in order to match with that of the SPs by controlling the angle of incidence (θ) [2].

As gold (Au) and silver (Ag) provides low losses and strong resonance responses so they are widely used in plasmonic applications than other metals. Ag provides higher sensitivity by producing narrower SPR curve and sharp SPR resonance dip while Au produces wider response curve which limits the sensitivity. On the other hand, Ag is more susceptible to oxidation while Au is impermeable to oxidation and chemically stable. Therefore, in terms of sensitivity Ag may be a promising candidate if it is possible to insert a chemically inert layer on its surface [3]. A dielectric layer like indium phosphide (InP) can be used on Ag surface to protect it from undesired oxidation. InP has a large real part of dielectric constant which can helps to absorb light energy in the metal. It provides larger fraction of the evanescent field in the analyte region which enables SPs to spread along it and support a guided mode. To improve the SPR sensor performance of the existing Kretschmann configuration several works have been conducted by using Ag metal [2, 3, 4, 5]. A. Verma et al. proposed graphene based SPR biosensor with air gap providing 2.35 times higher sensitivity than the configuration without air gap [2]. In [3] T. Haque et al. proposed a graphene based SPR sensor which provides higher sensitivity and it is 1.4 times better than [4] where in [4] S. H. Choi et al. proposed a graphene on silver film based SPR sensor which provides more than 3 times higher sensitivity and higher imaging detection for graphene monolayer. A. K. Sharma et al. proposed a graphene on silver based SPR sensor by using ZBLAN fluoride glass substrate. They observed the impact of graphene chemical potential (μ) with layer numbers on sensor performance and found higher sensitivity for $0.7 < \mu < 0.1$ eV and graphene monolayer [5].

In this work we have carried out a comparative study between proposed and basic Kretchmann configuration shown in Fig. 1. In the proposed SPR sensor a titanium (Ti) layer is used for better adherence on prism glass. Silver as metal layer is used to get higher sensitivity. The thickness of Ag is optimized at 47 nm. To get a larger fraction of the evanescent field in the analyte region we have also used a thin dielectric layer of InP which enables SPs to spread along it and support a guided mode. Inclusion of air gap layer in the proposed sensor increases the sensor performance. Thereafter SPR

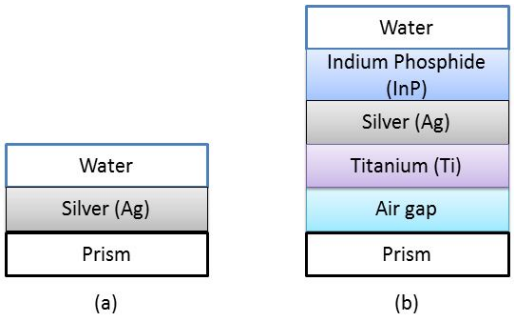

Fig. 1. Schematic diagram of (a) Kretschmann configuration and (b) proposed SPR sensor.

sensor performances are measured with different performance parameters including sensitivity factor or sensitivity, full width at half maximum (FWHM) value, detection accuracy and quality factor. Simulation has been carried out by using finite-difference time-domain (FDTD) method to study the reflectance curve and also metallic film optimization has been performed. Proposed sensor structure provides better sensitivity (70.65^0/RIU against 52.82^0/RIU) and quality factor of the proposed sensor configuration is 2.4 times higher than that of the Kretchmann configuration.

II. Theoretical Modeling

For the calculation of reflectivity of the SPR sensor, matrix method for an N-layer model is used. Considering the SPR sensor configuration of Fig. 1 as an N-layered multilayer system the tangential fields at the first boundary are related to those at the final boundary by

$$\begin{bmatrix} U_1 \\ V_1 \end{bmatrix} = M_2 M_3 M \dots M_{N-1} \begin{bmatrix} U_{N-1} \\ V_{N-1} \end{bmatrix} = M \begin{bmatrix} U_{N-1} \\ V_{N-1} \end{bmatrix} \quad (1)$$

where, U_1 and V_1 represent the tangential components of electric and magnetic fields, respectively, at the boundary of the first layer and U_{N-1} and V_{N-1} are the corresponding fields for the boundary at N^{th} layer [6].

For p-wave at boundary k

$$\begin{aligned} U_k &= H_y^T + H_y^R \\ V_k &= E_y^T + E_y^R \end{aligned} \quad (2)$$

and

$$M_k = \begin{bmatrix} cos\beta_k & -i \sin(\beta_k/q_k) \\ -i\, q_k\, sin\beta_k & cos\beta_k \end{bmatrix} \quad (3)$$

where

$$\begin{aligned} q_k &= (\mu_k/\varepsilon_k)^{1/2} cos\theta_k \\ \beta_k &= \frac{2\pi}{\lambda} n_k\, cos\theta_k (d_k) \end{aligned}$$

From Eq. (3), after some straightforward steps, the reflection coefficient for p-wave incident light is given by

$$r_p = \frac{(M_{11} + M_{12} q_N) q_1 - (M_{21} + M_{22} q_N)}{(M_{11} + M_{12} q_N) q_1 + (M_{21} + M_{22} q_N)} \quad (4)$$

From Eq. (4), M_{ij} is the characteristics matrix of the combined structure of the sensor and for p- polarized light it is given by

$$M_{ij} = \left(\prod_{k=2}^{N-1} M_k \right)_{ij}, i,j = 1,2,\dots \quad (5)$$

Finally, the reflectivity R of a given multilayer structure is given by

$$R_p = |r_p|^2 \quad (6)$$

Several parameters are used to analyze the performance of a SPR sensor. Sensitivity (S) of the SPR sensor describes the change in resonance angle ($\delta\theta_{res}$) per unit change in the refractive index of the sensing medium (δn_s) [2]:

$$S = \frac{\delta\theta_{res}}{\delta n_s} (deg/RIU) \quad (7)$$

The detection accuracy (DA) describes the ratio of shift in resonance angle ($\delta\theta_{res}$) to the full width at half maximum (FWHM) of the reflectance curve [7]:

$$DA = \delta\theta_{res}/\text{FWHM} \quad (8)$$

The quality factor (QF) is defined as the ratio of sensitivity (S) to the FWHM of the reflectance curve [7]:

$$QF = S/\text{FWHM} \quad (9)$$

III. Proposed SPR Sensor Design

In Fig. 1(a) we have shown the schematic of basic Kretschmann configuration. The schematic diagram of the proposed SPR sensor is shown in Fig. 1(b). This SPR sensor is comprised of six layers where it includes a glass prism, air gap layer, titanium (Ti) layer, silver (Ag) layer, indium phosphide (InP) layer and water as sensing layer. To convey this sensor design we have used an operating wavelength of 750 nm which is optimum. The design consideration of proposed SPR sensor with thicknesses of all layers and refractive indices are described below briefly. A prism is used as a first layer that indicates a substrate for the design with high RI of 1.723.

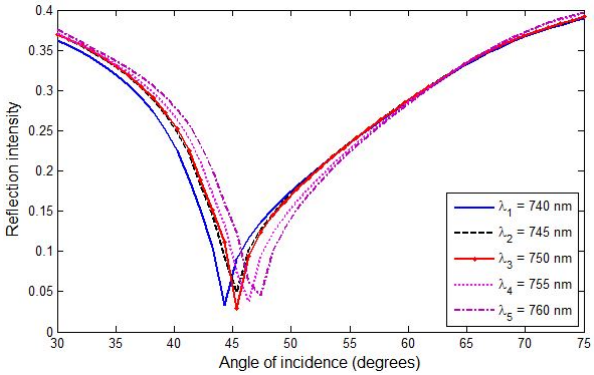

Fig. 2. Reflectance curves variation as a function of incidence angle at different operating wavelengths (λ).

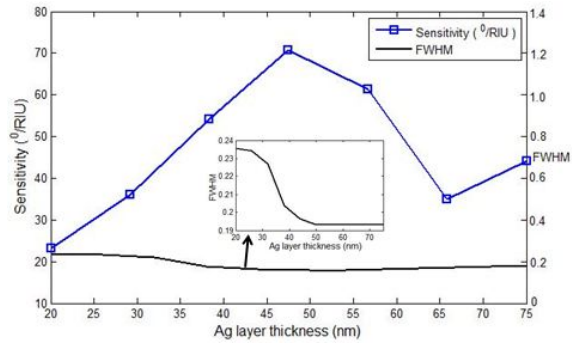

Fig. 3. Variation of sensitivity and FWHM as a function of Ag layer thickness.

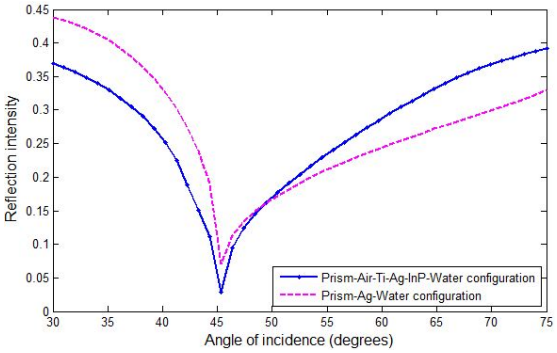

Fig. 4. Reflectance curves as a function of incidence angle for two different configurations.

Inclusion of an air gap layer between prism and metal increases the sensitivity of the sensor where RI of air is 1 and thickness is optimized. As silver has low adherence with prism glass so it must be needed to insert a titanium (Ti) layer between them to enhance the adherence of silver layer on prism glass having refractive index of 2.9838 + i4.0042 [8] and thickness is 15 nm. A silver (Ag) metallic layer is deposited on the titanium layer to take the advantage of higher sensitivity. In this case the refractive index of Ag is 0.1468 + i4.8604 [9] where optimized thickness is 47 nm. Thereafter a thin dielectric layer of indium phosphide (InP) having RI of 3.4719 + i0.23111 [10] and thickness 20 nm is used to support a guided mode. The last and sixth layer is water having RI of 1.33 is used as sensing medium.

IV. Result and Discussion

Numerical simulation using finite-difference time-domain (FDTD) method is used to study the proposed SPR sensor and optimize the thickness of the metallic layer. There exists an operating wavelength at which maximum energy transfer is occurred from incident light to SPs. So, from the very beginning it is necessary to find out this specific resonance wavelength. In Fig. 2 we have shown reflection intensity as a function of incidence angle for different wavelengths. At specific incidence angle, SP is resonantly coupled with incidence angle which is known as resonance angle (θ_{res}). When perfect coupling between SP and incident light wave is occurred then SPR condition takes place at θ_{res} with a fixed

TABLE I. Performance of Sensor at Different Wavelengths.

Wavelength λ	θ_{res} (deg)	R_r	Sensitivity (^{0}/RIU)	Detection accuracy	Quality factor (RIU^{-1})
740	44.32	0.0325	69.85	0.71	227.8
750	45.34	0.0288	70.65	0.85	365.9
760	47.39	0.0454	67.77	0.62	207.5

TABLE II. Performance Comparison of Proposed SPR Sensor Against Kretschmann Configuration.

Configuration	θ_{res} (deg)	R_r	Sensitivity (^{0}/RIU)	Detection accuracy	Quality factor (RIU^{-1})
Proposed SPR sensor (P-Air-Ti-Ag -InP-W)	45.34	0.0288	70.65	0.85	365.9
P-Ag-W	45.34	0.0708	52.82	0.55	155.1

P=Prism, Ti= Titanium, Ag = Silver, InP=Indium Phosphide, W=water

operating wavelength and a dip is appeared due to the absorption of light energy in the metal which is decreased to nearly zero. Therefore from Fig. 2 it is observed that at the operating wavelength of 750 nm and for resonance angle of 45.34^0 the dip of the reflectivity curve is lowest. So 750 nm is an operating wavelength for this proposed design. When the wavelength is increased from 740 nm to 760 nm it is observed that the dip of the reflectivity curve is going up with broadening which decreases the sensitivity. In Table I performance parameters at different wavelengths are summarized. Full width at half maximum (FWHM) describes the width and sharpness of the reflectivity curve. A sensor provides better sensitivity at lowest FWHM value. So among the entire wavelengths 750 nm provides lowest FWHM value (0.19308497^0) which indicates its better sensitivity than other wavelengths of 740 nm, 745 nm, 755 nm and 760 nm. Therefore, at the operating wavelength of 750 nm the proposed sensor provides a better performance (S, DA, QF).

The maximum energy transfer from incident light to SP also depends on an optimum metallic layer thickness. So it is important to find out optimum metal layer thickness. From Fig. 3 we can clearly observe that at 47 nm of Ag layer thickness the sensitivity of sensor is highest (70.65^0/RIU) and FWHM is almost constant after 47 nm. As Ag dielectric constant imaginary part is increased with the increment of Ag layer thickness, so we can observe from Fig. 3 that for 20 nm to 47 nm thickness of Ag layer the FWHM value is drastically decreased due to absorbing incident light photon energy by the metal. But after 47 nm of Ag layer thickness the metal do not absorb significant amount of energy and the curve shows almost constant. Hence, we get lowest value of FWHM (0.19308497^0) at 47 nm of Ag layer thickness with highest sensitivity.

A comparative study between proposed sensor (Fig. 1(b)) and Kretchmann configuration (Fig. 1(a)) has been carried out where proposed sensor shows improved performance. In Fig. 4 we have observed that the lowest dip of reflectivity curve is appeared for proposed sensor structure at an operating wavelength of 750 nm. The proposed SPR sensor provides better sensitivity of 70.65^0/RIU against 52.82^0/RIU for Kretschmann configuration. The proposed one also provides higher quality factor of 365.9 RIU^{-1} (against 155.1 RIU^{-1}) which is 2.4 times higher than Kretschmann configuration. All of the performance parameters are summarized in Table II. By evaluating Table II and Fig. 4 it is undoubtedly clear that the proposed SPR sensor enhance the performance.

V. Conclusion

A SPR sensor has been designed having improved sensitivity, quality factor and other performances. Inclusion of an air gap enhanced the sensor performance. Using Ti as adherence layer and InP as dielectric layer we have achieved an enhanced performance. InP protect the Ag metal from oxidation. It also enables SPs to spread along it and support a guided mode. A comparison between proposed SPR sensor and Kretschmann configuration has been carried out where proposed one provides better sensitivity 70.65^0/RIU than another and proposed SPR sensor provides 2.4 times higher quality factor.

***Abstract*—This methodology uses information from the water flow sensors which identifies leakage in water pipeline progressively. Testing the leakage in pipeline is done on every sensor hub and data is then sent to the Arduino UNO micro-controller for further procedure. The output of this proposed strategy can be accomplished by contrasting different water flow reading with the sensors. The threshold value is set by taking examination of the sensor reading. If the water flow reading is not exactly limit esteem, at that point leakage is available in the pipeline is appeared on the yield show. Consistent flow is set for no leakage condition.**

Keywords— Water Flow Sensor, Arduino UNO, Pipeline Leakage, Flow Monitor.

I. INTRODUCTION

Water is a significant element for each country. Water leakages are being one of the serious issues which each country is confronting [1]. Financially, leaks are costing where in addition to wasting water; it devours significant capacity to treat water or to exchange it starting with one point then onto the next [8]. In underground pipeline leakage identification is a troublesome assignment. Now a days so many countries are suffering in terms of financial loss, fitness, energy and surroundings due to pipe leakages. In a study of smart water systems, it is seen that the leakage rate percentages in Bangladesh is the highest among many countries [1]. According to Dhaka Water and Sewer Authority (WASA), they faced system loss (non-revenue water) 22% in 2015 [2]. Also, Dhaka WASA shows that water supply demand is 2250 MLD, where the supply is 2420 MLD but every citizen of this city does not get safe water from Dhaka WASA though there is no shortage of supply of safe water [2,9]. In Bangladesh along with water leakage, unauthorized connections also make the situation worst for Dhaka WASA [7]. As of late, however, leakage checking hypothesis and application has extraordinary advancement [10,11].

There are several methods in literature for detection of leakages in pipelines such as infrared, SVM Classification and automated meter reading [3-5]. The Infrared technique is utilized to recognize pipe leakages moderately in the nations which contain deserts using impact of the difference in the temperature of the ground because of the leakages. But the disadvantage of this method is the countries in which even least precipitation occurs, this method does not work properly. However, the automated meter reading method measures meter read using a vehicle equipped with a communication technology like GSM-GPRS. But the constraint of the method are slow data rate and high complexity. In the contrary, In SVM Classification method, detection of pipe leakage and location is predicted from a dataset of CSIR- Central Electronics Engineering Research Institute (CEERI). Without this particular dataset it won't give exact output for detecting leakage and location. Nevertheless, there are few methods where wireless communication system is introduced [12-14] which is a future plan of this project.

To recognize the constant water leakage this project is proposed which utilizes two water flow sensors, when water flows through the rotor, rotor rolls. Its speed changes with various rate of flow. This project utilizes water flow sensor as it is effectively accessible in the market, it gives extraordinary productivity and savvy. Sensor detected information is put away in Arduino UNO micro-controller in which pressing is finished. This information is exchanged to the PC or head office through wire. In background of PC different strategies were utilized for examination of sensor information, for example, Arduino IDE.

The rest of the paper is organized as follows. Section 2 describes the theoretical study and methodology that we are going through. Section 3 describes the proposed model with a block diagram, circuit components with detailed description. Additionally, hardware implementation of the proposed model is demonstrated in this section. Moreover, Section 4 shows the output data and analyzes it. Finally, section 5 concludes the paper.

II. METHODOLOGY AND THEORY DISCUSSION

The data collected from water flow sensor are taken into micro-controller. Precise water flow estimation is a crucial step both in the terms of subjective and financial perspectives. Water flow sensor have proven excellent machine for estimating water flow, and now it is anything but difficult to construct a water monitoring system utilizing the G 1/2" Water Flow sensor. This sensor sits in accordance with the water line and contains a pin wheel sensor to quantify how much water has traveled through it. There is an integrated Magnetic Hall-Effect sensor that outputs an electrical pulse with each revolution. Here we have decided flow rate by the change in velocity of water. Velocity relies upon the pressure that forces the through pipelines. As the pipe's cross-sectional area is known and stays steady, the normal speed means that

the stream rate. In such cases, the principle for deciding the water flow rate is

$$Q = V * A \quad (1)$$

Where, Q is flow rate/total flow of water through the pipe, V is average velocity of the flow and A is the cross-sectional area of the pipe [6].

Next, the data from two points are analyzed to determine the result. The water flow of these two points can be denoted as Q_1 and Q_2 where Q_1 is source flow and Q_2 is ending flow of the two points.

$$\Delta Q = |Q_1 - Q_2| \quad (2)$$

The data is taken from all the points of the systems-Central Supplier, Hubs and end-users. The expected average flow of water from Central Supplier to Hub and Hub to end users are different. When the flow is less than the expected average flow the system detects a leakage as ΔQ will be greater. And if Q_2 is close to zero then there might be a clog between the two points. A threshold will be determined for normal flow of water by the minimum and maximum value of ΔQ denoted as T_{max} and T_{min} respectively. The decisions that can be taken are

- $T_{max} > \Delta Q > T_{min,} \rightarrow$ Normal flow
- $\Delta Q > T_{max} \rightarrow$ Leakage
- $Q_2 \approx 0 \rightarrow$ Clogged pipe

A. Hardwear

1) Sensors utilized:

Water flow sensor comprises of a plastic valve body, a water motor, and a hall-effect sensor [13]. At the point when water moves through the motor, it rolls. Later on, Its speed changes with various rate of flow. The hall-effect sensor yields the relating pulse signal. It utilizes a basic turning wheel that pulses a hall effect sensor. Flow rate range is 1～60L/min. Operating temperature is ≤80℃. Water pressure tolerance ≤1.75 MPa (Max 2MPa). Storage temperature needs to be -25℃～+80℃.

2) Micro-controller

Arduino Uno is a micro-controller board dependent on the ATmega328P. It has 14 digital input/output pins (of which 6 can be utilized as PWM outputs), 6 analog input pins, a 16 MHz quartz crystal, a USB association, a power jack, an ICSP header and a reset button. It contains everything expected to help the micro-controller; just associate it to a PC with a USB link or power it with an AC-to-DC connector or battery to begin.

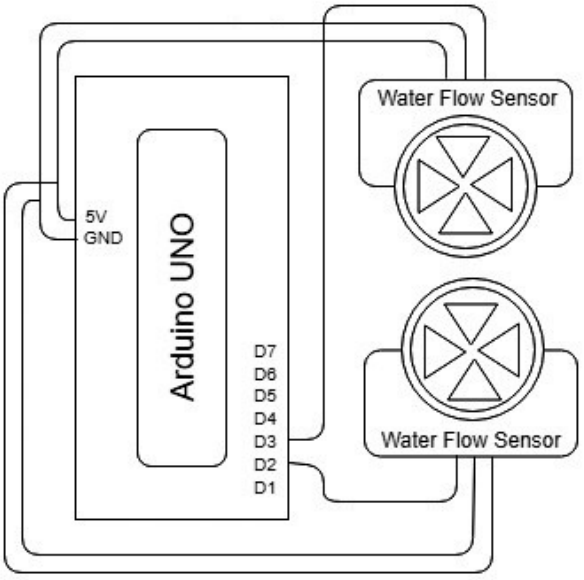

Fig. 1. Water flow sensor pin layout required for the system.

3) LCD display

The LCD display is used to observe the data which are useful for users for analysis. 16*2 LCD display is used here. The data pins 4-7 are connected to the Arduino UNO.

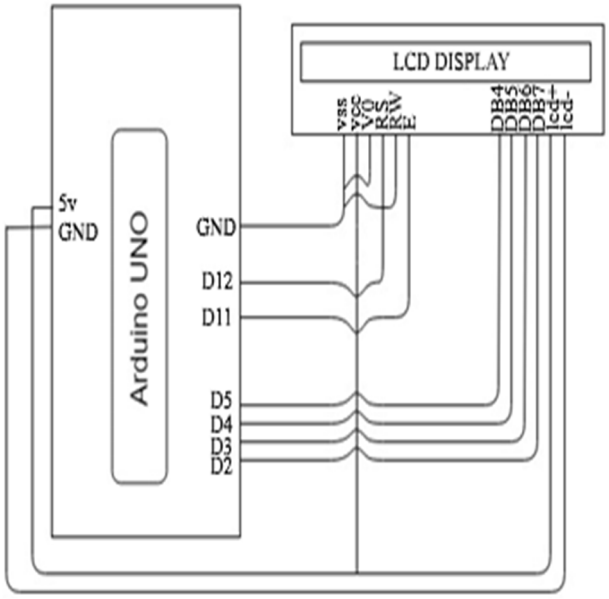

Fig. 2. LCD Pin layout of the system

B. *Flow chart*

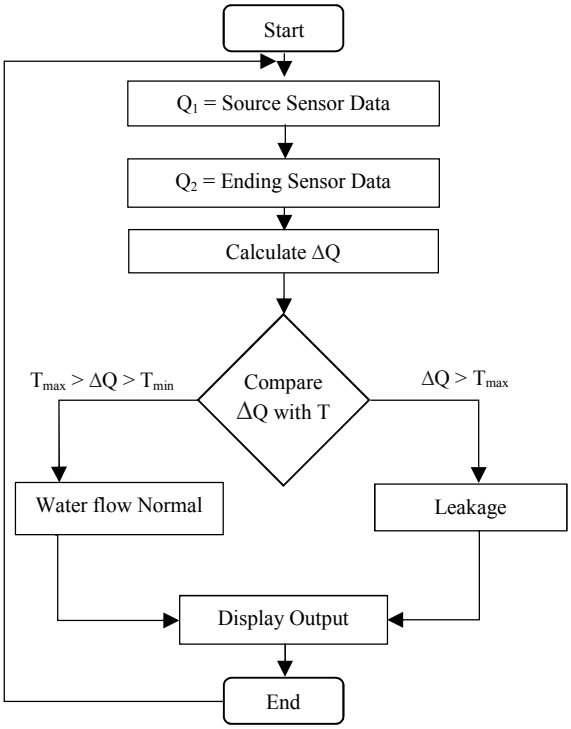

Fig. 3. Flowchart

The above Flow chart shows how leakage detection functions in the system. Leakage detection happens between every two nodes of WDS. To start with, flow sensor information from source between the two nodes is taken. Next, the ending sensor's information is taken. At that point, ΔQ is calculated and compare it with threshold T and see whether there is a leakage or the flow is normal. At last, the decision output is appeared in LCD display. The checking proceeds in a loop.

C. *System Design*

This system contains hardware part like water flow sensors, power supply, microcontroller and LCD display.

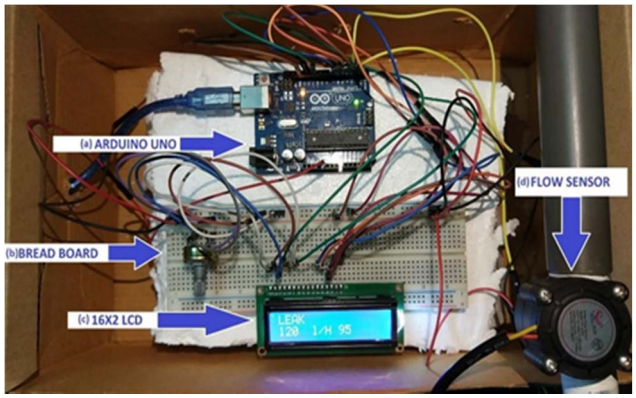

Fig. 4. The components of our project are shown in the figure. (a) is the Arduino Uno (b) is the bread board (c) is the 16x2 LCD (d) is the flow sensor.

III. PROPOSED MODEL

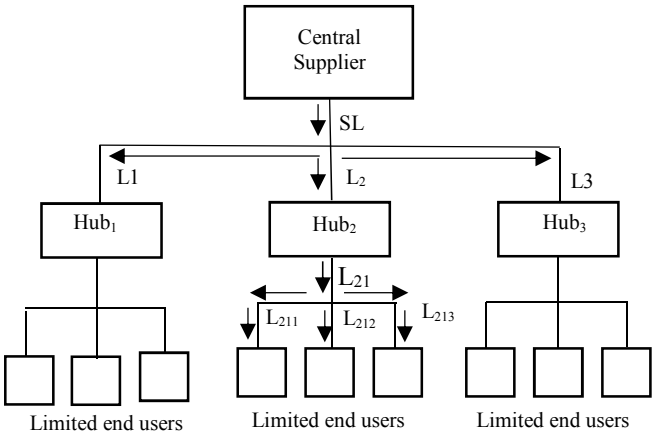

Fig. 5. Proposed Model

The whole system architecture follows the water distribution system (WDS). In earlier approaches, other researches were not able to detect the leakage in real time [8]. The WDS approach makes it possible to get the real time data and detects the exact location of the leakage within the shortest possible time. The central water supplier is divided into hubs which distributes water to the end users. Each hub distributes water to the limited number of end-users. The device is designed to be placed on each node shown in fig. 5. The system can detect leakage in between two nodes. When the node in line L_{213} gives an alert for water leakage the system determines the position of leakage in two ways. The leakage may be in line L_{21} or in line L_{213}. When detecting the problem, ΔQ calculated from Hub_2 to its end-users are same then the problem is in line L_{21}. However if only ΔQ calculated in line L_{213} determines leakage value and other two values are expected then the problem is in line L_{213}.

IV. RESULT ANALYSIS AND DISCUSSION

Fig. 4 shows the experimental test system implemented to monitor the test section of a pipe line using two water flow sensors. The system consists of two water flow sensors, bread board, Arduino UNO, some wires and LCD display to show the outputs. The test was done connecting a pipe with flow sensors and creating water flow through the pipe to simulate actual buried pipeline. A split was made in the pipe to reproduce leakage. For simulation, some pipes are used which have piped grade standard ANSI Sch40 and the size of the pipe was NPS1. The pipe's water velocity in the environment was 0.5~0.7 ft/s. The average water flow was found 1204 lit/hr on average. The proper threshold was found as 0 lit/hr~200 lit/hr. Therefore, if ΔQ greater than 200 lit/hr is found between two nodes then there is a leakage between the two nodes.

TABLE I. FLOW RATE IN DIFFERENT CONDITION

Scenarios	Q1 (L/H)	Q2 (L/H)	ΔQ (L/H)	T (L/H)	Output
1	1200	1100	100	0~200	Normal Flow
2	1200	800	400	0~200	Leakage
3	1200	0	-	0~200	Clogged

[a] L=Liter, H=Hour, T=Threshold

V. CONCLUSION

This paper exhibits water pipeline leakage detection model. Leakage is identified utilizing water flow sensor and correspondence is done remotely. By comparing different reading of sensors leakage is identified. Arduino UNO is used to show the consequence of sensors. This model gives ongoing leakage present in the pipeline. Utilizing this model water misfortune and water misfortune causes, water contamination issues that are effectively recuperated. However, there is not much cloud computing, IoT and wireless based method has been implemented yet to detect the leakage in pipeline. There is various opportunity of research in this field that could be focused.

***Abstract*—In recent times, the use of furnace in industrial sectors has increased. Furnace deals with high temperature for melting and die casting purpose. The smart gas furnace basically made by G.I metal sheet (outer part of the furnace), solenoid valve, ceramic fiber, Plaster of Paris, black fire cement, crucible and gas as a fuel. Among different types of furnace, higher efficiency can be achieved from smart gas furnace. A smart gas furnace is the minimum expensive melting process introduced for melting any types of metal or alloy compared with other furnace. The objectives of this project work are to control the flow of gas for maintaining the required temperature inside the furnace and melt the material. The goal of this project work is to build a gas fired crucible furnaces and develop a controlling system which provide more benefit compare with other furnace. In this project Arduino is used to maintain the required temperature inside the furnace by switching the solenoid valve which controls the flow of gas. Whenever the temperature reaches the desired temperature the gas flow will automatically stopped by solenoid valve resulting in minimum gas loss. Which will reduce fuel cost. Thermocouple is used as a sensor. It continuously sends data (temperature) to Arduino, and by comparing the both data (required temperature and available temperature inside the furnace) the Arduino switches the solenoid valve.**

Keywords—Crucible, G.I metal sheet, solenoid valve, ceramic fiber, Plaster of Paris, Black fire cement, Arduino Uno.

I. INTRODUCTION

Material melting plays a very significant role in different types of melting industry for variety of purposes such as making steel and heat treating of materials to change their molecular structure to give them a perfect shape and this process is performed by the furnace. The furnace is a melting machine which produces heat by burning different types of fuels or electricity or other means. The name of furnace is originated from the Latin word fornix, which implies oven [1]. Material reusing is particularly critical for industries and this difficult work is performed by the furnace. The use of furnace in industrial sectors has been increased in the past few years. There are different types of furnaces are available for melting materials in industrial scale such as blast furnace, open hearth furnace, electric arc furnace, etc. In 1970s electrical furnace started replacing furnace due to energy crisis but the popularity of the gas furnace is still high. And it is one of the most effective method of melting materials in remote areas. Most of the furnace use gaseous fuel like as natural gas, manufactured gas, liquefied petroleum (Lp) as the energy input. Smart gas furnace can reduce the wasting of gas to save the natural resource.

II. LITERATURE REVIEW

The idea of melting metal by using furnace is centuries old. In early years people mainly used wood to generate heat in furnace. 1776 is the year from where the roots of crucible can be traced, when a steel mill named Naylor and Sanderson steel Mill was built in Sheffield, England to produce fine quality tools steel using the crucible method. Sanderson Brothers Steel Company built a new gas fired crucible melting furnace in 1883. Up to 30 graphite's furnace was held by this high temperature furnace, called crucible. Each charged with 60 to 100 pounds of iron plus selected alloy additions [3].

A. State of the art technology

Furnace is a melting machine which deals with high temperatures more than 400 degrees Celsius for melting materials. In industrial furnace heat generally generated by burning fuel with the help of air or by electrical energy. Furnace designs varies with its function, heating duty, types of fuel and method of introducing combustion air [4].

B. Furnace categories:

Different kinds of furnace have been using in industries from many years. Furnace can be classified into four categories based on its design and efficiency.

1) Natural draft: This type of furnace consisted of cast-iron. It is very simple in design and carries few controls. For operating this system operation wood, coke, coal, trash, paper, natural gas, fuel, oil can be used [4].

2) Forced air: Forced air is another types of furnace, atmospheric burner style with a cast-iron. Big natural draft type furnace was replaced by it. But stills its operations can be found in large brick chimneys [4].

3) Forced draft: Forced draft third categories of furnace with a steel heat exchange and multi-speed blower. It is much more compact than the previous styles. This kind of furnace is called mid-efficiency furnace [4].

C. Combustion controls:

There are many types of combustion controllers is used for controlling the flow of gas. Among them main three types are discussed below.

1) Single stage or ON/OFF control: It can operates only one stage operation; it is either on or off. So, it is called the simplest controller. It operates with noise and always running highest speed and pumping out the hottest air with highest velocity [4].

2) Two stage or HIGH/LOW/OFF controls: It is slightly more complex system compare with single stage. It has two firing rate, one slower firing rate and another is full firing as needed. But most of the time it operates at slower speed. Operating system is quieter than one stage and moves the air at velocity [4].

In this project two stage or HIGH/LOW/OFF controller were used.

III. METHODOLOGY

The figure in below explain the basic structure and methodology of smart gas furnace.

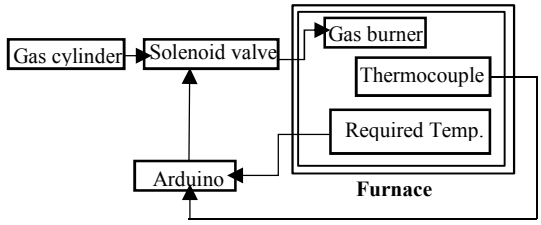

Fig. 1: Block diagram of a gas-fired crucible furnace

This project is done based on three important parts,

- Sensor
- Mechanical parts
- Controlling parts

A. Sensor: In this project thermocouple is used as a sensing device. Details about thermocouple device is given below,

1. Thermocouple: Thermocouple is a sensing device which is used to measure temperature. It has two different metal wires which are connected together to create a junction [5]. In this project thermocouple will sense the amount of heat inside the furnace and send the data to the Arduino.

B. Mechanical parts: For building the mechanical part G.I metal sheet, solenoid valve, gas burner torch has been used. Details about mechanical parts are given below,

1. Outer body frame: At First, the outer frame of a furnace body was made. The outer frame is cylindrical in shape which is made by GI (Galvanized iron) metal sheets. This metal sheet is one kind of sheet where the thickness of steel is 5mm.This metal sheet is very high temperature resistive. The total height of the cylindrical shape is 16.5 inch and only body height is 15 inch and total side insulation is 2 inch. The furnace will be open or close from the upper side of the cylinder where there will be coverage at the top of the furnace. There is one thermocouple is used in the chamber vertically for measuring temperature. The thermocouple sends data continuously in an Arduino. There is also a gas burner which is placed at the bottom of the furnace body which will rise the temperature at a very high level by burning the gas into the chamber.

Fig. 2: Outer body of the furnace.

2. Insulation inside the furnace body:
The main and most impotent part of the furnace is internal structure of the furnace body. There are some insulating materials like as ceramic fiber blanket, plaster of Paris which are adjusted at the inner side of the outer frame where the thickness of the ceramic fiber 1.5 inch and the thickness of the plaster of Paris is 05 inch. The ceramic fiber can protect the outer part of the furnace up to 1200-1250 degree Celsius from the effect of high temperature operation and the plaster of paris can protect up to 1200 degree Celsius [6]. Double layer ceramic fiber was used in this system and connected one with other using black fire cement which tolerates 1200 degree Celsius. Plaster of Paris is a soft mixture which tolerates 1200 degree Celsius was used for joining ceramic fiber with furnace body to build a hard surface. The thickness of Plaster of Paris is 0.5 inch. Now lower insulation of the crucible furnace body is 4 inch, where ceramic fiber Lear is 3 inch and Plaster of Paris Lear is 1 inch.

Fig. 3: insulation inside the furnace

3. Solenoid valve: Solenoid valve is known as an electromechanical control valve which has electric coil with ferromagnetic core in its center. This device is used to control the liquid or gas flow. A 2/2-way solenoid valve has inlet and outlet ports and also have two position (open or closed) [6]. In this project solenoid valve controls the flow of gas inside the furnace. Arduino controls the solenoid valve for maintaining the required temperature inside the furnace.
4. Gas burner torch: Gas burner torch is a heating device through which gas will be brunt and heat will produce inside the furnace.

C. Controlling parts : In this project Arduino is used as a controlling device. Details about Arduino is given below,

1. Arduino Uno: Arduino is an open-source platform which is used for building electronics project [7]. In Arduino, open-source means that its can modify and produce different Arduino boards which provide different factor and functionality. In this project Arduino is used as a controlling device. It takes data of furnace inside temperature from sensing device (thermocouple) and compare it with the required temperature. And maintain the required temperature

inside the furnace by switching off/on the solenoid valve.

D. *Measurements and Equations:*

The internal diameter = 7 inch

And, external diameter = (internal diameter + thickness of the refractory)

= (7 inch +4 inch) = 11 inch

Internal height of the furnace = 10 inch
External height of the furnace = (Internal height + metal sheet thickness + Ceramic fiber thickness + Plaster of Paris thickness)

= (10 inch + 2 inch + 3 inch + 0.5 inch)
=16.5 inch

To maintain the required temperature inside the furnace, the following equations were used.

- Heat produce to reach melting point temperature to melting point of the desire material

  $Q1=ms\Delta t$

  Here,
  m= Mass of melting product
  s = Specific heat
  Δt= Temperature difference
- Heat produce for melting material at melting point

  $Q2=mlf$
- Heat produce to increase 1℃ of the desired material,

  $Qint=ms*1$
- Final heat produced, Q= Q1 + Q2
- Required temperature,

  $T=Q/Qint$

IV. HARDWARE AND SOFTWARE INTERFACE

The main idea of this research is to automate the gas furnace operations. For this reason, this smart automation process is done by using a microcontroller Arduino which will control the operation of a solenoid valve.

A. *Overview of the system*

This complete automation system is done by following the flowchart below. This flowchart also displays the interconnection between the hardware and software section of the project.

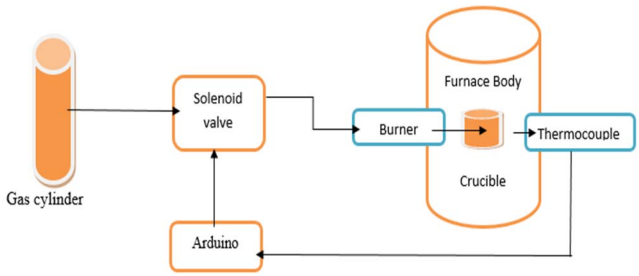

Fig. 4: Flowchart of interfacing the smart gas furnace system.

B. *Simulation and results:*

The schematic diagram of our project is as follows:

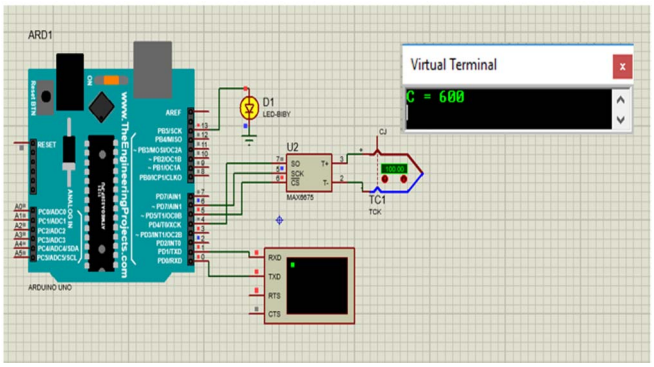

Fig. 5: Schematic diagram of Smart Gas Furnace

This figure represents the simulated circuit of controlling portion of the title project. Here virtual terminal is used for showing the temperature. It is connected with the serial pins of the Arduino and k type thermocouple is connecter with the digital pins of the Arduino. Because of unavailability of solenoid valve a LED light has been used. Whenever the temperature reaches the required temperature the led will turn on. Turning on the LED is the indication of switching off the solenoid valves furnace can reduce the wasting of gas to save the natural resource.

C. *Full hardware impletentation process:*

This whole procedure is done to build up the hardware portion of the project

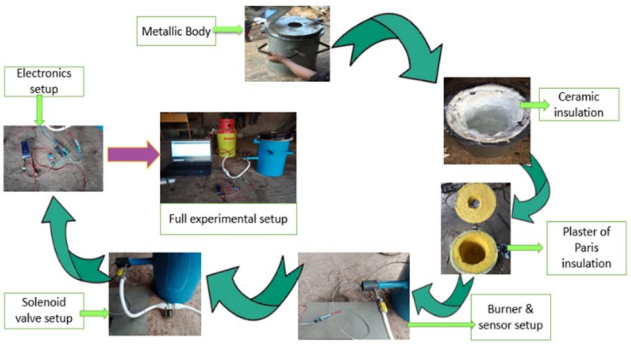

Fig. 6: Diagram of smart furnace building procedure

The main and most impotent part of the furnace is internal structure of the furnace body. There are some insulating materials like as ceramic fiber blanket, plaster of Paris which are adjusted at the inner side of the outer frame where the thickness of the ceramic fiber 1.5 inch and the thickness of the plaster of Paris is 05 inch. The ceramic fiber can protect the outer part of the furnace up to 1200-1250 degree Celsius from the effect of high temperature operation and the plaster of Paris can protect up to 1200 degree Celsius. A double layer ceramic fiber was used in this system and connected one with other using black fire cement which tolerates 1200 degree Celsius. The lower insulation of the crucible furnace body is 4 inch, where ceramic fiber layer is 3 inch and Plaster of Paris layer is 1 inch.

D. *Final combination of hardware and software*

Full experimental setup are shown below:

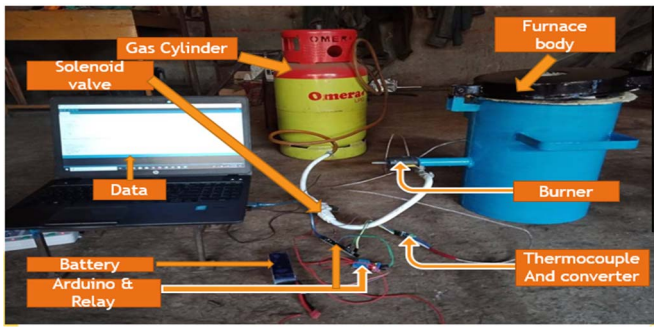

Fig. 7: Full experimental setup of the project.

Here, Arduino is connected with solenoid valve and thermocouple so that it can control the inside temperature of furnace body. Arduino take data from thermocouple (temperature sensor) and maintain the required temperature inside the furnace body by switching the solenoid valve. When the inside temperature reaches to the required temperature the Arduino switch off the solenoid valve and whenever the temperature remain below the required temperature the solenoid valve is open. This is how a smart gas furnace is built which can melt any type of metal within its maximum temperature range. Actually a metal will be kept inside the crucible. According to the metal and furnace heat capacity a required temperature will be set and after that gas will flow up to required temperature and the metal will be melted where melting metal keep any type of mold and also making any types of shape.

V. Result Analysis

Table 1: Valve operation according to required temperature (considering required temperatures 600°C)

Serial number	Temperature (°C)	Time(sec)
1	565.00	64.18
2	573.50	65.22
3	582.50	66.25
4	592.50	67.29
5	601.75	68.32
6	607.25	69.36
7	605.25	70.39
8	601.75	71.42
9	597.50	72.46
10	603.25	73.49
11	610.00	74.53
12	605.25	75.56
13	601.25	76.59
14	592.25	77.62

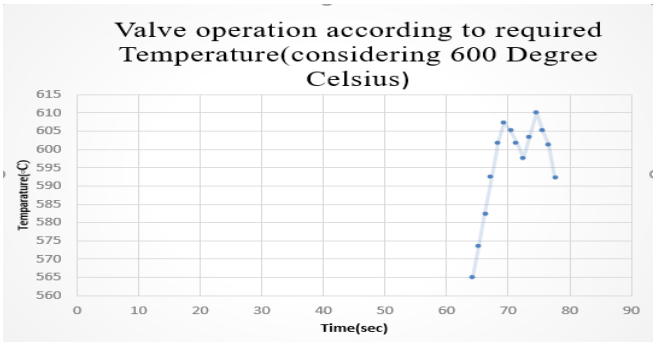

Fig. 8: Graphical representation of valve operation

From the graph it is clearly seen that when the temperature is below required temperature (600°C) then the valve opened and temperature inside the furnace body start increasing rapidly But when the temperature has reached the required temperature the Arduino switched off the valve. But due to enclosed surface temperature goes beyond the required level. As the valve remain closed the temperature inside the furnace started decreasing again. Whenever its goes below the required level the Arduino will switch on the solenoid valve and similar procedure will be followed again.

Fig. 9: Material (aluminium) melted in Smart Furnace

The above figure shows the clear image of melting procedure of desired material in Smart Gas Furnace. For melting aluminium (91gm), 1000°C is kept fixed inside the furnace.

VI. Energy Consumption Calculation

Some electronics devices like Arduino, solenoid valve, thermocouple and rely are used in this furnace designing project.

Table 2: Energy consumption of the proposed model

Electronics Devices	Ratings	Power consumption (W)
Arduino	5V, 13.92mA	0.348
Solenoid Valve	12V, 320mA	3.84
Thermocouple	5V, 30mA	0.15
Relay		0.45
	Total:	4.778W

A solar panel (12V, 1A) charge a battery for 6 hours can supply 72W. By using this solar panel furnace can be

operated for, (72/4.778) = 15.07 hours. A battery of (12V, 1A) can be used for storing the electricity from solar panel. So this proposed model consumes very low electricity. For this reason, it is a very effective for melting industries located in remote areas.

VII. Novelty Of This Project

- This proposed model will be very effective for jewelry shops and melting industries which are situated in the remote areas. Because in many country it is not possible to supply high voltage current in every corner of the country, so smart gas furnace will be very effective for that areas.
- Big melting industry can also keep this model as a backup. During the electricity failure and maintenance period they can continue their production by using smart gas furnace.
- This proposed model needs very small amount of power to operate its operations and this little amount of current can also be provided from solar energy, so this proposed model will play an effective role in remote areas.
- For insulation, double layer of ceramic fiber, plaster of Paris and black fire cement has used which made the system highly heat resistive, so high amount of heat can be produced inside the furnace which will make the melting process much faster.
- Easily transportable due to small in size, so bringing it to any remote areas will not be a big challenge.

VIII. Limitations Of This Project

In this research work some limitations are found such as, the weight capacity of the crucible is very low, high amount of heat loss due to using graphite crucible which takes huge amount of heat to heat up itself before transferring the heat to the material inside it, cannot maintain the required temperature precisely inside the furnace.

IX. Future Enhancement

Although the objective was fulfilled, but there are some update that can be done. Here, the weight capacity of crucible need to increase. As there is an issue of high amount of heat loss so it need to be reduced to increase the efficiency of the furnace. For getting higher demand in market the required temperature need to maintain precisely inside the furnace.

X. Conclusion

This system is used to melt any type of metal within its heating capacity. In our project material selection were carefully done so as to enable it operate the system it was designed for. It was manufactured following to the design specification. It produced high temperature to melt the metal. This is electronics based project. Arduino is the main controlling part in our project and solenoid valve which taken command from the Arduino to on/off the gas flow. As a result, we successfully control the gas flow and taken rising temperature data with time duration.

***Abstract*—In this paper, we have discussed about DOORMOR - a standalone, fully functional search and rescue robot prototype which can come to aid for humans in many cases. With the help of Wi-Fi technology, this robot can be controlled within up to hundred meters. It can search for alive human bodies underneath a pile of debris, clear out debris and other obstacles, stream live video of the surrounding environment wirelessly and assist people in search and rescue operations. In this paper, we have tried to give a brief idea about DOORMOR, it's architecture, facts and features, used components and techniques used to build up the whole robot.**

Keywords—Bot, Live Video Streaming, Control Application, Living Body Search, Debris Clearance, Microcontroller, PIR Sensor

I. INTRODUCTION

Nowadays, robotics and mechatronics is considered as one of the most prominent topics in research. In robotics, architecture, design, manufacturing is important as well as implementation of software to give robots better artificial intelligence to make them appropriate for the tasks which they should handle. Mechatronics is the consolidation of mechanical, computer and electronic engineering in the design of integrated systems with high capabilities that accommodate numerous intelligent traits [1]. It's a derived branch of engineering which is getting more and more popular in this era. From defense to public sectors, robots are being used everywhere. Today, due to unplanned civilization and industrialization, environment pollution has become earth's greatest enemy and a threat to our existence. We have never been more prone to natural calamities as we are today. Earthquakes, cyclones, tsunamis are becoming common incidents day by day. But, often due to lack of proper disaster management and implementation of technology, people die in large numbers. In this particular area, robots can help save many valuable lives. Often, humans face a situation while rescuing that, they can't reach the affected people due to lack of proper path and there is always a risk of the rescuers getting hurt themselves. Robots on the other hand don't have these limitations, they can slip through even the smallest and slender paths, and they can operate without anyone getting hurt.

II. RELATED WORKS

The concept of search and rescue robots is still relatively new. It emerged roughly at the beginning of the 1980s. Nevertheless, actual developments in this field began after the 1990s. Although robots are not widely used in actual search and rescue operations at the moment, the development in this field seems quite promising. In Eastern Japan Earthquake, various robot technologies were applied and achieved productive results for nuclear plant accident response, port inspection, victim search, structural inspection, etc. [2].

Trupti B. Bhondve, Prof. R. Satyanarayan, et al proposed a rescue robot, which can search for alive humans in disaster events in both auto and manual mode. They used a Radio Frequency (RF) modem to maintain connection to the bot from the control device [3]. Albert Ko and Henry Y. K. Lau proposed an autonomous bot circumscribing a wireless network of sensors specially designed for rescue operations. This robotic system can navigate autonomously into rubbles and search for living human body heat using its thermal array sensor [4]. Zachary Cody Hazelwood and Dr. Saleh M. Sbenaty proposed a robot that can move autonomously and avoid obstacles while moving. It also has a user input mode in which the robot takes instructions from the user [5]. Siobh´an Grayson proposed the deployment of multiple robots in disaster events, each having different functionalities. The robots each would have their own assigned tasks [6]. Luis Pineda, Takeshi Takahashi, et al introduced a smart, sophisticated algorithm which is capable of automatically detecting distressed people in the event of a disaster and ease the work of the rescuers [7]. Jingchao Zhao, Junyao Gao, et al introduced a robot which is capable of sensing various kinds of gases in coal mines. Live video of the surrounding environment is captured through a webcam and then broadcasted over a local wireless area network [8]. Jaeeun Shim and Ronald C. Arkin introduced deception of robots in SAR contexts and presented a novel computational approach for an autonomous rescue robot's deceptive action selection mechanism [9]. Johannes Maurer, Gerald Steinbauer, et al tried to document the state of the art in disaster robotics in their paper, in order to provide an overview of the technology already available or currently under development [10]. Illah R. Nourbakhsh, Katia Sycara, et al, in their paper, discussed about the automatic determination of disaster victims using sophisticated algorithms [11]. J. Ju´arez-Guerrero, I. Pissokas, et al, in their paper, discussed about the implementation of smart algorithms for determination of disaster victims in unknown environments without human assistance [12].

III. DESIGN AND BOT MECHANICS

At the very core of the bot design, four wheels have been used for moving the bot. On the front side, two wheels have been used, and on the back, another two, thus two wheels have been used per side. The chassis was designed in a way that it can carry all the electronic equipment like batteries, circuits, drivers as well as the arm and other components. Full dimension of the bot is $9.5'' \times 7'' \times 7''$. The dimension of the chassis of the bot is $9.5'' \times 7'' \times 2''$. The body is built of stainless steel to ensure maximum distortion tolerance. When we try to turn the bot in the left direction, the right wheels go

forward and left wheels go backward thus creating an uneven pressure in the bot's body and the bot turns left. When we try to turn the bot in the right direction, the left wheels go forward and right wheels go backward, and the bot turns right. In this bot, four gear motors [13] have been used so that moving on an uneven surface becomes easy.

The bot's arm has three parts: base, elbow and wrist. The base and the elbow of the arm can rotate up to 180 degrees. The bot uses two servo motors [14] to perform this task. The servo motors [14] are placed respectively in the base and elbow, which gives a sophisticated hand movement. Using two servo motors [14] gives us two Degrees of Freedom (DOF). The claw [15] used in DOORMOR is two fingered, which also holds a servo [14] for materializing the grabbing action. The bot is designed this way so that it can overcome any hazardous situation.

IV. Bot Electronics

The main controller of the bot is the microcontroller *Atmel ATMega328P*. In other words, it's the brain of DOORMOR. An *Arduino Nano* [16] has been used for utilizing this microcontroller and programming it easily. A microprocessor was needed for rendering live video data as microcontrollers don't possess such powerful CPUs. So, a *Raspberry Pi 3* [17] has been used which has a quad-core *Cortex A57* CPU, more than capable of rendering HD video data.

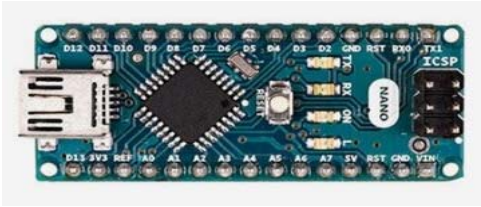

Fig. 1: Arduino Nano.

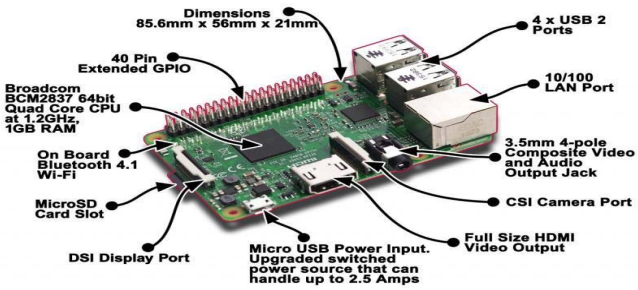

Fig. 2: Raspberry Pi 3 Model B.

Two 5V Lithium-Ion rechargeable power supplies [18] have been used to power the bot. One for powering all the power-hungry components such as, gear motors [13], servo motors [14] and the motor driver [19]. The other one is for powering the *Raspberry Pi* [17] and the *Arduino Nano* [16]. The *Raspberry Pi* [17] and the gear motors [13] require 5V to perform properly and the optimum voltage for the servo motors is also 5V (Input Range: 4.8V – 7.2V). The *Arduino Nano* [16] receives 5V directly from the *Raspberry Pi* [17]. No separate power supply was used for the Passive Infrared Ray (PIR) sensor [20] as it receives power directly from the *Arduino Nano* [16] pins. There is also a 5MP camera module [21] which is powered through the Camera Serial Interface (CSI) port on the *Raspberry Pi* [17]. The L293D dual-channel motor driver [19] has been given 5V as input because the gear motors [13] that we have used, perform best under 5V. Four gear motors [13] have been used to power up four wheels and all of them are given power through the motor driver [19]. Two motors are connected in parallel with reverse polarity on each channel of the motor driver [19]. As both of the power supplies [18] have onboard voltage regulators, additional voltage regulation wasn't required. In average, the total power consumption of the whole bot is around 5A in medium terrain. The power supplies that have been used, can handle the loads flawlessly. The *Arduino Nano* [16] was used to control everything and collect sensor data because it's easier to connect different modules to it as it has 5V output whereas the *Raspberry Pi* [17] has an output of 3.3V, which some modules and sensors don't accept. Also, generating Pulse Width Modulation (PWM) signals with various duty cycles for servo control with the *Pi* is a bit inefficient.

Fig. 3: PIR Sensor Module.

V. Communication System

FCC standards and regulations were followed regarding the communication between the bot and the control device. A 2.4 GHz Wi-Fi router [22] has been used to transfer video data from the bot to the network and control signals from the control device to the bot. The onboard Wi-Fi module of the *Raspberry Pi* [17] which connects to the Wi-Fi router [22], was used to transmit video information to the router and receive control signals from the control device. IEEE 802.11 b/g/n wireless distribution was utilized in all the network components. An android app (DOORMOR Controller) was used to maintain the connection from the control device to the bot. The control commands are collected from the app and then sent to the *Arduino Nano* [16] by the android device through the Pi's onboard Wi-Fi module. The Passive Infrared Ray (PIR) sensor is hooked up to the *Arduino Nano* [16] and feeds data directly to the microcontroller. The microcontroller then redirects the data to the control device through the Wi-Fi module and Wi-Fi router [22]. The redirected data is then translated in the app.

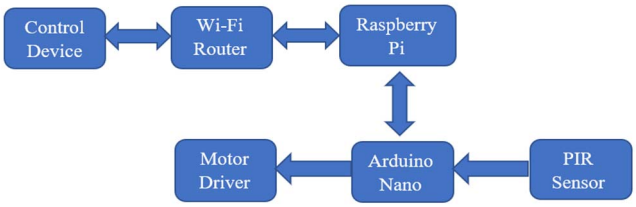

Fig. 4: Diagram of the Communication System.

VI. Live Video Streaming

The 5 megapixels camera module [21] has been used to remotely see what is going on at the desired location. It is

connected to the mainboard [17] via the Camera Serial Interface (CSI) port. It was set up in a way so that we can avoid data loss and other consequences. It can capture full HD (1920x1080) videos at 30 frames per second. The video data is transmitted over a Wireless Local Area Network (WLAN) created by the Wi-Fi router [22] and can be viewed from any smart device connected to the network through a web browser. The video encoding has been implemented by the FFMPEG [23] open source video library. Video data is temporarily stored in a webserver inside the Pi and then it is broadcasted over the WLAN using User Datagram Protocol (UDP) for fast data transmission.

Fig. 5: Video Data Transmission Path.

Fig. 6: Raspberry Pi Camera Module (5 MP).

VII. Bot Software and Associated Hardware

The microcontroller (*Atmel ATMega328P*) was programmed in the *Arduino* language (a subset of C++) for ease of programming. The *Raspberry Pi* [17] was programmed in Python as it is the official programming language for the device. The *Raspberry Pi* [17] works as a server and the android device acts as a client. PHP and HTML languages were used to create a webpage, which is hosted on the *Raspberry Pi* [17] server. LIGHTTPD [24] was used in this regard. It is a light, flexible, fast and less resource-consuming webserver which is very easy to use. Single-board computers like the *Raspberry Pi* [17] are usually low on hardware resources and as such, we need lightweight software to compensate for the hardware limitations. Additionally, CRTMPSERVER [25] was set up for temporarily storing the video data coming from the camera module [21].

Fig. 7: DOORMOR Controller (Control App).

The bot software or control app establishes a central control system to control the bot from a remote distance with the help of an android device. It offers a user-friendly Graphical User Interface (GUI), which includes all the necessary tools and information display areas.

A. Bot Movement Controller

The motor driver [19] has six control pins. Four are for controlling the direction in which the motors [13] should rotate, e.g. clockwise or anti-clockwise. They are also used to start or stop the motors [13]. So, these pins are pulled HIGH and LOW with a combination from the L293D's truth table [26] to execute different actions. Six *Arduino Nano* [16] digital pins are connected to the motor driver [19]. These pins generate high and low logic to materialize the desired bot movements. The *Raspberry Pi* [17] has been programmed to act as a server here. Server-client communication is done through Transmission Control Protocol (TCP) for secure communication. The client software named "DOORMOR Controller" was written in the Java programming language. It has a GUI which consists of FORWARD, BACKWARD, LEFT, RIGHT and STOP buttons as well as a status box to display the state of the bot. These buttons have predefined values which are sent in packets. With the help of sockets [27], the *Raspberry Pi* [17] receives these values and sends appropriate signals to the microcontroller. A query is sent to the bot per second, in order to see if the connection to the bot is maintained or not. If no reply is received, all the *Arduino Nano* [16] pins turn low in order to protect the bot from malfunctioning.

Input A	Input B	Motor State
High	Low	Turns clockwise
Low	High	Turns anti-clockwise
High	High	Braking occurs
Low	Low	Braking occurs

Fig. 8: Single Channel Truth Table of L293D.

B. Arm Movement Controller

A portion of the 'DOORMOR Controller' app has the necessary tools to control the arm movement. There are three sliders for controlling the three servos [14]. The sliders have values from 0° to 180°. These sliders need to be moved in a systematic way in order to obtain desired arm movements. The status area of the control app shows in which degree the servo [14] is at, whenever the concerned slider is highlighted.

On the programming side, these sliders have different predefined underlying values at different points, e.g. the first slider has a value range of 1000-1180, the second slider has a value range of 2000-2180 and the third one has a value range of 3000-3180. These values are sent as integers which are stored inside arrays in the microcontroller. The first digit represents the servo number and the rest three digits represent the degree at which the servos need to rotate and stay. After receiving signals from the control device, the microcontroller generates appropriate Pulse Width Modulation (PWM) signals for driving the servos [14]. PWM signal generation is handled by the Servo library of the *Arduino* language.

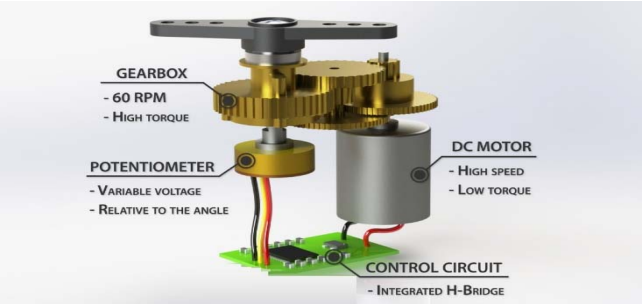

Fig. 9: Servo Mechanism.

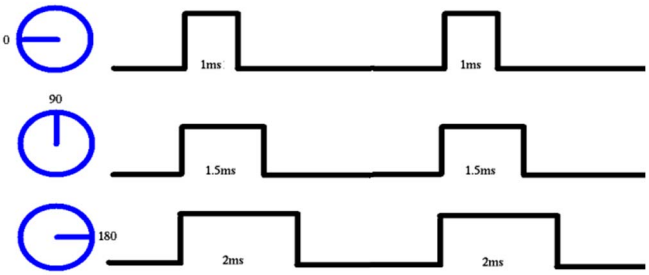

Fig. 10: Different PWM Signals for Servo Control.

```
if(realservo >= 1000 && realservo < 1180)
{
  int servo1 = realservo; //storing values for servo 1..
  servo1 = map(servo1, 1000, 1180, 0, 180); //mapping down to suitable degree values..
  myservo1.write(servo1); //sending positional information to servo 1..
  Serial.println("SERVO 1 ON"); //prints confirmation message on the serial monitor..
  delay(10); //waits for 10 millisecond for the servo to adjust it's position..
}

if(realservo >= 2000 && realservo < 2180)
{
  int servo2 = realservo; //storing values for servo 2..
  servo2 = map(servo2, 2000, 2180, 0, 180); //mapping down to suitable degree values..
  myservo2.write(servo2); //sending positional information to servo 2..
  Serial.println("SERVO 2 ON"); //prints confirmation message on the serial monitor..
  delay(10); //waits for 10 millisecond for the servo to adjust it's position..
}

if(realservo >= 3000 && realservo < 3180)
{
  int servo3 = realservo; //storing values for servo 3..
  servo3 = map(servo3, 3000, 3180, 0, 180); //mapping down to suitable degree values..
  myservo3.write(servo3); //sending positional information to servo 3..
  Serial.println("SERVO 3 ON"); //prints confirmation message on the serial monitor..
  delay(10); //waits for 10 millisecond for the servo to adjust it's position..
}
```

Fig. 11: Partial Source Code.

C. PIR Sensor Status

Another portion of the 'DOORMOR Controller' app displays the status of the PIR sensor [20]. The PIR sensor [20] can detect Passive Infrared Rays (PIR) emitted from living beings, such as, alive humans and other animals [28]. A dead body doesn't emit such rays. Inside the PIR sensor, all the thermal energy is at first focused on to the Pyroelectric sensor through the focusing lens in front of the sensor. If PIR is available, the voltage across the sensor changes. This change in voltage is too delicate to be detected by the microcontroller, so we need an amplifier circuit which will amplify the change. The output of the amplifier is connected to a voltage comparator, which compares voltages from the amplifier with a reference voltage and generates HIGH/LOW logic [28]. So, the module sends a HIGH logic to the microcontroller whenever it detects a living being within 1 meter. The microcontroller then sends a signal to the control device through the Wi-Fi network. This signal is translated in the app. The app shows "Human Detected" in the sensor status area, whenever a living body is detected. If there's no living body, the app shows "No Human Detected". The mechanism of the PIR sensor [20] is shown in Fig. 12.

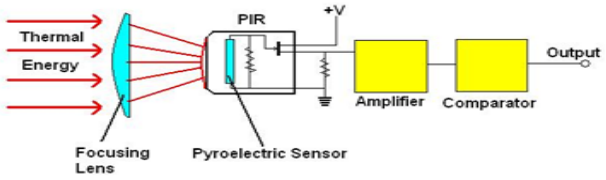

Fig. 12: Passive Infrared Sensor Mechanism.

VIII. DESCRIPTION OF THE TASKS

The bot can perform several tasks. They are respectively:

1. Searching for alive humans under pile of debris.
2. Picking up and clearing debris using the arm.
3. Capturing live video of surrounding environment and streaming it through a wireless network.

Task 1 is shown in Fig. 13, where the bot has detected the existence of a living body.
Task 2 is shown in Fig. 14, where the bot is picking up demo debris.
Task 3 is shown in Fig. 15, where the bot is streaming live video to a Windows PC connected to the bot's wireless network.

Fig. 13: Live Human Detection.

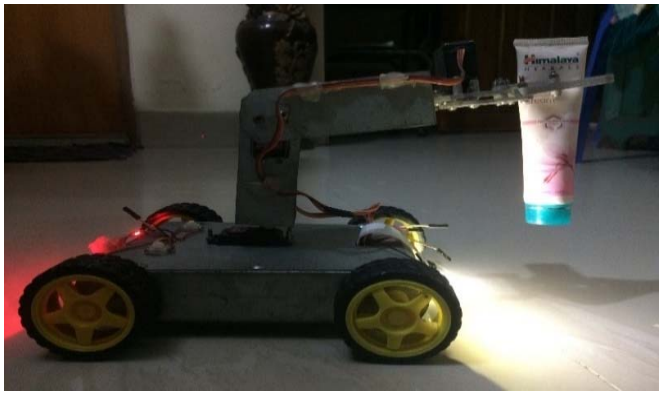

Fig. 14: Demo Debris Cleaning.

Fig. 15: Live Video Streaming.

IX. Observations and Experiments

Several experiments were conducted to ensure proper functionality of the bot. This helps to accurately determine the future complications that may occur in actual field. The experiments can be split into several steps:

A. Live Video Streaming Test: Success scenarios of the bot during the live video streaming test are shown in Table I.

B. Traversing Test: Success scenarios of the bot's traversing test are also shown in Table I.

C. Arm Test: Success scenarios of the bot's arm test are shown in Table II.

D. Sensor Test: Success scenarios of the bot's PIR sensor test are shown in Table III.

TABLE I. Bot Test Results

Test Run	Terrain	Vision	Control	Status
1	Plane	Operator's eye	With bot	Success
2	Medium	Bot camera	Blind from operator	Success
3	Plane	Operator's eye	With bot	Success
4	Medium	Bot camera	Blind from operator	Success

TABLE II. Arm Test Results

Test Run	Type of Object	Weight	Action Performed	Status
1	Demo Debris	50 gm	Picked up & moved	Success
2	Demo Obstacle	100 gm	Picked up & moved	Success

TABLE III. Sensor Test Results

Test Run	Sample	Output	Status
1	Living body	'Human Detected' shown in the control application	Success
2	Living body	'Human Detected' shown in the control application	Success
3	Living body	'No Human Detected' shown in the control application	Failure
4	No living body	'No Human Detected' shown in the control application	Success
5	No living body	'No Human Detected' shown in the control application	Success

As seen in the tables above, DOORMOR showed success scenarios when tested. The sensor test returned a success rate of 80%. We conducted further investigations on the signal range of the bot and found out that DOORMOR sometimes does not respond to control signals at distances more than 90 meters and stops responding completely at distances greater than 95 meters. So, it is safe to say that, the range efficiency of DOORMOR is 90%.

X. Advantages of DOORMOR

The main advantage of DOORMOR is that it doesn't require any additional remote controller or wireless network for operation. Any android device can be used to control the bot and any existing Wi-Fi network can be used to transfer video data and control signals between the control device and the bot. Wi-Fi repeaters can be used anytime to expand the range of the bot without any kind of hassle. These features also add to the overall cost reduction of DOORMOR and make the robot distinguishable from rest of the similar systems.

XI. Areas of Further Development

As this is only a prototype, the actual robot will be superior to the prototype in many ways. First, the chassis will be a lot stronger compared to the prototype's chassis with better metal alloy construction. Metal chain will be added on the wheels for traversing on rough terrain for hours. The wheels will also be made out of metal. The metal alloy will be selected in such a way that the robot can withstand extreme pressure and heat for a descent amount of time. Better motors will be used to ensure maximum torque and Rotation Per Minute (RPM) under heavy load. The motors will be picked in a way so that they can be powered through the available power source. The power source will also be upgraded to ensure maximum current supply to the components for a longer period of time. The camera module will be upgraded to a night vision camera module to ensure clear imagery even in the dark. The arm will be redesigned with better gears to ensure maximum performance. The Degree of Freedom (DOF) of the arm will be upgraded for better arm movement. Face and object recognition will be added in order to recognize people and objects while searching an affected area. This will help the rescuers to efficiently locate the distressed people.

The robot can be slightly modified for military use, specially bomb disposal. The claw [15] can be replaced with a cutting tool that will allow the robot to cut wires for disposing bombs. Also, the robot can be used as a spy robot.

Another interesting addition would be live GPS location streaming which would help us pinpoint the bot, and addition of sonar sensors which would stop the bot automatically before it accidentally crashes into something. Thus, some sort of Artificial Intelligence (AI) would also be in action.

XII. Conclusion

In this modern era, robotics has become such a field which has made our lives easier, safer and efficient through variety of its applications. In almost every aspect of our daily life, we can see the benefits of this particular field. However, our effort was to develop a life saver. Its applicability is not confined within the pre-specified scientific tasks. Again, its software and the integration amongst the associated hardware components made it equally capable of performing other similar tasks with minimum modification. In the previous section, we have discussed areas of further development. Concentration on traversing task gave the bot such an infrastructure that can withstand expected adversities up to a certain limit and made it capable of exploring places that are almost out of bounds for humans. The compilation of the mechanics, self-developed control system, software and hardware provides the blueprint of such a standalone system that can accommodate certain utilities in favor of assisting humans in various horizons. As there is no end of perfection, with more resources and logistics support plus keen observation of its performance on different sectors, the scope of improvement of the bot is still on the table.

XIII. Acknowledgement

The authors would like to express profound gratitude to Global Emerging Technology Network, Dhaka, Bangladesh for their endorsement as well as technical supervision. Also, the authors of this paper are very much thankful to the Department of Computer Science and Engineering, Bangladesh Army University of Engineering and Technology, Natore, Bangladesh and Department of Computer Science and Engineering, Daffodil International University, Dhaka, Bangladesh, for their support throughout the build of this robot. Without their support, we could never pursue such a complicated project.

***Abstract*—With the advancement of technology and rapid overpopulation, people are constantly trying to ease their daily life by adapting with newer technology. Transport is one of the daily amenities for us to depend on, yet not sufficient enough for the growing population. This is one of the common issues which people try to solve with vehicle purchasing. The increasing amount of vehicles create mismanagement in controlling traffic leading to accidents. Although accidents happen due to various factors other than traffic management, such as unstable weather, reckless driving, faulty vehicles or maybe road conditions. But the most important part after an accident is to detect the accident and take immediate action upon detection. Bangladesh has registered a significant increase, 19.58%, in road accidents in 2018 compared to 2017 and 3,472 accidents in 2017, where there were 4,317 deaths in 2018. All this time we overlooked the fact that immediate aid to an accident scene can reduce the number of people getting traumatized, disabled or lose their precious lives due to lack of emergency facilities. Also, delayed action can lead to criminal activity of the accident doer as the person gets enough time to flee from the scene. We built this system to solve these issues by detecting and confirming the accident using the MPU6050 module, and notifying the proper authorities by sending the location of the incident using SIM808 module.**

***Index Terms*—accident, detection, notification, message, MPU6050, SIM808, GPS, GSM**

I. Introduction

The increasing amount of automobiles causing frequent hazardous traffic situations leading to life-threatening accidents. In most cases, poor emergency facilities increase the level of fatality. Our system provides an optimal solution to an accident scene. This system is able to detect any causality in every possible direction and confirms if the accident occurred or not. On the findings, the exact location in longitude and latitude form is sent to the authorized number through SMS. On any nonfatal situation, drivers have the full privilege on cancelling the notification sending system.

II. Motivation

Our motivation for working on this project came from a recent issue of two students who died in a road accident [1]. Therefore, it came to our mind that accidents can occur in any situation, but the golden time is to take action immediately after the accident as people are traumatized to decide what action they should do next and fall into grave risks. If all vehicles are set to detect accidents and send automated SMS containing location to help the injured right away, the chances of such unfortunate events can be reduced.

The objective of our project is to prevent fatal situation for lack of emergency facilities when an accident occurs. Using this system, if anyone faces an accident, his or her close relatives and nearby help centre will get a notification so that they can immediately come to aid and help them as our system provides the exact location of the accident spot.

III. Related Works

This section demonstrates some of the previous research works and these co-respond to our proposed work. C. Prabha et al. [2] worked with GSM and GPS modem for detecting an accident and messaging system, whereas some works had been done with new methods which do not require GSM and GPS modem. J. R. Barfield, et al. [3] worked with on board devices to detect car crashes. R. C. McKown and J. T. Mader [4] focused on notification and they did it by producing a decision of 3-digit emergency call from an in-vehicle TCU to a local PSAP operator, but before notifying they qualify vehicle crash events.

IV. Abbreviations and Acronyms

SMS(Short Message Service): SMS is a text messaging service in cellular-device systems and the internet. To exchange short text messages it follows standardized

communication protocols.

GSM(Global System for Mobile communication):
GSM is a mobile communication modem, transmits mobile voice and data service. It is an open and digital cellular technology operating at the 850MHz, 900MHz, 1800MHz and 1900MHz frequency bands. It has the ability to carry 64 kbps to 120 Mbps of data rates.

GPS(Global Positioning System): A global navigation satellite system which provides Geo-location (latitude and longitude) and time information to a GPS receiver if there is an unobstructed line of sight to four or more GPS satellites.

V. Components

A. Arduino NANO:

The Arduino Nano uses the Atmega328p Processor. There are total 8 Analog pins and 14 digital Pins on our Nano board. To interface sensors as input pins or drive loads as output pins we used the digital pins. Functions like pinMode and digitalRead, digitalWrite performs the desired actions. [5].

B. SIM808:

SIM808 is integrated with a high-performance GSM/GPRS engine, a GPS engine and a BT engine which meets almost all the type of space requirements, such as M2M, smart phone, PDA, tracker and, other mobile devices. [6].

C. MPU6050:

The MPU-6050 is a device which combines a 3-axis gyroscope, 3-axis accelerometer, and a Digital Motion Processor (DMP). It has dedicated I2C sensor bus, which directly accepts inputs from an external 3-axis compass to provide a complete 9-axis Motion-Fusion output. The MPU-6050 features three 16-bit ADC for digitizing the accelerometer outputs and three 16-bit analog-to-digital converters (ADCs) for digitizing the gyroscope outputs. For precision tracking of both slow and fast motions, the parts feature a user-programmable accelerometer full-scale range of $\pm 2g$, $\pm 4g$, $\pm 8g$, and $\pm 16g$ and a user-programmable gyroscope full-scale range of 250, 500, 1000, and $2000/sec(DPS)$ [7].

D. 16×2 LCD Display:

A 16×2 LCD (Liquid Crystal Display) screen is an electronic display module which can display 2 such lines having 16 characters in 5×7 pixel matrix per line [8].

E. Buzzer:

A buzzer is a small component, adds sound features efficiently to any system. It needs DC power supply ranging from 4V to 9V. it is usually associated with a switching circuit to turn ON or OFF at required time and interval.

F. Push Button:

Push-Buttons are normally-open tactile switches, allows to power any circuit or make any particular connection on pressing the button.

G. Potentiometer:

Potentiometers are nothing but variable resistors which also known as POT. By simply rotating the knob on top of its head, they can provide variable resistance. Potentiometer standards values are $500\,\Omega$, 1KΩ, 2KΩ, 5KΩ, 10KΩ, 22KΩ, 47KΩ, 50KΩ, 100KΩ, 220KΩ, 470KΩ, 500KΩ, 1 MΩ. Potentiometer used in an LCD to adjust the contrast level.

H. Breadboard:

Breadboards consist of four rows of 63 vertical columns with 5 connected holes which is the circuit area. Also, 8 rails (or distribution strips) connected horizontally for power and ground or to carry a signal if it is not needed for power or ground.

I. Jumpers:

A jump wire (also known as jumper wire, or jumper) is an electrical wire used to interconnect the components without soldering, or group of them in a cable, with a connector or pin at each end (or sometimes without them simply ”tinned”).

VI. Proposed System

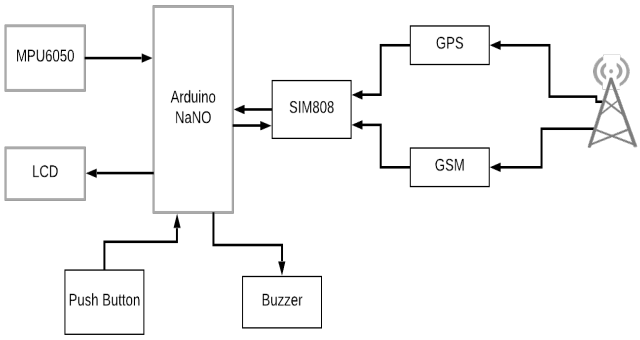

Fig. 1. Block Diagram of the system

Figure 1 shows the working process of the system. Values taken from MPU6050 and SIM808, Arduino has processed them to detect an accident. Upon detection, Buzzer has turned on. Based on the decision, GPS has traced the location and an SMS is sent using GSM. Each status of action is displayed on the LCD.

Figure 2 breaks down the continuous workflow of the system. It continuously checked the conditions of the detection scheme from current values with the previously stored values to identify any type of anomalies. The system is terminated when the notification message is sent.

VII. System Mechanism

For our system, we have tried to consider all possible ways to detect an accident based on the values of acceleration and deceleration of X-axis, Y-axis and Z-axis, pitch and roll and angular offset for rotation of the vehicle. In reality, an accident has many factors but our system has been able to detect most accidents in any situation using these conditions.

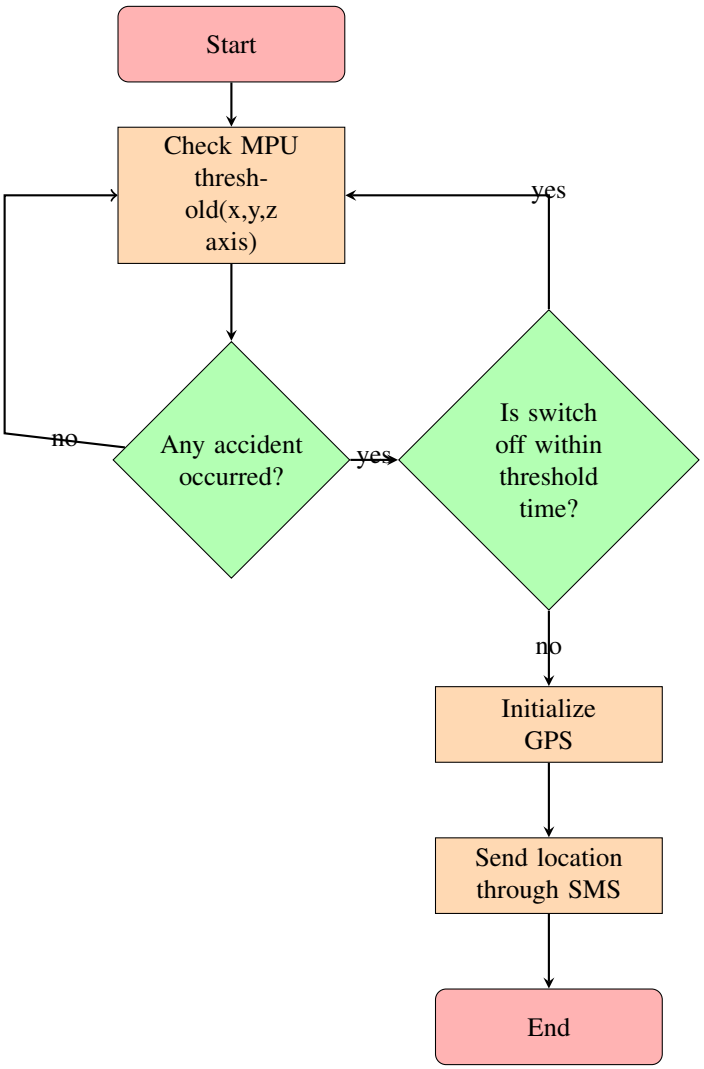

Fig. 2. Flow chart of the system

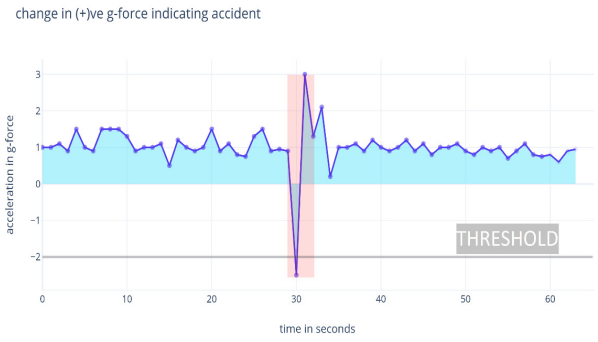

Fig. 3. Spike shows the anomaly of acceleration

Initially, we have set some values such as threshold values lets the system detects an accident, a cellphone number for sending SMS if an accident occurs and initialize an array to check any disruption in the acceleration of the vehicle.

In Figure 3 and 4, we have provided two examples of accident occurring situation. In Figure 3, the acceleration of the vehicle is relatively close to each other but at a point, the acceleration suddenly spikes and we have consider this as an accident. Moreover, a spike point is an anomaly and this usually happens when an accident occurs. Figure 4, shows the deceleration situation of the vehicle.

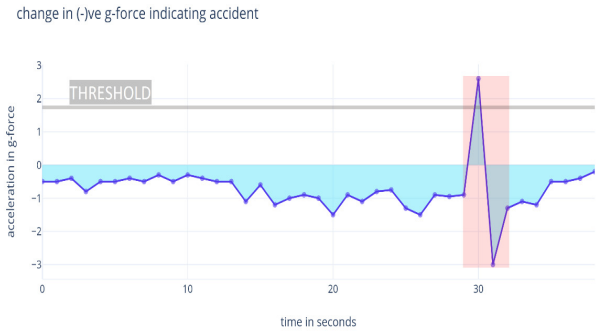

Fig. 4. Spike shows the anomaly of deceleration

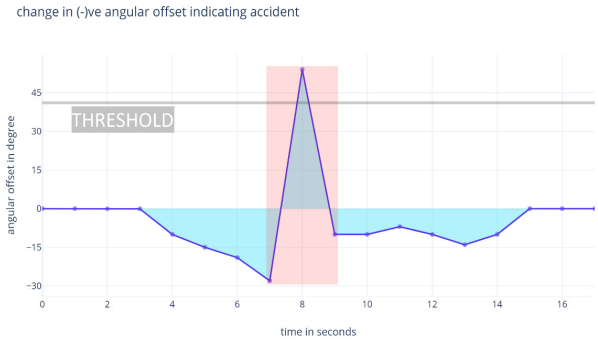

Fig. 5. Angular offset change

We have normalized the raw accelerated values we got from the moving vehicle and have calibrated the values of a gyroscope. Comparing these values with our preset thresholds, the system has decided on any accident occurrence. Moreover, the pitch and roll values were calculated using the following two equations to let the system detect an accident.

$$pitch = \frac{180}{\pi} * \tan^{-1}\left(\frac{aX}{\sqrt{aY^2 + aZ^2}}\right) \quad (1)$$

[10]

$$roll = \frac{180}{\pi} * \tan^{-1}\left(\frac{aY}{\sqrt{aX^2 + aZ^2}}\right) \quad (2)$$

[10]

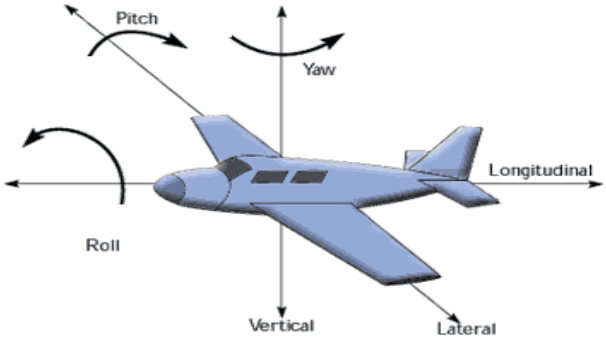

Fig. 6. Movement of an object in three different axis [9]

Here,

$$pitch = \text{rotation of lateral axis}$$

$$roll = \text{rotation of longitudinal axis}$$

$$aX = \text{acceleration about X axis}$$

$$aY = \text{acceleration about Y axis}$$

$$aZ = \text{acceleration about Z axis}$$

$$\pi = 3.1415926535, \text{mathematical constant}$$

Figure 5 and 7 shows the graph of the sudden change on any angular offset of a vehicle. We had situations where a vehicle can take a 360-degree turn but the speed of the car would be within a range. If the acceleration of the vehicle is very much high compared to the previous acceleration rates, in that case, we have considered it as an accident.

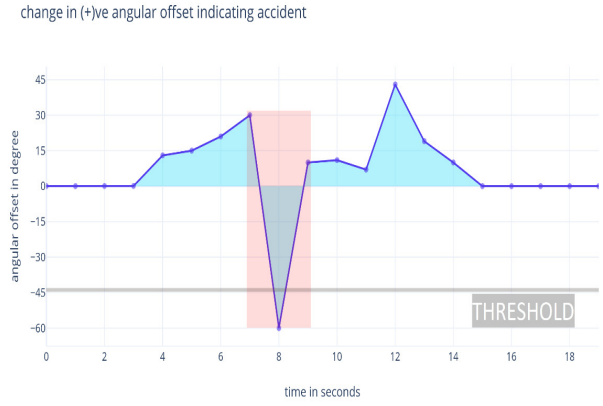

Fig. 7. Angular offset change

Our special technique was to detect an accident in Z-axis. Naturally accidents on Z-axis are the underwater situations, where any vehicle might fall from any cliff and fall into open water. In real life any vehicle accident detection methods are not applicable to the underwater situation.

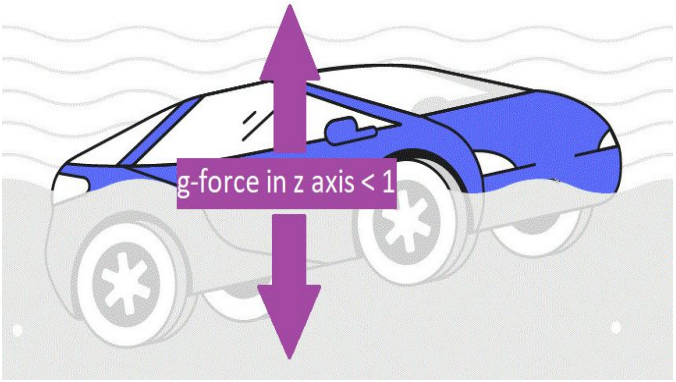

Fig. 8. g-force value change in underwater

If a vehicle faces an accident due to a height such as a fall from a bridge or hill, and falls into water. In these types of situation, our system has managed to detect it is an accident and the techniques for this is g-force checking. Usually, g-force is always 1 for any flat space but in underwater it becomes less than 1, which is shown in Figure 8. Our system has overcome the limitation to detect an accident in underwater.

If an accident is detected by our system, the buzzer is immediately turned on which we initially affix with the vehicle. In case of less severity of the accident or no causality, if the driver wishes not to notify anyone, we have given the privilege to cancel out the notification sent. If the buzzer is turned off within a given threshold time, no message is sent to the authorized number.

After any accident detected, our system waits for the threshold time to run out. If the threshold time has run out but the buzzer is not turned off indicates an accident actually occurred and authorized persons must be notified. Thus an automated message is generated containing a Google map address of the accident location and sent to the authorized number from the number which is already inserted in our system. Since the system is able to identify the exact location of the accident through GPS, thus the accident spot is easily traceable and can be reached within short time.

VIII. Limitations

We have designed the system in a way that can trace the location and send notification only by mobile network. It is not possible for the system to send notification using another network.

IX. Conclusion

Detecting accident and notifying immediately after the accident through SMS provides emergency facilities for any kind of unfortunate situation. In this paper, we have considered all possible ways to detect an accident which usually occurs. We have analyzed different situations logically and mathematically calculated them to make it accurate enough to serve its users.

X. FUTURE WORK

The future direction of our work is to reduce the severity of after accident causalities using more robust modules so that the detection system can become more accurate. We plan on improving the notification system, where we can send a message to the closest response sites i.e. Police station, hospitals. If an accident occurs, our system will match the location and search for nearby help stations and notify them This will help to use the time after accident more efficiently and possibly will save more lives.

***Abstract*— In the passage of time, the number of population in Dhaka city is increasing very rapidly. Most parts of this city are highly affected by the huge traffic jam. Peoples of all ages have to suffer and valuable times are being wasted for this long-standing hobble. The inadequate and inadvertent parking system is one of the main reasons for causing traffic congestion. Our prime aim is to develop a smart-phone based car parking model to minimize traffic jam and to ensure efficient car parking facilities in Dhaka city. To attain our aim we have designed and simulated a prototype of reservation based car parking system. Our developed smart-phone application will help the users to find the available parking spot in the nearest location. To maintain the parking details of different users a Java SE application has been developed.**

Keywords*— *IoT, car parking, double-layer security, request process, park share

I. INTRODUCTION

Dhaka is one of the most densely populated cities in the world whose population growth rate is increasing rapidly. At the time of Bangladesh coup, the population of Dhaka was just 3 million, which increased from 48 years to 20.28 million [1]. The population density of the city is approximately 13854/km^2, where the area is 1464 km^2. In this vastly populated area, traffic jam is one of the most burning questions to us. The average speed of automobiles in this city has decreased from 21 km/h to 7 km/h and it is estimated that in 2035 this speed will be reduced to about 4 km/h which is less than mass people walking speed [2].

Over the previous decades, the amount of automobiles has been increased tremendously in our country, especially in Dhaka city. These excessive increases of automobiles work as a vital reason for the city's parking problems, fuel wastage, time wastage, and user frustration which have a greater impact on the urban ecosystem of Dhaka. According to the BRAC Institute of Government and Development, Dhaka city has lost approximately 5 million working hours per day for this traffic congestion, which damages $11.4 billion per year [2]. To overcome this situation, the Bangladesh government (Revised Strategic Transport Plan, 2014-15) has taken various effective steps including five metro rail lines, two rapid bus routes, 1200 km of new roadways, 6 existing elevated expressways and three ring roads [3].

Although these steps can play an effective role in solving traffic congestion, if we considering Dhaka city then only 7 % of the roads are available compared to the area [4]. On the other hand, Paris and Vienna have 25% and Washington DC and Chicago have 40% roads. In Dhaka, 70% of this small number of roads is occupied by automobiles. Moreover, about 3700 new automobiles are being added to the city in every year [4]. In modern metropolitan cities, it takes an average of time to get a user's parking facility which is analyzed, 35% of the cases require 10 to 15 minutes, in which 30% of the cases increase by more than 20 minutes [9].

In Dhaka city, where there is a lack of parking reservation policy, our main aim is to increase the parking reservations as well as modernize the system with an Internet of Things (IoT) technology. On the contrary, accelerating its development by providing parking spot share facilities is also a key factor. Often the users faced the problem of finding a parking spot to their desired location. However, they are unable to manage a parking position according to their needs and therefore they cover a long distance from that position to the workspace. Although the numbers of new automobiles are being added to the city every year, there has been no development of the parking system. As a result, many of these automobiles are parked on either side of the streets. There are also a few parking reservation systems, but they do not have enough modernization, hence searching for a desired parking spot at the correct time has always been a challenge in Dhaka with impact on traffic, pollution level, wastage of fuel, and user frustration. Our main focus is to develop a convenient car parking mechanism in order to alleviate the traffic congestion at Dhaka city. Moreover, we have portioned our model into threefold: Android Application, Embedded Controller and Java Desktop Application.

II. RELATRD WORK

We have studied various related articles for the development of our proposed architecture. In this segment, we will briefly discuss some relevant work that helps us to gain additional information that is available in literature.

Kianpisheh *et al.* [5] proposed a Smart Parking System (SPS) Architecture using Ultrasonic Detector which is actually works on echolocation (the location of objects by reflected sound), emits a sound and then it is reflected and return to the sensor. In this paper authors only provides information on parking lots and the available numbers of parking. It can be defined as a general Informative Parking System (IPS) rather than Smart Parking System (SPS).

In another study, Kaarthik *et al.* [6] showed an Image Processing Based Intelligent Parking System where they developed an empty lot detection technology by processing of image and displayed the data through 7 segments LED display. In this method, they showed only parking lot in a

specific parking zone and they were not concerned regarding data storage.

A. Nandugudi *et al.* [7] proposed a crowd sourcing-based automated system called PocketParker for informing the free parking available to the users. However, this system is unable to provide a probability of free parking spot and accurate information about free parking or street parking.

In another paper, Rachapol et al. [8] also proposed a Smart Parking Using IoT Technology and showed an approach by using a mobile application to know vacant parking lots. The significance of this article is, they added a mechanism for detecting vehicle plate number to monitor vehicles in the parking area. They also designed the payment process using a mobile application. But in certain cases, if any user needs urgent parking, their system won't be able to perform accordingly to address the issue.

Authors in [9] proposed an incentive-based crowdsource bidding service for parking reservation. Here they presented a method to solve parking problem by using crowd source based approaches. In their paper, the central system only collects information on free parking with the help of third-party users called bidders and provides services to the users. This system is smart and cost-effective to simulate. If bidders are dishonest or absence, the whole process will fail to execute.

O. Orrie *et al.* [10] presented a wireless smart parking system providing location and availability of parking spots using android application. Their proposed system informs users about the nearest lots status within 2 km away and they used proximity sensors to read current data in every 2 minutes.

Chungsan Lee *et al.* [11] addressed a unique approach in terms of smart parking system by employing the Bluetooth communication between smartphone and wireless sensor. They used Ultrasonic sensor and Magnetic sensor to detect vehicle in indoor or outdoor parking field.

Authors in [12] proposed an algorithm to increase the efficiency of crowd source based smart parking system. Here, they proposed a system that helps users to find free parking using least cost by considering the distance and a total number of free places in each car parking reservation system. By this system, the user can get information about the nearest free parking but in crowded cities where finding free parking is a great challenge, this system will not function properly.

Chieh-Hsun Huang et al. [13] designed an intelligent parking system where drivers can get parking information like vacant parking space, parked vehicle status, remote end monitoring etc. through Micro Aerial Vehicle (MAV). Here they also proposed QR code scanning method for finding vacant space or parked vehicle position. In their system, authors focused only on a large parking reservation system rather than providing information about all nearby parking location.

In another exploration, Vanessa *et al.* [14] proposed a wireless sensor networks based car parking model by deploying wireless sensors into car parking field. They only designed a parking spot by providing availability information, security management system and static report.

III. System Architecture

In this segment, we will describe in detail regarding our system architecture. Following Fig.1. illustrates our proposed architectural diagram. Each module of our designed model is interconnected with other components, which can easily be analyzed from Fig. 1. According to our proposed architecture user needs to complete their registration with a unique username. After successful registration, users are allowed to log into their account and be able to access all facilities of our designed system. By using our developed mobile application, users can book a parking spot, share their free parking spot, request for urgent parking and so on. In order to ensure safety, we also designed a Double-layer security mechanism.

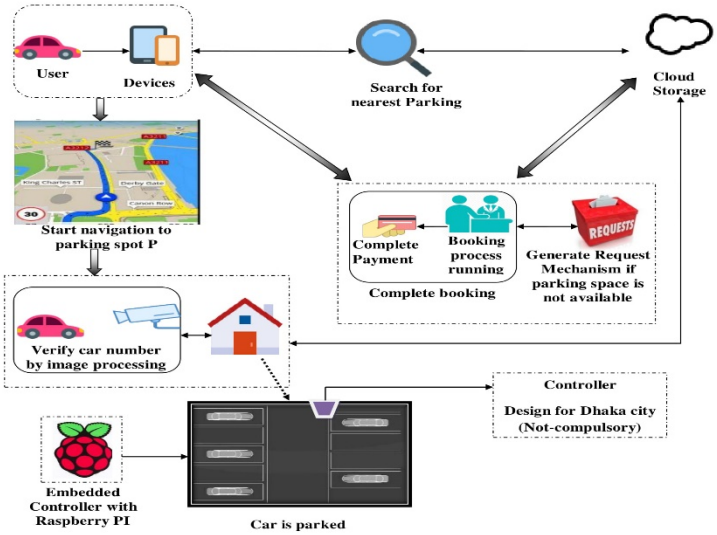

Fig. 1. Architectural diagram of our proposed model

A. Overview of our proposed system

In this section, we will briefly discuss the working procedure of our proposed architecture. We have segmented each module into individual processes. Following processes will provide us with an overview regarding the working approaches of this system.

Process (1): *Checking the nearest parking location*

After successfully login into android application, users can easily check for the vacant space through Google map using our developed mobile application. They also will be able to find all information including parking rate, vacant status, with the street address of the desired parking location and so on.

Process (2): *Request and booking procedure*

Based on availability of parking spot user will be able to confirm booking and they can request for urgent parking if there is no vacant space.

Process (3): *Booking confirmation and payment completion*

After selecting a vacant parking slot users need to complete the payment either the online payment gateway system or via cash to confirm their booking.

Process (4): *Driving to the parking lot and park the vehicle*

Users will be able to reach their desired location whenever the booking is confirmed. The process of number plate detection will be performed in order to entering to the parking spot.

Process (5): *Releasing the vehicle and Exit process*

In order to releasing the vehicle from parking space, number plate verification process will be performed to exit from the spot.

B. Elements of the system

The following section will discuss the interconnection between various components that we have proposed to build this Model. Following Fig. 2. clearly depicts the architectural diagram of our proposed model. All the connected elements of this model are discussed briefly in this segment. We have segmented our system elements as follows.

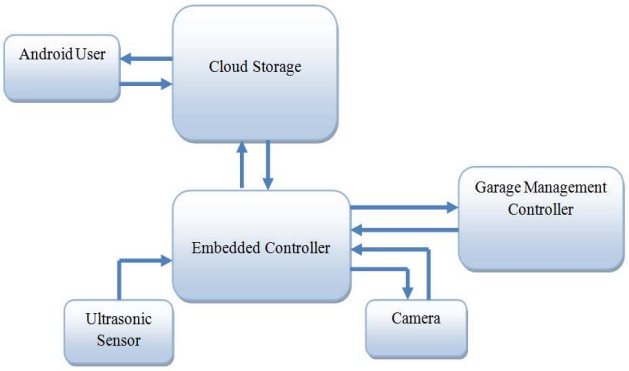

Fig. 2. Architectural diagram of interconnection of individual elements of our proposed system

Hardware Elements:

Sensor: We have used the ultrasonic sensor in order to detect the exact location and any displacement from previous location to new location of the respective car.

Camera: For capturing real time data of parked cars, we developed an image processing model. A quality camera will be used to capture the data of respective cars.

Embedded Controller: Among all components, it is considered as prime one. We have used Raspberry pi3 as an embedded controller.

Software Elements:

Cloud Control API : By Cloud Control API, the image of the number-plate is converted into text data through image processing and later the data is stored on the cloud server (Cloud Storage Databases).

Android Application: Through the mobile application, it provides information using the various Google API to find parking at the desired location.

Desktop Application: One of the features of our proposed ParkEasy is to control the garage through the desktop application. Therefore, we have developed a Java desktop based application to handle the real time data from the sensor.

Garage Management Controller (GMC): GMC is another controller that is designed for providing services both registered and unregistered users.

IV. METHODOLOGY

In this portion, we will explain each module of our proposed model with in-depth analysis. Moreover, our main methodology behind this effort will be enlightened here. To develop an effective and secure car parking system to alleviate traffic congestion at Dhaka city we have followed the following methods which derives us to develop a cost-effective and useable car parking model for Dhaka city. The following phases are obligatory in order to build our proposed propositions.

Garage Automation: Existing parking reservation systems of Dhaka city will be coordinated with the Ultrasonic sensor and digital camera which will be combined with IoT technology. The data from the camera and the sensor will be updated in real time to the cloud storage. As a result, it is possible to get all the information about parking from any place through our smart-phone application. Following Fig. 3. indicates a sample diagram of an automated garage. Aside from parking reservation systems, there will be an available parking lot display, where real-time data will be displayed at every moment. Also, we will include modern facilities like Indicator display, Garage map, Security alarm and so on.

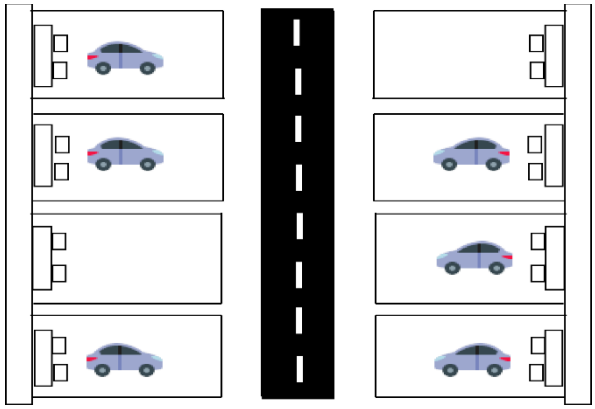

Fig. 3. Sample diagram of an automated garage

***Embedded Controller*:** IoT technology based Embedded Controller plays a vital role in building our model. In our system, we will use Raspberry pi3 as an embedded controller. This embedded controller fetches the data from the sensors and cameras. It also operates simultaneously collects real time data and transfers the processed data to the cloud server.

***Application Functionality and User Interface Design*:** Our developed smart-phone application is another prime component of the system. Through this application user will be able to find parking lot at desired location by the help of Google API. Following Fig. 4. shows the User Interface (UI) of our developed Mobile application. Users will be able to book and request parking places by clicking on the desired location on the Map. From the garage map, user also will be able to view the real-time image of the desired parking spot and its status.

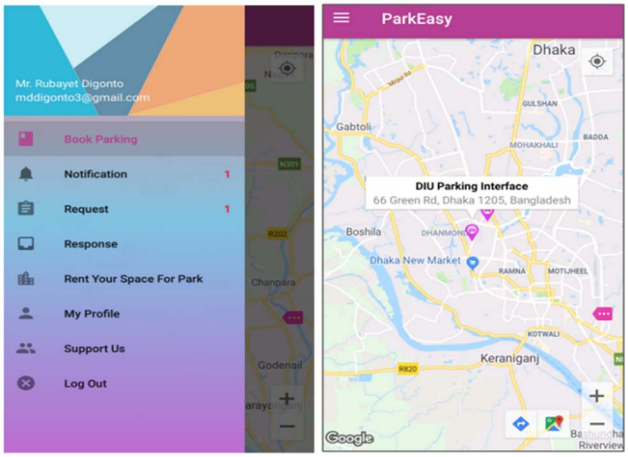

Fig. 4. User Interface (UI) of our developed application

GMC: By introducing the concept of GMC, we already have developed a Java SE based desktop application. Following Fig. 5. provides us with an overview that how our developed desktop application works.

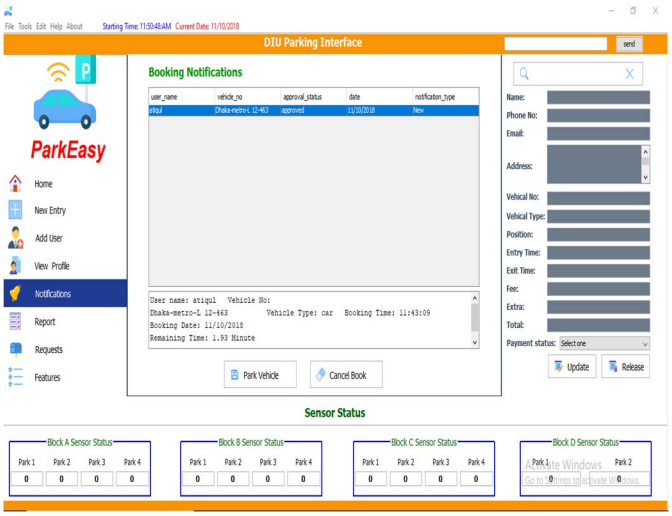

Fig. 5. Java based desktop application

***Number plate detection and recognition*:** Authentication will be provided through number plate detection for both car entry and exit. Following Fig. 6. depicts the captured images with different measurement for number plate verification purposes. To confirm the location of the car in the parking space, we will use the Cloud API. Image processing method will be applied through Number plate detection and respective data will be sent to Cloud server.

Fig. 6. Captured number-plate at different distance and angle(*44cm and 55cm*)

***Double-layer security system*:** To ensure the maximum security of parking cars, we have developed a double-layer security system that is depicted in the following Fig. 7. In the first layer, we will follow the number plate verification process and in the second layer, parking slots will be surrounded by sensors and cameras. So if the car moves away from the sensor's coverage area, the alarms will be ringing and also it will be notified to the user as well as GMC via our developed application.

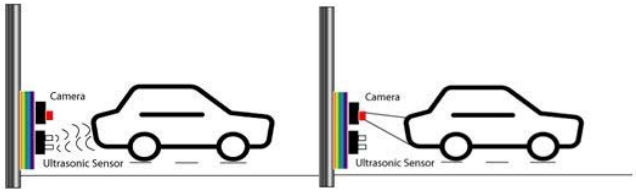

Fig. 7. Vehicle covered by ultrasonic sensor and camera

Share the Park or Rent your space: The unused basement of buildings like Shopping malls, Residence-buildings, Hospitals etc. that will be converted into a parking zone. Anybody interested can rent or share single to N numbers of unused spaces by using our developed mobile application. As a result, it is possible to increase parking lots without creating new parking reservation system. The complete process for sharing the parking lots is illustrated in following Fig. 8.

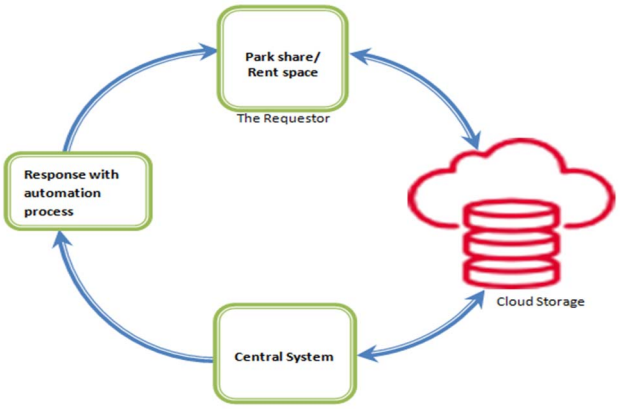

Fig. 8. Process diagram of parking zone sharing

Visualization of Parking Garage: Visualization of the parking garage helps the users to track the status of parking spot, mapping and direction to the slots inside the spot and so on. Following Fig. 9. shows how our developed mobile application interface will visualize the real time availability of parking slots.

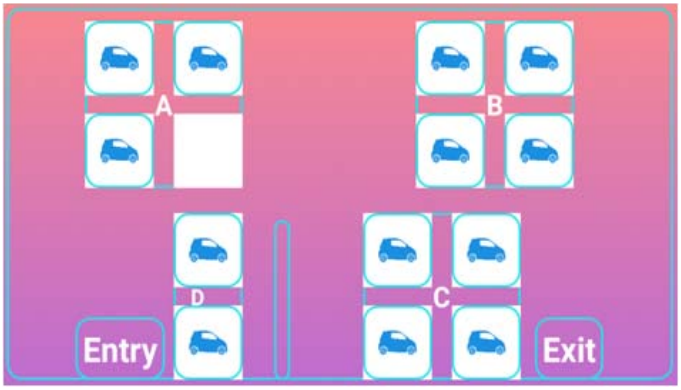

Fig. 9. Garage Map visulation of our designed parking garage

Request Mechanism: This mechanism specially is designed for those users who cannot manage parking spot at their desired location. In this case, users can request for urgent parking for their desired location. Fig. 10. depicts the UI of request and response process for urgent parking of our developed application.

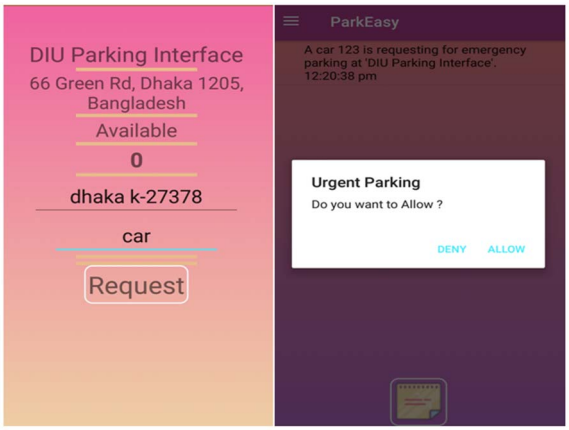

Fig. 10. Request and response process for urgent parking

V. IMPLEMENTATION

This segment will cover implementation procedure of proposed methodologies. In this portion, we will represent our simulation model with working procedure of our designed architecture. Apart from that, we will also explain how car booking process, parking and releasing process, and process of request mechanism works. Following Fig. 11 depicts the entire architecture of our simulation. In general we used some toy cars for simulating our proposed design with the support of developed android mobile application, garage management controller, and embedded controller. The later part of this section will emphasize on the various process and the sequential steps of its working procedure.

Fig. 11. Simulation of *Parkeasy* model

A. Booking process

TABLE I. SEQUENTIAL STEPS FOR BOOKING PROCESS

Step 1: Take user location
Step 2: Find nearest parking location
Step 3: Select the digit note node
Step 4: Book a new Space to park if available exist
Step 5: Request to a parking space if available does not exist
Step 6: Confirm the request if gets any response for urgent parking
Step 7: Get Notification

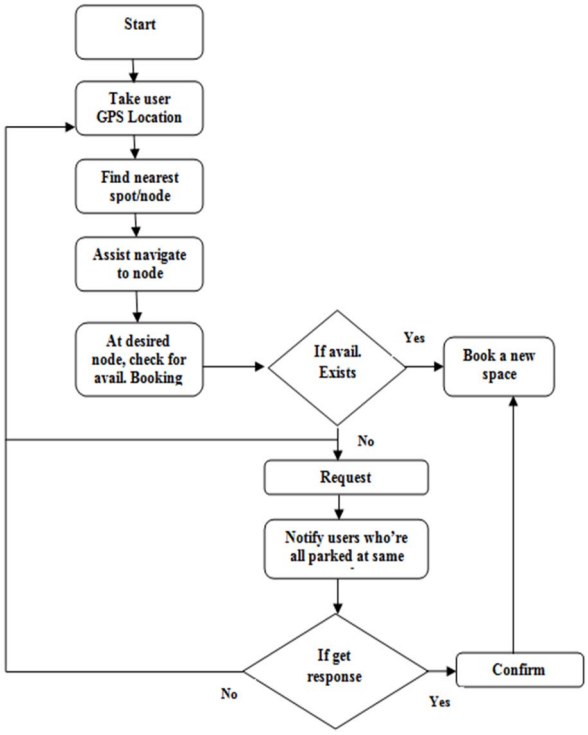

Fig. 12. Flowchart of Booking process

B. Parking and Releasing process

TABLE II. SEQUENTIAL STEPS FOR PARKING AND RELEASING PROCESS

Step 1: Complete brooking a space for parking
Step 2: Transaction of payment
Step 3: Getting the chosen or given slot number/opposition
Step 4: Verification by vehicle number plate detection and recognition
Step 5: Opening the gate to enter to the parking lot
Step 6: Notifying after successful parking
Step 7: Displacing of vehicle, notify to the user
Step 8: Repeat of step 4
Step 9: Release vehicle and exit
Step 10: Notify to the user

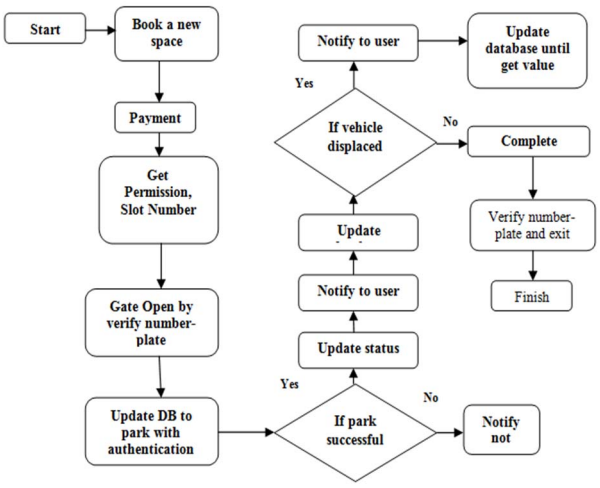

Fig. 13. Flowchart of Parking and Releasing process

C. Process of RequestMechanism

TABLE III. SEQUENTIAL STEPS FOR REQUEST MECHANISM

Step 1: Request to a parking space if available is zero
Step 2: Generate request to the all users who are currently parked at the same parking lot
Step 3: Notify the requestor if any response for urgent parking
Step 4: Release the donator
Step 5: Confirm the donator's slot for the requestor (here, first donator's slot will be booked for the requestor if donator releases himself)
Step 6: Notify the requestor

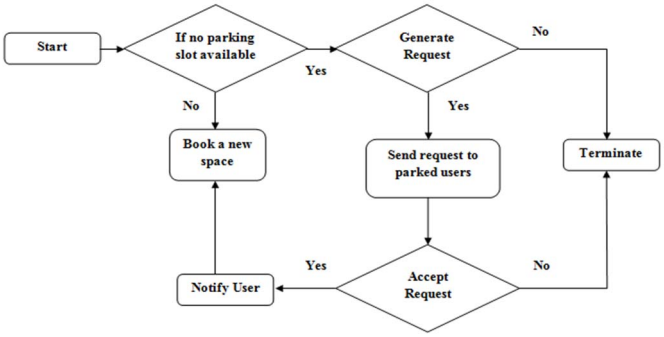

Fig. 14. Flowchart of Request Mechanism

VI. EXPERIMENTAL RESULT

In order to evaluate the effectiveness of our proposed model we have performed a street survey based on the different status shown in TABLE IV. We surveyed 100 people around the Dhaka city.

TABLE IV. SURVEY RESULTS ON CAR PARKING STATUS(BEFORE PROVIDING INFORMATION)

Status	Percentage
Do not know about parking location	60%
Do not know about parking system	17%
Cannot manage lot at desired parking location	10%
Not interested to park	8%
Don't care about parking	5%

After providing information by mobile application, the following users will be informed about the advantages. The number of users will know about parking location (60*90/100) or 54%, since 90% users of them have smartphone. Similarly, the other status of the TABLE IV will have different proportion and we have enlisted them in TABLE V.

TABLE V. SURVEY RESULTS ON CAR PARKING STATUS (AFTER PROVIDING INFORMATION)

Status	Percentage
The number of users will know about parking location	54%
The number of users will know about available and others information	15.3%
The number of users will know about urgent parking but failed to manage parking	9%
The number of users will know about the parking info though they are not interested	7.2%
The number of users will know about the parking info but they do not care	4.5%

So the total number of people will be benefited (54+15.3+9) or 78.3%. As 9% of users cannot manage the parking spot, the actual number of users will be (78.3-9) or 69.3%. At this initial stage, if we are able to provide service to 20% among the 69.3% users, then (69.3-(20/100*69.3)) or 55.4% will remain parked beside roads. By increasing from 20% to 50% and 80%, the number of parked vehicles beside roads will be reduced. The calculated value based on the result is summarized and shown in the following TABLE VI.

TABLE VI. COVERAGE USERS UNDER SERVICE ACCORDING TO EXPERIMENTAL DATA

After providing service to 20%, vehicles remain parked beside roads	After providing service to 50%, vehicles remain parked beside roads	After providing service to 80%, vehicles remain parked beside roads
55.44%	**34.65%**	**13.86%**

VII. CONCLUSION

In this era of rapid urbanization, designing the city system modern and systematic by maintaining everything is a major challenge. Under the pressure of increasing population, Dhaka is becoming tougher to change. Our proposed solution is to keep the city parking system as a fully automated and additionally use garage management controllers system so that user can get parking facilities with the android application as well as without android application. To best of our knowledge, we are the first to design an IoT based parking system with request mechanism and parking share facility. To make parking spaces more secure, we also developed a Double Layer Security System. Currently, we are working on it and in near future, we will be able to implement it for real-life development at Dhaka city.

***Abstract*— As the world is globalized day by day, so the demand of automated machines has increased rapidly. In industry or any power plant boiler hold a significant contribution. To control it industry need uninterrupted monitoring at frequent interim. But there have number of restriction to measure various stage of boiler by worker. In this paper there has been designed and implemented an automated boiler control system using programmable logic control system (PLC) to exceed respective errors. The main operation of this project is to start and stop boiler system automatically according to set value. There has used sensor to measure the temperature and control it by sending this signal to PLC. Moreover, the boiler system can run for a certain period using the ON-OFF push button.**

Keywords—Boiler Automation System; Programmable Logic Controller (PLC); NTC, SMPS.

I. INTRODUCTION

The demand for automated machines that can operate much efficiently to produce higher quality products has increased. In case of boiler plant, there needs proper control of sensors and proper monitoring of temperature regularly. Thus handling the plant manually is become arduous job.The idea of boiler automation was introduced to achieve the goals involves with the automation control system are operation development, improving management level and high efficiency process . As handling the boiler manually is become arduous job, industrial sector is adopting automation.

A programmable logic controller (PLC) is an industrial automated system that constantly monitors the input device states and makes decisions based on a custom program to control output device states[1].Basically boilers are used to produce steam which will be used for different operations like to run the turbine which in turn produces the electricity. During this process it is essential to monitor the temperature, steam pressure, water level, etc. for reliable operation and to avoid errors and damages. But with the human workers there are a number of possibilities of errors while measuring at different stages. The boiler automation techniques are very much important to avoid the errors due to human workers. Previously, a several number of studies has been done on boiler automation system. In industrial sector automation was done using various techniques. T. Karuppiah and Dr. Azha developed a system by using microcontroller and GSM technology for power plant boiler automation[2]. In their proposed system there have a number of boilers supplied by a main water tank. There have ultrasonic sensor for controlled the water level in the main water tank. There have some temperature sensor in every pipes of boiler which controlled the temperature of the system. The GSM module is used for give information to the consumer. Udaykumar S. Kulkarni & Venkat N. Ghodke proposed a design of boiler automation using FPGA & GSM[3]. In their proposed design a main water tank is connected to several boilers. water level sensor & temperature sensors are used to control the water level of the main tank & temperature of the boilers. GSM mobile phone are used to get information about the current temperature in any boiler. VHDL (VHSIC Hardware Description Language) is used and implemented in hardware using FPGA (Field Programmable Gate Array).Aaron James et. al. proposed a boiler automation system for a power plant using distributed control system (DCS)[4].The system conventionally used as a water tube boiler up to approx. 300 bar or as a quick steam boiler up to approx. 30 bar. Here with the assistance of DCS the output steam from the steam distribution header encompasses a desired temperature by proper controlling of temperature. However, the functions of this systems have not yet been clearly defined. The cost is so high in Distributed control System & in using FPGA. In a boiler system by using

microcontroller, response rate is low. Its operation is not flexible and durability is high.

The main aim of this paper is to design and implement a boiler automation system using PLC for ensure efficient operation of boiler and digitalize the industries. To achieve the goal of this project a LOGO PLC was employed to control the operation of the boiler. In this project a heater jug was used as a prototype of boiler. A NTC (Negative Temperature Coefficient) thermistor along with a temperature showing module is used to measure the temperature. Then the thermistor sends signal to the PLC through a regulator IC 7812. And therefore according to the predefined value set via ladder diagram into the logo PLC, it performs the on-off operation of the boiler accordingly.

II. Overview of the System

"Fig. 1", shows the block diagram of the complete system. 220v AC voltage is used to give the power supply from which necessary power is given to all equipment to activate it.In this system water heater tank is used as prototype of the boiler where there have temperature sensor which senses the temperature.This resulting temperature signal sends to PLC through op-amp as a voltage and PLC makes decision based on the predefined programing. The boiler system is shut down by PLC when the temperature exceeds set maximum value. At the same time, a cooling fan starts running to release the high temperature to a certain limit and then the cooling fan stops. Then when the temperature is below set minimum value, the boiler system is started by PLC again. Thus, the above process is continued. Timer is used for timing operation of the boiler and manual switch is used for emergency switching off the whole boiler system.

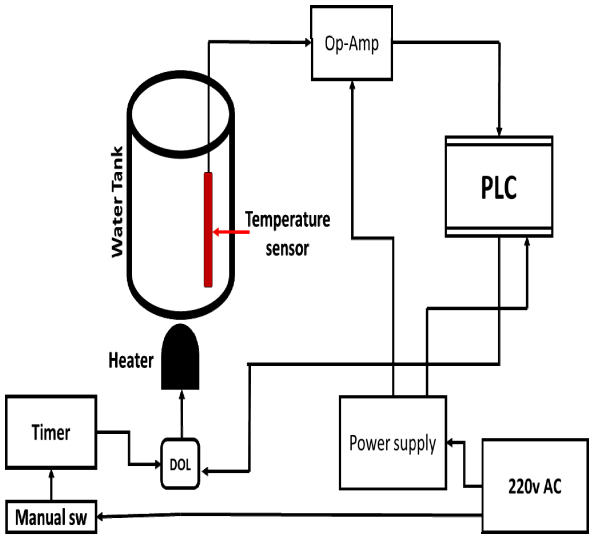

Fig. 1. Block Diagram of the System.

III. System Design

This section describes the methodology to develop the prototype of the system. In this project a LOGO PLC was employed to control the operation of the boiler. The development process includes a heater jug, NTC(Negative Temperature Coefficient, Regulator IC 7812, Timer and DC relay.

A. PLC(Programmable Logic Controller)

The functions for the system of PLC is simple and genuine which is shown in "Fig .2." It has three processes completes by CPU. first one is reads or scans from the input devices. Then it solve the program logic and at last updates a Program or Logic for the CPU to execute. Ladder Logic, Instruction List, Sequential Function Charts, or any of the IEC languages can be written for this logic. Then the program is downloaded to the PLC by the programmer which is done for short time to connecting the programmer to the PLC. If the program is installed once to the CPU then its unnecessary for the PC to remain connected [5].

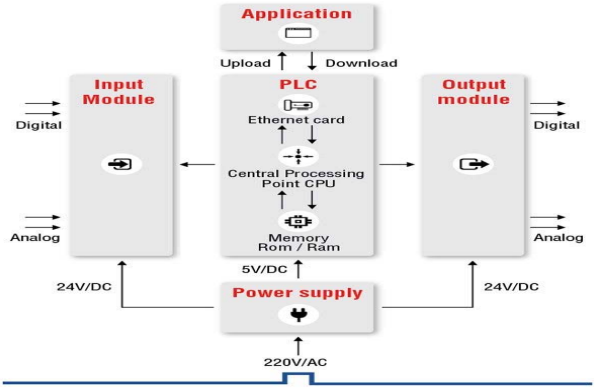

Fig .2. Operation of PLC [5].

B. NTC(Negative Temperature Coefficient) Thermistor

NTC thermistors shown in "Fig.3." are temperature sensors, basically are resistors have a negative temperature coefficient.It means the resistance of this sensors decreases with the increasing temperature.The temperature sensitivity coefficient of this sensors is about ten times greater and five times greater than that of resistance temperature detectors (RTDs) and silicon temperature sensors (silistors) respectively. NTC sensors are usually employed at −55°C to 200°C [5]. But some special families of NTC thermistors can be used at temperatures close to absolute zero (-273.15°C) and some are specifically designed for use above 150°C. The temperature sensitivity of NTC sensors is expressed as "percentage change per degree C" which depends on the materials used in it and the specifics of the production process. For change of every °C the temperature sensitivity range changes from -3% to -6%[6]. The characteristic curve of NTC thermistor is shown in "Fig.4."

Fig. 3. NTC thermistor [6].

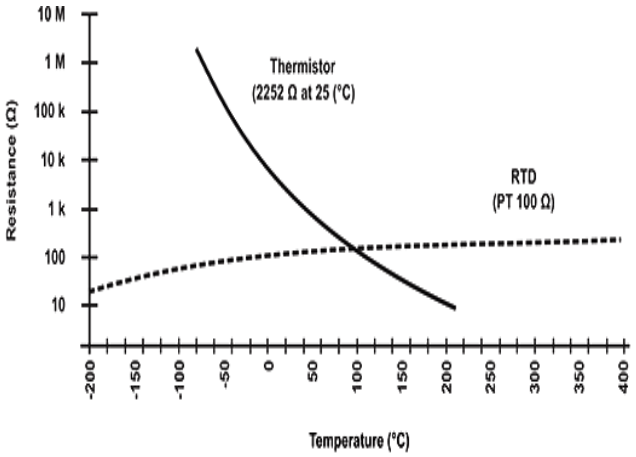

Fig .4. Characteristics of NTC Curve [6]

C. *Switched Mode Power Supply(SMPS) (AC to DC)*

SMPS is an AC to DC converter which is used to attain a fixed DC output voltage from unconditioned AC or DC input voltage.When it get an AC input SMPS convertes this AC input into DC by using rectifier and filter and by using a power MOSFET amplifier the switching is done.By this way very high gain can be attained. The switching action is controlled by a feedback through PWM oscillator and a switching frequency is chosen which must be inaudible to normal human beings (mostly above 20KHz). A feedback circuit is used which control the output voltage by comparing it with the reference voltage.If there is AC portion in the output side this AC voltage is again fed to the output transformer shown in the figure to step up or step down the voltage levels and by using the output rectifier and filter the output of this transformer is again rectified and smoothed [7]. The operation of AC to DC converter SMPS is shown in "Fig.5."

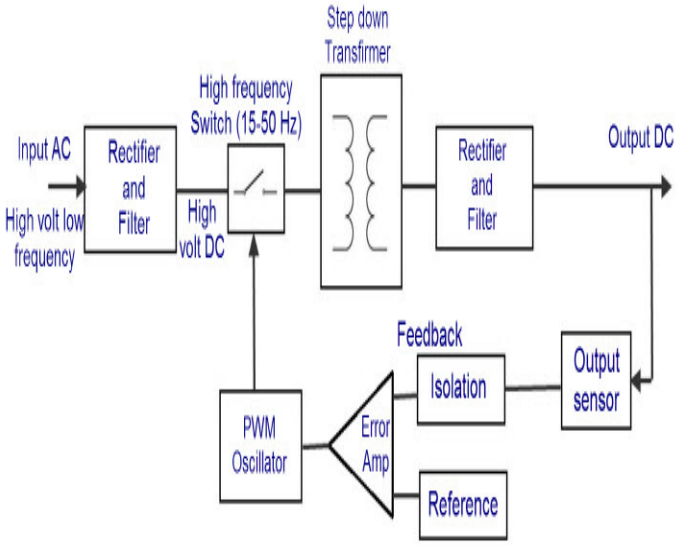

Fig.5. Operation of SMPS [7].

D. *Ladder diagram of system*

LOGO! Soft Comfort V6.1 software is used in this system. Ladder diagram method is used as a programming language here. The Logo PLC was enabled using this software. This software is used for drawing the ladder diagram of this system.

In the ladder diagram I have used make contact, break contact, timer, analog input, analog threshold trigger, lathing relay and relay coil blocks. There is two type of operation in this system. One is normal operation and another is timing operation. In normal operation, analog input (AI1), analog threshold triggers (SF001, SF003, SF005, SF007, SF009) lathing relays (SF006, SF008) and relay coils (Q1, Q3) are used. And in timing operation, break contact (I1), make contact (I2), Timer (T004), Timer break contact (T004) and relay coil (Q2) are used as shown in "Fig.6." and "Fig.7."

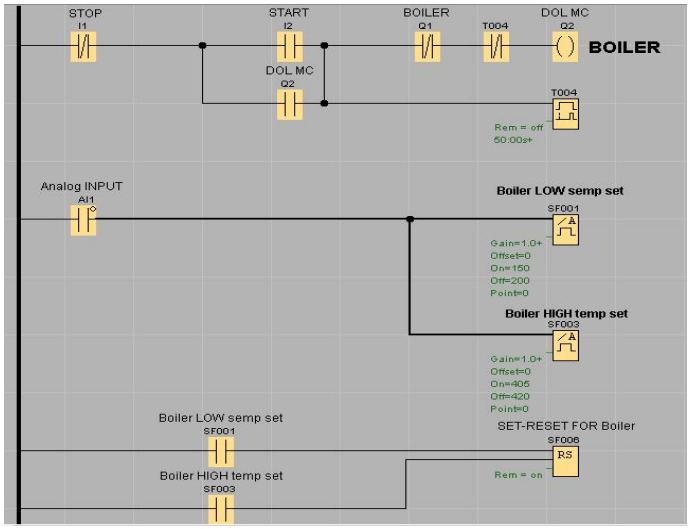

Fig. 6. Ladder diagram of the system.

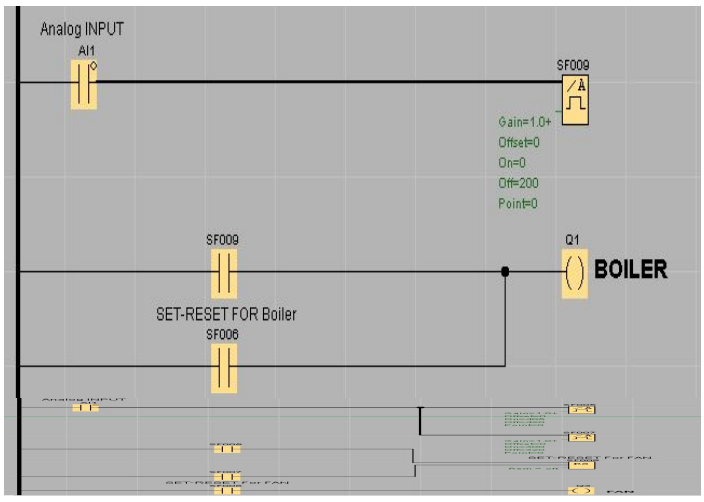

Fig.7. Ladder diagram of the system.

E. *Circuit diagram of this system*

After giving AC power and switching on the power button, the main power supply gets activated. NTC Thermistor is used to sense the temperature of the boiler. NTC Thermistor has internal resistance of 10K at 25°C that changes with the change of temperature. In this project, the voltage divider rule is applied and the divided voltage is given in analog input 1 of PLC. But due to change of temperature the internal resistance of NTC Thermistor changes and thus the voltage of analog input 1 changes. By calculation it is possible to get the voltage of analog input 1 of Logo PLC (OBA5) for every temperature changes. By using ladder diagram I have set the function of Logo PLC (OBA5) to work as follows:

At 30°C the voltage at analog input 1 is 1.5V due to change of internal resistance of NTC Thermistor with the change of

temperature. So, Logo PLC (OBA5) is given command through ladder diagram to start the boiler system when voltage in analog input 1 is 1.5V. Therefore, boiler system starts running when the voltage in analog input 1 is 1.5V i.e. the temperature is 30°C.At 96°C the voltage at analog input 1 is 4.05V due to change of internal resistance of NTC Thermistor with the change of temperature. So, Logo PLC (OBA5) is given command through ladder diagram to shut down the boiler system when voltage in analog input 1 is 4.05V. Therefore, boiler system shuts down when the voltage in analog input 1 is 4.05V i.e. the temperature is 96°C.

Moreover, the boiler system can be run for certain period of time using the ON push button. It will run for certain period of time and then stop. The OFF push button is used to stop theoperation of the system. And to stop the boiler system manually, a manual switch is used. Circuit diagram of the project is shown in "Fig.8".

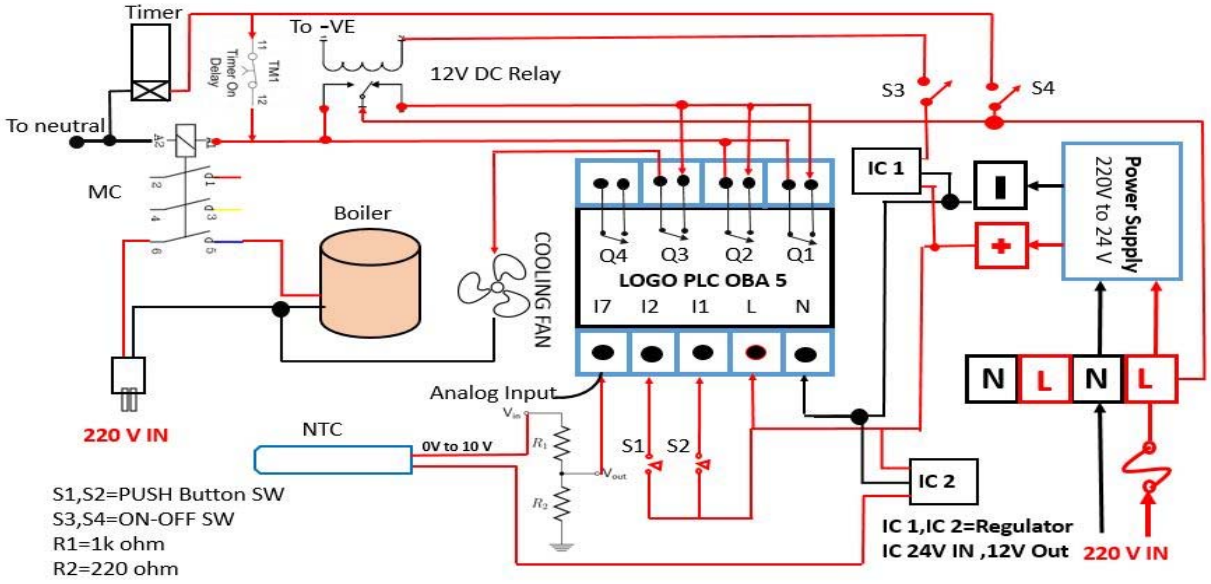

Fig. 8. Circuit diagram of the system.

IV. Programming and Implementation

This section illustrates the algorithm and practical implementation of our system.

A. Algorithm

"Fig.9." and "Fig.10." shows the flow chart of the system. At the beginning of the operation as soon as the main switch is turned on boiler system starts thus the temperature of the boiler starts increasing. And the NTC thermistor starts measuring the temperature of the boiler. The measured temperature is displayed on a digital thermostat temperature control module. When boiler temperature exceeds the set maximum value of temperature the boiler system shuts down. Then the cooling fan start running until the temperature is reduced to certain limit. The boiler system remains off till the temperature gets below the set minimum value of temperature. As soon as the temperature gets below the set minimum value of temperature the boiler system starts again. This operation is continued and maintained. And in case of timing operation we can use the ON push button to start the boiler system and run it for a certain period of time according to our need. After the certain period of time the boiler system will stop. The OFF push button can be used if we want to stop the boiler system during the timing operation and before the certain period of time. In both the ways the entire operation is controlled by Programmable Logic Controller. The programming of PLC is done using Ladder Diagram (LD).

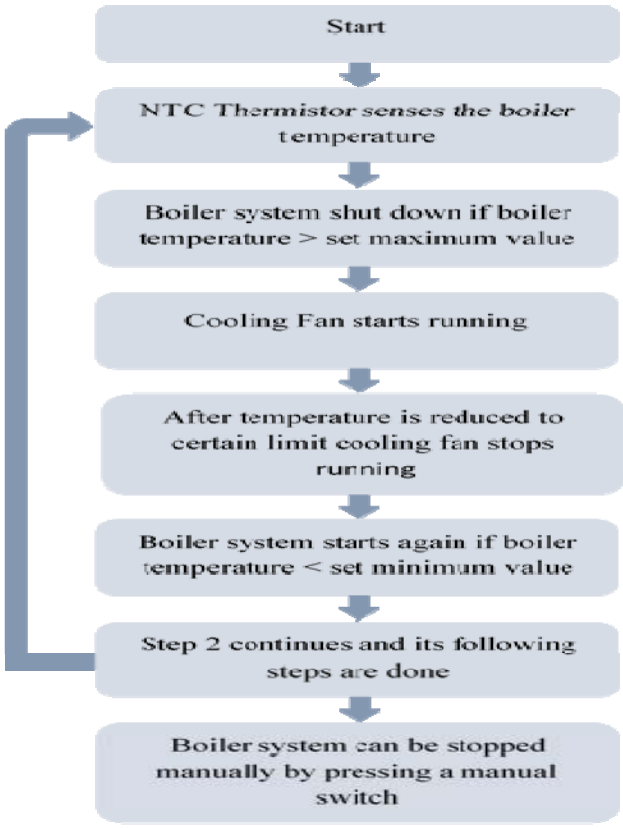

Fig. 9. Flow chart of the system (Normal operation)

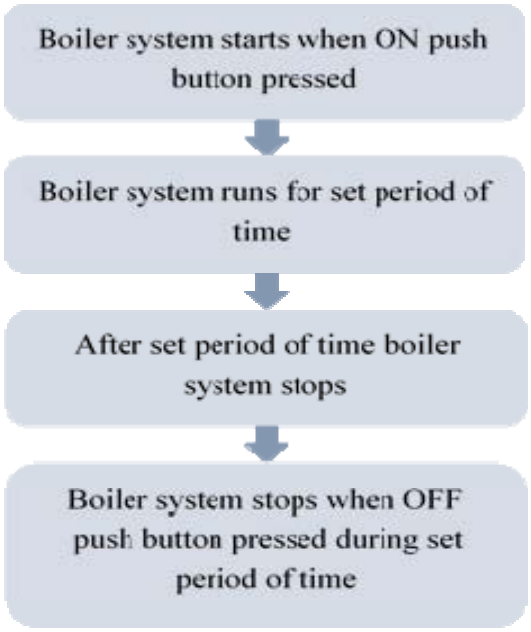

Fig. 10. Flow Chart of the system (Timer operation)

The flow chart of the sequential PLC operation for normal and timing both the operation is shown in "Fig.11." and "Fig.12." respectively.

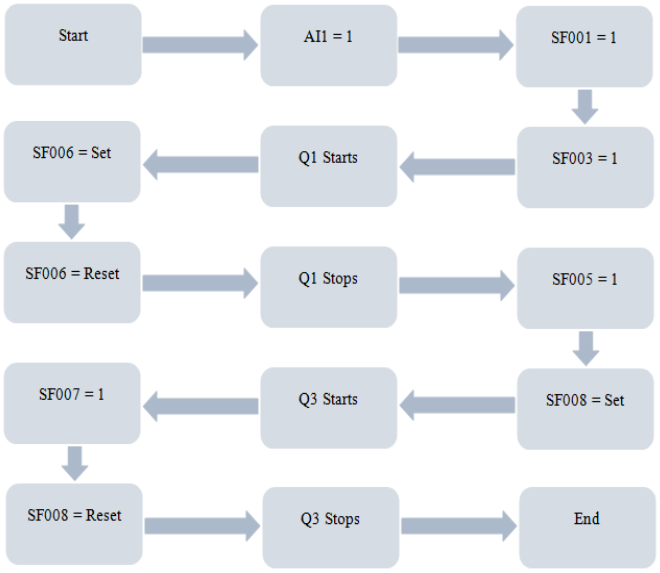

Fig. 11. Flow chart of PLC (Normal operation)

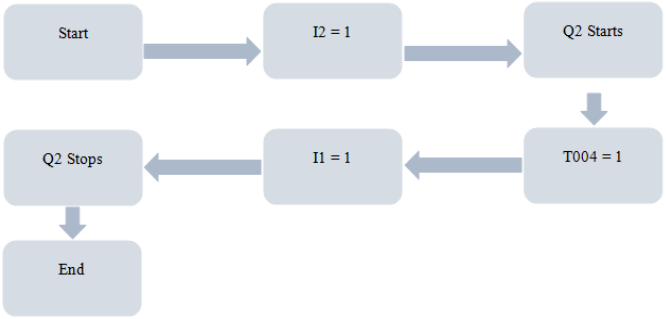

Fig. 12. Flow chart of PLC (Timer operation)

B. Hardware Implementation and Results

The overall performance of the boiler automation system was satisfactory but some improvement can be done on this system. The switching operation of this system was fast and accurate.The overall performance of this system is shown in below:

When the temperature is equal or above 30^0C as well as the voltage in LOGO PLC analog input (AI1) is 1.5V the boiler system starts running. The running condition of boiler system is shown in "Fig.13."

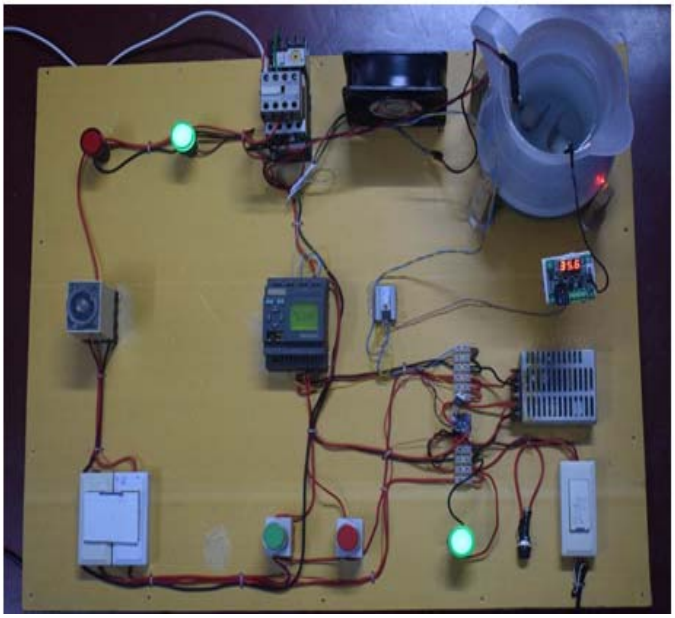

Fig. 13. Running condition of boiler system.

When the temperature is equal or above 96^0C as well as the voltage in LOGO PLC analog input (AI1) is 1.5V the boiler system will be shut down. The shut down system is shown in "Fig.14."

Fig.14. Shut down system of boiler system.

In order to stop the overall boiler system, a manual switch is used. When the manual switch is pressed the whole boiler system is shown in "Fig.15."

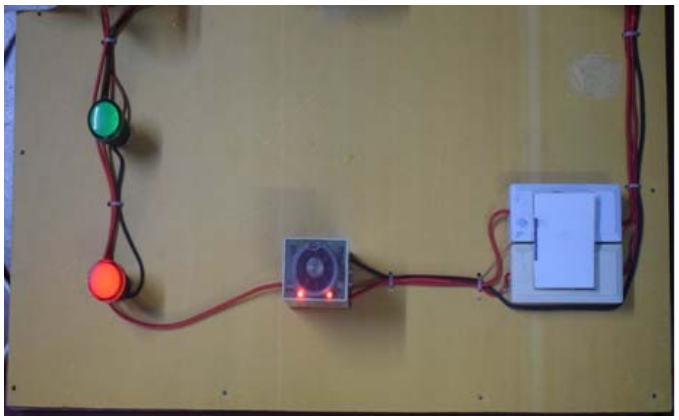

Fig.15. Boiler system switching off manually

C. Comparison with Real System

The system is developed primarily for research purpose as we design the prototype here. Real system may need some modification to be done. In this project heater jug is used as prototype of the boiler so during heating there is risk of hot water pouring out of the jug. But in practical industrial purpose real boiler is used which is usually closed vessel. So, there is less risk in the real system. In the prototype system, AC to DC and several voltage conversion is needed for operation purpose of the project. So, several extra devices are needed. However, in practical system these conversions may not be needed. Therefore, extra devices are not needed and thus the cost is reduced. In prototype system only the temperature of one boiler is controlled using single PLC. But in practical system temperature of several boilers can be controlled just by a single PLC.

V. CONCLUSION

To consider the necessities and demand of the industrial sector, there has been given significance attraction to boiler automation system which is done in this paper by using PLC. This system overcomes the lacking of the microcontroller.It also assures protection and safety to the human workers by automating the temperature control of boiler as it is risky due to high temperature during operation.Although the cost of this system is higher but the response rate of this system is faster and the operation of this system is more flexible compared to others.This system can be used to digitalize factories by making manually operated boilers fully automated. In future the system can be developed with considering the application-oriented implementation of remote monitoring of boiler automation by SCADA internet access.

***Abstract*—Human face recognition plays an important role in video surveillance, human-computer interface, personalizing different applications. In this paper, we present an approach to detect and identify a human face from the real-time video that tracks a face and compares it with stored data of known individuals. Our approach recognizes an individual within a fraction of a second which completely ignores any background effect. It also shows additional information about that individual. Besides, this method also works on different lighting conditions which make it suitable to execute its purpose in a wide variety of environment without encountering any significant error. We have implemented our work using a Raspberry Pi. And this approach utilizes the benefits offered by different python libraries like OpenCV and numPy. SQLite database management system is used as the backbone of its memory. Through its faster and authentic performance, this system is worthy enough to be integrated with any applications to boost up automation and user-friendliness.**

***Index Terms*—— Real-time Face Detection, OpenCV, NumPY, SQlite, Gray-scaling, Raspberry pi**

I. INTRODUCTION

Human identification is a process to identify a person based on one or more unique features of that person. Many wide varieties of personal verification procedure are available in the commercial and law enforcing field. The most common personal verification method is Password identification number (PIN) or password system. But these methods are vulnerable to forgery, theft, and lapses in the user's memory. For these reasons, we are focusing on verifying a person through his/her unique biometric features [1]. These features include fingerprint, palm, iris, retina, and face detection if we want to identify the person using his unique biological structure. Human activity is a major concern in a wide variety of activities such as human surveillance, human-computer interface, [2], [3], and face recognition based database management [4]. Thirty years ago, face recognition was considered as one of the hardest in artificial intelligence technique. But through a series of successes in recent years, it is now not only technically feasible but also economically practical. In short, we can say that nowadays face recognition is a popular identification technology which has numerous commercial and law enforcement applications.

In recent years, application of image recognition in different parts of our life has increased many-fold. A foolproof security system solution which includes the sub-system such as surveillance CCTV, video management and wireless backbone has been developed by A. Mike *et al.* in their paper named "Face Recognition in Poor-Quality Video: Evidence From Security Surveillance" [5]. The System is capable of identifying an intruder within a restricted area covered by CCTV cameras. Usually, we need to see the video for a long period of time to inspect the intrusion. But the use of face recognition in the security system will show us the parts of the video where intrusion took place. ATM booths become more secured when face recognition is used. The face recognizing evaluation with exceptional occlusion handling (EOH) is feasible in most realistic environment [6]. Besides, Face recognition approach is also handy to count the number of people in a place by using the frame difference to detect the rough edges of moving people and then using the chromatic feature to locate the people's face [7]. The attendance system of educational institutes become more efficient and easy if face recognition is used to take attendance. Using personal component analysis

(PCA) in face recognition makes it much more feasible to record the attendance of a student. It also provides the facility to the faculty to access the information about the attendance of students easily by maintaining a log for clock-in and clock-out time [8]. Hospitals and medical centers can be widely benefited by using a face recognition system. In many cases hospitals receive patients who are unconscious. Facial recognition offers a faster way to access medical information of patients and the process of providing fast medical care can be accelerated. Even, to keep the track of newborn babies face recognition can be used [9]. Goods kept in the inventory of an industry having an image recognition inventory management system are safer than the conventional approach [10].

II. SYSTEM ARCHITECTURE

Raspberry Pi is the microprocessor used in this system. And we have used python for coding. Open source libraries of python like OpenCV and NumPY are used to process the image recognition algorithm. SQLite is used to store data of the desired people. The whole working process of the system can be best explained with three segments. These are:

Data segment: This segment of the python code is mainly dedicated to recording a person's identification data. Basically, it instructs the camera to take 20 sample pictures. And users need to provide information about their Name, age, gender, and department. This information is stored in SQLite database along with the 20 sample pictures. When the data of a person matches with any previous record, his/her sample pictures are updated. This feature makes our system adaptive to small changes in a person's facial pattern. The work flow diagram of data segment is shown in Fig.1.

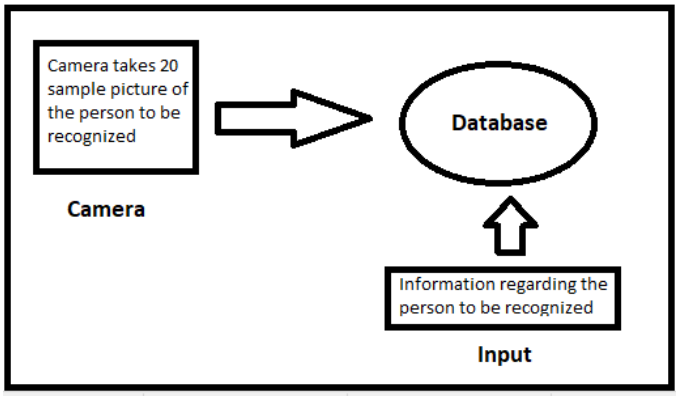

Fig. 1: Data Segment

No.	ID	Name	Gender	Age	Department
1	15	Noushad Hossain	Male	23	EEE
2	13	Mustafiz	Male	23	EEE
3	16	Saem	Male	22	EEE
4	12	Taskin	Male	23	EEE

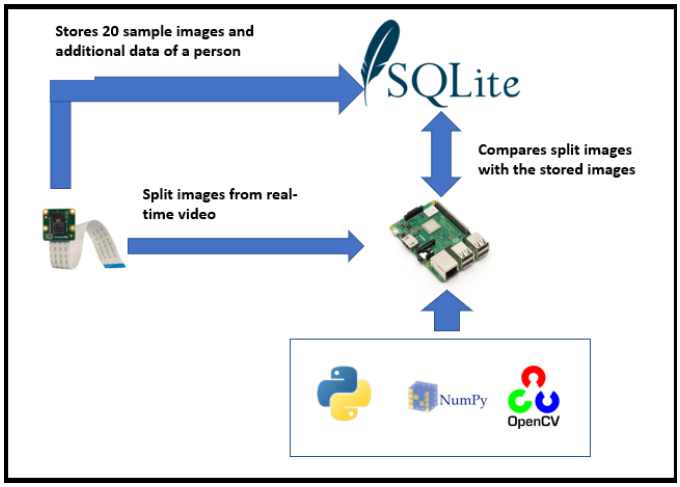
Fig. 2: Database Table

The database of Fig.2 is made using SQL language. The ID and Age attributes of the database are integer type. Gender is basically text type and Department name is a string type attribute.

Trainer segment: This segment mainly trains the system to be able to identify specific persons. The sample pictures of a person are converted into the grayscale format. This system does not need the color explicitly. Besides, information regarding the color of an image sometimes makes it difficult to identify important edges. Therefore color in an image can be considered as noise in our study. Hence, grayscaling is done. So, Grayscaling makes the image processing algorithm more efficient and faster [11]. When an RGB image is converted into a grayscale format the 3D pixel values are converted into 1D values. As a result, we will need to deal with less data if grayscaling is used. Fig.3 shows the grayscale format of an RGB image.

Fig. 3: Conversion to grayscale

Detection segment: The camera feeds the microprocessor with real time video. The video is imported to the python code of the microprocessor as a two dimensional matrix. NumPy is a open source library of python which makes it easier to process the multidimensional matrix [12].



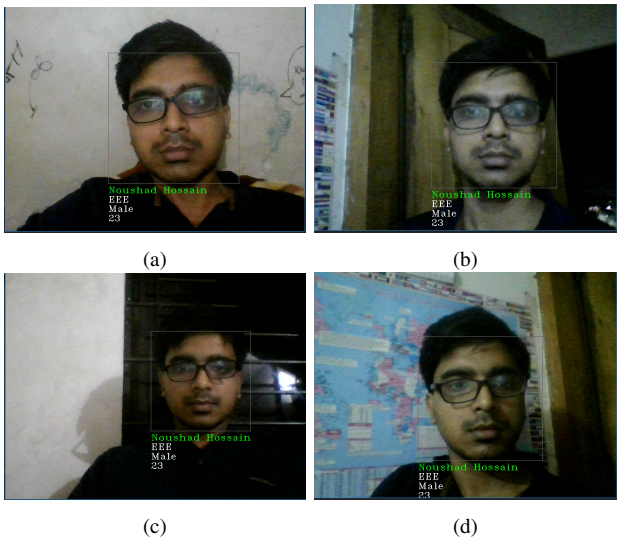


Fig. 4: System Architecture

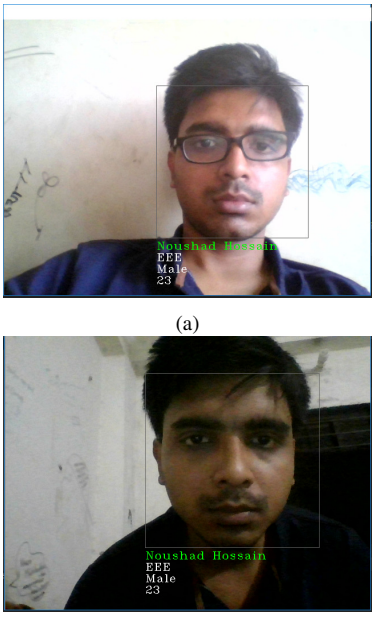
First, the part containing the face is extracted from the full image to reduce the effect of background in image processing and stored in a matrix. Then the matrix is manipulated and compared with the sample photos for identifying any match. If any match is found, the real time video display shows the name and additional information of the identified person with a

green square mark tracking the recognized face of that person. The additional information is taken from SQLite database management system. The system architecture is illustrated in Fig.4.

III. System Performance

Zero background effect: In most cases, the face recognition approach is usually favorable for the place where previous data is taken. As a result, it does not function authentically when a test is run in a new environment. This happens when the total picture is compared with the stored data. But there is no effect of background on the performance of this system. Because the algorithm extracts the face of the person from the images stored in the database. Therefore, it works perfectly even though the background changes. In Fig.5 we see that an individual's face is being recognized though he is changing places.



(a) (b)

(c) (d)

Fig. 5: Face recognized in four different backgrounds

Insensitive to small changes: Usually small beard, make-up, effect of light in a room has a small effect on a human face. So, gradually the performance of face recognition algorithm declines. It might work satisfactorily one day but will not be consistent for a longer period of time. But this system is smart enough to ignore these small changes and detect the human perfectly. The algorithm also checks the structure of an individual and compares the edge of different parts of a face. The system is capable of identifying a person in both natural and artificial lighting conditions. Again, if a sample picture of a person is taken where he had spectacles. But the person is recognized without any error when he had no spectacles. This is because the algorithm of the system checks the different structures of the face for finding a match. Fig.6 illustrates the insensitivity of the system to these small changes.

Fast recognition: Real-time face recognition system needs to have faster and efficient processing speed. This system is fast enough to complete the whole recognition

(a)

(b)

Fig. 6: Insensitivity of the system to small changes.A person is recognized a) With spectacles in a bright day light. b) Without spectacles in artificial lighting

process minimum three times in a second. At best the detection cycle is completed five times in a second. Fig.7 shows the time taken to complete each detection cycle. Our study shows, on average four detection cycle is completed in a single second. As a result, image recognition is not hampered even if the person is in motion. There are several reasons behind the faster recognition approach. A PNG (Portable Network Graphic) file is much more difficult and time-consuming to process than XML (Extensible Markup Language) file. For this reason, we have used an XML format to save the images in the database. The algorithm is designed to extract the face of a person only. So, other information of the images except the face is not processed and hence the image processing time is decreased. Grayscaling also plays a vital role to reduce the processing time. As a result, identifying a moving person is much easier. On the contrary, a slow image recognition algorithm fails to identify a moving person.

IV. CONCLUSION

In short, we can say that The system is built on Raspberry Pi which is the brain of the system. Python is used in this system for its open source library facilities. The open source librariy we used is OpenCV which mainly aim to process real-time computer vision. The still image from the video is stored in the python as a two-dimensional array. NumPy which is a python library for processing multidimensional array is used to process the still image faster. The system has a storage management system which is intended to store the data of the persons of interest. SQLite, a popular database management system is used for data management purpose. The database contains information regarding the person to be

Fig. 7: Demonstration of fast recognition process

detected. The system is very helpful and efficient because there is no background effect for recognizing the person. It can recognize a person even though the environment and background changes. And it works satisfactorily in different lighting conditions. Small changes in a person's face like make-up, the spectacles have little effect on the recognition process. Moreover, the system is fast enough to process four frames per second. So, it can be integrated with any system to enhance automation, effectiveness, and user-friendliness of that system.

***Abstract*—Energy conservation is one of the major issues of recent days because all the natural resources will end up soon as the earth has a limited amount of such non-renewable resources. This paper ensures the conservation of energy by minimizing the wastage of electricity. Two microcontrollers are used for this setup. One of them is used to control the electrical appliances automatically depending on human presence in a particular room or area. When the passive infrared sensor (PIR) and proximity sensor find the motion and presence of human inside the area then it will turn on the electrical appliances and will count the number of persons. And the opposite action will be taken for the absence of human movement in a particular area using a relay circuit in the system. Although everything will be controlled using this system there is also a scope to control the appliances manually using separate switches. Once the switches are kept ON, the system will automatically shut down and turn ON when necessary. Another microcontroller is used to operate the safety features of the building and the entrance gate opening which will automatically open or close the door when someone enters or leaves the room and will show it on the LCD. With the help of the humidity sensor, it will show the temperature and humidity level in the LCD. A smoke detector sensor is used which will ring the fire alarm when smoke is detected and it will open the emergency exit door as well as the entrance door.**

Keywords— energy conservation, microcontroller, motion detection, PIR sensor, proximity sensor, smoke detection.

I. INTRODUCTION

"Energy cannot be created or destroyed; it can only be transformed from one form to another." quoted by one of the greatest minds of the 20th century [1]. Energy is a major concern for our generations nowadays because everyone is in need of it. Non-renewable resources are being used up to suffice the demands of the people's needs. Non-renewable resources are such resources which are from sources which will run out in the near future e.g. coal, petroleum, fossil fuel, and natural gas. The burning of such resources results in the production of energy which is converted to electricity to suffice the demands of the world. These resources produce a huge amount of energy and they are readily available to some countries and are cheap [2] [3].

Conservation of energy had been a major issue since the development of technology because as the earth is getting older its natural resources are decreasing from time to time. So long ago the research on conservation of energy began, some conservations are listed as Use of efficient lighting- light emitting diode (LED), Use of energy efficient appliances- Compact Fluorescent Bulb, use of efficient computers- Laptop, Turning off electrical appliances- Disconnection of appliances after use [4] [5].

Several works have been done in recent years regarding energy conservation for reducing the wastage of energy in both residential and industrial areas. In recent years, researchers adapted a method where the system can turn on or off the electrical appliance by sensing and counting the presence of a person through IR sensor and visitor counter in a particular area and also can control the speed of the fan by sensing the temperature of the monitored area through temperature sensor [6]. A microcontroller-based wireless remote control system is applied to a protection system which is used for wave energy conversion [7]. The smoke detection and alarm system are executed by using a microcontroller-based fire extinguisher [8]. A low-cost energy management system can be developed by using campus card system for controlling the classroom lighting [9].

The proposed system is to establish an energy conserving society with the help of some common components found every day in our electric component shops. The project is based on microcontroller and using PIR and proximity sensors energy will be conserved by saving electricity.

II. METHODOLOGY AND MODELING

The most basic and eventual requirement in an energy conservation system, a connection between some components such as sensors, relay, corporate appliances like fans, lights etc. with microcontroller are important. There are various way to link the devices, user and the system and the linking depends on the system, range, size of a corporate office, ease of users. If a user wants to control all the corporate appliances through the system, then all the appliances need to interface with this system. If the user wants to control a few of the appliances, then only those appliances need to interface with the system and other appliances can be controlled manually.

The basic concept of this project is to turn on or turn off the corporate appliances like fans, lights etc. automatically. Here, relay operates as a switch by passing information in between microcontroller and appliances. PIR sensor and proximity sensor is connected with a microcontroller. Control devices are also connected with the microcontroller. Microcontroller receives information from human detection PIR sensor and proximity sensor. According to information received by the microcontroller, it turns on or turns off the corporate appliances automatically.

In Fig. 1. microcontroller 1 is connected to PIR sensor, proximity sensor, loads through relay, power supply, and LCD display. The proximity and PIR sensor detect the presence or absence of a human movement in a particular area. Then this data is sent to the microcontroller. After getting this data microcontroller analysis this data and based on this data

microcontroller controls the loads (light, fan) with the help of a relay.

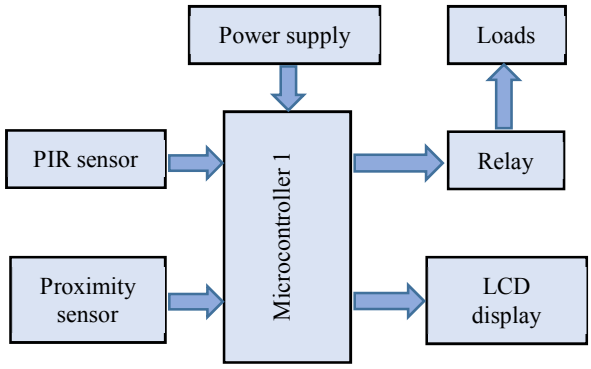

Fig. 1. Block diagram of the energy conservation system.

Microcontroller 2 in Fig. 2. is connected to the system which automatically controls the entrance gates, fire alarm, and humidity. There are three sensors connected to the microcontroller which are a smoke detector, IR LED and photodiode and humidity sensor.

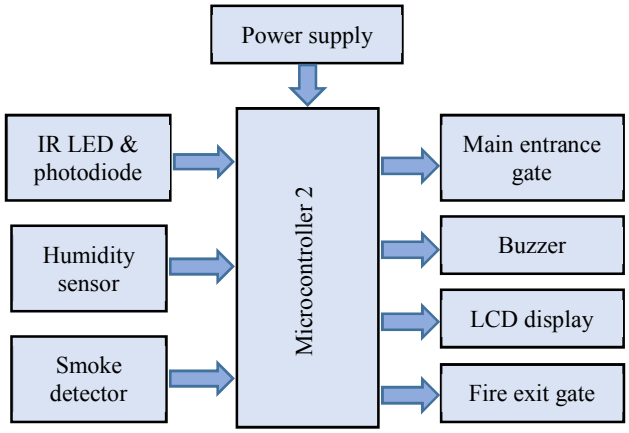

Fig. 2. Block diagram of the automated control system.

The smoke detector detects smoke and sends a signal to the microcontroller which triggers the buzzer and its ring indicates that there is smoke from the fire which is a safety measure required in a corporate building. Then the IR LEDs detect human figure and output is sent to the microcontroller which opens and closes the gates automatically receiving signals from the microcontroller. Lastly, the humidity sensor senses temperature level and humidity level and they are shown through an LCD which helps keep track of the temperature and humidity level of a room. All these sensors are controlled by the second microcontroller.

To design an energy conservation system for corporate appliances by using a microcontroller, PIR and proximity sensor some basics need to be considered. In the microcontroller, some programs are installed. It works with the programs are installed in it. Proximity sensor is used to detect any human entering or leaving the room. The PIR sensor is used to detect the movement of the human. If the sensor does not detect any movement more than 15 seconds then the loads will automatically turn OFF. Smoke detector is used to detect smoke and humidity detector measures the humidity.

III. Software Implementation

Simulation results of the total circuit are taken in different conditions using PROTEUS 8 Professional software in three different parts. The following components are used in simulation: microcontroller ATMEGA8, a battery, transistor BC547, capacitor, inductor 'ELJ-FA1R8KF', a diode, a motor, different LEDs, LCD 'LM016L', POT, a relay, resistors, AC input, MQ-135, HSM 20G, buzzer, and LOGICTOGGLE. As there is no way to use a PIR sensor in the simulation software, we can't vary this input in the simulation software. So, outputs are taken by varying only the count number of proximity sensor. These two conditions are described below.

A. Using only PIR sensor

1) When PIR sensor does not sense movement

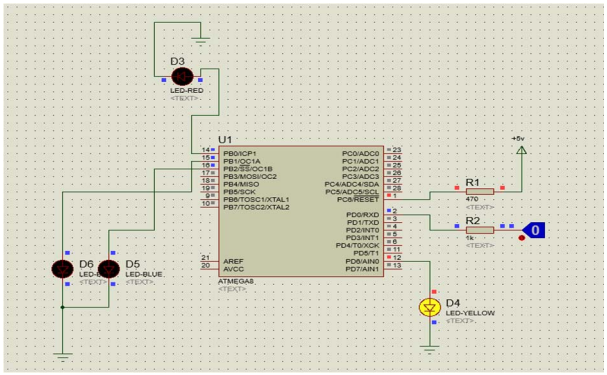

Fig. 3. Simulation result when PIR sensor does not sense any movement around it.

Here, PIR sensor input "0" indicates that it does not sense any movement up to 60 cm around it. As a result, the red LED is OFF and both the loads are also OFF. But for sensing the detection of movement, the yellow LED is blinking. Here input PIR sensor input is varied by toggling the input in the PIR sensor position.

2) When PIR sensor senses movement

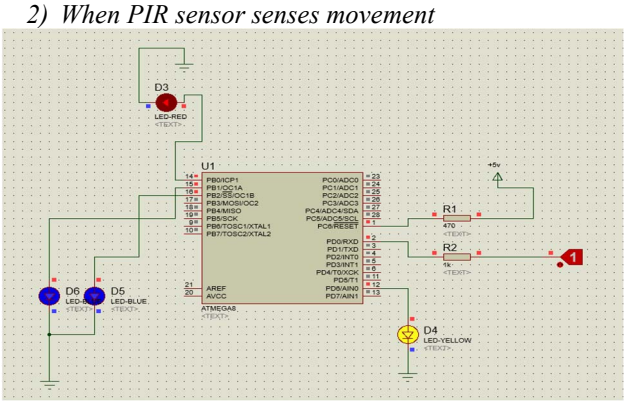

Fig. 4. Simulation result when PIR sensor senses movement around it.

Here, PIR sensor input "1" indicates that it senses movement around it. As a result, the red LED is ON and both the loads are also ON. The red LED at ON state indicates that there is movement around the PIR sensor. It will stay ON as long as there is movement. If the sensor suddenly does not sense movement, it will wait up to 15 seconds to detect the movement. During these 15 seconds, if it does not sense any movement, the loads will automatically turn OFF. But if it senses movement during these 15 seconds, it will keep the loads ON. By this method, PIR sensor will keep the loads ON and OFF in the room.

B. Using both PIR sensor and Proximity sensor

1) When the count number of proximity sensor is zero

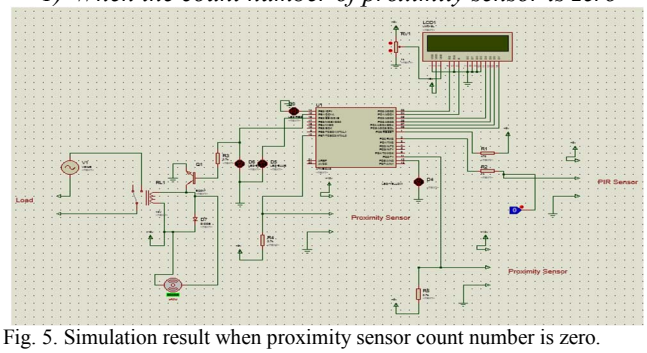

Fig. 5. Simulation result when proximity sensor count number is zero.

When proximity sensor input is zero, which indicates there is no person inside the room. As a result, both LEDs are off and the AC loads and red LED are also OFF. The fan also does not move. A relay is used in this case as AC loads are used. As no one is present inside the room, there is also no movement. For this purpose, PIR sensor input is kept at zero states.

2) When the count of proximity sensor is greater than zero but there is no movement

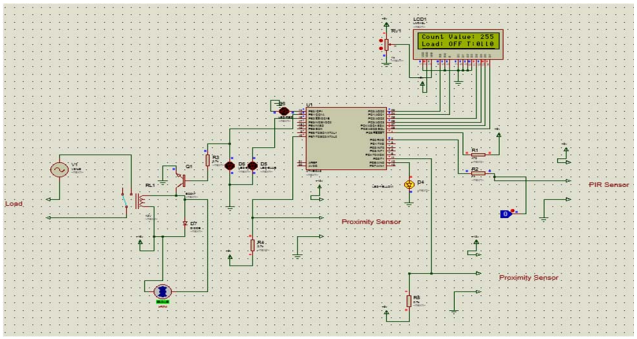

Fig. 6. Simulation result when proximity sensor count number is greater than zero without movement.

When proximity sensor input is greater than zero, which indicates there is at least one person in the room. But here, the PIR sensor input is zero. That means there is no movement inside the room. As a result, both the LEDs are OFF and the AC loads and red LED are also OFF. The fan is also not moving.

3) When the count of proximity sensor is greater than zero and there is movement

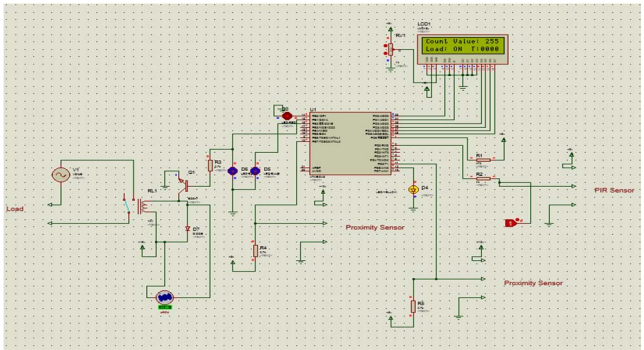

Fig. 7. Simulation result when proximity sensor count number is greater than zero with movement.

When proximity sensor input is more than zero and again there is movement inside the room that means there is at least one person in the room. Again, PIR sensor input "1" indicates there is movement inside the room. As a result, both the LEDs are ON and the AC loads and red LED are also ON. The fan is also moving.

C. With servo motor, fire detector, humidity sensor, IR LED and photodiode

1) The system before giving the power supply

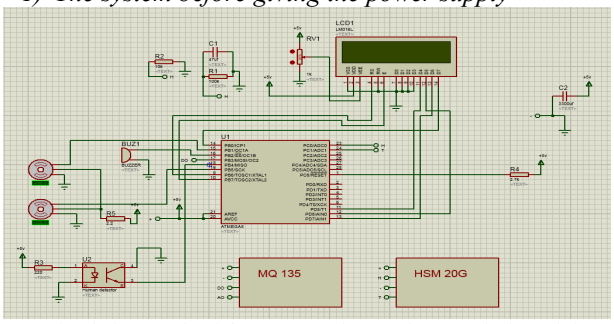

Fig. 8. Simulation result of the automated control system before giving the power supply.

Here, the second microcontroller is connected with different parts such as two servo motors, photodiode, IR LED, buzzer, smoke detector MQ-135, humidity sensor HSM-20G. The servo motors don't rotate as there is no human around IR LED and photodiode, which in this case is a human detector.

2) The system after fire smoke is sensed by the fire detector sensor

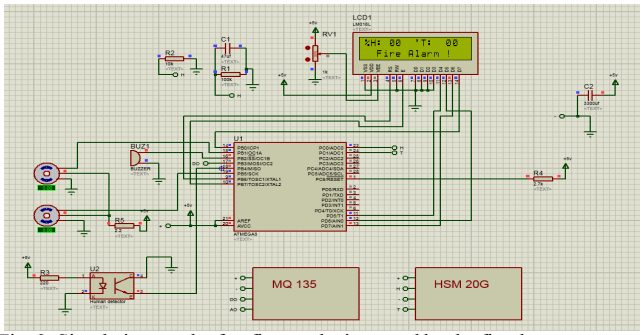

Fig. 9. Simulation result after fire smoke is sensed by the fire detector sensor.

When fire smoke is sensed by the fire detector sensor, the LCD shows the "FIRE ALARM" sign. As there is no scope to show humidity and temperature in the simulation, so it shows zero for both the cases. Here servo motor rotates when there is a presence of human around the human detector sensor which are actually IR LED and photodiode.

IV. Hardware Implementation and Result Analysis

In this section, hardware implementation, as well as result, have been discussed.

A. The initial setup of the system

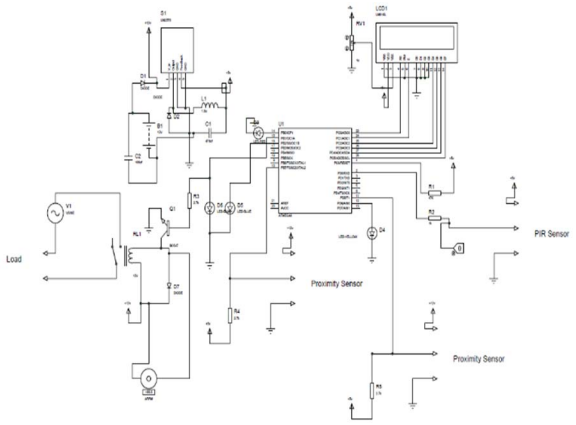

Fig. 10. The overall circuit diagram of Energy Conservation System.

This is the main circuit diagram of the power conservation system part. It includes PIR sensor, proximity sensor, LCD display, LEDs, loads and power supply unit.

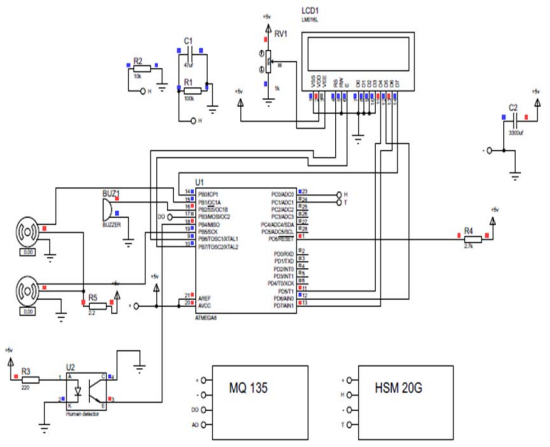

Fig. 11. The overall circuit diagram of the automated control system.

It is the circuit diagram of the automated including fire detector sensor, humidity sensor, human detector sensor, and LCD display.

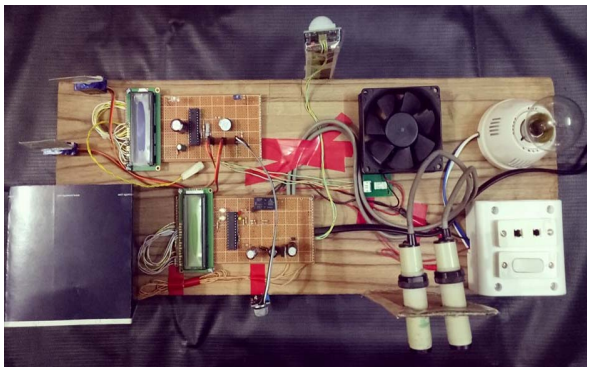

Fig. 12. Hardware implementation of Energy Conservation System.

This is the main hardware setup of our proposed system before turning ON the power supply. It consists of one PIR sensor, one proximity sensor, two microcontrollers, two LCD displays, transistors, capacitors, one motor which is used as a fan, different resistors, one relay, one power supply, different AC loads, two servo motors, IR LED, photodiode, buzzer, smoke detector MQ-135, humidity sensor HSM-206 and a switch to manually control a load.

B. The system after turning ON the power supply

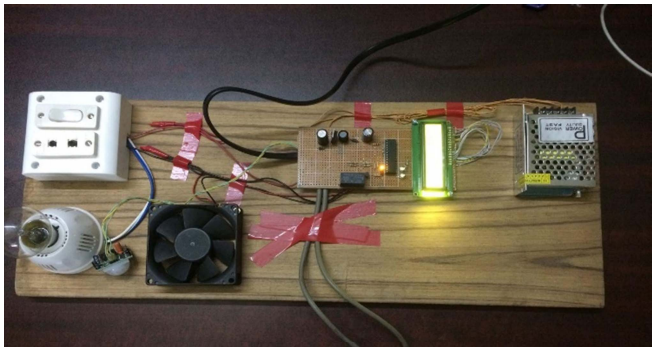

Fig. 13. The setup after turning ON the power supply.

Fig. 14. LCD display after turning ON the power supply.

This is the setup after turning ON the power supply. The LCD display is ON and yellow LED in blinking to detect any movement near the PIR sensor. The LCD display is shown in the second picture. The count value is zero. As a result, both the LEDs and AC loads are OFF.

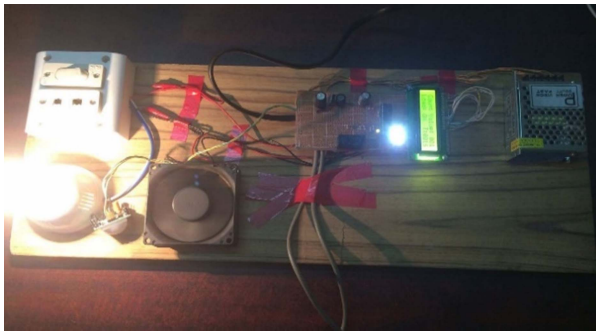

Fig. 15. The setup when the count for proximity sensor is greater than zero.

Fig. 16. The LCD display when the count for proximity sensor is greater than zero.

Here, the count value for proximity sensor is 3. As a result, both the LEDs are ON, the AC loads are also ON. This is applicable for any count value more than zero. But, when the count value is more than zero and still there is no movement around the 60 cm of PIR sensor for more than 15 seconds, the white LEDs and the AC loads will turn OFF. This is not shown here because it was not possible to capture the picture by not moving about 15 seconds. But the situation can be observed.

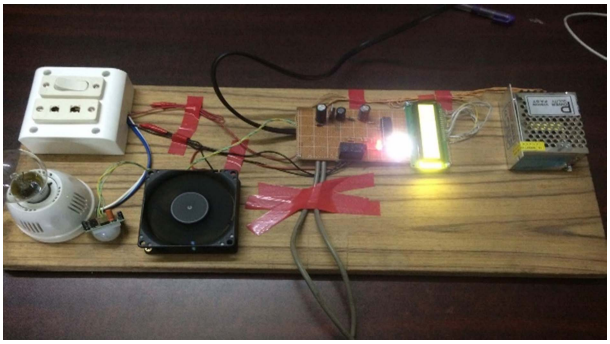

Fig. 17. The system after manually turning OFF the bulb.

The AC loads can also be controlled manually by using switches. In the above picture, the count value of proximity sensor is more than zero. As a result, both the white LEDs are ON. But among the AC loads, the only motor is ON, the bulb is OFF. A switch is used to control the bulb manually. So, in

spite of there is greater than zero counts in the proximity sensor and there is movement around the PIR sensor, the bulb is OFF. It will work according to the system only when the switch is turned ON. This manual setup can also be done for other loads but separate switches are needed for this case.

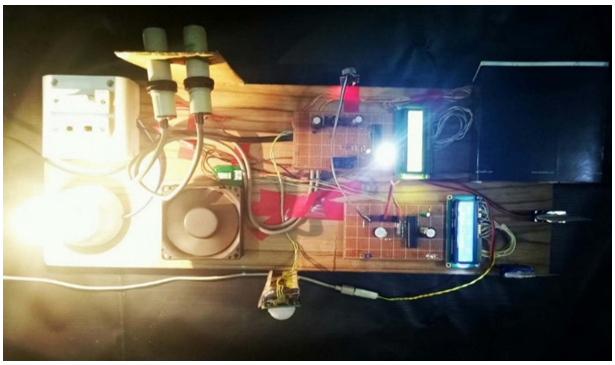

Fig. 18. The system after adding the automated control part.

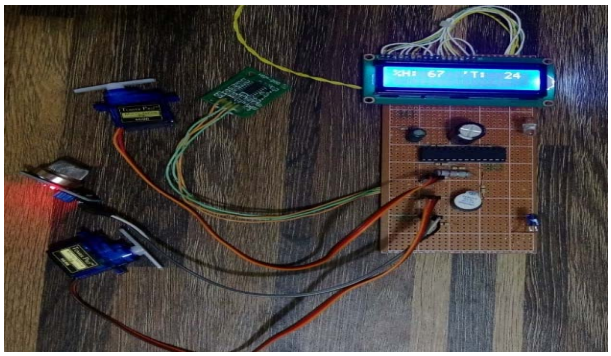

Fig. 19. The system when any person enters into the room.

Fig. 20. The LCD display when any person enters into the room.

Fig. 21. The LCD display after any person enters into the room.

There is a photodiode and IR LED in the entrance of the system. When someone passes these 2 devices the servo motor 1 with rotate 90 degrees that means the entrance gate will open instantaneously. The LCD display shows “Gate Open”. After that, the servo motor 1 will rotate to the opposite direction which indicates the door will be closed. The LCD display shows “Gate Closed”. But at that time servo motor 2 does not rotate.

Fig. 22. The system showing temperature and humidity.

The humidity sensor senses the humidity of the environment and shows the temperature and humidity in the LCD display.

Fig. 23. The system after there is smoke around it.

When the fire detector sensor senses smoke around it, both the servo motor rotates 90 degree that means both the door will open instantaneously. The LCD display shows “Fire Alarm!”.

V. Discussion

Such automated systems are encouraged nowadays to reduce human efforts and conserve energy but there are also many limitations. This system will work for a small space because the PIR sensors and proximity sensors that are used are not very strong. Therefore, for a large space, more than one system will be needed to ensure proper working rate. When an electrical appliance is manually turned off, it will not be turned on automatically until the switch is manually turned on. Several initiatives can be taken to improve the proposed system. The designed system may be implemented wirelessly. The circuit may be reorganized to get better output. Fewer components may be used to make the system more cost-effective.

VI. Conclusion

The system is built to conserve the energy which is being wasted by people while there are scopes to save the energy because the energy is produced by burning the natural resources which are vanishing with time. The system offers the loads to be controlled automatically and also manually which ensures energy conservation. Loads are connected to a relay system which is controlled by a microcontroller depending on inputs from the sensors that are used to detect motion. The system can be used to count the number of persons entered and left the room in an office. It consumes a very small amount of electricity to operate which is also cost effective. The loads connected can be operated automatically and if needed also manually depending on the operator's demand. The system is not expensive to build and consuming less energy proves it to be cost-effective and also eco-friendly. Although it has some drawbacks such as the PIR sensor is weak and will not be able to detect motion very far away from it. Secondly, if the loads are to be controlled individually then for every load there has to be a separate relay system connected to them individually. One relay system cannot control more than one load differently. By using more powerful sensors the system can be used to cover a large area which will increase the system cost by a little amount however it will not affect the demand of the system.

***Abstract*— This project uses some sensors and Arduino to design and implement the Affordable Smart ECG Monitoring System. ECG monitoring is now becoming part of everyday life. Through ECG characteristics such as patient's heartbeats, heart conditions, and heart disease can be analyzed. The proposed system sensed the patient's ECG through 3 lead electrode system via AD8232 which amplifies minor and small bio-signals to the Arduino which processes them. This sensor was used to measure the heart's electrical activity called ECG. In this project, Arduino and Bluetooth module are used to collect and transfer the heart activity and send it to the mobile application. The current portable ECG technologies are costly so that anyone can't use that on their home for an emergency if they want and this new technology is less expensive.**

Keywords*— *ECG Monitoring system; Portable; Arduino; Bluetooth;

I. INTRODUCTION

In many cases, the patient requires continuous monitoring and it needs a long time to stay in hospitals which is expensive now a days. Traditional monitoring system enables monitoring of vital parameters requiring the sensors to be connected to bedside machines and the patient is essentially confined to bed. However, busy in today's world and the increase in sudden death events motivate a monitoring system that monitors patients remotely located on a continuous basis. With the technological advancement, it has become possible to design low-cost, home-based healthcare monitoring system in which the system records and displays the signals from the human body and transmits to any other location. Different studies have been carried out in connection with the development of remote healthcare systems, particularly heart rate monitoring systems.

II. LITERATURE REVIEW

UMHMSE introduced a real-time mobile healthcare system for monitoring elderly patients indoors or outdoors [6]. The main components of the system are a bio - signal sensor and a smartphone. The data that the bio - signal sensor collects is transmitted via the GPRS / UMTS network to an intelligent server. The system can monitor the elderly patient's mobility, location, and vital signs from a remote location.

In the Wireless Sensor Network Wearable Smart Shirt[7], a smart shirt has been designed. In order to monitor the continuous and real - time health of a patient, this shirt can measure electrocardiogram (ECG) and acceleration signals. The shirt consists mainly of sensors and conductive fabrics for the body signal to be received. The measured body signals are transmitted via IEEE 802.15.4 network to a base station and server PC. The wearable devices have low power consumption and are small enough to fit in a shirt. An adaptive filtering method was also proposed in this work to reduce the noise associated with the ECG signal.

While mobile devices are always considered a promising tool for monitoring and managing patients' own state of health, computational or data-intensive activities have some inherent limitations on these appliances. In Enabling Smart Personalized Healthcare[12], a new hybrid mobile computing solution has been proposed to overcome these limitations. A mobile cloud-based electrocardiograph monitoring system was implemented by the authors. The experimental results show that the proposed system can significantly improve the diagnostic accuracy, performance efficiency, and energy efficiency of the conventional mobile-based medical monitoring system.

In the ECG Remote Monitoring System and Human Body Temperature Signals[14], a remote healthcare system for monitoring electro-cardio graphic and temperature data has been described. The system consists of three modules namely (i) a hardware module, (ii) Bluetooth module, and (iii) display module. For data acquisition, the hardware module is used. As well for data transmission, the Bluetooth module is used. Finally, the display module displays the data. Using GPRS or Wi-Fi, the acquired clinical data is sent to a database server. The system performance has been tested on various patients

and the proposed change has been found to be very helpful to the physicians.

III. Methodology

A simple architecture has built here to monitor the Electrocardiogram. Here, Microcontroller is working as the core part of the whole system. Here the AD8232 sensor getting the analogue signal and send it to the microcontroller. Microcontroller converts it into digital data. Then holding the digital data, the microcontroller sends it to the android device via Bluetooth module.

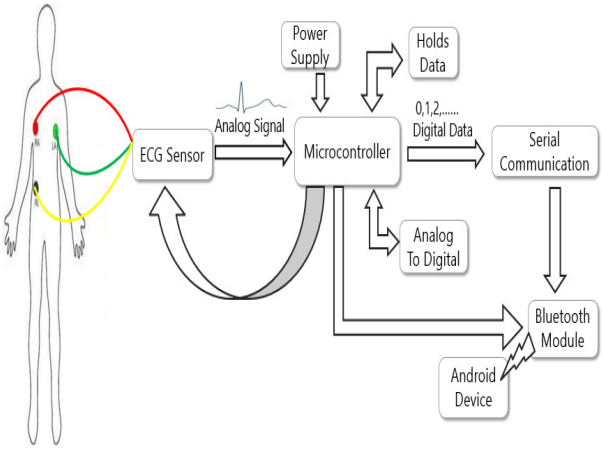

Fig. 1. Block Diagram of the Proposed System

A. Circuit Diagram

Here A8232 chip has 6 pins, we have used only 3 pins above them, which are output, voltage, ground. The Bluetooth module has 4 pins which are tx, rx, vcc, gnd. Arduino's TX1, RX0, 5V,GND pin are connected with the Bluetooth module through tx, rx,vcc and gnd respectively. The output, voltage, ground pin of AD8232 are connected with the Arduino's analog pin A0, 5V, GND. Arduino's VIN and GND is connected with the batteries positive and negative respectively.

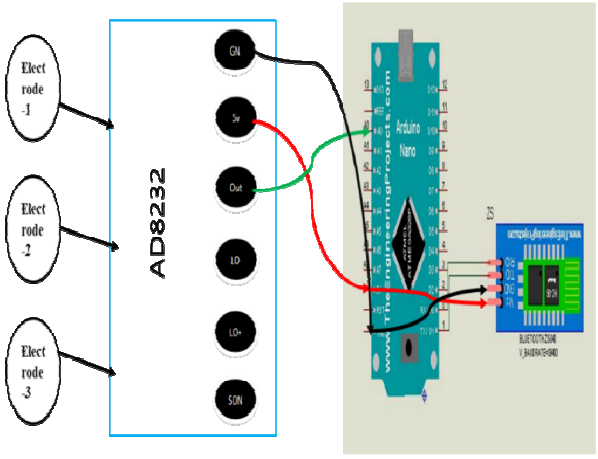

Fig. 2. Circuit Diagram of the Proposed System

IV. Designing Process of the Layout

After all the schematic circuit design process, the layout design process was done where several steps are required until the layout can be done properly. The layout design procedures are stated as follows:-

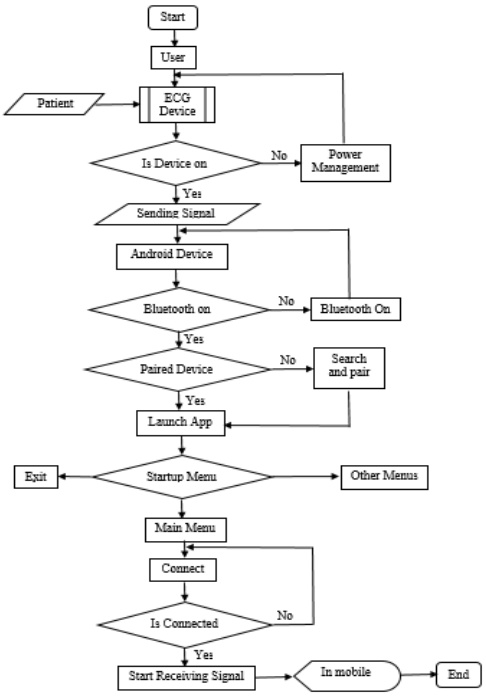

Fig. 3. Flow Chart

- Annotate the circuit of Portable ECG Monitoring Device.
- Run the Design Rule Check (DRC).
- Netlist process.
- Creating the circuit layout process.
- Rearrangement of the circuit.
- After all the process had been done, then the circuit will be route in automatically and so on, then it will be checked again using the design rule check.

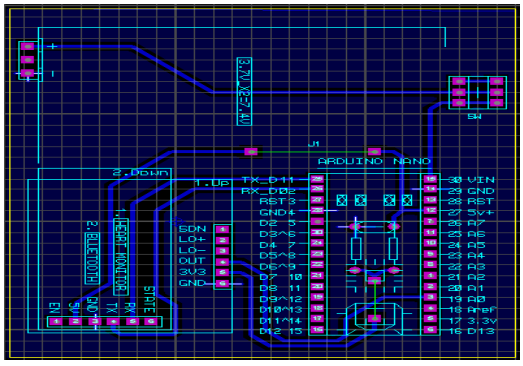

Fig. 4. Proteus Final Design

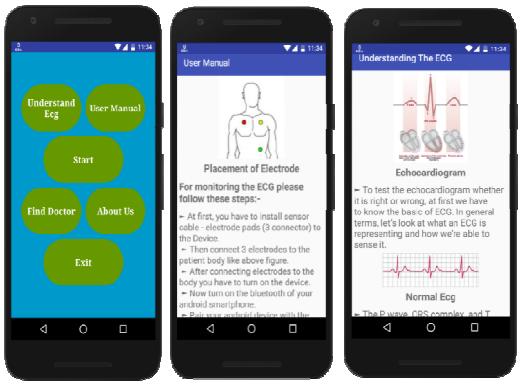
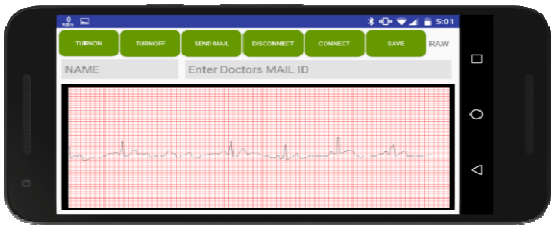
A. *User Interface*





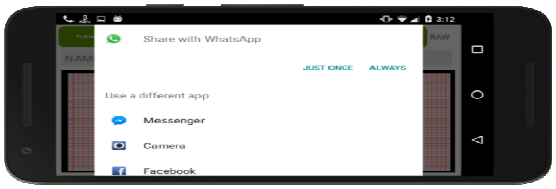


Fig. 5. (a) Startup Menu (b) User Manual (c) Understand ECG.

(d)

(e)

Fig. 6. (d) Showing ECG (e) Sharing Option

V. IMPLEMENTATION

Implementation takes a week to produce the printed PCB, completing each component located with the mark and drilled holes for mounting components. Firstly, this work printed the proteus design image on Photo Paper on a printer and make sure the output quality is the best.

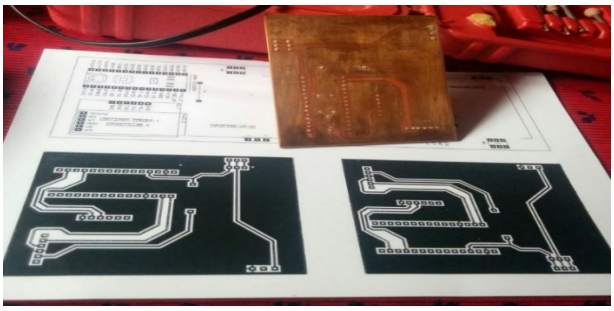

Fig. 7. Photo paper print

In this work placed the PCB transfer face down on the copper clad and set the household iron.

Fig. 8. Iron heat for making PCB

After 15 minutes, all the visible copper is gone, and then removed the PCB from the etchant and gave it a wash in cool water and dry with a towel. Then the board became ready to populate with parts.

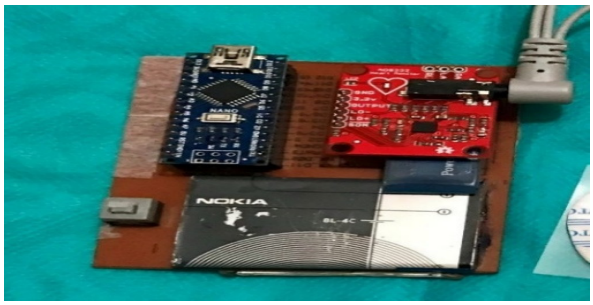

Fig. 9. Complete PCB

VI. OPERATING PRINCIPLE

In this system, Arduino is the main junction of all these peripheral devices and sensors. At first, we have to install sensor cable - electrode pads (3 connector) to the AD8232 sensor. Then connect 3 electrodes to the patient body like figure 10.

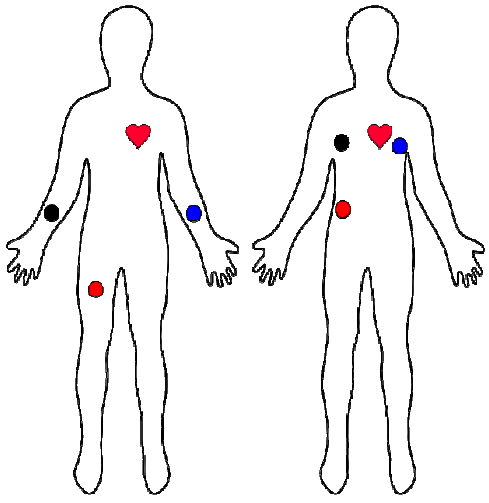

Fig. 10. Connecting Electrodes

After connecting electrodes to the body, have to turn on the proposed device and Bluetooth of the android device. Then this system have to pair the device with android device through via Bluetooth. Now we have to open the android app. Then press the start button. After opening the app, have to

press the connect button to connect with the ECG device. Then the device will show the electrocardiogram of the heart.

A. *Understanding the ECG*

To test the echocardiogram whether it is right or wrong, at first we have to know the basic of ECG. Generally speaking, let's look at what an ECG stands for and how we can feel it. The ECG is divided into two basic intervals, the interval of PR and the interval of QT as described below.

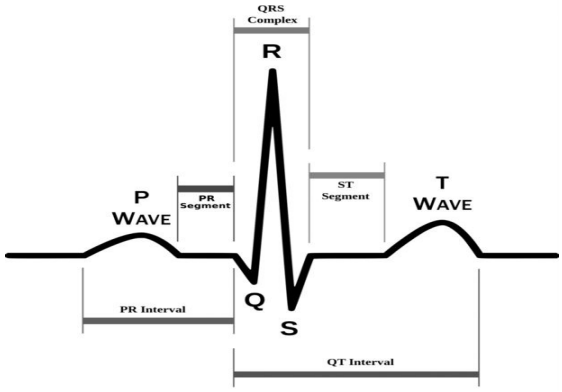

Fig. 11. .Basic ECG

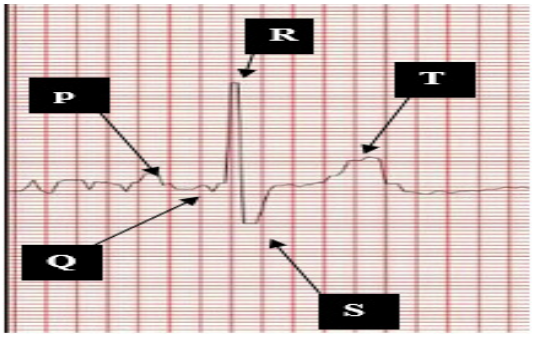

Fig. 12. Resultant ECG

In the above figure we compared our ECG with a normal ECG, which almost looks like. The P, Q, R, S, T segments are almost same in both pictures. Therefore, we can say that our system is showing normal ECG.

B. *Result*

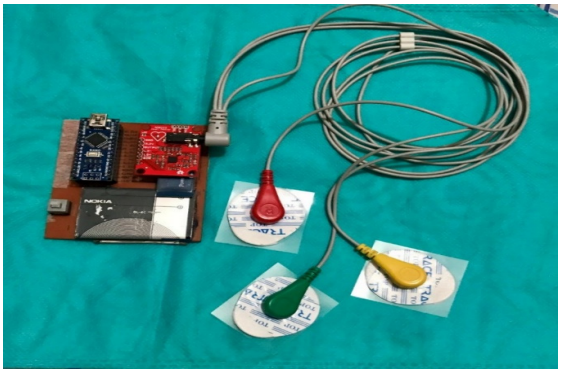

Fig. 13. Device Main view

Finally, in this season we are going to discuss about ECG monitoring and testing result. In this system, we will measure ECG through AD8232, Arduino and Bluetooth module and transfer it to the connected Android device. This project worked perfectly but sometimes it cannot give us the perfect reading due to ac noise.

VII. Conclusion

The project developed and implemented an affordable Arduino - based ECG monitoring system. The system aspects are developing a low - cost portable ECG monitoring system to analyze the heart conditions of the patient. This project proposes an effective heart attack detection system that helps to reduce deaths caused by heart attacks as the main cause of deaths from heart attacks is due to delay in proper treatment. This can be avoided as with the ECG report, the system will notify the doctor. In this work, an android application has been proposed that can receive ECG signals from the acquisition device wirelessly, detect QRS complexes, calculate heart rate and plot the real-time ECG signal for the cell phone display. It can also send this information to the physician concerned for medical decision by means of a server. Experiments show that the system proposed is unobtrusive and that the user can use it comfortably during daily activities.

***Abstract*— This study presents a security system for transporting or storing valuable while restricting unauthorized access. The system consists of Memory Module, PIR sensor, fingerprint security, Encoder-Decoder, RF module, GPS and GSM module etc. to provide the maximum level of security. The proposed security system can be a major uplift in transporting important documents, money or ornaments from one place to another especially for banks in transporting valuables as the proposed security system is designed in such a way that the vault can only be opened by an authorized person, in specific places, using proper credentials, hence providing maximum security.**

***Index Terms*— DS3231 RTC module, PIR sensor, RF module, Encoder Decoder, Fingerprint sensor, Password keypad, Global positioning system (GPS) and Global System for Mobile communications (GSM).**

I. INTRODUCTION

The job of a security system is to keep valuable objects safe and secured for its rightful owner. Day by day security for valuable objects is becoming a major issue with increased crime rate. The conventional method of lock and key system is no longer appropriate in today's modern world. In recent times, use of alarm systems with dual key lockers, digital passwords, RFID, etc. is common. Variety of locker or vault type systems are available but each has its room for improvement, hence having its own flaws in the system. Theft of gold ornaments from Amin Jewelers is still a thing of commotion in Dhaka, Bangladesh [1]. Also, in terms of documents, leaking of classified information is nothing new. For example, over the years SSC and HSC examination question leaks was a threateningly auspicious debatable issue for Bangladesh. [2][3].

As a solution to these addressed issues and more, the study of a six-tier locker system has been proposed keeping in mind the drawbacks of the available systems. It has been prototyped, focusing on transporting valuables from one place to another in the most secured form. These valuables can be jewelry, bank drafts, antiques, gemstones, stamps, question papers and many more. The six-tier locker system is made using DS3231 RTC module, PIR sensor, RF module, Encoder Decoder, Fingerprint sensor, Password keypad, GPS and GSM.

II. BACKGROUND STUDY

One widely used security system is a locker having two keys and both are needed to open the lock, where one key generally is for the owner of the contents in the locker and another key is for the agent (a person who ensures security of the locker). But in this case, someone can easily pick the lock or make duplicates of the keys to open the lock causing a security issue.

There are also digital locking systems available but the problem with this is that by knowing the password or hacking into the system one can easily gain access.
Also, Srivatsan Sridharan in a paper [4] proposed a method which uses two levels biometric authentication meaning 2 people's biometric identities are needed to open the vault, ensuring only certain individuals to be able to open the vault. But it has no security check on time, date and location the vault is being opened at.
Authors in paper [5] showed a project which uses RFID reader module along with fingerprint and iris to secure the locker. Similarly, in the paper [6] they proposed a GSM-based locker system using RFID with fingerprint and a password.
In paper [7], they used GPS, fingerprint module and password protection to make a secured vault hence denying any access inside the locker while in transit.
Ch. Sumalatha et al in a paper [8] in 2016, proposed a bank locker security system also on RFID and GSM technology. The system was developed using GSM modem, microcontroller AT89C52, RFID reader, keyboard, and LCD. The id number is read via the RFID

reader and conveyed to the microcontroller. After that, the microcontroller checks if the id is authorized and if authorized, the locker is opened.
In paper [9], U. J. Ogri, D. E. B. Okwong and A. Etim created a model to use in security doors. Here one GSM device is used as a transmitter and another GSM device with the DTMF associated with the motor attached to a door with the use of DTMF decoder, a stepper motor and microcontroller unit.

All these existing systems are promising but all have their own drawbacks or faults in the system.

III. System Description

This system is developed for smart and efficient performance. Below are the main components of the Six Tier Security Locker System:

TABLE I. MAIN COMPONENTS AND THEIR FEATURES

Component name	No. of unit	Use
Arduino Mega	1	• To control all of the sensor and module. • Input voltage 6-20V
DC3231 RTC Module	1	• Operating voltage 3.3-5.5V • Used as a real-time clock • Storage capacity is 32K
PIR Sensor	1	• To detect any suspicious movement inside the box. • Operating voltage 4.5V
Fingerprint sensor	1	• Operating voltage is 3.6-6V. • For inserting a biometric password.
Password keypad	1	• For inserting a keypad password.
Encoder Decoder	1	• Wide operating voltage and high noise immunity • For encoding and decoding operation.
GPS	1	• The global positing system is used for tracking location. • Operating voltage 5V.
GSM	1	• GSM is used to send the updated status of this box to the user through SMS or phone call.
RF module	1	• This module has two part one is receiving and another one is transmitting. • RF module and Encoder Decoder is used to make a wireless password system.

[a] Components feature.

IV. System Design

A. Simulation:

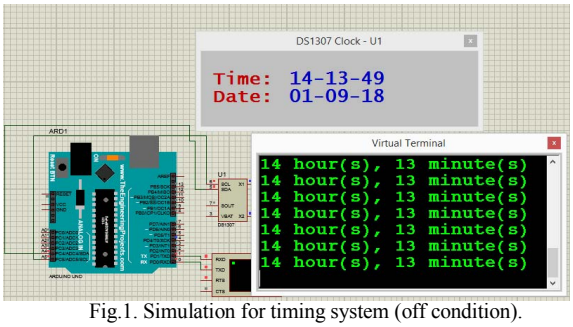

Fig.1. Simulation for timing system (off condition).

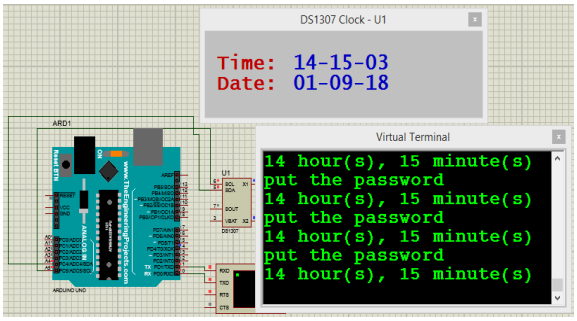

Fig.2. Simulation for timing system (on condition).

In Fig 1 and 2, it shows the simulation of the timing part. Where the Arduino and DS1307 RTC module has been used instead of DS3231 RTC module. Here DS1307 RTC module is working as a real-time clock. The whole system has been programmed in such a way that it will ask for the password over and over again after certain periods of time. For the rest of the time it will be inactive.

B. System overview:

The system will only unlock at specified destinations and at specified time. Upon arrival at the correct geographic location, when the clock approves of the correct time, to unlock the system user will have to enter the correct password as shown in fig. 4. Once the password has been accepted, the authorized person's fingerprint needs to be provided as shown in fig 5. An extra feature of grand access has been also added to the system. If a person has grand access, he/she shall be able to open the locker using his fingerprint alone, regardless of time and location.

Fig.3. Prototype box.

Fig.4. Giving password.

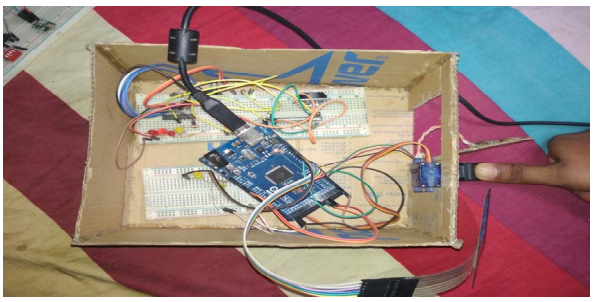

Fig.5. Box unlock by giving fingerprint.

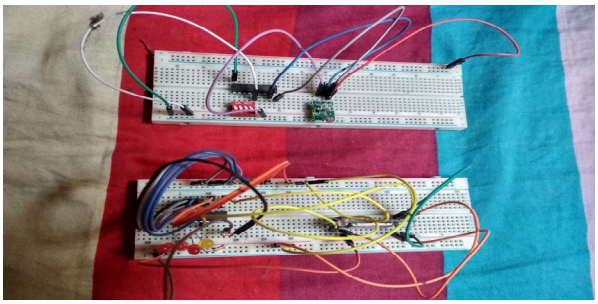

Fig.6. Transmitter and receiver circuit.

V. FEATURES OF THIS STUDY

- Six layers of high-security level.
- All electronic component used has low power consumption.
- Only one grand access using fingerprint is provided, making the system very secure.
- Suspicious movement inside the box before opening of the locker door will be notified to the owner using GSM module.

VI. WORKING PRINCIPLE

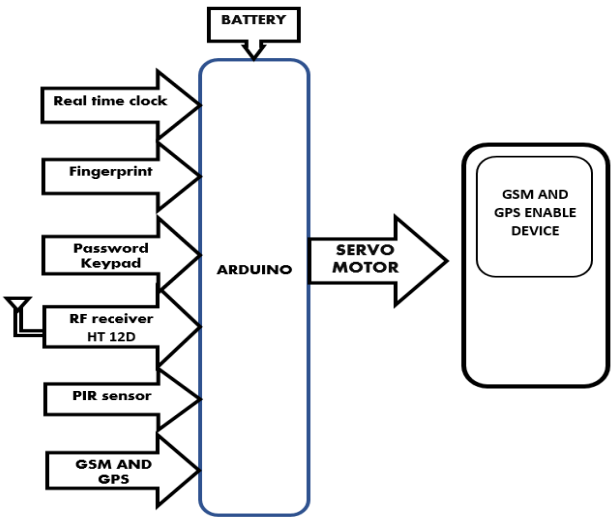

Fig.7. Working block input and output.

Fig '7' shows the Inputs and Output block diagrams. The battery is working as the power source of the system. On the left side of the diagram, the inputs are shown and the output is shown on the right side. All the inputs on the left side are connected to the Arduino and all the inputs are taken from the users of the system, except the GSM and GPS. The Arduino analyses all the inputs according to the instruction given and provides the desired result on the output end.

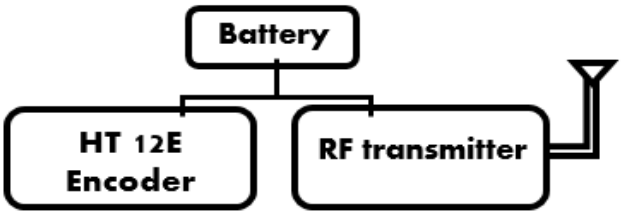

Fig.8. Working block of wireless password system.

Fig '8' shows the wireless password generation. It includes a battery, encoder and an RF transmitter. Combining the encoder and the RF transmitter a wireless password generator is created that generates a password which will be counted as input at the receiver end of fig '7'. And if the input password matches with the preset password then Arduino will get a positive feedback.

A. Flow diagram:

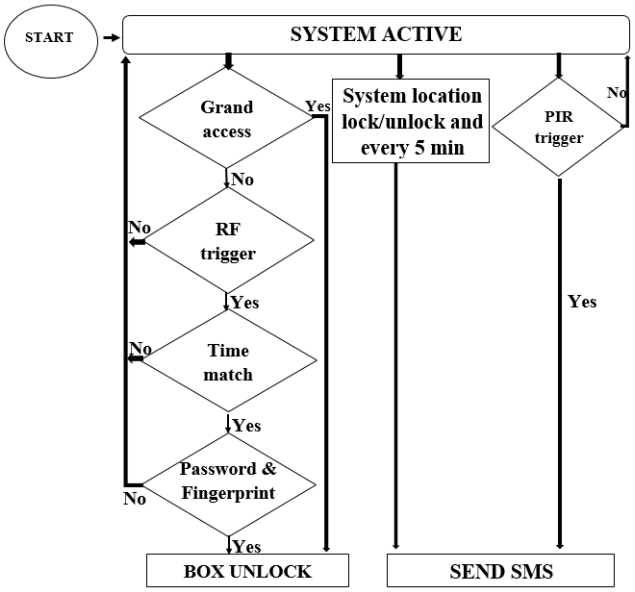

Fig.9. Flow diagram of six tier security locker system.

The Six Tier Security Locker System starts initiating at the very moment it has been locked. Locking gives the Six Tier Security Locker System power to initiate and it starts all the components inside the box. Arduino Mega (ATmega2560), RF module, DS3231 RTC module, Fingerprint sensor etc. This system's flow-diagram works in two stages. At the first, stage, if the fingerprint of the grand access is matched with the pre-set fingerprint it doesn't need to go towards the 2nd stage. But if somehow, it's unmatched then it will definitely go on to the 2nd stage, for unlocking and other security purposes.

After the initiation of the Six Tier Security Locker System, firstly the RF module will be triggered. The RF

module has a receiving part and a transmitting part and combining with an Encoder-Decoder module, such a system has been made that will transmit value from the transmitting part and that value will be received at the receiver part. If the value matches at both the transmitting and receiving parts it will be analyzed at the Arduino Mega (ATmega2560) as positive and the DS3231 RTC module will then be triggered otherwise, it won't. The memory module has been programmed in such a way that it has been clocked at a fixed time to initiate the password keypad. When the Memory module has been initiated, it will be analyzed at the Arduino Mega (ATmega2560), if it has reached at the preprogrammed fixed time or not. If the analyzed time meets the requirement of the DS3231 RTC module, only then the password keypad will be triggered and will be ready to take input otherwise it won't. If the input password matches with the stored preset password, the fingerprint sensor will be triggered. The Fingerprint sensor has been on from the very beginning of the initiation of the Six Tier Security Locker System and now that it has been triggered, it can take input and given the correct input, finally, it will unlock the Six Tier Security Locker System otherwise it won't unlock.

To provide a better security level, a GPS module has been implemented that will detect the latitude and longitude of the Six Tier Security Locker System and through a GSM module, the latitude and longitude along with the current status of the locker weather it has been opened or not, this information can be sent through SMS to a specific cellular device. And this information will be updated at 5-minute intervals. That way the location of the Six Tier Security Locker System will be traceable. The user can choose not to share the location of the box as well.

Another feature that has been integrated is, to trace any kind of movement inside the Six-tier Security Locker System through a PIR sensor and send the location of the box to the tracing devices, before opening of the locker door.

B. Power calculation

The power consumption of the whole system has been shown in the table II. We have calculated the power consumption and predicted the time for sending the system to its proper destination. We have used 5V, 20 mAh battery, that gives the system approximately 11 to 12 hours backup which is enough for the system to reach the destination.

TABLE II. POWER CONSUMPTION OF THE SYSTEM

Component	Power Consumption per day (mA)
Servo motor (6sec ON)	2 A/s *6s (max 6s ON) =12A
Arduino Mega (30 min ON)	170mA*60s*30min =306000mA =306A
GPS module (24 hour ON)	0.006(mA/h) *24h =0.144 =1.44*10^-4A
GSM module(24h)	2(mA/s) * 60s*60min*24h =172.8A
Fingerprint module(30s)	150(mA/s) *30s =4500mA =4.5A
Memory module (24h)	40(mA/h) *24h =0.960A
Matrix keypad(60s)	30(mA/s) *60s =1.8A
RF module (24h)	5(mA/s) *60s*60m*24h =432A
PIR sensor(24h)	504mA
Total	929604.144mA/d
Total	38733.506mA/h
Total Service Hour	~ (11 or 12) h We Provide (5V 20000mAh battery) All Components Input 5V

[b] total power consumption.

VII. COST CALCULATION

Each component with their corresponding price is given in Table III.

TABLE III. COST CHART

SL NO.	Component List	Price Per Unit (*Dollar*)	Quantity (PCS)	*Total Cost* (Dollar)
01.	Arduino mega2560	$10.10	1	$10.10
02.	DS3231 RTC module	$1.92	1	$1.92
03.	PIR Sensor	$0.95	1	$0.95
04.	Fingerprint sensor	$19	1	$19
05.	Password keypad	$2.5	1	$2.5
06.	RF module	$3.45	1	$3.45
07.	Encoder Decoder	$2.38	1	$2.38
08.	GPS and GSM	$23.78	1	$23.78
09.	Battery	$23.78	1	$23.78
10.	**Total Cost**			**$87.86**

[c] Device cost.

VIII. NOVELTY OF THE WORK

The tradeoff between cost and quality of work is something to point out in this study. The components used to build this system are very cheap, although the

output and the end results are very satisfactory. With the use of PIR sensor we can easily detect any intrusions that may appear very effectively and easily. Also, another contributing factor when it comes to novelty is the use of RF module instead of using RFID. Whereas RFID needs its own set of components and Arduino system to work, RF module has no such hassle. An RF Module consists two major components such as a transmitter and a receiver. One is placed inside the locker system and another at its destination, ensuring the locker to be only enabled for opening at desired destination(s). Adding to this, with the use of GPS and GSM the location and status of the locker is sent to a specific cellular device at 5-minute intervals making it traceable and ensuring the locker doesn't go off route. The user can also choose to opt in and out of the location sharing option.

IX. Future Aspects

Future improvements include three major upgrades. Firstly, using iris recognition along with fingerprint to add an extra layer of security. Secondly, use of a CMOS camera inside the box for monitoring, which will act as a complement to PIR Sensor. This will provide a visual view of any disturbance the PIR sensor detects. Lastly, syncing and preserving all kind of information sent from or received to the locker in a server. This may act as a log of all kinds of alarms, warnings or actions.

X. Conclusion

In Six Tier Security Locker System, all the features that help in the security of the device are brought together in a single module. Here Memory Module (real time clock) has been used to determine the preset time to unlock the Six Tier Security Locker System. PIR sensor has been used to detect any kind of action or movement inside the box. The fingerprint sensor has been used to provide fingerprint unlocking security, only when the preset time on the timer module is reached. Only one single fingerprint has been used as the grand access to unlock the box anytime. An RF module with encoder-decoder is used to create a wireless password system to generate passwords for the Six Tier Security Locker System to unlock. GSM and GPS module has been used to trace the current location of the Six Tier Security Locker System and sending the location details and other information via SMS service as an additional security feature. Overall the system is also very much cost effective. It took only $87.86 to build the whole system, without the structure of the safe, which may vary depending on the size and the material of the locker, required by the consumer. The device can be considered affordable to anyone or any organization at an affordable cost, while ensuring safely.

***Abstract*—In the era of technology, humankind is now looking for a rapid and prominent solution for day to day problems which can meet the demand and makes life easier. As security is an essential perspective with the end goal to protect our secret belongings, people are looking for an advance, unbreakable and user-friendly solution. However, considering a vault security system, we have to think a step further, as vaults usually used for higher security purposes. Security system using facial recognition, fingerprint scanner, password lock and RFID reader is going popular and common these days because of the availability and trustable security. The main goal is to implement a security system including all of these four sensors in single hardware which is able to provide much stronger security. The system is able to detect multiple human faces and also able to monitor the area continuously using one single camera sensor with the help of real-time video processing using open CV method. The system implemented in such a way that anyone who wants to enter the vault has to pass through all of these four (facial recognition, fingerprint, password and RFID scanner) steps. Neither one can be skipped. All the sensors are connected with Raspberry Pi to achieve the goal.**

Keywords— Security, Facial recognition, Open CV, Raspberry Pi, Fingerprint scanner.

I. INTRODUCTION

At present human work diminished by technology, thus technology plays a major role to ensure possession of individuals belongings. The automation of electronic equipment made it possible rather than wasting human resources and money for security [1]. Relying on technology this project develops a system that restrains human substances in a comprehensive way. This system can be served any individuals or any institutions to defend their confidential such as bank vault, money locker etc. Consider a breach of security the system is a combination of biometric and prior tech to ensure security escalation of this system. The objective is delivering security progression over extremely concealed premises effortlessly at an affordable cost [1]. Surveillance and facial recognition being operated by a camera for premium security purpose as it stores surveillance data on a memory chip for a definite period. The camera is continuously searching for a human face, and an authorizer is able to see the situation through the camera in real time. To achieve this goal, wireless communication established between the security system and the authorizer via VNC viewer. When a person places himself in front of the camera, the camera immediately scans his face with the image database stored in Raspberry Pi. The authorizer is able to see the name of that person at the top of his face in real time video. If the face doesn't match with the database, the name will be replaced by an unknown, and the system generates a sound which indicates the sound of an unknown person. After facial recognition, the system will ask for fingerprint, password and RFID card scan.

II. PRIOR AND RELATED WORK

Almost every smart device uses facial recognition to secure their devices from unauthorized people. It is also massively used for smartphone, network security and Deep learning-based video analytics. Other sensors like Fingerprint sensor, RFID reader are also used in security system and various application. A smart security system based on face recognition was proposed by Dwi Ana Ratna Wati and Dika Abadianto in 2017 [2]. The security system was based on MyRIO 1900 and programmed using LabVIEW [2]. The system can detect a person's face when the distance is less than or equal to 240 centimeters or even if the person uses various accessories like glasses or cap [2]. But it cannot identify the face if there is too much change or if the person is a little far from the camera. Another face recognition security system was implemented in 2018 by Ibrahim Mohammad Sayem and Mohammad Sanaullah Chowdhury using Raspberry Pi based on Python language with the help of OpenCV Library which is very similar to the face detection process used in this paper [3]. The device also sends email to the authorizer if there is an unknown person in front of the camera [3]. But as the system is only based on face detection, it is easy to break or bypass. An improved version of the security system was implemented by Teddy Mantoro and

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

Suhendi which can detect multiple faces at a single time using a hybrid method of Haar Cascade Classifier [4]. This system is more efficient and accurate compared to others. An advanced bank security system was designed by Raj Gusain, Hemant Jain and Shivendra Pratap which use face recognition, iris scanner and palm vein for authorization [5]. But the system is hard to maintain and very costly. Whether there is also a cost-effective solution, which is based on Arduino designed and implemented by Kanza Gulzar, Jun Sang and Omar Tariq [6]. But the time consumption is higher in that device and the device is not able to recognize a human face in real time video [6].

III. System Overview

The following "fig. 1" represents the block diagram of this system. To assure real-time broadcasting without interrupting the whole system, two of the separate virtual environments introduced. One is for live image processing (Open CV), and another is for other sensors (fingerprint, password and RFID). i2c communication is established to ensure a continuous connection between these two virtual environments. The camera sensor is continuously monitoring the area send signals to another environment if there is a person (e.g. alpha for an unknown, beta for David, gamma for Raj etc.). Thus, the Open CV environment is only focusing on video broadcasting and transferring signal. As a result, an authorizer is able to monitor the area continuously without any interruption. The second environment analyzes the signal received from the Open CV and commands the system for further instruction. In this case, if the signal represents an unknown person (e.g. the signal alpha which represents an unknown person) the system provides a buzz. But if the signal represents a known person (e.g. the signal beta which represents David) the system will command for fingerprint scan with the help of a 20x4 LCD display which placed at the system. When the person/visitor placed his/her finger on the fingerprint scanner, the system matched the fingerprint template with stored fingerprint of that person. If the fingerprint is matched, the system will give the confirmation and ask for a password to the person/visitor via a 20x4 LCD display. At this time, the visitor will place his password to the system via a 4x4 matrix keyboard and can also able to see whether it matched or not. If the password is matched, the LCD display confirmed it to the visitor and asked for RFID card scan. In this stage, the person/visitor will place the RFID card in front of the RFID scanner. And if the RFID card is matched, the system will activate the electronic door lock and allow that visitor/person to enter the vault.

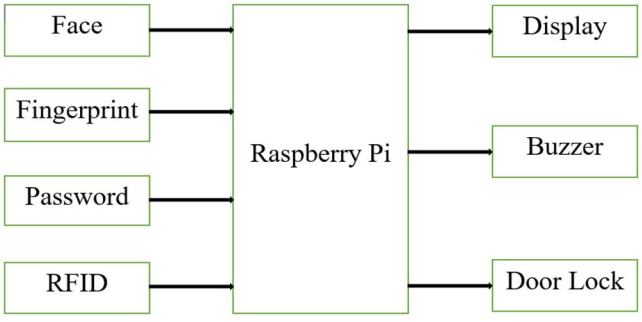

Fig. 1. System block diagram

If one of these steps is failed or not matched, the system will start from the beginning. Keep in mind that, password, fingerprint and RFID card vary from person to person (for example, if the face matches with David, the system require Divides fingerprint, password and RFID card). Neither of them can be entered changeable even if both of them are authorized.

IV. System Methodology

This section demonstrates the methodology of how this system work and interfacing with sensors and Raspberry Pi. Raspberry Pi is the main brainer in this system which interprets all the data to establish a decision.

A. Facial Recognition using Open CV

The facial recognition of a human is made possible with the help of Open CV library in python language. Open Source Computer Version Library which is known as Open CV, provide a common infrastructure for computer vision application [7]. Open CV library contains over 2500 optimized algorithms including a comprehensive set of both classic and state-of-the-art computer vision and machine learning algorithms which can be used to detect and recognize a face, identify objects, classify human actions in videos, track camera movement, track moving object and many more [7].

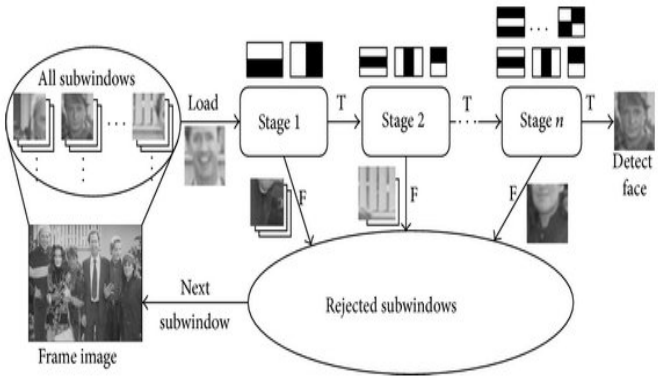

Fig. 2. Cascade structure for Haar classifiers [8].

Here, the goal is to detect/identify a human face in real time video. The algorithm used to achieve the goal is Haar Cascade Classifier. The hybrid method of Haar Cascade Classifier is used in this system so that the system can detect multiple faces at a single time. The cascade function is trained from a lot of positive and negative images to detect an object in other images [7]. Three types of features (edge features, line features and four-rectangle features) are used to train the classifier obtaining single value by subtracting the sum of pixels under the white rectangle from a sum of pixels under the black rectangle [7]. The classifier uses a fixed scale, for example, 50x50 pixels. Applying each and every feature on all the training images, the classifier can find the best threshold which will classify the faces to positive and negative [7]. As most of the image is non-face region, the features are grouped into different stages of classifiers and applied one-by-one [7]. The window, which passes all the stages is a face region [7]. Open CV contains two parts (Trainer and detector). Trainer is used to train the classifier and the detector is used to detect the face. To train the

classifier a dataset of images is needed. Every image contains cropped face of a human from a different angle in grey scale.

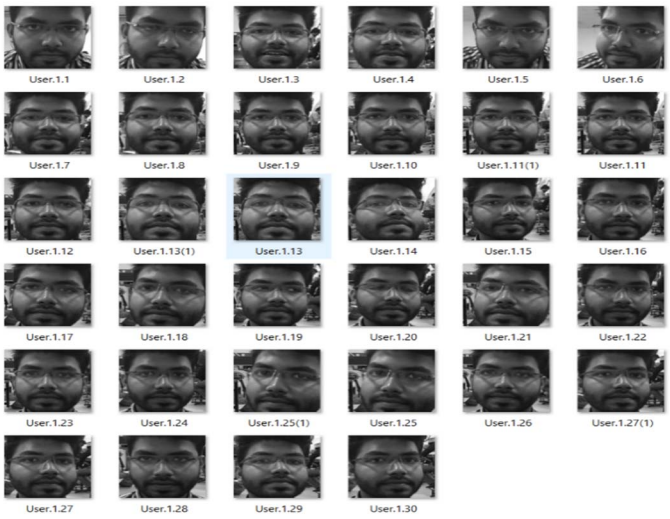

Fig. 3. Dataset of images in grey scale.

With the help of python language, the detector continuously matches the real-time image with those images stored in the dataset.

Fig. 4. Face recognition using Open CV.

B. *Fingerprint Scanner*

The fingerprint matching algorithm is responsible for producing a similarity score for the input and template prints. After analyzing similarity, the resulting match score will be compared with a certain threshold if both original fingerprints are formed (or not) from the same finger. Many methods are available for fingerprint matching among them minutia-based matching technique commonly used due to his less computational cost and good performance [9]. Minutiae-based algorithm established on local structure (point pattern matching), and global structure (finding the alignment of the corresponding pair of minutiae sets) [9].

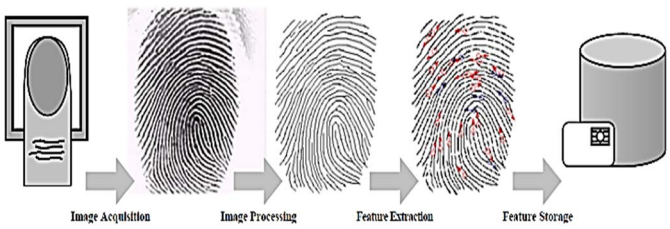

Fig. 5. Finger-print enrollment process [9].

First, the local structure of each minutia point is obtained in both minutiae sets to determine the similarity of fingerprints. The local structure describes minutiae spatial characteristics taking into account its meticulous neighborhood. This local descriptor (ridge ending, ridge bifurcation) is an invariant feature of rotation and translation that is inherent in minutiae [9]. Comparing both the template and the input minutiae a similarity matrix formulated in order to analyze the score of similarities between any combination of minutiae pairs. Local structure similarity scoring allows the best-matched minutia pair to be identified and exercised as a reference for global structures.

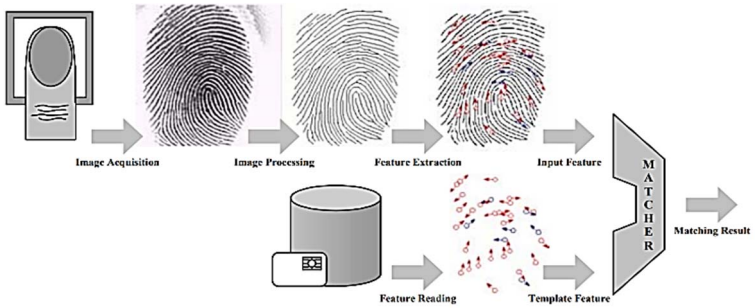

Fig. 6. Finger-print authentication process [9].

Global structures defined by minutiae sets where it describes the spatial characteristics from a reference point. After accomplished with the global structures the system decides the results obtain from global structure compared with the certain threshold.

C. *4x4 Matrix Keypad*

The 4x4 matrix keypad is used to input a password into the Raspberry Pi. The number of pin requirement for digital input can be reduced, by using the matrix keypad. The matrix keypad contains 16 pins in 4 rows and 4 columns. The keypad has 8 pins. 4 is for columns and 4 is for rows. By making 4 rows as output and considering them logic low, and 4 columns as input, the possible key pressed can be detect when correspondent columns gets o or low [10]. When the switches are not pressed it needs to make the column pins as high or 1, otherwise it is not possible to detect the logic changes when the switch is being pressed [10]. But there is a chance of spikes or noise generation if multiple switches are pressed at a time [10]. To avoid the noise, a few milliseconds delay is required to recheck the switch conditions [10].

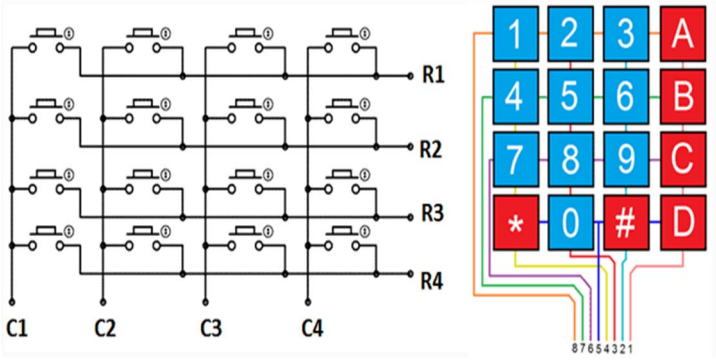

Fig. 7. Connections of a 4x4 matrix keypad [10].

D. RFID Card Scanner

The Radio frequency identification namely called as an RFID. It has two main components a transponder, associated with the object which is supposed to identify. The other one is Transceiver which consists of a radio frequency module, a control unit and antenna coil, which generates a high-frequency electromagnetic field [11]. When the transponder approaches towards the transceiver, a voltage induced due to induction and a microchip inside the transponder gets power to operate. Load manipulation technique is used to transfer data between transponder and transceiver. Switching of tag antenna using control unit causes a voltage drop that resultant in ones and zeroes [11]. This data used to transmit the signal between the transponder and transceiver.

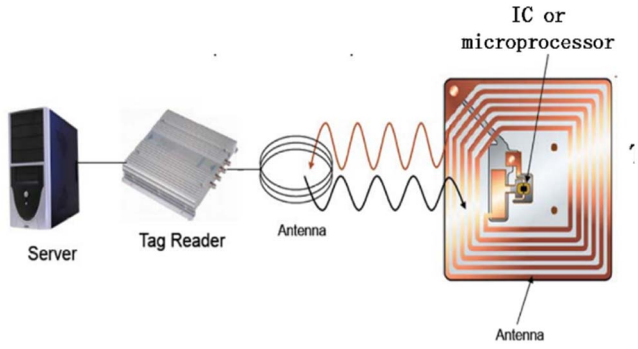

Fig. 8. RFID system [11].

V. Experimental Setup & Programming Flow Chart

The Experimental Setup with all the interfaced components are shown in "Fig. 9".

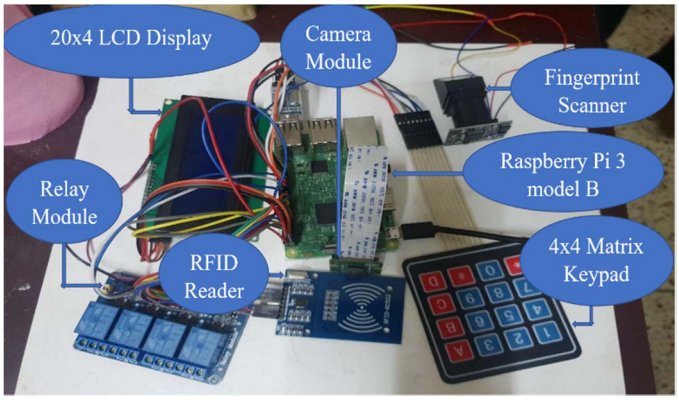

Fig. 9. Experimental setup of the system.

The programming flow chart of the system is shown in "Fig. 10".

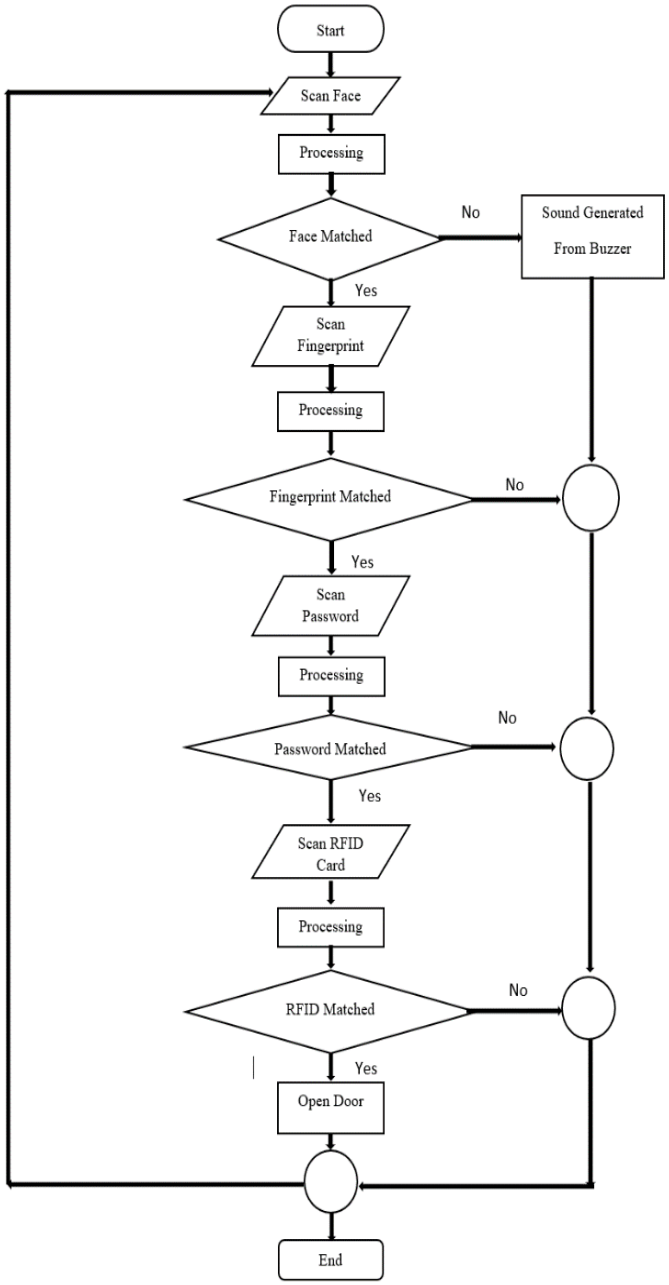

Fig. 10. Flow chart of the program.

VI. Implementation & Results

The system is developed in a single Raspberry Pi board using python language. Raspberry Pi is a mini portable onboard computer which has 4 USB ports, an Ethernet port, a HDMI port, a 3.5mm audio jack, onboard camera and display port, a MicroSDHC slot, 40 GPIO pins including power and ground and a micro USB port to provide 5 volts dc power. The system is powered by a Broadcom BCM2837 chip with ARMv8-A instruction set architecture (ISA) using 4 core Cortex A53 based CPU clocked at 900 MHz. It has 1GB RAM shared with Broadcom VideoCore IV GPU. The Raspberry Pi 3 model B also comes with on-board network (2.4 GHz wireless and Bluetooth 4.2). The system consists of a controlling device (e.g. laptop, smartphone etc.) over same Wi-Fi connection, a camera module, fingerprint scanner, matrix keypad, RFID reader/scanner, relay module, electronic door lock, buzzer and some LEDs. "Fig. 11" shows the real time monitoring over wireless communication via VNC viewer.

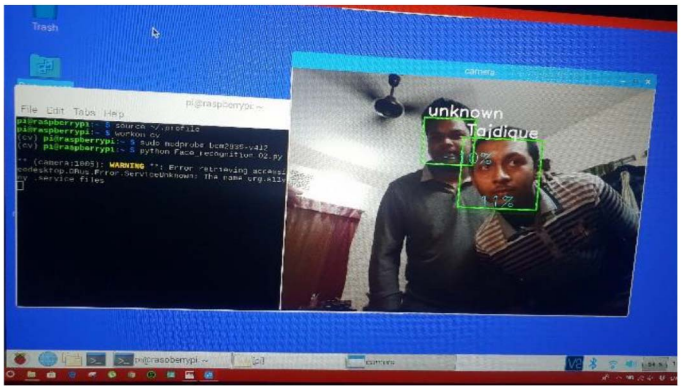

Fig. 11. *Monitoring real time video streaming via VNC viewer.*

A 20x4 Character LCD Display is used in this system to communicate with the user. The display is connected with the GPIO pins of the Raspberry Pi. An I2C LCD Gadgeteer module is used to reduce the connecting wire. The display provides instructions to the user. “Fig. 12” shows the initial state of the LCD display.

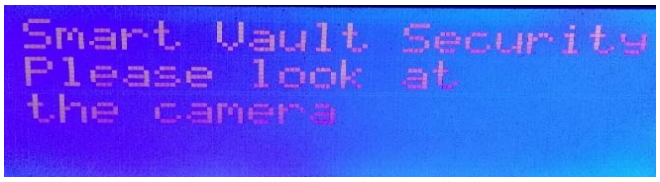

Fig. 12. Initial stage of the LCD display.

The Raspberry Pi Camera Module V2 is connected with the Raspberry Pi using onboard camera port for the purpose of real-time video broadcasting and facial recognition. The Camera Module has a 8 megapixel Sony IMX219 sensor which can be used to take high-definition video and photo. The camera identifies the person/visitor and the LCD display sends the confirmation and farther steps to the person/visitor which are shown in “Fig. 13” and “Fig. 14”.

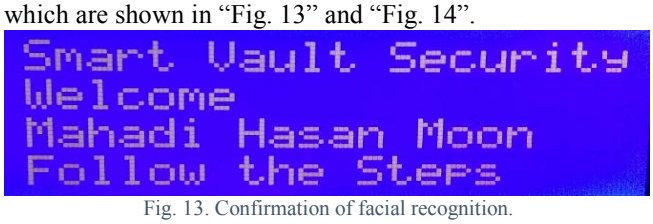

Fig. 13. Confirmation of facial recognition.

Fig. 14. Instruction for finger placement.

R30X Fingerprint Sensor is used to scan and identify the fingerprint of the visitor. It requires a UART interface over USB port. To connect the Fingerprint Sensor with Raspberry Pi a PL2303 USB to TTL Converter is needed. The voltage requirement is in between 3.6 to 6.0 volts. The Fingerprint Sensor will activate after facial recognition. The visitor is able to see whether his/her fingerprint is matched or not. All the results and steps are being placed on LCD display which will shown in “Fig. 15” and “Fig. 16”.

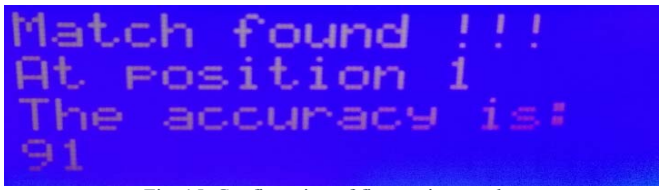

Fig. 15. Confirmation of fingerprint match.

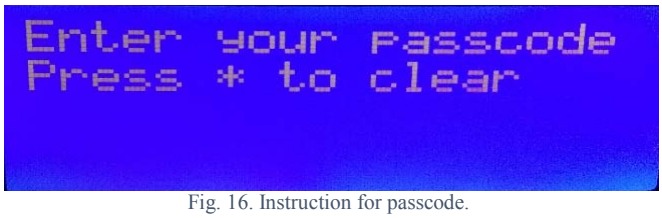

Fig. 16. Instruction for passcode.

A 4x4 matrix keyboard is used to enter the password to the system which is directly connected with Raspberry Pi GPIO pins. From total 8 connectors, 4 of them are input and 4 of them are output. The process wise results are shown in following figures from “Fig. 17” to “Fig. 19”.

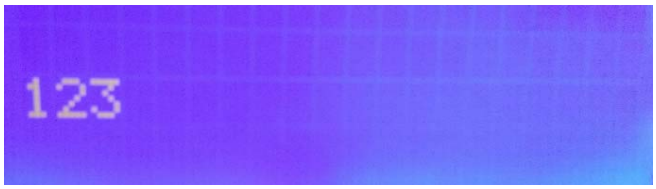

Fig. 17. Input Password.

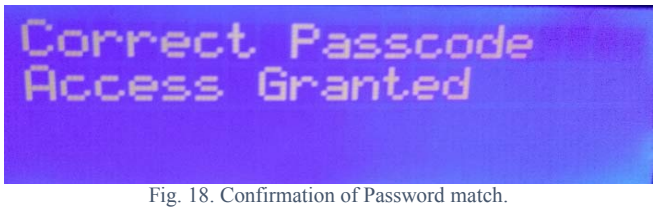

Fig. 18. Confirmation of Password match.

Fig. 19. Instruction for RFID Card placement.

To read and write RFID cards, MFRC522 RFID sensor is used. It is a highly integrated RF frequency reader/writer IC for contact less communication at 13.56 MHz and also supports ISO/IEC 14443 A/MIFARE mode. The voltage requirement for the sensor is 3.3 volts. It is the last and final stage of this security system. After placing the RFID card on the RFID sensor, the system matched the card number and gives the confirmation which shown in "Fig. 20".

Fig. 20. Confirmation of RFID match.

After completing all the steps, the system turned on the 12 volts electronic door lock which is connected with the raspberry pi via relay module. A 1100mAh 12 volts Lithium Polymer Battery is used to power the electronic door lock. “Fig. 21” shows the complete setup of the system.

Fig. 21. Complete setup of the system.

VII. LIMITATIONS

Each project has some limitation that can be eliminated by conducting future research or development. In this project, the calculation of entering people in a vault or confidential room is not ensured. Face detection of the night mode is not available. In the limitation side, the real-time delay in broadcasting the surveillance has been counted.

VIII. CONCLUTION

The ultimate goal is to provide society with a reliable and uncompromising security system that people can afford to obtain better security assurance. The system improvises the multi-step security authentication to obtain a result. It strengthens security by effectively limiting trespassing, heist, or security threats of any kind. This project has developed with the raspberry pi embedded with the identification sensors. The OpenCV environment has used for face detection, which bases on viola jones algorithm using Haar cascade classifier which superimposes the positive image over a set of negative images known as favored face detection classifier in OpenCV. The entire project framework has programmed with the python language. Future development can be developed adding gas sensors, humidity sensors for measuring their concern-parameters. An emergency alarm can be generated in the event of Emergency. Although the system is designed for vault security, it can be used for any security purpose like home security, office security etc. Considering the social impact of this project, it has done with a lot of dedication and integrity.

Abstract— **This paper presents an implementation of a human machine interface (HMI) for a programmable logic controller (PLC) based automated packaging process that can be remotely controlled and monitored using mobile application. A conveyor belt does the moving of products to a destined place for packaging, is controlled by Siemens LOGO! 230 RCE PLC. Microcontroller (arduino uno) operates the relays according to the output of IR sensors, which are used to sense the products. States of relays are taken as the input of the PLC. An HMI is designed with an android application and the microcontroller (as the processor) that establish a communication path between the operators and PLC based plant. The interface provides remote controlling and monitoring feature. The proposed design minimized the overall cost by replacing the widely used supervisory control and data acquisition (SCADA) system with normal sensors and mobile application based control. The performance of the implemented prototype is evaluated through several real-time operations, which shows satisfactory results.**

***Keywords*— PLC, Arduino Uno, Android-based application, SCADA, Conveyor belt, Packaging process.**

I. INTRODUCTION

Industrial automation is one of the most global trends that enhances the quality of production, safety and proper utilization of plant and resources. From the economic view, mass production is the main goal of any industry to stay ahead in the recent competitive market [1]. The mass production can be eased through the process automation. In any kind of industry, packaging is a widely used process. Packaging is done for providing protection and safety of products from dust, moistures and other objects that are harmful to the products. The packaging also provides better handling, transporting and, stable storage capability, company branding and many more [2]. The manual packaging process is toilsome work and costly, as a large number of workers is required for it. Therefore, many companies switching to industrial automation for cost-effective and uninterrupted production. Automation of the packaging process with remote control and monitoring system will provide more reliable and developed packaging with less error and less probability of hazards [3]. In industry, an essential equipment of product processing is the conveyor belt. Conveyor belt performs the functions include rotation, accumulation, flipping, stacking, and diversion of products depending upon the application. There are several conveyor belt systems are used in industries. In Table I, numerous conveyor belt systems are enlisted with their working domain [4].

TABLE I
CONVEYOR BELTS AND WORKING DOMAIN

Types	Working Domain
Roller	Belt, rings or chains powered rollers
Sortation	Diverts product one region to another or one belt to another. Mainly used for sorting.
Accumulation	Holds products for a fixed time or for a fixed quantity gathering.
Screw	Consist of helix pushes loose products forward such as powdered or mixed products.
Carousel Indexing	Conveyed products to upward.

In the area of industrial automation, programmable logic controller (PLC) found greater interest for its robustness and low-cost implementation. PLC is a kind of small computer specially designed for industrial purpose, performs several functions including logical operations, counting and arithmetic functions to control various process or machinery through digital or analog modules [5]. Various automation of packaging using PLC and supervisory control has been proposed and implemented by numerous researchers around the world. Each automation has its own pros and cons. A brief discussion has been made on the various automation of packaging processes in Section II. It is found that most of the automation is applicable for large industries, complex in nature, expensive and not affordable for small industries. To overcome the aforementioned limitations, an affordable, less-costly and simple packaging process is proposed. The main contributions of this paper are:

i. For lower capital industries, SCADA and other supervisory devices are used for feedback and

monitoring, which are costly to implement. In this paper, an HMI is implemented with low-cost equipment and easier accessing technology.

ii. Implemented a mobile-based user interface i.e. an android application that is user-friendly and easy to operate and learn.

iii. Developed a platform for improvising and innovation in mobile-based industrial automation with low cost, robustness, and reliability.

In this paper, a prototype of two conveyor belts is considered, one for products carrying to the destined box and another for carrying filled and unfilled boxes. PLC is designed as the controller for a constant speed geared DC motor, which rolls the conveyor belt. An interface is designed based on android platform, arduino uno and bluetooth module to control and monitor the packaging process. The novelty of the proposed system is that it has been found suitable and cost-effective for small industries where capital is small. This work can also be implemented for large industries considering the requirements of robustness and application field.

II. Related Works

In recent years, many works on automation and remote monitoring and control of packaging process have been done. Numerous papers are studied and the contribution have been enlisted, which is represented in Table II.

TABLE II
Related Works on Automation of Packaging Process and Remote Control and Monitoring

Author	Contribution
Marie M. Baroro, Joanna & Alipio et al. [6]	Implemented packaging and material handling using PLC and recommended an HMI for controlling purpose.
Abueejela, Yousef & A. Algitta et al. [7]	Implemented automatic packaging machine by controlling the conveyor belt using PLC.
P.Thirumurugan et al. [8]	Implemented metal separating and packaging machine using PLC and a metallic sensor for detecting metals and non-metals.
Gupta, T & Kamboj, S et al. [9]	Proposed a design of packaging process using PLC and SCADA for remote control and monitoring with a software interface to visualize the process. SCADA and PLC inter-connection has been proposed for re-programming the PLC.
Shyr, Wen-Jye, Te-Jen Su and Chia-Ming Lin et al. [10]	Developed and implemented a methodology for remote controlling and monitoring of plant using PLC. A web-server based computer system and Web-Cam are used to remote monitoring and connected computer through the internet can control the plant from the remote place.
J. Garcia et al. [11]	Using SCADA and TCP/IP developed a platform using Motronic software interface for real-time remote monitoring and controlling of the plant and configure new device to add with, re-configure the existed device.
S. Da'na, A. Sagahyroon et al. [12]	Designed and implemented an automated platform through which the PLC-based plant can be remotely monitored and controlled through TCP/IP or by GSM. They also developed a backup control and monitoring system through mobile-based communication by using SMS.
D. S. V. S. Vardhan and Y. S. Narayan et al. [13]	Using feedback sensors for monitoring and PLC for controlling, an automated control and monitor system has been designed.

From Table II, It has been seen that, robust and more costly remote controlling and supervisory systems are used or proposed for industrial applications. However, for small industries or industries where robustness is not required, these above-mentioned proposed designs seems unnecessary. For this reason, the purpose of this paper is to find alternate technology and reduce cost of automation. Moreover, an automation system has been designed which can be easily implemented for low cost industries and for large industries where only monitoring is required rather than robustness.

III. Methodology

The proposed design of automatic packaging machine using PLC LOGO! 230 RCE can be divided into four steps illustrated as following:

A. Start Packaging System

Tapping the "Start" button on android application, a specific data (e.g. "a") sent from mobile. Bluetooth module (HC-05) receives the transmitted data, which are processed by a microcontroller (arduino uno). Arduino uno makes a particular pin as logical "High" for one second, which will control the switching of relay switch (four-array relay switch 5v DC). This will make arduino uno to send a string e.g., "packaging starts" through bluetooth module to the mobile. This relay switch provides logical information to the respective PLC input (e.g. I1). PLC module then operates its logical operations to close or open respective output relay. Electrical dc motor can be used as an output actuator to move box or sample conveyor belt, as shown in Fig. 1.

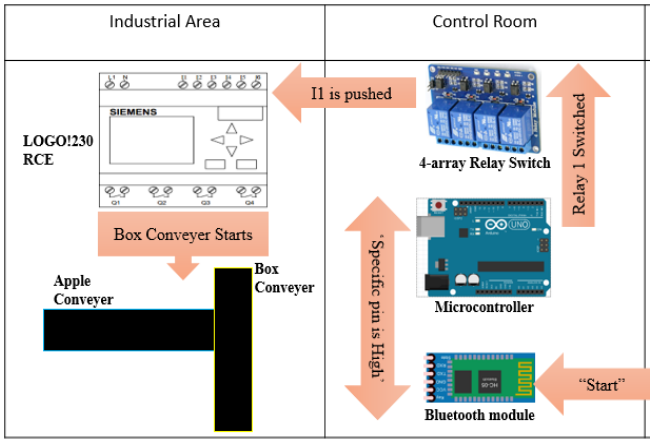

Fig. 1 Proposed procedure of start packaging system.

B. Box Sensing and Counting

Box conveyor run until a box is sensed by the IR sensor. Sensing of a box makes arduino uno to make another pin logical "High" for one second and send another string e.g., "1 box is sensed" to mobile phone including the number of boxes. That pin also controls the switching of a relay switch providing logical information to the respective PLC input (e.g. I4). PLC module stops the box conveyor belt and begins to move sample conveyor belt.

C. Sample Sensing and Counting

Samples (e.g. apple) on the running sample conveyor belt are passed before the IR sensors (mounted on the sample conveyor structure). IR sensors senses and arduino uno process this signal to make a pin logical "High"

for one second. Moreover, arduino send a string to mobile e.g., "1 sample is sensed" and a counter is started to count the sample. The logical "High" pin provides logical information to the respective PLC input (e.g. I3). PLC module stops the sample conveyor belt when three samples have been counted and begin to move box conveyor belt. In such a way, every box is filled with three samples.

D. Stop Packaging System

Box sensing, apple sensing, and counting will be continued until an interruption command is sent from the mobile application. When the "stop" or "exit" button is tapped on the mobile application, the PLC module stops the packaging system and initializes the number of boxes and samples.

IV. Software Implementation

Software implementation includes implementation of PLC ladder diagram, developing an android application and configuring necessary programs (remote control and monitoring system) for arduino.

A. PLC Ladder Diagram

For programming and operation of the presented prototype, a PLC ladder diagram is applied by using LOGO! Soft V8. For a faster, uncomplicated and space-saving solution, LOGO! is a perfect choice. LOGO! Soft Comfort makes possible of easier installation with a minimum wiring effort [14]. This ladder diagram, as shown in Fig. 2 provides two stages of the packaging operation. The input, output, relay switch and counter configuration are shown in Table III.

TABLE III
INPUT, OUTPUT AND RELAY CONFIGURATIONS OF PLC

Input				Output	
I1	I2	I3	I4	Q1	Q2
PLC starts	PLC stops	Apple or sample sensed	Box sensed	Apple or sample conveyor belt	Box conveyor belt
Relays				Counter	
M1		M2		C001	
Relay contacts		Relay contacts		Apple Counter	

1) Carrying Empty Boxes to Desired Location

Flag "make contact" M1 is connected with "make contact" I1 (packaging starts) to provide an OR gate operation. The output of the OR gate and "break contact" I2 (packaging stops) provides an AND logic gate operation to operate flag output coil M1. Flag "make contact" M1 and flag "break contact" M2 provide an AND logic gate operation to operate relay output coil Q2 (box conveyor). Flag "make contact" M2 is connected with "make contact" I4 to provide an OR gate operation. The output of the OR gate and "break contact" C001 provide an AND logic gate operation to operate flag output coil M2. Therefore, once packaging starts (I1 logically high), box conveyor (Q2 relay output coil energies) starts to move unless "packaging stops" (I2 logically high) command is applied or a box is detected (flag M2 is logically high).

2) Packaging Samples into Boxes

Relay output coil "make contact" Q1 is connected with "make contact" I4 and provides an OR gate operation. The output of OR gate, relay output coil "break contact" Q2, the flag "make contact" M1 and sample counter "break contact" C001 provide an AND logic gate operation to operate relay output coil Q1 (apple or sample conveyor). An apple or sample counter C001 is introduced. C001 will be reset if relay output coil Q2 (box conveyor) is logically high. Flag make contact M1, relay output coil make contact Q1 (apple or sample conveyor) and "make contact" I3 provide an AND logic gate operation to count the number of samples.

B. Developing an Android Application

Android-based PLC remote control and monitoring application is developed using Android Studio (emulator) [15]. This application provides a single row display for wireless monitoring and three control buttons, as shown in Fig. 3.

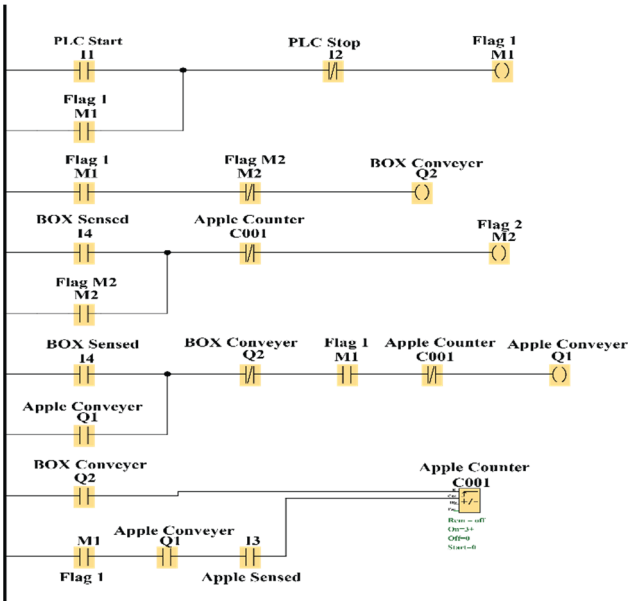

Fig. 2 Ladder diagram of the automatic packaging system.

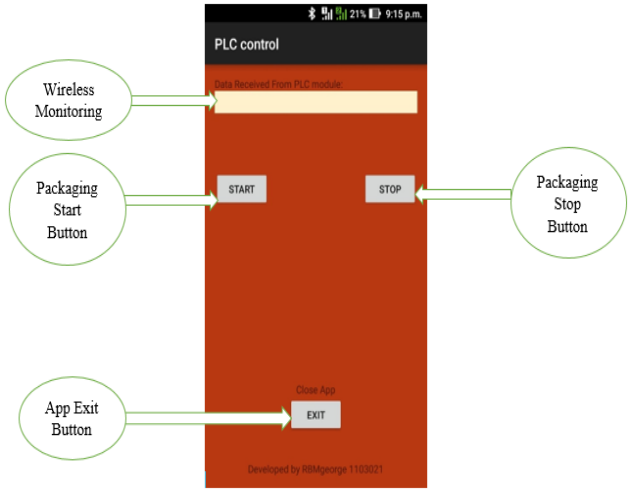

Fig. 3 An android application of automatic packaging & monitoring system.

C. Configuring Remote Control and Monitoring Programs to Arduino

Arduino, an open-source electronics prototyping platform that is based on flexible, easy-to-use hardware and

software. Arduino is a tiny computer system that can be programmed with specific instructions to interact with various forms of input and output and can be reprogrammed as many times depending on the microcontroller used [16]. Arduino uno performs a various function including data exchange between mobile and PLC, counting, calculate and monitor samples and provides necessary data string to the mobile application.

V. Hardware Implementation

The required equipment for complete hardware implementation of automatic packaging and monitoring system is shown in Fig. 4.

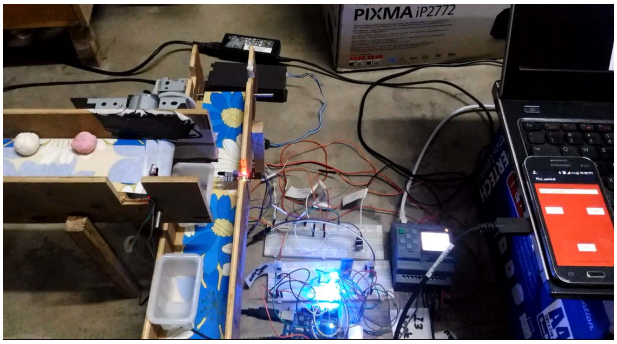

Fig. 4 Overall view of automatic packaging & monitoring system.

The major hardware equipment of the automatic packaging system are the following:

A. LOGO! 230 RCE PLC Module

LOGO! 230 RCE is a small PLC module that is made for home appliances. It provides higher system stability and performance rather than a microprocessor. It comes with easy programming features i.e. ladder diagram that can be programmed using the installation software LOGO! Soft V8. The inputs (220V AC pulse) are provided by a four-array relay switch to the PLC according to the command of arduino uno and the outputs (relay switch) that are connected with the conveyor motor circuits.

B. Arduino, Bluetooth Module and Android phone

Arduino uno is used to communicate between mobile phone and PLC (LOGO! 230 RCE) via bluetooth module. Moreover, IR sensors are directly connected to the arduino uno to generate respective logical input of the PLC module. Data strings provided by arduino uno are shown in Table IV.

TABLE IV
Data Strings Provided By Arduino Uno

Operations in android phone and IR sensors	Data String	
	Data send by arduino	Data receives by arduino
"Start" button	"Packaging Starts"	"a"
"Stop" or "Exit" button	"Packaging Stops"	"b"
Box is sensed	"X box is sensed"	
Sample is sensed	"X sample is sensed"	

C. Conveyor Belts

Two conveyor belts are made from wood, dc motors with proper gearing, belts, and sensors. Belts are used for transporting samples from one location to another, which would be packaged into a specific plastic box later. Through the entire process, dc motors are used as actuators to move the conveyor belts. Proper gearing structure is included for high torque with moderate speed. Two IR (infrared receiver) sensors are used, one for box detection another for sample detection. Detection timing of IR sensors is modified by arduino programming. Even arduino sends necessary data strings to the mobile phone via bluetooth module for every detection of box and sample. The conveyor belt system making procedure is shown in Fig. 5.

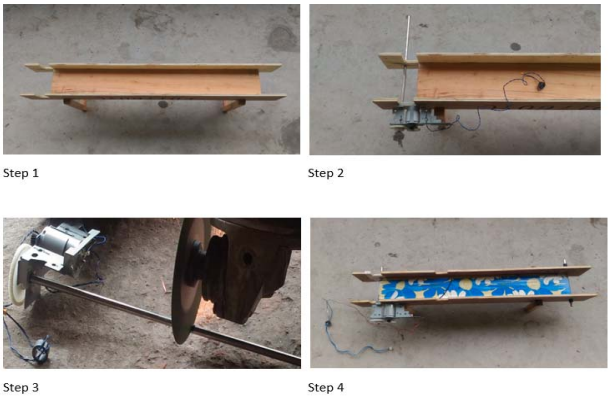

Fig. 5 Making procedure of conveyor belt.

VI. Cost Analysis

An approximate analysis of the cost of equipment used in the proposed design and existed automation is represented in this section. DC motor, conveyor belt are the common equipment in both proposed automation and existed automation. Therefore, their cost is not considered in the analysis. Other equipment that are used in proposed automation and existed automation are compared with respect to their cost and comparison of cost is represented in Table V. It is seen that a reduction of approximately 1700 USD can be possible by using the proposed automation.

TABLE V
Cost Comparison

Proposed Automation		Existed Automation	
Equipment	Cost (USD)	Equipment	Cost (USD)
PLC (LOGO! 230 RCE)	243	PLC (LOGO! 230 RCE)	243
Arduino Uno	24	SIEMENS HMI	700
Bluetooth Module	9	Network Module/ Communication System (TCP/IP, Internet, GSM)	800*
Mobile with Android OS	70	Computer	300
IR sensors	10	CAM/ Sensors	50*
Total	356	Total	2093

*Approximate cost of Network Module and CAM

VII. Conclusion

An automated packaging process with remote control and monitoring capability has been implemented. The main purpose of this design implementation is the reduction in the cost of automation. For lower capital industry or small industries, large automation or high-configured devices are not economical. A reduction of almost 1700 USD become possible using the proposed design. The proposed design provides low-cost HMI to interact with the machine from

remote places using the mobile. A notification or alert system and communication path have been developed that monitoring and control of plant can be done from a distant place from the plant. This ensures the reliability and errorless process of the plant. The proposed design has successfully tested using numerous trial and get a satisfactory result with greater performance of reliability, robustness, and less-error in packaging. This design is feasible for low-capital industries as well as can be implemented for large industries.

***Abstract*— Book digitization is the procedure of converting paper books or documents into digital media such as images, text files, electronic books (e-books) and audio books. On this paper we have proposed a low-priced book scanner and translator using Raspberry Pi. We have built a complete prototype that is able to read a book, translate parts of it to English if necessary and scan the whole book in the process to create a digitized soft copy of the book. Thus, a printed book might be converted to an audio book or PDF. For the conversion process, we interface an external webcam with the Raspberry Pi. The pictures taken from a book are processed and converted to text with the Tesseract OCR. Any part, that is not in English, is translated using the Google translator API, then the text is converted to audio file with eSpeak TTS engine. The processed images of the pages are combined and converted into e-book after the whole book is scanned. The entire process was made spontaneous by including automatic page turning mechanism with the hardware implementation.**

Keywords— Image processing, optical character recognition, text-to-speech, book scanner, book translator, book reader

I. INTRODUCTION

On this era of information and technology, digital books are gaining popularity over paper ones. Digital books are easily accessible, more available, easy to store and require little maintenance. Most of the recently published books now provide digital version as well. In a paperless world, almost all documentation is now carried out by storing data in digital format. The problem that arises is with the older books and documentations that only has printed copies. We are faced with the tedious task of converting those numerous books and documents into e-books and audiobooks (where necessary). Major steps of the conversion process include scanning individual pages, processing the scanned images, converting it to text and then to audio (for audio book), combining and converting the processed images of all the pages to a single e-book (e.g., in PDF format) or audio book (e.g., in MPEG format). Various commercial companies have come forward to solve the problem and have built book scanners that are able to automatically convert a given paper book to a digital one. The price of a document scanner (without automatic page-turner) that is presently available in the market is too high starting from 200 to few thousands USD. In this paper, we are presenting a low-cost alternative to the existing book scanners with some additional features.

Optical Character Recognition (OCR) is the process of identifying text characters from printed or scanned text images and converting it to editable text [1]. The Tesseract OCR is an open source optical character recognition engine developed at HP in between 1984 to 1994 [2]. It has since been modified and improved for greater accuracy for the few last decades. It was made open source in the late 2005 and is now maintained by Google. It provides support for various languages such as English, Japanese, Hindi, Spanish, French, German, etc. The Tesseract OCR has been used to convert scanned book pages to editable text files in our project.

The artificial production of human speech is called Speech Synthesis [3]. Text-to-speech (TTS) Engines are a form of speech synthesis which were first developed to aid the visually impaired by offering them spoken words with text. A TTS engine has two parts, front-end and back-end (Synthesizer) [4]. The front-end converts the text to symbolic linguistic representation which is then converted to sound by the back-end [5]. In our project, the text file prepared by the OCR has been converted to audio using the eSpeak TTS engine.

There are several available book scanners in market at the moment, like CZUR ET16 Plus smart book scanner, FUJITSU Image Scanner ScanSnap SV600, Aibecy Adjustable High Speed USB Book Image Document, Aibecy Portable High Speed Document Camera Scanner etc. [6–8]. Most of the book scanners are not available in Bangladesh and the cost of the scanners (including shipping) is higher than what the general people can afford. We are presenting a low-cost alternative for the book scanners that can be built from easily available ingredients. Our scanner has added features like translation and audio book conversion that none of the existing products offer and production cost of the scanner is below 70 USD.

The rest of the paper is organized as follows: section II describes the proposed method, section III describes the software development process, section IV presents the hardware implementation process and section V provides a comparative analysis (between existing products and the proposed one) and discusses the humanitarian impact of this project. Finally, section VI concludes the paper by mentioning the future work we have planned.

II. PROPOSED METHOD

At first, an image is taken using the camera interfaced with a small single-board computer. The image is then processed and supplied into the OCR software to convert it to a text file. The text file is supplied to Google translator API to translate the necessary parts. Then the processed text is read using TTS engine and is recorded for the audio book. The page is then turned using the page turning mechanism implemented on the hardware. The process is repeated until all the pages are done. After that, the images of the pages are converted into a single PDF file. Fig 1 describes the process through a simple flow chart.

For the software implementation, Raspberry Pi 3 (Model B) with Raspbian Operating system has been used as the single-board computer. Raspberry Pi 3 (Model B) has been

chosen for the implementation because of its processing power (1.2 GHz 64-bit quad core processor) and on-board WiFi capabilities [9]. The processing power is needed to use the OCR and TTS engine and the WiFi capabilities has made it possible to use Google translator API, which needs Internet connectivity to operate.

We have used the Python 3 programming language for developing the underlying software part. The OS library has been used to execute the commands that operate the OCR and TTS.

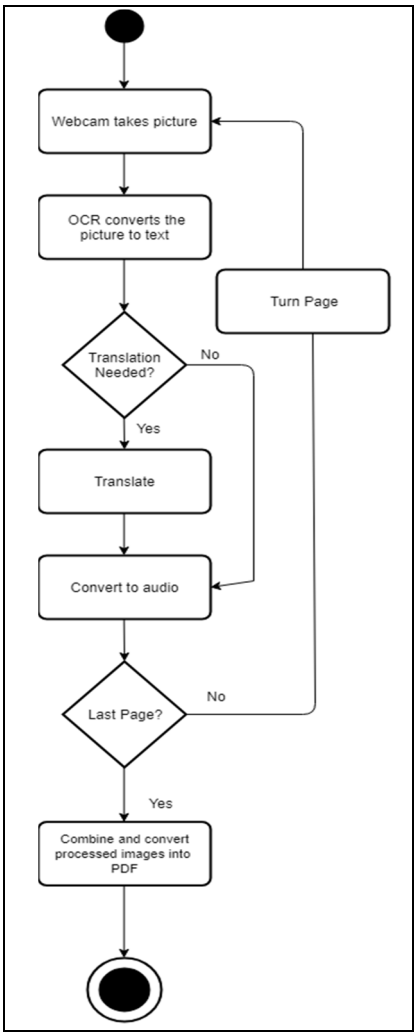

Fig.1 Working procedure

III. DEVELOPING THE SOFTWARE

For the successful operation of the system, we need to develop both software and hardware parts. The hardware or the mechanical part is controlled by the software and thus, the synchronization of their operation is crucial. Some major software used are the Tesseract OCR software to convert the image to editable text for processing, the eSpeak TTS engine to convert the text to audio, and the ImageMagick software to convert the images to e-book.

Tesseract OCR has been used on our project to convert the scanned pages to text for further processing. When an image with text is given to the Tesseract OCR, it is first converted into binary Images from which the character outlines are extracted using connected component analysis [2]. Then, Character outlines are converted into blobs that are organized into text lines [2]. The lines are converted into words and then the recognition of the words start as two-pass process [1]. An endeavor has been made in the first pass to recognize the words from text. Next, the successfully recognized words are passed to an adaptive classifier [2]. Adaptive classifiers are algorithms used to classify unclassified data using an adaptive iterative process that allows to learn from the input data (Called training data). The correctly classified words from the first phrase are used as the training data for the adaptive classifier in the second phrase. The trained classifier is then used to effectively recognize the remaining words from the image [2]. Fig. 2 describes the whole process in a simple flow chart.

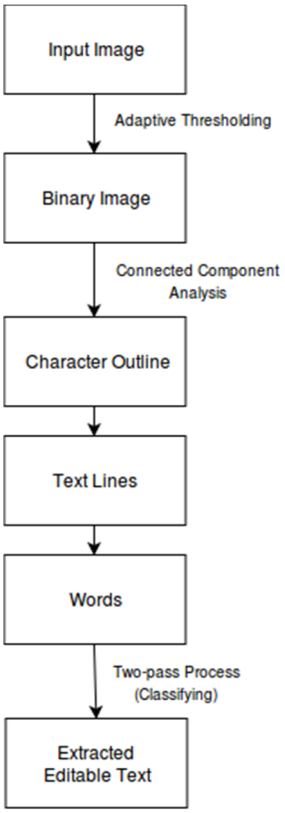

Fig. 2 OCR working procedure flow chart

To convert a paper book to an audio book, text-to-speech functionalities are required in our project. The editable text, prepared by the Tesseract OCR, has been used as input for the eSpeak TTS engine to convert it to speech, which in turns become an audiobook. The eSpeak TTS engine contains two parts: the front-end and the back-end. The front-end converts raw text to equivalent written-out words, then assigns phonetic transcriptions to each word and finally divides and marks the text into prosodic units such as phrases, clauses, and sentences [3]. These are also called symbolic linguistic representation. The back-end (called Synthesizer) then converts these symbolic linguistic representations prepared by the front end to appropriate sound [3]. Fig. 3 describes the process through a block diagram.

For paper book to eBook conversion process, the images of the pages are processed slightly and saved in a common directory. When images of all the pages are taken and processed, they are combined and converted to a single PDF

using ImageMagick software, which contains the functionality needed for the conversion.

The OCR software and the TTS engine are manipulated in our project using the OS library available on Python 3 programming language. It provides needed functionalities to execute commands (similar to the command prompt of an Operating System) provided in the form of string from inside the code. We have used this to make the whole conversion process spontaneous by executing the necessary commands on some simple loops and conditions. The pseudocode of the program is given in Algorithm 1.

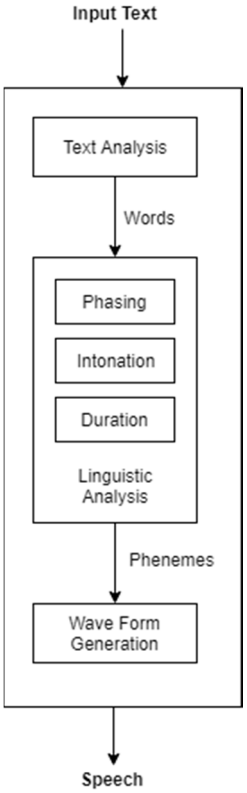

Fig.3 TTS engine working procedure

Algorithm 1: Pseudocode of the developed program

```
1.  Initialize N to total number of pages in the book
2.  for i = 0 to N do
3.      Command OS to take a picture and save it in directory D
4.      Command OS to use OCR to convert the picture to text
5.
6.      Text = read text file into string
7.      new_Text = Text, after being translated by Google
                   Translator API
8.
9.      Audio = Audio returned TTS with new_Text as input
10.     Save Audio on directory D1
11.
12.     Instruct DC and servo motors to move (to turn page)
13.     Instruct DC and servo motors to return to initial position
14.
15. Command OS to use ImageMagick to convert images saved
                   on D to a single PDF
16. Audio_book = Merged Audios from directory D1
17. Save PDF and Audio_book in home directory
```

IV. HARDWARE IMPLEMENTATION

Since the design goal of the project was to develop a low-cost solution, we have carried out the hardware implementation using easily available parts in an affordable price. The steps we have followed are:

1) We have made a box like structure out of cocksheet and fixed a stand on it.
2) The wires and the Raspberry pi has been fixed within the box.
3) An adjustable webcam (1.0 megapixels) has been fixed on the stand to take images of the book.
4) For the automated page turning mechanism, we have used a thin plastic board structure with a small wheel (with a DC motor to operate it), servo motor with an extended head and a motor driver to control the motors from the Raspberry pi.

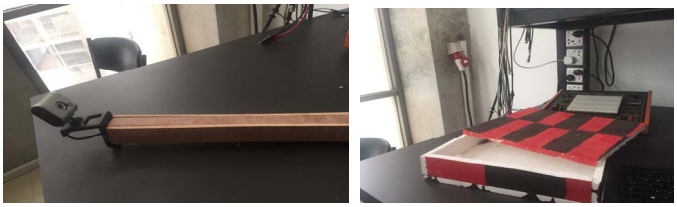

Fig.4 a. (left): The stand with the webcam, b. (right): The box like structure on which the stand was fixed

Fig. 4(a) shows the stand with the adjustable webcam, Fig. 4(b) shows the box like structure, Fig. 5(a) shows the page turner and Fig. 5(b) shows the assembled project.

Fig.5 a. (left): Page turner, b. (right): Assembled Project

The page turner on our book scanner contains two rectangular plastic boards, the first board is fixed on a movable structure and contains a servo motor with an enlarged head. The structure can be moved in accordance to the book's length. The second board is on the top of the first one and can be moved upward or downwards. It can be adjusted according to the book's height. A small wheel is fixed on this part. To turn a page, the page turner first turns the wheel on the direction opposite to the direction at which the page is bound. This causes the page on the front to go up a bit and then the head of the servo pushes the page away from that height, successfully turning it. Fig. 6(a), Fig. 6(b), Fig. 6(c) and Fig. 6(d) demonstrate the process sequentially.

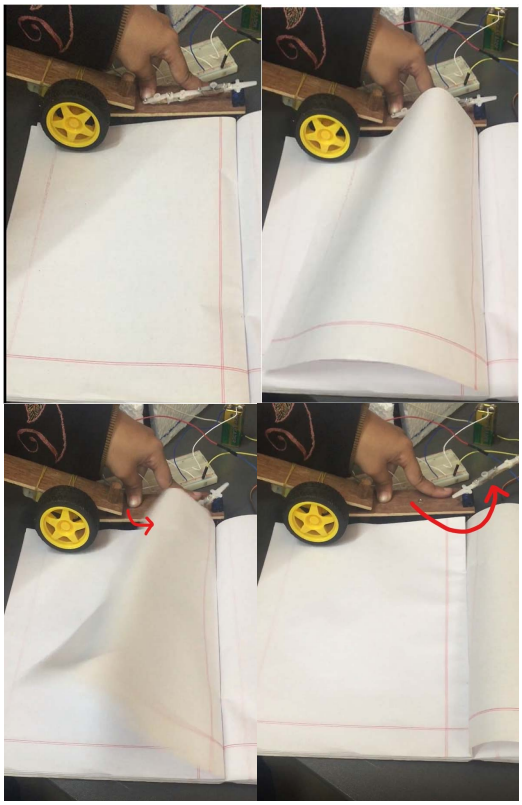

Fig.6 a. (upper-left): Initial state, before turning the page, b. (upper-right): After the wheel was turned, c. (lower-left): After servo starts moving in the direction of the arrow, d. (lower-right): After the servo is done moving and the page is turned

V. Discussion

A. Comparative Analysis

To build our project, the needed elements are Raspberry pi, 8GB micro SD card, an old webcam, a small wheel, a DC motor, a servo motor, 9V batteries, few thin plastic boards and a cocksheet. The Raspberry Pi costs 30 USD, the micro SD card costs 10 USD, the old webcam costs under 5 USD and the rest of the elements sum up to around 15 USD [9]. In total, the production cost for this project is around 60 USD. Most of the book scanners are not available in Bangladesh. Many from the renowned brands do not ship to Bangladesh as of date. Out of the few available ones, the CZUR ET16 Plus CZUR Book Scanner costs 400 USD, the Fujitsu Image Scanner ScanSnap SV600 costs around 500 USD and the Aibecy Adjustable HD High Speed USB Book Image Document Camera Scanner costs 175 USD, which cannot be afforded by smaller organizations and general people in Bangladesh [6–8]. Our implementation of the book scanner can be marketed under 100 US dollars with some fine tuning and further improvements on speed. It should be noted that none of the mentioned book scanners provide automated page turning mechanism and translation facilities.

B. Humanitarian Impact

Reading is a challenging task of the visually impaired people. Our solution provides conversion of paper book to audio book, and thus can also be used as a book reader. The price range of the book scanner is within the affordability of general people. The visually impaired people also can easily afford it. With little help from others, the book scanner can be set up and once the book is given, it will not need further human supervision. Due to its automated features, the book would be read page by page while it is being converted to an audio book. The converted audio book can also be stored and played at later times without the paper book, making it possible to build a collection of books for the visually impaired persons. It can also be used to read to children who has yet to learn reading. The low cost and the affordability of the book scanner and translator enables it to serve blind people from across the world.

VI. Conclusion and Future Work

We have built a low cost Raspberry pi based book scanner and translator that can convert paper books to e-books and audio books. The whole process is automated and does not need human supervision aside from the initial setup. The working procedure of the book scanner is simplistic, and the hardware part can effortlessly be built from easily available elements. Given a paper book, the pages are sequentially scanned (pictures are taken and then are processed) and converted to audio. Future work will include improvements on the scanning speed and quality of the audio and scanned images. The scanned images are combined and converted to PDF using another software that includes many features that we have not explored for this project. The project can be further improved by customizing the open source software to include the PDF conversion function. The image processing for the PDF conversion is done manually now, we plan on using the OpenCV library on python to make it automatic. Though our presented project has many places to improve on, it can serve its purpose as an book scanner in its current state. It is affordable and is specially designed for the use of people in low-income countries such as Bangladesh where book scanning technologies are still out of reach for the general people.

***Abstract*—Recently, agro sensor communications are getting popularity with the advent of wireless sensor networks (WSNs) and mobile ad hoc networks (MANETs). Infrastructure less MANETs are considered as a potential solution for agricultural domains to provide robust and effective operations in wireless networks by enabling routing characteristics at each mobile node. The efficient use of routing protocol is pivotal for network management in MANETs. In this research, we demonstrate a strategic routing analysis to evaluate the performance of different routing protocols, e.g., proactive and reactive in terms of various network quality of service (QoS) parameters for multiple data rate enabled agro sensor mobile nodes. Two different network scenarios (low-node and high-node) are simulated for various network parameters. Simulation results indicate that OLSR protocol provides higher throughput than others for all nodes. This investigation also shows that GRP has the highest network load capacity than other protocols for agro sensor applications. Another finding from this research is that proactive protocols have the lower average end to end delay and MAC delay than reactive protocols.**

***Index Terms*—Wireless sensor networks (WSN), Mobile ad hoc networks (MANET), Routing protocols, Agro sensor, Traffic Sources.**

I. Introduction

Agriculture is one of basic priorities in any country to ensure food security for peoples' lives. The proper maintenance of the agricultural field is required to increase the productivity. However, in developing or under-developed countries, agriculture mainly relies on some natural and environmental functionalities such as seeding, harvesting, irrigation, flood, drought, etc. Random climate changing, limited cultivation capacity, and other stress factors affects agricultural production heavily. In these respects, flood risk management and prediction, real-time control and treatment of crops provided by technology, i.e., wireless sensor networks (WSNs) can be a solution for better production by using improved agro-climatological estimation and smart sensors monitoring [1]. Although there are a range of different applications of WSNs such as situation realization, sensing intruders, identification of rival's movement on land and marine area, unmanned aerial networks, and surveillance of battlefields; this network is also intended for monitoring an agricultural environment for transmitting and receiving information from a particular domain, process them and throw it to the sink. The collaboration of different nodes is a requirement to ensure the communication between sender and receiver through intermediate nodes. Due to the limitation of installing regular infrastructure-based network models in agriculture fields, mobile ad hoc networks (MANETs) are considered as an appropiate style of WSNs to sense, gather, distribute, synthesize, and monitor environmental risks [2]. The increasing demands of various applications (crop surveillance video, crop production, weed, insect, nutrient management, field guide, pest management, diseases, etc) in agricultural domains motivate us to evaluate the impact of multiple data rates (CBR, VBR, and FTP) enabled nodes on transferring information through a MANET. Interested readers are encouraged to go through [3] for the network analysis of multiple data rate applications in case of wireless mobile communication.

In this research, the performances of different routing protocols (e.g., proactive and reactive) in MANETs are evaluated for multiple data rates enabled sensors to be used for agricultural fields. We consider an agricultural field, where ten and twenty sensor nodes (any quantity) are operating in battery power. The sensor nodes are put in a fixed distant area of an agricultural field for measuring the moisture and PH of land. For coordination of each node in this distributed MANET environment, the routing is the vital concern. This research work mainly focuses on obtaining an optimistic result in perspective of different network parameters (e.g. throughput, end to end delay, network load, MAC delay, re-transmission, jitter, and packet drop) either by using reactive or proactive routing protocols for multiple data rates enabled sensors.

Due to dynamic changes of network topology in MANETs, routing protocols need to adapt quickly. The routing protocols of MANETs are broadly divided into two categories: reactive routing protocols and proactive routing protocols. Reactive protocols does not start the a route discovery process until a destination route is required, for example, Ad hoc On-Demand Distance Vector (AODV) and Dynamic Source Routing (DSR). On the other hand, in proactive protocols, tables are generated to portrait the whole network topology. These tables are revised systematically to maintain an update routing information for all nodes, for example, Optimized Link State Routing Protocol (OLSR) and Geographical Routing Protocol (GRP). However, reactive routing protocols work differently compare to proactive routing protocols. The evidence from this study suggests that AODV protocol results higher throughput for all cases. This investigation also shows that DSR has the highest network load capacity than other protocols. Another

finding from this research is that proactive protocols have the lower average end to end delay and MAC delay than reactive protocols in all cases.

Paper organization is as follows. Section II mentions the related works. Section III illustrates the simulation environment. Simulation results are discussed in Section IV. Section V concludes this paper.

II. Related Works

As a prospective tool towards the development of agriculture, WSNs are simplified by the universal characteristics of function, self-organized small nodes, adaptable and cost-efficient technology.

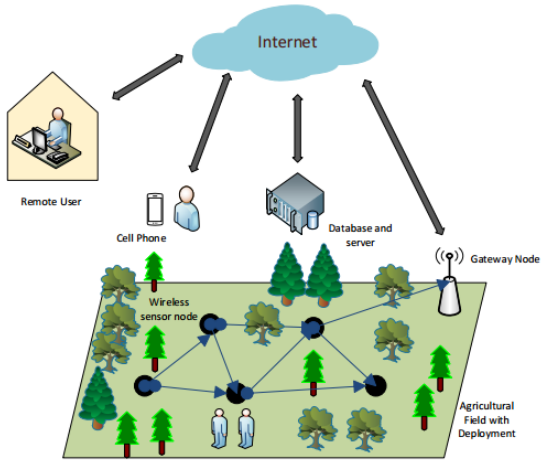

Fig. 1: Agro Sensor Deployment in a typical MANET.

Fig. 1 shows a typical MANET deployed for agricultural applications. Akyildiz highlighted the applications of WSNs to boost conventional farming [4].

Ojha reviewed the dynamic applications of WSNs and associated challenges for WSNs deployment to enhance farming [1]. Some of the popular applications of WSNs in agricultural domains are enlisted as: irrigation arrangement system, husbandry systems governing, disease and pest control, controlled use of fertilizers, cattle movement superintendence, ground water quality managing, greenhouse gases monitoring, remote control and recognition etc. Shiravale proposed a WSN for agricultural which helps the farmers in collecting weather data from meteorological department, planning for the right crop, communicating with agricultural experts [2]. Panchard explored the potentiality of WSNs in the context of agricultural fields for small landowners and farmers while they faced water shortage problems [5]. Author in [6] introduced an IEEE 1451 based framework which works on the acquisition of smart data in precision agriculture. Le demonstrated a WSN for precision agriculture in which the farmers can superintend the agricultural andenvironmental parameters [7]. Lightweight unmanned aerial vehicles (UAVs) were used to capture videos sensing which acts like a real-time precision sprayer [8]. In precision farming and ecological governing, a multi-level sensor network was designed for data acquisition and processing [9]. In a similar research, heterogeneous WSNs are used for a flood prediction scenario to make decision support systems [10].

MANETs are suitable alternative solutions of WSNs where regular infrastructure setup is difficult or expensive. A small agriculture field can be used as a MANET as the large sized network mainly consists of terrestrial WSNs or wireless underground sensor networks [1]. Routes between two communicating nodes may consist of multiple paths through other nodes in the network. The information passed through these mobile nodes causes existing links to overflow, discontinue or establish new routes. Thus, finding and maintaining routes in MANETs are challenging tasks. In this context, performance of routing protocols plays a pivotal role in MANETs. Several research have been carried out to assess the performance of routing protocols in MANETs or WSNs for various applications [11]–[17]. Some of the popular simulation are generally used such as Optimized Network Engineering Tool (OPNET), Network Simulator 2 (NS2), OMNET++, and QualNet.

Different types of routing protocols were compared in MANETs for CBR traffic [11]. Thool investigated the performance of DSR and DSDV routing protocols using different network conditions under NS2 simulation scenario. They analyzed performances with respect to packet delivery, end to end delay, and throughput [12]. Kuppusamy studied the features of adhoc routing protocols TORA, OLSR, and AODV based onthe performance metrics such as PDR, end to end delay, routing overhead by increasing number of nodes in the network [14]. Al-Baseer presented a comparative study for DSR, AODV, OLSR and DSDV routing protocols using OMNET++ simulator [18]. Author in [15] highlighted an overview of OPNET Modeler architecture by implementing a new routing protocol. Hussen analyzed the performance of MANET routing protocols for unmanned aerial vehicle networks in terms of end to end delay, throughput, and network load using OPNET modeler [17].

Although, numerous research have been conducted on different routing protocols in MANETs or WSNs for various application scenarios, few of them only focused on routing protocols on agro sensors or agricultural applications. Farjana *et al.* evaluated the MANET routing protocols in an small sized agro sensors network. They analyzed the performance of routing protocols in respect to some network parameters such as average end to end delay (average), network load, and throughput using OPNET software [19]. In a similar research, Siddiquee investigated the optimal dynamic routing protocol for agro sensor communications for two different sized networks; large (20 nodes) and small (10 nodes) by using both OPNET and NS2 while evaluating the same parameters [20]. In their study, they investigated that AODV routing protocol shows enhanced results in large size network and for a small size network, DSR performs better. Both of these papers [19], [20] consider MANET nodes can deliver only FTP traffic. *However, to the best our knowledge,* no research has been carried out on the impact of multiple traffic (CBR,VBR, and FTP) enabled mobile nodes while considering different

routing protocols of MANETs for agro sensor applications. This paper fills the gap and provide a strategic routing analysis.

III. Simulation Environment

We consider an agricultural field as a MANET, where 10 or 20 nodes are deployed and all are coordinating each other shown in Fig. 2 and Fig. 3. A destination node is used as a gateway to connect with the Internet. Simulation aids in analyzing the performance and behavior of communication networks before implementing it as a real application. We have investigated this network scenario using a most popular networking simulation software, e.g., OPNET.

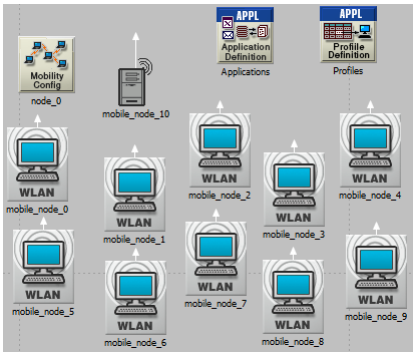

Fig. 2: Simulation setup for 10 nodes.

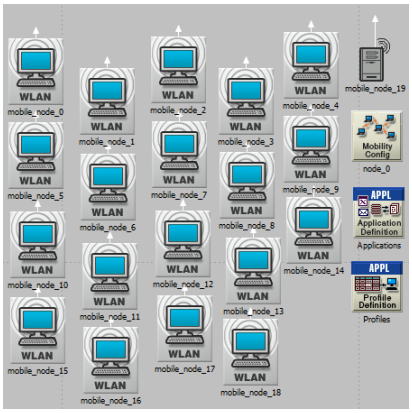

Fig. 3: Simulation setup for 20 nodes.

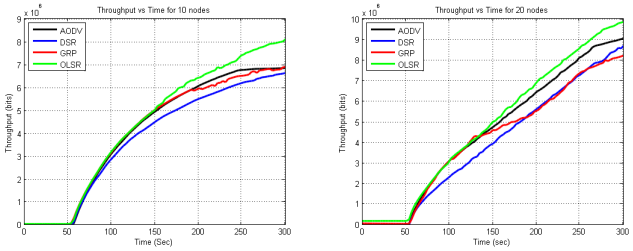
For this research, we used a popular network simulator, i.e., OPNET Modeler version 17.5 Academic version (Riverbed) for evaluate the network performances. Simulation experiments were performed under three applications (FTP, CBR, and VBR) scenarios that have been created for IPv4. All mobile nodes are enabled with three types traffic. Table I shows the simulation parameters. OPNET Modeler [21] is a adaptable and efficient tool which supports discrete event simulation, statistical analysis, and analytical modeling for the communication networks and distributed systems. Two different network scenarios are considered for this research. We used 10 nodes for the low density network (first scenario) and 20 nodes for the high density network (second scenario). Network Size is fixed on 1000 $\times$ 1000 meters.

TABLE I: Simulation Parameters

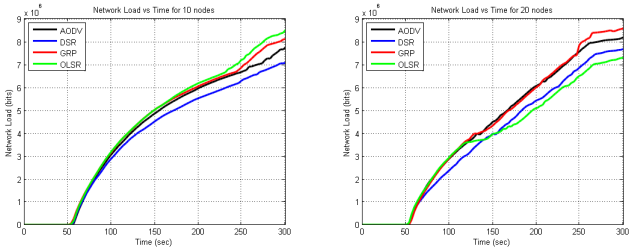


Parameter	**Value**
Simulator	Riverbed OPNET Modeler 17.5
Area	1000 m x 1000 m
Network size	10 nodes, 20 nodes
Protocols	AODV, DSR, OLSR, GRP
Mobility Model	Random Way Point
Speed	5 m/s
Trajectory	vector
Simulation time	300 s
Address mode	IPv4
Traffic Source	File transfer protocol
	Constant bit rate
	Variable bit rate

AODV is a routing protocol that works on on-demand route acquisition algorithm. It conducts two operations, i.e., route discovery and route maintenance. It diminishes required broadcasts number by forming routes in an on-demand scheme. AODV assigns three key route messages: Route Requests(RREQ), Route Errors (RERR) and Route Replies (RREPs) to forward data packets from sender to receiver [22]. DSR is a routing protocol which dynamically discovers a route. In source routing, the header of the packet contains all the information regarding the route as well as the information of nodes from end to end which the packet may pass, this approach guarantee loop free routes for information transfer [23]. OLSR is a link state proactive IP routing protocol optimized to work for MANETs that discovers and distributes link state information of the entire topology of the network to the other nodes in the network. The key feature of OLSR is that it basically uses a Multi-Point Relaying (MPR) to optimize flooding [24]. GRP is proactive routing protocol, follows hop by hop routing type and make periodical frequency updates. In order to keep the information about the neighbor nodes Hello Messages are spread-ed periodically. GRP forwards packets to the destination regarding shortest distance, a node receive a packet send the closest node the packet following the destination route.

IV. Results and Discussion

In this section, various performance parameters of network will be discussed from simulated results.

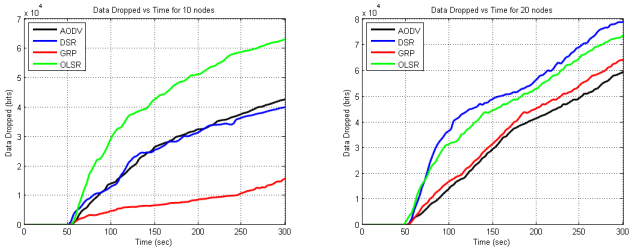


The network *throughput* is defined as the ratio of successfully transmitted information to the time taken for transferring this information. In MANETs, due to mobility of nodes, power constraints, limited bandwidth and traffic load, throughput is immensely affected by the dynamic characteristics of the topology. The discussion of the results begin with the analysis of throughput for four routing protocols (AODV, DSR, GRP, and OLSR) depicted in Fig. 4 in case of low density (10 node) and high density (20 node) networks. OLSR protocol attains higher throughput for both scenarios, whereas DSR protocol has lowest throughput. Simulation was run for 300 s and the average values of throughput were calculated for each case while considering different types of data rate applications.

(a) 10 nodes (b) 20 nodes

Fig. 4: Throughput.

Network load handles the total load sent to WLAN layers. A large amount of incoming traffic load is difficult to maintain and highly affects the delivery of routing packets in MANETs. This also increases the collision of these control packets. In

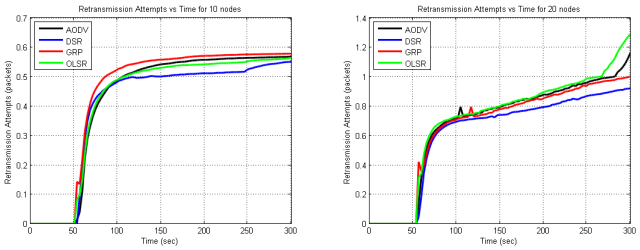


(a) 10 nodes (b) 20 nodes

Fig. 5: Network Load.

case of network load, Fig. 5 exhibits that OLSR has the highest value while AODV and GRP result almost equal (10 nodes). DSR shows the lowest load in this case. With the increment of mobile nodes (20 nodes), GRP provides the highest network load while OLSR results the lowest load. The average network load was calculated from all simulation scenarios.

Data dropped (Packet loss) is the amount of lost packets while transferring data from source to destination in MANETs. This parameter informs the higher layer dropped packets as MAC failed to receive any ACKs for transmitting these packets or segments within a short retry threshold.

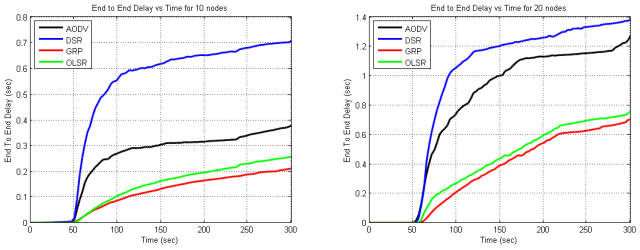


(a) 10 nodes (b) 20 nodes

Fig. 6: Data Dropped.

In the first simulation scenario (10 nodes) portrayed in Fig. 6, it is observed that the highest amount of data dropped is caused by OLSR protocol and less number of packet lost is provided by GRP protocol. For the large network (20 nodes), AODV provides the lower number of packet loss. In case of both scenarios, OLSR performs worst among all protocols.

In a network, the *re-transmission*is required to resend the packets which are already lost or damaged. Network protocols use this basic mechanism for a packet switched communication network to provide reliable communication. Figure 7



(a) 10 nodes (b) 20 nodes

Fig. 7: Re-transmission.

portrays that DSR has the lowest re-transmission attempts compare to other protocols for both scenarios. The behavior of other protocols fluctuate for high density (20 node) networks.

End to end delay means the transfer time for a packet traveled from the source to target within a network. It considers processing, queuing and propagation time of the link.

(a) 10 nodes (b) 20 nodes

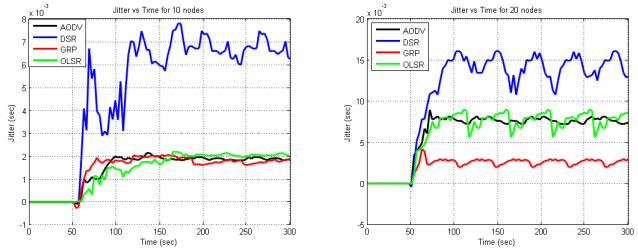


Fig. 8: End to End delay.

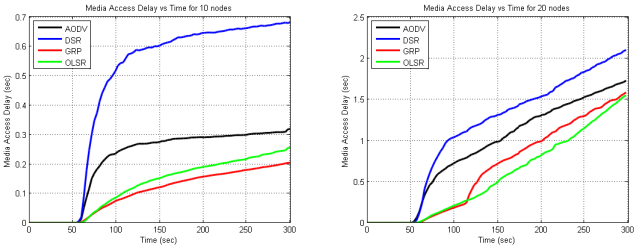
The comparative analysis of average end to end delay among four different protocols are illustrated in Fig. 8. GRP protocol shows the lowest end to end delay for small number of nodes (10 nodes) while maximum delay are observed for DSR protocol. For scenario 2 (20 nodes), DSR protocol shows the highest delay while lower delay are observed from both proactive protocols. In case of average end to end delay, DSR performs worst among all protocols for agro sensor communications while considering different type of data rate applications. The proactive protocols shows enhanced results than reactive protocols in case of average end to end delay.

Sometimes, timing differences (*Jitter*) are observed in the network,i.e., signal are deviated at the receiving end compared to sending end packets. This is happened mainly for network congestion and timing drift and it is expected the minimum value.

TABLE II: Average Values.

Protocols	AODV		DSR		OLSR		GRP	
Performance Parameters	**10 Node**	**20 Node**	**10 Node**	**20 Node**	**10 Node**	**20 Node**	**10 Node**	**20 Node**
Throughput (Kbps)	387.52	916.34	262.45	539.98	294.43	990.17	302.30	811.03
Network Load (Kbps)	74.15	110.25	95.26	106.25	84.75	119.67	84.92	110.72
Data Dropped (bps)	14164	3685	14807	7708	24024	8301	6332	5757
Re-transmission (Packets)	0.4169	0.6714	0.3984	0.6102	0.4132	0.6948	0.4381	0.6555
End to End Delay (s)	0.2632	0.5647	0.5554	0.7061	0.0848	0.0591	0.0812	0.0432
Jitter (s)	0.0014	0.0061	0.0049	0.0111	0.0014	0.0061	0.0014	0.0022
MAC Delay (s))	0.2134	0.9162	0.4672	1.1423	0.1286	0.5754	0.1056	0.6701



(a) 10 nodes (b) 20 nodes

Fig. 9: Jitter.

Figure 9 illustrates that DSR protocol results highest jitter for both simulation cases. GRP protocol performs lowest jitter in high density (20 nodes) network.

Media access delay is elucidated as the delay of the packets to arrive the MAC layer until it is effectively transmitted out on the wireless means. This parameters is helpful for many real-time applications which have a certain limit of delay. Consequently, it is vital to exhibit low delay for real-time flows.

(a) 10 nodes (b) 20 nodes

Fig. 10: MAC Delay.

From the Fig. 10, it is evident that DSR protocol provides higher MAC delay compare to other protocols in both scenarios. The proactive protocols GRP and OLSR exhibits lower delay than reactive protocols. The average data of four protocols for all above parameters is mentioned in Table II.

V. Conclusion and Future Work

In this research, we evaluated the performance of four different routing protocols in MANET for agro sensor communications. The topological and management issues in agricultural field lead to choose MANET with WSN to assess the performances of protocols. Though several researches have been conducted in comparing the routing protocols, but the application scenario and multi data rate enabled sensor nodes differs our contribution from those. We draw a strong scenario for various number of nodes (10 and 20) with a powerful simulation environments (OPNET) to highlight different performance characteristics such as throughput, end to end delay, network load, jitter, MAC delay, re-transmission attempts, and packet loss. This study has shown that proactive protocols have the lower average end to end delay and MAC delay than reactive protocols for all network size. Another observation is that OLSR protocol provides higher throughput and GRP provides higher network load than other protocols in case of agro sensor communication. Future research will consider the massive density of nodes such as thousand sensors may be mounted into a MANET. In addition, we will focus the cost and energy optimization for routing in these protocols for better QoS applications.

Abstract— **In this research, a single band micro-strip square patch antenna at 28GHz is proposed. The design of patch antennas are very efficient and widely used in wireless communication due to their lower cost of fabrication, light weight and can operate at microwave frequencies but it offers low efficiency, low gain etc. Future upcoming 5G wireless communication is needed of high gain, good protection from path loss because of their millimetre wavelength of antennas. The main features of this proposed antenna are its very low return loss (S11), high gain, better efficiency and higher bandwidth are of 57 dB, 10.3 dBi , 97% and 4.3GHz respectively which makes it appropriate for 5G wireless communication. The proposed square patch antenna is designed and simulated using CST Microwave studio at operating frequency of 28 GHz. The gain of the antenna is improved by using air substrate. The proposed antenna design gives results of a very low return loss of 57 dB by which the antenna can provide high radiation power in 5G communication.**

Keywords — 5G, mm wave, square patch antenna, 5G antenna, 28GHz, high gain, low S11 parameter

1. INTRODUCTION

With the prosperity of wireless technology, there is an increasing need of microstrip patch antenna with better data transfer speed, efficiency and light weight and lower cost of fabrication [1]. The currently ongoing 4G network technology cannot meet demand of modern wireless technology such as dynamic information access, HD streaming or reducing energy wastage and reducing latency. 5G technology promises mobile data that will be as much as 1 thousand times faster than 4G [2]. Hence 5G network system will provide high data rate, large bandwidth and high capacity. [3]There are several bands aimed for 5G one of them is 28 GHz which is declared by Federal Communication Commission (FCC).Proceeding to these millimetre waves band it will create modern challenges in the design of antennas for the smart phone devices and base stations towers. There are numerous contraventions using millimetre wave frequencies including propagation loss, path loss, signal attenuation and atmospheric distractions. To exceed these challenges, high gain and high directional antennas are needed. The high gain antennas can be applied to overcome the challenges existing at millimetre wave frequencies such as path loss and propagation loss [4]. The problem with using these high frequency bands or millimetre wave bands is that the path loss or free space loss is intense in these bands, which results in the deterioration of signal to interference plus noise ratio (SINR) [5].

The patch antenna with low dielectric constant material is one of the methods to increase the gain [6]. In this design, air is used as the substrate whose dielectric constrains is 1.
In reference paper [1], at operating frequency 60 GHz, they managed to obtain gain 5.48 dB and return loss -41 dB by using H-slot and E-slot. In reference paper [8], work has been done by using air substrate at operating frequency 28GHz and managed to achieve -40dB return loss, 9.8dB gain and 96% efficiency.

In this paper, the proposed patch antenna introduces high realized gain of 10.3dBi and very low reduction loss of 57dB which are the main requirements to overcome the challenges of future 5G wireless Communication. The introduced antenna provides higher realized gain and very low return loss than other referenced works which means our proposed design radiates more efficiently.

2. Design Specifications

The following are the equations needed to calculate width and length of the patch to design the proposed antenna.

$$W = \frac{c}{2f_r}\sqrt{\frac{2}{\epsilon_r+1}} \qquad (1)$$

Where, c= velocity of light ($3 \times 10^8 ms^{-1}$)
fr= resonant frequency
ϵr = dielectric constant (ϵr =1)
The length of the patch can be calculated by using the following formula as shown in equation (2)

$$L = L_{eff} - \Delta L \qquad (2)$$

Where we need to calculate the effective length of the patch to get length of the patch as follows

$$L_{eff} = \frac{c}{2f_r\sqrt{\epsilon_{eff}}} \qquad (3)$$

Where ϵ_{eff} the effective dielectric constants as are stated below

$$\epsilon_{eff} = \frac{\epsilon_r+1}{2} + \frac{\epsilon_r-1}{2}\left(1 + \frac{10h}{w}\right) \qquad (4)$$

Now extension length ΔL as follows:

$$\Delta L = 0.412h\frac{(\epsilon_r+0.3)\left(\frac{w}{h}+0.264\right)}{(\epsilon_r-0.258)\left(\frac{w}{h}+0.8\right)} \qquad (5)$$

The above five equations are used to design the proposed patch antenna and simulated the antenna by using CST Microwave Studio Simulation Software.

Fig 01 illustrates the geometric view of the proposed square patch antenna. As we have seen the substrate is designed by using dimensions of Ls × Wswith air substrate which has dielectric constant and height are 1 and 0.5 respectively.The dimensions used to design the proposed square patch antenna are shown in TABLE 1 and TABLE 2.

Parameters Symbols	Description of Parameters	Value (mm)
Ls	Substrate length	6
Ws	Substrate Width	6
hs	Substrate Height	0.5
ϵ_r	Relative permittivity	1

3. SIMULATION RESULTS AND DISCUSSIONS

(A) Return-loss plot:

Return loss generally refers to the reflection coefficient which is denoted by (S11) describes the input output relationship between ports and represents how much power is reflected from the antenna. The return loss plot gives the information of how the feedline is matched to the antenna. If (S11) is 0 dB then it shows that all the power is reflected from the antenna, nothing is radiated. (S11) value should be at least -10 dB to give efficient performance by the antenna. The less the (S11) value the better performance of the antenna. Hence our proposed antenna has (S11) value of -55 dB at 28 GHZ frequency which is very less value and very less loss of power and maximum power is radiated to antenna. Fig 03 shows the plot for Frequency Vs S parameters in (dB).

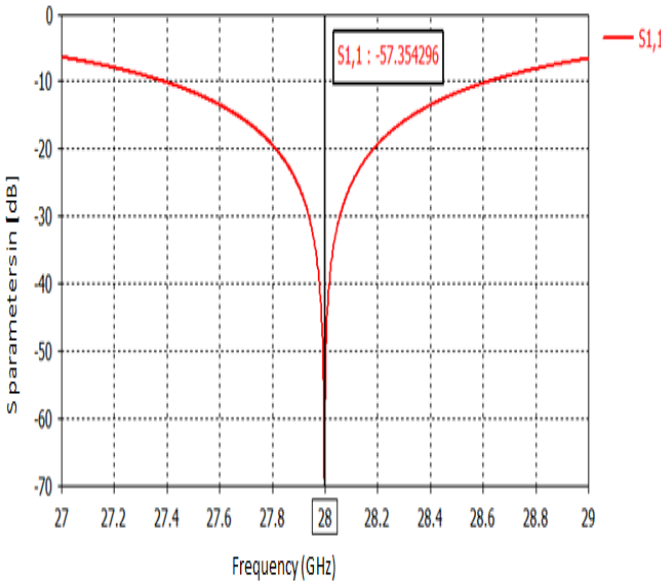

Fig 3: Frequency Vs S parameters in (dB)

(B) Voltage Standing Wave Ration (VSWR) Plot:

The plot of Frequency Vs VSWR is shown in Fig 04 which shows the information that how much antenna is matched to the transmission line and how much power is reflected from the antenna. As shown the proposed antenna has a VSWR value of 1.00 at 28 GHZ which satisfies the requirements range 1≤VSWR≤2 that is very efficient and all power is radiated and no power is reflected.

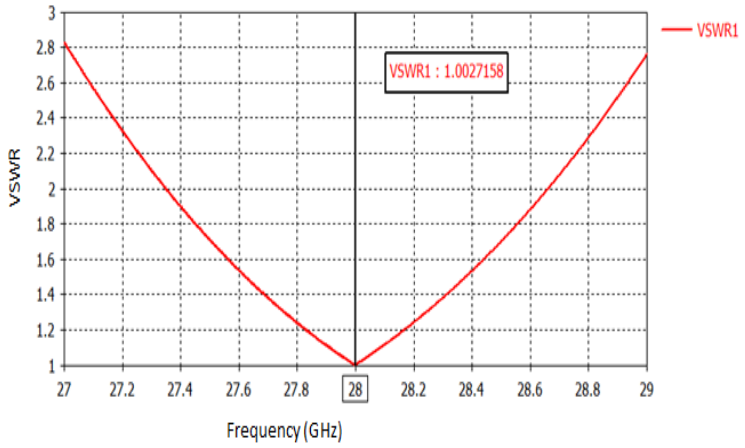

Fig 04: Frequency Vs VSWR

(C) Radiation Pattern:

The antenna radiation pattern represents how much energy is radiated by the antenna. The respective radiation pattern can be seen in 3D and 2D as shown in Fig 05 and Fig 06.

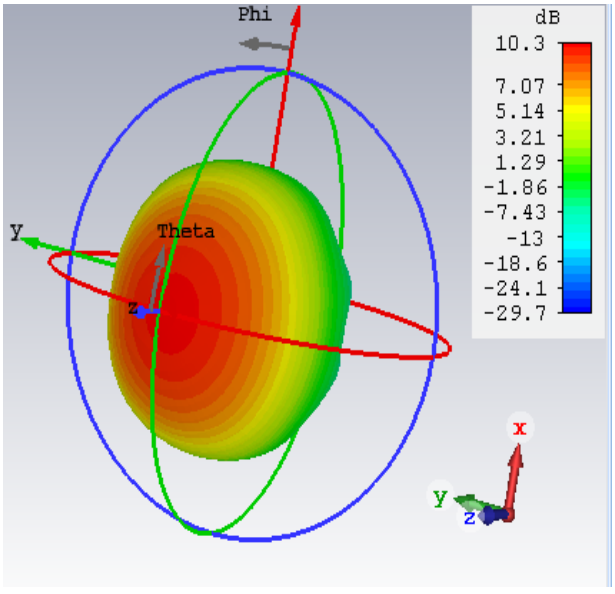

Fig 05(a): 3D radiation pattern

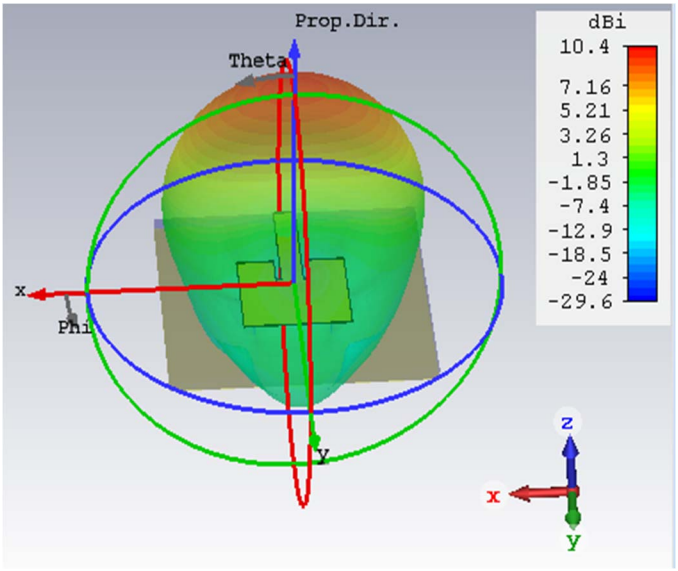

Fig 05(b): Fairfield Transparent 3D radiation pattern

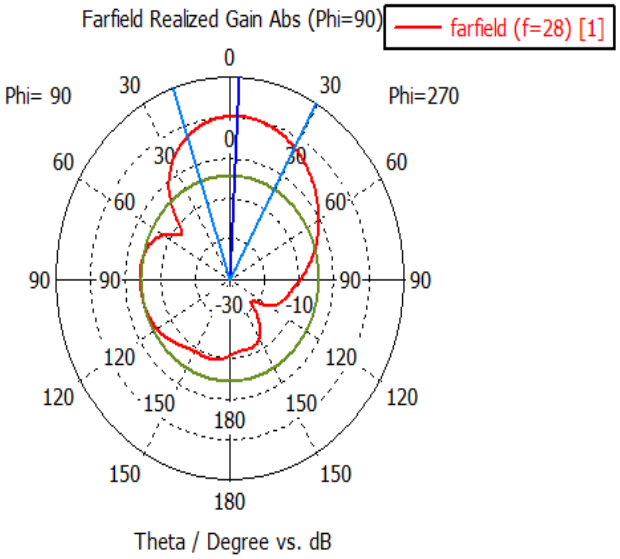

Fig 06: (b) 2D at 28 GHZ when $phi = 90°$

The 2 dimension (2D) radiation plot of the proposed patch antenna can be seen as shown in Fig 6(a) and (b) for both phi=0 degree and phi= 90 degree respectively.

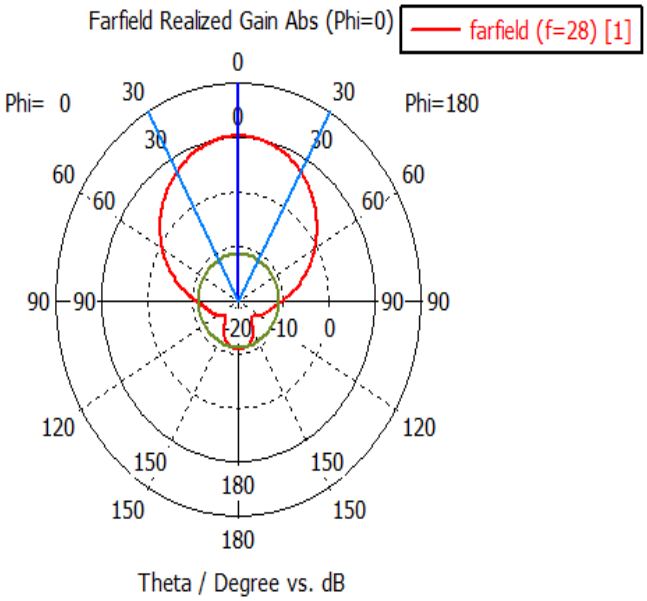

Fig 06: (a) 2Dat 28GHZ when $phi = 0°$

(D) Efficiency plot:

The following figure illustrates the plot of both radiation efficiency and total efficiency Vs Frequency which shows that 97% radiation efficiencies of power for both that exhibit the antenna radiated maximum power and very few signal or power loss at peak 28GHz.

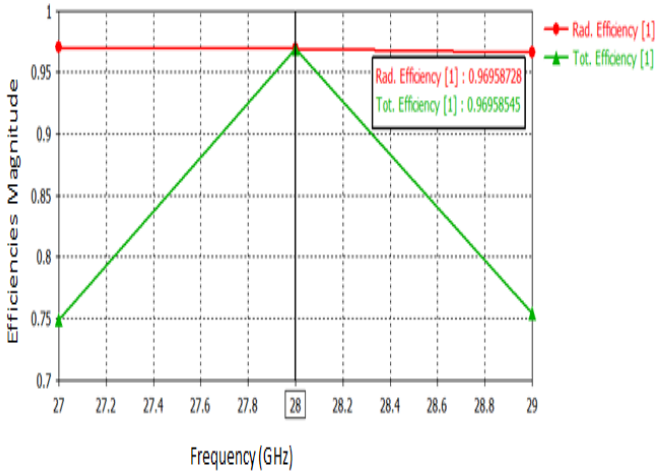

Fig 07: Radiation Efficiency

TABLE 3

Final Characteristics of the proposed antenna

Proposed 5G Antenna	Resonant Frequency	Return Loss	Gain	Bandwidth	Efficiency
	28	-57dB	10.3 dBi	4.3 GHz	97 %

TABLE 4

Comparison of our proposed antenna with existing 5G antennas

Reference Papers	Resonance Frequency (GHz)	Return Loss (dB)	Gain (dB)	Efficiency
[7]	28	-38.1	6.16	91%
[1]	60	-41	5.48	-
[4]	28	-23	7.8	-
[8]	28	-40	9.8	96%
Proposed	28	-57	10.3	97%

4. Conclusion

Our proposed antenna was designed and simulated using CST Microwave Studio. From our simulation result it is found that the antenna has a gain of 10.3 dBi which is higher than the most antenna designed as shown in the comparison TABLE 4. The proposed antenna bears a return loss of -57 dB which means that a very low amount of power is reflected from the antenna and most of the power is radiated to the antenna. Our introduced antenna has a bandwidth of 4.3 GHz and the efficiency is 97%. Hence our simulation results exhibit that it is on per standard of future 5G wireless communication.

***Abstract*—The ongoing relentless innovation of technologies like Big data, cloud computing, virtual reality is creating the need for more secure, further reliable, more scalable ultra fast networks. For meeting these objectives Software Defined Networking (SDN) arises. Distinguished control plane and data plane have made SDN more dependable, fast, secure and increased its widespread acceptance. The crucial part of such a network is the controller which handles the flow control and makes the network more effective. So, for ensuring better performance of the network, selection of the right controller according to the need is imperative. Thus performance evaluation of available SDN controllers is a high-priority. Though there are many researches pursued on the performance analysis of SDN controllers in terms of wired network, there is a lack of studies involving controller efficiency in wireless network. In this paper we have examined the performance of some popular SDN controllers like Ryu, POX, ONOS and Floodlight in an emulated wireless network. Analysing the test results we have asserted our observation regarding the controller performance which can be of considerable importance while determining the right SDN controller for wireless network.**

***Index Terms*—SDN, Mininet-WiFi, controller performance, OpenFlow, wireless, SDWN.**

I. Introduction

Software Defined Network (SDN) is considered the future of networking as it is shaping the era of wired and wireless communication into a new image. The principle factor that differentiates SDN from traditional network is that the separation of control and data plane. Whereas, in traditional networks decision making and data forwarding elements are embedded together, in SDNs they are distinguished between control and data plane. The emergence of centralized controlling capability has introduced controllers which play as a vital part of the network. It can be compared with the brain of human body as it makes the decisions and keeps the network up and running [1]. The better performance, increased security, reliability, flexibility and scalability benefits have made Software Defined Networks more efficient than conventional networks and increased its acceptance to be the standard for internet of the future and Next Generation Networks (NGN) [2]. The future of communication networks mostly involve wireless data transmission. High speed wireless network is enabling technologies like IoT, cloud computing, artificial intelligence, wearable technologies etc to become more effective and efficient. Uses of mobile devices such as smartphones, tablets, laptops rely much on wireless networks. So it is imperative to develop techniques to improve the performance and security of such networks. In this case, SDN is contributing to make wireless communication more versatile in an enormous scale. Thus the concept of Software Defined Wireless Network (SDWN) is introduced [3]. Software Defined Wireless Network paves the way for implementing many future technologies like D2D (Device to Device) communication, NFV (Network Function Virtualization), Edge computing and so on. But performance of a SDN vastly depends on selection of the controller. As operating systems denote performance of computers, controllers play the same role for Software Defined Networks [4]. So performance analysis and comparison of the SDN controllers is a must for ensuring the right choice. Although there have been many researches conducted upon the comparative analysis of SDN controllers, there is hardly any proper paper on the performance analysis of Software Defined Network controllers from the perspective of wireless networks. In this paper, we have selected some of the popular SDN controllers such as- Ryu, POX, ONOS and Floodlight to measure their performance in an emulated SDWN. We have taken Mininet-WiFi as a tool for emulating a wireless network and tested the controllers and considered several parameters those could help us to derive some conclusions. These are: Delay Jitter Throughput.

The rest of the paper includes: section II-Background, which describes previous works related to the topic. This section also overviews important features of the chosen SDN controllers. Section III-Experimental setup, which discusses the tools

used to set up a wireless environment and to measure the performance of the controllers. Section IV-Discussion, which includes the results of the experiment conducted and important implications from the result analysis. Section V-Conclusion and Future work, which concludes the study and provides directions for further research.

II. Background

A. Related Work

As selection of the right controller bears huge importance for ensuring consistent performance of the network, there have been a good number of researches on the performance evaluation of SDN controllers. Bholebawa et al performed comparison in [1] between two leading controllers- Floodlight which is Java-based and POX which is based on Python. The authors have designed several topologies in Mininet such as single, linear, tree and custom. In these topologies RTT and throughput are measured for the two controllers. They concluded that Floodlight shows better performance than POX regarding both of these criteria. Although Floodlight is suggested for achieving efficient network performance, POX is also recommended for its ease of use.

In paper [2], Shamim et al selected three SDN controllers Ryu, POX and Pyretic for performance evaluation. Authors used Mininet as a tool for simulating a wired SDN. The parameters for measuring the performance was RTT or Round Trip Time. It designates the length of time taken to send a signal plus the length of time required for an acknowledgement of that signal to be received. The paper indicates among the three controllers, Pyretic performs better than both Ryu and POX.

In [4], Fancy et al. conducted analysis of performances of two popular SDN controllers- Floodlight and POX. They have considered some basic parameters like delay and throughput. The controllers were tested in different topologies. After observing the results, it is concluded that Floodlight shows far more better performance than POX. However, Floodlight uses mentionable amount of memory space for execution because of its inbuilt java files. POX is better in this case as it is based on python.

Jany et al. [5] evaluated the performance of OpenFlow based wired and wireless network. Authors used the tool Mininet-WiFi to emulate a wireless network. They used Ubuntu Xterm to acquire client-server interfaces and also used iperf test to measure basic parameters like delay, bandwidth, jitter etc. In the Software Defined Wired and Wireless Network (SDWWN), a single controller administered all the switches and access points together. Analyzing the results, authors concluded that the network shows promising results and creates further opportunities to conduct research upon SDWWN using Mininet-WiFi.

Shalimov et al. performed the comparison of SDN controllers- Beacon, MuL, Mestro, POX, NOX, Floodlight and Ryu based on certain criteria like throughput, latency, reliability, security etc. in paper [6]. In this study it appears that Beacon, Floodlight, NOX, POX and Ryu are capable of lasting long-term test when the traffic load is average. MuL and Maestro do not perform the same way. They also performed security analysis by sending malformed packets which can terminate TCP sessions and eventually causing a failure of a network portion or even the entire network.

In [7], comparative performance analysis of some SDN controllers is carried out by Tootoochian et al. NOX-MT, Beacon and Maestro are chosen to conduct the research. NOX-MT appeared to be ahead of others according to the analysis. Although these controllers are no longer popular.

Khattak et al. evaluated performance of two SDN controllers OpenDayLight and Floodlight in [8]. They used Cbench which is a handy tool for benchmarking SDN controllers. In that study they concluded ODL includes memory leakage problem. On the other hand, Floodlight has average higher response time than ODL.

In paper [9], comparison of five popular controllers based on various features is provided by Khondoke et al. Authors have considered several criteria for evaluation such as- GUI, programming language, operating system, virtualization, southbound interfaces, REST API support, OpenFlow version support etc. Although the results vary when the priority of criteria is changed, RYU was voted as the best amongst other controllers by the authors.

In [10], Rastogi et al. carried out the comparative performance analysis of two popular python based SDN controllers- POX and RYU. The authors conducted the study putting traffic handling capabilities into perspective. Mininet was used for emulation and D-ITG for traffic generation. The research concludes that POX provides better results in case of layer 1 switching. Whereas, in case of layer 2 switching RYU appears to be better than POX.

In [11], Beacon, Maestro, IRIS, OpenDaylight, Floodlight, Ryu, POX, NOX, ONOS, MUL, Libfluid-based SDN controllers are assessed by Salman et al. Authors concluded that amongst these open-source controllers Maestro is the topmost considering the latency performance. Mul and Libfluid-based were ahead of others when it comes to throughput.

In [12], both feature oriented comparison and performance analysis of some very popular SDN controllers are done by mamushiane et al. The controllers include OpenDayLight, Ryu, ONOS and Floodlight. After analyzing the results it is stated that Ryu exhibited better performance than others in terms of latency. On the other hand, ONOS proves itself the best when throughput performances are considered. Authors also recommend using OpenDayLight for its enriched features.

Among all these studies it appears that only the last paper [5] includes performance evaluation of a Software Defined Wireless Network. Although in this paper, authors evaluated the performance of the network rather than of any controllers. Thus it appears to us that a research based on the performance evaluation of certain SDN controllers in terms of wireless network comprises considerable significance.

B. SDN Controllers

A Software Defined Network consists of some radical components such as south-bound interfaces, north-bound interfaces, controllers, network applications etc. Among these, south-bound interface works as an interface between controller and infrastructure. It accumulates the status of the network, updates the rules regarding packet forwarding to the switching devices at the infrastructure layer. On the other hand, the north-bound interface functions as an interface between controller and application. It receives policies from SDN applications and communicates them to the controller. These policies are given in high level programming languages [13]. Network applications decides the path for a packet and commands the controller to install necessary forwarding rules in the switching devices. Therefore, SDN controller is the key for implementing the control logic which is gained from the applications and defined by the operator of the network [14]. Controllers can be centralized or decentralized in terms of architecture. They can be built based on several high level programming languages like java, python, C++ etc. Along with delivering the forwarding devices with forwarding rules the controller also provides other services like management of topology, host tracking, security services etc. for the network [15]. There are many SDN controllers developed to this day for various purposes using several languages. We have taken some popular controllers in consideration. They are brought up in Table I with their common features.

TABLE I
COMMON FEATURES OF SDN CONTROLLERS

Name	Ryu	POX	Floodlight	ONOS
Architecture	Centralized multi-threaded	Centralized	Centralized	Distributed
GUI	Yes	Yes	Web/Java-based	Web-based
Programming Language	Python	Python	Java	Java
Platform support	Linux	Linux, Mac, Windows	Linux, Mac, Windows	Linux, Mac, Windows
Network	Campus/ Research	Campus/ Research	Campus	Telecom/Data center
REST API	Yes	No	Yes	Yes

***The features are obtained from [16], [17], [18], [19].**

III. EXPERIMENTAL SETUP

A SDWN separates the control plane from the data plane of the network. It occurs outside the Access Points or APs. There are stations which are managed by Access Points (APs) and the station perform connection with Access Points (APs) through both authentication and association. APs are in charge of transmission and reception of traffic over the wireless network and they receive related instructions from the stations [5].

Mininet-WiFi: It is a tool for emulating Software Defined Wireless Network. It is derived from the Mininet SDN emulator [20] through adding wireless functionality using virtualized WiFi stations and access points. It has several limitations like limited (100) WiFi nodes, not supporting WDS etc. Despite these limitations it is useful for emulating SDWN as it has capabilities for performing all normal SDN emulations like Mininet network emulator [21].

OpenFlow: Mininet-WiFi supports OpenFlow (OF) which is one of the pioneer SDN standards. It explicates the communication protocol which empowers the controller to interact directly with the forwarding plane of the networking devices. It was first introduced by Stanford University in 2008 and version 1.0 was released in 2009. There are several versions released since then. OF is managed by Open Networking Foundation (ONF) which is an organization led by the users for maintaining open standards and SDN adoption [22].

Iperf: We have used iperf for generating traffic which is a tool intended for performance measurement and network troubleshooting. Using iperf, TCP and UDP bandwidth performance can be measured. It produces the traffic on either TCP/IP or UDP and provides measurement according to bandwidth, jitter, delay etc. [23].

In our machine, we have Ubuntu 18.04 LTS installed. We also have used Xterm [24] which is a terminal emulator for Ubuntu and other UNIX-like operating systems. It provides interfaces for both client and server.

The topology we have used is illustrated in figure 1 (Fig. 1). The topology consists of three stations, three access points and a SDN controller which supports OpenFlow. We can acquire this topology by default in Mininet-WiFi using this command-

sudo mn –wifi controller=remote,ip=127.0.0.1 –topo=linear,3,protocols=OpenFlow1.3

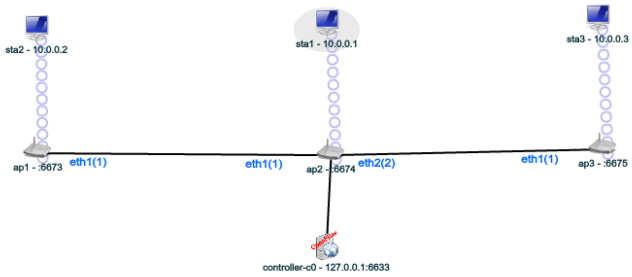

Fig. 1. Samlple topology

Delay: We have examined the packet delay between server and client. Server-client is declared using iperf command. Packets are transmitted and received between the two ends. tcpdump command is used to analyze and save the packet information. The difference between transmission-time and reception-time indicates the delay.

Jitter: The variation in the delay regarding packet flow between server and client is indicated by jitter. For

measuring the jitter we have used iperf command. Essential commands include:

iperf -s -u -p 5566 -i 1

iperf -c 10.0.0.1 -u -b 10M -t 15 -p 5566

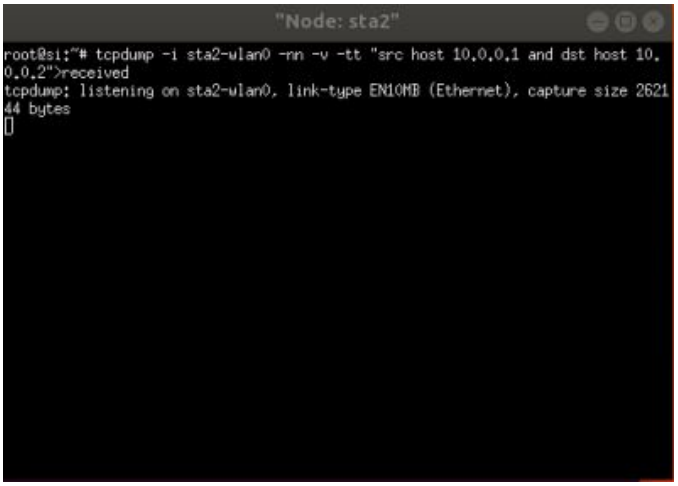

Fig. 2. Receiving terminal for tcpdump

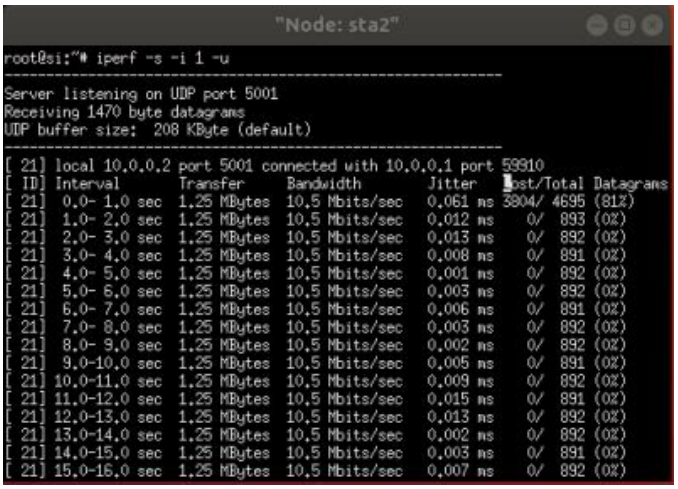

Fig. 3. Server-side terminal for iperf

Throughput: The amount of successful data transferred between two end systems in a given time period is called throughput. We have measured the TCP throughput in Mbits/s. Iperf command is further used here for generating traffic.

IV. Discussion

We have established connection between the controller and Mininet-WiFi. After the establishment, we have waited for a certain duration (20-30 seconds) for the connection to become stable. Then we collected the data associated with delay, jitter and throughput. After collecting the data we have plotted them in several graphs.

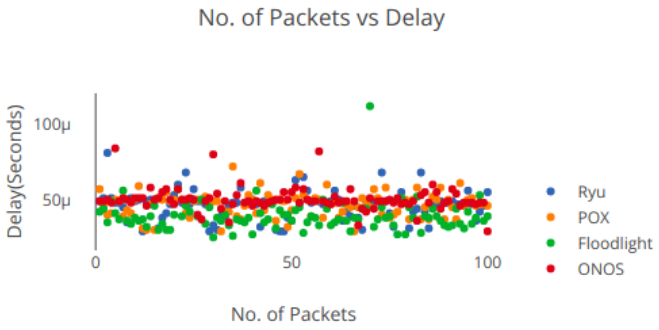

Fig. 4. Delay Comparison

A. Delay Comparison

In the above figure (Fig. 4), the X-axis represents the number of packets and the Y-axis represents delay in seconds. It can be also seen that we have taken packet numbers up to 100 and delay up to 100 micro seconds. We have considered End to End transmission delay in our experiment. It can be observed that among all the SDN controllers-

- Floodlight has the lowest delay. Thus it has outperformed the others in terms of delay.
- On other hand, ONOS has the worst delay performance.
- The rest of the controllers have average performance.

B. Jitter Comparison

The X-axis in the figure below (Fig. 5) represents time in seconds and the Y-axis represents jitter in milliseconds. We have measured jitter for 30 seconds time. From the definition given earlier we know that jitter is the inequality in time delay while transmitting packets of data in a network. There is a certain level of variation (below 30 ms according to Cisco Systems, Inc.) in irregular packet delay that is regarded as acceptable jitter. From the figure we can clearly state that all the controllers show acceptable jitter performance. It appears that-

- Floodlight has the minimum jitter. So it exhibits the best jitter performance.
- On the contrary, Ryu displays the worst jitter performance.
- Among the others, the jitter caused in POX is less than ONOS.

C. Throughput Comparison

The above figure shows the performance of the SDN controllers in terms of throughput. The X-axis entitles time in seconds and the Y-axis entitles throughput in Mbits/s. We have allocated 10 Mbits/s throughput for 30 seconds time. As the throughputs of the SDN controllers do not differ much from one another, it can be stated that they all show the same throughput performance.

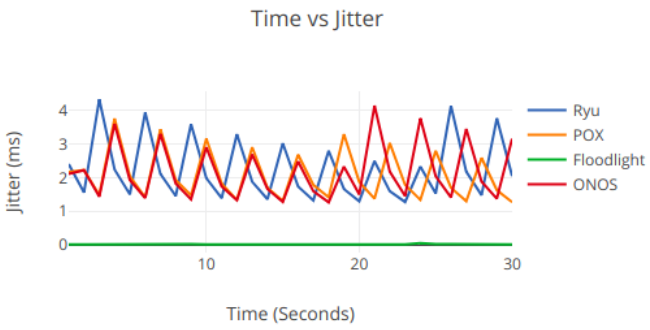

Fig. 5. Jitter Comparison

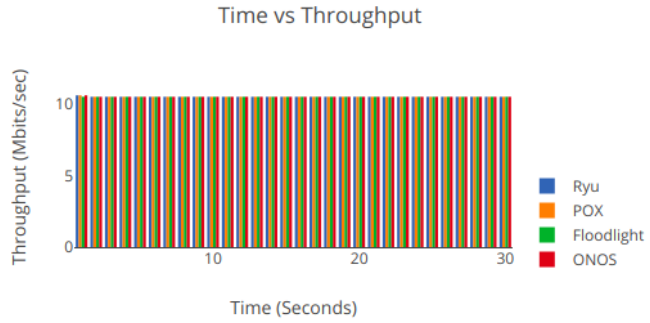

Fig. 6. Throughput Comparison

V. Conclusion and Future Work

From the experimental evaluation we can cease to a decision that Floodlight performs the best among the four SDN controllers in a SDWN in terms of delay and jitter. We can also conclude that in terms of delay, ONOS shows the worst performance. On the contrary, Ryu displays the worst performance when we consider jitter. However, POX exhibits an average performance in all terms. Although we have taken these three criteria in consideration, there are various other properties based on which controller-performance can be evaluated. Such as workload, datagram loss, security etc. We have excluded these parameters. We would like to measure controller performance in terms of these criteria in future. Moreover, we intend to deploy a SDWN in our campus using Floodlight.

***Abstract*—In recent years, the need for reliable, short-ranged underwater wireless communication has been proliferated because of the surge in underwater exploration. Underwater Wireless Sensor Networks (UWSN) can be used in vehicles and sensors to perform collaborative monitoring and data collection task. Due to the high density and contamination, limited bandwidth, high propagation delay, media access control, and power constraint underwater communication is a very challenging task. Researchers developed different research methodologies to overcome this problem. In this paper, an acoustic communication-based system is proposed by using Piezo-Ceramic transducers and practically developed. The acoustic wave can travel easily in water without much attenuation. Piezo-Ceramic transducer creates vibration according to the electrical pulses and does not need much modification of real data signal. This paper describes a wireless low-cost acoustic system for underwater communication. The system is built with some filters and amplifiers and power booster circuits. Finally, a cost effective underwater communication system is proposed that has been successfully implemented on a submarine bot.**

***Keywords*—Acoustic system, Underwater communication, Power amplifier, Signal Processing, Receiver, Transmitter, Ultrasonic transducer.**

I. INTRODUCTION

A commonly used electromagnetic signal, radio signal's electromagnetic wave cannot pass through the water smoothly due to high attenuation and it's strength decrease and which is noticeable in the water. Optical signal attenuate for reflection, dispersion, etc. But sound wave can propagate through the water very well, so an acoustic system can be used to overcome this problem. The underwater communication system can be used to communicate with a submarine, in marine research, oceanography etc[1]. In recent years, rapid progress has been made in clean deep water communication and shallow water communication but it is considered very challenging. High-speed communication in the underwater acoustic channel is very difficult because of some factors such as multi-path propagation, small available bandwidth and high signal attenuation co-factor, refractive properties of the medium, severe fading, large Doppler shifts [2]. The available bandwidth in an underwater acoustic communication channel is severely limited for transmission loss which increases with both frequency and range[3]. An ultrasonic transducer is used here to send and receive data for reducing attenuation co-factor. In recent years many research works are done for underwater communication. For example, the Persistent Littoral Undersea Surveillance Network (PLUSNet) describes multi-sensor and multi-vehicle antisubmarine warfare (ASW) technique for underwater communications[4]. A short-range shallow water network is proposed for observing pollution in Newport Bay, CA[5]. A network of acoustic modems is proposed for low range, low power acoustic communications for seismic monitoring system development[6]. In this paper, in order to make underwater communication smooth a low power consumption digital acoustic system and cost effective underwater communication system is proposed and developed. Our proposed system is a new acoustic technology system in the world of underwater communication which is different from others and helpful for smooth underwater communication. Our underwater system consists of a transmitter, receiver, voltage booster, power amplifier and signal processing unit. In section II total system overview is discussed, Section III transmitter circuit full system is discussed, Section IV receiver circuit is discussed, Section V data analysis, difficulties and its solution and result analysis are discussed, Section VI conclusion section, here our future work and overall review of paper are discussed. Our main focus is to make this system cost effective, according to data Linkquest, Benthos, and DSPComm underwater communication system cost is more than $8000 [7]. But we make some change in our ultrasonic transducer to use it properly and also design our transmitter, receiver, voltage booster and power amplifier circuit so that cost will be minimized and the total cost to make our underwater wireless communication system is $625. Some problems are found when we started working with the ultrasonic transducer. Authors will describe the problems and their solutions in different sections.

II. SYSTEM OVERVIEW

The present work demonstrates a stable low-cost underwater wireless communication system. It has been successfully tested on eight feet long water pool. The communication system is divided into two parts, namely- transmitter and receiver. The transmitter consists of three stage power amplifier. On the other hand, the receiver consists of three stage noise filter and three stages signal amplifier. A custom made transducer is used in both receiver and transmitter of the system. Piezo Ceramic Transducer named SMC20D17H5 is used which costs about $35.

Fig. 1: Piezo-ceramic Transducer without coating (left) and with coating (right)

This ultrasonic transducer [8] is used for transmitting and receiving data. If an electrical (voltage) signal is applied to it, it generates radial mode vibration and if it senses vibrations, it generates an analog electrical (Voltage) signal. It has very low internal damping. When an electrical pulse is applied, it takes 4-5 cycles to propagate the wave. Its typical output impedance is 50 Ohms and the center frequency is around 47KHz. It can create radial mode vibrations means sound waves. But the materials used in the transducer (silver electrode) is very sensitive to the water at the presence of voltage. When 40v DC voltage is applied to the silver electrode of the ultrasonic transducer, the electrode starts to react with the water and within a few minutes, it has been damaged completely. To solve this chemical reaction problem, a resin coating is applied to encapsulate the silver electrode from the water and the problem is solved.

It is tested on a 100uV input signal & 15V (p-p) output signal is obtained.

III. Transmitter

In this section, transmitter converts electrical signals into ultrasounds and this ultrasonic sounds can propagate through the water easily. Transmitter unit can be divided into four stages:

1) Signal processing
2) Voltage booster
3) Power amplifier
4) Transducer

A. Signal processing

First of all the data is converted into a character string and send to the main processing unit of the transmitter, which is actually a micro-controller. The character string is converted into an 8-bit binary number. The 8-bit binary is divided into two 4-bit binary segments.
A start bit is added to those 4-bin binary segment separately to make the starting clear to identify and error detection.

B. Voltage Booster

For long range transmission, ultrasonic transducer requires higher voltage. As the primary power is supplied from a 12v battery, the voltage has been boosted to 40v to increase the range. The is LM2577 is used for the boosting purpose [9].

C. Power Amplifier

For power amplification, a boosted voltage from the boost converter is used. As a transmitter transducer requires enough power to deliver the signal through the water so Darlington pair circuit is used to increase the current. [10].

IV. Receiver

The receiver converts the ultrasonic sound signals into electrical signals. The receiver is a very high gain multistage signal amplifier. The receiver unit can be divided into some stages :

1) Transducer
2) Amplifier
3) Filter
4) Clipper
5) Microcontroller

It is a three stage amplifier. It's Gain is more than 100000. It has been tested on 100uV to 15 Volts. It has some high pass and low pass filters.

A. Amplifier

Three stage high gain amplifiers are used. In the first stage, the signal is amplified by a transistor PN2222. To determine the gain following equations are used[11].

$$Gain = \frac{V_{out}}{V_{in}} = \frac{\triangle V_E}{\triangle V_B} = -\frac{R_E}{R_C} \tag{1}$$

Then the signal is passed through a bandpass filter. In the second stagethe pre-amplifier's signal is amplified again by an op-amp LM318. Finally, this signal reached to the third stage through another bandpass filter and amplified to an output of peak to peak 12-15 volt.

V. Data Transfer Process

Frequency Shift Keying (FSK) modulation is used for the underwater communication system.

- 4 bit communication system is used (can be extended to 8 bit).
- Start bit: 47kHz frequency, 3 clock cycles time.
- Binary 0: 47kHz frequency, 1 clock cycles time.
- Binary 1: 47kHz frequency, 2 clock cycles time.

In the developed system every clock cycle uses 40 kHz frequency for 50 ms. Here 50 ms is the optimal time for that carrier frequency as lowering time will cause more distortion. Start-bit contains 3 clock cycle, Binary 0 and 1 take 1 and 2 clock cycles and there is a gap one cycle between every bit transmission. So the total time is,

*Maximum time = 50*start bit + 50*4*binary 1 + 50*4*Gap*
*or, Maximum time = (50*3 + 50*4*2 + 50*4*1) ms*
or, Maximum time = 750 ms
*So, time for 1-byte (8-bit) = 750*2 ms = 1500 ms.*
So, The minimum data rate = 1/1.5 byte/second = 0.67 byte/second

B. Command flow diagram of data receiver

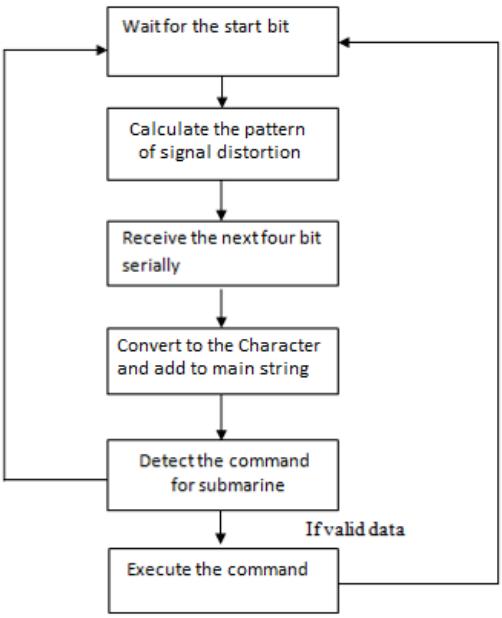

Fig. 8: Flow diagram of data receiver (used in submarine bot)

In figure command flow diagram of data receiver is shown.

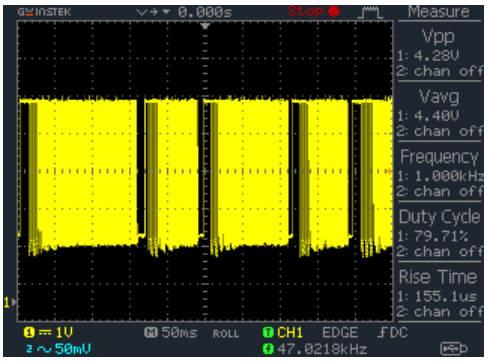

Fig. 9: Received Signal

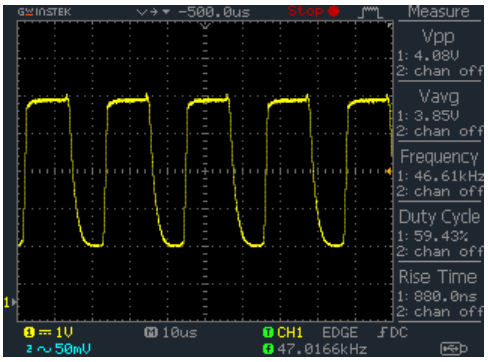

Fig. 10: Received Signal

C. Error Correction

The start bit is predefined and is known to the transmitter and receiver unit. If any distortion occurs, it affects both the start-bit and data bit in the same way. Calculating the distortion in the start-bit, an algorithm is developed to attempt a recovery in all individual bits. However, the recovery can work on only for a certain amount of distortion.

VI. Conclusion

In this work, main focus was to establish a smooth communication for the underwater acoustic channel. Frequency Shift Keying (FSK) modulation technique is used here for data transmission. Four bit communication system is developed and studied here. The data transfer result is very smooth which has been seen shown in the oscilloscope graph. The future plan of this project is to increase the range of communication distance by implementing powerful voltage booster and making the error correction algorithm more efficient and also working with higher frequency to get increased data transfer rate.

***Abstract*— Cache management has become one of the key issues in future generation 5G wireless communication network. The feature of high-speed mobility along with vast users of the 5G network increases complexity in cache management. Depending on the cache location and user's mobility, the handoff has become even more prevalent in the content-centric 5G network architecture. As a result, an increased number of dropping and blocking might occur hindering the desired quality of service (QoS). Keeping that in mind, in this paper we have proposed a mobility-aware handoff priority-based request admission control (RAC) policy for managing cached content requests by utilizing limited bandwidth. By reducing the dropping probability and ensuring lesser force termination of already admitted requests; our system provides a better QoS. This paper investigates the scope of the betterment of QoS by reducing the dropping probability in a mobility-aware 5G heterogeneous network (HetNet). The analytical results show better performances than the general scheme in handling the effects of user mobility.**

Keywords—5G, cache, mobility, handoff, dropping probability, blocking probability, bandwidth utilization, request admission control.

I. INTRODUCTION

In the near future, user demands such as- increased capacity, improved data rate, decreased latency, and better quality of service are needed to be addressed with future generation communication technologies. The 5G future generation systems are expected to provide enhanced device- and network level capabilities. It is anticipated that the upcoming 5G network should fulfil requirements such as- 1000 times greater mobile data traffic volume compared to current traffic, 100 times more connections, 10Gbps peak data rate, above 10Mbps affordable per-user data rate anywhere and anytime, and 100Mbps for some particular user, lower latency, delay in milliseconds (ms) for the end-to-end user plane, and within 10ms for the control plane, higher spectrum efficiency, 3-5 times higher than that today for large-area coverage and even higher for special cases, lower cost, nearly 1/1000 of cost per bit than today, higher energy efficiency, almost 1/1000 of energy consumption per bit than today [3]-[5], [7].

While 100 times more user connectivity is an expectation from 5G technologies, this network shall also incorporate high mobility requirements as an integral part. For instance, the high-speed deployment which focuses on continuous coverage along the track in high-speed trains is reported in [6], and the higher user mobility as one of the use case families is proposed by NGMN (Next Generation Mobile Network) [12]. For 5G, the targeted maximum user speed at which a defined QoS can be achieved is 500km/h [6]. Whereas a lot of things can be developed in the field of 5G technology, in this paper the focus has been centered on significantly reducing the dropping probability of handoff requests due to high speed user mobility and improving bandwidth utilization.

The sections of this paper are organized as follows-

Chapter II discusses the previous works related to this one. Chapter III has information about the methodology that is developed for this work while chapter IV illustrates the experimental evaluation of the stated work before rounding it off. We conclude the paper, indicating the scopes of future works, in chapter V.

II. RELATED WORKS

Over the years, a lot of research works has been done to improve the quality of service (QoS) in wireless cellular communication technology. In reference [8], the developed CAC scheme enables to minimize the call dropping probability, as well as it improves bandwidth utilization. Although the proposed scheme blocks more new calls, it reduces the number of handoffs and average call duration and forced call termination probability as compared to the non-prioritized bandwidth-adaptive scheme. Just like in the voice-centric (aka call-centric) systems, Admission Control scheme can be equally significant in the emerging content-centric heterogeneous 5G wireless communication system where the provisioning of quality of service (QoS) is a major concern. In recent years, with the development and increase of mobile devices, we see an exceptional global growth of mobile data traffic (reached 7.2 exabytes per month in 2016) [9], [10]. Due to enormous users and their numerous demands, it has become a mandate to make the best use of the limited resources that assure the highest standard of Quality of Service (QoS). To meet the guaranteed level of QoS for the maximum number of users, maximum utilization of bandwidth and some other factors like- call dropping probability, call blocking probability etc. are needed to keep under consideration. The lower performances of these factors may retrograde the overall cellular networks performances [11]. In such cases, releasing some bandwidth from the already admitted non-real-time traffic calls and the released bandwidth is used to handle handoff calls, and then the resulting probability of dropping a handoff call is lesser than the probability of blocking a new call [8]. Reference [16] also suggests a channel borrowing scheme for efficient resource management. Studies have shown that an effective admission control scheme can evidently reduce blocking or dropping probability along with higher bandwidth utilization by ensuring the best use of limited resources [15], [8]. As the user mobility is rapidly increasing and predicted to reach about 500kmph in 5G [1], [2], [6]; managing handoff requests is a challenge in the content-centric 5G network architecture. Under high mobility scenarios, there shall be quite frequent handoffs; new algorithms are needed to reduce the number of handoffs, the handoff latency, and the handoff failure probability [7]. While the fifth generation (5G) mobile networks, in fact, can enhance mobile network

performances, yet reducing the latency of network services remain a major challenge. Because of the escalating requirements of the mobile applications and services on prompt delivery of contents or real-time user interaction delays occur [13]. To overcome latency issues, different caching techniques have been proposed and those have proven caching as to be an effective way for improving users' quality of experience (QoE) [14]. Hence, the efficient management of contents cached in a 5G network is worth the efforts being put in research in this regard.

In our work, to meet the guaranteed QoS in the content-centric next-generation 5G wireless communication technology, we focus on effective cache management in high-mobility scenarios and utilizing the limited resources of bandwidth with request admission control.

III. METHODOLOGY

A. Network Architecture

The design of the proposed scheme is a two-tier heterogeneous network (HetNet) consisting of macrocell base stations (MBSs) and ultra-densely deployed several small cell base stations (SBSs) under each MBS. A model of the proposed network architecture has been displayed in Figure 1. In 5G HetNets, MBSs are responsible for network coverage with control signaling, whereas SBSs are expected to be densely deployed to boost network capacity in a "plug-and-play" manner. The topologies of both the MBSs and SBSs are modeled as regular hexagonal cells. MBSs and SBSs use orthogonal spectrum bands to avoid inter-tier interference [17]. Both MBSs and SBSs are connected with the core network through wired backhauls. Each user is connected to either an SBS or an MBS depending on the location of the cached content for which the user has requested.

B. Request Admission Control (RAC) Scheme

The flow diagram in Figure 2 represents the proposed cache management based on a handoff prioritized Request

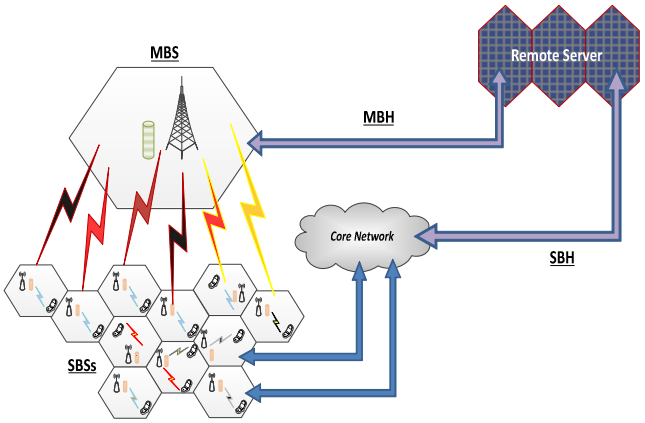

Figure 1: System architecture for the proposed scheme

Admission Control (RAC) policy. Here, as we can see when a request (content request) arrives at the system node, if the content is already cached in the system then depending on the cache location the scheme is followed.

Generally, a channel receives two types of requests; new request and request being handed over from another channel. In our study, we consider handoffs which are initiated by crossing a cell boundary due to the user's mobility. So, for a handoff request, the client is served with priority. Through the available Radio Access Network (RAN) bandwidth of the respective SBS or MBS reserved for handoff requests serve this type of clients coming into the system owing to mobility issues. In case of unavailability of the reserved bandwidth (BW), handoff requests are served by the remaining non-reserved BW of the requested BS. When even that is not available, then the request is to be served either by the non-reserved RAN BW of respective MBS of the requested SBS. In that way, some unused bandwidth is borrowed from the MBS in order to serve the frequent handoff users of popular contents at SBSs. When handoff request enters a channel at BS where no remaining RAN BW is available, then backhaul (BH) connection is established to accept that request.

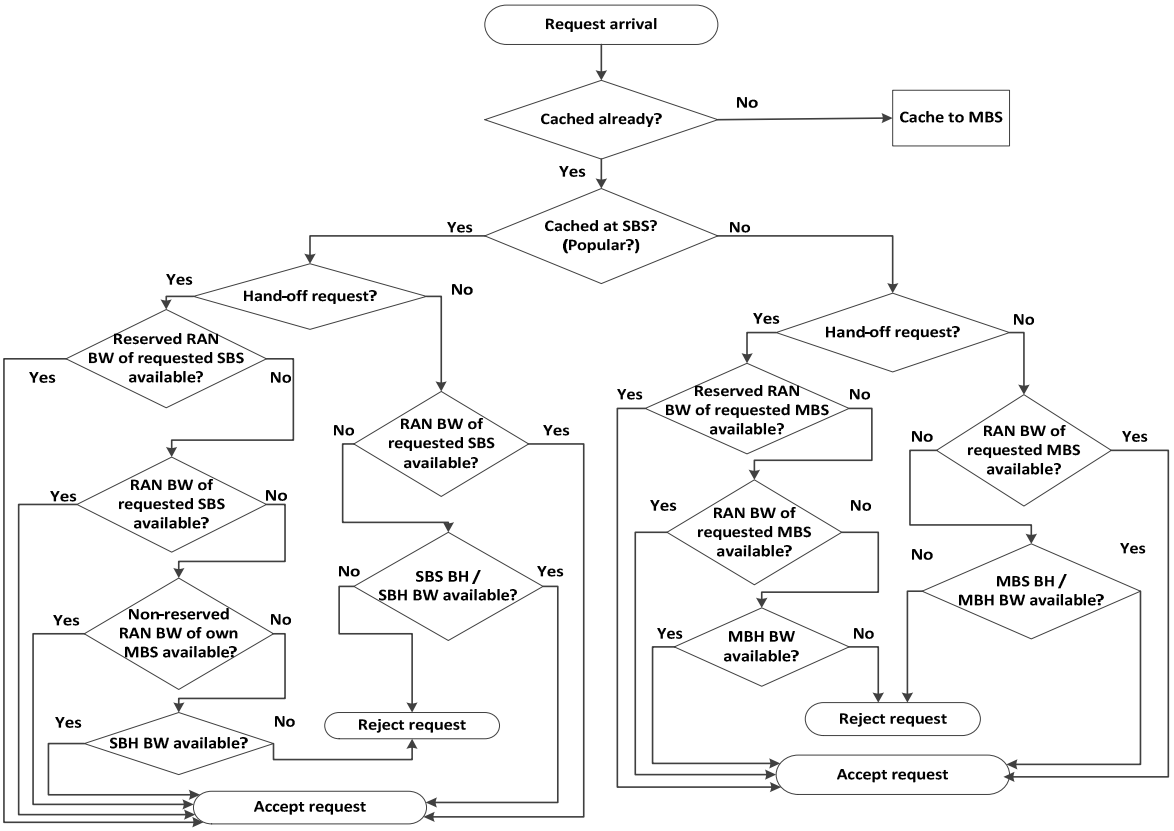

Figure 2: Flow Diagram of the proposed Request Admission Control (RAC) scheme

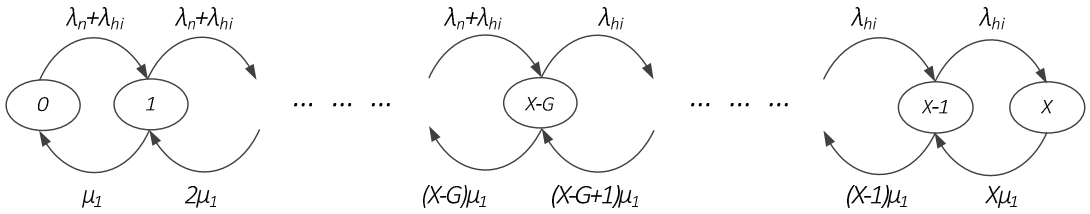

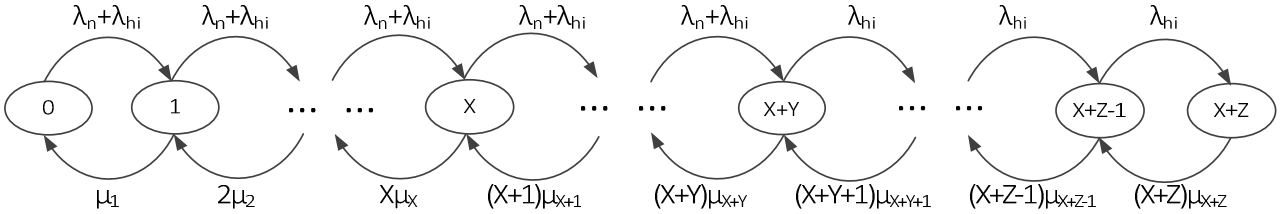

Figure 3: The Markov chain for the general scheme

$0 \leq Y < Z$

Figure 4: The Markov chain for the proposed mobility aware HO-prioritized RAC scheme

For new requests (not handoff), if the requested content is cached then it is accepted if 1) the non-reserved RAN BW of the requested SBS/MBS is available or 2) through BH network to the core network. Otherwise, the requests are rejected.

The RAC illustrated in Figure 2 explains how a handoff (HO) request is given priority over a new request with the best utilization of the limited bandwidth resources. As a result, our proposed approach can achieve a significant reduction in dropping probability which is a critical factor in maintaining QoS. Also, sharing of non-reserved bandwidth of a parent MBS with its own SBSs can provide with improved BW utilization to the system. Nevertheless, as a consequent of prioritizing HO requests, more new requests are to be rejected in this method. Rejection of some new requests will cause a minor increase in the probability of blocking. But, as our approach intends to majorly address user mobility, rejecting some new requests will not be a severe issue in the growing 5G future generation network. Because declining some new requests for accommodating HO ones, said otherwise, is guaranteeing less force termination of user requests in the system. That again contributes to the betterment of QoS.

C. *Queueing Analysis*

The proposed policy is a queuing system that is analyzed mathematically by using the birth-death process of Markov chain queueing analysis. Figure 3 shows the Markov chain of the general scheme. General scheme is defined as a system where no request is being prioritized over another and no bandwidth is being shared. Therefore, bandwidth is not being utilized to the fullest. On the other hand, bandwidth sharing takes place in our proposed scheme as depicted with the Markov chain in Figure 4. As a result, the number of states is increased so that more users can be served without being terminated at handoff situations, most likely occurring because of their high-speed mobility. This adaptive nature of the proposed approach allows for better resource utilization.

In the proposed mobility-aware handoff prioritized RAC scheme, the mathematical equations are used with the help of equations from related works [8] and [15]. The terminology of the queuing analysis is introduced in Table I.

For the system states $0 \leqslant k \leqslant X$, when there is enough bandwidth in the system, all the requests are allocated the requested bandwidth according to the content cache location. For system states $X+Y+1 \leqslant k \leqslant X+Z$, users with handoff requests are served with priority. This is the reserve BW in the proposed plan to treat HOs from user mobility. And from states $X+1 \leqslant k \leqslant X+Y$, the shared bandwidth is available which is allocated to the HO requests once being shared.

For queuing analysis, the probability that the system is in state k, is given by equation (1). In the proposed scheme, a new request is blocked if the system is in the state (X+Y) or larger. However, a handover request is dropped only if the system is in the state (X+Z). Thus, from equations (1) − (7) are used in computing the proposed policy.

TABLE I. NOMENCLATURE

Symbol	Definition
$P(k)$	Queueing probability at k^{th} state
$P(0)$	Queueing probability at 0^{th} state
λ_n	Arrival rate of new request
λ_{hi}	Arrival rate of handoff request
λ_t	Total arrival rate of a state
μ_s	Departure rate of each state from 0 to X
μ_r	Departure rate of each state from (X+1) up to (X+Z)
$1/\mu$	Average call duration
$1/\eta$	Average cell dwell time
$P(H)$	Request probability
$P(B)$	New request blocking probability
$P(D)$	Handoff request dropping probability
X	Number of non-reserved states (bandwidth) for accommodating both new and handoff requests
Z	Number of reserved states (bandwidth) for accommodating only handoff requests
BW	Bandwidth utilization factor

$$P(k) = \begin{cases} P(0)\dfrac{(\lambda_n + \lambda_{h_i})^k}{k!\mu_s{}^k}; & 0 \le k \le X \\ P(0)\dfrac{(\lambda_n + \lambda_{h_i})^k}{k!\mu_s^k \prod_{r=X+1}^{k} \mu_r}; & X \le k \le X+Y \\ P(0)\dfrac{(\lambda_n + \lambda_{h_i})^{X+Y}(\lambda_{h_i})^{\{k-(X+Y)\}}}{k!\mu_s^X \prod_{r=X+1}^{k} \mu_r}; & X+Y \le k \le X+Z \end{cases} \quad (1)$$

where, $$P(0) = \left[\sum_{k=0}^{X} \frac{(\lambda_n + \lambda_{h_i})^k}{k!\mu_s^k} + \sum_{k=X+1}^{X+Y} \frac{(\lambda_n + \lambda_{h_i})^k}{k!\mu_s^X \prod_{r=X+1}^{k} \mu_r} + \sum_{k=X+Y+1}^{X+Z} \frac{(\lambda_n + \lambda_{h_i})^{X+Y}(\lambda_{h_i})^{\{k-(X+Y)\}}}{k!\mu_s^X \prod_{r=X+1}^{k} \mu_r} \right]^{-1}$$

$$P(\mathrm{H}) = \frac{\eta}{(\mu + \eta)} \quad (2)$$

$$\lambda_t = \lambda_n + \lambda_{h_i} \quad (3)$$

$$\lambda_{h_i} = \frac{\mathrm{P(H)(1-P(B))}}{(1-(\mathrm{P(H)}(1-P(\mathrm{D}))} \lambda_n \quad (4)$$

$$\mathrm{P(B)} = \sum_{k=X+Y}^{X+Z} P(\mathrm{k}) \quad (5)$$

$$P(\mathrm{D}) = \mathrm{P(X+Z)} \quad (6)$$

$$BW = \frac{(\lambda_n(1-\mathrm{P(B)})) + ((1-\mathrm{P(D)})\lambda_{h_i})}{(\mu+\eta)(\mathrm{X+Z})} \quad (7)$$

In the non-prioritized scheme, where there is no priority of handover calls over new calls, the total number of states remain X. But in the proposed RAC HO priority scheme the total number of states increases with the bandwidth sharing and reservation combination.

IV. Experimental Evaluation

The performance analysis has been done in MATLAB for the proposed scheme in comparison with the conventional scheme that does not include the idea of priority for mobility. Since the mobility of the user is prioritized in here, our primary focus remains on reducing the probability of dropping of handoff requests, notably. Along with the curves of dropping probability, we observed the patterns of the curves of blocking probability and bandwidth utilization to show the benefits of the proposed approach as well as its minor drawbacks.

At first, we compare the of probability of dropping, *P(D)*, probability of blocking, *P(B)*, and bandwidth utilization, *BW* of the proposed policy with the general non-prioritized approach with respect to the increasing total request arrival rate, λ_t (requests/sec).

For Probability of dropping, we analyzed a comparative study as illustrated in Figure 5. Here, it is shown that the dropping probability of handoff requests due to user mobility is significantly reduced in the proposed mobility aware RAC scheme. It has been made possible with the prioritized scheme. In the non-prioritized scheme, with the increasing number of requests coming into the system, the probability that a HO request will be dropped goes higher easily. But as per the proposed scheme, the reserved bandwidth allocated for HO requests and also the shared bandwidth works in favor to reduce the dropping probability. Hence, it can be an effective policy to employ in the massive high-speed user scenarios of 5G.

For Probability of blocking we get results as shown in Figure 6. It is shown that the blocking probability of new requests has slightly increased in the proposed mobility aware RAC scheme, but only by a maximum of 14%. This increase is a tradeoff that is to be done to prioritize the high-speed mobility in 5G scenario. But, as it is occurring due to accommodating more HO requests in the system, the policy ensures that less number of requests are forcefully terminated which were already admitted into the system and thus confirms the better quality of experience to the connected users.

For Bandwidth utilization the results are represented in Figure 7. The figure shows that the bandwidth utilization of the proposed mobility aware RAC scheme is slightly lower than the general scheme, although the growth pattern is more realistic. But since the values are very close as the arrival rate goes higher, it indicates that the proposed scheme could be a preferred option in highly dense areas.

Subsequently, we observe the before mentioned factors with respect to the increasing value of new request arrival rate, λ_n (requests/sec). This observation is meaningful since the effect of mobility i.e., hand-off probability, *P(H)* is directly related to the new request arrival rate, λ_n.

With the increasing new request arrival rate, the dropping probability of handoff requests of the two schemes is illustrated in Figure 8. Here, it is graphically showed that the dropping probability of handoff requests due to user mobility is significantly reduced (by almost 35%-40%) in the proposed mobility aware handoff priority based RAC scheme. Such minimization of dropping probability has occurred since our policy gives priority to HO requests which is not the case in the non-prioritized general scheme. In a general scheme, when higher number of requests comes into the system, the handoff probability increases as well. But in our case the reserved bandwidth allocated for handoffs serve the purpose of minimizing dropping probability. Moreover, the bandwidth being shared between an MBS and an SBS works in favor to reduce the effect of user mobility upon system's quality of service. Therefore, the proposed policy is an efficient one in the 5G high-speed user scenario.

In Figure 9, it is shown that the blocking probability of new requests has slightly increased in the proposed mobility aware RAC scheme, that also by a maximum of 21%. This increase happened due to acknowledging handoffs with higher priority over new requests. But, as our approach intends to serve more users with higher mobility, this will not be a serious problem in the emergent 5G future generation network. With significantly better dropping probability, one of our major concerns is being treated successfully. That is, requests are less likely to be terminated while being handed over from one base station (BS) to another. Thus, lesser termination is another way of improving QoS through efficient management of cache requests.

Figure 10 depicts that the Bandwidth utilization in the proposed RAC scheme gradually grows high with the increasing arrival rate. The growth pattern is also more realistic than the general scheme. The somewhat lower value in our scheme in the low arrival rate region is not an issue. The reason is that in 5G the arrival rate will be higher than the usual. So, Figure 10 connotes that the proposed RAC scheme is a preferred option in the 5G high-speed and high-arrival rate scenario.

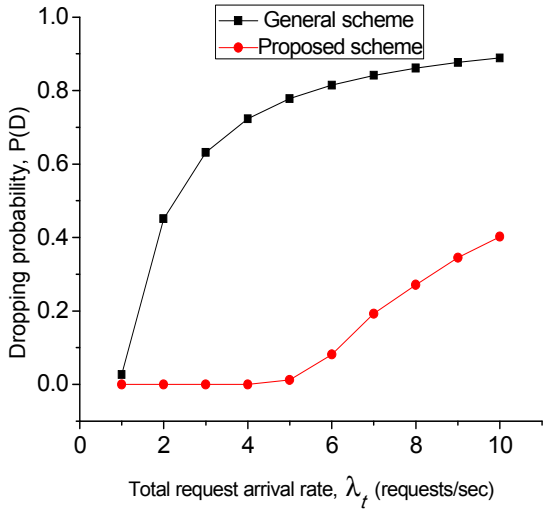

Figure 5: Comparison of handover request dropping probability

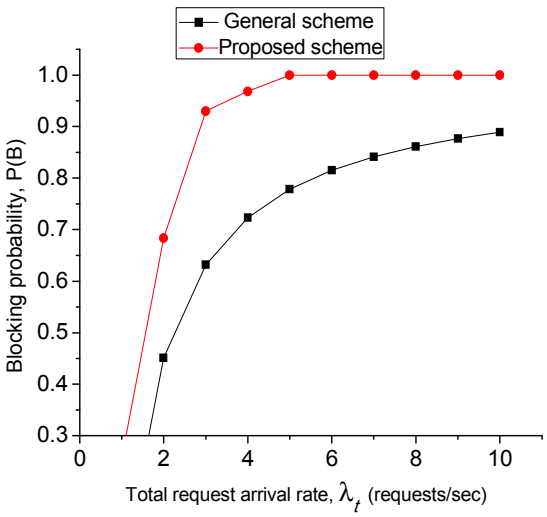

Figure 6: Comparison of new request blocking probability

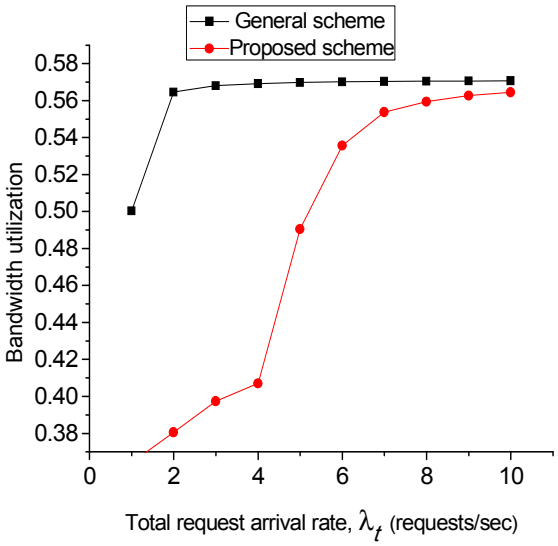

Figure 7: Comparison of bandwidth utilization

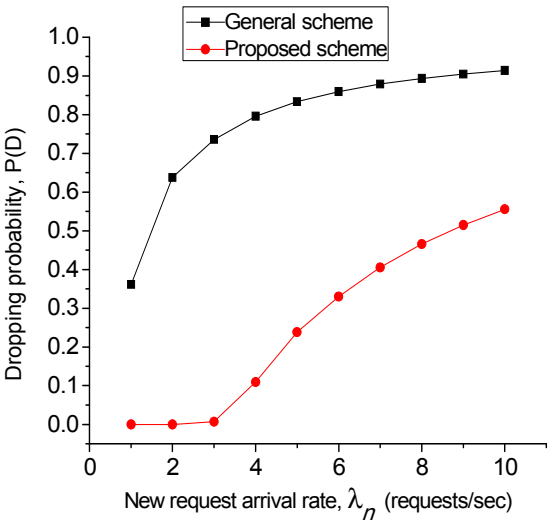

Figure 8: Comparison of handover request dropping probability

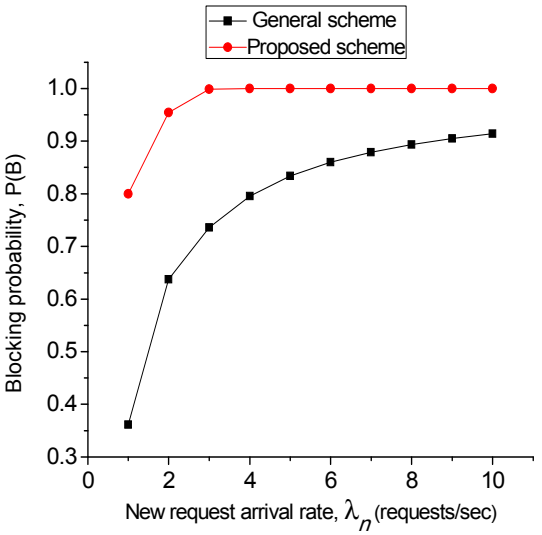

Figure 9: Comparison of new request blocking probability

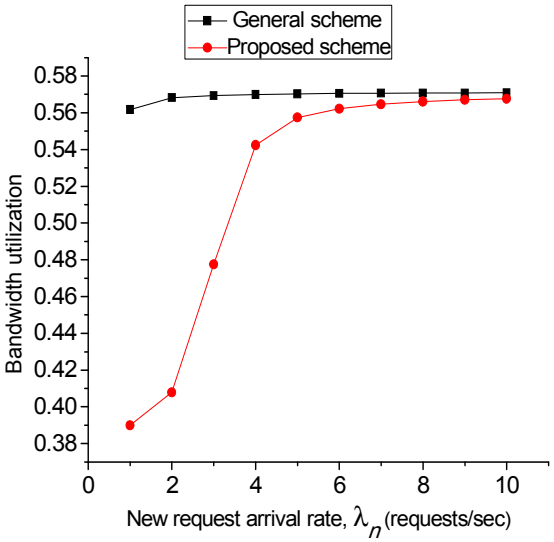

Figure 10: Comparison of bandwidth utilization

Now, from the discussed numerical analysis and graphical performance evaluation, we can conclude that from the user mobility aspect of 5G communication the proposed RAC HO prioritized scheme successfully reduces the dropping probability occurring due to handoff requests from high-speed mobile users on a significant scale. Lower dropping probability ensures a lesser number of force terminations of the already admitted requests. And the slight increase in blocking probability is not an alarming concern since the already admitted requests are facing less forced termination because of the new requests in the considered 5G scenario. Consequently, the mobility of the user is dealt with priority and requested cache is being efficiently allocated in the proposed scheme.

V. CONCLUSION

This paper has presented a handoff priority-based Request Admission Control (RAC) scheme. The proposed scheme allows for efficient cache management for content requests in a user mobility-aware heterogeneous fifth generation (5G) system by utilizing the existing bandwidth resources. The proposed scheme majorly addresses the area of prime effect of high-speed user mobility, which is the probability of dropping of hand-off requests. As the experimented results show, a minor increase in blocking probability of new requests was accepted while reducing the probability of dropping of hand-off requests significantly. Moreover, in this handoff prioritized request admission control (RAC) based cache management indicates further improvements in bandwidth utilization.

We will focus on enhancing the accuracy and adaptability of the proposed scheme in our future works. Besides, we will concentrate on simultaneously minimizing two performance metrics- the probability of dropping a handoff request and the probability of blocking a new request in order to develop a scheme for class-based cache request distribution and higher bandwidth utilization.

***Abstract*—Alzheimer's Disease (AD) is a chronic neurodegenerative disease that causes to develop dementia. Alzheimer's patients find it hard to remember recent events, reason and even to recognize people they know. As the disease advances, symptoms can include difficulty with language, disorientation including getting lost, mood swings, loss of motivation, lack of self-awareness and overall behavior. Though a limited number of IT based solutions exist to provide support for Alzheimer's patients, but most of these provide very isolated services either for the patients or for the caregivers. The objective of this research is to propose an assistive tool for Alzheimer's patients and their caregivers to provide support like health monitoring, assist to find lost items, provide reminder to take medicine and assist to monitor patient's location. A light-weighted evaluation study was carried out with 15 participants. The evaluation study showed that the proposed system was effective and usable for the patients and their caregivers.**

***Keywords*—Alzheimer, mobile application, heart rate, assistive tool, intelligent system, sensors.**

I. Introduction

Alzheimer's disease is a progressive disease in which the destruction of memory cells causes slow depreciation in memory, thinking and reasoning skills. A great deal of difficulties are faced by an Alzheimer's patient including short term memory loss, aggression, loss of communication skill, repetitive behaviour, anxiety, agitation etc [1].

According to [2], 24.3 million people have Alzheimer's disease today, with 4.6 million new cases every year (one new case every 7 seconds). The number of people affected will get doubled every 20 years to 81.1 million by 2040. The increasing rate of Alzheimer's patient is not uniform for all over the world. The experts have forecast the increasing rate by 100% between 2001 and 2040 for the developing countries whereas the rate is more than 300% for India, China, and their south Asian and western Pacific neighbors. The number of patients facing dementia caused by Alzheimer's Disease is increasing in the entire world including Asian subcontinent [3].

With the advancement of technology, it is seen that, technology plays a vital role as caregivers for those people who cannot take care of themselves [4], [5]. Therefore, the objective of this research is to develop an intelligent assistive tool for Alzheimer's patients to ease their daily life by measuring their heart rate, locate their personal belongings, monitor medication taking status and find their current location, while these necessary states of patients will be delivered to their family members and caretakers through a mobile application.

The rest of the paper is organized as follows. Section II discusses the related researches previously done in this area. Section III presents the conceptual framework of the system. The detail implementation of the proposed system is discussed in Section IV followed by the evaluation of the system in section V. Finally, section VI concludes the article.

II. Literature Review

A significant number of research has been carried on the design, development and evaluation of the assistive tool for the special need people, blind persons, aging population, and for the Alzheimer's patients [6]–[9]. This section will briefly introduce some work focusing to the development of assistive tool for Alzheimer's patients.

A limited number of papers were conducted focusing to mobile applications and software systems. In [10], Yamagat et al. showed that tablets and iPads could be utilized with Alzheimer's patients portraying favorite music and family photographs, as it helped them remember. In another study, Armstrong et al. [11] highlighted the potential explicit and implicit interaction techniques for Alzheimer's patients to receive care using smart phone buttons, touch screens, motion sensing and voice recognition. Similarly, in [9], Donnelly et al. developed a mobile application to provide a virtual caregiver which would give frequent memory cues through video reminders for mild AD patients. A medicine dispensing system is proposed in [12] that reminded the user to take medicine at the predetermined time interval and informed caregiver if they had taken the medicine or not. Some other studies [13]–[15] discussed the smart medication systems that would help patients who require medications several times a day. These devices would deliver medication in the proper chronological order and at correct time intervals.

Again some studies were conducted focusing on hardware systems. For example, an IOT based wearable ECG wireless sensor system was proposed in [16] which monitors whereabouts of Alzheimer's patients and triggers alarms to caretakers in case of emergencies. The use of pervasive computing technology to provide better live-at home facility for the elderly citizens are discussed in [17] and [18]. However, their system neglected the possibility of the outdoor experience and specific cases of visiting outdoor by the old people. In

TABLE I
SUMMARY OF PREVIOUS WORKS

References	*Technology*	*Objective*
[9]	Internet based technology	To give video reminder about daily activities to the patient
[12]	Real time clock, timer, sensor to detect presence of bottle, audible alert	To work as a medication reminder and overdose safeguard
[13]	Computer controlled medication dispensing system	To ensure the proper medication and timing
[15]	Mechanical technology	To indicate the number of pills that has been taken
[16]	IOT based wearable ECG wireless sensor	To monitor whereabouts of Alzheimer's patients and trigger alarm in case of emergencies
[17]	Voice interface, smart phone, ultrasonic location interface	To make the patient do their daily works and taking care of patient's medication
[19]	Multi-agent systems together with the use of RFID technology	To guarantee that patient is getting the right care from the assigned nurse and doctor
[20]	Electronic pedometer	To monitor a person's movement and show heart rate
[21]	Sensors, wireless communication	To record the patient's movement and daily behavior
[22]	GPS and GSM technology	To track the location of patient
[23]	Microchip Wireless Technology	Tracks patient in a range

[19], researchers presented an autonomous intelligent agent for monitoring Alzheimer's patient's health properly. In [20], a fitness monitoring device was proposed that included a wireless heart rate monitor which was coupled to the electronic pedometer without any wiring. The wireless heart rate monitor provided a heartbeat signal indicative of an exertion level of the user, while a visual display was provided to display the pedometer functions and the heart rate signal. In [21], a device was described, which was attached to the patient's body, monitoring the movement and behaviour of the patient and informing the caregivers whenever unexpected or alarming incidents occurred. According to [22], real-time GPS-GSM tracking could be helpful for dementia patients to ensure their safety when they go outside of their house. In [23], authors emphasized on memory loss of an Alzheimer's patient who tends to forget things and came up with the solution of Wifi and wearable technologies. Google map-based tracking system and notification to caretaker was an efficient way to help these people.

A summary of the previous works is shown in Table I. In sum, the previous studies suggested separate modules to assist the patients from different angles. It is certain that no collaborative system was developed to help the patients integrated with physical health monitoring, smart medication system, smart tracker for lost items and locating patient both inside and outside home. In addition, inclusion of caregiver and smart phones were also missing parts of the puzzle. Thus, this research aimed to develop an autonomous system integrating all necessary features (constant monitoring, reminder for taking medicine, monitoring heart condition and finding lost items) including relatives and caregiver to make Alzheimer's patient's life easier.

III. CONCEPTUAL FRAMEWORK

A conceptual framework was proposed to develop an intelligent assistive tool for Alzheimer's patients as shown in Fig. 1. The framework consists of four modules: heart rate monitoring, lost item finder, smart medicine box and lost patient locator. The functionalities of these modules can be accessed/used from a single mobile application that can be used by the patient's caregiver or nurse. Each of these modules will perform independently to help Alzheimer's patients.

A. Heart Rate Monitoring

The heart monitoring device allows to monitor the heart rate of the patient and notify the concerned person in case of irregular heart rate. If the heart rate of the patient rises above a threshold value, the nurse/concerned person will be informed about the patient's condition. Based on the situation the nurse will take first aid measures and call on doctor in case of emergency (see Fig. 2).

B. Lost Items Finder

It is hard for Alzheimer's patients to keep track of their important things like spectacles, keys, wallet. So, a tracker is attached to their important accessories so that whenever they lose something, they can find it using a mobile application which will buzz an alert to that accessory (see Fig. 3).

C. Smart Medicine Box

Alzheimer's patients might forget to take their medicines on time. Thus, continuous monitoring of patient's medication is another vital thing. Whenever the patient will take medication, smart medicine box will activate a WiFi module and send data of medicine intake to server. If the patient does not take medication on time, then a text alert will be sent to the concerned person/nurse (see Fig. 4).

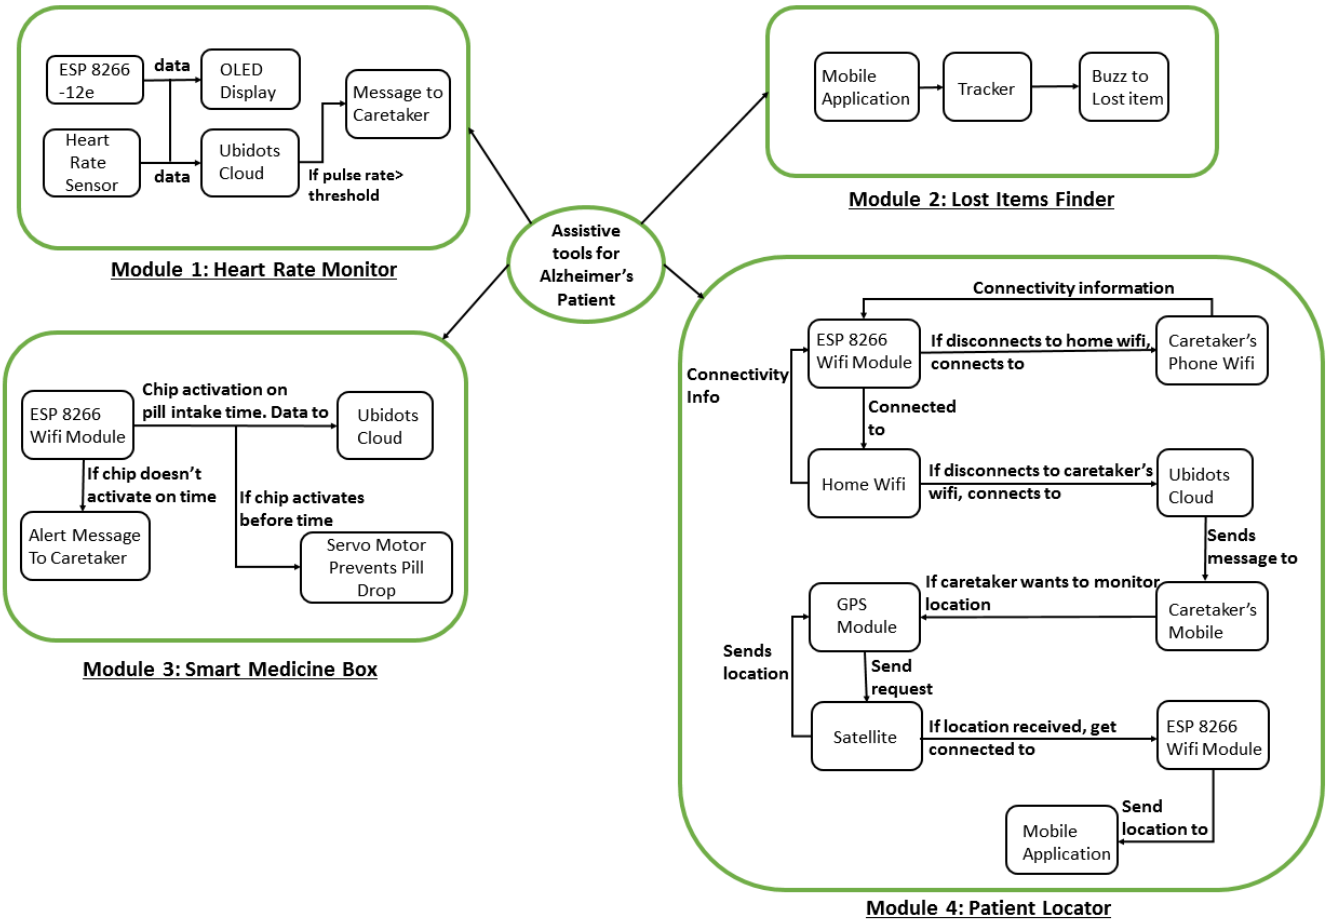

Fig. 1. Conceptual framework of the proposed assistive tool.

D. Lost Patient Locator

If Alzheimer's patient goes out of home unattended, he/she might get lost. The GPS-WiFi tracking system will always keep track of the patient's whereabouts. If the patient goes out of boundary line of the house or is far away from their caretaker, the caretaker will be notified by a text alert and will be able to continuously monitor patient's location through a mobile application (see Fig. 5).

The four individual modules creates such a system environment for the Alzheimer's patients so that their medication and health is on check, they can easily find necessary items if lost and their whereabouts and location can be tracked. It also helps the caretaker of the patient as the system makes sure the patient is always within reach and does not get lost which is a common scenario in case of Alzheimer's patient.

IV. Developing The Assistive Tool

The assistive tool was developed in two parts: hardware (see Fig. 6) and a mobile application. The required hardware components are shown in Table II. The Ubidots cloud platform was used to develop the mobile application. The mobile application holds the monitoring and assistive control of four features that include patient locator, smart medicine box, heart rate monitor and lost items finder. Fig. 7(a) portrays the home screen of Alzheimer's assistant application.

(a) Patient locator - The GPS tracking system was used to keep track of Alzheimer's patient's movements. The tracking system was divided into phases. In the first phase, if the patient goes outside of home with his/her caretaker and gets lost, the caretaker can know the patient's location through a mobile application (see Fig. 7(b)). The GPS module continuously fetches the location of the patient with latitude and longitude and sends the data to caretaker's mobile application via WiFi module.

TABLE II
Required Components of the System

Module	*Components*
Heart Rate Monitor	Esp8266 12e,Pulse sensor, OLED display,Battery, Wires
Smart Pill Box	Esp8266 12e,Servo Motor,Batteries and other power sources,OLED display,Wires
Lost Items Finder	Piezo buzzer, Hc-05 Bluetooth module,Arduino Uno,Battery
Lost Patient Locator	Esp8266 12e,Neo 6m GPS tracker,Battery

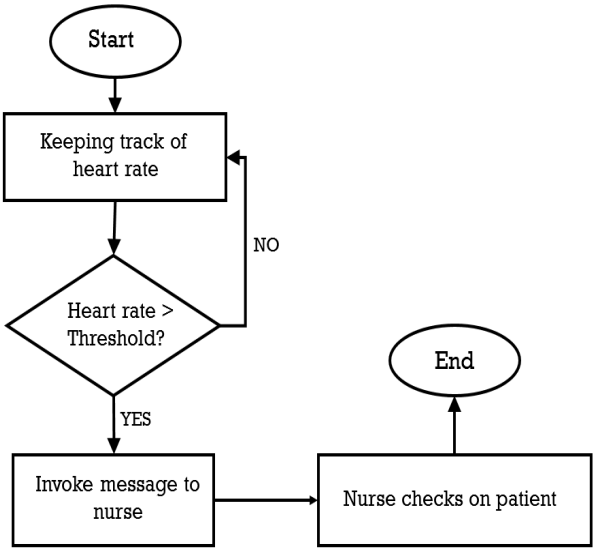

Fig. 2. Heart rate monitor

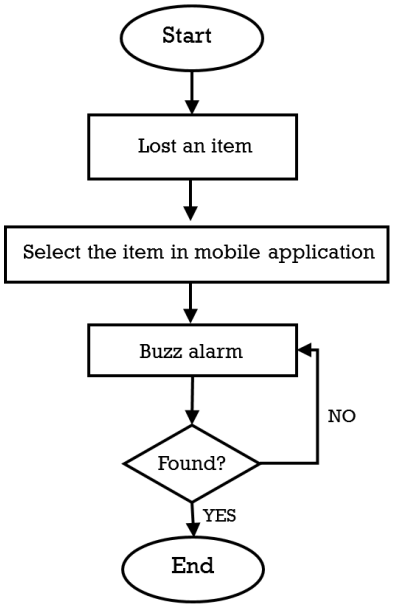

Fig. 3. Lost item finder

The second phase is that, if the patient goes outside of their home alone, the caretaker will be informed through a text alert and can see the patient's location through the application. This is done by an ESP-12E Wifi module which is also connected to the home Wifi. Whenever the patient steps outside of their home, the Wifi module will try to connect with caretaker's mobile network. If it fails to connect, it assumes that the patient has gone outside alone and so it sends a message to the caretaker's mobile to notify him/her.

(b) Smart medicine box - A smart medicine box was developed to keep track of the pill intakes by the patient. Whenever it is time for the patient to take medicine, the

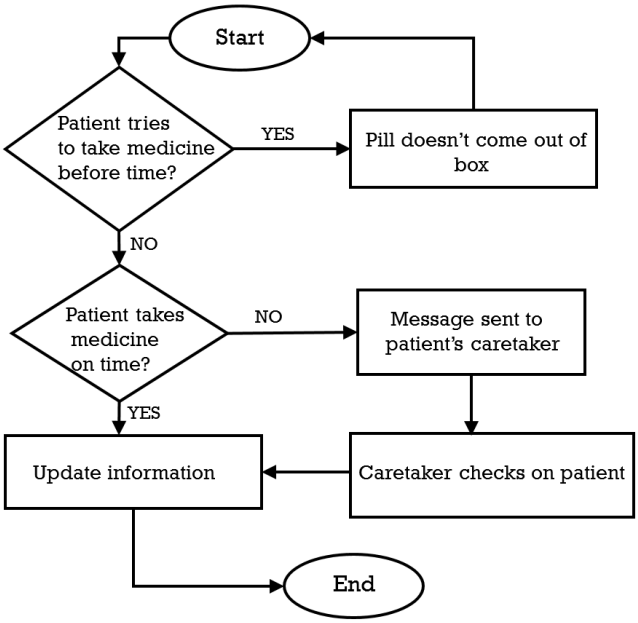

Fig. 4. Smart medicine box

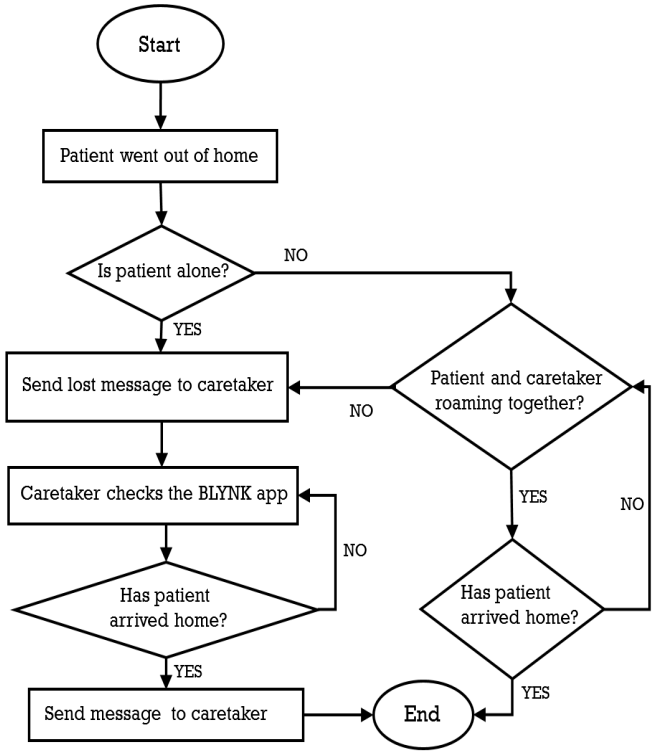

Fig. 5. Lost patient locator

medicine box will automatically open. Also, a buzzer will make sound to remind the patient that it is pill intake time. If the patient still does not take medicine, then an alert message will be sent to patient's caregiver. After the patient takes medicine, the box will be closed again. It will again open

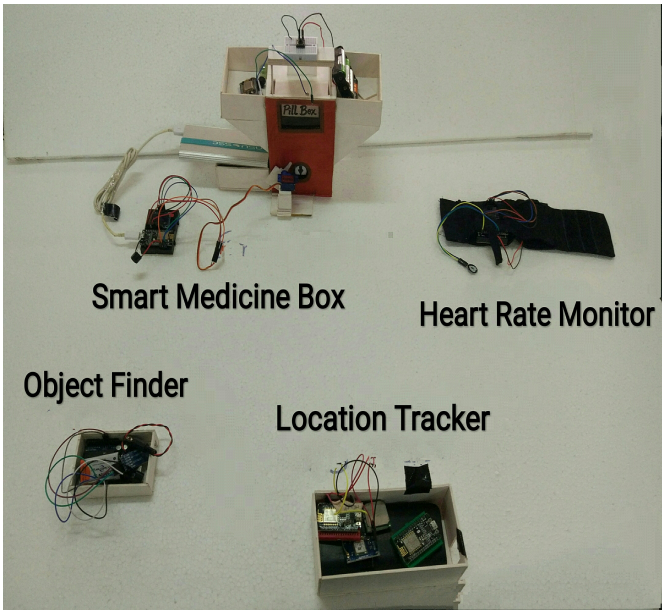

Fig. 6. Hardware parts of the proposed system

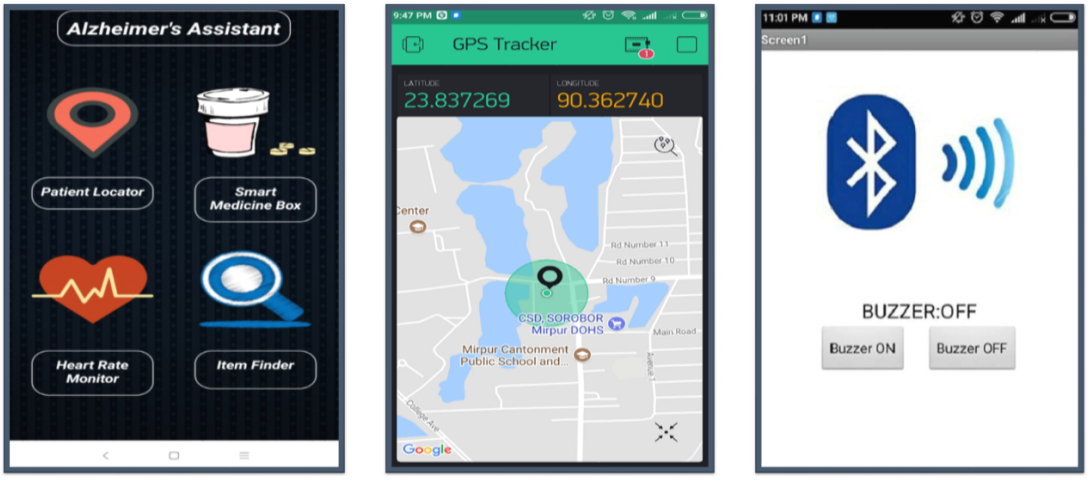
when the next pill intake time will come. An OLED display is also attached with the medicine box that displays the time remaining for next pill intake.

(c) Heart rate monitor - The heart monitoring system takes the pulse rate of the patient through pulse sensor attached to patient's fingertip. If the Heart rate exceeds a threshold value (e.g. 150 BPM) immediately a message will be sent to the caretaker.



(d) Lost items finder - Alzheimer's patient loses their belongings very easily. The object finder helps the patient to find the lost items. If the lost items are at Bluetooth range of their mobile, the application (see Fig. 7(c)) will ring a buzzer. With the help of the application and by following the sound the lost items can be found.

V. Demonstration and Evaluation

A Focus Group Discussion (FGD) [24] was carried out to evaluate the performance and usability of the proposed assistive tool. The FGD session was replicated with randomly selected 10 final year under-graduate students and 5 faculty members. During the FGD: firstly, the proposed tool was demonstrated; after that we gave them opportunity to explore and use the tool for 20-30 minutes. At the end, participants were asked to provide their opinion about the system's functionality, usability and usefulness. 13 out of 15 (87%) participants found that the system performs accurately each function, while all of them (100%) were opined that the system was easy-to use. Some of them suggested to include more features related to patient's health, while few other participants suggested to improve the safety of the device by putting the circuits inside a box.

VI. Conclusion

In this paper, an assistive tool was designed and developed for Alzheimer's patients. In respect to the earlier works, this research contributed in two folds: firstly, several features are integrated in a single system, and secondly, a mobile application was developed to utilize those features effectively from a single platform. Thus the proposed system provides an integrated round the clock service to the patients both in home and outdoor. Alzheimer's patients and the caregivers of patients will be greatly benefited from the system, since the system will provide support for constant monitoring, provide assistance for taking medicine, look after the heart condition of the patient, and help to find patient's belongings whenever needed.

(a) Home screen of Alzheimer's assistant app

(b) Patient locator

(c) Item Finder

Fig. 7. Alzheimer's assistant app

However, there are still certain limitations of this proposed system. The system was built as a prototype. It was developed in an academic environment and thus no evaluation study with real-users were obtained against it. Also, the smart medicine box module does not work without a Wifi connection. These issues will be addressed in our future work. Apart from these, the system modules can be developed as wearable. Furthermore, few more features can be added to provide more medical/health details of the patient.

ACKNOWLEDGEMENT

This research was supported wholeheartedly by faculties of Department of Computer Science and Engineering, MIST. We would like to show our gratitude for their great support. The first two authors of this paper have contributed equally in terms of implementation of the proposed system, while all authors have contributed to literature review, evaluation study and writing of the article.

Abstract— In this paper, an enhanced security solution is proposed for industry grade safety vault system. Electronic security and safety have been offering robust mechanism for implementation in ensuring proper shelter of key documents and goods in offices, banks, institutions, libraries, laboratories etc. Development of various sensors have enabled systems to have preventive and corrective measures in this regard significantly. In order to deliver a concrete security solution for critically important and confidential documents and goods, we proposed an Automated Safety Vault with Double Layered Defense Mechanism. The solution comprised of an Electronic Lock driven by password verification and a Biometric authentication for users using a Fingerprint scanning and sensing tool. Both of these two layers ensured the authenticity of the user by preventing any unauthorized access to the Vault. Moreover, actions of PIR and LDR sensors would also safeguard the vault from any breakout access other than the double layered defenses by being positioned within the periphery of the vault. The system was then implemented in a prototype scope for testing and validation of the proposals. The implemented system and testing data showed that the Automated Safety Vault with all its security features had successful operation. The specification of the whole system as well as the results are documented in this paper.

Keywords—vault, locker, arduino, pir, ldr, safety, fingerprint, biometric, numeric

I. INTRODUCTION

Security is of primary concern and in this busy, competitive world, human being cannot find ways to provide security to his confidential belongings manually. Instead, he finds an alternative which can provide a full-fledged security as well as atomized. In the ubiquitous network society, where individuals can easily access their information anytime and anywhere, people are also faced with the risk that others can easily access the same information anytime and anywhere. Because of this risk, personal identification technology, which can distinguish between registered legitimate users and imposters, is now generating interest. Various attempts are made for providing security for all domiciles. Up to date, complete security is not discovered but continuous enforcement of modern day technologies can always contribute to add the next level.

In automatic security systems generally passwords, identification cards and PIN verification techniques are being used but the disadvantage is that the passwords could be hacked and a card may be stolen or lost. The most secured system is fingerprint recognition because a fingerprint of one person never matches the other. Biometrics studies commonly include fingerprint, face, iris, voice, signature, and hand geometry recognition and verification. Many other modalities are in various stages of development and assessment. Among these available biometric traits fingerprint proves to be one of the best traits providing good mismatch ratio, high accurate in terms of security and also reliable. That's why we are motivated to do this project.

Many researchers have implemented security system and continuously they are working to develop them. Crystalynne D. Cortez et.al designed a microcontroller based biometric locker system with short message service. This proposed system has implemented on finger print sensor and GSM module. Finger print sensor is used to scan finger after matching it with the saved pattern and unlock the locker. GSM module sends a text message consist of an information when an unrecognized fingerprint was encountered [1]. Another finger print-based security system has implemented which is finger print-based door locking system. If the fingerprint matches, the door will be opened automatically otherwise the buzzer connected to an audio amplifier will be activated so that the people near the surroundings will get an alert. This system has proposed by A. Aditya Shankar et.al [2]. Sheikh Izzal Azid et al. have proposed a low cost home security system [3]. In this system, different sensors have used to secure home. They have used motion sensor, smoke sensor, humidity and light sensors. Home security based on ZigBee technology and GSM/GPRS network has implemented by J. Tan, Q. Wang et.al. They implemented this system form real time surveillance and remote monitoring of the home [4]. Another wireless module based security system has been implemented by Mohd Adib B. Sarijari et al. In this system ZigBee IEEE, 802.15.4 standard has used to develop smart home environment [5]. M.K.Hossain et al have implemented a three-layer security [6]. In this security system, they have used NFC tag; fixed password and motion .To open the door these three requirements have to provide. Arduino and GSM based advanced security system has been implemented by C. Malarvizhi et al. In his system chloroform sprayer is used to unconscious the thief inside the home [7]. Another security system based on Arduino had been implemented by Saurabh Kul et al [8]. This system has implemented by using Keypad, fingerprint, motion and PIR sensor and they implemented their system in five separate parts.

Therefore, the study of all these approaches intent to solve the dire problem of security to critical systems of an institution with proper authorization. Such systems are only accessible by the designated users and not by the mass. Moreover, the solution must ensure the obstruction of all possible ways of violation of security within the periphery of the secured area. It is also expected to regulate the access to certain users divided in different using capacity groups.

II. The Proposed Solution of Double Layered Defense Mechanism

The key objective of the proposed solution is to obtain the result of collective decision making based on the data provided by multiple sensors. To attain this performance, a controller is employed to analyze the sensor data and to generate desired controlled variables in order to ensure the security of the vault. Arduino UNO platform, is a modern day phenomenon for achieving prototypes of such controlling tool with various peripherals.

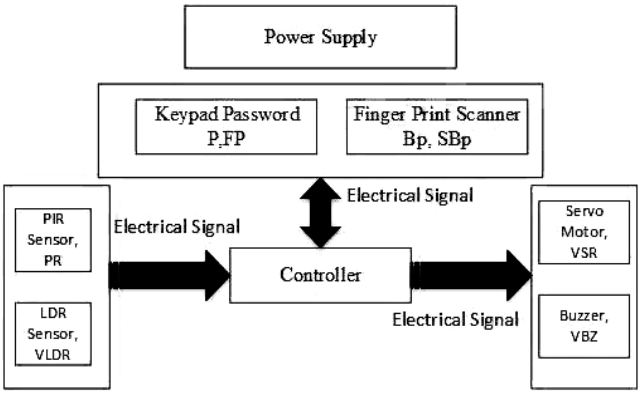

Fig. 1. Block diagram of proposed system.

As shown in fig 1, the controllers played the key role of decision making populated with the biometric and the physical motion detecting sensors and generated the controlled response or regulated to drive the servo motor of the vault door or buzzing the alarm due to unauthorized entry. However, the proposed solution does not only ensure vault security, but also provides certain degree of assistance in designing other similar prototypes involving biometric as well as physical sensing.

In addition to these conditions, the objectives were to develop a prototype featuring:

- Automated vault locking mechanism driven by actuated servo motor controlled and directed by ensuring double layers of safety.
- Allowance of access by verifying securely stored pre-registered password by the user which could confirm the primary layer of safety to the vault in terms of unauthorized entry.
- Pattern recognition of biometric data of user's fingerprint which would be pre-enrolled by scanning the fingerprints of the thumb and index fingers. The patterns were stored in the system database. It ensures the secondary layer safety to the secured vault after successful adherence to the primary layer of password protection.
- Motion detection in case of extreme violation of both layers of protective measures using PIR motion sensor and LDR light dependent sensor to assist physical intervention of security in charge from the law-enforcement agencies.

III. Components of the Prototype Implementation

The implementation of the prototype was based on the combination of the individial blocks of fig. 1. A brief detail of the components which were used to build each block to enable the system to behave to obtain the expected results are as following –

A. Power Supply: 5V DC power supply was prepared using simple bridge rectifier with ripple filters.

B. Keypad: A numeric keypad of 4x4 structures was used as the input method of password entry. Only the numeric spaces of the keypad were used for password generation and verification of the password at the time of operation.

C. Fingerprint Scanner: A biometric fingerprint scanner manufactured by Shenzen CAMA, China was used.

D. PIR Sensor: Used for motion detection within the vault premise.

E. LDR: Used for detection of any unnecessary lights within the vault.

F. Servo-motor: A 10 gram Servo motor with No load speed indicated as 0.12 seconds/60 at a rotary angle of 180 degrees. The operating voltage is with 4.8 – 6 Volts.

G. Buzzer: A locally sourced buzzer used outside the vault premise to alert the security enforcement personnel about any unauthorized entry into the vault.

H. LEDs: Used as Status Indicator LEDs (SIL), placed above the vault door for indication of modes of operations as mentioned in table III.

I. Controller: Two Arduino Uno hardware solution packs were used as the controlling unit of the proposed solution which initiated all the processes indicated in fig. 2, 3 and 4.

IV. Working Principle of the Proposed Solution

As already mentioned in section II, the controller served as the brain of the proposed system which being specified with the sensors' data, set the system trajectory to follow security compliances. Moreover, the components as mentioned in section III, were arranged in such a manner that the controller was driven to follow three separate yet inter-connected algorithms each gathering the sensed variables which are listed in table I. All the sensors delivering the deciding factors to operate and ensure security of the vault are segregated in three layers as well.

TABLE I. SENSOR DETAILS

Sensors	Sensed Variables	
	Variable	*Reference Values/status & Output type*
PIR	Motion_detect	1
LDR	Light_detect	Logic, LOW
Keypad (initial configuration)	Prestored_password	CHAR, ARRAY
Keypad (user operation)	User_password	CHAR, ARRAY
Biometric (initial scan of fingerprint)	Prestrored_finger_print	IMAGE, BIN
Biometric (user operation)	User_finger_print	IMAGE, BIN

TABLE II. LAYER DETAILS

Layers	Layer Sensors	Leading to -
Violation Status	PIR, LDR	Layer 1 or Vault Status
Layer 1	Keypad	Layer 2
Layer 2	Biometric Fingerprint Scanner	Vault Operation or Vault Status

The vault was considered to be a square shaped structure and naturally, in safe and normal operation there would be no presence of any light. Electric lighting system would still be disbaled when the vault was in the locked state and the controller would only lit up the space of the vault when it was securely accessed through Layer 1 and Layer 2 approach.

The first layer was responsible for primary authentication of a user. The verification in this cased was based on the comparison of a prestored password and a password input from the same user through a numeric keypad. The operation of Layer 1 was followed as per the flow chart shown in fig. 2. The authentication followed a procedure of password verification with a trial limit of three input from the user. Failure to provide the correct password within that limit of attempting to access the system would result in system lock down and buzzing the alarm. After successful initalizing of Layer 1, the next layer of authentication using fingerprint scanner would be presented to the user for scanning his\her fingerprint. Upon the complete match with the prestored fingerprint would activate the servo motor attached to lock of the door of the secured vault to be opened as depicted in fig. 3. However, the vault again would move to locked state ending with the triggering off the alarm. Thus the Double Layer security would be ensured for the safe and legitimate use of the vault and safeguard the content or elements to be kept protected.

Apart from the mentioned causes of safety violation, a rather emergency case of infringement could still occur due to forceful break in. If a breach in to the system occurred in such a manner bypassing the layers of password and fingerprint affirmation, a motion detector sensor (PIR sensor) was placed within the perimeter of the vault which is only active while the procedure of the Layer 1 and 2 would be missing from the controller. Similarly, a Light detection Sensor (LDR sensor) was also stationed along side the PIR sensor to assist the controller to decide any unauthorized access existance of a person/object within the secured peripherry of the vault. While any of these sensors were delivering any sensed data to the controller, the locking procedure would behave as it used to the situation of safety enforcement of Layer 1 and Layer 2. This layer of guranting the vault safety was termed as the Violation Status layer and its working principle is shown in fig. 4.

Along with the conditions to switch on or off the buzzer to monitor the security of the vault, a LCD display was also attached adjacent to the door of the vault, in the right side and the numeric keypad as well as the fingerprint scanner was situated in the opposite side at the same elevation. On the other hand, three LEDs were placed at the top of the locking door which indicated the operational modes of the vault and are termed as Status Indicator LEDs (SIL) in this report which are detailed in table III.

TABLE III. MODES OF OPERATION

Modes	SIL	Operational Status
V-111	GREEN	Vault “SECURED”
V-A	BLUE	Vault “UNDER USE”
V-0	RED	Vault “SECURITY BREACH”

V-111 indicated that all the layers and violation status procedures are active and the vault was secured. In contray of that, V-0 indicated that some kind of violation of any of the security feature of the vault had occurred and would update the ooperational status. However, V-A would mean that the vault was being used by a user following both layers of access and it would remain so till the user had completed the requirements of accessing. The switch from V-A to V-111 occurred after the user came out of the vault by mechanically opening the door from the inside and securing it again till the SIL was updated as per the status of V-111. In any case of delayed update between V-111 and V-A after mechanical lock was initiated, the system would again move to V-0 and follow the operation of breach as per vault violation rules shown in fig. 4.

V. OBSERVATIONS FROM THE IMPLEMENTATION

The proposed model was implemented as a prototype for validation of the working criteria to ensure the safety of a vault using double layers of security. The model was built as per the block diagram outlined in fig. 1. The controller was programmed according to the algorithms presented in fig. 2, 3 and 4. The door of the vault operated as per the modes of operation already discussed in earlier sections, following table III. The vault security was tested by instigating forced breaking in as well as inputting false biometric and numeric authentication parameters. In all those scenarios, the buzzer of the system was set off and operational status got reconditioned through the SIL. For the proper and natural operation of the vault security, user verification tools of password protection and biometric sensing were investigated which assured that the prototype was functioning with all its attributes and protocols of double layer security being commissioned.

In fig. 5(a), the implemented prototype can be seen with all the peripheral components and the vault door being energized by the servo motor. The SIL are indicating the states of operation as per the categories mentioned in table III. Rest of the components, including the control unit as well as the motion and light detectors for the detection of security breach were placed within the premise of the vault of this prototype.

All the states of operation indicated by the SIL as well as the texts of LCD display were shown in fig. 5(b), fig. 5(c) and fig. 5(d) respectively.

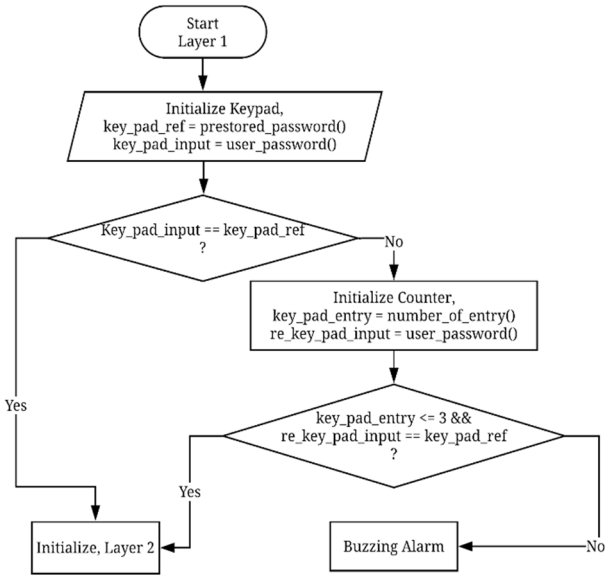

Fig. 2. Flowchart of primary layer (Layer 1) of vault security.

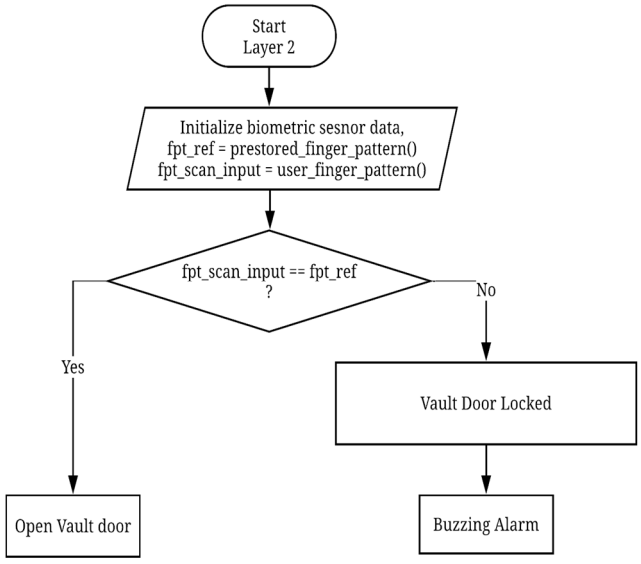

Fig. 3. Flowchart of secondary layer of vault security.

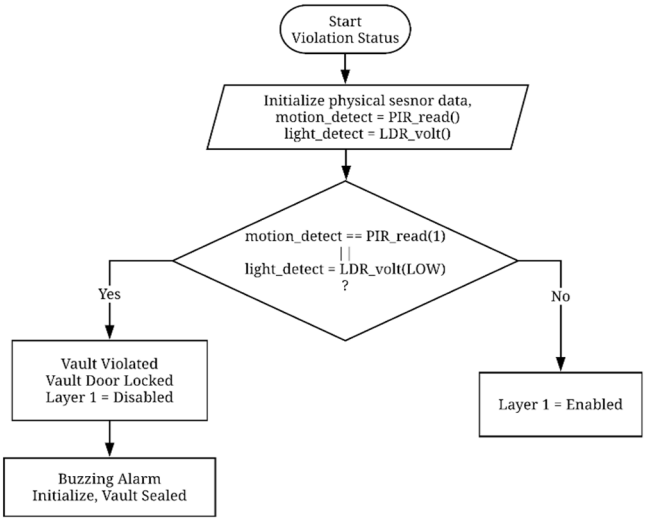

Fig. 4. Flowchart of continuous violation status verification.

The vault door can be noted to be in operation with SIL indicating the BLUE light being after successful entry of numeric password and verification of biometric data through fingerprint scanner as the system prepared itself to be in V-A mode of operation. A forced break-in was performed to test the V-0 state which was also properly working due to the adequate detection of motion and illumination by the PIR and LDR modules respectively. During the user's access of the vault, the door was kept open at an angle of 90^0. After the secured access, the user is required to lock the vault door using the keypad by pressing the "*" key. To initiate the access, the system needed to be enabled by pressing "#" key of the keypad.

In fig. 6, the control unit components can be found installed within the vault premise of the prototype including the PIR sensor and LDR module.

All the components were used and configured according to manufacturer's specification. It can also be added that the prototype was implemented in a very reasonable budget. The cost of implementation can be found in table IV which can be scaled for commercial manufacturing.

TABLE IV. COST OF IMPLEMENTATION

Components	Manufacturer	Cost (in BDT)	Cost (in USD)
Fingerprint Scanner	Shenzen CAMA	2100	25.07
LCD Display 16*2	Shenzen Shanhai	150	1.8
PIR	Ningbo Best Group	90	1.07
LDR Module	Fut-electronic Tech. Co.	120	1.43
Arduino Uno (2 units)	Sparkfun Industries & Adafruit	800	9.55
Keypad, Cables and accesories	Locally sourced	350	4.18
Total:		3610	43.10

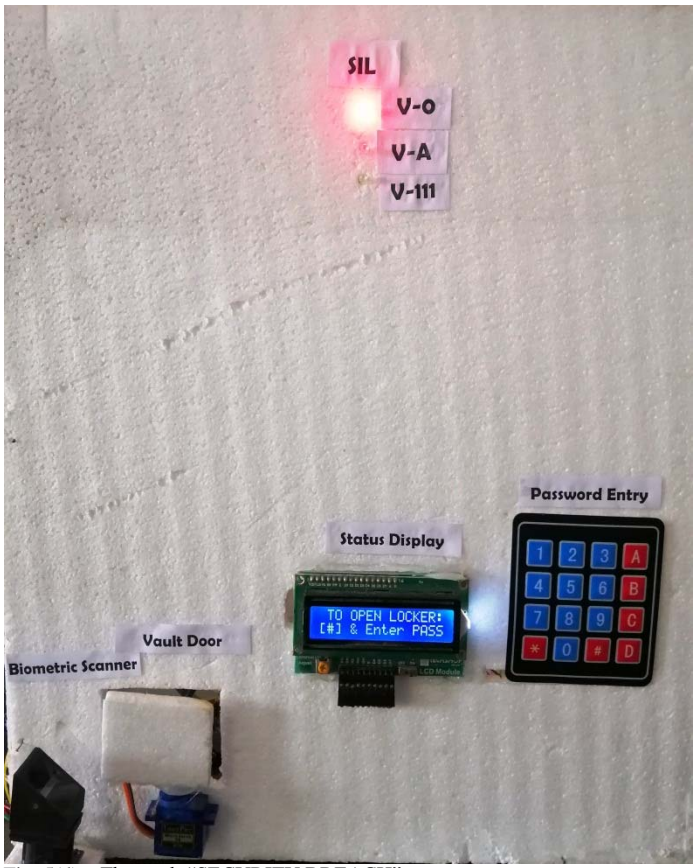

Fig. 5(d). The vault "SECURITY BREACH" state

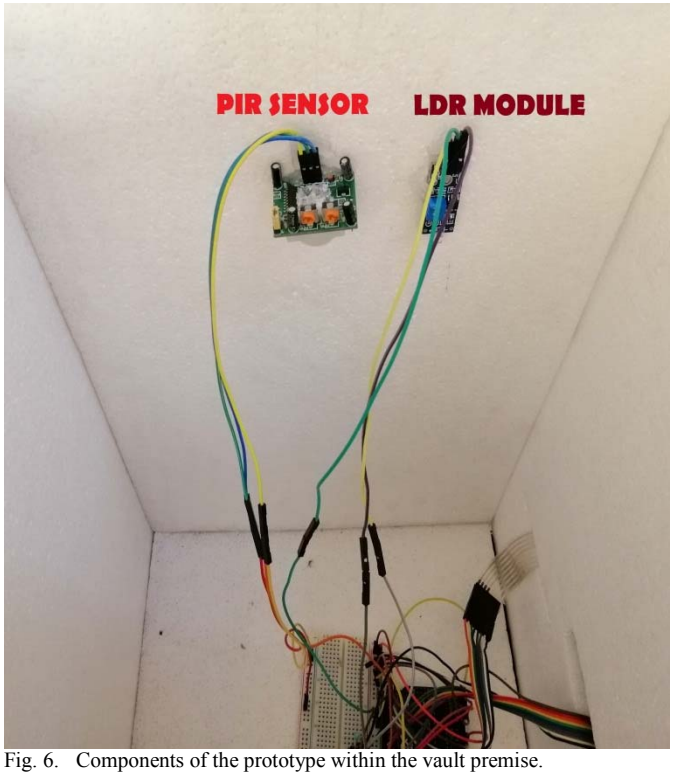

Fig. 6. Components of the prototype within the vault premise.

VI. Conclusion

Secured vaults are a basic requirement in various industrial scopes of financial, educational, management institutes and many more. In This paper, the design and implementation of a prototype of an automated vault door locking system is presented which warrants double layer of security. It ensures the proper user of the vault by securing the door with numeric password and biometric authentication. It monitors the conditions of operation of the vault from both the inside and the outside by employing several sensors which are continuously feeding information to the controller of the proposed system to confirm the robustness in terms of rightful access and security of the contents within the vault. The entire system can be easily managed with all the status updates being reeled by the controller to the administrators eliminating the unforced reasons of human errors. Implementation at a reasonable budget can also be mentioned as another beneficial aspect of the system. The observations of its operation are very encouraging to provide an easy solution to a sophisticated and unavoidable problem faced by various institutions which is quite user friendly. Furthermore, accessing the sensor data for remote monitoring, administering and handling the breach circumstances are being considered for future implementation using the vast dimensions added by IoT and cyber-physical system models. In that spectrum with enormous amount of capacity to process and store big data, an enhanced state-of-art vault door locking system is being researched and developed by the authors.

***Abstract*— Among many of human disabilities, blindness is a very common and unendurable one. Different techniques have been established to define the degree of vision defect and visual deficiency. To minimize the sufferings of visually impaired people various research works have been carried out in recent years. But still, there are a lot of aspects yet to be explored in this field. Our motive of the research work is also to lessen the sufferings by developing a cheap and easy to use the device to assist the visually impaired persons Hence we have developed a microcontroller based smart cane to assist the blind The smart cane can detect all obstacles about 180 degrees range around the direction of moving of a blind person. As soon as an obstacle is detected, it generates a voice message to warn the blind instantaneously. The device re-charging facility is the most interesting feature of our research work. An arrangement of raw magnets produces mechanical rotation which in turn produces sufficient backup power from a small DC motor. In addition to this, we have used GSM module with a panic button for getting the current location of crisis situations.**

Keywords—Cane, ATmega-2650, Ultrasonic Sensor, Speaker, GSM, Moisture Sensor, Magnets, Generator, Rechargeable Battery.

I. INTRODUCTION

Blindness or visual impairment is a major issue that has been affecting many people around the world. According to the World Health Organization (WHO), an estimated 285 million people live with vision Impairment: 39 million are blind and 246 million have moderate to severe vision impairment [1]. People who suffer from a severe reduction in vision that can't be corrected with conventional means, such as refractive correction or medication and reduces a person's ability to function at certain or all tasks. Hugh Herr said,

"Humans are not disabled. A person can never be broken. Our built environment, our technologies are broken and disabled. We the people need not accept our limitations, but can transcend disability through technological innovation."

There is a large number of problems associated with simple canes or guide dogs [2]. A simple cane offers a limited preview range in which the user has to be very careful and saunter. Use of attendant dogs is also not appropriate for all the visually impaired people because they require training and coordination with dogs and also it is not reliable. But nowadays we can see, there are so many techniques, and devices have been developed, which help these persons to move freely even in a dynamic environment [3][4]. Still, these researches existed some restrictions, as some of them can't be utilized for indoor space [5]-[10]. The cane consists of a circuit board containing an Atmega-2650, inputs from sensors, speakers for voice commands, GSM, magnets, and generator as a source of power generation and a rechargeable battery. It can only be operated by the possessors as the Microcontroller is code protected. It also can serve blind people to detect obstacles, road holes by giving voice commands.

After surveying the walking speeds for visually impaired people [11][12], Clark-Carter, et al. presents the average walking speeds for visually impaired is 1.61 m/sec [11] and Nakamura shows that the walking speeds for late blind and congenitally blind are 1.11 and 0.86 m/sec, respectively [12].

In our design, we have incorporated some new features that were not been used previously. It is equipped with battery recharging capability. It can detect obstacles in a wider range. It also provides sufficient information about the obstacle height to avoid any collision. Through its panic button feature, it can promptly send its current location information to another person to get external help quickly whenever necessary. While ensuring all these essential features the cost is not increased much and it is still very user-friendly.

The paper is organized with the following sections. In section II we have observed previous works on this type of projects. The proposed method is presented in details in section III. Our measured output accuracy is presented in section IV under experimental accuracy subheading. And finally, in the Conclusion part we have summarized our works and purposes.

II. RELATED WORKS

After World War II, people started to develop electronics devices to help disabled peoples. The 1st step towards smart stick was detecting obstacles in front of visually impaired people. Nitish Sukhija proposed A Smart Stick for Blind Man, which contains Ultrasonic Sensors, IR Sensors, and Atmega8 microcontroller unit. The model follows a specified path [13]. Mithiles Kumar proposed a system which was A Low-Cost Smart Stick for Blind and Partially Sighted People. They used ultrasonic sensors, infrared sensors, water sensor, fire sensor and light (LDR) for sensing the atmosphere around a blind person, and it gives output in the form of speech instructor, vibrator, and buzzer, so both auditory and tactile feedback is provided [14]. It has a dual feedback system and easy to use. Ashraf Anwar proposed A Smart Stick for assisting visually disabled people which consists of ultrasonic, IR, and light (LDR) sensor, a microcontroller (Arduino Uno R3), buzzers and vibrators [15]. It has Voice based navigation system with fire and light sensor which assist visually impaired people more effectively. L. Dong proposed the system based on the ultrasonic sensor distance measurement method which was called DBG Crutch Based MSensors [16]. The drive of this scheme is to help blind persons in spotting and ducking the obstacles in front, left and right of the person. The system uses a package of three ultrasonic sensors. The whole system is controlled by the STC15F2K60S2 microcontroller. Other systems used light instead of ultrasounds to detect obstacles.

Some used laser, such as the C5 laser cane [17], and, later, the Teletext [18]. Other used unfocused light, usually in the infrared range; this was the case of the Tom Pouce [18]. Devices of this type generally rely on a single sensor to provide one-dimensional range information: the user orients the device in the direction she or he wants to scan and gets a distance measurement in the result, usually in the form of vibrations sound frequency or haptic feedback. The problems associated with these devices are the necessary training requires to use them [18], their cognitive load and their limited robustness. Radio Frequency Identification Walking Stick (RFIWS) was designed in [19] to help blind persons circumnavigating on their path. This system aids in sensing and calculating the estimated distance between the path border and the blind being. RFID is used to handover and accept signal through radio wave medium. An idea of a smart wheelchair named 'HARUNOBU-6' is also a blind navigation system developed by Mori et al. [20]. Here differential GPS mechanism is used as its basic principle.

The above-discussed sticks don't give a solution to pothole and stairs detection, and also if a device runs out of battery, he won't be able to find out his way without recharging. So in this paper, we are proposing the solutions for these problems along with water detection, ultrasonic sensors, magnets & generator.

III. PROPOSED METHOD

The block diagram of the proposed method shown in **Fig. 1** consist of ATmega-2650 Microcontroller, Seven organized Ultrasonic Sensors (Six for obstacle detection and one for hole detection), Moisture detector (for detecting mud and water), Amplifier (for magnifying voice output), Headphone (as a hearing device), Vibrator (to notify through vibration), Rechargeable Battery (to power up the device), Magnets And Generator (to recharge the battery if needed), GSM And Panic Button (to notify the lover ones in crisis).

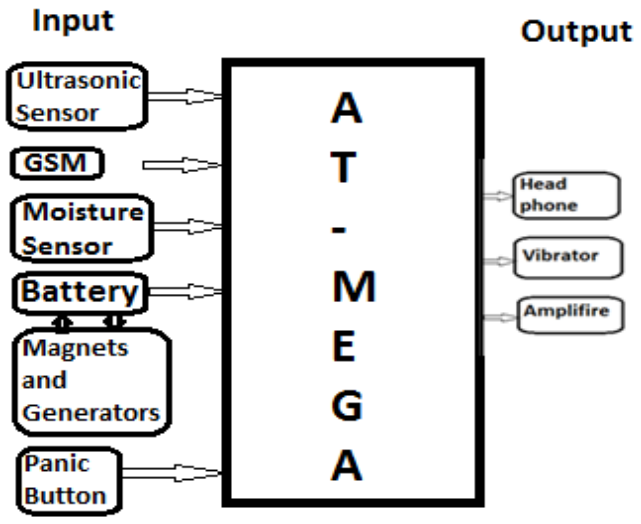

Fig. 1: Block Diagram of Proposed Cane

Here Ultrasonic Sensors, Moisture Detector, GSM and the panic button will work as the input of Microcontroller. Then the Microcontroller will process data as given instruction and will give output through Amplifier, Vibrator, and Headphone. Here Magnets and Generator will work as the device to power up the battery. After the construction of **Fig. 1,** we get a smart cane which looks like **Fig. 2**

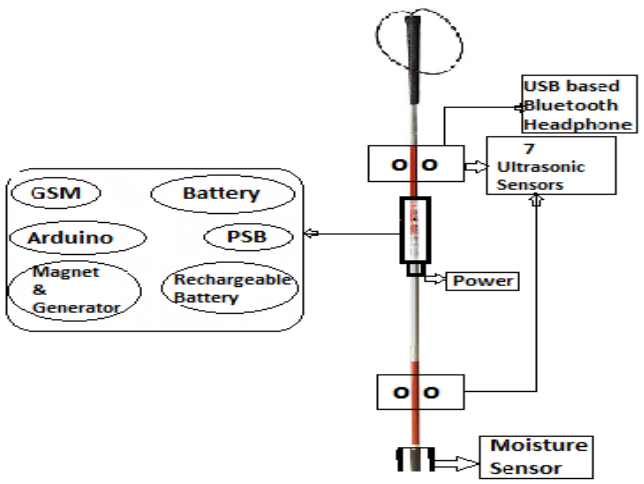

Fig. 2: Proposed Smart cane.

Obstacle Detection Procedure:

The input of the cane consists of seven ultrasonic sensors which are capable of detecting obstacles in front (about 180 degrees) of it at a range of up to 30 cm (Maximum-Efficiency). The inputs are interfaced to the Microcontroller, which determines if an obstacle is too close to the cane and hammers the output. The output consists of a vibration which provides a response and amplifier which is attached to the headphone for audio feedback.

In this process, there are too many assumptions firstly above knee level obstacle detection system in which three ultrasonic sensors (Right Upper, Middle-Upper, and Left Upper) are placed on the cane at about 3 ft. from the ground. The other one is ankle level obstacle detection system in which three ultrasonic sensors (Middle Lower, Right Lower and Left Lower) is placed on the stick at about 0.4 ft. above the ground level. The following **Table-1(a, b, c & d)** shows the variation of measurement for different assumptions.

Table-1(a): Measurement for multiple assumptions

Sensor / Case	Right upper (cm)	Left upper (cm)	Middle upper (cm)	Right lower (cm)	Left lower (cm)	Middle lower (cm)	lower (cm)
Hole	>30	>30	>30	>30	>30	>30	>30
Stair	>30	>30	>30	>30	>30	<30	<30
Front (knee level)	>30	>30	<30	>30	>30	>30	<30
Front (Ankle level)	>30	>30	>30	>30	>30	<30	<30

Table-1(b): Measurement for multiple assumptions

Sensor / Case	Right upper (cm)	Left upper (cm)	Middle upper (cm)	Right lower (cm)	Left lower (cm)	Middle lower (cm)	Lower (cm)
Above 3ft. heighted object (Front)	>30	>30	<30	>30	>30	<30	<30
Above 3ft. heighted object (Right)	<30	>30	>30	<30	>30	>30	<30
Above 3ft. heighted object (Left)	>30	<30	>30	>30	<30	>30	<30

Table-1(c): Measurement for multiple assumptions

Sensor / Case	Right upper (cm)	Left upper (cm)	Middle upper (cm)	Right lower (cm)	Left lower (cm)	Middle lower (cm)	Lower (cm)
Right (knee level)	<30	>30	>30	>30	>30	>30	<30
Right (Ankle level)	>30	>30	>30	<30	>30	>30	<30
Left (knee level)	>30	<30	>30	>30	>30	>30	<30
Left (Ankle level)	>30	>30	>30	>30	<30	>30	<30

Table-1(d): Measurement for multiple assumptions

Sensor / Case	Right upper (cm)	Left upper (cm)	Middle upper (cm)	Right lower (cm)	Left lower (cm)	Middle lower (cm)	Lower (cm)
Hole & Object (Front)	>30	>30	<30	>30	>30	<30	>30
Hole & Object (Right)	<30	>30	>30	<30	>30	>30	>30
Hole & Object (Left)	>30	<30	>30	>30	<30	>30	>30

Pot-hole detection Procedure:

In this process, we planned to detect the holes. For that, an ultrasonic sensor is placed on the bottom of the cane and at a right angle using extra support which will look like **Fig. 3.** If the sensor senses the value more than 30 cm in distance, it will provide audio and tactile feedback through headphone and vibrator.

Table-2: Practical VS Theoretical value.

Theoretical Value	Practical Value
57 cm	55.6 cm
Our accuracy of measurement is **97.5%**	

We have measured both practical and theoretical values. The theoretical calculation is shown in **Measurement and Fig. 4.** Comparing these values we got some slight deflection between them.

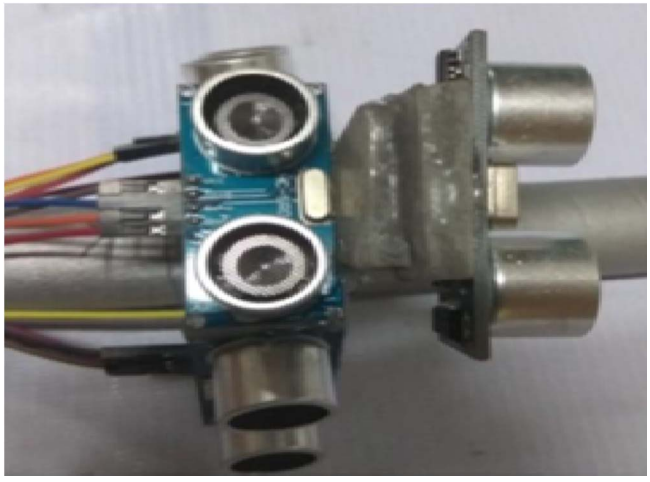

Fig. 3: Holes Detection

Measurement:

We can measure the holes from safe distance. Theoretical measurement:

$$\sin 30 = x/105 \qquad \cos 30 = z/5$$
$$\Rightarrow x = 52.5 \text{ cm.} \qquad \Rightarrow z \simeq 4.5 \text{ cm}$$
$$\text{So, } S = (x+z) = 57\text{cm.}$$

We got the above calculation from **Fig. 4**

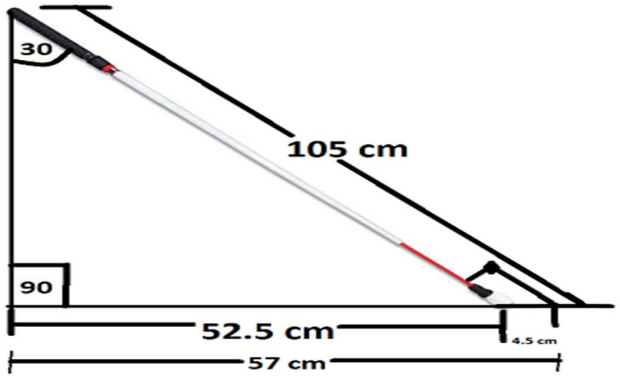

Fig. 4: Measurement of holes detection.

Moisture Detection:

We've placed the moisture detector at the bottom of the cane to sense water or mud. The sensing range of the detector is almost 3.7 cm. If the sensor detects water level or mud it alerts the user providing audio feedback at the same time the moisture sensor can declare the property of the soil such as electrical resistance, dielectric const. or interaction with neutrons as a proxy for the moisture content. It can also detect environmental factors like soil type temp. (10 -30 degree Celsius) or electric conductivity. **Fig. 5** shows a demo of moisture detection.

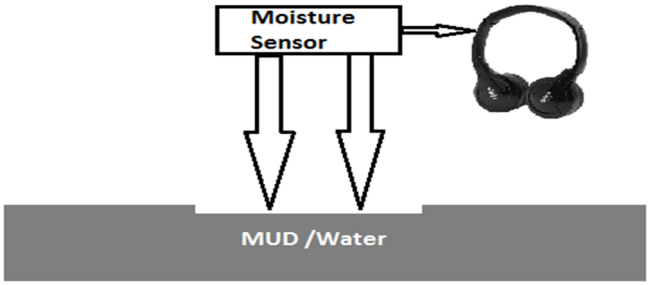

Fig. 5: Demo of Moisture Detection

GSM System and Panic Button:

Actually, we're using a function named Panic Button which is directly connected with GSM module. If anyone pushes the panic button in crisis GSM Module will turn on and send the location of the person to his/her loved ones. Information comes through a massage which is shown in **Fig. 6.**

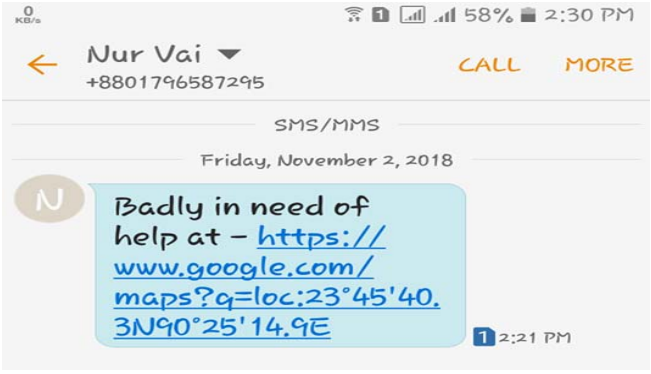

Fig. 6: Massage from the device when needed.

In the above figure, we can see the message of a Visually Impaired person with his/her exact location. The message was sent from the cane because of activating the Panic Button.

Backup Power Generation:

We're using a rechargeable battery which gives us 5v output and it is directly connected to the **Vin** of ATmega-2650. As we know the battery isn't sufficient to provide long term service (10-12 hours). So, we've thought about a backup plan to recharge our power source. We've used the magnetic field and the attraction and repulsion between two raw magnets. For this magnetic characteristics, we are able to rotate our generator which will create Mechanical Energy. It will be automatically converted into Electrical Energy.

When the battery of the cane is lower than 50%, User of the cane will be notified through the vibrator. Then the user has to press a button which will turn on the reproduction system. After this process, we got a measurement of voltage production which varies with the speed (rpm) and size of the generator and magnets respectively (such as 3.78, 4.9, 5.53, 6.3, etc). We've converted the gained voltage into a constant 5V by taking help from POLOLU S7V7FS module [21]. The module schematic is taken from POLOLU website [22] and shown in **Fig. 7(a).**

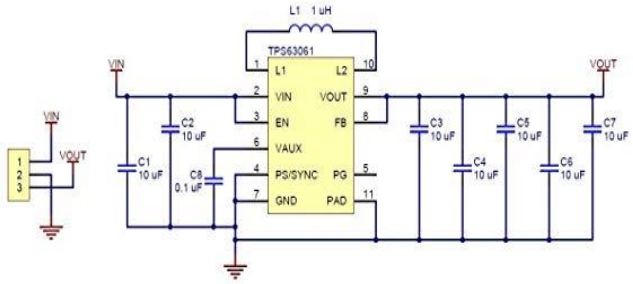

Fig. 7(a): Step up/down voltage regulator.

We've compared two types of a motor having different revolution per minute (100 & 300 rpm) and got different initial output voltages. Table (3&4) shows the measurement of the recharging process.

Table-3: Measurement of the recharging process.

Magnet Level	Initial Output (100rpm)	Initial Output (300rpm)	Voltage Regulator.	Final Output. (Voltage)
LOW	**4.9 V**	**3.6 V**	**S7V7F5**	**5**
MEDIUM	**6.8 V**	**5.2 V**	**S7V7F5**	**5**
HIGH	**9.2 V**	**6.8 V**	**S7V7F5**	**5**

Table-4: Measurement of the recharging process.

Magnet Level.	Output Current (100 rpm)	Output Current (300 rpm)
LOW	**3.60 mA**	**2.10 mA**
MEDIUM	**4.20 mA**	**2.50 mA**
HIGH	**5.66 mA**	**3.20 mA**

The whole tiny system looks like Fig. 7(b) in real life which becomes the ultimate back up [23] function for our power source.

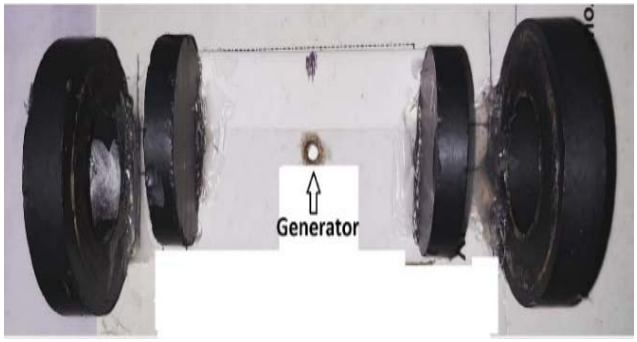

Fig. 7(b): System to recharge the Power Source.

- GENERAL DESCRIPTION OF SENSORS

Ultrasonic Sensor:

An Ultrasonic sensor is a device that can measure the distance by using sound waves at a frequency of 40 Hz. We have used HC-SR04 in our cane which helps us to determine the possible distance between the stick and any objects. The distance that one can possibly measure with the non-contact object is about from 2cm (0.8 inches) to 3 meters (approx. 118 inches). The module consists of the control circuit, ultrasonic receiver, and transmitters. It has four pins VCC, GND, Trigger, and Echo. The basic working principle [24] is: (1) It uses IO trigger for at least ten microseconds high signals; (2) The Ultrasonic sensor module repeatedly sends eight 40 kHz wave and sense if there is a signal comes back; (3) If the signal comes back in high level, time of high output IO duration is the time from sending a wave to receiving it back.

Distance = (high level time * speed of sound (344m/s))/2 [25].

Table-5: Working range of HC-SR04 [26].

Working Voltage	DC 5V
Working Current	15 mA
Working Frequency	40 Hz
Max Range	4 m
Min Range	2 cm
Measuring Angle	15 degree
Trigger Input Signal	10 us TTL pulse
Echo Output Signal	Input TTL lever signal & the range in proportion.
Dimension	45*20*15 mm

Moisture Detection:

Moisture detector is one kind of a sensor which determines the ratio of hydrogen and oxygen and measure the moisture of the surface if there is any water on the ground or not. This concerns visually impaired people to detect water and mud. It gives visually impaired people the confidence to move freely.

Global System for Mobile communication:

Global System for Mobile communication (GSM) is a second-generation cellular network usually used by mobile devices or digital devices which includes microcontrollers. GSM (SIM900A kit) have used for the communication purpose. The onboard resources in it are Serial port circuit (with protection) Antenna interface circuit (SMA bend female port) SIM card circuit (flip SIM slot) 4*3.5 fixture hole 4pcs SIM900A serial port output terminal. It has improved spectrum efficiency, international roaming, compatibility with ISDN (Integrated Services Digital

Network), SIM phone book management and short message service (SMS).

IV. EXPERIMENTAL ACCURACY

We've compared the theoretical and practical values of random distances using the Ultrasonic Sensors that were used in the cane. We saw that the values were too close but not 100% accurate. We made a graph after taking several values from random distances which are shown in **Fig. 8**. From the graph, we can see there are some floating errors (%) in between one to three percent. So,

Accuracy = (97 to 99) %.

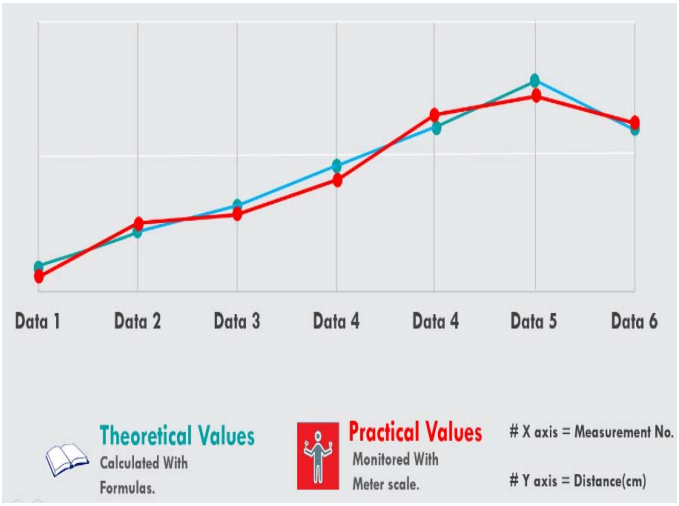

Fig. 8: Comparison between Theoretical and Practical Values

V. Conclusion

Our proposed cane removes most of the hurdles during movement of visually impaired people all over the world. Especially the blind people in the underdeveloped and developing countries will be benefited most as the cane is very cost effective and easy to use. In this system, we've used the most available components to reduce cost and complexity. People can use or repair it whenever needed because of the availability of components. The cane is equipped with a rechargeable feature which ensures its power efficiency. The cane is designed to achieve maximum durability with a compact & power efficient structure. Maintenance and repairing procedure is also kept simple. The panic button feature not only relieves the tension of the blind person but also his relatives by promptly ensuring his location in case of any undesired crisis moment. In the future, this work can be upgraded into a more compact, lightweight and user-friendly cane. This will surely contribute a lot to make life easy for visually impaired people.

***Abstract*— Light emitting diodes are the commonly used street lighting solution nowadays. As saving energy in all aspects is the primary concern in the 21st century, researches are going on to make LED lights much energy efficient like, to make it adaptive with traffic flow and daylight intensity and some other factors. We have proposed a model using some sensors to design an adaptive and efficient lighting system with LEDs. Moreover, we have collected some real-time data for analyzing the traffic rate in three dominant type of roads in Chittagong city and found dimming time slots for the lights. Finally, we have calculated the electricity consumption cost with our model considering 10% consumption of power at dimming hours and 100% consumption at the rest of the times; which saves 88.26% of the lighting cost in comparison with conventional sodium lamps per year.**

Keywords—Adaptive Lighting System, Dimming Circuit, Luminous Intensity, Light Emitting Diode

I. INTRODUCTION

The street lighting system is one of the essential parts of the basic structure of a city. A city may have a different type of streets depending upon some basic rules like the number of lanes depending on vehicle speed and class, ease of entrance and exit, connection with other roads, flyovers, overpass, underpass etc. There are three types of routes: major arterial, minor arterial and collector roads. All the roads must have at least two street lights at the same place focusing on two opposite lanes placed on the road divider. For proper lighting at night, the light posts are usually set at 25/40/50 meters intervals depending upon the type of road. Sodium lamps (100 watts) are the most commonly used lights in a city. But it consumes much electricity for lighting the streets. Light emitting diodes (LED) are being used from the past few years instead of sodium lamps, halogen lamps, fluorescent lamps, light bulbs etc., to reduce the electricity consumption. An LED light may only consume 30 watts, which significantly reduces the cost by 70%. Moreover, it has a longer lifetime and low maintenance cost and appropriate lumens of brightness.

As the production of electricity is costly and saving from system loss of power is a crying issue; we have proposed a system of adaptive LED lights, which will switch on or off the lights depending on daylight intensity as well as will adjust brightness of light depending upon detection of vehicles or pedestrian passing by the light posts. If the system detects a moving/stopped object like a car or a human by a sensor placed for both side of the road, the light above the road will flash with 100% brightness; otherwise it will be dimming with only 10% brightness using less amount of power and hence will save a significant amount of energy.

II. LITERATURE REVIEW

Light emitting diodes (LED) are efficient, long-lasting and proper luminary for 21-century street lighting. In comparison with other lighting systems like HPSV, LED street lights were proved much efficient for luminosity regarding specific standards [1], [2]. Although LEDs can save significant power, research is still going on to make it adaptive with environmental situation and needs, for saving much more energy. A situation-based traffic adaptive street light control was proposed by T. Novak and K. Poll hammer [3], which used two different traffic adaptive dimming strategies and could save power from 35% to 50%. Some other techniques were applied to reduce power consumption based on astronomical clock and microcontroller [4] and local controllers, motion sensors, video-camera and electronic devices for video processing etc. for counting traffic [5] and controlling light intensity, with saving 65% power. Such techniques required employing some electronic and electrical devices which may cost much money. To make the system more reliant and less costly, some dimming methods were proposed over the years. The breakthrough in dimming traditional lighting systems was first introduced by G. Velasco-Quesada et al. [6], where multiple-tapped autotransformer and high-frequency switch converter dimmer system technologies were used. But for LEDs, the intensity controller system was proposed [7] based on the detection of humans and vehicles in the vicinity to the sensors used for the system. Pulse width modulation (PWM) was also employed at 25 KHz frequency for intensity control [8]. Further studies were done to control LED streetlights like multi-sensing [9],

the smart module (SM) and control module (CM) [10], different sensors with IoT [11] etc.

All the works described above, and any other papers didn't show how much money they can save, quantitatively. In this paper, we proposed an adaptive street lighting system based on ultrasonic sensors and LDRs for each LED light pole. The sensors will switch on or off the lights and control the intensity of the lights depending on the detection of moving objects near the sensors. We also have studied how vehicular movement in different types of roads can be considered for the calculation of power saving.

III. Methodology

Firstly, we have designed a model for automatic and adaptive street lighting system as shown in figure 3. We have shown that the system works perfectly with dimming conditions.
Secondly, we have arranged some specific data of vehicular movement during lighting hours (i.e., at night) in three different type of streets in Chittagong city area, in Bangladesh. We have collected data for consecutive seven days and taken mean value for a day. Then We have used those data to calculate dimming time for the proposed LED light.

A. System Design

The development of the system starts with the system block diagram as shown in figure 1.

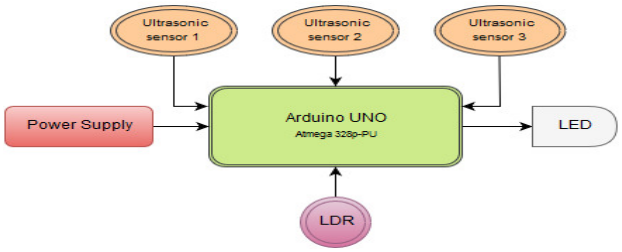

Fig. 1. Block Diagram of the system

We have declared three principal components as input for the model; these are Ultrasonic sensors, input power and LDR (light dependent resistor). Another one element that is proclaimed as the output of this system is LED. All the processes, like switching on/off the street lights (LEDs) and dimming LEDs in the absence of vehicles and humans are managed and controlled by the Arduino.

B. Hardware Specifications

Two main components are used as the input for the proposed method. LDR has been used to track out the daylight level. Its responses to daylight or any changes are measured in volt. Ultrasonic sensors have been used for tracking the vehicles and humans. When any car or human pass by the sensor range, LED will give 100% brightness.

Arduino UNO Atmega 328p-PU has been selected [12] and used for controlling the system. LED was connected to the Arduino and its intensity has been controlled by intensity module. Two levels of brightness were loaded as the command in the program for Arduino: for power saving, 10% power for lighting up in case of no traffic or passers-by and 100% power when vehicles and/or humans are passing by the road/lane.

The LDR starts the process of the proposed system. The process begins when the LDR detects no light and then LED lamps will be switched on. This system is programmed with two distinct levels of lighting. It will be switched off when the sunlight is sufficiently bright and switched on at night time when there is no sunlight. But when there is no traffic and less pedestrian, LED lamps will be dimming with 10% brightness only and will be lightened with 100% brightness when any vehicle or human pass by the lane and sensed by the sensors. The whole operation will be as below.

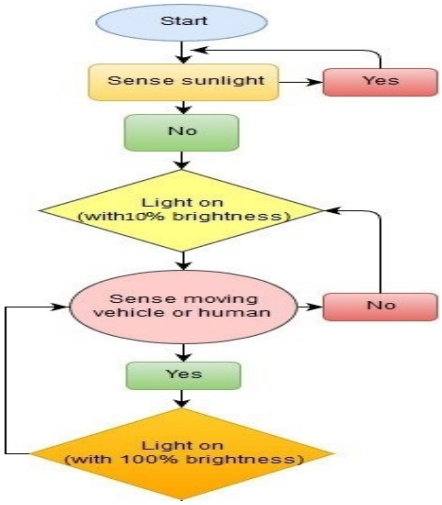

Fig. 2. The flowchart of the operation of the proposed design

IV. Implementation of The System

We have designed a prototype of the system with real-time experimentation and found it useful for our purpose, as depicted in figure 3.

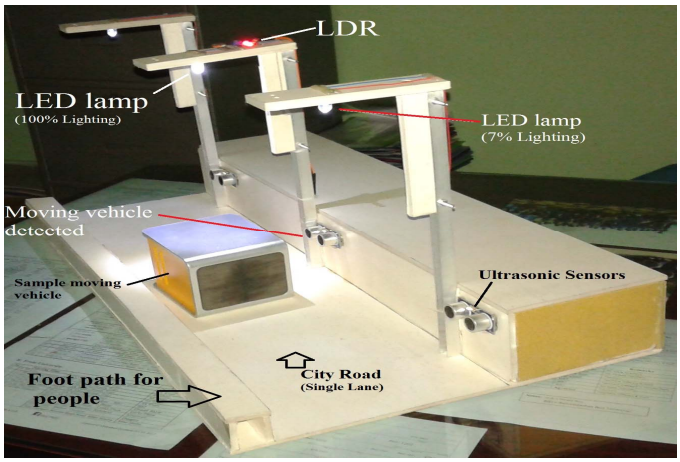

Fig. 3. Experimental setup of the system

It is clear from the figure that, LED lamps will only light up for 100% brightness when the system detects a moving vehicle or a human. Otherwise, it will just light up by 10% brightness during the absence of the car on the road and human on the footpath.

V. Data Analysis

We have collected the rate of moving vehicles in three different types of roads like Major Arterial (3 lanes on both sides), Minor Arterial (2 lanes on both sides) and Collector Roads (2 or 1 narrow lane) during dark hours (from dusk to dawn) of the day. Then we categorised the data for peak (6:00 pm to 12:00 pm) and off-peak (12:01 am to 6:00 am) times for the sake of power saving during the off-peak time of traffic.

A. Vehicle movement rate in different types of roads

Traffic for different kinds of roads has been listed in table 1. We recorded the average (from 7 days data) of vehicle movement during the dusk to dawn for a whole day for all three streets, for calculation. We listed how many vehicles moved during this time. We observed that so many cars ran on the Major Arterial from dusk to dawn. The Minor Arterial also had vehicle pressure during this time. But we found that Collector roads had a little bit pressure up to 12 pm as compared to other routes. After 12 pm, there was not so much vehicle movement during 12.01am to 6 am-midnight in the city area. The graph in figure 4 depicts the calculation.

TABLE I. Vehicle Movement Rate in Different Roads during Dusk to Dawn

Time Period	Average no of vehicles counted on		
	Major Arterial	***Minor Arterial***	***Collector***
6.00-7.00pm	7452	5004	268
7.00-8.00pm	8332	5464	240
8.00-9.00pm	7336	5380	236
9.00-10.00pm	7144	4576	204
10.00-11.00pm	6868	2052	208
11.00-12.00pm	2728	1300	168
12.00-1.00am	1584	696	80
1.00-2.00am	816	508	12
2.00-3.00am	624	272	4
3.00-4.00am	516	172	4
4.00-5.00am	580	104	0
5.00-6.00am	788	304	44

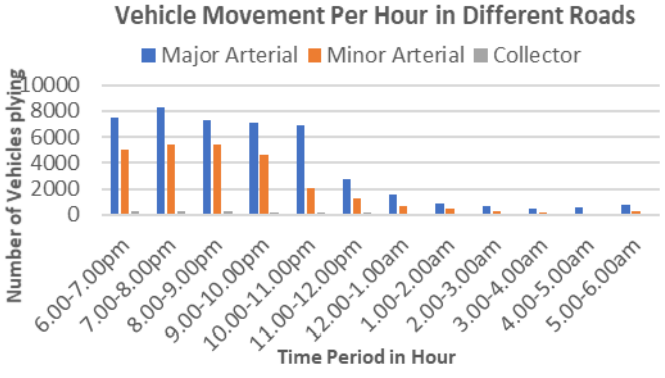

Fig. 4. Traffic movement of different roads from dusk to dawn in a day

Figure.4 shows that much traffic moves in the Major Arterial area and less traffic movement in the Collector area. From the figure, we can also see that after peak time (that means after 12 am) traffic movement in all roads decreases significantly.

B. Power Consumption

We have calculated total power consumption in all three types of roads. In present time Sodium lamps are being mostly used in all these roads. We have considered two lights for both sides of each kind of road. We also have considered the distance between two lamp posts for Major Arterial, Minor Arterial and Collector roads as 50 meters, 40 meters and 25 meters respectively.

TABLE II. Power Consumption by Sodium Light irrespective to Vehicle Movement [for 1 kilo meter]

Time Period	Power Consumption by Sodium Light in kWh		
	Major Arterial	***Minor Arterial***	***Collector***
6.00-7.00pm	4	5	8
7.00-8.00pm	4	5	8
8.00-9.00pm	4	5	8
9.00-10.00pm	4	5	8
10.00-11.00pm	4	5	8
11.00-12.00pm	4	5	8
12.00-1.00am	4	5	8
1.00-2.00am	4	5	8
2.00-3.00am	4	5	8
3.00-4.00am	4	5	8
4.00-5.00am	4	5	8
5.00-6.00am	4	5	8

According to the vehicle density per hour, Sodium Street light operates 100% brightness with constant power consumption value for each road. This is shown in table 2.

If we can replace the Sodium lamps with light-emitting diodes (LEDs), we will get the scenario, as per calculation shown in table 3 and table 4. We have programmed the system for 100% brightness of LED lights for 5 seconds, after detection of a moving vehicle or a human.

As the number of vehicles is greater than 1 for every 5 seconds in present time, the LED Streetlight operates at 100% brightness (without dimming), The ultrasonic sensors have been used to sense moving vehicles and people using the road. The recorded power consumption is shown in Figure 5 as per table 4. In this figure, the highest power consumption value is recorded 1.2 kWh from 6:00 pm to 2:00 am in Major Arterial and from 6:00 pm to 12.00 am in the Minor Arterial roads. For rest of the time, the recorded data start to decrease. Peak time is the rush hour for traffic movement as we have already seen in figure 5. So, both sodium and LED lamps consume the highest level of their power. There is no scope for dimming

the light (our proposed LED) due to the high rate of traffic movement.

TABLE III. BRIGHTNESS OF LED STREET LIGHT ACCORDING TO VEHICLE MOVEMENT RATE IN DIFFERENT ROADS DURING DUSK TO DAWN

Time Period	The brightness of LED Street Light according to Vehicle Movement		
	Major Arterial	*Minor Arterial*	*Collector*
6.00-7.00pm	100%	100%	10%
7.00-8.00pm	100%	100%	10%
8.00-9.00pm	100%	100%	10%
9.00-10.00pm	100%	100%	10%
10.00-11.00pm	100%	100%	10%
11.00-12.00pm	100%	100%	10%
12.00-1.00am	100%	10%	10%
1.00-2.00am	100%	10%	10%
2.00-3.00am	10%	10%	10%
3.00-4.00am	10%	10%	10%
4.00-5.00am	10%	10%	10%
5.00-6.00am	100%	10%	10%

Table 3 shows the brightness of LED Streetlight according to vehicle movement. In this table, we see that in Major Arterial, LED street light brightness is 10% from 2:00 am to 5.00 am, in the Minor Arterial from 12.00 am to 6.00 am, and in Collector Road LED light brightness is always 10% (from 6:00 pm to 6:00 am). The power consumption by LED lights with dimming technique is shown in table 4.

TABLE IV. POWER CONSUMPTION BY LED LIGHT (DIMMING 90%) ACCORDING TO VEHICLE MOVEMENT (FOR 1 KM ROAD)

Time Period	Power Consumption by LED Light in kWh		
	Major Arterial	*Minor Arterial*	*Collector*
6.00-7.00pm	1.2	1.5	0.24
7.00-8.00pm	1.2	1.5	0.24
8.00-9.00pm	1.2	1.5	0.24
9.00-10.00pm	1.2	1.5	0.24
10.00-11.00pm	1.2	1.5	0.24
11.00-12.00pm	1.2	1.5	0.24
12.00-1.00am	1.2	0.15	0.24
1.00-2.00am	1.2	0.15	0.24
2.00-3.00am	0.12	0.15	0.24
3.00-4.00am	0.12	0.15	0.24
4.00-5.00am	0.12	0.15	0.24
5.00-6.00am	1.2	0.15	0.24

***[Red Value Indicate Dimming]**

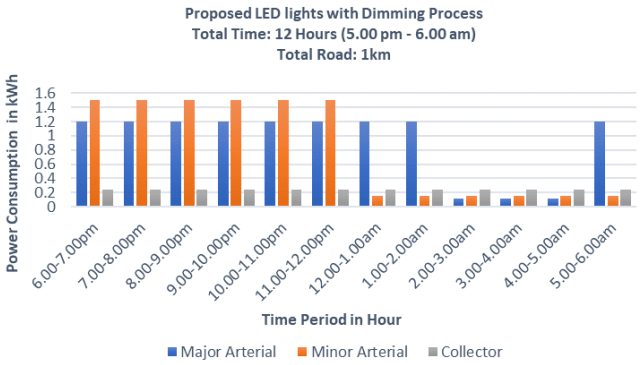

Fig. 5. Power Consumption by LED by Dimming Process

From the table 4 and figure 5, we can see that, the power consumption with the dimming operation is recorded at 2:00 to 5.00 am on Major Arterial, 12.00 am to 6.00 am on the Minor Arterial and 6:00 pm to 6.00 am in Collector roads. While the recorded data start to decrease and at the last moment it will be increased. LED light consumes less power in off-peak time because we have proposed that when traffic movement is relatively low, it (LED) will be dimming. A 30W LED light will consume only 3W, which is 10% while dimming. So, in off-peak time, power consumption will be much less.

TABLE V. COMPARISON OF POWER CONSUMPTION PER DAY PER KM

Power Consumption Duration (5.00 am – 6.00 pm)	**100W Sodium lamps**	**Proposed LED**
As per tables -2 & 4	204 kWh	23.94 kWh
Dimming Condition	Not applicable	Applied

From the table 5, we have seen that in total 12 hours, 100w sodium light consume 204 kWh per day and 30w LED light consume 23.94 kWh per day. This is because; from table 4 we can see that, the maximum power consumed by LED lamps is 1.2 kWh and the minimum is 0.24 kWh. Hence, our proposed model will save electricity cost significantly.

TABLE VI. COMPARATIVE COST ANALYSIS

Expenditure	**For calculated 1KM (in BDT)**		**For Chittagong city (3500 Sodium lamps) [13] (in BDT)**	
	100w Sodium Lamp	LED (90% dimming)	100w Sodium Lamp	LED (90% dimming)
Per day	1,570.80/=	184.34/=	32,340/=	3,795.26/=
Per month	47,124/=	5,530.14/=	9,70,200/=	1,13,857/=
Per year	5,65,488/=	66,362/=	1,16,42,400/=	13,66,285/=

VI. DISCUSSION AND CONCLUSION

From table 6, we can see how much money is needed for sodium and our proposed LED lighting systems. Now, 3,500 sodium lamps are used for Chittagong city streets [13]. We have seen that per day 32,340/= taka is needed as the expense

for sodium lighting for the whole of Chittagong city whereas using our LED light will cost 3,795/= taka only as per latest billing rate in Bangladesh [14]. Also, per month charge of sodium lighting and LED has a vast difference. Sodium lighting needs 9,70,200/= taka and LED needs 1,13,857/= taka only. Consequently, the yearly expense behind Sodium is 1,16,42,400/= taka and LED 13,66,285/= taka. So, a significant difference is apparent between using our proposed adaptive LED lights and existing sodium lights. Our system will save almost 88.26 % cost of the total consumed power of the present street lighting system of the Chittagong City in Bangladesh, as well as it will reduce the cost for any other city in the world.

***Abstract*—Steering of water vehicles is mainly dependent on the aero and hydrodynamic forces. The adverse situation caused by any of the natural disasters inhibits the movement of vehicles. During the hostile situation, the most important thing is safety. In this paper, a method to compute the optimal safe position for water vehicles during instability caused by the vulnerable swing is proposed. A 3-axis accelerometer is used to obtain the roll, pitch, and yaw angles, and using these, we derive a function which gives us the instantaneous instability of the vehicle. If the instability exceeds a predefined threshold, our proposed method calculates the safe angle to reach the optimal safe position. This method is computationally efficient and is suitable for on-board real-time implementation as well as autonomous marine robotic vehicles.**

***Index Terms*—Safe angle, Y-Factor, tilt angle.**

I. Introduction

During the summer and rainy season, along with the increasing water level in the river and ocean all over the world, a vast quantity of waves are generated by the rain or stormy weather. Due to the rapid rotation of the waves, steersman cannot understand which direction the boat needs to be headed. The safe position of a waterways vehicle is the state, in which the vehicle is most stable in terms of wind, vulnerable swing, and whirlpool – which may cause the vehicle to sink into water or displace its heading. To remain safe in the hostile situation caused by any of the natural disasters, it is necessary to find the safe position. The safe angle can be defined as the angle between the current position of the vehicle and the safe position. Thus, measurement of the safe angle is the precondition to reach to the safe position. In this paper, we propose a method of getting the safe angle due to vulnerable swing.

To do this job, at first, we identify the tilt, which exceeds the threshold values. Here, threshold values are the pre-calculated tilt angles in which the boat is in danger. It varies from boat to boat. Tilt angles are calculated from a 3-axis accelerometer. To set the threshold values, we first run an experiment on the boat. Then we determine the safe angle depending upon the threshold, the boat factors, and tilt angle. Our device is capable of measuring the safe angle dynamically.

Our contribution to this paper:

- we calculate the roll and pitch angle of different types of boats and established a relationship between them.
- we perform real boat experiment using our device.
- we propose a complete hardware and software architecture for determination of safe angle for any type of water vehicle in dynamic and unknown environment.

The remainder of this paper is organized as follows: Section II highlights on an overview of related work. Section III elaborates the principle of the measurements. Section IV and V describe the implementation of the proposed technology. Section VI delineate the experimentation and results. Finally, Section VII concludes this paper.

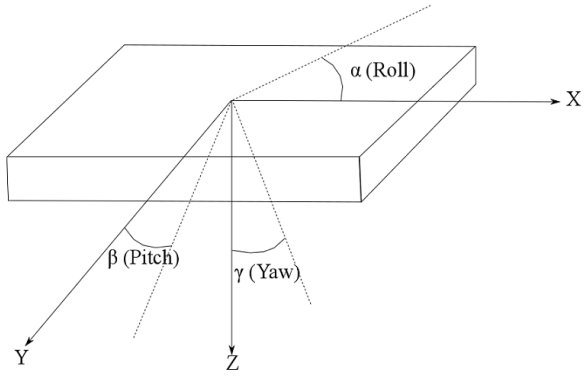

Fig. 1: Tilt angles from 3-axis accelerometer.

II. Related Works

In recent years, there were published different works based on tilt angle calculation. Among them,

Yosi et al. proposed a method to calculate the tilt and heading from an Inertial Measurement Unit (IMU) that have 3-axis gyroscopes, 3-axis accelerometers, and 3-axis magnetometers [1]. They have measured tilt values using Euler angles, the pitch (α), roll (β), and yaw (γ). By using sensor fusion algorithm they have shown that the output is likely similar to the actual value, however, the one without sensor fusion has a growth error value every step [1].

Saoud et al. present a method for calculating an optimal sailing angle that maximizes the speed of a sailboat ensuring that the heeling angle remains bounded by a pre-defined value [2]. They have shown that using this method, the heeling angle is implicitly limited to $\pm\pi/4$.

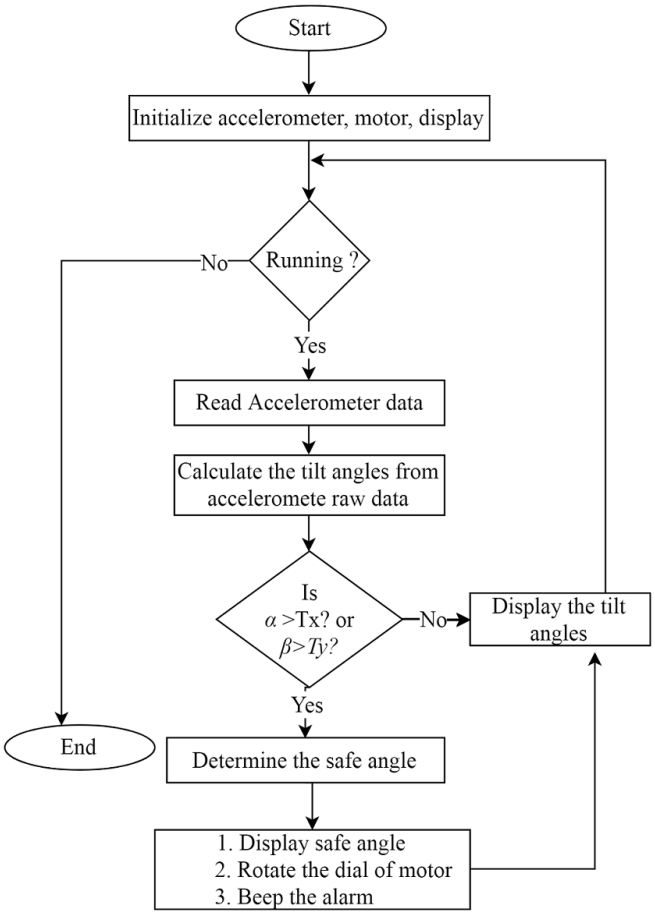

Fig. 2: System architecture of the proposed method.

Surendran et al. discussed two ways of measuring ship stability - using the available linear ship motion theory and the nonlinear theoretical model. They have obtained the solutions using the fourth order Runge-Kutta (RK) method [3]. Mainly they discussed the importance of roll angle in the stability analysis of a ship.

Furthermore, Newaz et al. described a method to generate an alarm system for waterways vehicle due to experiencing vulnerable swing [4]. They have measured tilt values using Euler angle principle. Although they have calculated threshold values, yet they did not mention the strength of boat. Moreover, they did not consider the shape of the boat. Therefore, the system can only generate an alarm in the dangerous situation, however, cannot determine the safe angle.

III. Methods

A. Measuring tilt angle

In this work, the ADXL345 accelerometer – which is a MEMS (Micro-Electromechanical System) based accelerometer, has been used to calculate the tilt angle. It is capable to provide high-precision output up to ±16g. To calculate the tilt of an object using earth's gravity, a ±1g accelerometer is enough. The accelerometer experiences acceleration in the range from -1g to +1g through 180° of tilt.

$$1g = -9.8m/s^2 \tag{1}$$

TABLE I: Output of the accelerometer for different orientation of the device.

Device position	Accelerometer reading		
	A_x	A_y	A_z
X_b Down	+g	0	0
X_b UP	-g	0	0
Y_b Down	0	+g	0
Y_b Down	0	-g	0
Z_b Down	0	0	+g
Z_b Up	0	0	-g

In Table. I, A_x, A_y, and A_z are the acceleration in x, y, and z axes respectively measured by the accelerometer. The changes in orientation of the device are described by rotations in roll α, pitch β, and yaw γ about the x, y, and z axes respectively [5]. The roll, pitch, and yaw rotation matrices are:

$$R_x(\alpha) = \begin{bmatrix} 1 & 0 & 0 \\ 0 & cos(\alpha) & sin(\alpha) \\ 0 & -sin(\alpha) & cos(\alpha) \end{bmatrix} \tag{2}$$

$$R_x(\beta) = \begin{bmatrix} cos(\beta) & 0 & -sin(\beta) \\ 0 & 1 & 0 \\ sin(\beta) & 0 & cos(\beta \end{bmatrix} \tag{3}$$

$$R_x(\gamma) = \begin{bmatrix} cos(\gamma) & sin(\gamma) & 0 \\ -sin(\gamma) & cos(\gamma) & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{4}$$

These matrices transform the earth's gravitational field vector g by angles α in roll, β in pitch, and γ in yaw about the x, y, and z axes respectively. Hence, equations driven for calculating the angles from the accelerometer outputs are as follows [6]:

$$\alpha = \arctan\left(\frac{A_x}{\sqrt{A_y^2 + A_z^2}}\right) \tag{5}$$

$$\beta = \arctan\left(\frac{A_y}{\sqrt{A_x^2 + A_z^2}}\right) \tag{6}$$

$$\gamma = \arctan\left(\frac{A_z}{\sqrt{A_x^2 + A_y^2}}\right) \tag{7}$$

The coordinate system of the accelerometer which will be used in this document are shown in Fig. 1. Here-

- the x-axis is aligned along the width of the device.
- the y-axis is aligned along the length of the device.
- the z-axis points downwards so that it is aligned with gravity and also aligned at right angles to both the x and y axes.

B. Measuring boat-factors

Due to their different shapes, the capability of floating and tolerance of vulnerable swing varies from one boat to another. When a ship is at sea, due to the influence of waves, there cause a variety of motions, such as rolling, yaw, pitch, sway, heave, and so on. Among the 3 tilt angles − roll, pitch, and yaw the roll angle has a great importance on its stability and safety. The significance of yaw angle is negligible [2]. Hence we are considering only roll and pitch angles. To understand the impact of roll and pitch on the boat we need to find the relationship between them.

The length of a boat is usually termed as LOA (Length overall). On the other hand, the width of it is known as BOC (Beam on Centerline). The ratio of LOA/BOC is used to estimate the stability of a boat. The lower the ratio, the greater the boat's stability. For example, a boat with LOA/BOC = 1 is square or circular in shape and has the highest stability. Usually, the LAO/BOA for small sailboats are from 2:1 to 5:1 and for large ships the ratio is 20:1 [7]. Due to the architectural shape of the boats, the bow is more stable than beam during the swing while on the water. However, due to different draft or draught of a boat's hull, the LAO/BOC ratio does not always work although if we consider draft in the calculation.

Roll motion is considered to be the most important in the stability analysis of a water vehicle. The factors that dominate roll angles of different water vehicles are [3]:

- the ratio of the period of rolling and the encountering period of the wave
- the shape of the hull, total weight, and floatage
- the wave steepness, H/L, where H and L are the height and length of the wave
- the damping effect of the underwater parts of the hull
- the encountering angle and speed of the wave

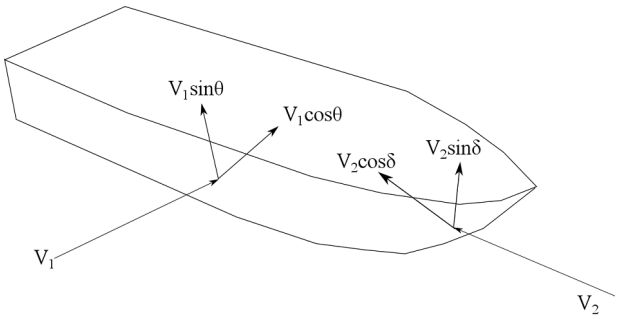

Fig. 3: Y-$Factor$.

Lemma 1: Tilt angle is proportional to the sine component of the wave force acting on a boat.

Proof: Assume that, currently the boat position is at θ degree to the wave force. When the wave, V strikes on the boat, the wave force acts on the boat with two components: $F_x = Vcos\theta$ and $F_y = Vsin\theta$. The F_x cause the thrust which is responsible to push the boat forward and F_y is the cause of tilting. Therefore, tilting depends only on F_y. Mathematically,

$$Tilt \propto Vsin\theta \tag{8}$$

From eqn. 8, the wave V_1 with θ degree will tilt the boat with $V_1 sin\theta$ force. Similarly, the wave V_2 with δ degree will tilt the boat with $V_2 sin\delta$ force. If $V_1 = V_2$ and $\theta = \delta$, then we get, (tilt by $V_1 sin\theta$) = k×(tilt by $V_2 sin\delta$). Where k is a proportional constant. The tilt angle caused by $V_1 sin\theta$ is α and $V_2 sin\delta$ is β. Hence, $k = \alpha/\beta$. We named k as Y-$Factor$. Therefore, the Y-$Factor$ is defined as the ratio of rolling α and pitch angle β of the boat.

$$Y\text{-}Factor = \frac{\alpha}{\beta} \tag{9}$$

The above equation gives the Y-$Factor$ of a boat. For any specific boat, before measuring the safe angle, we need to determine the Y-$Factor$ of it. Additionally, the actual F_y is Y-Factor times greater than the apparent F_y. Therefore,

$$F_y = Y\text{-}Factor \times \beta \tag{10}$$

C. Measuring threshold values

We will use two thresholds- T_x, the threshold for x-axis and T_y, the threshold for y-axis. We will measure the maximum threshold values, $T_{x_{max}}$ and $T_{y_{max}}$ for the boats in which angle the boat will sink. Then we can use any appropriate threshold values $1 \leq T_x \leq T_{x_{max}}$ and $1 \leq T_y \leq T_{y_{max}}$. Note that the threshold values are for both positive and negative tilt angles. Therefore, we take absolute values as input.

D. Measuring safe angle

Safe angle θ is defined as the angle between the current position of the boat and the position in which the boat is in the highest stable in the situation of vulnerable swing.

To simplify the calculation we assume 2 cases. They are:

Assumption 1: The wave velocity is assumed to be always parallel to the water surface, moreover is also assumed to be flat.

Assumption 2: Tilt angle along y-axis is not-null ($|\beta| > 0$) for all time.

If two forces $\vec{F_1}$ and $\vec{F_2}$ acting on an object, then the angle of the resultant force with respect to $\vec{F_1}$ is given by the following equation [8],

$$\theta = arctan\left(\frac{\vec{F_2}}{\vec{F_1}}\right) \tag{11}$$

Applying on eqn. 11 we get,

$$\theta = arctan\left(\frac{\vec{F_\alpha}}{\vec{F_\beta}}\right) = \arctan\left(\frac{|\alpha|}{Y\text{-}Factor \times |\beta|}\right) \tag{12}$$

Where $\vec{F_\alpha}$ is the force that creates roll angle α and $\vec{F_\beta}$ is the force that creates pitch angle β.

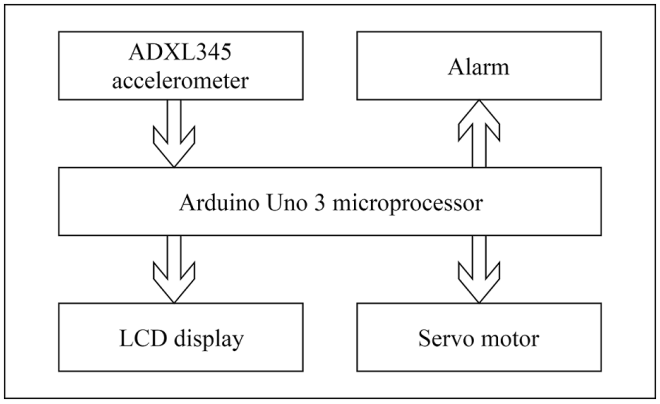
If $|\alpha| \geq T_x$ or $|\beta| \geq T_y$, then we step to find the safe angle. The safe angle is calculated between 0 to 90 degrees. Then the direction of rotation is calculated. Hence, the range of safe angle remains 0 to ± 90 degrees. The direction of the angle is determined by Table II.

TABLE II: Safe angle direction.

X	Y	Angle direction
$\alpha \geq 0$	$\beta \geq 0$	Clockwise
$\alpha \geq 0$	$\beta < 0$	Anti-Clockwise
$\alpha < 0$	$\beta \geq 0$	Anti-Clockwise
$\alpha < 0$	$\beta < 0$	Clockwise

IV. Hardware Implementation

The main board used for this system is Arduino Uno 3 which contains an ATmega 328 microcontroller, 2 MB built-in ROM. All other components are connected with the Arduino Uno 3 board. The adxl345 accelerometer gives the acceleration data to the main board. The main board process data to get the tilt angle. Under certain conditions, the Uno board display the Safe Angle to the display. It also displays the regular tilt angle. An indicator dial connected to the servo motor to display the safe angle in an analog way. If the boat is not in safe position, then a continuous alarm will be played in buzzer. Fig. 4 shows the block diagram of our proposed device. In Fig. 5, a snapshot of our developed device is shown. Fig. 5a is the internal circuitry of the device and Fig. 5b is the top view of our device.



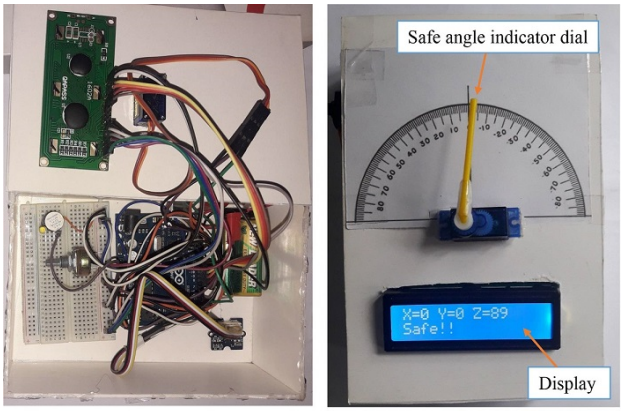


Fig. 4: Block diagram of the device.

V. Software Implementation

We implement the software of the proposed system in C++. At first, the components of the system initialized. Next, the Arduino reads the accelerometer data and process to determine the tilt angles. If $|\alpha|$ is greater than or equal to T_x or $|\beta|$ is greater than or equal to T_y then calculate the safe angle. The safe angle is normalized between 0 to ± 90 degrees and displayed in the LCD as well as indicated in spines of the servo motor. Otherwise, display the tilt angle and place the indicator in the zero degrees. The process repeats unless the device turned off. The algorithm for our developed system is given in Algorithm 1.

VI. Experimental Results

A. Y-Factor Result

We have tested in unwavering water on the stationary boat by creating artificial waves. The device was installed parallel to the boat. Table III shows the 10 readings of roll and pitch angle as x_{α_1} and y_{β_1} respectively for port and starboard and 10 others x_{α_2} and y_{β_2} for stern and bow.

We perform several tests on different types of boats and compare their $Y\text{-}Factor$ in Table IV. The detailed data are displayed in Fig. 8. We observe from Fig. 8a that, the artificial wave force is applied along the x-axis of boat no. 1. Therefore, the tilt angle with respect to x-axis α_1 vary from 10 to 30 degrees and tilt angle with respect to y-axis β_1 is nearly zero

TABLE III: Data for measuring $Y\text{-}Factor$.

	x_{α_1}		x_{β_1}		y_{α_2}		y_{β_2}	
Sl.	Port	Star board	Port	Star board	Stern	Bow	Stern	Bow
1	22	19	1	0	1	1	10	10
2	23	18	1	1	1	1	10	10
3	23	20	1	1	1	1	10	9
4	23	20	0	1	1	1	12	9
5	25	19	0	1	1	1	11	10
6	26	20	0	0	0	2	10	10
7	27	21	0	1	1	1	10	9
8	27	21	0	1	1	3	10	10
9	27	20	0	1	1	1	10	10
10	28	17	0	1	1	1	10	7
Total	251	195	3	8	9	13	103	94
Avg.	25.1	19.5	0.3	0.8	0.9	1.3	10.3	9.4

degrees. After that, when the force is applied along the y-axis of boat no. 1 then, the boat experience a little swing along the x-axis (α_2) and the tilt with respect to y-axis β_2 remains under 10 degrees. These two different situations raised while both the wave force applied on the boat has the same value. Rest of the observations also admit the same property except for Fig. 8e as the boat no. 5 have no change in x-axis and y-axis. From these experimental values we can say that, the LOA/BOC ratio does not always works since they differ in their height.

TABLE IV: $Y\text{-}Factor$ Comparison for several types of boats.

Sl.	LOA (ft)	BOC (ft)	X (θ°)	Y (θ°)	$Y\text{-}Factor$
1	9	2	21.83	9.27	2.35
2	12	3	19.5	7.99	2.44
3	12	3	23.85	9.57	2.49
4	5	2	31.15	4.44	7.02
5	0.66	0.66	41.32	41.03	0.99

B. Threshold values

We have tested on the same five types of boat from $Y\text{-}Factor$. The roll angle α just before drowning the boat is the maximum threshold $T_{x_{max}}$ and the pitch angle β is the maximum threshold $T_{y_{max}}$. The threshold values are given in Table V.

TABLE V: Maximum threshold values for several types of boats.

Sl.	LOA (ft)	BOC (ft)	$T_{x_{max}}$ (θ°)	$T_{y_{max}}$ (θ°)
1	9	2	30	44
2	12	3	34	45
3	12	3	34	46
4	5	2	35	40
5	0.66	0.66	47	47

C. Safe Angle Result

Table IV gives the $Y\text{-}Factor$ of different types of boats that we experimented. From Table V, we get the maximum thresholds that can be set to a boat. We have run over experiment on a real boat (boat no. 1) with T_x = 10, T_y= 5, and Y_f = 2.35 and another boat (boat no. 4) with T_x = 20, T_y = 20, and Y_f = 1. The boats are assumed to be safe state if the tilt angles are below the thresholds values ($\alpha < 15$, $\beta < 10$ for boat no. 1 and $\alpha < 20$, $\beta < 20$ for boat no. 4). In this state, the boat is in the safe position and at low risk. Hence, we have nothing to do with the boat. If the tilt angles exceed the threshold values then the device calculates the safe angle form the tilt information. We rotate our boat accordingly with our device's calculation to reach the safe position. After reached the safe position, the boat was displayed as safe on the display. Since the wave was not unidirectional therefore the boat always faced some tilts. Yet we can see that, it was the minor tilt angles after we rotate the boat.
The result for the boat no. 1 shown in Fig. 6. The result for the boat no. 4 shown in Fig. 7. Both Fig. 6 and Fig. 7 shows the 100 experimental reading. The device gives the tilt angles and the safe angle. According to the device suggestion when we rotate our boat, we can see in both Fig. 6 and Fig. 7, the safe angle values minimizes and the boat achieves more stability. As there always some wave in the river, therefore, our device continuously display the safe angle with a 0.5 sec interval. It is our observation that the safe angle between 0 and ± 5 degrees is practically safe.

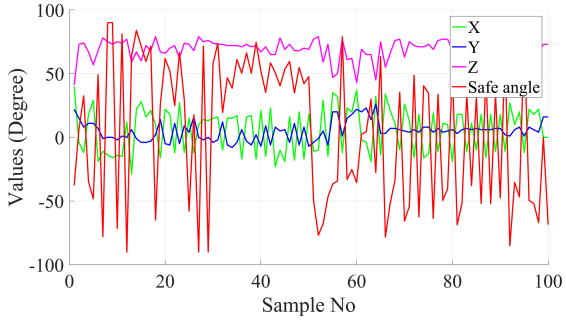

Fig. 6: Experimental reading from boat no. 1.

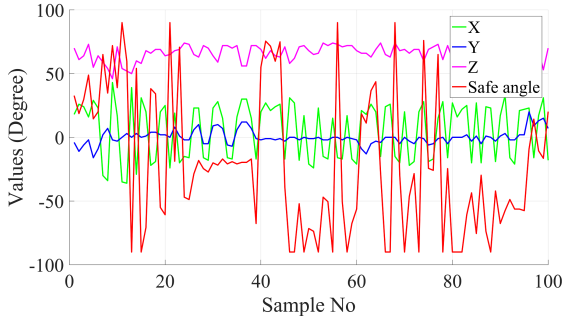

Fig. 7: Experimental reading from boat no. 4.

VII. Conclusion

In this paper, a method has been designed to determine the safe angle for water vehicles in order to remain safe during the vulnerable swing caused by the natural disaster. Due to the mechanical imbalance, the analog output may vary from ± 2 degrees. Our calculated values for $Y\text{-}Factors$ are

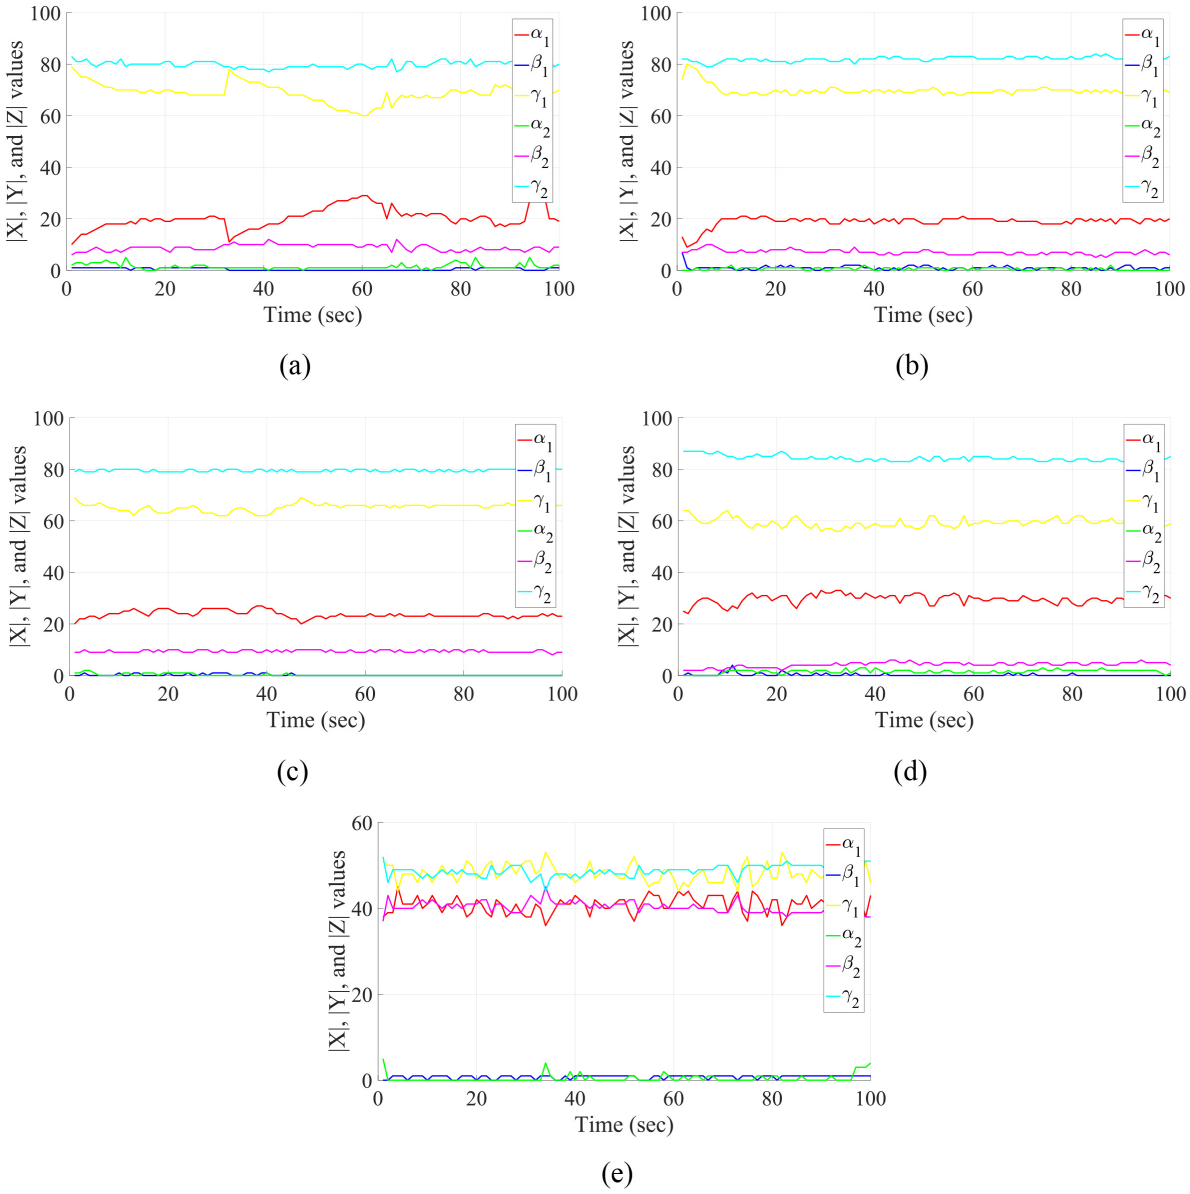

Fig. 8: $Y\text{-}Factor$ result of 5 boats. Tilt angles when the artificial wave force applied on: (a) Boat-1 (b) Boat-2 (c) Boat-3 (d) Boat-4 (e) Boat-5 . α_1, β_1, γ_1 are the tilt angles when wave force applied on x-axis and α_2, β_2, γ_2 for y-axis.

not universal to all the boats with the same dimension. It depends on the area of the hull, water line, height of the boat, materials of the boat, etc. Therefore, before using the device, the $Y\text{-}Factor$ of the boat must be calculated explicitly.

The average maximum threshold values are taken from several test case just before drowning the boat. The experiment was done artificially. In practical, the maximum threshold or the tilt angles while drowning may depend on the nature of the wave.

***Abstract*—The number of visually impaired people is growing with the fast increase of population. The visually impaired people face much difficulty in their day-to-day lives due to losing their vision. This paper analyzed the performances of the raspberry pi and Arduino for the obstacle detected to assist the visually impaired people. We have used raspberry pi, Arduino and ultrasonic sensor as hardware components in this paper. The position of the obstacles is varied from the sensor and the data is measured corresponding to actual distance. The average accuracy and error rate are obtained 98.47% and 1.53% from the raspberry pi. In addition, Arduino achieved the average accuracy and error rate of 95.22% and 4.78%. Raspberry pi obtained more accuracy and lower error rate than Arduino.**

Keywords- Raspberry Pi; Ultrasonic Sensor; Arduino UNO; Visually Impaired; Obstacle Detection.

I. INTRODUCTION

As per World Health Organization (WHO) statistics [1], there are approximately 253 million visually impaired people. Among them, 36 million people are blind and about 217 million people have low vision. The people who are visually impaired need help mostly to continue their daily activities. Most importantly they are to know the position of the obstacle and other interference [2] when they are in new or unknown places for their safe navigation. Sometimes, the visually impaired people use dogs as their guide for their navigation. However, this is expensive as well as difficult to maintain. The use of a stick or cane [3] is an alternative option for the visually impaired people to detect an object without any prior idea.

Modern science is trying to reduce the difficulties of visually impaired people. Some of the tools have already been developed to fulfil the demand of the blind users. Navguide [4] provides the surroundings information and detect the knee-level and head level obstacles to the users. Smart walking stick [5] detect obstacles, pit, and water on the road to help the blind. Electronic Mobility Cane used Atmega328 microcontroller for obstacle detection and iWalk [6] detects the obstacles using Arduino having the accuracy of about 90%. A wearable head mounted device [7] detects the obstacle in left, right and front direction using ultrasonic sensor and the Arduino.

To aid the visually impaired people, previously we have proposed few approaches as shown in [8], [9] and [17]. However, these approaches are able to detect the obstacles in front of the visually impaired people. These tools are sensor based and able to detect the obstacles and generate an alarm signal to notify the users. The existing literature reflects that most of the walking assistance devices are developed using microcontrollers (Arduino, Raspberry Pi etc.). However, an extensive comparative study to evaluate the performance of these technologies is somehow missing. Hence, we have analyzed detection accuracy and error rate for both raspberry pi and Arduino in our study.

The rest of the paper is organized as follows. The related work that covers the recent developments in this area is described in Section II. The major hardware components that are used to develop the system are described in Section III. The system design is illustrated briefly in Section IV. Section V outlines the experimental outcomes of the system. Section VI concludes the paper.

II. OVERVIEW OF THE STATE OF ART

Many research groups from different parts of the world have been developing different systems to help the visually impaired people with their daily lives. The work associated with this field is outlined briefly as follows.

Mulky et al. [10] developed an autonomous scooter that can aid the visually impaired people to navigate individually and securely in unknown environment. The system provides the current location, maps, and nearby obstacle's location to the users. The system used stereo camera and raspberry pi as sensing and processing device respectively. However, the scooter provides short-range vision-based mapping. Sareeka et al. [11] developed a wearable device named as pseudoEye that captures the texts from the environment and converts it to voice signal which is delivered to users. The system used a mini camera, a push button, raspberry pi and a SoC (System on Chip) attached to a cap. The raspberry pi captures the data from the environment using camera and extracts texts from the images and generates voice signal corresponding to texts. A portable power bank is used to power on the raspberry pi. However, the system can recognize few numbers of texts and fails to detect handwritten character. Xiao et al. [12] proposed a low cost system to aid the visually impaired people using raspberry pi. The system used magnetic compass and gyroscope to measure the forward direction of the users. In addition, the users can provide input their address through a microphone. The device is light weight and wearable at waist. The overall production cost of the proposed system is approximately $138. The system provides 3-D sound as a feedback signal. However, the system cannot recognize landmarks and the position as well as the velocity of the users is not addressed in here. S. Khade and Y. Dandawate [13] developed an obstacle detection framework for the visually impaired people in unknown surroundings using Raspberry Pi. The system perceived the obstacles in the ROI without the help of cameras. The hardware used in this

scheme is 'Raspberry Pi 2-B', a wearable camera with 5MP resolution and the overall system is simulated in MATLAB as well as Python language. The authors generated the database by visiting a school for the blinds. The database is retrieved by capturing the video of the blind head, and approximately 25 videos are taken for the research purpose. The database is converted into a video frame initially, and the motion vectors are used for the obstacle detection. The segmentation is done using background subtraction procedure. Finally, the Region of Interest (ROI) is created to detect the obstacles. The system is cost-effective and has lesser weight, but the illumination and brightness situations are constant. However, in the real-world scenario, these properties change frequently. So, the prototype is not compatible with the real world. The system can detect the obstacles only, but is not able to categorize them.

Aljahdali et al. [14] proposed a smart assistive walker device that decreases the risks of accidents of the visually impaired people. The hardware parts of the system are sensor, controller, output and the software part of the system are "Map" and "Find Me" Apps. The sensors collect the real time data and when the system detects an obstacle, the controller sends it via IoT signal to the output to avoid collision. However, the system is not able to measure the distance from the user to obstacle and unable to alert the authority. Khan et al. [15] developed a mini hand-carrying device that can be used as an alternative of smart stick/cane. The system can detect the obstacles, manholes as well as potholes and notify the users by alarming buzzer. The system used Arduino UNO, two sonar sensors, two buzzers, 9v battery and a voltage converter. However, the performance of the system has not been assessed by the blind users. Sharma et al. [16] developed a smart stick for the visually impaired people in order to provide independent mobility. The system can detect the ground level and knee level obstacles, potholes and staircases. It provides vibration signal with the presence of hindrances. The system is comprised of three sonar sensors, a moisture sensor, two vibration motors, two buzzers and Arduino microcontroller. However, the detection range of pothole is approximately 30 cm which is too small to avoid risks of accidents.

Kamal et al. [17] developed a walking assistant for the visually impaired people to aid them in navigation by avoiding obstacles around them. The system consists of two modules such as wearable spectacle module and smartphone module. The wearable spectacle module perceives an object midpoint and receives the copy of the surface for processing. The smartphone module obtains the copy sent from the wearable spectacle module and then processes the copy and finally computes the smoothness of the surface. The developed module is small, wearable and lightweight. Pissaloux et al. [18] proposed a system that assists users in walking with obstacle avoidance, orientation, real physical displacement, etc. It is based on the real gist. The system consists of TactiPad for obstacle detection and tactile gist for display. The system is beneficial for the visually impaired people in their mobility in an unfamiliar environment, but the system is comparatively bulky. Ponnada et al. [19] proposed a manhole and staircase detection system for the visually impaired people that can help the individuals to avoid the manhole and staircase in the way of walking. The system used ultrasonic sensor for the detection of manhole and the staircase and computer vision-based technique to detect the hindrances. The SURF algorithm extracts the features from the real time images and Bivariate Gaussian Mixture Model (BGMM) detects the staircase and manhole. The main components used in the scheme are Arduino Kit, ultrasonic sensor, vibrator, HC-05 Bluetooth and camera. The proposed device is small and lightweight and will be effective for the blinds and deaf people as the system will give notification about the current position and give direction to them about the stairs. However, the system may faultier in the dark or in a place where there is noise. The system fails to categorize the moving obstacles in case of staircase detection.

III. MAJOR HARDWARE COMPONENTS

The major hardware components which are used to analyze the performances of raspberry pi and Arduino are outlined as follows.

A. Raspberry Pi

Raspberry pi is mini sized single board computer that is used to conduct any kinds of real time research. It has 17 GPIO pins that can easily connect with electronic devices (LEDs, switches etc.). The raspberry pi B+ model contains four USB ports, an audio jack port, two ports for camera interfacing, a HDMI port and an Ethernet port. The logic level of raspberry pi is approximately 3.3v. It is compatible with operating system Raspbian. It supports Python, Java, C, and C++ as programming languages and has a 700MHz single core processor.

B. Arduino UNO

Arduino is referred as a platform where software and hardware both can be embedded through Arduino board. It is compatible with operating systems like Windows, Linux, Mac OS and built with microcontrollers as well as microcontroller kits. Arduino can detect the set of instructions and perform the tasks through these microcontrollers. Nowadays, it is serving as a brain of thousands of projects. It consists of digital pins, analog pins, power pins.

C. Ultrasonic Sensor

Several sensors are used to construct different types of assistants to provide various services. Among the different sensors, ultrasonic sensors are widely used. The sensor can measure the distance of the obstacles in front of it in a certain range. The range can be 3cm to 3m and can cover up to 15 degrees. It consists of only 4 pins. The pins are Vcc, trigger (transmitter), echo (receiver) and ground. VCC pin is used to power-up the sensor. It accepts up-to +5V and ground pin is connected to ground. It sends ultrasonic pulse continuously through trigger pin. When the signal is reflected by any obstacles the Echo pin receives the signal and a control circuit measures the distance of the obstacle.

IV. SYSTEM DESIGN

In the study, an ultrasonic sonar sensor is used for obstacle detection to assist the visually impaired. The distance from the obstacle to the individuals is determined. The ultrasonic sonar sensor sends a sound wave at a specific frequency towards the obstacle and receives it back when it is reflected

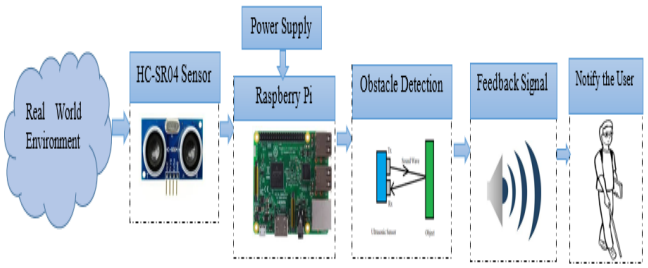

Fig. 1. A typical example of developed walking assistance tool (using raspberry pi).

by the obstacle. It archives the travel time of sound wave for forth and back. By using the travel time, sensor calculates the distance between the user and the obstacle.

$$Distance = (speed\ of\ sound \times elapsed\ time)\ /2 \quad (1)$$

In the study, the real-world data will be collected using ultrasonic sensors. The collected data will be processed using raspberry pi and Arduino for obstacle detection. A typical example of developed assisting tool (using raspberry pi) is illustrated in Fig. 1. The system generates feedback signal with the presence of obstacles and send it to the users for notification.

The connections of components are mapped with the raspberry pi and Arduino which is depicted in Table I. From the Table I, it is shown that the Trigger and Echo pins of the sensor are connected to D_9 and D_{10} pin of the Arduino. In case of raspberry pi, the Trigger and Echo pins of the sensor are connected to GPIO 17 and GPIO 18 pin. The GND and VCC pins of the sensor are connected to GND and VCC pin of raspberry pi and the Arduino.

V. Experimental Results Analysis

The experiment was performed in a virtual environment to measure the performances of the raspberry pi and Arduino. We have created five regions for positioning the obstacles. The regions are as follows.

- Region 1: (0-100cm)
- Region 2: (11-20cm)
- Region 3: (21-50cm)
- Region 4: (51-100cm)
- Region 5: (101-150cm)

The obstaclaes are placed at above described regions and the sonar sensors are used to measure the distances of the obstacles.

The data that are gathered from sensor using raspberry pi and Arduino are depicted in Table II and Table III.

TABLE I. MAPPING BETWEEN RASPBERRY PI, ARDUINO AND SENSOR

Raspberry Pin	Arduino Pin	Connected Device
GPIO 17	D9	Trigger pin of sonar sensor
GPIO 18	D10	Echo pin of sonar sensor
5V	5V	Common +5v for all device
GND	GND	Common ground(-) for all device

The comparison between the actual distance and measured distance for Arduino and raspberry pi is illustrated in Fig. 2 and Fig. 3.

Fig. 2 and Fig. 3 reveal that the measured distance and actual distance is nearly identical at the beginning when the obstacles are very close to users. These representation shows the distortion of the measured distance from the actual distance. It is shown that the distortion is not severe and the measured distance is acceptable. The distortion of Arduino is comparatively higher than the raspberry pi.

TABLE II. REAL TIME DATA COLLECTED FROM ULTRASONIC SENSOR USING RASPBERRY PI

Actual Distance (cm)	Measured Distance (cm)	Error Rate (%)
10	10.11	1.13
20	19.83	0.86
50	48.44	3.12
100	98.05	1.95
150	150.89	0.59

TABLE III. REAL TIME DATA COLLECTED FROM ULTRASONIC SENSOR USING ARDUINO

Actual Distance (cm)	Measured Distance (cm)	Error Rate (%)
10	9	10
20	19	5
50	48.65	2.7
100	96.12	3.88
150	146.49	2.34

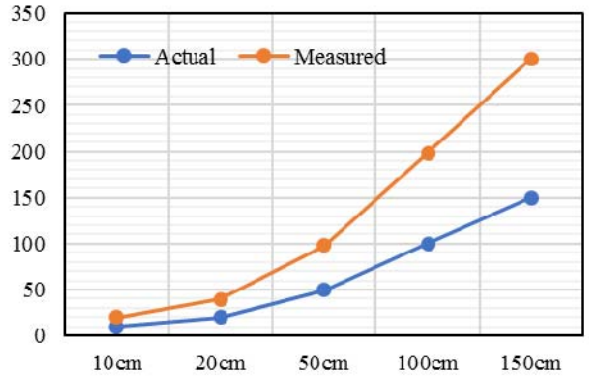

Fig. 2. Comparison with actual and measured distance in Raspberry Pi.

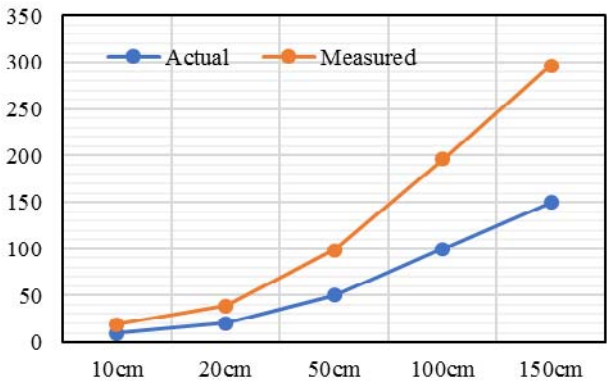

Fig. 3. Comparison with actual and measured distance in Arduino.

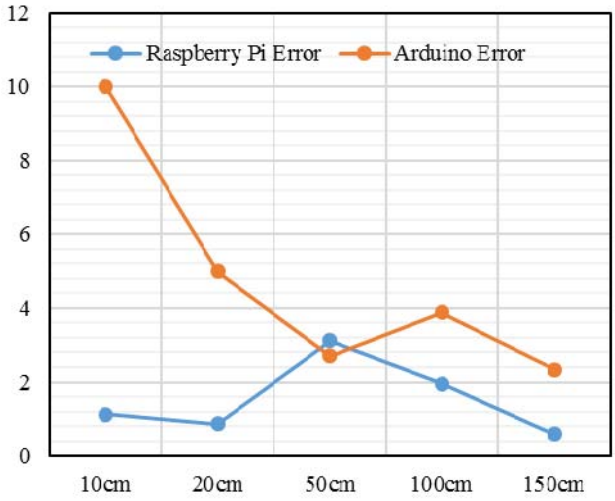

Fig. 4. Error rate for raspberry pi and Arduino for the obstacle detection using ultrasonic sensor.

The performances of obstacle detection are assessed by calculating the errors at different regions. In our study, the error represents the Mean Absolute Error (MAE). The errors at diverse regions is illustrated in Fig. 4. The error rate at region 1, region 3 and region 5 are about 1.13%, 3.12% and 0.59% respectively in case of Arduino. In addition, the error rate of 10%, 2.7% and 2.34% are achieved from region 1, region 3 and region 5 respectively. From the Fig. 4, it can be shown that raspberry pi obtained the lowest error rate that Arduino for each case except the region 3. The lower the error rate depicts the higher accuracy. The average error rate is 1.53% and 4.78% is achieved from raspberry pi and Arduino respectively. Therefore, we can conclude that the raspberry pi performs better than Arduino for the obstacle detection using ultrasonic sensor.

The performance and cost comparison of raspberry pi and Arduino are demonstrated in Table IV. From the Table IV, it can be shown that raspberry pi performs better in case of obstacle detection but the price of the raspberry pi is much higher than the Arduino.

TABLE IV. PERFORMANCE, COST AND WEIGHT COMPARISON

	Raspberry Pi	**Arduino**
Accuracy (%)	98.47	95.22
Error Rate (%)	1.53	4.78
Cost	$35	$5
Weight	368gm	400gm

TABLE V. PERFORMANCE ANALYSIS OF THE PROPOSED SYSTEM AND EXISTING SYSTEMS

Authors	**Cost**	**Weight**	**Accuracy**
Olanrewaju et al. [6]	N/M	N/M	90%
Sadi et al. [8]	$10	160gm	96%
Bhatlawande et al. [20]	$280	0.503 kg	85%
Zahir et al. [21]	$30	N/M	N/M
Proposed System	**$42**	**368gm**	**98.47%**

***Not Mentioned: N/M**

Table V illustrates the performance analysis between proposed system and existing systems. Olanrewaju et al. [6] developed iWalk that obtained accuracy of 90%. Sadi et al. [8] proposed a system that cost and weight are about $10, 160 gm respectively and achieved accuracy of 96%. Bhatlawande et al. [20] developed an EMC having the cost and weight $280, 0.503kg respectively with accuracy of 85%. Zahir et al. [21] developed a system with cost of $30. The cost and weight of the proposed system are about $42 and 368 gm respectively and obtained accuracy of 98.47% in case of raspberry pi.

VI. Conclusion

The study evaluated the performance of the walking assistance technologies developed by raspberry pi and Arduino. The system that is able to detect the obstacles accurately assists the visually impaired people in mobility. The raspberry pi based system is more perfect than an Arduino based system for obstacle detection. The raspberry pi based system achieved the accuracy of 98.47% and error rate of 1.53% whereas for Arduino based system accuracy and error rate were achieved as 95.22% and 4.78% respectively. The system is the preliminary study before developing a walking assistant for the visually impaired people. The paper suggests that raspberry pi is the most significant processing device to develop any obstacle detection system. The limitation of raspberry pi based system is that it is very expensive. In future, this work may be integrated with a stick that can support the visually impaired individuals in safe navigation.

***Abstract*—This paper presents a wearable planar printed meandering monopole textile antenna design having operating frequency of 2.4 – 2.45 GHz on 3 flexible substrate materials: Jeans, Leather and Cordura®. The printed elements have been designed by using a mender line technique to reduce the size of the antenna significantly than the proposed antennas of past literature. Antenna performance is analyzed for different bending conditions and Specific Absorption Rate (SAR) is evaluated when the antenna is in contact with human body using CST Microwave Studio. The compact design and miniature size of the antenna is suitable for easy integration in smart clothing for tracking, healthcare, security and other ISM applications.**

Keywords—textile antenna, wearable antenna, bending conditions, SAR

I. INTRODUCTION

Flexible textile antennas are currently under an extensive research focus to develop applications based on smart and wearable systems. Textile antennas are an emerging solution to the challenges of monitoring people's healthcare, protection and safety. To integrate textile antennas in clothing, antenna substrate need to be flexible, low profile and hidden as much as possible. For this reason, research efforts are continuing around the world on developing efficient and flexible antenna substrate materials and miniaturizing the size of the antenna. An extensive survey was conducted in the past to accumulate the key points for the design and development of textile antennas [1]. Comparison of different textile materials used in past research works for ISM and WLAN applications was made on this survey, such as: Cotton/Polyester (relative permittivity, $\varepsilon_r = 1.6$ & loss tangent, $\tan\delta = 0.02$) with Flectron as conductive material [2], Fleece Fabric ($\varepsilon_r = 1.04 – 1.25$) with Flectron and knitted Copper fabric as conductive material [3]-[5], Woolen Felt ($\varepsilon_r = 1.45$, $\tan\delta = 0.02$) with Silver-copper-nickel plated woven fabric as conductive material [6], Felt ($\varepsilon_r = 1.30$, $\tan\delta = 0.02$) with Zelt as conductive material [7] and Cordura® ($\varepsilon_r = 1.1 – 1.7$) with Copper tape as conductive material [8]. All of the antennas analyzed in this survey was microstrip patch antennas which have very large antenna size. S. Zhu and R. Langley also have conducted a detailed antenna substrate material survey before choosing Felt ($\varepsilon_r = 1.3$, $\tan\delta = 0.023$) over Silk, Tween, Panama, Moleskin and Perspex to design a dual-band coplanar patch antenna integrated with an electromagnetic band gap substrate having Zelt as the conducting material for WLAN applications [7]. Modern wearable on-body communication system requires more efficient small sized antennas for smart clothing and other ISM applications.

Very few research works have been conducted on the development of textile antenna using Leather and Jeans substrate. M. I. Ahmed and et al. have conducted an investigation on the characteristics of 3 different textile materials: Goch, Jeans and Leather [9]. This work measured the dielectric constant, ε_r and loss tangent, $\tan\delta$ of the 3 substrates (Goch, Jeans & Leather) using 2 different methods: (a) using a microstrip ring resonator method and (b) using Dielectric Assessment Kit (DAK). The proposed antennas are averagely 30mm x 45mm in dimension. Fabrication techniques of textile antennas such as: Copper foil, Copper mesh, Conductive spray and Copper with rubber were analyzed by J. G. Santas and et al. [10]. This paper presented 3 textile antennas (60mm x 80mm) designed on Leather substrate applying, (a) Copper tape, (b) Woven Copper thread and (c) Conductive spray. Another textile antenna on Cotton Jeans substrate was proposed in past literature [11]. However, these antennas are very large in size to consider for modern day wearable on-body communication system to integrate in smart clothing. Miniaturization of textile antenna is now a necessity and requires more research efforts. Additionally, these works lack sufficient experimental or simulation data of antenna performance under bending conditions and Specific Absorption Rate (SAR) evaluation in the presence of human body.

In this paper, we are presenting a 2.4 – 2.45 GHz Planar Printed Meandering Monopole Textile Antenna designed using 3 substrates: Jeans, Leather and Cordura® to meet the challenges of wearable on-body communication systems. The meandering monopole design of the antenna reduces the antenna size significantly and can be easily integrated in smart clothing for monitoring, ensuring security, tracking and healthcare. The antenna patch and ground plane is printed on both sides of the substrate ensuring efficient antenna performance. The antenna was tested under bending conditions and SAR was evaluated in the presence of human tissue box model using CST Microwave Studio 2018. Besides Jeans and Leather, the antenna was also designed on Cordura® Fabric substrate as it is a high-tech durable Japanese fabric made for producing bags and backpacks [12].

II. METHODOLOGY

The proposed 2.4 – 2.45 GHz Textile Antennas were designed on 3 substrates: Jeans, Leather [9] and Condura® [1]. The dielectric properties characterization of the substrates is summarized in Table 1.

TABLE I. DIELECTRIC CHARACTERIZATION OF THE SUBSTRATES

Substrate Material	Dielectric Constant (ε_r)	Loss Tangent (tanδ)	Substrate Height (mm)
Jeans	1.78	0.085	0.6
Leather	1.79	0.042	1.1
Cordura®	1.1	-	0.5

The patch elements and ground plane are made out of annealed copper (Cu). The antenna patch and ground plane are printed on both sides of the substrate and are mirrored to each other. The antenna patch and ground planes of both sides are connected to each other through a via made out of knitted copper wire. Meander line technique was used to design the printed elements of the antenna for the reduction of the size of the antenna. There are two ways to reduce the resonant frequency of a monopole by meandering the monopole element.. First one is by increasing the width of the meander line sections. Therefore the increment of the capacitance to ground reduces the resonant frequency. In order to maintain the overall length of the antenna, reduction of meander section numbers also reduces the effective self-capacitance of the monopole element. This phenomenon concurrently increases the effective self-inductance which leads to the reduction of resonant frequency [13]. Secondly, resonant frequency can be reduced by increasing the total element length while maintaining the same physical volume. The increment in total element length also increases the effective self-inductance which eventually reduces the resonant frequency [13]. Through parametric sweep optimization process using CST Microwave Studio the resonance frequency at 2.4 – 2.45 GHz was obtained. Figure 1 presents the design of both front and back side of the antenna and table 2 summarizes the optimized parameter values for each antenna element.

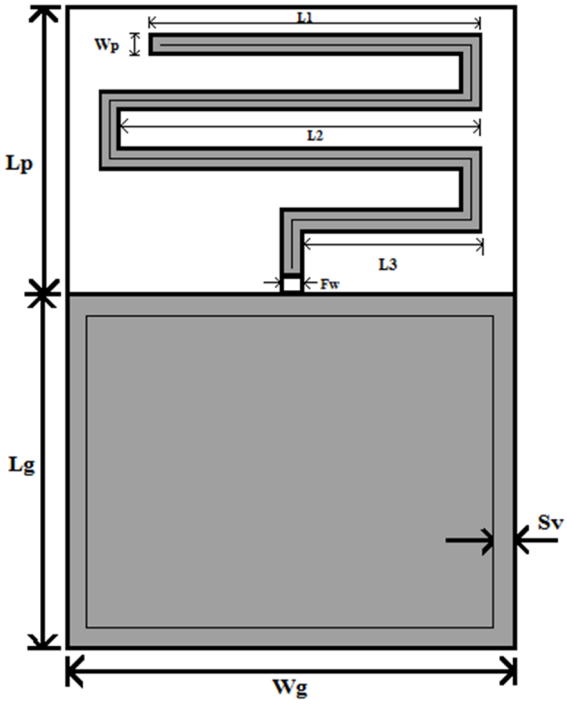

TABLE II. DESIGN PARAMETERS OF ANTENNA FOR JEANS, LEATHER & CORDURA® SUBSTRATES

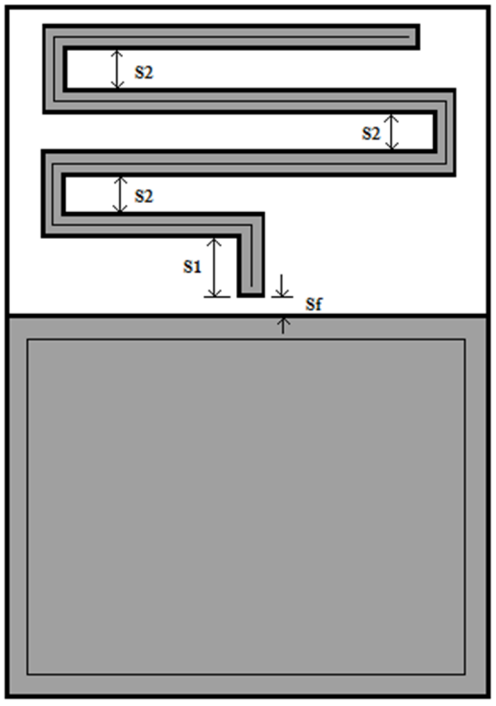
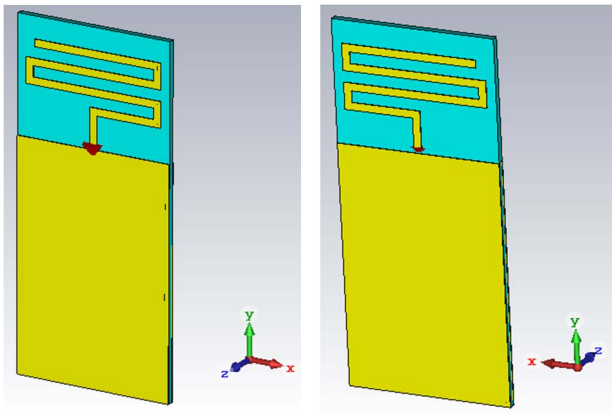
Design Parameters (mm)	Substrate Materials		
	Jeans	Leather	Cordura®
Lg	23.54	23.84	23.18
Wg	16.07	16.27	15.82
Lp	11.96	12.11	11.78
Wp	0.74	0.76	0.75
Fw	0.22	0.22	0.22
Sf	0.37	0.38	0.37
S1	2.99	3.03	2.94
S2	1.12	1.14	1.10
Sv	0.37	0.38	0.37
L1	6.73	6.81	6.62
L2	13.45	13.62	13.25
L3	13.27	13.43	13.06



The designed 2.4 – 2.45 GHz textile antennas are fed with respect to the upper ground plane using discrete port feeding technique. CST Microwave Studio 2018 was used to analyze and measure the performance of all 3 antennas. The antenna has a linearly polarized omnidirectional pattern like a conventional dipole. The antenna has a low input resistance ≈ 20 Ω due the reduction in size by meandering the monopole [14]. The performance of the antenna under bending conditions and when placed on the human body are evaluated in terms of SAR.

III. ANTENNA DESIGN & SIMULATION

3 Planar Printed Meandering Monopole Antenna of 2.4 – 2.45 GHz operating frequency are designed in CST Microwave Studio's simulation environment on 3 substrates: Jeans, Leather and Cordura®. Discrete port feeding technique was used during the simulation and port input impedance was 20Ω. The designed antennas in CST Microwave Studio are presented in figure 2.



(a) Front Side of the antenna

(b) Back side of the antenna

(a) Front (b) Back

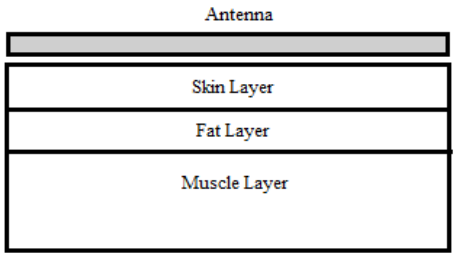

Fig 2. Antenna Design (Jeans Substrate) in CST Microwave Studio

IV. Human Tissue Model & Tissue Properties

The 2.4 – 2.45 GHz antennas were simulated over a human tissue model consisting of 3 layers of tissue: Skin, Fat and Muscle which is shown in figure 3. The permittivity, electrical conductivity, density and dimensions of all 3 layers of the tissue were considered from the Tissue Properties Database of the Foundation for Research on Information Technologies in Society (IT'IS Foundation) [15]. The tissue properties of all 3 considered tissue layers at 2.4 GHz are summarized in table 3.

(a) Antenna over human tissue box model in simulation environment

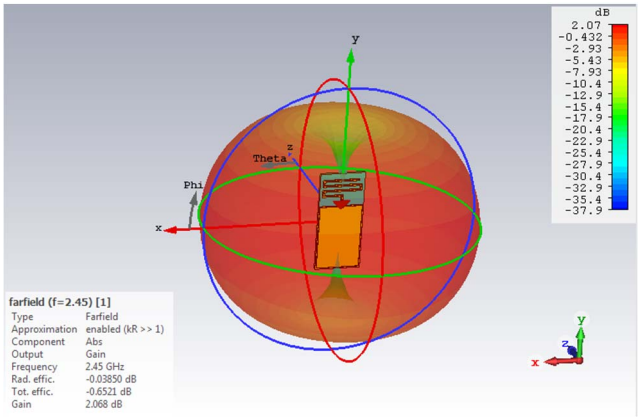
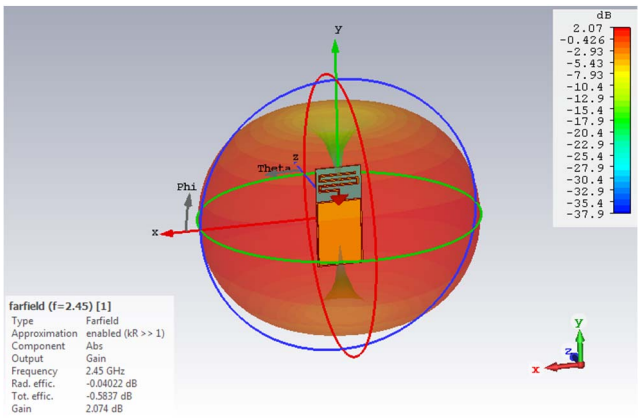
TABLE III. Tissue Properties at 2.4 GHz

Tissue Name	Skin	Fat	Muscle
Permittivity	3.80E+1	1.08E+1	5.27E+1
Electrical Conductivity (S/m)	1.46	2.68E-1	1.74
Density (kg/m^3)	1109	911	1090
Dimension (mm)	20 x 40 x 2	20 x 40 x 4	20 x 40 x 15



V. Results & Discussion

A. Antenna Performance Evaluation



All 3 antennas made out of Jeans, Leather & Cordura® substrate are simulated using CST Microwave Studio. The antennas exhibited uniform and linearly polarized omnidirectional radiation pattern presented in figure 4. The simulated directivity, gain (IEEE), E-Field (Emax), H-Field (Hmax), power flow, surface current and Voltage Standing Wave Ratio (VSWR) of the antennas are summarized in table 4. The reflections coefficients S11 of all 3 antennas are presented in figure 5. The center frequencies of the antennas are between 2.4 – 2.45 GHz and average bandwidth of the antennas were 0.18 GHz ranging from 2.36 GHz to 2.54 GHz.

(b) Leather

(c) Cordura®

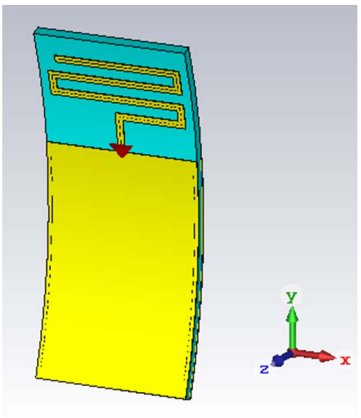

Fig 6. Gain Plot of all three 2.45 GHz textile antennas

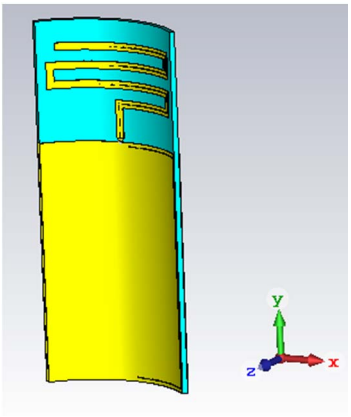
B. *Performance Evaluation Under Bending Conditions*



To Evaluate the antennas under bending conditions different types of bending were tested on the antennas. For the purpose of this investigation Jeans substrate antenna were single sided bended at an angle of 45 degrees, the Leather substrate antenna was bended horizontally along a 50mm radius cylinder and the Cordura® substrate antenna was bended vertically along a 50mm radius cylinder. The bended textile antennas are presented in figure 7. After the bending the center frequency of the antennas shifted by 0.02 GHz which is very negligible (figure 8) and the other performance parameters remained the same. The results signify the durability of the textile antennas.

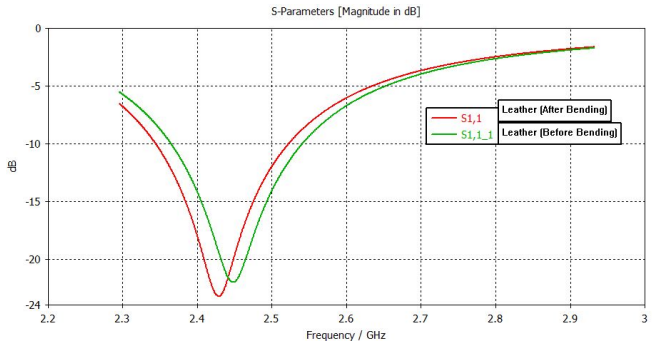
(b) Leather



(c) Cordura®

Fig 8. Center Frequency Shifting After Bending of the Antenna Substrates

C. SAR Evaluation

The 2.4 – 2.45 GHz planar printed meandering monopole textile antennas designed using Jeans, Leather and Cordura® substrates are simulated over a human tissue box. The SAR distribution is presented in figure 9.

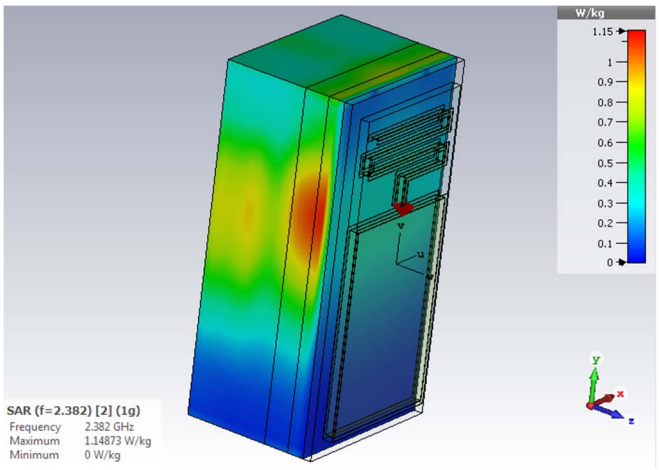

Fig 9. SAR Distribution

The simulated maximum SAR was 1.14873 W/kg for 1g of tissue which satisfies the IEEE and ICNIRP standards of SAR of 1g of tissue which is 1.6 W/kg [16].

VI. Conclusion

This paper presents three wearable 2.4 – 2.45 GHz planar printed meandering monopole textile antennas designed using Jeans, Leather and Cordura® substrate. Meanderline design technique can be utilized to reduce the size of the antenna maintaining efficient performance and durability. Modern era research is concentrated on technologies based on micro and nano scale. Miniaturization of textile antennas is needed to support the evolution of wearable smart on-body communication systems. The proposed antennas of previous literature proposed very large microstrip patch based designed antennas which are incompatible with smart clothing. The proposed antenna dimension in this paper is only 16 mm x 35 mm and the antenna exhibits satisfying performance under different bending conditions and in contact with human body. Further research can be done by fabricating the antenna and testing the performance in practical environment.

***Abstract*— Eyesight is one of the most useful in living organism, visually impaired people do not consist of that sense. They are unable to see the beauty of nature except by using the imagination, facing several problems in their daily life continuously in executing certain movements such as walking, feeling something properly, seeing the world and the surrounding people. All the problems faced by the visually impaired people cannot be solved totally, as in some cases there is no option to give their eyesight back. This project, "Intelligent Path-Finder" will tend to make life easier and less problematic. Visually impaired people use general stick for their movement but the sticks are not capable of detecting the obstacles or other objects in front of them automatically; as a result, they have to poke the obstacles to understand the type. To overcome these problems, the "Intelligent Path-Finder" is a remarkable device which can detect various types of obstacles from knee level to ground level, for example liquid, uneven surfaces. In the dark, a special feature is used to prevent any accident by glowing led light by sensing darkness that can protect the user from moving vehicles and some other difficulties by warning normal people. If the user is in trouble, he can send location by pressing an emergency switch, and his family can also know his location by sending SMS. This device consists of a microcontroller, Ultrasonic sensor, Light dependent resistor etc. The combination of all this equipment together will be making this device relatively accurate, user-friendly, robust and cheap. The device is not a third eye for the blind but it is really helpful to them by making their daily life easier than the previous one.**

***Keywords*— Ultrasonic sensor, Light dependent resistor (LDR), Global positioning system (GPS) and Global System for Mobile communications (GSM), Blind people.**

I. INTRODUCTION

Visual impairment is known as partial or complete loss of sight. Blindness may be caused by injury, by lesions of the brain or optic nerve, by disease of the cornea or retina, or by pathological changes originating in systemic disorders [1]. There are a lot of visually impaired people all over the world. According to the report of World Health Organization (WHO) on October 11, 2018, it is estimated that there are 1.3 billion people who live with some form of visual impairment [2]. There are 188.5 million people with mild vision impairment, 217 million people with moderate to severe vision impairment and 36 million people are blind [2]. 82% of the totally blind people are aged fifty or more [3].

According, to The International Agency for the Prevention of Blindness (IAPB), the total number of blind people in 2015 is 253 million [4]. From, this huge number of people, 89% of visually impaired live in low and middle-income countries [4].

Blind people are helpless in their daily life, in terms of mobility. They are not capable of going anywhere without the help of other people or devices. Sometimes, they take help from trained dogs, but they are very costly. As a result, blind people use ordinary sticks to walk from one place to another by touching the obstacles or poking them. It is also unsafe for them to walk with the ordinary stick because in most cases, they do not understand the type of object and the distance of the object from them. There is also possibility to collide with obstacles and in most cases, causing an accident, with severe injury and sometimes even causes death. In the circumstances stated above, there are many devices, available in the market for assisting visually impaired people, but the cost, accuracy and reliability of those devices are still up for debate.

To overcome the situation, this study led to a prototype of an "Intelligent Path-Finder" with high efficiency and user-friendly features in low budget. The device uses properties of sound to detect obstacles, especially uneven surfaces

and liquid, with high reliability. LDR is integrated in this device to detect the darkness. GPS and GSM are also integrated to track the location continuously and for sending data to a phone number. The user can choose not to share his/her location by simply turning off the tracker if he/she wishes.

II. Integrated Equipment

The prototype has been assembled using various types of components are integrated together. In this section, integrated components are described below in details:

TABLE I IMPORTANT FEATURES OF THESE COMPONENTS USED IN THIS PROJECT

No. of component	No. of unit	Important features for this project
Arduino Mega	1	• Main processing unit. • 30 Digital pins used out of 54 pins. • 1 Analog pin used out of 16 pins. • 5V is used to operate all of the components. • To power up the Arduino 9V is used in this project.
Ultrasonic sensor	5	• To measure the distance. • It can measure 0 to 13 feet. • To detect obstacles and uneven surface
Light-dependent resistor	1	• To detect light intensity. • To lighten up the stick in the dark period.
SIM808	1	• Detect user location. • Send SMS to user family in an emergency situation.
Vibration motor	4	• To inform the position of the obstacles using vibration.
Buzzer	1	• To inform the user by alarming if any kinds of liquids are found.
LED	10	• To concern the vehicle or normal people in a dark period.

[a] Important features of each component

III. System Description

The working principle of the system has been described with the help of system level block diagrams, to minimize the effort in understanding complex circuitry. Some simulations have also been added before final implementation of the project was done.

A. *Block diagram*

This diagram shows the input-output relationship with the main processing unit and the source. The diagram is given below:

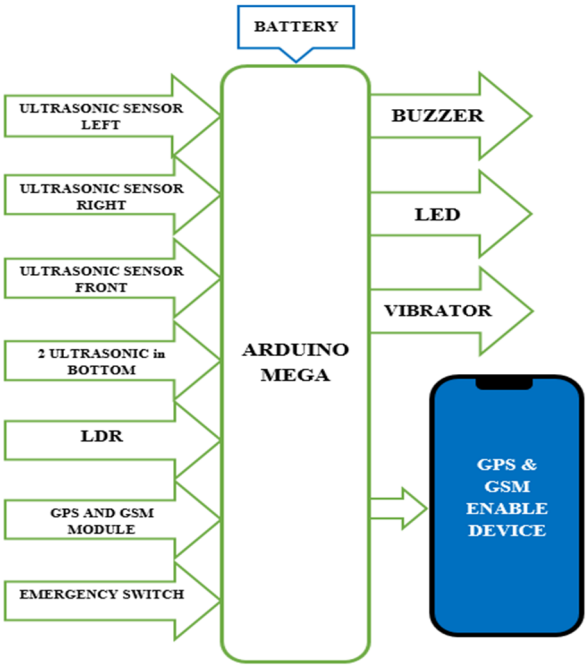

Fig.1. Block diagram of the system.

On the left side of Fig.1, inputs of the device are shown connected with the main processing unit. There are total 5 ultrasonic sensors used in this system. These sensors sense the obstacles around the user and then send signals to the microcontroller to process them. LDR is added in the left side as an input which detects the darkness of the surrounding environment and sends signals to the microcontroller. GPS-GSM module is added as an input of the device. GPS works for locating the position of the user and GSM works for sending the message to the accessed phone but both of them send signals to microcontroller for the further process. An emergency switch has been added as an input of the system which sends a signal to the microcontroller for sending a text whenever the user wants. A battery is integrated in this device as the power source. Buzzer has been added as an output of the system which provides a beep when liquid is detected in front of the user. A total of 4 vibration motors have been integrated in this device as outputs. These motors vibrate when obstacles are detected around the user and also when uneven surface is detected in the walking path of the user.

B. *Flow diagram*

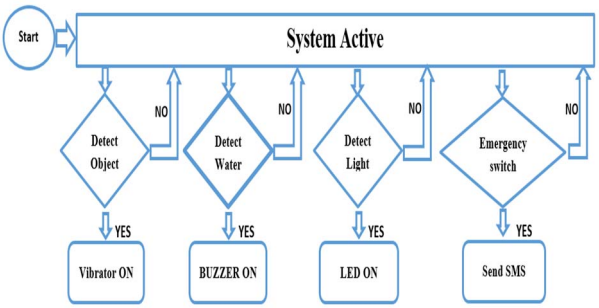

Fig.2. Flow diagram of the system.

Fig. 2 represents the flow diagram of the system. After activating the system, HC-SR04 ultrasonic sensor starts to detect obstacles in front of the device as shown in fig. 4. The sensor works with the simple formula that is given below [5]:

Distance = Speed × Time [5].

The Ultrasonic transmitter transmits an ultrasonic wave, this wave travels in air and when it gets objected by any material it gets reflected back toward the sensor and this reflected wave is observed by the Ultrasonic receiver module as shown in the picture below [5].

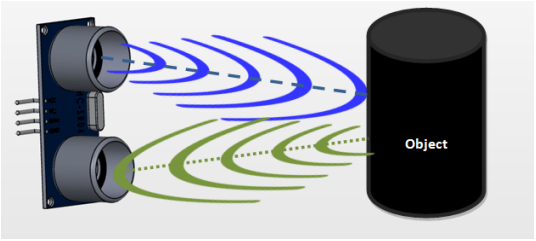

Fig.3. Obstacle detection by an Ultrasonic sensor [5].

Now, to calculate the distance using the above formulae, we should know the speed and time [5]. Since we are using the Ultrasonic wave, we know the universal speed of US wave at room conditions which is 330m/s [5]. The circuitry inbuilt on the module will calculate the time taken for the US wave to come back and turns on the echo pin high for that same particular amount of time, this way we can also know the time taken [5]. Now, using the Arduino Mega (ATmega2560) distance can be calculated simply [5]. The device can detect the liquid in its path and this system is implemented by a very simple method. Two wires are connected in this device in such a way that these are open in the bottom of the device. If any liquid is present bottom of the device then the wires become shorted and current starts flowing through the device. This will send a signal to the Arduino Mega (ATmega2560) and after processing the signal a beep is heard from the buzzer as an output of the water detection system. Darkness detection system is also introduced in this device. Light Dependent Resistor (LDR) is used as the device which can detect the darkness. A graph of fluctuating resistance of LDR with the intensity of the light is shown in fig. 4.

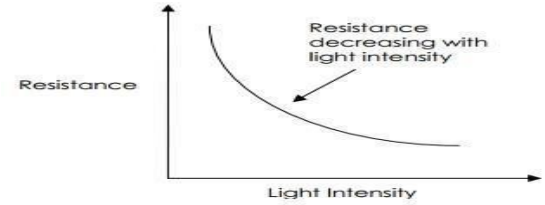

Fig.4. relation between light intensity and resistance [6].

The most common type of LDR has a resistance that falls with an increase in the light intensity falling upon the device (as shown in the image above) [6]. The resistance of an LDR may typically have the following resistances [6]:

Daylight = 5000Ω

Dark = 20000000Ω

LDR is used in such a way that when light intensity is lower, all the LED of the device are turned on and when light intensity is higher all the LED are turned off. Another special feature of tracking the location and sending a message to an accessed phone number is also introduced in this device. GPS system continuously tracks the location of the user and when the user wants, he can send the text with his location by pressing the emergency switch and GSM module works for sending the text to the accessed phone number. This system also works in another way, when someone wants to know the location of the blind people from any distance, they have to send a text to the number which is inserted in the device by writing the word "Location". After receiving the text with the word "Location" the device will give a reply automatically to the sender number with the location of the blind people

C. *Simulation*

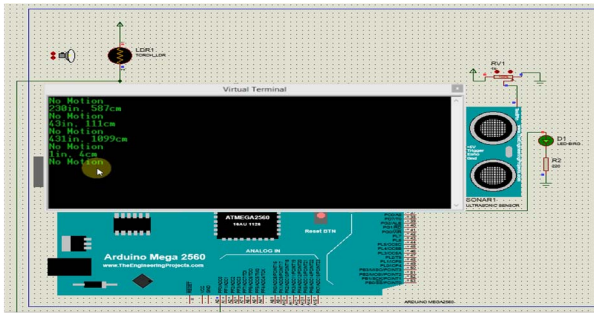

Fig.5. simulation of the system

Fig. 5 shows the simulation of the system. The figure shows that there are two sensors in this simulation, one of them is Ultrasonic Sensor and another one is LDR. The simulation was done in Proteus.

D. *Overview*

The image of the device is given below:

Fig.6. Design of the device.

Fig.6 shows the full hardware parts integrated with the device. In this figure, it is seen that there are 4 vibration motor on the top side of the device. The first vibration motor is on the front side, the second one is on the left side, the third one is on the right side and the last one is situated at a place where the user will keep his palm. A circuit box is situated in the middle portion of the device. Three ultrasonic sensors are added under the circuit box and another two ultrasonic sensors are added in the bottom side of the device.

E. *Power consumption:*

The overall power consumption of the device is shown below:

TABLE II POWER CONSUMPTION PER DAY

Component	Power Consumption Per Day
Arduino Mega	170mA*60s*60*24h =14688000mA =14688A
SIM 808(GPS & GSM)	1mA*60*60*24h =86400mA =86.4A
HC – SR04 sensor	5*15mA*60*60*24h =6480000mA =6480A
LDR sensor	0.5mA*60*60*24h =43200mA =43.2A
Vibration motor	4*17mA*60*60*24h =5875200mA =5875.2A
Buzzer	15mA*60*60*24h =1296000mA =1296A
LED	2*20mA*60*60*24h =3456000mA =3456A
TOTAL (A)	**31924.8A**
TOTAL (mA)	**31924800mA**
SOURCE POWER 5V,10000mAh	**36000000mA**

[b] Total power needs to operate this device

All the components assembled in the device has a supply voltage rating of 5V and the power source used for this device a 5V-10000mAh standalone battery pack. The power consumption table has been completed assuming all the equipment are running at the same time, continuously and after calculating the values it appeared that the device can run for 24 hours, efficiently.

F. The outlay of the device:

The expense of all the equipment used in the device is shown table-III, given below:

TABLE III COST CALCULATION

COMPONENT	Quantity	Price (USD)
Arduino Mega	1	$8.95
HC-SR04	5	$5
LDR & Buzzer	1 & 1	$0.2
Vibration motor	4	$4
LED & resistor	2 & 2	$0.15
GPS & GSM (SIM 808)	1	$19.08
Switch	1	$0.06
Syb170 mini bread board	1	$0.4
Battery	1	$12.16
TOTAL PRICE		**$50**

[c] Price list of the components

The total cost of the device is only $50. Compared to the features and usefulness of this device, the cost is very low and the device is easily affordable.

IV. FEATURES AND COMPARATIVE ADVANTAGES:

Features available in the device:

- Detects any kind of obstacles in its path up to 180°.
- The device detects liquid.
- Uneven surface detection is another special feature of this device.
- Location tracking and sending a text with the user location in two ways. When the user needs to share his location or the family members needs to know the location of the user.
- This device also detects the darkness to make others known the user.
- Highly effective, much accurate, user-friendly and affordable.

Comparative advantages of the device:

The cost of this device is lower than many devices available in the market having the same features. The name of the device which was introduced before was An Assistive System of Walking for Visually Impaired [7]. This device offered $30 cost but there were many lacking accuracies about measuring distance and there was no any system of detection uneven surface and liquid, as well as there, was no any GPS-GSM module to track the location and to send the data. Another device named Radio Frequency
Identification Walking Stick (RFIWS): A Device for the Blind [8] used RFID technology to make their device but there is no liquid detection system and location tracking system. Overall, they proposed a good solution but the user was biased to follow a specific path whereas using our device user is independent of which path to follow. Also, their proposed solution is costlier because cost increases along with path length but our device having no dependencies to which path to follow and path length, only the device cost is to be taken into account. Making it a lot cheaper in comparison. The other paper proposed a device named An Electronic Walking Stick for Blinds [9]. They used the GSM module to send a text with a warning but there was no location tracking system and the GPS-GSM module could be used together to track the location and to send a text with the exact location. Another group proposed a device-SWSVIP–Smart Walking Stick for the Visually Impaired People using Low Latency Communication [10]. They used the GPS module and mobile application to send the data via Bluetooth but the problem is that a Bluetooth enabled phone is always needed with user of the stick. The system actually made the device complex but, in our device, there is no need of any mobile phone to send the data to another phone number and this system makes the device simple and easily affordable. Another group introduced a system named Blindar: An Invisible Eye for the Blind People [11]. They proposed a system which was a combination of ultrasonic sensor, MQ2 gas sensor, Wi-Fi and GPS module but they also did not introduce any liquid detection system and they proposed the GPS system and Wi-Fi system which is

unreliable because Wi-Fi is not available everywhere especially in street to upload the data to the selected website. To overcome the drawbacks of the proposed devices earlier we have introduced the “Intelligent Path-finder” for the blind people. One of the main advantages of this device is that the location tracking in two ways. Sending a text to an accessed family member is available when the user wants at any time and the other way to get the location of the user is sending a text from any phone number from anywhere with text having a word “Location”. Liquid detection with 100% accuracy without any sensor has been achieved in this prototype, making the device less costly and this system was not introduced in any other devices earlier. Also, special advantage of this device is to make the user visible in dark and this feature also was not introduced before in any device.

V. CONCLUSION

We are living in a modern, civilized and a very developed world, constantly trying to make the life better. Though the people of the modern world are trying to make this living place more beautiful and peaceful day by day, there are many subjects which are not updated according to the developed world and one of those subjects is the cure for the visually impaired. The attempt of trying to do something for them and, as a result, many autonomous devices are introduced earlier for the visually challenged. It seems that those devices are either out of range for the blind people or they are not suitable and accurate for them. In order to really help the blind people, a device named “Intelligent Path-Finder” is already introduced in this paper. This device consists of a few sensors with a combination of microcontrollers and a power source which is already described in the system description section. As a result, it can detect any type of obstacle and uneven surface up to 180° around the user. It also detects the liquid and darkness with its inbuilt method with 100% accuracy. Despite being so accurate and advanced, the cost of the device is kept in a very low range which may be approximately $50 and the cost tends to be lower than the many devices available in the market having same or less features.

***Abstract*— Physical disability has been incessant thinking for the past several eras. Wheelchairs are the sift partner for most of the disabled people in their day-to-day life. In order to collaborate with physically disabled people, a multi-controlled semiautonomous wheelchair is developed in this paper which can carry them prudently without the assistance of any other human caretaker. The disabled people can navigate and control the speed of the wheelchair by joystick, voice command or gesture command. The system can detect the obstacle in the front side and back side of the wheelchair and can stop the movement automatically to avoid collation. It can also detect any hole when it is moving in the font direction and stops the movement to protect the disabled person from an accident. In case of an accident if wheelchair tilted extensively from its normal orientation the system automatically stops the motors, sends SMS to the relative with GPS location and sounds the buzzer to draw the attention from others. The evaluation of the performance of the system shows that it can be a very helpful friend in the daily life of physically challenged people.**

Keywords*— wheelchair; voice control; gesture control; microcontroller; joystick

I. INTRODUCTION

Disability in mobility can be either an inborn or acquired with age problem. It could also be the effect of a disease. People who have a broken bone also fall into this category of disability. Types of disabilities include various physical and mental impairments that can hamper or reduce a person's ability to carry out his day to day activities. These impairments can be termed as a disability of the person to do his or her day to day activities. Currently, around 15% of the world's population, or roughly 650 million people, live with a disability. In most of the countries, females have higher rates of disability than males. As the population ages, this figure is expected to increase. Eighty percent of persons with disabilities live in developing countries. Therefore it is a prodigious responsibility of the researcher to develop a user-friendly and cost-effective system to ensure the safe movement of the disabled people.

Wheelchairs driven by electric motors can be classified as autonomous, semiautonomous or manually guided wheelchair [5]. A lot of research work on a wheelchair has been done where the researchers proposed autonomous, semiautonomous or manually guided wheelchair to assist the comfortable and safe movement of physically challenged people. Voice, gesture, and the touch-based wheelchair is introduced in [1,2,3,4] in which the user can navigate the wheelchair by means of voice, gesture or touch switch. Computer vision based smart wheelchair is proposed in [7] where the system can detect the obstacle and track human. In [8], a smart wheelchair model is proposed which can be controlled by eye tracking. Some previous research only focused on controlling the speed and direction of wheelchair whether some proposed system also considered the detection of obstacle during movement of the wheelchair.

In our proposed system we have focused on combining all the possible features of previous work considering multiple options of movement control, safety issues, accident detection and tracking the location of the wheelchair. The major contributions of this research are listed as follows-

- The system has several options such as gesture, voice, joystick, and android application to control both the speed and direction of wheelchair.
- The system can detect the obstacle as well as a hole in the front and back side of the wheelchair.
- The 3-axis accelerometer sensor is incorporated to sense the orientation of the wheelchair to detect an accident.
- It sends SMS with location information to the relative of the disabled person and also plays sound by buzzer in an accidental case.
- By sending an SMS to the system the relative of the disabled person can know his/her current location.

II. OVERVIEW OF THE SYSTEM

The overall block diagram of the system is shown in "Fig. 1". An 8-bit microcontroller (ATmega328P) is used which is act as a brain of the system. It coordinates all the input-output devices of the system following the instructions loaded in its ROM. Sonar sensor-1 and sonar sensor-3 are used to detect the obstacle in the front and back side of wheelchair respectively, whether sonar sensor-2 is used to detect any hole in front of the wheelchair. The role of the

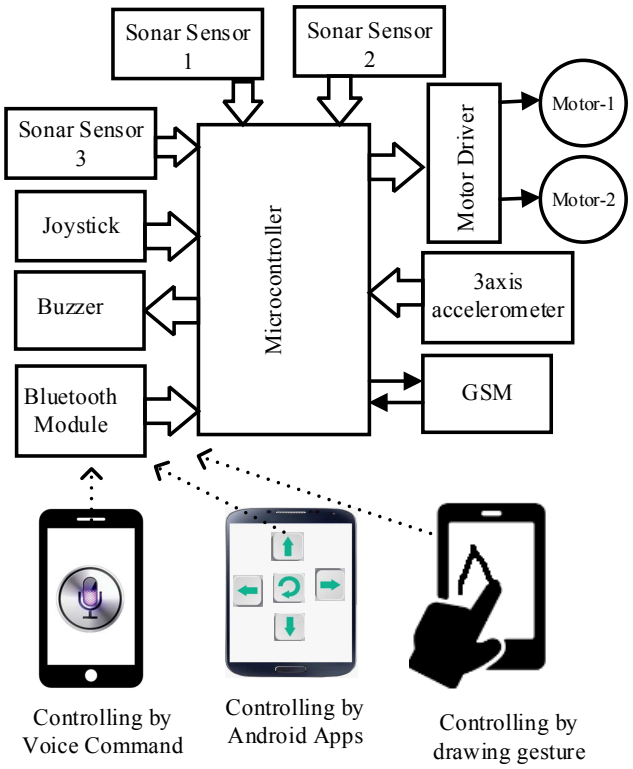

Fig. 1. Block Diagram of the System.

joystick is to control the speed and movement of the wheelchair. Controlling the movement of the wheelchair by voice, gesture command or android apps depends on a smartphone where a Bluetooth device in the system receives data from the smartphone and takes a decision. The microcontroller can detect the orientation of wheelchair with respect to the earth surface by reading data from a 3-axis accelerometer sensor. Abnormal orientation represents an accident to the system. Buzzer module is used to produce sound in case of an accident. Two dc motors move the wheelchair in forward, reverse, left or right direction. These dc motors are controlled by the microcontroller via a motor driver. The system read the location of the wheelchair through a GSM modem and also sends SMS to the relative of disable person in case of an accident. The system sends an SMS with the current location of the wheelchair through the GSM modem in the response of an SMS received from the relative of the disabled person.

III. System Design

This section describes the methodology of developing the prototype of the proposed system. The development process includes controlling speed and direction of DC motors by joystick, controlling the movement of the wheelchair by voice and gesture, detection of obstacle and accident, reading location and sending SMS by GSM.

A. Controlling speed and direction of wheelchair

The movement of the wheelchair depends on two DC motors. If both the DC motors rotate in the forward or reverse direction, the wheelchair goes in forward or reverse direction respectively. Turning left and turning right is performed by changing the speed or direction of DC motors.

In the proposed prototype, the microcontroller controls the speed and direction by L298N motor driver which is a dual H-bridge motor driver IC. It has 4 input (IN1, IN2, IN3, IN4) and two enable (ENA, ENB) pins. The microcontroller can change the direction of DC motors by changing the logic level of these four input pins of the motor driver. The speed of the motor depends on the enable pins. If the status of enable pin is logic 1, the motor will rotate with its maximum speed. But applying pulse width modulated (PWM) signal with different duty cycle to the enable pins can vary the speed of the motor. This technique is useful to control the speed of wheelchair as well as to turn it in the left or right direction. The relation of movement associated with the status of input and enable pins of the motor driver is illustrated in "Table-I".

TABLE I. Movement of Wheelchair

IN1	IN2	IN3	IN4	ENA	ENB	Movement of wheelchair	
						Direction	Speed
0	0	0	0	0	0	Stop	0
1	0	1	0	1	1	Forward	Maximum
1	0	1	0	PWM	PWM	Forward	Depends on duty cycle
0	1	0	1	1	1	Reverse	Maximum

To control the movement of the wheelchair by joystick, microcontroller read data from joystick and set the status of input and enable pins of a motor driver following "Table-I". A joystick has two potentiometers that allow us to measure the movement of the stick in 2-D. The potentiometers are variable resistors and they act as sensors providing us with a variable voltage depending on the rotation of the device around its shaft. The change of voltages with respect to the movement of the joystick shaft is anlog that changes from 0 to 5V for the complete movement in both x or y-direction. These analog voltages are converted into digital by using the A/D converter of the microcontroller. The microcontroller

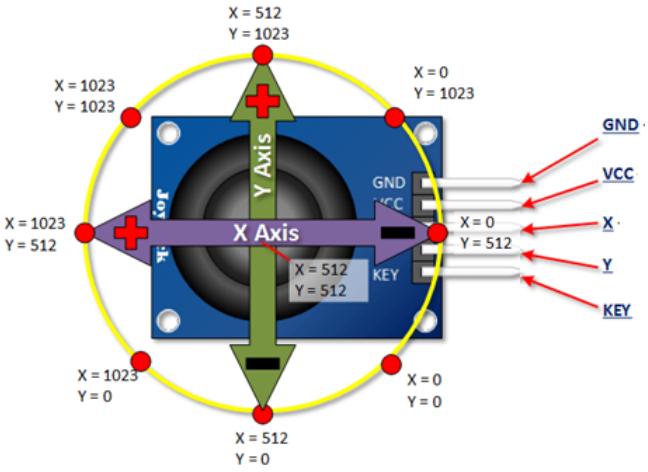

Fig. 2. Digital value of voltages in different positions of joystick shaft.

used in this project has a 10-bit A/D converter with six analog channel. We have set the reference voltage of A/D converter as 5V. Therefore, the conversion of the analog voltage from 0 to 5V results a 10-bit data which varies from 0 (00 0000 0000 in binary) to 1023 (11 1111 1111 in binary). In the normal position of joystick shaft the analog value of both x and y pins are around 2.5 V (corresponding digital data is 512). But if we move the shaft in right towards the x-axis the value reduces gradually from 2.5 V to 0 V (corresponding change in digital value: 512 to 0) whether moving left along the x-axis gradually increases the voltage from 2.5 to 5V (corresponding change in digital value: 512 to 1023). The digital value of voltages in different position of joystick shaft is shown in "Fig. 2". The relation of these digital data with motor direction and speed is shown in "Table-II".

TABLE II. MOVEMENT OF WHEELCHAIR

x-value	y-value	Motor direction and speed
400 to 600	400 to 600	Stop
601 to 1023	400 to 600	Forward direction with speed 0 to maximum.
399 to 0	400 to 600	Reverse direction with speed 0 to maximum.
400 to 600	601 to 1023	Left motor forward and right motor reverse with speed 0 to maximum.
400 to 600	399 to 0	Left motor reverse and right motor forward with speed 0 to maximum.

To control the movement of the wheelchair by voice we have used an android application named 'ARM_Voice'. It converts the human voice into text using 'google voice assistant'. The text is then transmitted to the microcontroller of the wheelchair circuit via Bluetooth. Analyzing the received text, the microcontroller controls speed and direction of DC motor. Another application named 'ARM_Gesture' is used which reads a gesture drawn in the smartphone and send different ASCII code for each different gesture to the microcontroller via Bluetooth. The ASCII code transmitted for the different gesture is listed in "Table-III". After receiving these code microcontroller sets the logic state of motor driver input pins and duty cycle of the enable pins to controls the movement of a wheelchair according to the user instruction.

TABLE III. CODE TRANSMITTED FOR DIFFERENT GESTURE

Gesture	Transmitted Code	Gesture	Transmitted Code
 Forward	0100 0001	 Fast	0100 0101
 Reverse	0100 0010	 Medium	0100 0110
 Right	0100 0011	 Slow	0100 0111
 Left	0100 0100	 Stop	0100 1000

B. Obstacle Detection

Sonar sensors are used to detect obstacle and hole in the front or back direction of wheelchair. A sonar sensor has four pins: Vcc, GND, Trigger, and Echo. The trigger pin is connected with an output pin of microcontroller where the echo pin is connected with an input pin. The microcontroller sends a low to high transition in the trigger pin of the sonar sensor. In response to the low to high transition in the trigger pin, the sonar sensor generates and transmits eight sound pulses of frequency 42 KHz. In the meantime, echo in of sonar sensor becomes HIGH. It becomes LOW if the sound transmitted from sensor reflected back to the sonar receiver. Therefore, the HIGH time of the echo pin represents the traveling time of sound to travel 2d distance, where d is the distance of the obstacle. The HIGH time of the echo pin is measured by using the internal timer of microcontroller and this time is placed in the following equation [13] to measure the distance of the obstacle

$$d=(0.0342\times t)/2 \text{ cm} \quad (1)$$

where, d is the distance and t is the time in microsecond measured by the internal timer of microcontroller.

C. Accident Detection

To detect the accident microcontroller continuously read the orientation of the wheelchair from a 3-axis

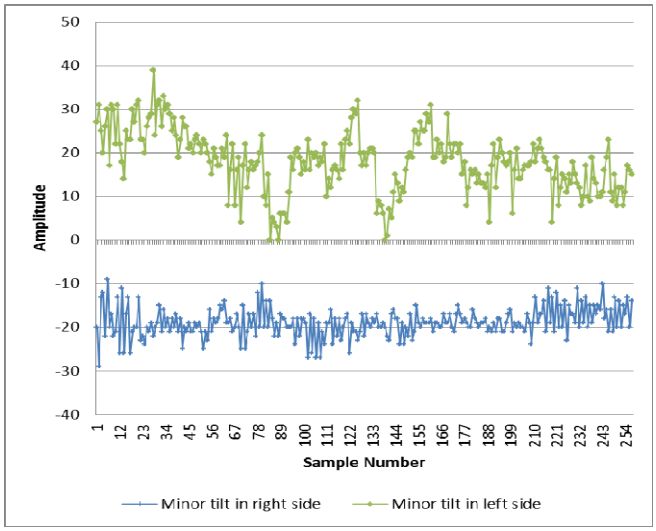

Fig. 3. X-value of accelerometer in normal orientation of wheelchair.

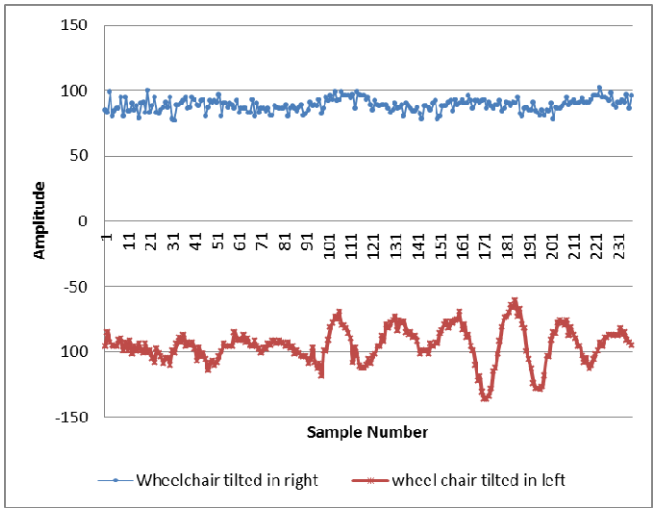

Fig. 4. X-value of accelerometer in abnormal orientation of wheelchair

accelerometer sensor (ADXL345). The accelerometer sensor provides six bytes data which carry information about the orientation (x-value, y-value and z-value) of the sensor with respect to the earth surface. The microcontroller reads the data from the accelerometer sensor through its I2C (Inter-Integrated Circuit) bus: SCL (Serial Clock) and SDA (Serial Data Lines). In normal orientation when wheelchair moves, the x-value, and y-value varies from -30 to 40 which is shown in "Fig. 3". On the other hand, if wheelchair tilted perilously or capsized due to accident x-value and y-value of ADXL345 will fall below -30 (up to -150) or rise above 40 (up to +150) which is illustrated in "Fig. 4". Therefore, the microcontroller can detect the accident examining the data of ADXL345.

D. Reading Location and Sending SMS

The GSM (SIM800) module is used to get the location and send SMS. The microcontroller communicates with the GSM through some AT commands using UART (Universal Asynchronous Receiver and Transmitter) communication protocol. The baud rate used for serial communication is 115200 bps. The list of AT commands [14] used to read location and for sending and receiving SMS are listed in "Table-IV".

TABLE IV. LIST OF AT COMMANDS

AT Commands	**Functions**
AT+CPIN	Returns READY when modem is connected with network.
AT+CMGF=1	To setup SMS as a TEXT message
AT+CMGS="Phone Number" <Enter> Message Body <Ctrl-Z>	To send a SMS
AT+CNMI=2,2,0,0,0	Activate direct reading of incoming SMS.
AT+SAPBR=3,1,"Contype","GPRS"	Set the connection type to GPRS
AT+SAPBR=3,1,"APN","www"	Enable the GPRS
AT+SAPBR=2,1	Query if the connection is setup properly, if we get back a IP address then we can proceed
AT+CIPGSMLOC=1,1	Read Location (latitude and longitude)

IV. IMPLEMENTATION AND RESULTS

In this section, algorithm of the project, the complete implementation and results have been discussed with the proper demonstration.

A. Flowchart

Flowchart of the program loaded in the microcontroller is given in "Fig. 5". The instructions (program) are written in two main functions: void setup() and void loop(). The instructions written in void setup() function are executed only one time where the instructions written in void loop() are executed repeatedly. Here, joining I2C bus as master, initializing I/O pins, sending control word to accelerometer, defining UART baud rate, etc are executed only one time and other instructions are placed in an infinite loop. In the infinite loop section, microcontroller continuously

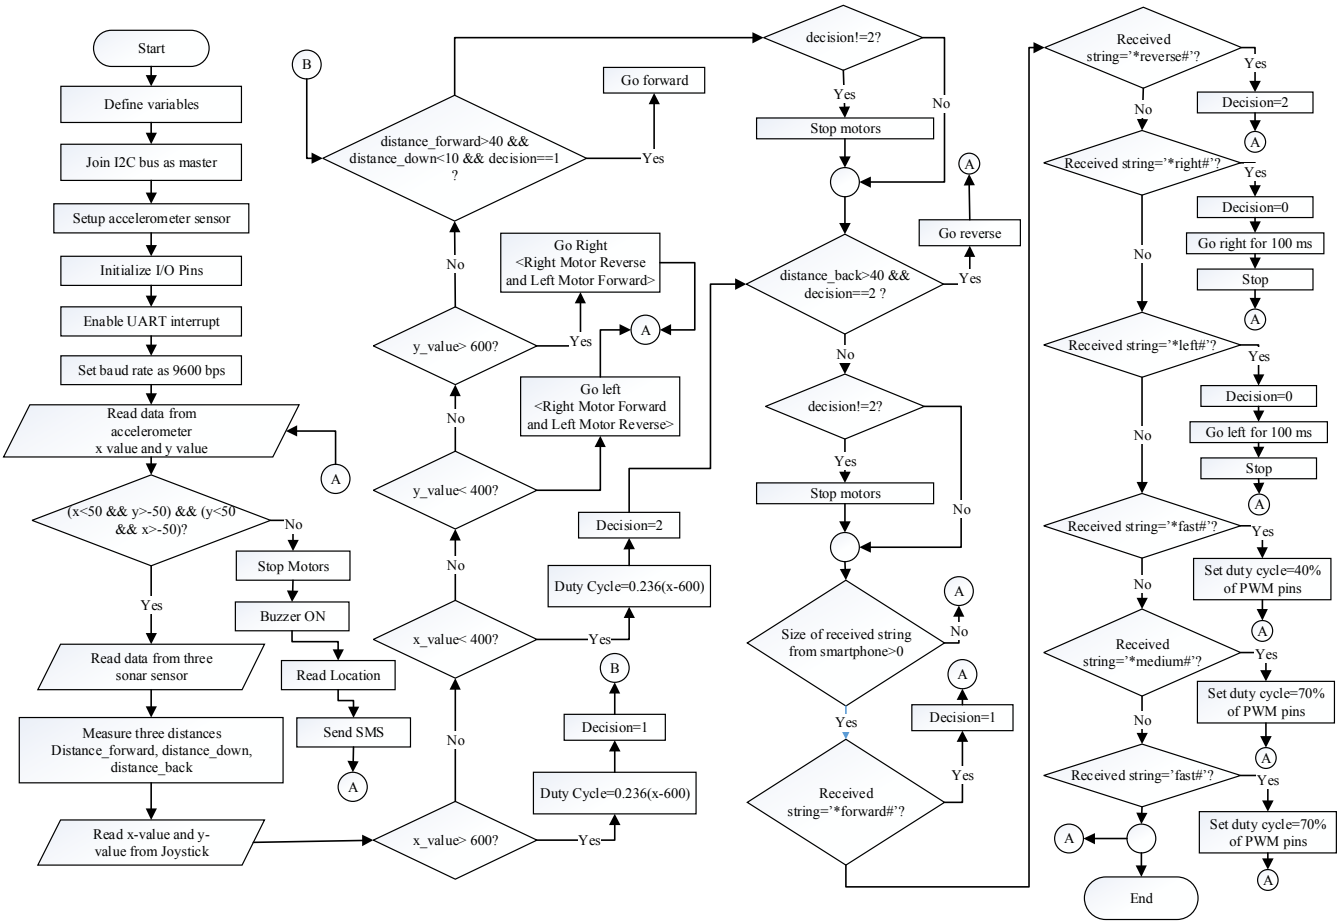

Fig. 5. Flowchart of the program loaded in microcontroller.

read the x-axis and y-axis value of 3-axis accelerometer and check the given condition. If the condition is false, microcontroller stops all motors and sends HIGH-LOW pulse to the buzzer. In case, the condition is true, the microcontroller reads all sonar sensors and calculates the distance of the obstacle from all sensors. Then it checks the given conditions, read the data from joystick and also read the user instructions transmitted from the smartphone to take a decision.

B. *Implementation*

A prototype of the system is implemented according to the methodology described above. The implemented prototype is shown in "Fig. 6". All the components used to develop the prototype and total price of the components are listed in "Table V". To implement a real system which can carry a human with a weight of 80 kg, we have to change only motors, motor driver and chassis of the developed prototype without changing the other components.

TABLE V. LIST OF COMPONENTS

Components Name	Quantity	Unit Price	Total Price
Microcontroller (ATmega328P)	1	420	420
Sonar Sensor	3	80	240
3-axis accelerometer (ADXL345)	1	890	890
GSM (SIM800L)	1	500	500
Motor Driver (L298N)	1	154	154
DC Gear Motor	2	400	800
Joystick	1	218	218
Bluetooth HC05	1	279	279
Buzzer	1	10	10
Chassis	1	1000	1000
	Total Price		4,511

Fig. 6. Implementation of speed controller circuit.

C. *Results*

To demonstrate the performance of the implemented prototype we have taken the value of different parameters such as data of joystick, the distance of obstacles (forward distance, backward distance, and down distance), and the duty cycle of PWM signals given to the enable pins of the motor driver (normalized speed of the left and right motor). All these parameters are the internal variables of the microcontroller and are recorded to an SD card during the operation of the system. Then to realize the operation of the wheelchair we have plotted the different parameters with respect to time. "Fig. 7" and "Fig. 8" represents the normalized speed (duty cycle of the PWM signals of motor driver enable pins) and direction of DC motors with the movement of joystick shaft. In "Fig. 7", the x-value of joystick has a value of 128 in normal condition and the speed of both motors is zero for this situation. But, when x-value increases from 128 to 255, the speed of motors also rises from 0 to 100% in the forward direction. On the other hand, when x-value decreases from 128 to 0, the speed of the motors is rising from 0 to 100% in the reverse direction. The variation of motor speed with the movement of the joystick shaft along the y-axis is illustrated in "Fig. 8".

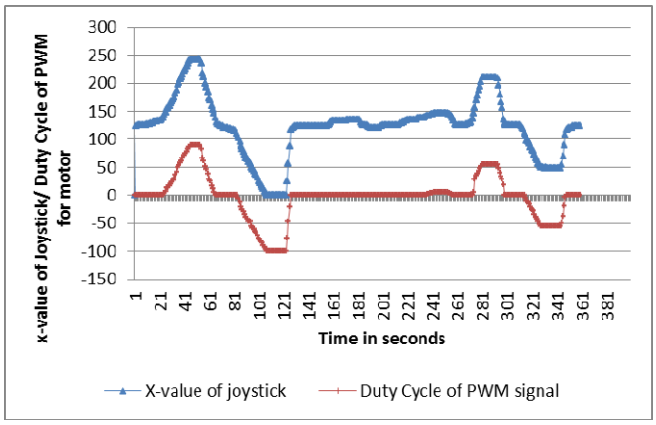

Fig. 7. Variation of motor speed with the movement of joystick shaft along x-axis.

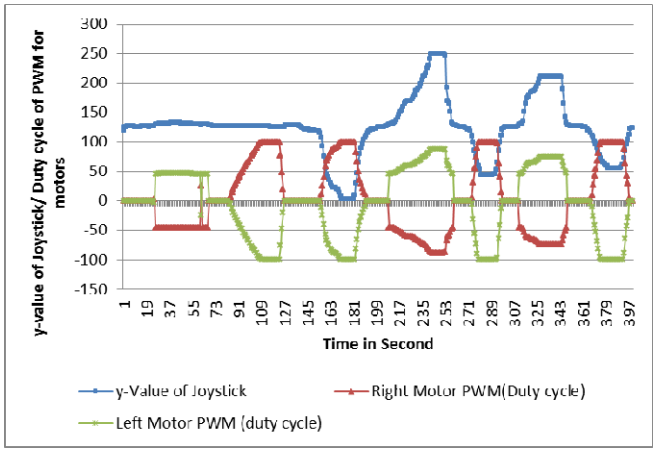

Fig. 8. Variation of motor speed with the movement of joystick shaft along y-axis.

"Fig.9 ", shows the performance of wheelchair in different voice command with the distance of obstacle in front, back and down direction. In the 8th second of operation, the system has received the voice command 'go forward', as a response of the command both motors are going forward with 100% speed. In the 23rd second, the system has received the command 'go slow' and motor speed decreases to 45%. Similarly, after 41 seconds later the system sets the

motor speed as 60% after getting the voice command 'go medium'. During the time (8th second to 56th second) as the wheelchair has moved in the forward direction, the distance of obstacle in the forward direction was coming closer. Eventually, when the distance of obstacle in forwarding direction reduced below 40 cm, the speed of the motor became zero.

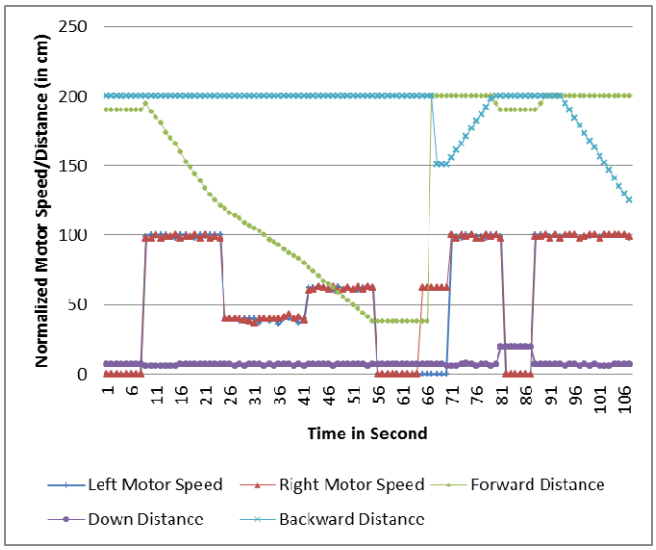

Fig. 9. Performance of the Wheelchair.

V. CONCLUSION

This project is comfortable for those people who are physically disabled. It provides more comfort to move their wheelchair in their own directions without the help of other people. This project greatly decreases the dependency of physically challenged people on their family members. The wheelchair also provides efficient risk management by obstacle detection and obstacle avoidance. During any emergencies or accident, disabled people can alert any of the people around him. He or she can easily do this by the help of the buzzer that is placed on the wheelchair. The wheelchair is designed in a cost-effective way so that if our project is commercialized the needy users in developing countries will get benefit from it. In future we can add some more useful features to the proposed system like autonomous tracking to carry disabled people from one location to another location, computer vision based object detection and IoT based health monitoring.

***Abstract*—Physical disability in people may be either congenital or acquired. In either case, the disabled person requires an aid for movement in both the indoor and outdoor environment. The most common form of assistance to provide support to the disabled is the wheelchair. Therefore, the aim of this article was to design and develop a prototype of the smart wheelchair to provide assistance to various types of mobility impairments. People suffering from various motor disorders are incapacitated and thus, the chair has the provision for both - voice commands as well as manual controls via a joystick. The wheelchair includes a customizable voice control system which is Bengali by default and incorporates a feature for asking help in case of necessity. Along with this, the provision of continuous monitoring is also present for ease of caregivers to locate the user when help is asked or the caregiver is unable to be physically present with the user. Other features such as obstacle detection, speed control on ramps, lighting up of the headlight in dark environment, reclining of the wheelchair have been integrated into the wheelchair as well. The prototype was demonstrated and evaluated in a controlled environment. The outcome of the experiments proved its effectiveness and efficiency for the focused users.**

***Keywords*—** Intelligent system; disability; congenital disability; mobility impairment; smart wheelchair; assistive tool

I. Introduction

Disability is a disorder that hampers the daily life of the affected people by limiting the person's movement, senses, ability to think or act. Disability can either be congenital or acquired. Congenital disabilities are usually inherited while acquired disabilities occur due to any accident or illness. According to the report of Australian National University, disabilities can be of different types i.e. vision impairment, deaf or hard of hearing, mental health conditions, intellectual disability, acquired brain injury, autism spectrum disorder, physical or motor disability [1]. Motor disability is the partial or total loss in muscular functions of the body [2]. These disabilities include arthritis, cerebral palsy, multiple-sclerosis, muscular dystrophy, acquired spinal injury (paraplegia or quadriplegia), post-polio syndrome, spina bifida [3]. All of these disabilities inhibit the normal movement of the affected people.

Nearly 15% of the world's population consists of people having disabilities and 2-4% of them have serious problems in functioning [4]. According to a U.S. Census Bureau report during the period of 2008-2012, nearly 40% of people aged 65 and above had at least one disability and of those 15.7 million people, two-thirds of them were reported to have problems in either walking or climbing [5]. In 2014, 3.8 million veterans in US had a disability that was a result of a disease or injury during their service in the military [6]. Bangladesh has a population of 163 million [1] of which nearly 10% comprises of people with disability[2]. So, a significant number of people in Bangladesh are suffering from some kind of disabilities.

Despite the fact that, one of the most common aids for movement for the physically impaired people is the wheelchair, it is still not enough to meet the needs of all types of motor disabilities. Wheelchairs are mainly designed to help people suffering from disabilities in the lower limb area. As a result, people who have issues like tremor or problems in the upper limb area are unable to operate the wheelchair properly. Along with this problem,it is almost impossible to always provide assistance to the affected patient. Smart wheelchairs are widely used in developed countries to address these problems which costs roughly between $750 to $13000 [7]. Thus they are not affordable to the disabled people of developing countries like Bangladesh. Moreover, language barrier has been a barrier in adopting technology in Bangladesh. Keeping these problems in mind, a smart solution has been devised that incorporates the disabled patient to have the maximum control of the wheelchair and can be operated with the help of voice as well as a joystick. It also includes continuous monitoring so that caregivers can check on the patient without being physically present near the patient at all times. The main aim is to provide complete freedom of movement without any external assistance. The smart wheel is also integrated with other features such as reclining back to avoid muscle cramps, asking for help via SMS by a simple click, obstacle detection, lighting up the wheelchair''s light in dark environment, and speed control to provide maximum ease to the patient.

Therefore, the objective of this research is to design a prototype of a smart wheelchair that will provide maximum assistance to the disabled so that they can move with maximum independence.

In the following sections, Section II presents the overview of the Related Works, Section III comprises of the Conceptual Design of the System, Section IV discusses the Implementation of the System. The demonstration and evaluation results are discussed in Section V. Finally, Section VI contains the Conclusion.

II. Related Works

A significant part of the world population is being affected by the motor or physical impairment. Thus a number of studies has already been carried out to assist them and to ease their struggle

[1] www.worldometers.info/world-population/bangladesh-population/
[2] www.wikipedia.org/wiki/Disability_in_Bangladesh#cite_ref-wbrep_2-0

[8]–[10]. This section briefly introduced the work related to the design. development, and evaluation of wheelchair to support the people with congenital and mobility disability.

A few earlier studies focused to the design and development of wheelchair controlled by voice-commands. For example, Meena et al. [11] developed a wheelchair for paraplegic and other physically disabled people that has feature of voice recognition in addition to the use of joystick. Similarly, the wheelchair proposed by Nishimori et al. [8] included the feature of controlling the system with three types of voice commands: the basic reaction command, the short moving reaction command, and the verification command. Again, wheelchair developed by Mazo et al. [12] and Simpson & Levine [13] also controlled by the voice commands and incorporated the features of detecting obstacles like holes, walls, etc. to reduce the number of collisions on a simple navigation task. On the other hand, a smart wheelchair was developed that used eye movements to drive the wheelchair [14]. A web camera has been used to detect the eye movement and an error handling mechanism has been used to calibrate values of threshold for the eye movement for the user.

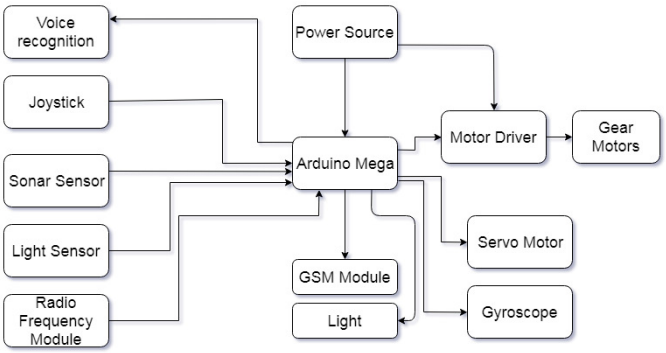
Some research highlighted the navigation feature and its accuracy while proposing the wheelchair. The objective of such studies was to provide personalized wheelchair with dynamic routing functions and better accuracy of position [15], [16] . This chair included the real-time navigation support, that helps to move in areas having ramps , doorways with sufficient width for the user to pass. Similarly, Levine et al. [17] developed the *NavChair* that support the navigation of wheelchair for users with large range of disabilities. The *NavChair* included the ultrasonic sensors, joystick and an interface module; obstacle avoidance; door passage and automatic wall following, and was able to move through crowds and make abrupt change in directions with minimal reduction in speed. In another work, Simpson et al. [18] developed a Smart Power Assistance Module (SPAM) which was intended for physically disabled people who were also blind. Keeping vision impairment under consideration, the chair provided obstacle detection to avoid the collisions on a simple navigation task.

The customization of seating position like changing the seat height, movie the seat support bar forward or rearward, transferring from a wheelchair to a bed, etc. were considered in [19], [20] to making the use of such wheelchair comfortable. Some other studies discussed how the Artificial Intelligence was being considered to develop the wheelchair. For example, Braga et al. [21] introduced the concept for intelligent wheelchairs called *IntellWheels* that took inputs from traditional and USB joysticks, keyboard ,head movement as well as facial expressions, while Prathyusha et al. [22], [23] developed an intelligent wheelchair that used the programmable voice recognition circuit for voice commands. Hartman et al. came up with a a smart chair [24] focusing on parallel computer processing where hardware, software and sensor technology was integrated. The system is designed in such a way that the human takes the decision and the rest of its motion is controlled by the smart control technology. Considering the cost associated with a smart wheelchair Simpson et al. came up with a smart wheelchair component system [25] that could be added to existing wheelchairs with minimal modification. It was then tested across four existing wheelchair models.

To sum up, most of the mentioned wheelchairs did not contain any continuous monitoring. Again, a survey conducted by Fehr et al. [26] found the inadequacy of the electrical wheelchair since people with severe disabilities will not be able to steer power wheelchair in areas where space is limited. To find the adequacy of control interfaces, control methods such as joystick, sip-and-puff and head or chin controls were used. The existing wheelchair could not be suitable for many of the physically disabled people from Bangladeshi due to the excessive cost and voice commands (in English). Along with these, the provision of light and speed control for ramps was not handled properly. Therefore, this research concentrates on building a smart intelligent wheel chair with continuous monitoring using Bengali command. This paper handles the aforementioned limitations which in turn paved the way towards an affordable wheelchair option with multiple functionality that can provide maximum support in a affordable cost to the disabled. The proposed system in this paper tries to use the existing technology in a new manner to help physically impaired people in Bangladesh.

III. Conceptual Design of the System

The proposed system is a voice controlled smart wheelchair which supports any language but Bengali has been chosen in order to support the physically impaired people of Bangladesh. Along with the voice control, it also supports manual control. The two methods have been kept for reaching out to various types of mobility impairments. Figure 1 represents the basic work flow of the wheelchair. .



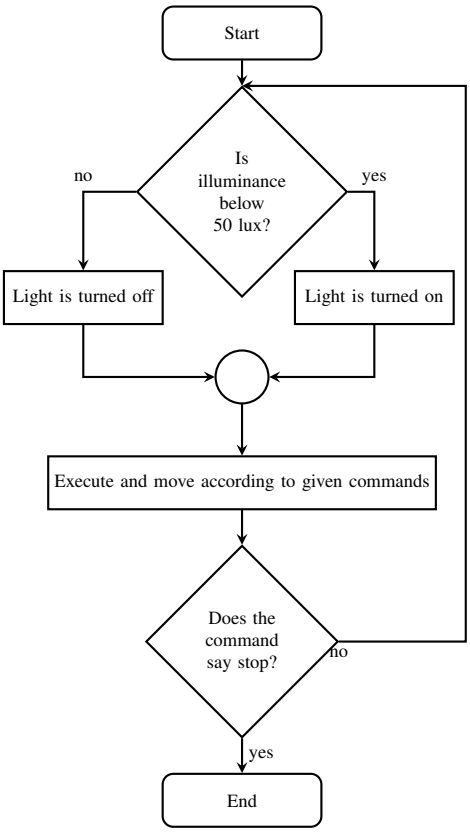


Fig. 1. Architecture of the proposed smart wheelchair

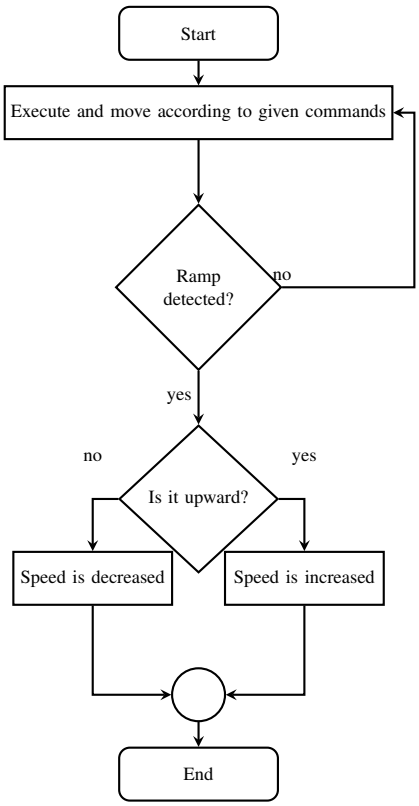
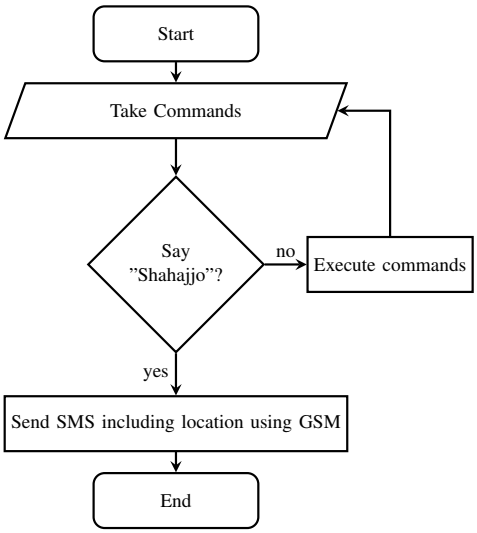


A. Features of the smart wheelchair

The smart wheelchair will include the following features to attain the objective of this research:



1) *Manual control*: Manual control is for those disabled people who are able to use their hands for controlling the movement of the wheelchair. A joystick is used for enabling the manual control which will move the wheelchair in the forward, backward, right and left direction.The joy stick is not fixed with the body rather it is wirelessly connected and movable.
2) *Controlling through voice commands*: Disabilities like quadriplegia make the users unable to use manual control for wheelchair for which voice commands has been incorporated with the system. The commands can be customized to any language. For this project Bengali language has been considered. The commands are 'Dane', 'Bame', 'Samne', 'Pichone', 'Thamo' which interpret in English as 'Right', 'Left', 'Forward', 'Backward' and 'Stop' respectively.
3) *Sending SMS for help*: Despite the various precautions taken, the user might still fall down from the wheelchair or need external help. For this, the voice command, ′Shahajjo′ (help) will send an SMS including the chair's current location to the user's caregiver asking for assistance. Figure 2(c) represents the working procedure of the system for Sending SMS.
4) *Longitudinal obstacle detection* : Obstacle detection is required so that the wheelchair does not bump into pillars, walls or any other object even if the user gives gives commands that would accidentally cause collision. Therefore, upon detecting, the wheelchair will automatically stop when a certain obstacle

(a) Light up

(b) Speed control

(c) Sending SMS

Fig. 2. Working procedure for light up (a), speed control (b), and sending SMS (c)

is present at the front or rear and will not execute any given command in that direction.

5) *Speed Control*: While going up and down the ramp, the speed needs to automatically counteract the increasing or decreasing speed due to gravity. So, for slopes or ramps, depending on the upward or downward direction the speed will automatically increase and decrease respectively.It works for both forward and backward direction. Figure 2(b) shows the working procedure of the process of speed control.
6) *Continuous Monitoring*: Many disabled people often have caregivers. Since it's not always possible for them to be present at sight, the continuous monitoring is kept so that the user's movement can be tracked with current location. Its done by receiving the satellite data through GPS. Then the WIFI module gets that data, decodes it into latitude and longitude and sends it to the cloud server. Thus the wheelchair's location can be accessed from the mobile phone. Figure 3 describes the architecture of Continuous monitoring using GPS and Wi-Fi Module.

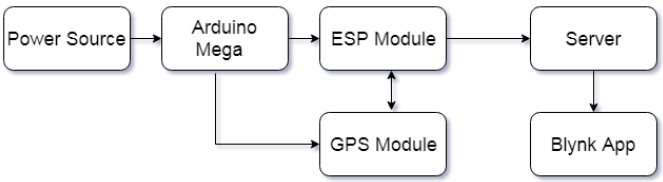


Fig. 3. Block Diagram of Continuous Monitoring

7) *Reclining the wheelchair*: Sitting down continuously in the same position is not good for the health of the user [27]. Moreover user's comfort have to be considered as well. So, option of reclining is kept to break the monotonicity and making it more comfortable. Therefore the back of the wheelchair can be reclined to any position as per the user's comfort.
8) *Light Up*: The user might have to move in indoor or outdoor environment with insufficient light or there might be unavailability of light due to power outage. In these circumstances the wheelchair will sense the shortage of light and automatically light up. Figure 2(a) demonstrates the working procedure of this feature.
9) *Controlling the Wheelchair from a distance*: The user will be benefited by this feature when he is not on the wheelchair. The user can give command from a certain distance and the wheelchair will move according to the command. This will prove to be helpful when the user is lying on the bed and the wheelchair has been moved away from him. We have preferred to use Bengali language for this.

IV. Implementation of the System

A prototype has been developed for demonstrating the above mentioned features which has been shown in Figure 4. The whole implementation was carried out in an academic environment. The wheelchair is powered with the help of two batteries. One low voltage battery is used to power up the Arduino which is programmed to control the wheelchair and another high voltage battery is used to power up the motor driver. The motor driver is able to drive only two motors. Therefore two pairs of motors on each side are connected in parallel and is being driven by the motor driver. There are four wheels for each of the gear motors.

The main hardware components are the different modules that are connected with the Arduino. An Arduino Uno is used for controlling the wheelchair from remote distance. Radio Frequency module is used for this purpose. Two Arduino Mega are used for integrating all other modules implanted on the wheelchair body. It could be done using one Arduino Mega. But to distribute the load and for proper wiring two Arduino Mega have been used.

A Joystick is used for controlling the wheelchair manually. Five commands can be given through this joystick. The commands are for forward movement, backward movement, right movement, left movement and stopping the movement.

Controlling the wheelchair by voice command has been done using voice recognition module. Firstly, the voice recognition module has to be trained. Based on the training, it recognizes the commands and moves accordingly. This wheelchair can be trained in any language. But the Bengali language has been chosen for our academic work. The commands are same as manual commands but in addition to that one more voice command has been added.

In case of danger or emergency,the user can speak out the voice command "Shahajjo" which means "help" in English. Then, it will execute the command and the current location of the wheelchair will be sent by SMS to the previously saved number with the help of GSM module. The current location of the wheelchair is computed from the data of the GPS module.

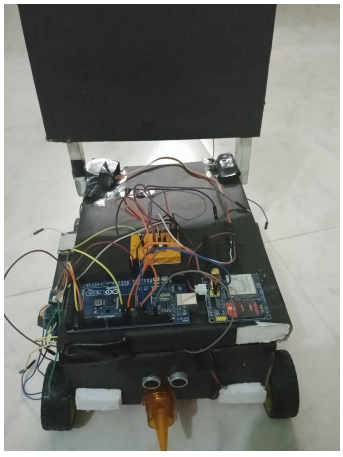

Fig. 4. Image of the Prototype

An additional pre-existing "Blynk" [28] application has been used for viewing the location for continuous monitoring. For this purpose, GPS module and WiFi module is paired up. GPS module collects the latitude and longitude of the current location of the wheelchair and sends to the Blynk app server using WiFi module.
In order to go up and down the ramps with constant speed, the previously mentioned setting of the wheelchair is not enough. So, a Gyrometer has been utilized for detecting the slopes and it has been programmed in such a way that the speed will increase while going up and decrease while coming down to combat the effect of gravity.

Two ultra-sonic sonar sensors have been used to detect obstacles. Inspite of getting command to move, if the sonar sensors sense obstacle in the forward or in the backward direction, the wheelchair will stop moving automatically and it will not further execute any commands in that particular direction till it is away from the obstacle.

If the illuminance of the wheelchair environment is below 50 lux, light sensor will sense this and a headlight which is placed in front of the wheelchair will automatically light up. When there is sufficient illuminance, the headlight will not turn on automatically.

Servo motor is used at the back of the wheel chair to recline the wheelchair according to user comfort. Two switches are placed in the wheelchair to recline the upper part of the wheelchair. Servo motor has been used for the prototype, but for actual implementation it might not be sufficient to balance the weight.

The total cost for making the prototype was near about $125 (10,500 Bangladeshi Tk). An additional $90 (7500 BDT) will be required for a real wheel chair. List of equipments and their costs are given in Table I.

TABLE I
LIST OF EQUIPMENTS WITH COST

Name of the Component	Quantity	Unit Price (BDT)	Price (BDT)	Price (USD)
Arduino Mega	2	750	1500	17.85

V. EVALUATION

The evaluation study was conducted at Software Engineering Laboratory of the authors' institute. The system was tested in a room of rectangular shape with 8 feet length and 6 feet width. The route and milestone points are showed in Figure 5. To test the effectiveness and efficiency of the system, a number of scenarios were trailed, that includes: (a) the system was run using joystick and then by Bengali voice command ('Dane, <Right>', 'Bame <Left>', 'Shamne <Forward>', 'Pichone <Backward>', 'Thamo <Stop>' from point A and ended at A via B, C, and D. (b) Help request were sent through a Bengali voice command 'Shahajjo <Help>'. (c) While the system was moving forward or backward the present location of the wheelchair was monitored via a mobile phone (that was supposed to be used by the caregiver). (d) the wheelchair was reclined in different position. (e) the wheelchair was run both in absence and presence of light (f) The wheelchair was called by Bengali voice command from facilitator positioned at point A, while the wheelchair was positioned at point C.

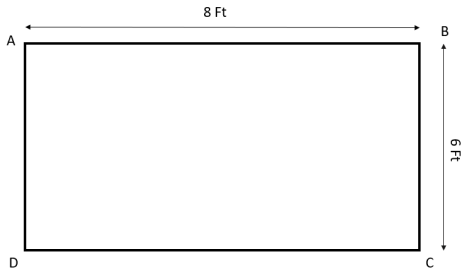

Fig. 5. Map of the place of experimentation

TABLE II
EXPERIMENTATION

Point	Time	Number of Attempts	Sequence of Commands	Collision	Command
A-B	12 sec	1	f	0	Forward
B-C	23 sec	1	r,s,l,s,l,s,f	0	Right, Stop, Left, Forward
C-D	11 sec	2	1st attempt: r; 2nd attempt: f	0	Right, Forward
D-A	4 sec	2	1st attempt, 2nd attempt: f	0	Forward

TABLE III
SUMMARY OF THE EXPERIMENT RESULTS

Feature	Experimental Scenario	Findings
Manual control	(a)	Left, Right, Forward and Backward command works properly and successfully complete the route. No difference was noticed between the manual and voice command.
Controlling through voice command		
Sending SMS for help	(b)	SMS were well successfully received with the location of wheelchair at mobile phone (used by the caregiver)
Longitudinal obstacle detection	(a)	The wheelchair was stopped in each obstacle/end of the route like at point A, B, C, and D (see figure 5)
Speed control	(a)	Accurately executed (observed the Increases and decreases the speed of the wheelchair)
Continuous monitoring	(c)	The present location of the wheelchair was consistently possible to monitor from the mobile phone (used by the caregiver)
Reclining the wheelchair	(d)	Accurately executed (observed the reclining of the wheelchair to different position)
Automatic light turns on	(e)	Light turns on automatically in absence of light in every trial-cases
Controlling/calling the wheelchair remotely	(f)	The wheelchair reached to the caller position successfully using Bangla voice command

To test the system, at first, the system was run along the length, from point A to B. Only forward command was given using voice and it took 12 seconds to reach to B. Since the entire

path is enclosed, the wheelchair stopped at B. The sonar worked successfully since the obstacle was detected. Next, to reach to C, a turn to the right had to be made in order for the wheelchair to be aligned across the path towards C.

One of the drawbacks of the prototype was that the speed was more while turning right and was less in comparison while turning left. So, initially when the right command was given, it had to be stopped first using the stop command and then the left command was used to align it properly. After the wheelchair was lined up properly, the forward command was given, to reach to the destination C. Since readjustments were required while turning, the overall time required to reach to C was comparatively more than before in spite of the distance being lesser than before. When moving from C to D, two attempts were required. In the first attempt, the right command wasn't working and the system had to be restarted. Then the forward command was given to move it from C to D. In the last traversal from D to A, two attempts had to be taken as well. The first attempt resulted in the failure of the voice commands since the transmitter's reception was hampered due to the surrounding noise. In the second attempt, the forward command worked successfully and it took only 4 seconds to reach A. In all of the mentioned steps of testing, the obstacle detection mechanism worked successfully.

VI. Conclusion

The wheelchair provides the means for people with disability to move around freely without requiring much help from the caregivers. It supports them by enabling voice command as well as manual command in order to cater to a large group of disabilities. Along with these, the features of continuous monitoring, sending SMS when in need, obstacle detection, speed control, ability to recline back and lighting up in dark environment work hand in hand to allow the disabled person to have maximum comfort. All of these combine to ensure relief for the disabled people. The prototype required an additional cost of $120 (Bangladeshi Tk 10,500) apart from the cost of the wheelchair itself which is cheaper than available wheelchairs based on the wide range of obtained functionalities.
Thus this can be affordable to the people of Bangladesh compared to the available ones in the market.

One of the limitations of this prototype was the inability to test out the wheelchair on disabled people since only a miniature version of the actual wheelchair was constructed.Future plan is to focus on constructing a normal sized wheelchair with the features mentioned above with the addition to autonomous blind navigation. This would provide the opportunity to create a wheelchair that can be used by disabled patients and required changes can be made according to the feedback obtained from them.

***Abstract*— For daily health checkup, wearable device plays an important role in healthcare applications. In this manuscript, we develop a visual multiple-input multiple-output (visual-MIMO) system for healthcare application. As a demo of healthcare device, we design a pulse oximeter device that can measure heart rate (HR) and blood oxygenation (BO) of a person. The HR and BO data are used to send through light-emitting diode (LED) to camera communication. We have used generalized color modulation (GCM) technique to modulate the HR and BO data into the LED array for transmission and smartphone camera is used as the receiver to demodulate the transmitted data. We demonstrate our proposed visual-MIMO system by developing an android app on smartphone.**

Keywords—heart rate, blood oxygenation, LED array, GCM, visual-MIMO

I. INTRODUCTION

For leading a healthy life, we have to take care of our health condition daily. From this sense, wearable medical device plays an important role in daily health checkup. Pulse oximeter is one kind of device that has remarkable application on healthcare. For primary checkup of a patient, doctors use this device to measure heart rate (HR) and blood oxygenation (BO). Based on the estimated HR and BO, they can take decision of further treatment processing. For monitoring HR and BO into the smartphone application, a wireless communication system is demandable. RF communication may one of the best option in this sense but it is not suitable in healthcare application because of the high sensitivity of electromagnetic medical devices to RF radiation. This sensitivity can occur electromagnetic interference and the performance of medical devices is largely affected by this interference [1, 2]. RF radiation is also bad for human health [2]. As a wireless communication technology, light-emitting diode (LED) to camera communication offers the solution against these RF-related effects on health.

In this manuscript, we have developed a visual multiple-input multiple-output (visual-MIMO) based system for healthcare application. Visual-MIMO refers to a wireless communication system between LED array and camera. Generalized color modulation (GCM) is one kind of color space based modulation technique by which information data can be modulated by selecting the colors from a color space. In receiver side, the receiver demodulates the transmitted data by applying image processing algorithm. J.-S. Kim described the application of visual-MIMO in fashion technology and also proposed an intensity variation on-off keying modulation technique [3]. T.-H. Kwon also showed a wearable visual-MIMO based implemented prototype system on fashion technology [4]. In this paper, we have shown an implementation prototype of pulse oximeter device based on visual-MIMO system for healthcare application. We use LED array as transmitter and smartphone camera as the receiver. But the demodulating operation is performed in server PC, MATLAB platform. We follow the method [5] to demodulate the information.

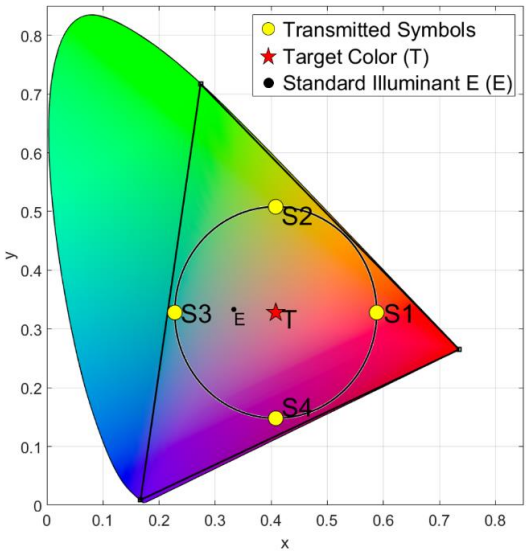

Fig. 1. Example of constellation diagram in CIERGB gamut area on CIE 1931 color space for GCM based visual-MIMO system.

We have organized the manuscript in six sections. Section II describes the GCM based visual-MIMO system. The system methodology is described in section III. We describe the system implementation in section IV. Section V discusses about the result and implementation outcome. We conclude the work through section VI.

II. GCM BASED VISUAL-MIMO SYSTEM

For developing a visual-MIMO based pulse oximeter device, we have to describe the modulation technique of the visual-MIMO system. For modulating information data, GCM demands a constellation diagram on a color space. In this case, we use CIE1931 color space. Fig. 1 shows the example of constellation diagram (a black circle) into the CIERGB gamut area (black triangle area) on CIE1931 color space. According to GCM technique, n-bit information data can be represented in 2^n points [6]. In this paper, we consider 2-bit information data and by taking a target color (T) as a center of the constellation diagram 4 color symbols (S1, S2, S3, S4) are constructed. In order to transmit a color symbol, the transmitter maps each color symbol into the RGB intensity of LED array. At the receiving end, the camera image sensor captures the LED array (transmitter) that emits light and processes the captured LED array to decide the transmitted symbol. For improving symbol decision accuracy, it is important to select a representative color which will be close to the transmitted color symbol.

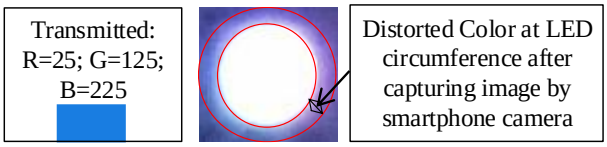

Fig. 2. Color distortion example of received LED image.

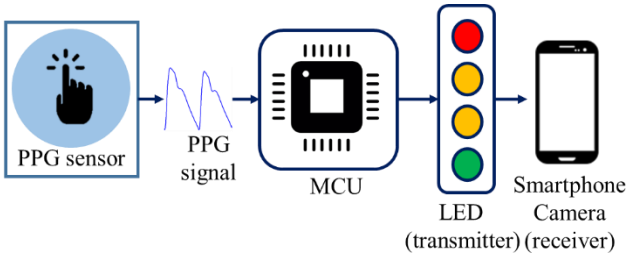

Fig. 3. Conceptual block diagram of the entire pulse-oximeter based visual-MIMO system.

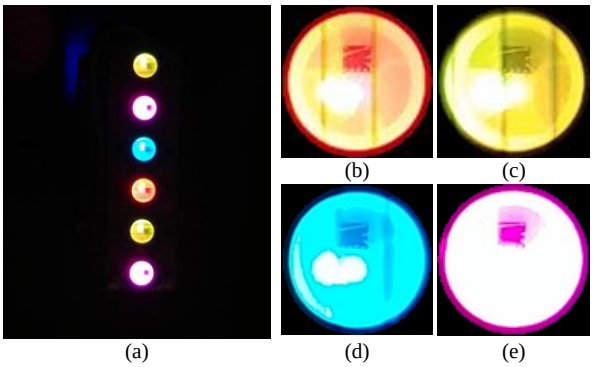

Fig. 4. (a) Captured LED array, (b)-(d) LEDs of four color symbol S1, S2, S3, S4, respectively.

Because of the limitation of smartphone camera dynamic range, the received LED image goes to the saturation. In a normal camera setting, this phenomenon is occurred, as shown in Fig. 2. As a result, the position of the fully saturated colors will be (x = 1/3, y = 1/3), which are coordinates of the standard illuminant E (R: G: B = 1: 1: 1). The edge of the light source circle (that means LED) bears the color information, as shown in Fig 2. This problem can be solved by capturing LED image with lower exposure by adjusting the camera settings [7]. To determine the representative color of the received color symbol, conventionally, representative color of the symbol is determined by taking average of all the pixels. This is an error-prone method. For this reason, we use the algorithm of paper [5] to determine the representative color of the transmitted symbol. In the symbol decision step, by using the Euclidean distance we decide the transmitted symbols according to the closest representative color position of the received symbol.

III. System Methodology

In this section, at first, we will describe conceptual block diagram of the entire system. Then, we describe the transmitter and receiver of our pulse oximeter based visual-MIMO system.

Fig. 3 shows the conceptual block diagram of the entire system. To develop the pulse oximeter device, we use MAX30100 Photoplethysmogram (PPG) sensor. We extract the PPG signal from this sensor. The PPG sensor is combined with two LEDs and a photodetector. Two LEDs

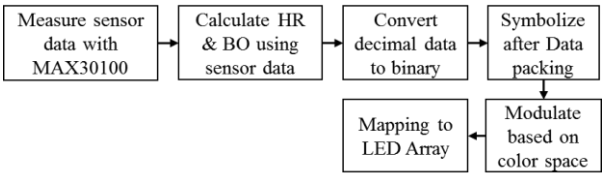

Fig. 5. Transmitter block diagram.

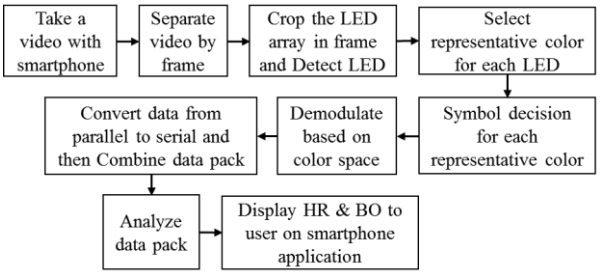

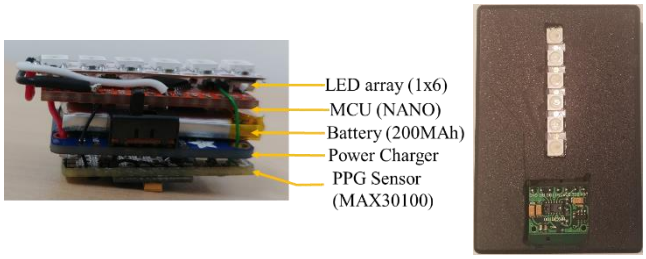

Fig. 6. Receiver block diagram.

are essential for measuring the BO rate. After extracting PPG signal, we give the two PPG signals as the input to the analog to digital converter (ADC) of microcontroller processing unit (MCU). The MCU measures the HR and BO from the PPG signal. Then, it converts the HR and BO to the binary data to send them into the LED array. In the receiver side, the captured LED array image by smartphone camera is processed by image processing algorithm. The LEDs are separated from the LED array by using circular Hough transform [8]. Fig. 4(a), and 4(b)-4(e) show the captured LED array, and separated LEDs for each color symbol (S1 to S4) from LED array.

Fig. 5 shows the block diagram of transmitter. In the transmitter side, at first, we measure the sensor data from MAX30100. Then we calculate the HR and BO by using this sensor data. We convert the HR and BO to the binary data. HR converts in 8-bit data and BO converts in 4-bit data. As every LED represents 2-bit data, we use 4 LEDs for HR and 2 LEDs for BO. So, in total, we use 6 LEDs for modulating HR and BO data by GCM technique. The reason of selecting 4-bit for BO is that in general, normal pulse oximeter is designed for the range of 90% to 100% [9]. But for our designed pulse oximeter, we set this range from 86% to 100% and 4-bit data can easily cover this range by subtracting 4-bit data from 100. Then, in total, 12-bit data is mapped to the 4 color symbols by using GCM technique. After that the symbols are mapped to 6 LEDs.

Fig. 6 shows the block diagram of receiver side. In the receiver side, at first, we take a video with smartphone and separate frames from video. Our processing is frame by frame. We crop the LED array that means region of interest (ROI). We do not need to do any image processing for selecting ROI region for further processing. Because we assume that user holds the camera in the given alignment of the LED array through the developed smartphone app. In [5], k-means clustering based algorithm is developed to select the representative color. Then we use Euclidian distance method to decide the corresponding transmitted symbol of the received symbol. After symbol decision, we can demodulate the binary data to decimal data by using binary to decimal conversion. Finally, the HR and BO are displayed in the smartphone application. Thus a visual-MIMO based pulse oximeter system is developed.

(a) (b)

Fig. 7. Prototype of pulse oximeter device; (a) side view, and (b) top view.

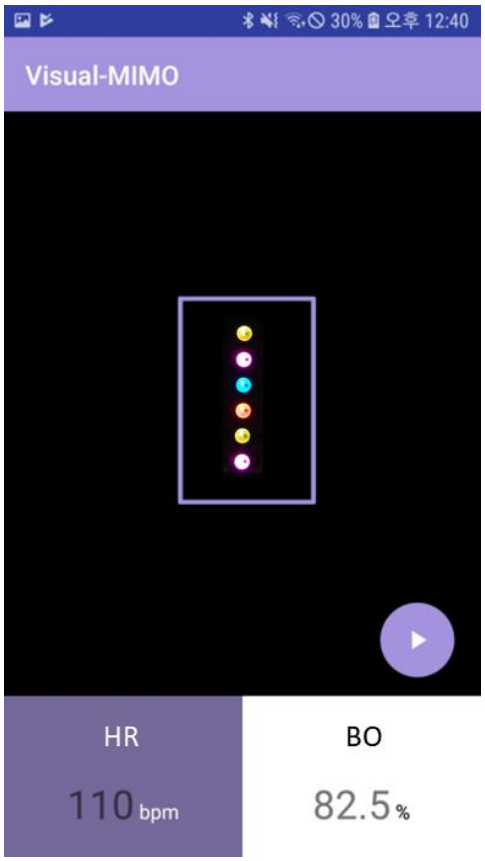

Fig. 8. The developed smartphone app for displaying HR and BO.

IV. System Implementation

We show the implemented hardware of the pulse oximeter device in Fig. 7. We use Arduino NANO MCU not only to configure the transmitter side (LED array) but also extract the HR and BO from the PPG sensor. A 200MAh battery is used to power up the MCU. Fig. 8 shows the developed android app to show the transmitted HR and BO by visual-MIMO system. An ROI region is drawn, violet rectangular box, shown in Fig. 8 for focusing the LED array on that box. The video on-off button is shown into right bottom corner, above the BO data display panel. This app is able to capture video in the constant frame rate of 30 with 50 ISO, 1/200 [s] shutter speed to achieve low exposure. Additionally, we can set the white balance by placing white paper in front of the camera lens with using auto white balance function of smartphone camera. As a result, we used automatic adjusted value (5400K) of white balance which is related to the temperature of the ambient light. We used smartphone LG G6, integrated IMX258 AF camera module with Android 8.0 operating system. We maintain 25cm distance between transmitter and receiver.

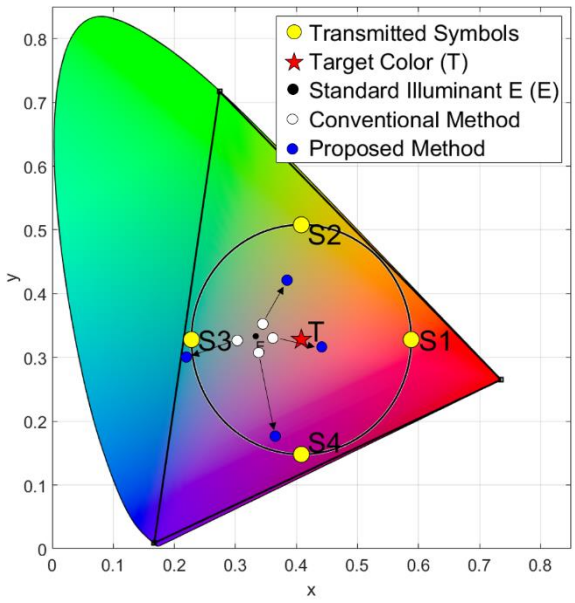

Fig. 9. Selected representative symbol color by using algorithm [5] for a single case of data transmission.

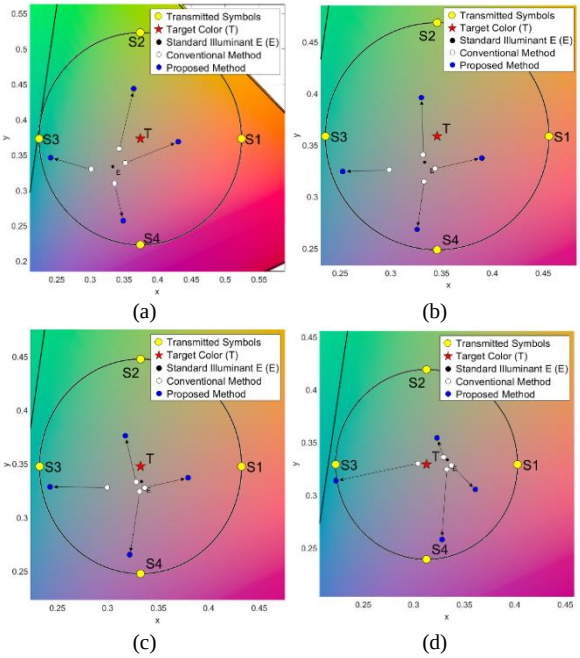

Fig. 10. Selected representative symbol color for different target color; for standard illuminant (a) F11, (b) D50, (c) D55, and (d) D65.

V. Results and Discussion

After capturing video, the demodulation is performed frame by frame. We set 3 clusters into the algorithm of [5] to select the representative color of the corresponding received symbol color for deciding the corresponding transmitted symbol color. Fig. 9 shows a sample case of the selected representative symbol color for the corresponding transmitted symbol color by using algorithm [5]. We also experiment it for different target color. We select F11, D50, D55, and D65 as target color because they are standard illuminants. The selected representative color symbol is also close to the corresponding transmitted symbol color for these target colors. Fig. 10 shows the selected representative symbol color for different target color.

VI. Conclusion

At last, we can claim that we successfully demonstrate the visual-MIMO based pulse oximeter system which is very useful for healthcare application. This type of LED to camera communication can reduce the extra installation and maintenance cost of RF device. Hospitals can easily install this type of system for monitoring the patients centrally and remotely. Moreover, the representative symbol color selection algorithm helps to reduce the color saturation noise in terms of transmitted symbol decision. The HR and BO are successfully transmitted through LED array by using GCM technique and receiver successfully demodulate the information data into the developed smartphone app. In future, we will measure the symbol error rate (SER) or bit error rate (BER) of this type of system by increasing the distance between transmitter and receiver.

Abstract— **Numerous loss of lives is seen each year and the sum is consistently expanding because of destruction, fiasco, cataclysm and so forth these incorporate natural and man-made fiascoes. To counter this we have structured a rescue robot that is autonomous, it pursues track way by dint of 3 ultrasonic sensors in the front. For the processing work Raspberry Pi Model B is utilized which incorporates a grouping of single board processors. The smaller card size is handful as we are utilizing 4wd Car Chassis and a motor controller to drive it through. The robot features computer vision and raspberry pi camera module is used to help with the vision. We trained the camera utilizing algorithm to empower it identify movement, consequently after detecting movement the robot utilizes PIR to detect and affirm human presence. When human life is recognized in a destructed place the web application helps us to observe the live streaming of that found human and the closest environment. The coordination of GPS Module gives us a chance to see the area of where rescue activity is occurring. The web application that is designed by us likewise gives us a chance to do as such. After rescuing the detected individual, it goes on its merry way in repeating the flow of work that is assigned to it helping achieve maximum amount of success and lives saved. The reality to stun is, all these are incorporated in a solitary car chassis and the expense behind the work is insignificant. The reason is utilizing raspberry pi and our work to make a pi camera module ready to recognize movement by help of raspberry pi while incredible and expensive processors are required by and large.**

I. INTRODUCTION

At this moment in time People are fronting different sorts of disaster. The types and the damage these disasters can cause are various. Typically, in Earthquake and Wartime individuals do not possess any awareness about the places where injured people can be stuck. So for identifying the places and the humans who can be in danger, we built a tiny Robot which can detect human presence and also enrich us with the nature of the places where natural calamity or disaster is faced.

The core idea behind this work is to aid the rescue teams with an added component which can come more than handy in rescue operations. As a developing country we lack the kind of state-ofthe-art resources that the developed countries use to conduct their rescue operations. In countless number of times the cost to import or use these kinds of rescue robot is beyond our ease. Hence, we are working on a tiny rescue robot, that is autonomous and it is cost effective and efficient at the same time.

We researched in Embedded Engineering and Robotics, used Image and Real Time video recognition and Internet of Things (IoT). Rescue Robotics is something which is at the core of this work. A Rescue robot is a machine that is aimed for rescuing people. Rescue robots are used in situations such as mining mishaps, urban catastrophes, hostage circumstances, and explosions.

So, our robot is fortified with the functionalities of a rescue robot yet it is very little in size making it proficient of gathering information in difficult circumstances. We are using RPI3 as the main processor of the robot and the rest of the components will be interfaced with it. The main unit is this, with several sub-components such as GPS Module, GSM module and Pi Camera interfaced with the Raspberry Pi 3. The stand out feature is the inclusion of Pi camera which enables us to process images and videos in real time. Motors are used to make the robot move from one place to another. Power is supplied to the robot through power bank.

II. RELATED WORKS

Surveillance system requires vision to monitor, server and network to stream[2]. Raspberry Pi for processing, USB Camera for recording, simple cv for motion detection and MPJG streamer for streaming is used in this work. Our system uses Raspberry Pi Model B with Raspberry Pi camera module powered by OpenCV for motion detection. We have used PIR as double layer assurance of human detection. Added advantage of our system is, it is a robot capable of contributing in rescue missions compared to static surveillance system. [1] Raspberry pi is used for educational purposes where students were asked to build a system having raspberry pi and image processing programs. Energy saving, and low-cost setup are the unique features of this work that makes it stand out. Remotely controlled Autonomous systems are used to aid the parents monitor children from distance[3]. It requires human intervention and android application to operate and observe. RoboFI is Autonomous so it does not require human intervention. Web Application developed using Asp.net MVC is used to share location and streaming information. Human detection is done in a number of ways. Neural network with doppler radar is used to identify human. Which is a complex procedure[4]. We have opted for OpenCV and background subtraction algorithm for motion detection. Passive Infrared sensor makes sure that identification is done in a proper manner.

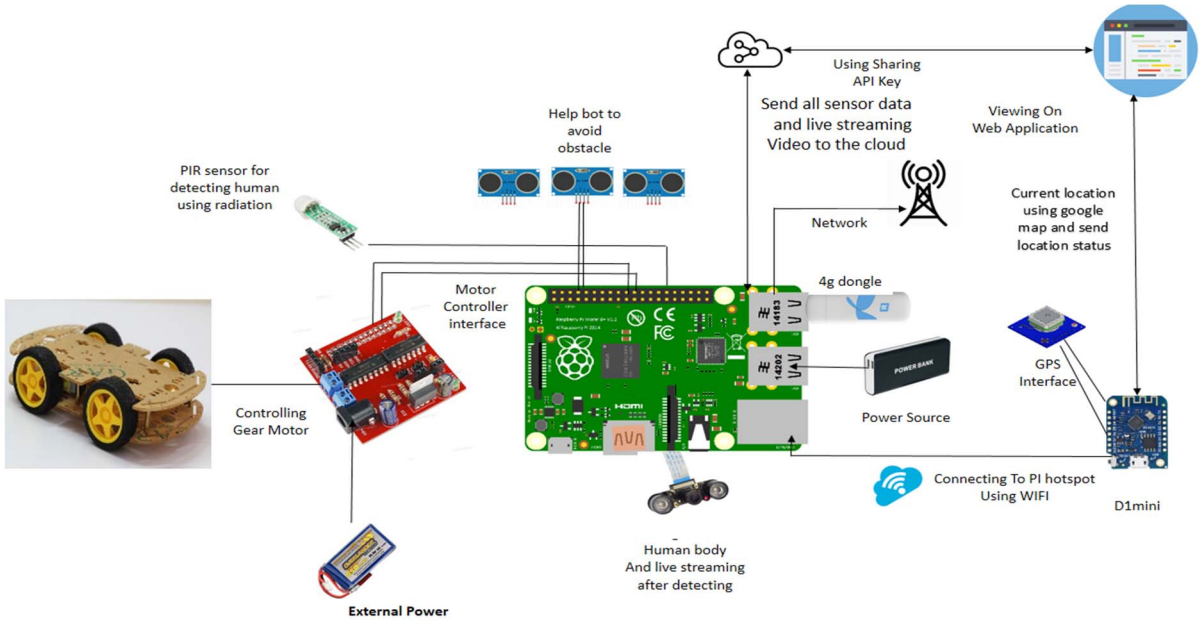

Fig. 1.System Architecture.

Obstacle avoidance is a major aspect of robotics. Various sensors such as visual, ultrasonic, infrared etc. are used to avoid obstacles. Ultrasonic sensor is used by them [5] for obstacle avoidance which is similar to ours. The system is capable of recognizing objects. RoboFI ensures human detection along with location and streaming of the human that we are looking to rescue. Surveillance systems require vast memory generally as it record and transmits video continuously. [6] OpenCV is utilized in order to detect motion using USB HD camera and it starts and also stops recording video based on motion. That ensures that minimum amount of space is consumed yet security is maintained. [7] It illustrates learning based approach for human detection using RGB-D images extracted from Microsoft Kinect sensors and it is indeed a challenge to detect human accurately. Depth sensing feature of these sensors is used in this work. But, they are quite costly to implement a system. Our sytem uses a more feasible approach of human detection. [8] Provides an in depth analysis of how to construct an autonomous robot. It [9] uses two cameras for vision and MATLAB for tracking and mapping. Rescue operations require adaptive rescuing. [10] uses Dijkstras shortest path algorithm after locating victims, to rescue them properly.

III. SYSTEM DESCRIPTION

A. System Architecture

Raspberry Pi 3 Model B is the core unit along with Raspberry Pi camera module powered by OpenCV to conduct the process of human detection. A couple of sensors namely Ultrasonic sensors and Passive Infrared sensor are used. These are placed on a 4wd car chassis which is driven by a motor controller. D1 mini GPS Module provides the location information of RoboFI. To view the streaming live Asp. net web application is developed by us that also plots the location in google maps by using the latitude and longitude data that is transmitted over the cloud (Thingspeak server) by D1 mini. Human is detected through vision and passive infrared sensor reassures the presence. Obstacle avoidance is achieved by using three ultrasonic sensors in the front of the robot. External power for raspberry pi is managed by using a power bank while a lithium polymer battery powers motor controller.

B. Logical Description

The system at first needs to detect any obstacles nearby and avoid them upon starting to move. For this, there are three ultrasonic sensors installed in the front side of the robot as stated in the system architecture. Three conditions for three sensors are used in order to avoid the obstacles. The obstacle can either be in front or on the right or left. So each of the cases are covered by us as illustrated in the logic diagram. The basics steps of distance measurement are:

1. Sonar[Trig, Echo]:
    a. Trig = 0
    b. time.sleep(.1)
    c. Trig = 1
    d. time.sleep(.0001)
    e. while:
        i. echo = 0
        ii. pulse start()
    f. while:
        i. echo = 1
        ii. pulse end()
    g. distance = pulse end() - pulse start()
    h. distance = round(distance,2)
    i. return distance
2. Sonar 1= Sonar[Trig1,Echo1]
3. Sonar 2= Sonar[Trig2,Echo2]
4. Sonar 3= Sonar[Trig3,Echo3]

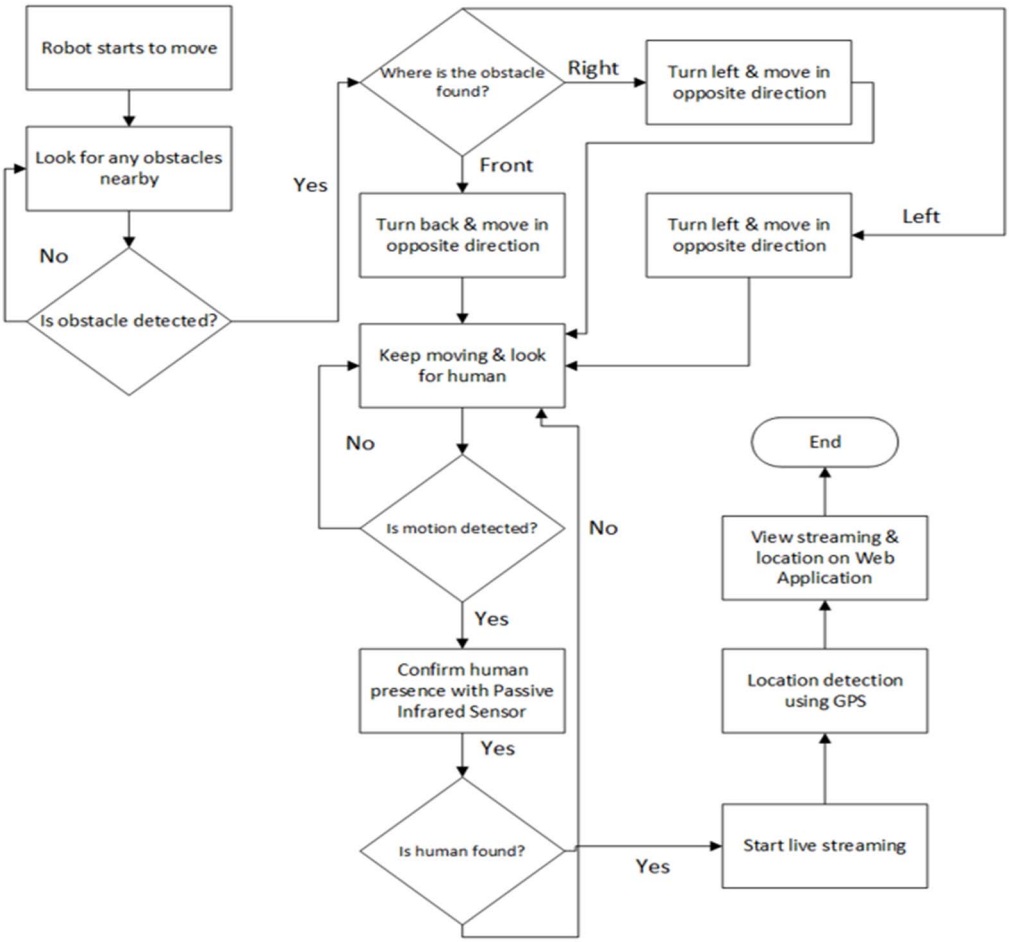

Fig. 2. Logic diagram of the system

The first task of this robot is to find a suitable path. Three ultrasonic sensors are used to do so. All measurements for the work will be considered based on the average of the values found from the three ultrasonic sensors.

The formula to find the average distance from all of the ultrasonic sensors is:

- average = (sonar1 + sonar2 + sonar3)/3

If the robot is switched on and placed somewhere, it starts looking for a path.

1. If the robot finds a path – (average>50 and all sonar value>45)

a) It traverses along the distance measured for that path.

b) After traversing, it starts checking for further path to move ahead and detect probable motion.

c) On detecting motion, it uses PIR sensor to assure human presence.

2. If it doesn't find a path or the path is blocked – (average <40)

a) It takes a turn of 180 degrees to the right. Then it looks up again at this position for navigation track.

b) If it finds no track, RoboFI starts rotating by 10 degrees to the left and keeps repeating the same task until it gets back to the starting position.

c) Coming back to the starting spot, it again rotates 180 degrees to the left to check for availability of path.

3. If the path is blocked and the distance to the obstacle is very low (average<10) then

It moves backward and repeats step 2.

All of these procedures are carried out based on the average of the values from the three ultrasonic sensors.

After the obstacle is successfully avoided RoboFI moves ahead in quest of human. To identify human we have used raspberry pi camera module and OpenCV. It allows us to use several built in libraries related to image processing and we used the method:

- Initialize the raspberry pi camera module.
- At the very beginning, capture a frame as background model that is the template image.
- Convert that frame into gray scale.

- Compute the difference between the frame that comes next and the background model.
- From the difference we find a threshold value.
- The average background image is then updated with the weighted running average.
- Noise reduction is done by thresholding the difference frame.
- Fit holes by dilating the threshold frame.
- Detection of the Contours.
- The motion is located by finding out the bounding boxes around the contours.

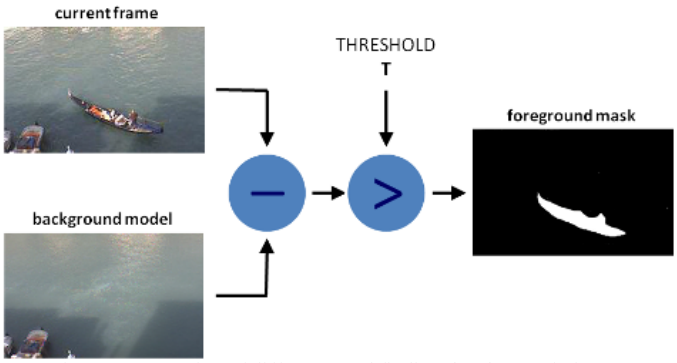

Fig. 3. Computation of difference and finding the changes in image

Once camera makes sure of human presence, Passive infrared sensor is used to reassure the presence. It is made to work as follows:

This sensor working principal depend on the motion. If any movement happen, it will start it's work, and the work is detecting Human.

- It will track 10 time for human searching. If it gets high, then human is there, and this recommends bot to start streaming.
- And if low then no human found, and this recommend bot to leave place. And the bot will move for others area.

After successful identification of human streaming of visulas begin on the asp.net web application. Location of the human found to rescue is also shown on the web application with the help of D1 mini and GPS Module which transmits location information to Thingspeak server and we fetch the location from cloud and plot on google maps in our web application.

IV. SYSTEM IMPLEMENTATION

To implement the system we are using two micro-controllers Raspberry Pi 3 model B and D1 mini arduino. Raspberry pi is the core processing unit. Raspberry pi camera module is interfaced with it using a CSI flex cable. By dint of the vision from camera we use OpenCV powered by python to conduct the process of human identification. Passive infrared sensor is connected to the raspberry pi to enable reassurance of human detection. These are placed on a 4wd car chassis which is controlled by a motor controller. To control the car and make sure that any obstacle is avoided in the track path three ultrasonic sensors are conncted to raspberry pi and placed in the front.

The motherboard named Raspberry Pi 3 acting as a Client is both a micro-controller and a CPU which has a processor of 1.2Ghz 64-bit quad-core ARMv8 Cortex A53 CPU alone with 1GB ram of 900Mhz, 4 USB ports, 1 HDMI port, 1 audio I/O port and 1 Ethernet port in it, including 40 GPIO pins which can be configured as digital input or output. The board Raspberry Pi 3 has built in wireless module in it that has both 802.11n wireless LAN and Bluetooth 4.1 including BLE feature by which we can both receive and transmit data wirelessly without any other partial device. We use these features to implement our system. After the initial phahses upon detection of human we are using D1 mini and GPS module in order to transmit location data to the cloud. The sreaming is done through the Ip address of raspberry pi using StreamingHandler and StreamingOutput library functions in OpenCV.

A. Steps of Implementation:

Step 1 (Configure the Programmable Devices): Seperately write code for each programmable device, raspberry pi and Arduino. Code for raspberry pi is written in python using OpenCV which is the library used for image processing and computer vision. Similarly, we wrote code in Arduino ide to extract location from gps module and then for transmitting it into thingspeak server.

Step 2 (Integrating the sensor modules): The ultrasonic sensors, passive infrared sensor and raspberry pi camera module all are integrated with raspberry pi. GPS module is integrated with D1 mini Arduino.

Step 3 (Connecting the motor controller): Motor Controller is connected with the motor of the chassis. Then In1, In2, In3 and In4 pin are connected to the GPIO pin of raspberry pi.

Step 4 (D1mini and gps Setup): The neo-6 gps module is setup with D1 mini. Neo-6 gps has 4 pins and an antenna. Antena is connected with neo-6 gps and vcc and gnd pin is connected with d1 mini 5v and gnd pin. Rx is connected with D3 pin and tx is connected with D5 pin. We have written a code for sending latitude and longitude data to the thingspeak through d1 mini and d1 mini is connected to the raspberry pi 3 using hotspot.

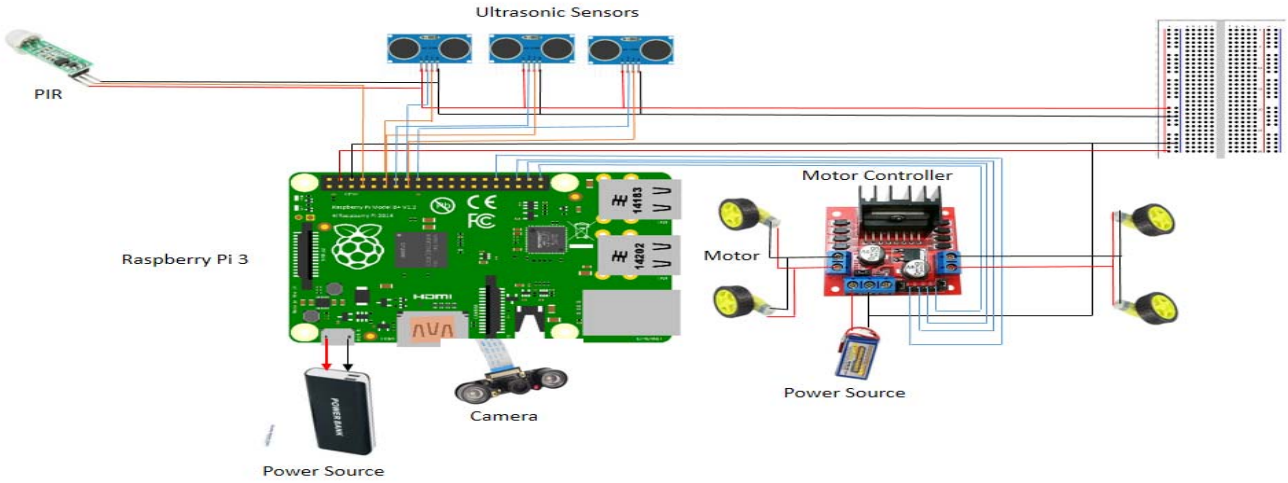

Fig. 4.Circuit diagram of the system.

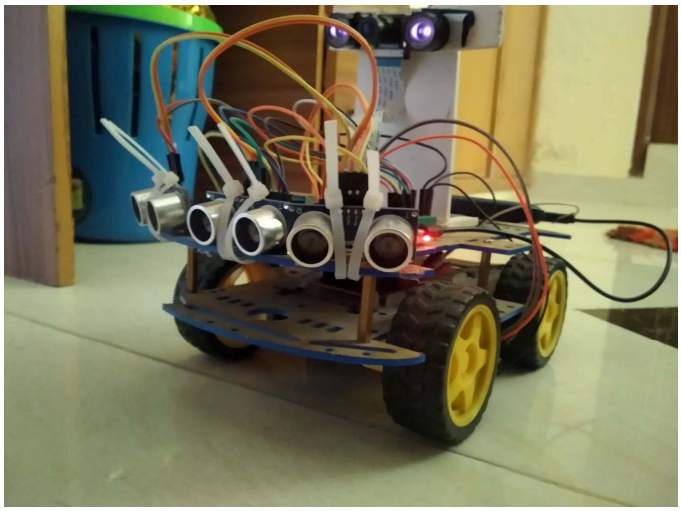

Fig. 5.RoboFI after implementation

Step 5 (Setting the whole system up in chassis): Next, we set the whole system on wooden chassis board. In this chassis we setup the raspberry pi along with camera module, three ultrasonic on front, pir also in front and motor controller. We set the four motors in the wooden chassis. We also setup the gps system on this board.

Step 6 (Powering up all the devices): In our system, the main devices that will be directly connected to the power sources are the Raspberry Pi 3 and Motor controller. Raspberry Pi needs to be connected with a 5v 2.5 amp. power supply powerbank. Motor controller needs external power. This is the reason that we set a lithium polymer battery to the motor controller. Camera Module is directly connected to camera space of raspberry Pi. The Three Ultrasonic and Pir needs exactly 5 volt and this power is coming from Raspberry Pi. D1 mini is connected in pi's usb and from this it gets the power. GPS is connected with the d1 mini's 5 v and GND pin as stated earlier.

V. EXPERIMENTED RESULT

After the system is implemented we run the robot and this provides the data of human detection, confirmation with passive infrared sensor, obstacle avoidance data from ultrasonic sensors, live streaming visulals and mapping of location in web application. All of these and efficiency and precision of the system is illustrated in this section. The results are provided here respectively. Firstly, different situations are provided while detecting human, confirmation with PIR and live streaming follows. The distance that is measured by ultrasonic sensors is also shown in this section along with the plotting in map using google maps api key and using our web application.

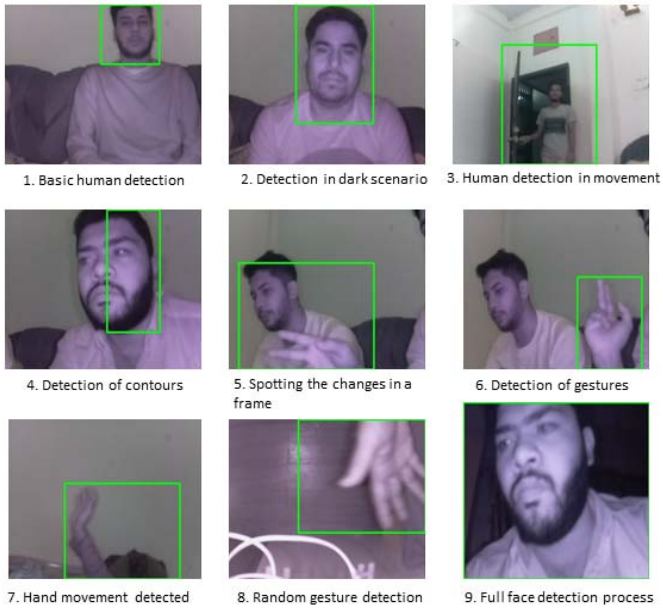

Fig. 6.Human detection in various situations

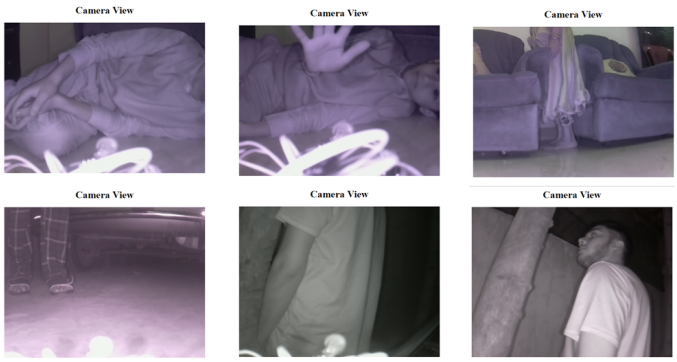

Fig. 7.Live streaming of detected humans

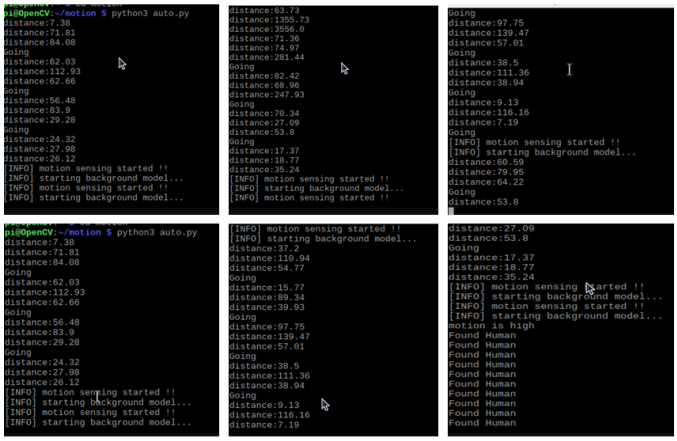

Fig. 8.Distance measurement for obstacle avoidance

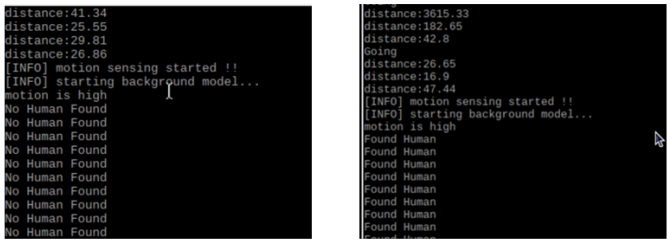

Fig. 9.PIR data when human is found and also when not found

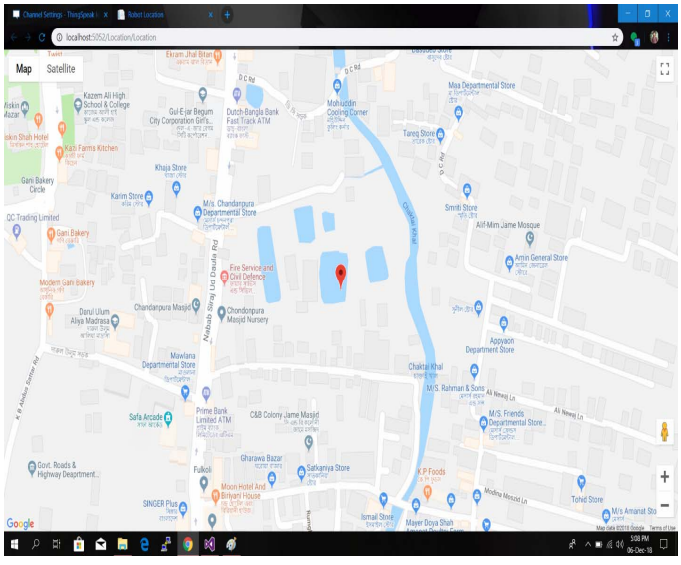

Fig. 10.Location information in web application

Fig. 11 depicts the time elapsed in traversing to human avoiding obstacles and accuracy of the detection. In the figure high or 1 signifies that the human was detected properly compared to low or 0 signifying inaccurate detection of human through random iterations of RoboFI.

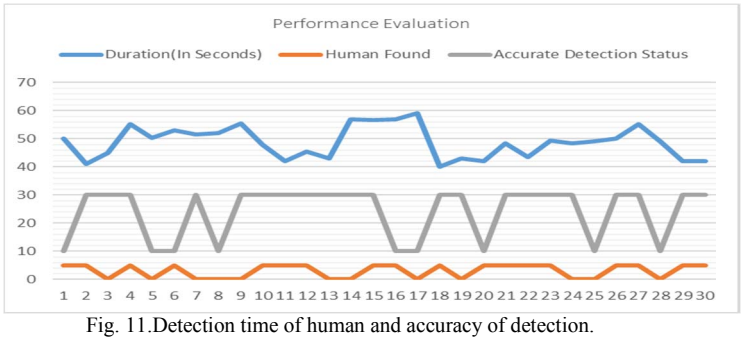

Fig. 11.Detection time of human and accuracy of detection.

CONCLUSION

In this paper, we illustrated our work on autonomous rescue robotics capable of human detection and Geolocalization. Couple of sensors and their working on our work is also discussed in this paper. Succesful use of this, can lead to a significant amount of success in search and rescue missions with respect to reduction in detection and locating. Saving people in time during crisis remains to be the motto of RoboFI, the autonomous path follower robot.

***Abstract*— Emergency evacuation is required for fast evacuation of people during disaster. In this paper, we develop a light following emergency evacuation chair to rescue and evacuate physically weak or disable people. The light following evacuation chair includes proximity detection and obstacle avoidance features in order to avoid collision. The chair follows the light sources fixed at different turn points in the Emergency exit track to determine the route and direction to the Emergency exit. We develop the Light Follower using light dependent resistors (LDRs). A motor driver circuit is used to control the direction of the chair depending on response of the LDRs. We use ultrasonic sensor and the motor driver to develop the proximity detector and obstacle avoidance system. A micro-controller is used to control the operation of LDRs, untrasonic sensor and the motor driver. We simulate the performance of the Evacuation chair in forward, left and right direction using an Emergency exit route model and verify its accuracy for different angle of arrival (AoA) of the incident light. We observe an average movement accuracy of 93% in all directions for all AoA of light.**

Keywords*— *Emergency Exit, Emergency Evacuation Robot, Light Following Robot.

I. INTRODUCTION

An Emergency exit is a special exit for dangerous scenarios during emergencies when people are required to be evacuated from a location or building quickly and it also provides an alternative if the route to the regular exit is blocked [1]. People does not have enough time and idea on navigation of the emergency exit path. Thus, the existing system such as emergency exit signs and evacuation maps, as well as alarm and audio announcements are installed to guide people to find the way of the exit. However, people with disabilities or physical weakness in a large venue as hospitals, business centers, super stores or shopping malls are unable to escape from the venue or walk down steps in order to reach a safe area.

The Disability Discrimination Act (DDA) 1995 and Equality Act 2010 works to protect people with disabilities including blind and partially sighted people from discrimination [2]. In order to comply with the DDA, it is the responsibility of different institutions to install evacuation systems which should be autonomous and efficient to rescue and evacuate such people with disability from the site immediately during the fire or other dangerous scenarios. Robots can play an important role in such emergency evacuation. Robots can be used for navigation task and for evacuation of people with disability from the site.

There are several works in the literature to develop evacuation systems using different sensors, wireless sensor network and robots to evacuate people. In [3], the authors propose an approach for detecting alive humans in destructed environments using an autonomous robot. The proposed robot in [3] uses an ultrasonic sensor in order to detect the existence of living humans and a low-cost camera in order to acquire a video of the scene as needed. Additionally, the robot includes sensors as temperature, fire and metal detector to detect the presence of bomb in warfield and in rescue operations. In [4], the authors develop a multiple source multiple destination Robot, which could differentiate various colors by using sensors and choose a desired line to reach the target location. It could also detect presence of obstacle using close loop control and correction system. In [5], the authors design a PC controlled robot which can detect live humans and transmit the location details wirelessly. In [5], PIR sensors are used to detect the motion of any kind, GSM is used for wireless communication and GPS is used for location estimation. In [6] the authors discuss the disastrous effect of overtrust on robot in emergency evacuation scenarios. In [7], the authors discuss current robotic technologies of crowd evacuation and also demonstrate how autonomous robots are effectively deployed for evacuation assistance task in disaster, as well as search and rescue missions. However, the robotic evacuation technologies presented in [3-7] do not address the evacuation issue of the patients or people with disability during emergency.

In this paper, we develop a micro-controller based Emergency evacuation chair to evacuate people with disability. The developed system uses a light following navigation system to guide the chair to the Emergency exit route. To implement the light following navigation system, the light sources are installed in different turn points in the Emergency exit route and light dependent resistors (LDRs) are used to sense the lights emitted from the light sources. A micro-controller unit (MCU) is used to control the operation of LDRs, ultrasonic sensor and the motor driver according to the instructions loaded. Light sources are installed at different points along the pathway to direct the chair to its destination. The light is sensed by three LDRs and the motor driver circuit is activated based on the response of LDRs by the MCU to move the wheels of the chair according to the light sensed by the front, left or right LDRs. We also use ultrasonic sensor to detect proximity of obstacle. When the ultrasonic sensors sense obstacle, the center LDR signal is turned off and the wheels stop moving to stop forward movement. We simulate the hardware and conduct experiment using an emergency exit route model to verify the performance of the light following emergency evacuation chair in forward, left and right direction. We also verify the performance of the robot by varying the angle of arrival of light and observe 93% average accuracy in all directions.

II. SYSTEM LAYOUT

Figure 1 shows the system layout of the emergency evacuation robot. As we can see from Fig. 1, the robot includes

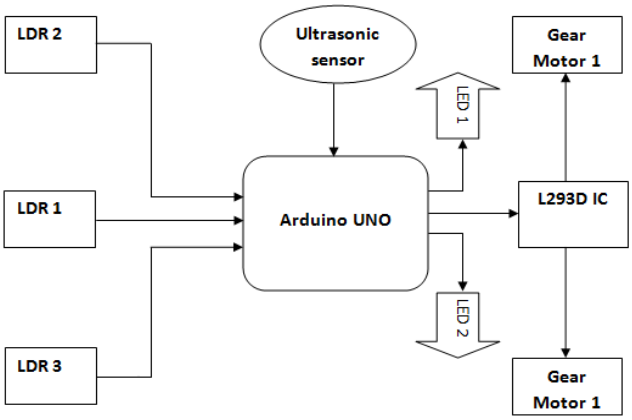

Fig. 1 System layout

three (03) LDR sensors which receive light and generate signals as it can sense light emitted from the light sources. LDR1 is used to sense light received from the front, LDR2 is used to sense light coming from right side and LDR3 is used to sense light received from left side. The system also includes an ultrasonic sensor to sense the proximity of any obstacle and avoid the collision. LDRs and the ultrasonic sensor sends their response signals to the Arduino UNO microcontroller unit (MCU). Based on the received signals from LDRs and ultrasonic sensors, the Arduino UNO operates the LEDs and the Motor driver IC L293D according to the instructions loaded in it. The right LED is lit when LDR2 receives light and Gear motor 1 is activated. The left LED is lit when LDR3 receives light and Gear Motor 2 is activated. The LEDs show in which direction the robot will go by blinking and the motor driver will drive the two Gear motor according to the signal received from Arduino UNO.

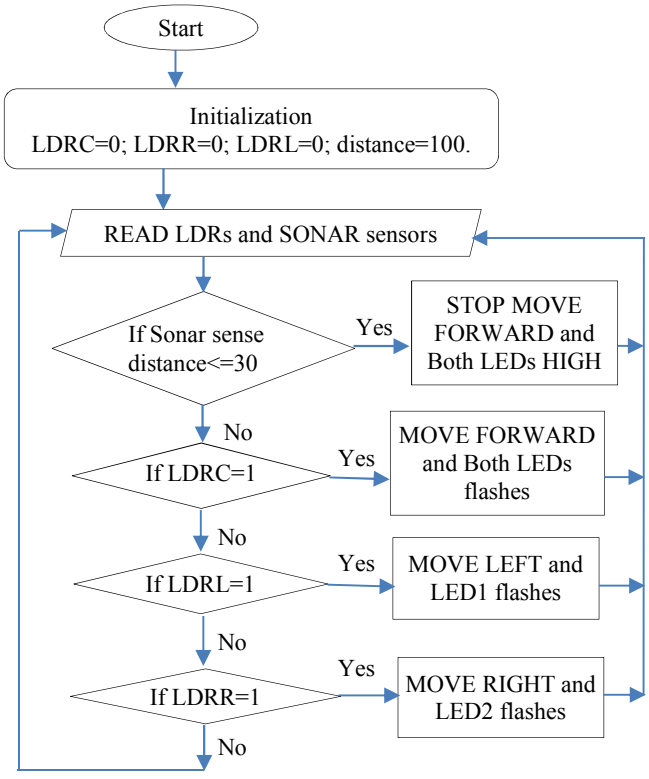

Fig. 2 Flow chart of emergency evacuation chair.

III. System Development of the Evacuation Chair

The Emergency Evacuation chair works using the working principle as shown in the flow chart in Fig. 2. We can see from the flow chart that the MCU always checks for response of the sensors. Whenever it receives any signal from LDRs or sonar sensor, it sends the corresponding signal to the motor driver for necessary movement action. The MCU is programmed using the language of Arduino 1.8.3 software.

TABLE I
LIST OF COMPONENTS AND THE COST OF DEVELOPMENT

Sl	Components	Quan-tity	Price ($)
1.	Arduino Uno R3	1	9.0
2.	L293D Dual DC Motor Controller	1	3.25
3.	Ultra-sonic Sensor (HC-SR04)	1	3.00
4.	LDR	3	4.50
5.	Robotic Chassis (2 Wheel with Gear Motors)	1	15
6.	Mini Breadboard	1	.50
7.	Battery 9V	1	3
8.	Jumper	30	1.5
9.	9V Battery Connector	1	0.10
Total			39.85

Using the above software development step, we develop the Emergency Evacuation Robot prototype as shown in Fig. 3. The components used to develop the core hardware of the system is listed in Table I which costs approximately $39.85. As we can see from Fig. 3 that the Evacuation system is developed in a shape of a chair. Thus, we call it Emergency Evacuation chair which can easily carry people with disability. The chair is powered on when people sit on this. The movement and direction of movement of the chair is guided by the light sources fixed on the Evacuation route. In this way, the chair can be used to rescue people and reach them to the exit point by following lights. The system consists of several sub-systems. The step by step development of each sub-system is explained as in the following

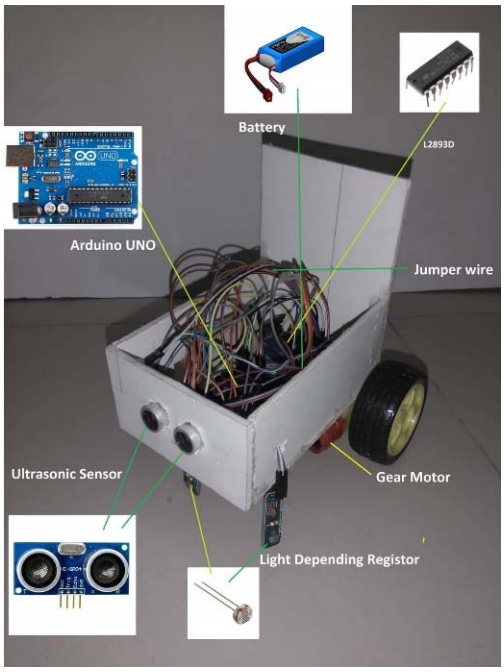

Fig. 3 Emergency evacuation chair.

A. Light Follower Circuit

The Light follower is developed using light sources and light dependent resistors (LDRs). The light sources are installed in different turn points in the track. Photo resistors, also known as LDR, are light sensitive devices most often used to indicate the presence or absence of light, or to measure the light intensity. In the dark, their resistance is very high, sometimes up to 1MΩ, but when the LDR sensor is exposed to light, the resistance drops dramatically, even down to a few ohms, depending on the light intensity [8]. Due to resistance variations, the voltage levels are also varied between 0 and 5V using voltage divider rule. The robot follows the light emitted from the sources by means of the central LDR (LDR1), the right LDR (LDR2) and the left LDR (LDR3) sensors. Figure 4 shows the connection diagram of LDRs and Arduino UNO.

Due to light variations if the resistance of LDR3 is dropped to R, then the voltage across R1 which is connected to Pin A0 of MCU can be expressed using voltage divider rule as,

$$V_{R1} = V_{total} \times \frac{R1}{R+R1} \quad (1)$$

Similarly the voltage across R2 and R3 can be expressed as follows

$$V_{R2} = V_{total} \times \frac{R2}{R+R2} \quad (2)$$

$$V_{R3} = V_{total} \times \frac{R3}{R+R3} \quad (3)$$

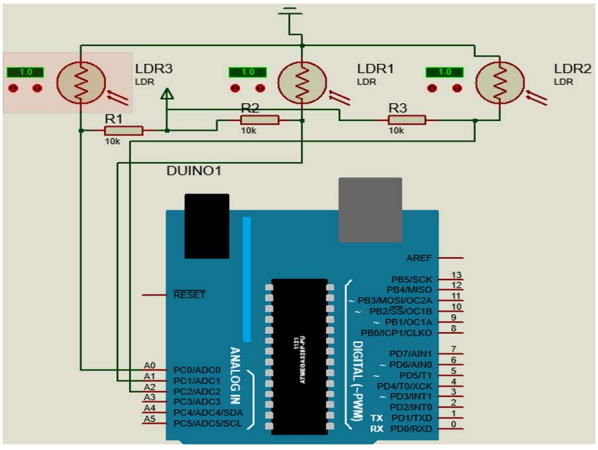

Fig. 4 Schematic diagram of Light Follower Circuit.

B. Obstacle Avoider

The ultrasonic sensor (HC-SR04) uses sonar to determine the distance of an object, just like bats. It offers excellent contactless range detection with high accuracy from 2 cm to 80 cm. The operation of the sensor is not affected by sunlight or black materials as sharp telemeters. It has four pins for VCC, GND, Trigger and Echo. The sensor works with the following formula

$$\text{Distance} = \text{Speed} \times \text{Time} \quad (4)$$

The untrasonic transmitter (trigger pin) sends a high frequency sound signal. When the signal finds an object, it is reflected and the untrasonic receiver (echo pin) receives it as shown in Fig. 5.

To calculate the distance using the above formula, we need speed and time of traveling signal. The speed of untrasonic (US) wave at room conditions is 330m/s. The time can be calculated by measuring the time difference between transmitting and receiving US wave by the trigger pin and the echo pin. Then, we can simply calculate the distance using equation (4) using the microcontroller (MCU). The MCU of the evacuation chair can avoid collision by measuring the distance of obstacles (within 2-80 cm) and by operating the motor driver circuit according to stop movement of the chair. Figure 6 shows the connection diagram of the Arduino UNO and the ultrasonic sensor.

Fig. 5 Untrasonic sensor transmitter and receiver.

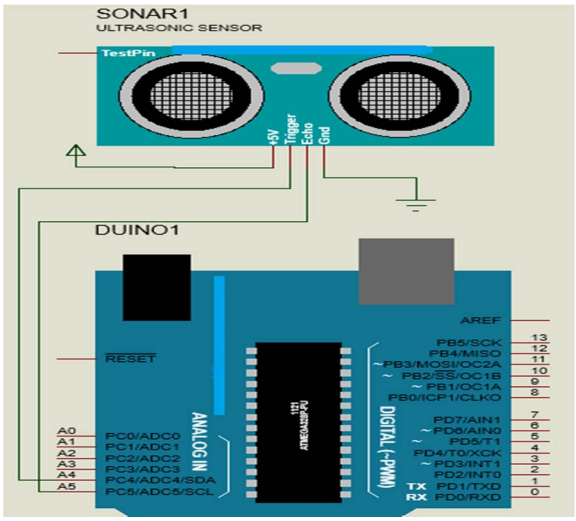

Fig. 6 Schematic diagram of Obstacle Avoider circuit.

C. Motor Driver Circuit

When the MCU gets signals due to light variations in LDR1, LDR2, LDR3 or the untrasonic sensor, the MCU sends signal to the motor driver circuit to move left, right, stop or forward actions accordingly. We use Motor driver IC L293D to operate motors of the two wheels of Evaculation chair.

It works on the concept of H-bridge. H-bridge is a circuit which allows the voltage to be flown in either direction. Voltage need to change its direction for being able to rotate the motor in clockwise or anticlockwise direction, In a single L293D chip there are two h-Bridge circuit inside the IC which can rotate two dc motor independently. Figure 7 shows the motor driver connections with Arduino UNO.

D. *LED Indicator circuit*

The LED indicator helps others to know the direction and movement of the chair to avoid accident or collision. As the chair stops, the MCU sends signal to the two back LEDs to flash continuously. As the chair turns left, the MCU sends signal to the left LED which flashes to indicate left movement. In the same way, the right LED flashes during right movement of chair. The LED indicators D1 and D2 are connected to the MCU Arduino UNO as shown at the bottom of Fig. 8 to indicate stop, left or right movements of the chair.

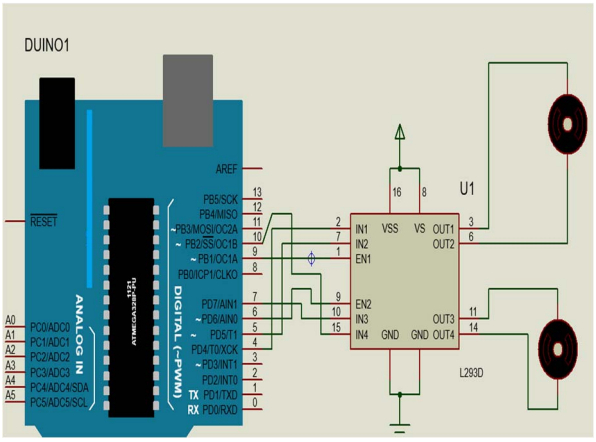

Fig. 7 Schematic diagram of motor driver circuit.

E. *Microcontroller Unit (MCU)*

An Arduino UNO R3 micro-controller (MCU) is used as the central processing unit of the system. The MCU receives the input signals from the sensors (LDRs and ultrasonic sensor) and sends the output to the motor driver and LEDs according to the instruction sets loaded in it according to the flow chart as shown in Fig. 2. The connection diagram of all components to the MCU is shown in Fig. 8.

The Evacuation chair is developed by combining all the above sub-systems. Figure 8 shows the combined circuit diagram of the whole system developed for Emergency Evacuation Chair.

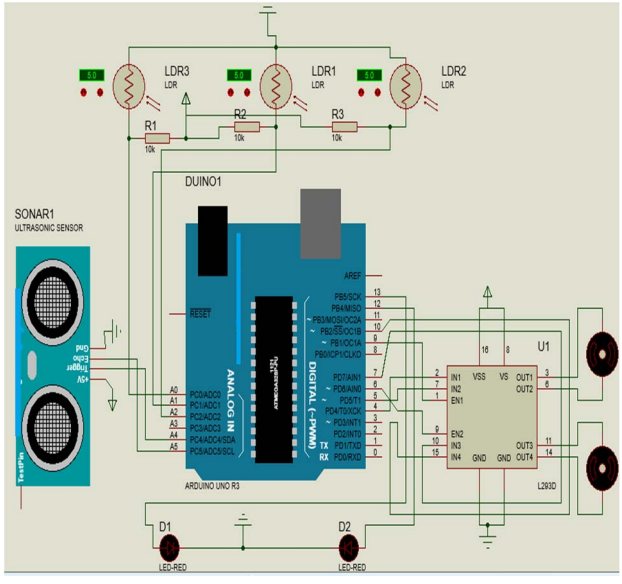

Fig. 8 Schematic diagram of the Emergency Evacuation chair.

IV. SIMULATION AND RESULTS

We simulate the performance of the Emergency Evacuation chair using the Exit Route model as shown in Fig. 9. When the Evacuation Chair travels from "Start" point, the LDRs continuously sense the presence of light. Light is emitted from the light sources indicated using two torches in the track as shown in Fig. 9. It detects the light emitted from the first light source in the track using LDR1 and move forward to follow the light until it detects proximity of any obstacle. It detects proximity by measuring distance of obstacle using untrasonic sensor. When it gets closer to the wall (<=30 cm), it stops moving and the back LEDs flashes. Then it detects the light emitted from the second source of light using LDR2 and turns "Right" to follow the light. During turning "Right", the right LED continues to blink. It continues to move forward in the right track until it detects any obstacle or wall. Then it stops again when it gets closer to the second wall at the end of right track and the back LEDs starts flashing. When it detects the light from second source of light fixed at the termination point using LDR3, it turns "Left" and the left LED continues blinking. Then it continues moving at the left track to follow the light set at the termination point. It moves forward until it reaches to the "Stop" or exit point of the Evacuation route.

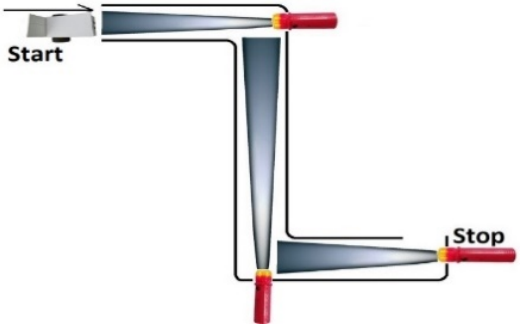

Fig. 9 Evacuation route model.

TABLE II
MOVEMENT ACCURACY IN FORWARD, LEFT AND RIGHT DIRECTION.

No. of exp.	Response of the LDRs and Motor Driver			Movement Accuracy		
	Forward	Left	Right	Forward	Left	Right
1	Yes	Yes	Yes	94%	87%	87%
2	Yes	Yes	Yes			
3	Yes	Yes	Yes			
4	Yes	Yes	No			
5	Yes	Yes	Yes			
6	No	No	Yes			
7	Yes	Yes	Yes			
8	Yes	Yes	No			
9	Yes	Yes	Yes			
10	Yes	Yes	Yes			
11	Yes	No	Yes			
12	Yes	Yes	Yes			
13	Yes	Yes	Yes			
14	Yes	Yes	Yes			
15	Yes	Yes	Yes			

To evaluate the performance of the Evacuation Chair, we simulate the system for different angle of arrival (AoA) of the light and evaluate the performance of the chair in forward, left

and right direction while traveling through the evacuation route model. Few of the simulation results for 220° AoA are summarized in Table II. In Table II, "Yes" means correct response and "No" means wrong response. We can see that the movement accuracy of the system in forward, left and right directions are 94%, 87% and 87%, respectively. Table III summarizes the movement accuracy considering different angle of arrival (AoA) of the light. As we can observe from the results in Table III that the average movement accuracy of the system in right, forward and left direction are 91%, 95% and 92%, respectively.

TABLE III
MOVEMENT ACCURACY FOR DIFFERENT ANGLE OF ARRIVAL.

Movement Direction	Angle of arrival	Movement Accuracy	Average Accuracy
Right Direction	220°	87%	
	315°	88%	91%
	330°	89%	
	345°	92%	
	360°	93%	
	30°	95%	
	10°	95%	
Forward Direction	25°	94%	95%
	40°	92%	
	55°	93%	
	70°	96%	
	85°	97%	
	220°	94%	
	115°	95%	
Left Direction	130°	92%	92%
	145°	92%	
	160°	94%	
	175°	96%	
	190°	94%	
	205°	90%	
	220°	87%	

From the practical simulation results, we observe that the Emergency evacuation chair can move in right, left and forward direction by following the light emitted from the source. The movement of the robot can be controlled in forward, left or right direction by using the light following LDRs. It follows light to reach to the exit point and can detect obstacle in the path of the robot to avoid collision. Therefore, it can move by avoiding damage caused by collision to an obstacle that makes it more robust and reliable. LED indicators helps the robot to avoid collision from backside and helps others to know the direction of the robot.

We can also see that the performance of the Evacuation chair is fairly accurate in all directions and for all AoA of the light. For any angle of arrival of the light, the movement accuracy of the chair is 95% in forward direction, 91% in right direction and 92% in left direction, i.e., in average the movement accuracy is 93% in all directions.

Thus, the developed Emergency Evacuation chair can be used to rescue and evacuate disable people from any place or hospital during emergency. It can carry disable people and reduce the risk of life of the patient and the rescue team.

V. CONCLUSION

In our paper, we have developed a Micro-controller based light following emergency evacuation chair. We have used three LDRs as light sensors to follow the source of light. We have used untrasonic sensor to detect obstacle in order to avoid collision. We have also used LED indicators to indicate the direction of movement of the chair. We have simulated the performance of the Evacuation chair for different angle of arrival of the light using an Emergency exit route model. We have observed that the evacuation chair can move in all directions following the light source fixed at different locations in the route. The performance of the chair in terms of movement accuracy is 93% in all directions for all AoA of light. Thus, the developed light following Emergency evacuation chair can be used to rescue people with disability and reduce the risk of their life by evacuating them from the location during emergency.

***Abstract*— In this modern world, we are developing the most innovative scientific solutions, where the robotics and embedded field also experienced an immense growth. Automation and robotics are widely used for solving many major problems that are part of our life. Robotics systems already make life easier. In critical situations such as natural disasters, robots can be utilized instead of humans to avoid more casualties. In this research, we focus on our garments industry to automate the warehouse management using robotics system. The problem is handling heavyweight objects which are to be kept in a storeroom and preparing them to be shipped. As a solution, we introduce the multi-robot system to pick up and drop those heavy objects to the designated point(s). The whole system is designed to locate objects at some point and pick them up based upon their need. The proposed system aims to contribute to the above mentioned applications using a proposed model to control a warehouse using the robot.**

Keywords—line follower bot, warehouse management robot, garments automation, heavyweight carrying.

I. INTRODUCTION

In recent years robotics and the embedded system sector has been revolutionizing the world industry with its solutions. The global competition of production efficiency is growing day by day. Garments Industry is the key export channel and giving huge support to the GDP in Bangladesh. At present, the country generates about $5 billion worth of products each year by exporting garments [1]. The global industry automation is already catching attention. Bangladeshi garments industry also needs to move with this growth rate. Many strategic leaders now think that automation in the warehouse sector has become a basic need in order to sustain in today's economy.

Fig.1.Scenario of a garment factory, source: BGMEA

The carts of products which were being picked up manually in the previous years are now getting more flexibility in terms of mobility because of automation. The performance of collaborative mobile warehouse robots has attracted many leading organizations such as DHL, XPO, and many others to accelerate their working process. Over the years DHL introduced conveyors and shuttle systems to see if it can fulfill the needs of customers and to maintain commitment towards them. But that did not work out eventually. Barcode scanning system was also introduced but scanning consumes time so this method is also not that effective [2]. So now they are also investing in flexible autonomous systems/robots which can scale with the volume of orders [3]. So robots can work as a human assistance [4]. At present, the design optimization of traditional distribution center picking system has caught attention and high automation is being integrated to improve the system [5]. In this paper we are proposing an autonomous solution which is a heavyweight carrying robot. Its impact will be all over the garments industry of Bangladesh as it will bring enormous changes by minimizing the cost and risk factors.

II. Related Works

In recent work, the system uses QR code-based technology to proceed. By scanning pre-coded QR stickers which are placed in a few locations the robot reaches to its destination [6]. In this way, the robot takes less processing time so the whole process is but if the system fails to recognize a QR sticker it will lose its way as there is no other way to receive information. Whereas our proposed solution receives information from various sources so the chance of getting lost is low. Another fully automated warehouse robot uses computationally efficient local path planning algorithm, named the RERAPF [7]. The computational cost of the algorithm is quite high and the whole process is lengthy, so despite providing the assurance of a robot not getting trapped in a fixed region, it is not maybe the best choice. On the other hand, our robot goes to the location based on the priority list that is stored in the stack which makes the whole process simple and less time-consuming.

III. MOTIVATION

Around Bangladesh, hundreds of textile industries need customized solutions and perform research on their activities to increase their productivity and minimize costs. According to the predictions made by PWC prediction, Bangladesh is going to become the 28th largest economy by the year2030. Industrial development will play a significant role in building this potential as it will be one of the most important factors which will help to flourish our economy. In our country, the ready-made garments (RMG) industry has immense strengths and lot of potentials to establish this growth [8]. A lot of

support is needed for the industry according to customization solutions.

IV. Optimization Process

The proposed solution is a prototype of a heavyweight carrying system which will collect objects from some points and deliver to another point inside a closed perimeter ideal warehouse or storeroom, which is likely similar with the fig.2. The robot can work in an orderly manner avoiding obstacles, which happens mainly due to the manipulation of the software system [9]. We consider garment factories that are producing wearable products and keeping them some points for the next stage of processing.

Definition, There are 04 locations with labeled, each location is a point of collecting the product upon on user calling system. The call is defining by the different switch for each location which has two states. When the product is ready for pickup, Call=1, else Call=0.

The environment and operations flow belongs to a garments production house, the product produce and holds in four (04) different locations labeled by A, B, C, and D. The produced product have to pick and delivered to a storeroom which location is labeled by E.

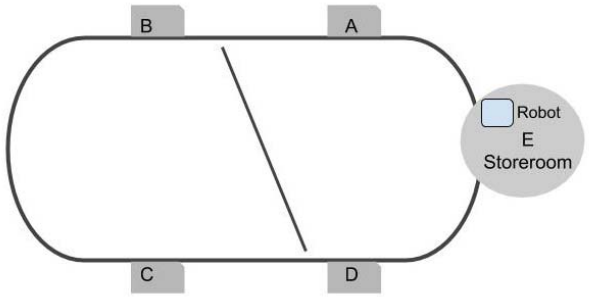

Fig.2. Operations Flow.

These four (04) locations are related with a specific time, t and there will be a priority rank system. From table 1, Location A has the top priority 1, as it contains a product that must be collected and delivered immediately. The robot must move by A and afterload, route the shortest part to location E. It's mean that whatever the calling state of four (04) locations, the robots will pass by the location A.

Table1: Priority ranking

Priority rank	locations
1	A
2	B
3	C
4	D
0	E

Table2: State table

Locations	State	Call (t=1s)
A	0	0
B	1	1
C	2	0
D	3	1
E	4	0

a. Define the state:

In order to understand the programming flow, the system is mapped using some index number according to the locations. After encode the locations name into index numbers with respect to the following the state table 2.

Where, the first line of each matrix, which has index 0, corresponds to location A. The second line/column, which has index 1, corresponds to location B. The robot are connected with control station (calling station) using Bluetooth communication and start the operations depending on their availability.

Form the table2, Say at t=1s, there are two incoming calls for pick up the product when robots position is at E. After call Robot is serving for location B, which means state 1. Robot will operate from A to B and come from B to C, D. After unload from E. Robot will again serve the D, which means state 3 and the call stored using array programming. The Robot will operate from A to D using the shortest part and come from D to E.

The Robot are collecting those products autonomously and dropping them at the designated points, as shown by the ideal workflow in figure 2. The right-hand rule has used for line flowing methodology [10]. This process will be continued until the completion of all tasks.

V. Electronics System

The Electronics system is based on the ATmega328P microprocessor. In this research project, we used Ultrasonic sensors, Load cell, IR sensor array, DC motor and controller, HC05 - Bluetooth module and Li-Po as the battery.

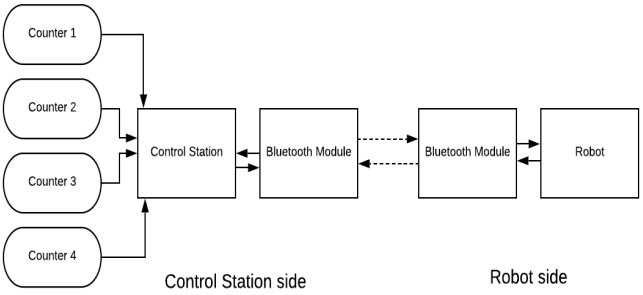

Fig.3. Over all system block diagram.

A. Embedded System (Robot)

We have used popular and very time effective controller, the Arduino Uno board in which the processor is the ATmega328P. The board consists of 14 digital input/output

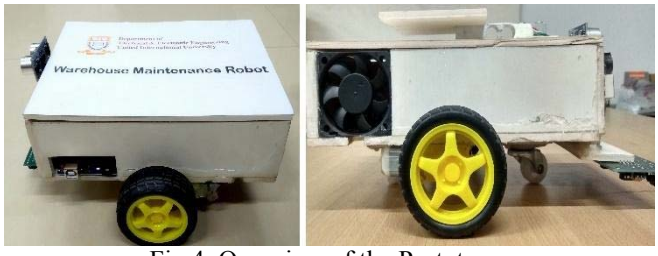

Fig.4. Overview of the Prototype.

Pins along with 6 PWM pins. We have used it to get a faster simulation for this research output. As a motor driver, we have used the L298N which is a monolithic circuit in a 15-lead multi-watt and PowerSO20 packages. It is a dual full-bridge driver designed in a way by which it will accept standard TTL logic levels, it operates at high voltage and current and it also works in low saturation voltage. The device can be enabled or disabled independently through two given enable input signals. An extra supply input is available through which the logic works at a lower voltage. The

maximum operating voltage is 46 V, and the total working DC current, is up to 4A.

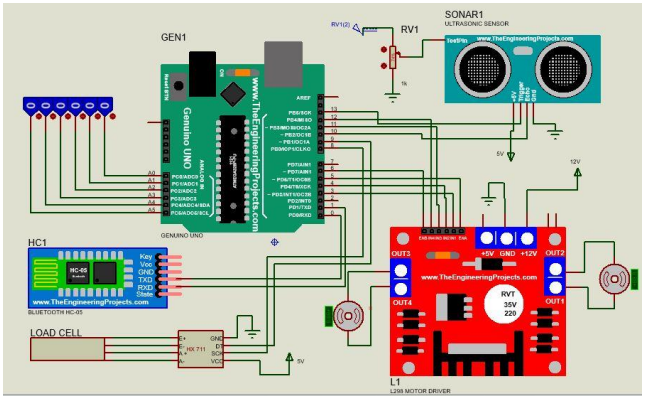

Fig.5. Simulation Circuit Diagram (Robot)

We used few sensors to make it perform autonomous movement. An ultrasonic sonar sensor was needed to determine the distance to an object like some creatures do such as bats or dolphins. To serve that purpose we have used the HCSR04 ultrasonic sensor. Excellent non-contract range detection with high accuracy and stable reading is offered by it. This device is user-friendly. Its detection range is 2cm to 400 cm or 1 inch to 13 feet. Sunlight or any black material like sharp rangefinders do not affect this senor's operation. Ultrasonic transmitter and receiver modules complete it.

For line follower robot and obstacle avoiding robot multipurpose infrared sensor is a must which gives the robot the ability to determine if there is any obstacle in front of it. The IR sensor we have used here detects the radiation which is reflected from its own infrared LED. It is able to detect light or dark lines or even obstacles in front of it by measuring the amount of reflected infrared radiation. There is a RED LED integrated on to the board in order to detect the presence of an object or line. Sensing range can be customized by integrating a built-in variable resistor.

As a force sensing module load cell has been used here, it is designed carefully with a structure of metal and tiny elements called strain gauges placed in some precise locations on the structure. Specialized amplification is required for this cell and the electrical signal output is very small. The 1046 PhidgetBridge will perform all the necessary amplification and measurement needed for the electrical output. This type of cell can measure force in only solo direction. In another direction, force can be measured also but then the sensitivity would be different.

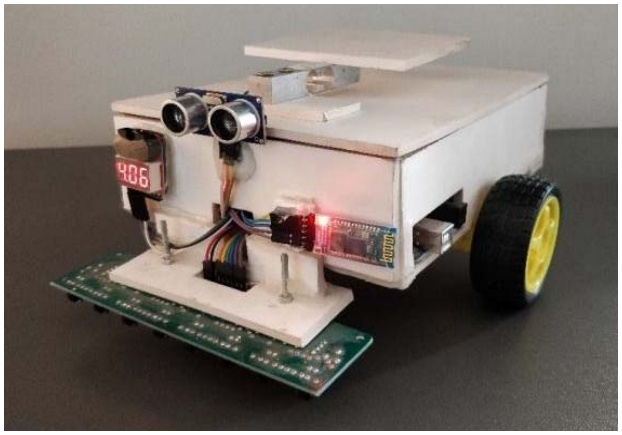

Fig.6. Prototype with Sensors.

B. Embedded System (Control Station)

The robot can take a maximum of four (04) "task calls" from the counter, and the bot will serve one call at a time. At the control side, we used the ATmega328P microprocessor based Arduino Uno board with the Bluetooth module, HC-05. As our ideal model has four counters we add four (04) "task call" buttons to call the robot.

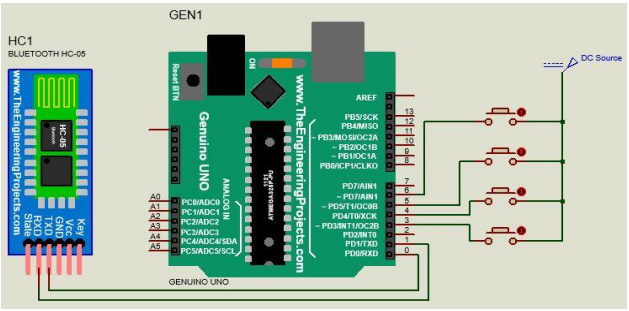

Fig.7. Simulation Circuit Diagram (Control Station)

C. Communication System

The communication system is built using Bluetooth module HC05, which is designed for wireless data transmission between short distance operations and it can also be used as personal area network (WPAN) as it works at ultra-high frequencies (UHF). Two Bluetooth modules have been used here for building the communication system. When pairing them, one of the Bluetooth modules is configured for the master role and another module is configured for the slave role. The modules are arranged in order response work mode so that commands are passed to them. The communication mode is enabled in both modules so that data can be shared amongst them.

D. Load Calculation:

According to the datasheet, for measuring the force a formula has been used to convert the load in to mv/V.

Force = X * Measured mV/V + C (offset)

The road cell output rated is 1.0±0.15mv/v and total capacity of the sensors is 5kg.

So, X is,

Capacity = X * Rated Output

X = Capacity / Rated Output

X = 5 / 1.0

X = 5

As the offset (C) is a variable, so for each sensor it has to be calculated.

C = 0 - 5 * Output

E. Cooling system:

12V DC Axial cooling fan has been used to cool the system. For motor driver, we using heat sink. The total cooling system consumption is 0.08 Amp.

Fig.8. Cooling system.

F. Safety System:

Robotics System are getting populated day by day and the safety system of robotics system has been deployed more. Robots are working with human and for that safety system is need to be properly design [13]. With the advancement of technology, the industry is seeing more robots that can perform tasks autonomously. But with all this development the industry is seeing a new dimension of risk. The robot

contains an emergency terminating button so that in a case of mechanical failure the robot can be turned off manually.
During the process of data collection, communication failure might occur. In such cases, Robot is working with the last command and after that buzzer will buzz for malfunctions. In order to prevent with obstacles sonar sensor data have been used.

VI. Embedded Software System

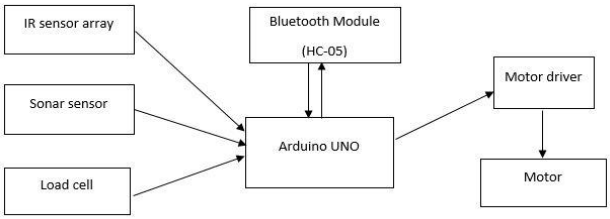

Fig.9. System Overview of the Embedded System (Robot)

The embedded system has been developed using unique method using Advanced C programming. The software system is divided into two subdivision, one is the robot operations system and another is control station system.

a. Robot Operations System:

The programming language that is used to develop communication is C language. Once the communication is established through the Bluetooth module, the robot will check the next command. It can receive four (04) "task calls" at a time currently, using array programming. It will execute the command by going to the counters one by one. The visiting order will be stored in the array. As per the instructions given by the user, the robot will start moving towards its destination by following a black line path. If there is any obstacle or object in front of the robot then it will stop and wait until the object is removed.

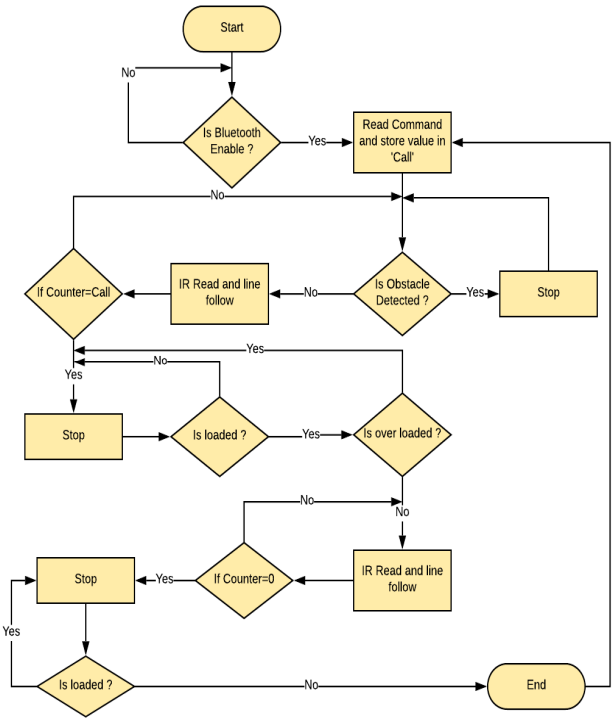

Fig.10. Software System Flowchart

When the robot arrives at the destination, it picks up the box. At this point, the bot will check if the box is overweight. If the weight crosses its limit then a red LED will be turned on to give a signal. If the weight turns out within limit then it will return to the storeroom by following the same black path line and unload the boxes there. If the bot receives another call from the control station while it is completing one task then it will receive the command and store it in the array like mentioned previously. The robot will continue to accept new tasks after it has placed the boxes back to the storage area [9].When the first task is finished it will go to the next destination to fulfill that task.

b. Control Station:

At the control station side we used some modern simple logic for generating faster "task calls" and increase the success of the real-time operation. When a "task call" button is pushed the data will receive the microcontroller and send the data to the bot through the Bluetooth communication system.

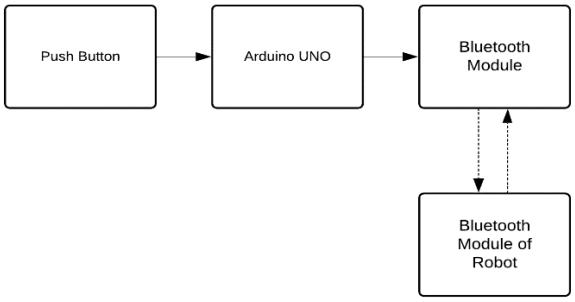

Fig.11. Control System block diagram.

VII. Power System:

The whole power system of this robotic system is divided into two individual parts. One is for the onboard power system and another is for the control station. The onboard power system is a 12V DC system. The total capacity of this system is 07 Watts. We used an integrated monolithic circuit as a motor driver, L298N. This package operates the full-bridge method with a high current dual driver. For this project we used a DC gear motor which is operated by 12V. The consumption of this motor is 500 mA.

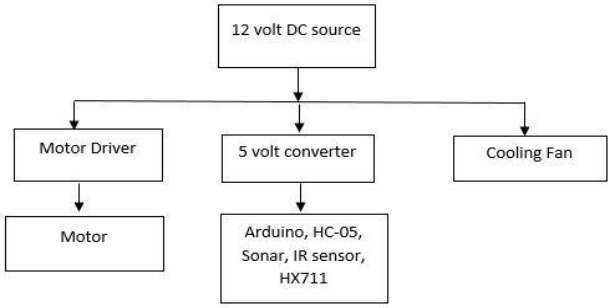

Fig.12. Block Diagram of Power System

All other devices, controller and sensors are operated by 5 Volts. A buck converter LM2596 is used to convert 12 Volts to 5 Volt. The total Watt consumption of this device is 1 Watt. The Control System is operated by a 5 Volt system. The total Watt consumption of this side is 0.50 Watt. We used a Lithium Polymer Battery, widely known as Li-Po Battery and as our system is in the prototype stage, we used a 2.2 Amp 12V Li-Po Battery.

a. Charge Indicator System:

Fig.13. Charge Indicator

There is a charge indicator system for tracking the voltage range. When the below voltage sets value, a buzzer loudly sets off, with a pre-set value of 3.3V. One button setup of alarm voltage

b. Buck Converter: (12V to 5V converge)

We used the voltage regulator LM2596, step down (buck) switching with 3A Load. Using this regulator we buck 12V to 5V for the sensors and motor driver.

VIII. Result

a. Trials & success:

According to proposed solutions the robot is tested in different conditions of calling states. Table 3 is showing the summery of trials results.

From the trail result the system is perfectly working 97.142%, which means robot had missed the task 2.857 times.

Table: 3 Trials & success

Condition Matrix [1=true, 0= False]	High priority state		Trial Results (Delivered to E)	
Initial state, [A,B,C,D]=[0,0,0,0]	Location	State [table2]	Success (out of 10)	Error (out of 10)
[1,0,0,0], call from A	A	0	10	0
[0,1,0,1], call from B, D	B,D	1,3	10	0
[1,1,0,0], call from A, B	A, B	0,1	10	0
[1,1,1,0], call from A, B,C	A,B,C	0,1,2	09	01
[1,1,1,1], call from A, B,C,D	A,B,C,D	0,1,2,3	10	0
[0,0,0,1], call from D	D	3	10	0
[0,1,1,1], call from B,C,D	B,C,D	1,2,3	09	01

b. Robustness:

Most of the robots are not perfectly operates and delivered their task like the human. [10] The system has been designed to help the human to carry the heavyweight product. The robots are enough capable to take the challenge of the current garments need. Currently, the total capacity of the maximum call is 04. But the robustness of the program and processor can take the more call and serve the purpose.

c. Limitation:

There is some limitation in the system. When the call state of C is high. The robot will pass through A and B which is not optimizing the shortest path. But at the call state of D is high, the robot will use the shortest path from A to D.

The robot is taking more than one call, but serve one position till comeback to E position (storeroom). It can be minimized by increasing capacity of the load carrying.

There is no automatic charging system. The user has to charge when the robot buzz for Low battery. This manual process will be overcome with the future adaptation of the charging station.

IX. Conclusion

This research project is just an inspiration of future real-time Artificial Intelligence-Based Systems. For future development, we have planned to research and implement on a robot navigation system, a control updated application improvement and analyze the data of some sensors to control loading/unloading time effectively. In upcoming days we plan to manage the whole inventory through robots. The robots will sort and rearrange the vast inventory 24 hours a day through incorporating deep learning methods. A complete automated system is designed to bring out the utmost efficiency of the garments industry. A fully automated and constant modernization of the processes has become the demand of all the industrial sectors. In this research we have presented our proposed solution to make our industry dynamic. The goal is to make people's life easier and reducing the percentage of error. As there will be less manual tasks chances of error will also be less. The whole world is going through a technological evolution and in order to keep pace with it, bringing improvement in present technologies which are currently used here is our target. Our proposed solution can bring immense change in the industry by reducing manual labor and making the process autonomous.

Acknowledgment

We would like to express our earnest gratitude to the Dept. of EEE, United International University for providing financial aid. We would also like to thank our honorable supervisor Dr. Kaled Masukur Rahman for providing necessary technical supervision. Finally, we are thankful to our Coordinator Dr. Hasan uz zaman for the coordination and supervision. We would also like to thank Ai Robotics Asia Ltd. for giving support through technological planning.

***Abstract*—For a swarm of mobile robots in an unknown environment, the most challenging task is to plan the optimal path and also to learn the environmental parameters. Machine learning is one of the solutions to this problem. This paper proposes a combination of particle swarm optimization (PSO) and Q-value based reinforcement learning (Q-Learning) for a swarm of mobile robots to find the optimal path in an unknown environment and to learn the environment. Q-learning combined with PSO enable the robots to learn the unknown environment with reward and action selection policy while reducing the time to find the optimal path in the environment using the iterative improvement method of PSO. The proposed algorithm is simulated and found performing faster than Q-learning and PSO performing alone. We also compared with some other established algorithm where the proposed algorithm outperforms each of them in accuracy and speed.**

Keywords—particle swarm optimization, reinforcement learning, q-learning, swarm intelligence, mobile robot

I. INTRODUCTION

Our mother nature is an inspiration for a lot of the machine learning algorithms, for example, Genetic Algorithm is inspired by the natural evaluation of the living beings, reinforcement learning is inspired by the behavioral psychology, swarm intelligence is inspired by the natural swarms present in the nature like birds flock, fish school.

There is two types of machine learning, i) supervised learning and ii) unsupervised learning. In supervised learning, the learning parameters are updated based on the training data. The training data is gathered upon the desired output for a known input. However, for the unknown environment, these data are not present. This is where unsupervised learning comes handy. In unsupervised learning, agents learn using the reward and action concept. There is a set of actions from which the agent selects an action and gets a reward for that action. The main aim of the agent is to find the action which gives the greatest reward. For reinforcement learning problems Temporal Difference (TD) is one of the most used concepts. TD is step based concept where the results are found after single time steps. Q-Learning is based on TD, but it is computationally simple and easy to implement [1]. Q-learning works by updating the state-action table where the values are the rewards associated with that action and state.

There a lot of evolutionary algorithm (EA) that are used to solve the reinforcement problems. Some of the popular ones are the Genetic Algorithm (GA), Particle Swarm Optimization (PSO), Ant Colony Optimization (ACO). They are population-based algorithms. Many agents are exploring through the solution space and collaborating to find the global optima. As this algorithm uses exploration and collaboration, there is a minimal possibility of them to trap into the local optima. However, in EA there is no limit on the actions that can be taken by the agents, which leads to longer time to reach the optima. On the other hand, reinforcement learning can select the desired actions, but there is no fitness function in these methods which can indicate how soon the agent can control the system's state into a set of goal states [2].

In our proposed method we combined the features of reinforcement learning and the evolutionary algorithms. This enables the action selection by the Q-Table added with the fitness of the PSO, so that the agents find the optimal path and learn the environment faster and with less associated complexity.

Rest of the paper is organized as follow: In section II related works of Q-Learning and PSO are summarized. Section III presents some background on PSO and Q-Learning. Section IV describes our proposed methodology for optimal path planning and environmental learning for a swarm of robots. In Section V our training and testing methods are described. Section VI explains the simulation results and performance of the implemented algorithm. Finally, In Section VII, we conclude the paper.

II. RELATED WORKS

Use of machine learning algorithms is getting popular in robotics. As the robots are used in different environment researchers, tend to use more unsupervised learning algorithms. On the other hand, due to the simplicity and the reliability of evolutionary algorithms, researchers are using hybrid algorithms with reinforcement learning.

In [3] researcher introduced Q-Learning as a TD based approach. While in [1] researchers proved that Q-learning convergences to optima and there is a relationship with dynamic programming and TD. Yi-Chang and Sheng proposed Q-value based PSO for a neuro-fuzzy system [2]. In [4] James Kennedy and Russell Eberhart introduced the PSO while they were studying the behavior of natural swarms.

Many researchers had worked on many hybrid systems as well. Like in [5] researches used Ant Colony Optimization (ACO) to select Artificial Neural Network (ANN) topology and PSO to adjust ANN weights. In [6] they presented reinforcement hybrid learning algorithm (R-HELA) combining the Compact Genetic Algorithm (CGA). Orawan

and Peerapun used modified Q-learning and PSO for target finding application [7]. In [8] researchers used Q-learning to help particle swarm optimization to avoid being trapped into the local optima. In [9] researchers proposed A Q-learning based swarm optimization algorithm for economic dispatch problem.

III. Background Study

A. Q-Learning

Q-Learning is model-free reinforcement learning algorithm [2]. It uses the action selection policy for the agents that are exploring through the solution space. The policy mainly defines the action that is related to a specific state. These actions are selected based on the reward it gets for that particular action. The algorithm maintains a Q table whose values are updated by the reward matrix using (1) after each action is taken.

$$Q(s, a) = r(s, a) + \gamma max_a (Q(s', a)) \quad (1)$$

Where

s is the current state

r is a reward

a is an action

s' is the next state

γ is the discount factor

Discount factor plays a vital role in learning. γ value is confined between [0,1]. Value closest to 0 (zero) makes the agent prone to short term rewards, while a value close to 1 (One) makes the agent more attracted to the long term rewards. In Fig. 1 the structure of Q-Learning is shown.

B. Particle Swarm Optimization (PSO)

PSO is one of the most commonly used evolutionary algorithms. It is a stochastic population-based algorithm inspired by the natural swarm behaviors. Each agent in the algorithm is considered as a particle in the multidimensional space. Individual particle tries to find the global optima by iteratively adjusting their trajectories. Each particle updates their position and velocity based on the best performance by itself and the best performance found in the swarm. The velocity and the position are updated by using (2) and (3).

$$v_i = w*v_i + c_1 * r_1 * (P_i - x_i) + c_2 * r_2 * (P_g - x_i) \quad (2)$$

$$x_i = x_i + v_i \quad (3)$$

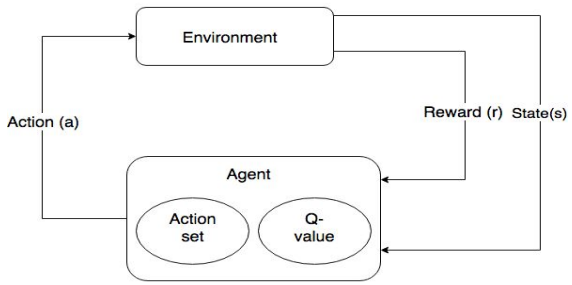

Fig. 1. Structure of Q-Learning.

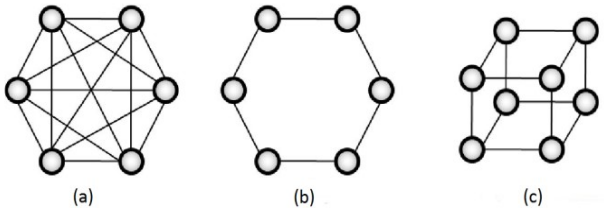

Fig. 2. Three topologies of PSO a) Fully connected,b) Ring and c) Square.

Here v_i and x_i is the velocity and position of a single particle. While P_i is the best position found by that particle and P_i is the best position found the swarm. Here r_1 and r_2 are a uniform random number, and c_1 and c_2 are the constants called the learning factor. Using c_1 and c_2 the algorithm's biases on the local or global best position can be adjusted. To control the effect of the previous velocity in the new velocity a constant w is used.

PSO work with different topologies depending on the population type [10]. The topologies are shown in Fig.2. Fully connected PSO trajectory of each particle is affected the global best performance while for square and ring each particle is affected by their neighbors.

IV. Proposed Algorithm

Our proposed algorithm combines Q-Learning and PSO, where the action is selected by the Q-value and trajectory is defined by the swarm optimization. The primary goal of this algorithm is to guide a swarm of mobile robots in an unknown environment toward the target. The architecture of the algorithm is shown in Fig.3. Here a swarm of particles is initialized with random trajectory, and Q-table is initialized with zeros. Based on the state an action is selected from the action set. The action set contains only four actions which are forward, backward, left and right. Depending on the action and state a reward is given to the particle. These rewards are the Q-value for the table. Using the q-value table of all particles best position in the swarm is determined; also particles learn their own best position by using the q-value. Then PSO operation is done on each particle, and a new trajectory is calculated. It creates a new swarm with updated trajectory and updated Q-table. In Fig.4 flowchart of the total algorithm is shown. We added a limited number of trial for

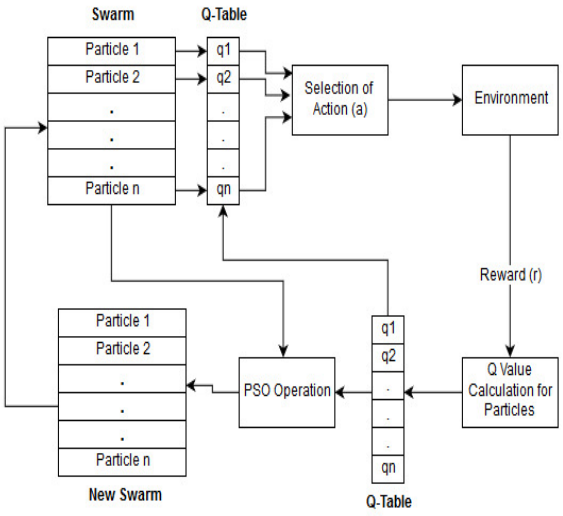

Fig. 3. The architecture of Q-Learning based PSO.

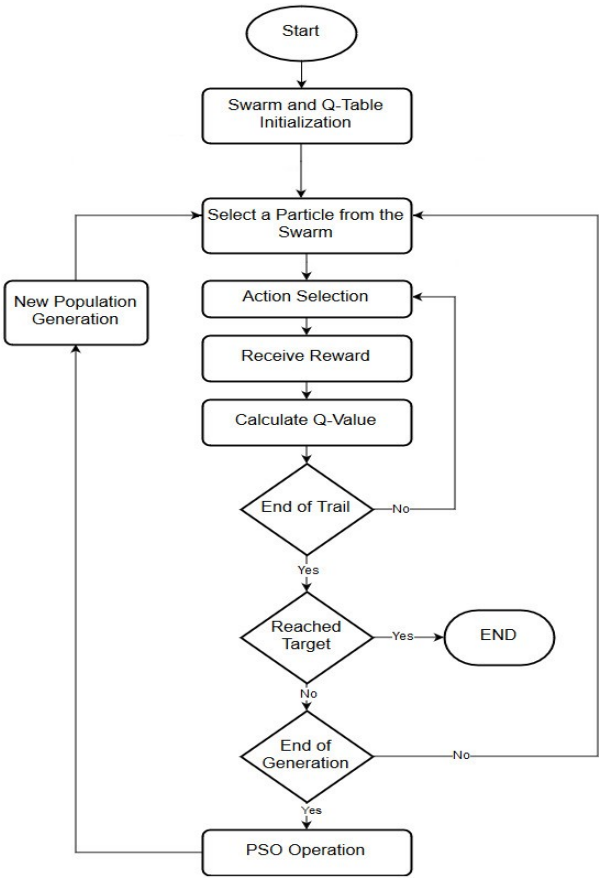

Fig. 4. Flowchart of the proposed algorithm.

each generation so that the algorithm does not stick in local optima.

V. Training And Testing

We simulated the algorithm using Processing which is an open source graphical library and integrated development environment. We created three environments that consist of different type of geometrical obstacles. These environments are characterized by Easy, Normal and Hard. This characterization is done by random walk algorithm where an agent walks randomly into the environment and counting the steps is required to reach the target. This process is done 100 times per environment, and the average number of steps are taken in the count. Environments are shown in Fig.5,6,7 and in Table I the average number of steps required for each environment is shown.

A. Learning

First, we initiate the learning phase to learn each environment. In the learning phase, 100 of agents are initiated at the start point and wanders around the environment till either the trial ends for all the agents in one generation or 95% of the agents each at the target destination which is a red dot in the Fig.5,6,7. After each learning phase, the Q-table is stored. We used different learning rates and found out that the system worked better at a learning rate of 0.9.

TABLE I. Step Required For Different Environment

Quantity	*Easy*	*Normal*	*Hard*
Average number of steps required for each environment	336	594	685

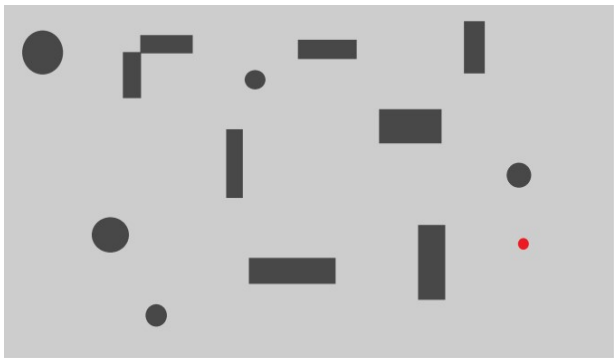

Fig. 5. Easy Environment.

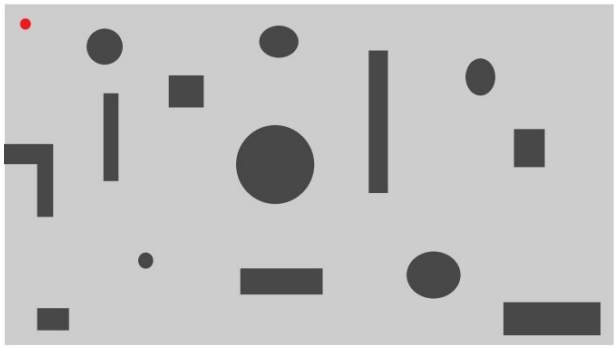

Fig. 6. Normal Environment.

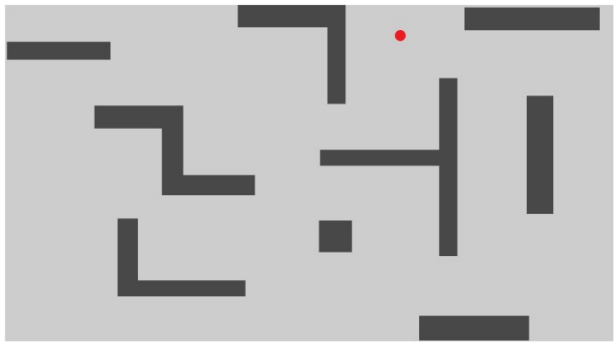

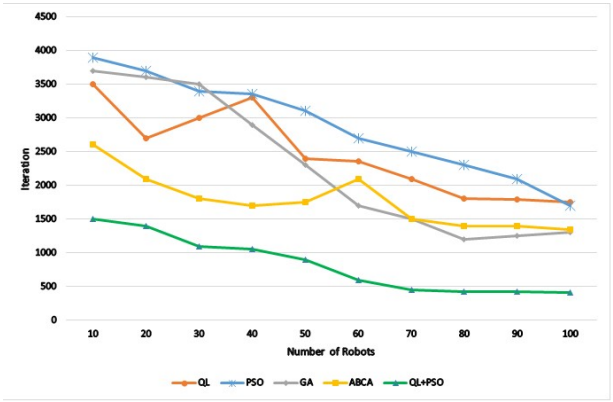

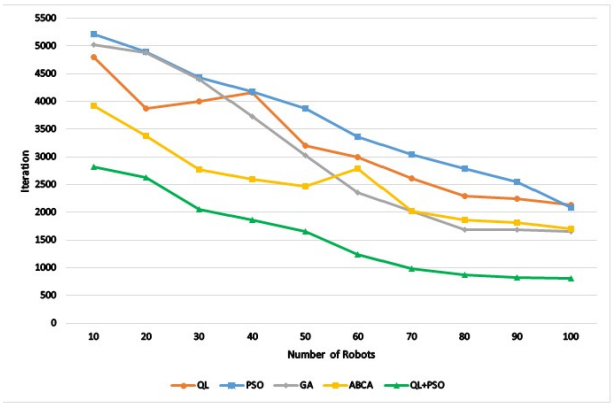

Fig. 7. Hard Environment.

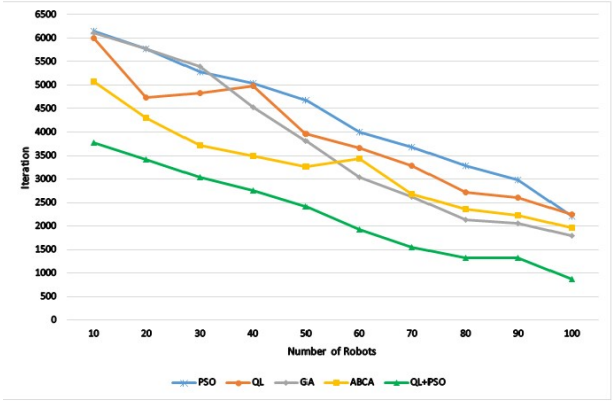
B. Testing



After the learning phase, the system is tested with a different number of agents in the three different environments and measured the performance by evaluating the iteration required to reach the target and also the time to reach the target. We also compared different algorithms like Genetic Algorithm (GA), Q-Learning and PSO and Artificial Bee Colony Algorithm (ABCA). Random walk algorithm is also included as the baseline for the comparison and to judge the difficulty level of the environment.

a) Easy Environment

b) Medium Environment

c) Hard Environment

Fig. 8. Iteration required in training phase

VI. Result And Analysis

We tested the performance of the algorithm by measuring the iteration it required to have 95% of the robots to reach the target in the training phase. Other criteria of performance measurement are the percentage of trials finished with 95% of the robots reaching the target. After the training phase, we measured the performance in the testing phase by measuring the time required to reach 90% of the robots reaching the target. We compared the results with other algorithms. We found that the performance of the algorithms is higher with the higher number of agents in the solution space. In Fig. 8 the required iteration for each algorithm is shown for three

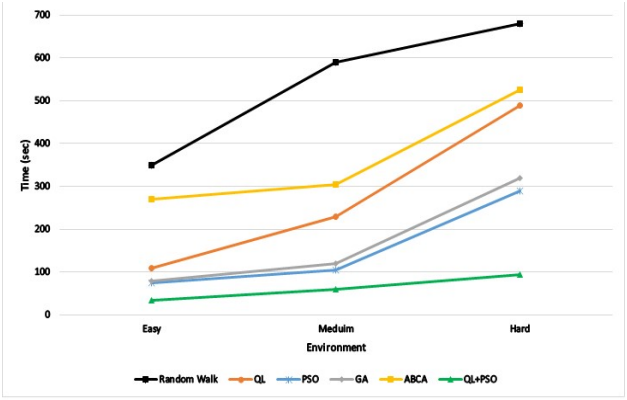


Fig. 9. Test Results

environments. It is visible that the proposed QL based PSO algorithm outperforms all other algorithms. Though the number of iteration required in the hard environment is much higher in other environments. It is due to the nature of the obstacles as the hard environment contains all rectangular obstacles which make it difficult for the robots to pass the obstacles. In Table II the percentage of the trials having 95% of the robots reach the target is shown. Here also the proposed algorithm having QL and PSO working together shown the higher performance than the other algorithms. In Fig.9 the test results are shown. We measured the time required for 90% of the robots to reach the

target in the testing phase. We used the same number of robots as the training phase and used the training data for the same batch of robots in the testing phase. We also compared with the time required for the random walk algorithm to reach 90% of the robots to the target.

TABLE II. Comparison Of Different Algorithms

Quantity	*QL*	*PSO*	*GA*	*ABCA*	*QL+PSO*
Percentage of trials on which 95% of the robots reaches to the target	62	89	87	74	96

VII. Conclusion

In this paper, an algorithm which has the convergence ability of Particle Swarm Optimization and the ability to reduce the number required action feature of Q-Learning is proposed. This algorithm is also compared with other popular machine learning algorithm for performance evaluation. It seemed that the number of iteration required in an unknown environment and time required to reach the target for the swarm is much lower than the other algorithms. Using two algorithms simultaneously increases the complexity and required computation power, but for an increase in accuracy of about 7-8%, it can be considerable.

***Abstract*—Indoor mobile robots are widely used in industrial environments such as large logistic warehouses. They are often in charge of collecting or sorting products. For such robots, computation-intensive operations account for a significant percentage of the total energy consumption and consequently affect battery life. Besides, in order to keep both the power consumption and hardware complexity low, simple micro-controllers or single-board computers are used as onboard local control units. This limits the computational capabilities of robots and consequently their performance. Offloading heavy computation to Cloud servers has been a widely used approach to solve this problem for cases where large amounts of sensor data such as real-time video feeds need to be analyzed. More recently, Fog and Edge computing are being leveraged for offloading tasks such as image processing and complex navigation algorithms involving non-linear mathematical operations. In this paper, we present a system architecture for offloading computationally expensive localization and mapping tasks to smart Edge gateways which use Fog services. We show how Edge computing brings computational capabilities of the Cloud to the robot environment without compromising operational reliability due to connection issues. Furthermore, we analyze the power consumption of a prototype robot vehicle in different modes and show how battery life can be significantly improved by moving the processing of data to the Edge layer.**

***Index Terms*—Edge, Fog, Cloud, SLAM, Efficiency, Computation, Offloading, Energy, Performance, Mobile, Robots**

I. Introduction

Small indoor robots which work alongside humans have become ubiquitous in different fields such as home-care, restaurant business and manufacturing plants. For instance, lightweight robots are used in exhibitions for guiding visitors to a desired stall, and are the operational backbone in logistic warehouses of the world's top e-commerce companies. In smart homes, small robots can be used as a pet which can communicate, watch over or play with children and elderly people and can notify or trigger alarm when abnormal situation occurs [1]. Companion robots can remind elderly people to take medicine on time. However, small robots have limited resources such as low battery capacity and light processing capability. In most cases, these robots cannot operate for a long period of time or cannot make useful decisions in complex situations due to these limitations.

Internet of Things (IoT) can be defined as a virtual platform which allows both physical and virtual objects to be interconnected and communicate with each other. It consists of advanced technologies such as sensor fusion, wireless sensor networks and Cloud computing to help improve the quality of services [2]–[6]. Besides, global storage allows users to access data anywhere at any time [7]. Proper utilization of IoT can help overcome some of the drawbacks of small robots. Particularly, real-time position of a small robot can be tracked and a system administrator can send control commands in cases of complex situations [8]. However, IoT-assisted small robots still have some disadvantages. For example, traditional gateways in IoT platform are mainly responsible for collecting data from robots and forwarding the data to Cloud servers. When the data volume is tremendous e.g., due to a large number of multi-sensor equipped robots operating simultaneously, the network bandwidth may be not adequate or the communication latency become too high [9]. Hence, an appropriate architecture is required which can overcome these limitations.

Edge and Fog computing can be described as extra layers between sensor devices, gateways and Cloud servers for enhancing the quality of services. These bring Cloud computing paradigms to the Edge of the network and help reduce the burden of Cloud providing faster services unsupported by Cloud computing. Edge and Fog computing help to reduce energy consumption of sensor nodes and diminish overall latency [10], [11]. The combination of Edge and Fog computing with IoT can provide a suitable approach for enhancing overall performance.

In this paper, we exploit the concept of IoT and Fog along with Edge gateways to enhance energy efficiency and operational performance of small indoor robots. We present a proof of concept for a hybrid Edge-Fog-Cloud architecture which facilitates use of Fog/Edge and Cloud computing for offloading computationally expensive tasks from robots with limited processing power. We discuss related works on how intensive tasks can be offloaded to Edge, Fog or Cloud services in Section II. Section III presents the proposed system architecture applying Edge and Fog computing. Section IV illustrates the results of different tests and discusses the advantages in terms of power saving and performance boost. Section V concludes the work and depicts on future improvements.

II. Related Work

Several works focus on increasing the performance of different algorithms which cannot be fully exploited in resource-

constrained devices. Dey *et al.* analyzed the advantages of leveraging Fog and Edge computing to offload computationally heavy tasks within SLAM algorithms for mobile robots [12]. They provided extensive simulations for different Robot-Edge-Fog-Cloud computational tasks distribution schemes. The authors concluded that Edge and Fog computing can bring significant enhancement to computationally intensive tasks such as localization and positioning tasks. Edge and Fog computing are shown to provide the same computational performance than Cloud offloading, with the benefit of reduced bandwidth and thus faster response time. However, the authors did not perform real-life tests where the communication layer can play an important role and become a bottleneck due to the high data rates between mobile robots and gateways.

Offloading Simultaneous Localization and Mapping (SLAM) tasks to Edge and Fog layers has only been considered recently while Cloud-based SLAM has been studied for the last decade. Benavidez *et al.* deployed an instance of the Robot Operating System in the Cloud to increase the computational capabilities of constraint robots for Visual SLAM (VSLAM) [13]. They pointed how this helps to overcome traditional bottlenecks in robots with limited computational resources with VSLAM performing feature identification and matching which usually need large databases. They demonstrated how parallel computing can be exploited with a multi-node Cloud deployment to facilitate multi-robot SLAM and with limited impact on the on-board computers that control the robots. A similar, more comprehensive work was carried out by Riazuelo *et al.* who presented C2TAM, a Cloud framework for cooperative tracking and mapping [14]. The authors used the unlimited computational resources available in the Cloud to enable the implementation of algorithms which fail to run on single board computers or even more powerful CPUs when the number of agents increases.

Similarly, Turnbull *et al.* utilized Cloud servers to enable advanced neural command for formation control in large groups of robots [15]. However, the network connection between robots and Cloud servers is unreliable and cannot be guaranteed. Therefore, a trade-off exists between the robustness of the solution in terms of available computational resources, operational reliability and performance. This is further explored by Salmeron-Garcia *et al.* in their work on Cloud offloading of a vision-based navigation system [16]. The authors stress in their paper that processing time can be matched to communication period with parallel computation in the Cloud and inferred of a bottleneck due to communication bandwidth and latency. They concluded that Cloud is necessary if the system needs to be easily scalable or precise operation is required. This occurs where the localization or navigation requirements are such that high quality images need to be processed. Extensive works exist in this direction by other authors in the field [17] [18], taking the trade-offs into account both in terms of communication and computational performance.

Kumar *et al.* gathered computational offloading techniques and algorithms into a survey where they accentuate how shifting of intensive applications will be essential in the future for battery powered devices [19] and explored the energy-saving potential of offloading computation to the Cloud.

Extensive work has been carried out on leveraging Cloud computing for offloading heavy computational tasks. However, most of this work have been focused on leveraging virtually unlimited computational resources of the Cloud. Fewer research have targeted the Edge and Fog computing paradigms as a solution to the high latency and unreliability of Cloud services. Keeping these in mind, we focus in both energy efficiency and performance improvement by placing the most expensive computational tasks in Edge and Fog layers leaving the Cloud only for monitoring and management and thus not entirely relying on network link to the Cloud services for normal operation.

III. System Architecture

The proposed system architecture consists of 4 layers: *Robot Layer*, *Edge Layer* for data processing and analysis, *Fog layer* for distributed storage and *Cloud Layer* for monitoring and general mission control. As shown in Fig. 1, we have combined the Edge and Fog layer because the Fog layer consists of the smart Edge Gateways and they use the same physical resources. The architecture we present is easily scalable, modular and distributed by definition. This section thoroughly describes the role of each layer and the distribution of the computational load through the network. Energy consumption, latency and computational power at different layers are the key factors taken into account when deciding the role of a layer.

In general, data is acquired by robots where minimal analysis is performed. Real-time decisions are taken at the Edge gateways to minimize the latency and share the computational load of different connected robots. The Fog layer provides additional services such as distributed storage and processing to enable an efficient handover mechanism with minimal data loss when a robot switches from one gateway to another. The handover includes sharing previous map data acquired by the robot switching gateways so that the result of the SLAM algorithm remains constant through the connection change.

Edge gateways also play an important role in reducing the energy consumption at the end nodes or robots by running the most computational expensive operations. Both Fog and Edge computing are essential in safety critical situations where they provide a more robust situational awareness and overall system control, and robot state knowledge. Finally, the Cloud layer enables end-users or administrators to control the system by giving general instructions and monitor the performance at different layers.

A. Robot Layer

In the robot layer, sensor data is gathered and streamed in real time to the smart Edge gateways. The control of the robot is run online and movement instructions are given in real-time. In the proposed system, the robot can be either aware or unaware of its current state depending on how extensively information is analyzed on-board and whether an

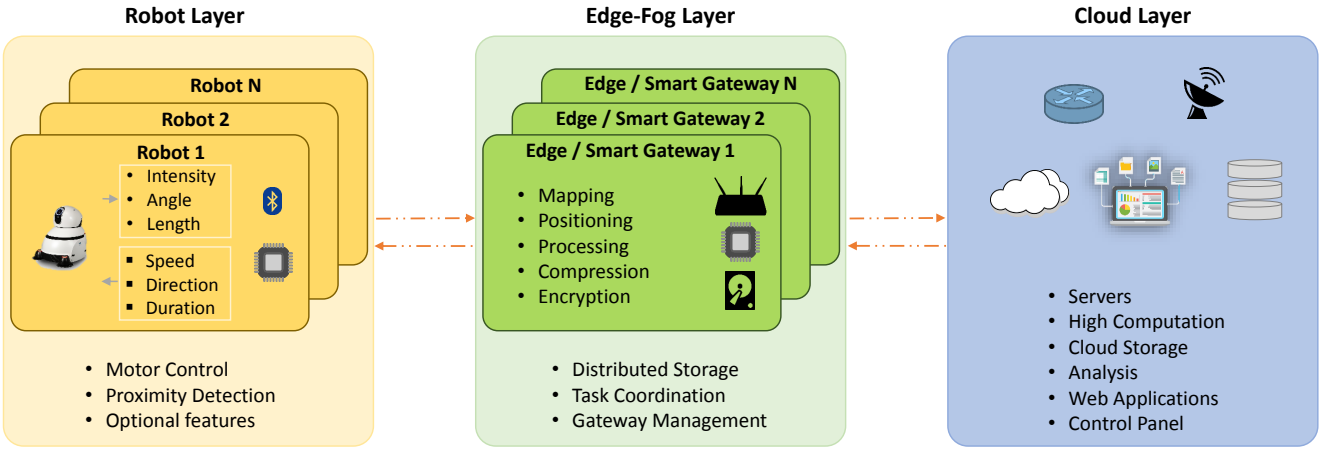

Fig. 1. Proposed System Architecture

Edge gateway provides enhanced state information to the robot or only movement instructions.

The robot relies on low power wireless communication technologies such as Bluetooth or nRF if the bandwidth requirements are met, or Wi-Fi for more bandwidth-intensive applications such as high-quality video transmission. By streaming sensor data directly to the gateway without being processed by the MCU, the robot gains in energy efficiency. Furthermore, low-power techniques can be applied to the MCU in order to further reduce the overall power requirements.

Compared to a traditional approach where sensing, obstacle detection, path planning and localization are made onboard the robot, we can significantly reduce the computing requirements of the robot's control system and downgrade them from processor-based to MCU-based. Only the most basic information is analyzed at the robot itself. This includes, for instance, wheel odometry or inertial data so that the robot is aware of its current acceleration, velocity and orientation. This can be combined with state estimation performed online at the Edge, Fog or Cloud layers to allow more accurate movement and simplify the instructions given to the robot.

B. Smart Edge Gateway Layer

Edge gateways receive sensor data from one or multiple robots in real-time. This includes, for example, images from on-board cameras or data from range sensors such as Lidars and radars, which is analyzed at the gateways to perform obstacle detection and avoidance, path planning, localization or mapping. Odometry data (e.g. wheel odometry, visual odometry) and inertial data (e.g. magnetometer, accelerometer and gyroscope data) is also transmitted from and processed at the gateway.

Acting as a central element, Edge gateways ensure a low-latency and robust solution and provide fast decision making while relocating computationally expensive tasks from the robots. Moreover, if multiple robots are connected to a single gateway, data from different sensors and sources is aggregated and analyzed in order to obtain a more comprehensive understanding of the environment. For instance, two robots operating in the same environment and connected to the same gateway are able to obtain information of larger areas through sensors of other robots and see through other agents if these are nearby and blocking their field of view.

The role of the Edge layer is of superior importance in safety-critical situations and scenarios such as industrial environments where human share operational space with autonomous or semi-autonomous robots. Compared to the more traditional practice of moving complex tasks to the Cloud, the Edge layer reduces the latency to the point where safe operation is achievable even in the case of network connectivity failure. From an operational point of view, smart Edge gateways receive information from sensors aboard multiple robots and are in charge of decision-making in terms of robot movement and task allocation. These instructions are transmitted continuously and wirelessly to the robots.

C. Fog Layer

The Fog layer includes the smart Edge gateways as part of it. Nonetheless, it is defined as a separate layer because its role in the proposed system architecture differs from the data analysis and instantaneous control role of the Edge layer. The Fog layer represents the interconnection of different Edge gateways, together with other services such as distributed databases or location services. In particular, the Fog layer takes care of the handover mechanisms when the robots disconnect from one gateway and connect to another one together with the procurement of additional services including distributed storage, external tracking and monitoring or location services.

Detailed research has been performed to minimize latency and data-loss during the handover [20] [21]. An alternative for managing the handover is to deploy Edge gateways just behind conventional gateways such as Wi-Fi routers so that the gateways can directly store the received information in distributed storage. Thus, the handover problem would be reduced to the distribution of the computational load of individual robots into

the set of Edge nodes, since all nodes are able to access robot data in real-time from the shared storage.

Localization algorithms are mostly run in the Edge layer in which real-time sensor data is matched with an area of an existing map. This is crucial in situations where the robot operates in a partially or totally unknown environment and simultaneous localization and mapping algorithms are run in the smart Edge gateways. In these cases, it is required that the local map stored in one gateway is shared to other gateways before or during the handover. Accordingly, our proposed system architecture includes a distributed storage deployment in the Fog layer. This can be implemented, for instance, in the form of a decentralized database where the maps and other essential robot data are stored and available to all nodes in the Edge/Fog layers at any time.

Other services included in the Fog layer are external sensor management, collaborative processing and monitoring. For example, while Edge gateways process the on-board sensor information from the robots, external monitoring cameras and other sensors can be used to increase the accuracy of localization algorithms or assure collision avoidance in cases of sensor failure or other local problems that might appear in the robot and go undetected by the Edge gateway. This results in an enhanced situational awareness [22] where both externally and internally collected information about a robot is available in the Fog layer. By introducing additional services in the Fog layer, we can enhance overall system robustness and its fault tolerance. For instance, if a gateway abruptly disconnects or any kind of failure occurs, all the information that it was handling will be available to other gateways due to the shared storage resources. This allows the robot to reconnect to the next available gateway and continue its operation with minimal data loss, operational interruption and latency.

D. Cloud Services

Time-series data of the robot state, including basic information such as position, velocity, acceleration, steering drift factor, drive torque variation, instantaneous current consumption and battery level is uploaded to the Cloud for monitoring, control and visualization by users or administrators [23]. Instead of uploading raw sensor data, it is pre-processed and compressed in the Edge/Fog layers and only sporadic local map updates or critical information is sent. This can be implemented in a dynamic way in which, for instance, the map around a robot or of a given area in the operation environment is updated and uploaded to the Cloud at different frequencies depending on whether an end-user is actively monitoring the operation or not.

The use of Cloud services facilitates generic control instructions to the robot and stable operation [24]. For example, factory managers can easily have an overview of the position of different robots around the factory floor, or override autonomous roaming to involve more robots assigned within a certain group or to prioritize specific tasks. Besides, the Cloud allows global access for the administrators and mission planners to have a collaborative overview in a cost-effective way.

Fig. 2. Prototype car with Lidar running on top, used for the experiment

However, due to comparatively higher end-to-end latency between the robot layer and the Cloud, it should not be used for primary control purpose as it can be subject to variation in network performance. The Cloud provides access to pertinently processed data from the robot layer which is periodically backed up at a reasonable interval. This yields a conclusive operation and data history which can be analyzed using high performance computing in the Cloud for machine learning, better prediction and big data analytics.

IV. Implementation and Experimental Results

In order to test the feasibility and validate the proposed architecture, we have constructed a car controlled via Bluetooth communication to produce a map of the perimeter it is bounded by. The car shown in Figure 2 incorporates a 360^o Lidar on top of the chassis, two independent motors- one for steering control and another for driving forward or backward with appropriate motor control circuitry. The car is connected to a gateway through a Bluetooth Classic module. An AVR 8-bit MCU is used to control acquisition of raw data from the Lidar and send to gateway via the serial port profile of the Bluetooth standard. A prototype is built using the chassis from an *Reely 1:10 Elektro-Monstertruck NEW1* RC car and replacing the control circuit and motors with lower power variants with an RPLIDAR A1 M8 on the top, a low cost 360^o 2D LASER scanner from *Slamtec* [25].

We have run experimental tests with a minimal setup where only Lidar is used for both localization and mapping purposes. Adding inertial sensors would provide more accurate positioning and control over the vehicle; however, that is not the main objective of this work and we focus on the implementation of the hybrid Edge-Fog-Cloud architecture and its benefits.

The MCU controlling the movement of the car does not save or analyze the data from the Lidar sensor in any form and is forwarded directly to the gateway as serial stream over Bluetooth. The gateway then runs an adapted version of the BreezySLAM algorithm by S. D. Levy [26]. The algorithm has been modified to take into account the intermittent nature of

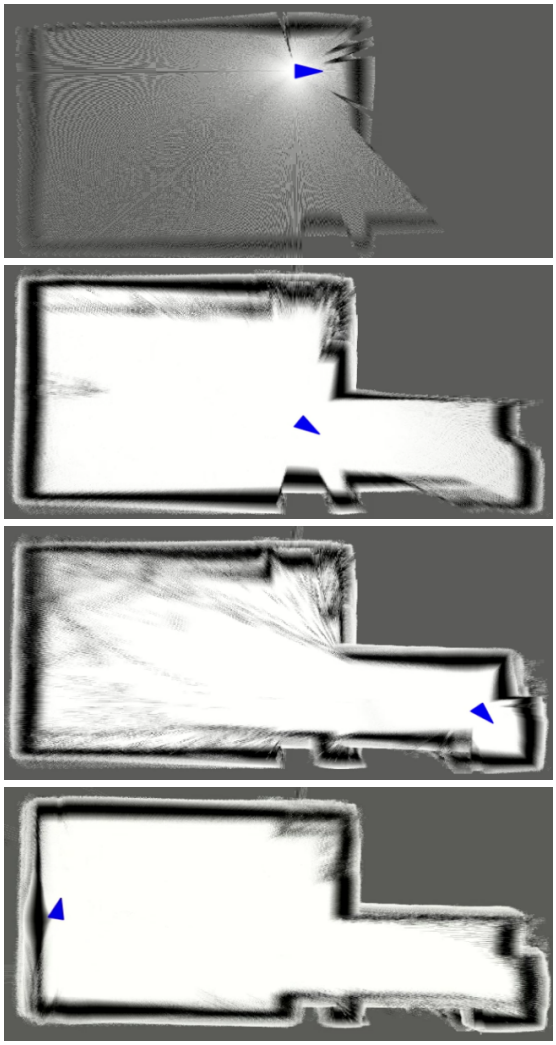

Fig. 3. Mapping and Localization at the Edge. (The position of the car is marked with a blue pointer)

the connection between the robot and the gateway, and execute accordingly when processing successive batches of data.

Figure 3 shows the result of applying the mapping and localization algorithm in the Edge gateway. As we are using an inexpensive Lidar and the SLAM algorithms run without any inertial measurement unit such as accelerometer and magnetometer, accurate positioning is hard to achieve in complex environments. However, with more input data from multiple sensors would suffice for enabling operation in non-trivial local environments.

The first map in Figure 3 shows the map obtained after the first few Lidar frames have been analyzed. The *RPLIDAR A1 M8* used in the tests is a low-cost Lidar and therefore several scans are processed before obtaining a good quality map. The granularity in the first map is derived from the relatively low scan speed of the device compared to more advanced sensors. Also, while the position within the map is accurate and consistent through the test, noise appears near the distant walls from the Lidar due to the low accuracy. However, the walls and corners in the local area around the robot are with little to no noise.

TABLE I
POWER CONSUMPTION OF THE PROTOTYPE VEHICLE AT 5V SUPPLY

Operation / Approach	**Average Current (mA)**	**Average Power (W)**
MCU Idle	4	19
MCU + Lidar	339	1695
MCU + Lidar + Streaming	378	1890
R.Pi Idle	301	1503
R.Pi + Lidar	622	3108
R.Pi + Lidar + Edge Processing	829	4152
Car (Drive / Steer)	122	607
Car (Drive + Steer)	184	918

In terms of performance, the recorded path elapsed a total of 44.3 seconds in which 314 Lidar frames were processed. This translates into 7 frames/s, which matches with the Lidar specification for a maximum speed scan of 10 Hz with an average car speed of 0.3 m/s. This frame rate can be compared to 1 frame/s processed on a Raspberry Pi 3 Model B running Ubuntu Mate Desktop with the graphical map display in real-time. While this can be optimized running a more trimmed, customized version of Linux on the Raspberry Pi, its computational capability limits the processing to about 5 frames/s. Since a MCU is able to handle the vehicle control and transmission of Lidar data, not only it significantly increases the system performance by offloading the SLAM tasks to the Edge gateway, but a considerable amount of energy is saved by replacing a power-hungry single-board computer such as the Raspberry Pi with a low-power MCU.

In particular, the specific power consumption and average current drawn by the prototype in different states are documented in Table I. In idle state, the Lidar consumes 300 to 350 mA, representing over 90% of the total power consumption. This can be replaced with low-power cameras or more energy efficient sensors for a particular SLAM implementation. However, when the prototype is moving, the Lidar's share of the power consumption goes down to around 60%. When choosing the Lidar, general purpose motors have been used to show that even with out-of-the-shelf devices, the overall energy efficiency can be improved by around 40% when a single-board computer such as a Raspberry Pi in this test is replaced with a MCU. This yields a significantly longer battery life and an increase in operational performance due to larger ratio of active-time with respect to idle or charging time.

V. DISCUSSION

Although Edge computing can bring advantages such as reduction in latency, bandwidth conservation, improvement in application robustness and security [11], [27], [28], there are inherent challenges. As the processing of the data stays near the Edge, specific data-oriented applications which require comparatively higher user interaction will have insignificant

performance gain. In the worst case scenario, performance can deteriorate due to the long path data has to travel.

As multiple robots can connect to the same smart gateway, communication latency and inter-unit interference can be an issue. Depending on the application, an appropriate communication medium must be chosen to ensure that specific parameters such as bandwidth, channel spacing, protocol, sampling frequency and data rate are properly considered for an interruption-free data transfer. Also, for wireless units, it is useful to examine the wake-up and sleep time of the radio communication module so that transmitter and receiver circuitry is not toggled unnecessarily and sleep modes are used appropriately. This yields better energy efficiency and communication at an optimal duty cycle.

Keeping the Edge gateways near the robot layer and a Fog layer provides distributed and scalable computing. However, as the number of robots and frequency of data transmission per node significantly increases, the gateways may not handle all requests within the highest permitted latency. In such a case, having more powerful and redundant gateways along with advanced load-sharing algorithm in the Fog and distributed data storage can effectively improve performance.

VI. Conclusion and Future Work

In this paper, the comparative advantage of using Edge computing for robots and nodes are discussed keeping the focus on energy efficiency and operational latency. Instead of directly transferring a large amount of data from robots to the Cloud, we proposed an Edge-Fog-Cloud based system for performance advantages. Run from the mains supply, the powerful Edge layer can pre-process and analyze data easily, implement advanced features and ensure data security by applying complex encryption algorithms. The Fog layer can intelligently manage the smart gateways of Edge layer.

This approach effectively takes the heavy computational tasks near the Edge layer and thus reduces the required energy for operation of the node or robot itself. The shorter path of data for a complete cycle improves latency and frees up valuable network bandwidth, especially when a lot of robots are connected to the same gateway. In addition, the reduced robot-to-Cloud transferable data eliminates potential bottleneck in the network and lowers the chance of system downtime due to a single point computing failure as in centralized computing architecture. We demonstrated an example of SLAM showing how a car in the robot layer can take advantage of the power of Edge computing for mapping a confined perimeter.

In future, we plan to implement a comprehensive system consisting of several vehicles, multiple smart Edge computing gateways constituting a Fog layer and an application for the Cloud layer. In addition, we plan to develop an autonomous roaming algorithm for the robot car so as to perform the mapping operation in shortest possible time. Besides, some stress tests to estimate the performance of smart gateways will be evaluated to emulate the scenario when the number of connected cars is sufficiently high.

***Abstract*— In recent times, soft robot has become an unconventional field of research in robotics. In comparison to classic robotics, soft robot shows an excellent adaptability in nature, surveillance with more pliability and of course a simpler structure. In this paper, a new approach for ferrofluid based soft actuator which shows various vertical motions when varying magnetic field is applied, has been introduced for the first time. Finite element method is used here to model different motions of the ferrofluid tube together with field, force and stress analysis. Eventually this simulation approach gave us values of the force exerted on the tube, the magnetic stream lines, direction of the flux, force direction and also the displacement of the tube when introduced to varying magnetic field.**

Keywords— ***ferrofluid, soft actuator, magnetic field, vertical deflection, finite element modelling***

I. INTRODUCTION

Harsh and extreme environments, on different locations in the universe, are a combination of fluctuating pressure, temperature and harmful radiation. Therefore more complex yet intelligent robotic devices are in need to be established which withstand these unfavorable conditions [1]. Introducing soft and flexible robots can be advantageous in many applications as they can pass though small tunnels, bear extreme conditions and interact with human. Meeting these conditions with soft robots can make a crisis free future with easy problem solving ability. As nature has always been an inspiration in the field of research with soft robots, starting from designing, fabricating and controlling the structure have grasped recent attentions of researchers from different field of studies, such as chemistry [2], physics [3], biology [4], and robotics [5][6]. The flexibility and smooth movement of robots is possible now due to the invention of soft materials. This simple yet flexible movement of soft robots has reduced the need for hard robots and of course lowers complexity of the system itself with less budget [7].

In comparison to classic form of robotics, fluid based soft robots are more advance in form of adaptability, flexibility and sovereignty [8]. A pneumatic fiber-reinforced actuator where the air pressure and external fiber arrangement replicated complex motions of the index and thumb of a human being [9], a soft anthropomorphic finger made with a low cost soft hyperplastic material were some of the recent breakthroughs in the world of robotics [10].

Beside those pneumatic actuators, some researchers used smart material like ferrofluid to make soft robots. Ferrofluid is a colloidal fluids which is composed of nano-sized ferromagnetic particles, made of magnetite ($Fe3O_4$) or hematite (Fe_2O_3) that are called ferromagnetic particles. It is a kind of smart fluid that flows to the direction of magnetic flux density therefore can be easily manipulated by applying magnetic field. A pumping device made with ferrofluid which changes its directions according to the change in magnetic fields has been developed in the year 2012, using permanent magnet [11], altering its own shape and position according to varying magnetic strength [12]. Also in 2013, performance of a solenoid type electromagnetic actuator with nano-ferrofluid was investigated and analyzed [13].The air gap of the actuator was filled with ferrofluid and was considered as a magnetic gap. A more improved version of it was designed later in the year 2014, for low energy consumption which caused the electromagnetic force increased up to 62% [14].

In addition, imitation of biology systems with soft robot has increased the softness of the robots and added more degree of freedom than rigid robots. In 2015, a soft robot with ferrofluid that resembles *Amoeba* like movements controlled by electromagnets was introduced. [15]. Ferrofluid actuation using both permanent and electromagnet is being used in energy harvesting system where an electromagnetic force is induced due to the movement of ferrofluid inside the device [16] and also in efficient levitation method [17],[18], [19]. Moreover, ferrofluid has also been used in smart drug delivery systems [20].

This paper presents the simulation technique used to evaluate the magnetic force and the displacement of the ferrofluid tube when varying magnetic field is applied on it by different coil placements. A thin rubber tube is filled with adequate amount of ferrofluid and introduced to tiny electromagnets with varying input voltage. The input voltage and the coil position is changed in such a way to create

various vertical movement pattern of the tube showing the degree of flexibility of the tube. Finite element modelling method is used for the magnetic field and solid mechanics simulation purpose. Simulation showed the values of the force exerted by the coils on the tube, the magnetic stream lines, direction of the flux, force direction and also the displacement of the tube when it was introduced by magnetic field produced in the coils. Recently in the year 2018, similar approach have been reported with ability to calculate reasonable velocity fields, forces, and temperature profiles of a ferrofluid-based passive cooling system [22].

II. METHEDOLOGY

The simulation procedure involves three stages: processing stage, solving stage and lastly the post-processing or result stage. In the processing stage, the fundamentals of the model are defined, that includes structural modelling, selection of materials and the meshing criteria. The solving stage includes two solver modules, magnetic field and solid mechanics which solves the model with related mathematical equations and appropriate study type (in this case, stationary study has been chosen). Finally after solving the model, the simulation shows the direction of the magnetic field lines, direction and values of the electromagnetic forces and the structural bending of the tube along with the displacement values. The flowchart showing the procedure involved in each of the stages is shown in Fig. 1.

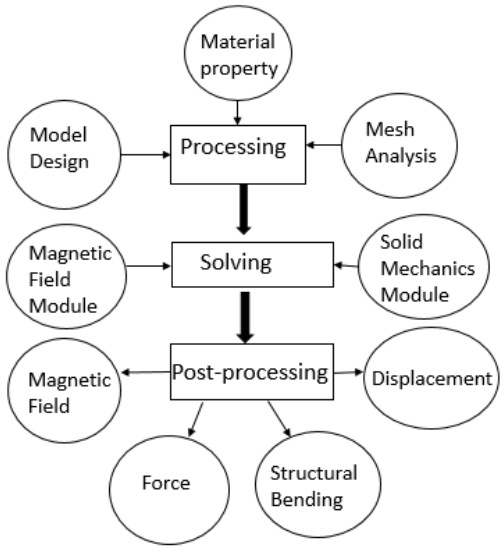

Fig. 1. FEM procedures involved in the simulation

III. MODEL DESIGN

A. *Flexible Tube*

A rubber tube of the height 13 cm and radius 0.7 cm has been considered for this study. The tube is filled with the ferrofluid which is a stable colloidal suspension of single-domain magnetic nanoparticles considering a relative permeability of 1.05, relative permittivity of 1, density of 1210 kg/m^3, Young's modulus of 0.05 GPa and 0.49 of Poisson's ratio.

B. *Electromagnet*

Standard Wire Gauge (SWG) 26 of 0.46mm diameter has been used as winding of the ferrite core (Ferrite F 3000 mu). The ferrite core is winded with 400 turns of wire to give the optimal force needed to create the required motion of the tube. The dimension of the electromagnet and the tube used are shown in Table I.

TABLE I. GEOMETRICAL SPECIFICATIONS OF THE ELECTROMAGNET AND THE RUBBER TUBE USED IN THE STUDY.

Geometrical parameter	**Length (cm)**
Diameter of Ferrite Core	0.4
Diameter of electromagnet	2.3
Height of electromagnet	2
Height of Ferrite Core	2
Height of tube	13
Inner diameter of tube	0.6
Outer diameter of tube	0.7

Three model designs built are shown in Fig. 2. Three different placement of coils, each with 2 cm gap between the opposite coils are used to show 7 different movement patterns of the ferrofluid tube. The coils are placed at different positions along the side of the tube and held in place by two plastic stands. For the first model shown in Fig. 2(a), three coils are placed 4 cm apart from one another, along each side of the stand. All the coils are given equal value of voltage. When one set was on the other set was turned off, so the tube deflected to the side which had the maximum magnetic field. For the second model shown in Fig. 2 (b), same arrangement of coil are used but coil 1 and 3, coil 2 and 4 had 2 cm distance between them. But coil 5 and 6 are 4 cm away from the other two coils in the same column. For the third model shown in Fig. 2 (c), the coils are placed at the three corners. The three coils are kept on, one at a time and the tube showed a three directional movement.

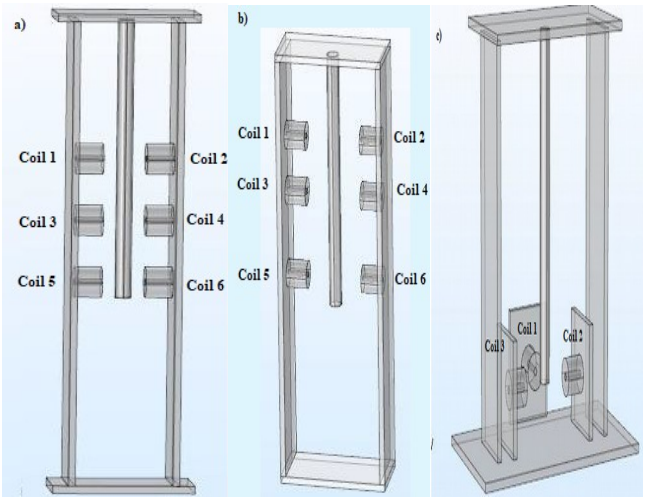

Fig. 2. Three different placement of electromagnet used in the study

IV. MATERIAL PROPERTY

Five important domains are considered in this simulation model. They are: (i) Ferrofluid inside the rubber tube, (ii) Copper for winding the electromagnet, (iii) Ferrite for electromagnet core, (iv)Rubber for the tube and (v) Air in the surrounding space. Individual properties of the materials used are described in the Table II.

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

TABLE II. PROPERTIES OF THE MATERIALS USED IN THE STUDY

Materials	Relative Permeability, μ_r	Relative Permittivity, ε_r	Electrical Conductivity, σ (S/m)
Ferrofluid	1.05	1	0
Copper	0.99	1	5.99×10^{7}
Ferrite	3000	1	1×10^{-12}
Rubber	2.4	7	10×10^{-14}
Air	1	1	3×10^{-15}

V. SOLVER SETTINGS

The model design is solved using (i) Magnetic field and (ii) Solid Mechanics solvers.

A. Magnetic Field Interface

The magnetic field and force are the two factors needed to be considered first in the simulation, therefore the magnetic field module has been chosen. The current direction and the voltage applied to the electromagnet are also specified in this module.

The circular coil type with specific current direction is chosen in the first place for each coil winding. Ampere's law and force calculation interface were the next things added to the module. This module determines the magnetic flux density, magnetic flux lines, magnetic field vector direction and electromagnetic force for the electromagnets. It is concluded that, regardless of the current direction (clockwise or anti clockwise) the direction of magnetic force vectors applied to the tube show the same pattern. This is because the core material of the tube is filled with Ferrofluid, which is composed of "Paramagnetic" nano particles that shifts its polarity according to the magnetic field applied on it. Fig. 3 shows the current and magnetic field directions when clockwise and anti-clockwise current is added to the coils.

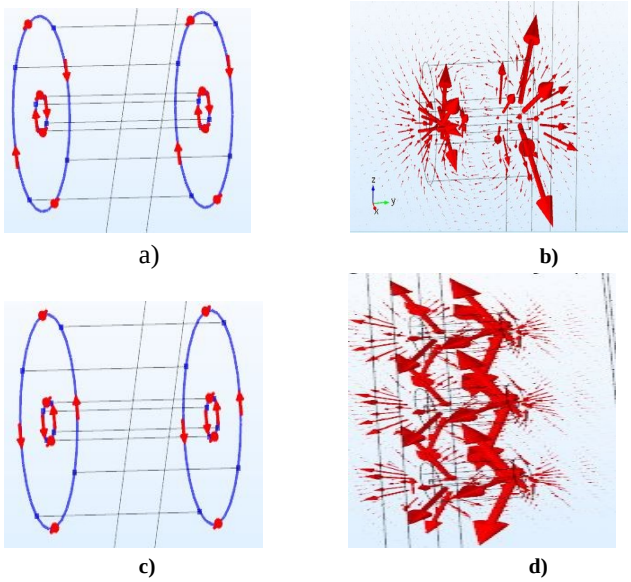

Fig. 3. a) Circular current path inside the electromagnet showing the direction of current flow when clockwise current is supplied across it, b) Directions of the magnetic field line vectors in the electromagnet for the current supply in clockwise direction, c) Circular current path inside the electromagnet showing the direction of current flow when anticlockwise current is supplied across it, d) Direction of the magnetic field line vectors around the electromagnet for the current supply in anticlockwise direction

B. Solid Mechanics Interface

To observe the different bending patterns of the ferrofluidtube this module is used. The fixed region along the tube together with the boundary load are the few parameters that are needed to be considered. The Boundary load used here is the electromagnetic force calculated from the previously discussed magnetic field module.

VI. MESH

One of the essential part of the pre-processing stage is selecting mesh for the model. Here triangular mesh is chosen i.e. the entire model is divided to non-overlapping triangular elements. Selecting mesh is the final stage of pre-processing after the model geometry has been drawn and the materials used is defined. In this design, an optimal physics controlled mesh with normal element size is selected to give a good accuracy of the results with less use of computational memory that in turn takes less processing time for the simulation without compromising the accuracy of the simulation results. The mesh for the model is shown in Fig. 4.

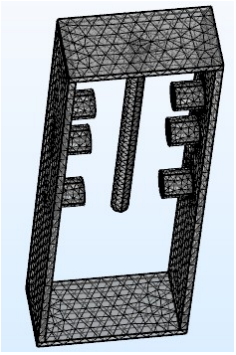

Fig. 4. Model design divided into non-overlapping triangular elements

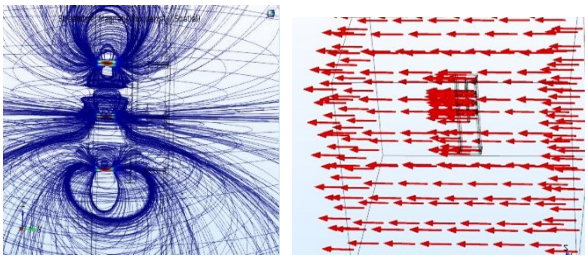
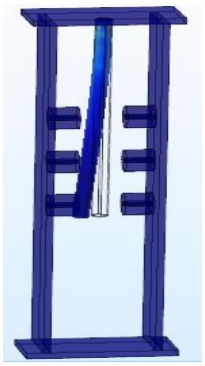


VII. RESULTS AND DISCUSSION

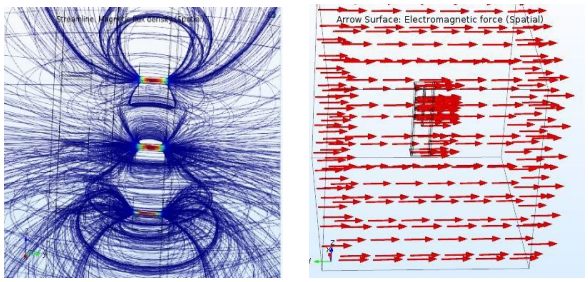
After all the parameters have been set, the simulation is evaluated and the result shows the various motion of the tube according to the magnetic field induced in the coils.



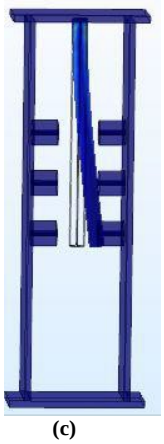
A. Flickering Motion

When the coils placed on the left hand side of the tube are given voltage supply of 9.2V, the tube shows the movement in the direction of the magnetic field introduced i.e. towards the left side. The results for the left flickering motion is shown in Fig. 5. Magnetic flux lines for the arrangement of coils are shown in Fig. 5(a), direction of force on the tube in Fig. 5(b) and finally the left hand flicker of the tube in Fig. 5(c).

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE



a) b)



c)

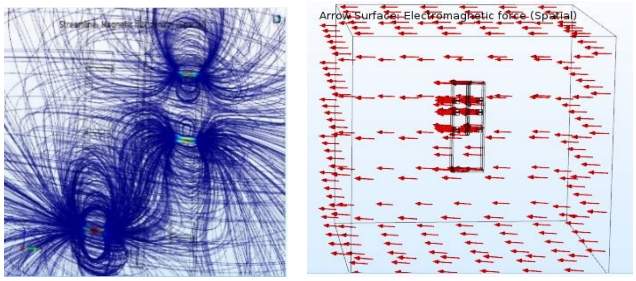
Fig. 5. a) Magnetic flux lines surrounding the three electromagnets in the model design, b) Direction of magnetic force vectors surrounding the model, c) left flickering of ferrofluid tube when voltage supply is given to the left hand coils

The procedure is repeated with the coils on the right hand and the corresponding results are shown in Fig. 6. Magnetic flux lines for the arrangement of coils are shown in Fig. 6(a), direction of force on the tube in Fig. 6(b) and lastly the right hand flicker of the tube in Fig. 6(c).

(a) (b)

(c)

Fig. 6. a) Magnetic flux lines surrounding the three electromagnets in the model design, b) Direction of magnetic force vectors surrounding the model, c) Flickering of ferrofluid tube when voltage supply is given to the right hand coil



The electromagnetic force and the displacement of the tube for the flickering motion are shown in Table III.

TABLE III. ELECTROMAGNETIC FORCE AND DISPLACEMENT FOR FLICKERING MOTION

	Electromagnetic force components (N)			**Resultant Displacement (cm)**
	x	***y***	***z***	
Right flicker	0.29	0.68	-0.21	3.09
Left flicker	0.28	0.63	0.27	3.14

B. Bending Motion

When coil number 2 and 4 are given with 4.2V, whereas Coil number 5 is given 9.2V the tube shows a bending motion towards the left direction. The magnetic flux lines are shown in Fig. 7(a), direction of force on the tube in Fig. 7(b) and finally the left hand bending of the tube in Fig. 7(c).

(a) (b)

(c)

Fig. 7. a) Magnetic flux lines surrounding the three electromagnets in the model design, b) Direction of magnetic force vectors surrounding the model, c) Bending of ferrofluid tube in the left hand side

Alternatively, when coil number 1 and 3 are fed with 4.2V input signal, whereas Coil number 6 is given 9.2V input voltage, the tube shows a bending motion towards the right hand side. The magnetic flux lines surrounding the three electromagnets in the model design are shown in Fig. 8 (a), direction of force on the tube in Fig. 8(b) and finally the right hand bending of the tube in Fig. 8(c).

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

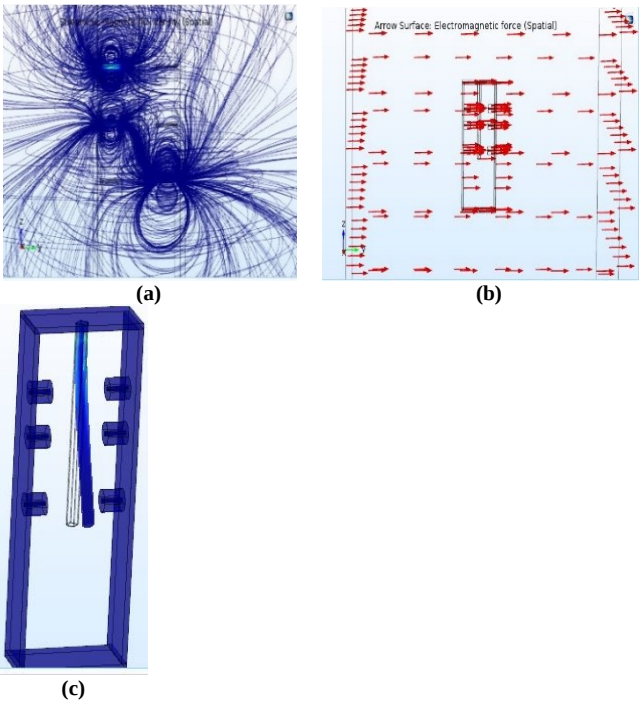


Fig. 8. a) Magnetic flux lines surrounding the three electromagnets in the model design, b) Direction of magnetic force vectors surrounding the model, c) Bending of ferrofluid tube in the right hand side

The numerical value of the electromagnetic force and the displacement of the tube for bending motion, both right and left are shown in Table IV.

TABLE IV. ELECTROMAGNETIC FORCE AND DISPLACEMENT FOR BENDING MOTION

	Electromagnetic force components (N)			**Resultant Displacement (cm)**
	x	***y***	***z***	
Right Bend	0.07	0.02	0.27	1.13
Left Bend	0.03	-2.94	7.37	1.18

C. Three directional movement

For three directional movement of the tube, all the three coils are given the same input voltage of 9.2V but one at a time. It is noticed that the tube moved to the coil which had magnetic field. Figure 9 (a) and (b) show the force direction and deflection of the tube when the coil placed at the middle is given 9.2V. Similarly, when the coil placed on the left side is given with 9.2V, the force and deflection of the tube to the left direction is shown in Fig. 9 (c) and (d). Again, when the coil placed on the right side in given with 9.2 V, It attracts the tube towards it. The force direction and the deflection is shown in the (e) and (f) of Fig. 9 respectively.

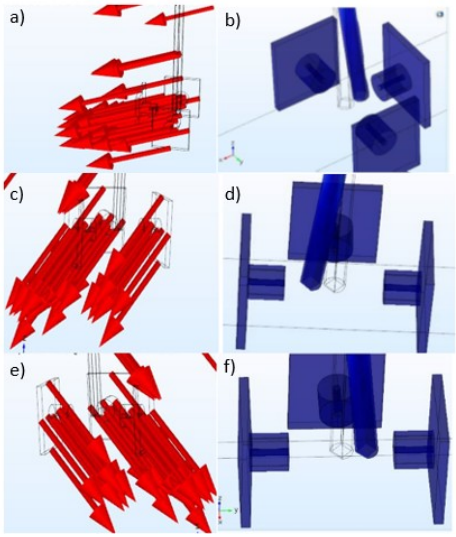

Fig. 9. a) Direction of the magnetic force vectors when middle coil is turned on, b) Position of the tube when coil placed at the middle is turned on, c) Direction of magnetic force vectors when left hand coil is turned on, d) Position of the tube when coil placed on the left side is turned on, e) Direction of the magnetic force vectors when right hand coil is turned on, f) Position of the tube when coil placed on the right hand side is turned onx

The electromagnetic force and the displacement of the tube for three directional movement are shown in Table V.

TABLE V. ELECTROMAGNETIC FORCE AND DISPLACEMENT OF THE TUBE FOR THREE DIRECTIONAL MOVEMENT OF THE TUBE

	Electromagnetic force components (N)			**Resultant Displacement (cm)**
	x	***y***	***z***	
Right Position	-0.04	-1.49	-0.38	1.18
Left Position	-0.05	1.49	-0.22	1.18
Back Position	-1.46	-0.06	0.49	1.18

VIII. CONCLUSION

Ferrofluid is widely used in many applications, starting from frictionless seals to maintain a vacuum while still allowing for moving or rotating parts. But using voltage control of electromagnet to control the vertical movement of the ferrofluid tube is completely a new approach. In this paper the simulation approach was able to calculate the electromagnetic forces and the displacement of the tube for the corresponding forces together with the various motion of the tube. This approach shows the flexibility of the ferrofluid tube when controlled magnetic field is applied to it from different directions. The simulation results obtained from this study will help refinement of a practical model and optimization of the parameters needed for building a prototype.

VIII. FUTURE WORK

From the results of this simulation approach, a practical implementation of the ferrofluid soft actuator can be built in near future that will have various medical applications as well as can be considered as soft robotic finger that has more degree of freedom and flexibility to handle tasks that rigid robots may unable to perform.

***Abstract*—A ferrrofluid based soft actuator which shows various vertical motions has been introduced for the first time in this paper. The flexibility as well as the potential of the prototype designed, is tested in this study. The soft actuator used here is made by injecting ferrofluid inside a soft and thin rubber tube. The system also consists of some electromagnets placed at different positions along the side of the tube, whose magnetic field intensity is controlled by changing the duty cycle of the input voltage supplied to the electromagnets. The position of the coils as well as the input voltage are varied during the experiment which created various vertical motions of the ferrofluid tube. The simple design of the prototype described in this paper made this system more cost effective and easy to configure.**

Keywords—soft actuator, ferrofluid, electromagnet, voltage control

I. INTRODUCTION

Soft robots have shown its astounding motion through its various pattern of movements including stretching, twisting, bending and expanding in the multifarious environment. In comparison to the widely known rigid robots, soft robot has shown a remarkable adaptation to the surrounding environment together with more flexibility and can be readily made [1]. As a result of their flexible nature, soft robots can easily alter its shape when subjected to an outside force but of course assuring the safety of itself and the user [2]. Often, soft robots have one or more flexible parts that take on the vital part of the robot and deform actively or passively under external pressure or force to acquire the desired movements [3].

Soft and flexible materials with which some of these robots are made are called smart materials commonly called Shape Memory Alloy (SMA) or material made of wax and foam [4] [5]. In 2015, a bioinspired Octopus has been created with SMA [6]. In the year 2016, two major innovations on artificial soft finger have been sited, one is a pneumatic fiber-reinforced actuator where the air pressure and external fiber arrangement replicated complex motions of the index and thumb of a human being [7], another is a soft anthropomorphic finger made with a low cost soft hyperplastic material which made a breakthrough in the world of robotics [8].

Beside these approaches, magnetic method of actuation where found to be more effective and shows noticeable movements keeping the softness of the structure unaffected. Therefore a combination of magnetism together with soft materials can create an effective system that can undergo remote as well as harsh environment [3].

A magnetic fluid named as ferrofluid is used as the main structural element for the soft robot developed in this study. Ferrofluid falls in the category of smart material that contains magnetite particles suspended in a liquid or oil and can be magnetized in presence of any magnetic field around it [9]. When a magnetic field is applied to this smart fluid, the nano particles in the fluid together with the carrier fluid accumulate towards the area that has exposed to the strongest magnetic field, this is because the gathered layer of the ferrofluid experience an external pressure caused by the generated magnetic field around it [10]. This concept is used by the researchers in developing ferrofluid based soft robots. Previously, ferrofluid has been injected inside a polymeric soft ball to make a soft ball which could pass through various obstacles and change shape accordingly [11]. A pumping devices made with ferrofluid which changed its directions according to the change in magnetic field has also been developed using permanent magnet [12]. Moreover, controlling this magnetic property of the magnet together with the movement of the fluid, researchers could successfully make the robot transport things placed on the surface of a sheet from one place to the other [13]. In 2015,

XXX-X-XXXX-XXXX-X/XX/$XX.00 ©20XX IEEE

a system using magnetic material to control the drug delivered to the human body made the use of these magnetic material more pronounced [14]. A microcontroller together with a L298N motor driver were used to control the motors placed on each side of the patient. Basics C programmed algorithm was constructed to control the magnet in the desired path so that the drug reaches the accurate disease area. Moreover, Ferrofluid assisted levitation mechanism [10] and the levitating nonmagnetic disc inside ferrofluid [15] are some major applications of ferrofluid during the last decades.

However, most of the studies that includes ferrofluid as the core material, either used permanent magnet [11, 12, 14, 16, 17] or both permanent and electromagnet [9, 10, 15] to move the fluid from one point to the other or moving the object containing the fluid forward and backward in horizontal direction. A very few research has been done on vertical deflection of ferrofluid by varying magnetic field strength of electromagnet. Therefore, the aim of this thesis is to make a ferrofluid based soft actuator that uses the concept of magnetism in creating vertical movements of a tube that is filled with ferrofluid.

In this study, a soft and flexible rubber tube of about 13 cm was filled with ferrofluid and subjected to a varying magnetic field. The magnetic field was created by the electromagnets kept at about 2 cm distance apart from the tube. As the magnetic field strength of the electromagnets are varied the tube shows different movement patterns in the vertical position. The electromagnets are controlled by a microcontroller module (Arduino Mega) together with a L298N motor driver that supplied the voltage to drive the electromagnets. A basics C programmed algorithm are also constructed to control the voltage supplied to the electromagnets so that the tube moves in the desired direction.

II. DESIGN& FABRICATION

A. *Thin Rubber Tube*

While designing the prototype the first thing that was taken into consideration was the ability of the robot to deform or change its shape like liquid, which leads to a noticeable softness and flexibility of the structure, when controlled magnetic force is applied to it. On the other hand, it will be undesirable if the robot when losing its control, sheds into droplets like liquid. Therefore, considering all the necessary conditions ferrofluid has been chosen as the core material of the robot as it can be controlled by external magnetic force and at the same time can attain the liquid characteristics. So, taking all the necessary requirements into consideration, the prototype has been designed. The shell of robot is made of the commonly known polymeric rubber which is mostly used in toy balloons. A rubber tube of 13 cm height, 0.6 cm inner and 0.7 cm outer radius is filled with the chosen ferrofluid which is stable colloidal suspensions of single-domain magnetic nanoparticles in 55-91% of distillate. The nanoparticles in ferrofluid used here are usually 3-5% of Magnetite (Fe_3O_4) particles, suspended in Petroleum as distillate.

B. *Electromagnet*

In order to make the tiny electromagnets of desired number of turns, Standard Wire Gauge (SWG 26) of 0.46mm diameter has been used in winding the ferrite core. The specification of wire and ferrite are shown in Table I. The ferrite was winded with 400 turns to give the optimal magnetic force needed to create the required motion of the tube.

The appearance of the electromagnet together with the flexible ferrofluid tube used in this study is shown in Fig. 1.

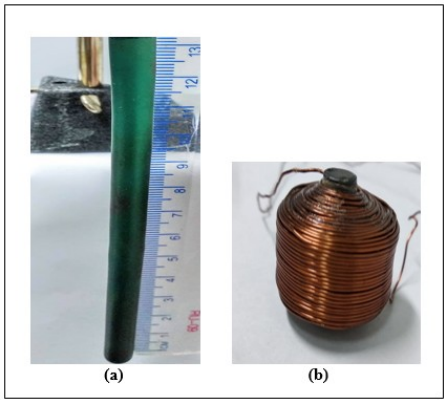

Fig. 1. a)The initial shape and dimension of the flexible tube, b) Electromagnet used in the model design

TABLE I. SPECIFICATIONS OF THE ELECTROMAGNET USED IN THE EXPERIMENT

Geometrical parameters	**Length (cm)**
Core material of electromagnet	Ferrite F 3000 mu
Height of the core in the electromagnet	2
Diameter of the core in the electromagnet	0.4
Diameter of electromagnet	2.3
Height of electromagnet	2

III. MODEL DESIGN

Three different models were designed for seven different movement patterns. The arrangement of the coils along with the input voltage are varied in such a way to give different motions to the ferrofluid tube.

A. *Placement of Electromagnets for Vertical Deflection Pattern*

Three electromagnets where placed on each side of the two stands placed on opposite of each other. The electromagnets are placed with 2 cm gap between the opposite one, keeping 4 cm gap between each consecutive electromagnets placed in the same column. The arrangement of the electromagnets are shown in Fig. 2.

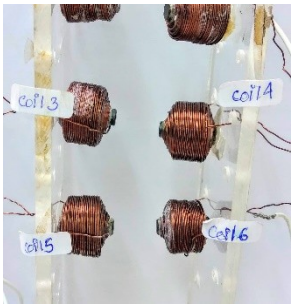

Fig. 2. Placement of electromagnet for the vertical deflection pattern of the tube

B. *Placement of Electromagnets for Bending Pattern*

The same arrangement of coil as that used for the deflection pattern is used here but coil 1, 3 and 2, 4 have 2 cm distance between them. But coil 5 and 6 are placed 4 cm away from the other two coils of the same column.

C. *Placement of Electromagnets for three directional movement*

For the three directional motion, three coils of the same number of turns as before are placed at the three corners of the ferrofluid tube and about 2 cm away from each other. Shown in Fig. 3.

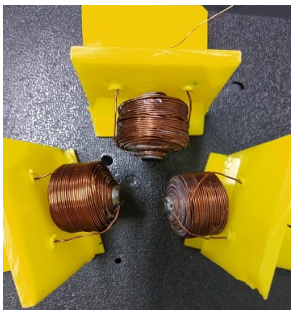

Fig. 3. Placement of electromagnet for the three directional movement pattern

IV. VOLTAGE CONTROLLER

The arrangement of coils are connected to a voltage controller circuit that includes three L298N motor drivers which is connected to an Arduino Mega microcontroller. The voltage of each coil are varied by varying Pulse Width Modulation (PWM) of the input signal which correspondingly causes different motions of the tube containing the ferrofluid. The arrangement of the circuit and the connection diagram are shown in Fig. 4.

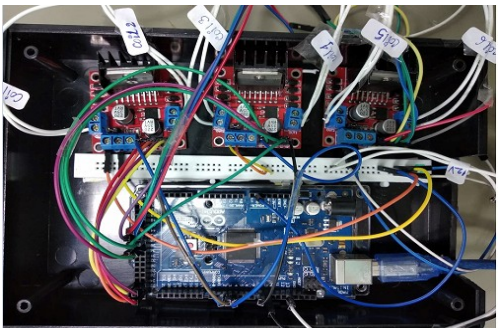

Fig. 4. Circuit design for Voltage control

The duty cycle of the input PWM signal for each of the electromagnet are varried in such a way that gives a controlled automatic movement of the soft tube containing the ferrofluid. The Logic control used to achieve the desirable movement of the tube in various direction is potraied in Fig. 5.

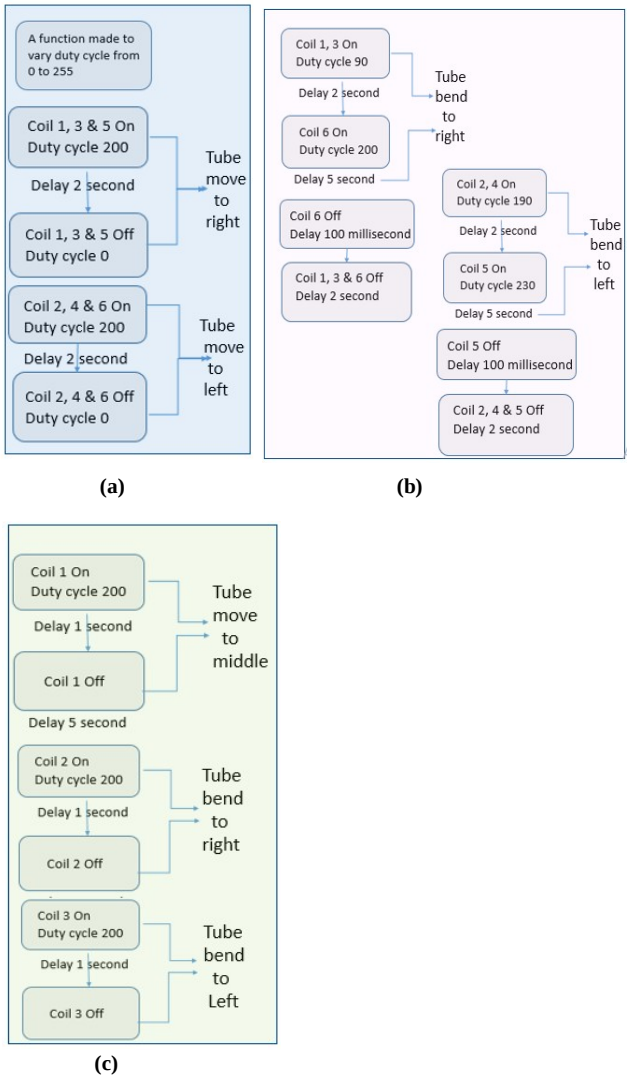

Fig. 5. Flow chart showing each steps used in the logic control of voltage used in the microcontroller

V. EXPERIMENT AND DISCUSSION

This section will investigate the performance of the ferrofluid tube when varied magnetic field is applied to it.

A. *Vertical Deflection*

When 78% duty cycle of PWM signal i.e. is 9 V of supply is given to Coil 2, Coil 4 and Coil 6 the tube showed a vertical motion on the right hand side towards the direction of the magnetized coils, shown in Fig. 6(a). When the same supply is given to all the electromagnets placed on the left hand side of the tube, i.e. to Coil 1, Coil 3 and Coil 5, the tube shows a vertical deflection but now to the left hand side, towards the magnetized coils which is shown in Fig. 6(b). The same procedure is repeated but with varying the amplitude of the PWM signal from a maximum value to zero, the tube shows the same motion but with more smooth movement but shows a longer reaction time. The displacement of the tube from its original direction are measured approximately to be 1cm toward each direction.

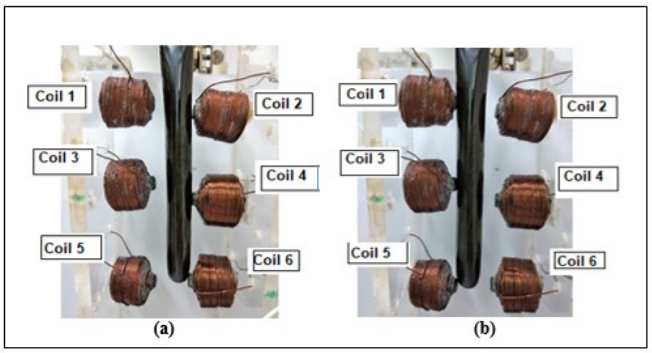

Fig. 6. Vertical deflection of the tube containing ferrofluid

B. *Bending motion*

When coil 2 and coil 4 are fed with 4.2V i.e. 35% of duty cycle of PWM signal, whereas Coil 5 are given 78% (9V) duty signal, the tube shows a bending motion towards left hand side shown in Fig. 7(a). Alternatively, when coil 1 and coil 3 are given 4.2V i.e. 35% of duty cycle of PWM signal, whereas Coil 6 is given 78% (9V) duty signal, the tube bend towards the right hand side shown in Fig. 7(b) The tip of the tube shows a displacement of approximately 1 cm from its original position towards the magnetized coils.

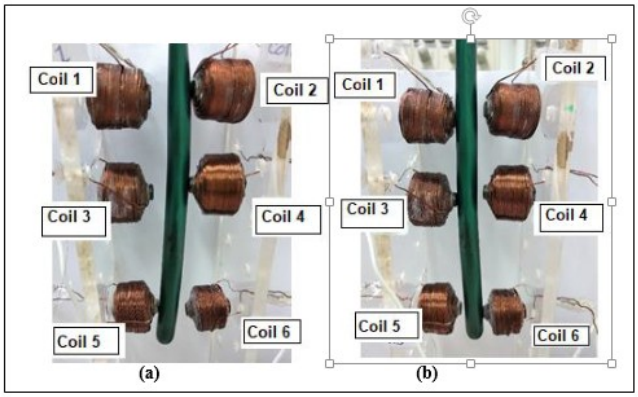

Fig. 7. Bending of the flexible tube in both direction

C. *Three directional motion*

When all three coils placed on the three corners of the tube are given an input voltage of 9.2V i.e. 78% duty cycle but one at a time, the tube shows movement to the direction of the electromagnet which is magnetized. The Fig. 8 shows the three different movement pattern of the tube.

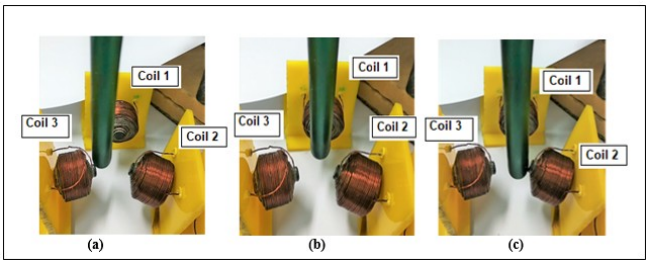

Fig. 8. Three directional movement of the flexible tube

VI. CONCLUSION

This concept of a ferrofluid soft actuator showing vertical motions is a new approach in the field of soft robotics. The simplicity of the design make the system more cost effective and readily made. The fabrication of the system is easy and the ability of the robot showing various vertical motions is fantastic. The different experiments performed in this study shows that intensity of the magnetic field greatly affects the shape of this soft robot and the deforming characteristics of the tubing material determines its flexibility. Therefore, it can be concluded that the magnetic field intensity together with the flexibility of the structure itself contributes in the moving capability of the ferrofluid tube.

This prototype is an initial proof of concept that ferrofluid can show vertical motions when controlled by small electromagnets. It has been created for the future design of a soft finger by using ferrofluid as the core material. In this initial stage, the tube is not much rigid to resemble a soft finger which could grab or even apply force to objects; but it shows some waving and bending motions which is indeed a major contribution to the design of the future soft finger.

VII. FUTURE WORK

This paper mainly focuses on the realizability of a prototype of ferrofluid based soft actuator and its performance with varying magnetic field. For future investigational approach, the ferrofluid used in this study can be combined with a liquid monomer and form into a polymer with magnetic properties (for example, magnetic rubber/plastic) or can be incorporated with a non-toxic polymer, Polydimethylsiloxane (PDMS), commonly known as dimethylpolysiloxane or dimethicone. This incorporation will make the structure more rigid and flexible with more degrees of freedom. In case of soft robots or actuators, the flexibility and rigidness of the structure (PDMS embedded with the ferromagnetic particle) can create a wide range of motions and bending when a externally controlled magnetic field is applied, which can lead even to a soft robotic hand.

ACKNOWLEDGMENT

The authors would like to show their gratefulness to Asian Institute of Technology for providing their support to perform the experiments needed for this study.

***Abstract*—The objective of the research is a stable gait generation on the level ground and some sloping ground of the 3-link biped robot with unbalanced masses using one actuator. We know the biped robot need actuator for stable walking on level ground. A biped robot with a torso model at least two actuators to achieve a stable walk. In the research we have investigated the only one motor which is very much challenging to achieve stable walking gait without the robot falls down, also there is used unbalanced masses where is very much difficult to achieve balanced walking. In this research, the numerical simulations show the robot with unbalanced masses can walk efficiently on level ground by only using one actuator. The robot can generate 2-period and 4-period gait without fall down. First, we introduced the 5-DOF (Degree of freedom) unbalanced masses model where used one actuator that walks the level ground. Second, describes the control system of Proportional-derivative (PD) controller between stance leg and torso, while the swing leg does not use any actuator and it does remain free. Third, we perform numerical simulations and show that the robot can generate a stable walk on level ground and some sloping ground by using one actuator. Furthermore, we conduct some parametric study to investigate the more natural human-like motion of the robot and achieved different results.**

***Index Terms*—Unbalanced masses, bipedal robot, one actuator, underactuated.**

I. Introduction

Since several years ago, humans have tried to make robots similar to humans. To build a humanoid robot is not an easy task due to the complexity in the design and control. Recent research has been shown that the human and animals structure is the best option to use for legged robots [1]. There is a tendency in mobile robotics to develop robots transported by legs; an advantage of using them is that legged robots may easily move in places designed for humans and it is better than wheeled robots. In this paper, we consider the unbalanced masses upper body biped robot which could better be understanding the biped locomotion in both human and robot. In 1989, McGeer started systematic research into "Passive dynamics walking mechanism", which walks down a shallow slope and need no motors and no control [2]. This research is very much inspired by walking the robotic field. The planer biped robot with torso can walk efficiently on level ground over a wide range of speed by only using hip actuators [3]. The rolling model was developed for semi-circular feet with hip and leg masses [4]. Narukawa [3] shows that swing leg control to enable the robot to walk on level ground. Furthermore, the biped robot also assists in the development of new rehabilitation devices with some control input. The energy efficiency is very much necessary for the biped robot. However, energy efficiency is a problem for many biped robots [5]. Besides the torso control; we investigate the change of parameters value and achieved different types of output through numerical simulation. Besides the torso control, Hobbelen [6] also used ankle control to allow the biped robot on level ground. The underactuated robot with the torso model can achieve stable gait on the slippery road surface [7]. Harata studied two asymmetric models in 2013. This model introduced a wheel without frame and the last model was a compass-like model with a curved tip. He showed the effect of asymmetries efficiency and energy consumption [8].

In this paper, we have developed a simple control strategy for an underactuated biped robot with unbalanced masses. In this technique, there is used only one PD controller which worked between the torso and stance leg, that time while the swing leg remains totally free. This controller utilizes both the torso different state states such as angle, angular velocity)and those of the stance leg. The numerical simulations display that, by applying this controller, a biped robot is able to walk stably on level ground and also slope ground. Thereafter, we searched for the differently desired angle and get the different types of result with suitable control parameters.

II. Mathematical Model of the Underactuated Bipedal Robot with Unbalanced Masses

A. Modeling of the robot

Fig.1 demonstrates the model of underactuated planar 5-DOF biped unbalanced masses robot with a humanoid torso body link. This is a straight vertical connection whose center of mass is arranged at the hip joint as appeared in Fig 1. Motion

is obliged to the sagittal plane, is made out of two identical rigid legs. The robot strolls on level ground by the symmetric walking approach. The two legs are associated deliberately to the hip joint. The model of the robot walks on level ground with unbalanced masses. Here, (x, z) is the end position of the stance leg θ_1 is the angle of the stance leg, θ_2 is the angle of the thigh of the swing leg and θ_3 is the angle of the torso. There are two legs different masses m_1 [kg] and m_2 [kg] and m_H [kg], m_t [kg] is the mass of position leg, swing leg and hip joint, torso individually. L is the complete length of every leg where $L = (a + b)$ [m], torso length L_t and g $[m/s^2]$ is the increasing speed because of gravity. The robot can walk on level ground since it utilized one actuator. Fig. 2 demonstrates the control model of the biped robot. We expect that this model can apply one torque u which is connected between the torso and stance leg.

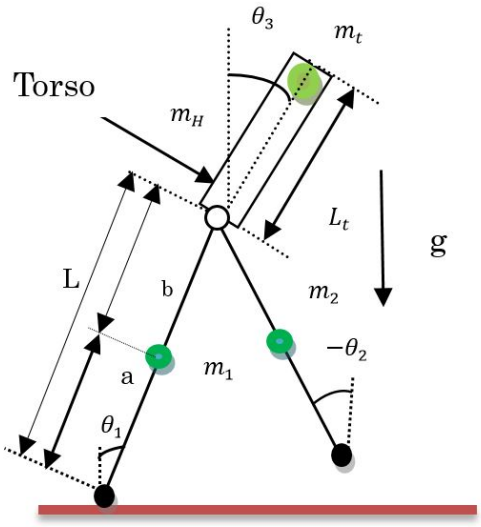

Fig. 1. Underactuated biped robot with unbalanced masses

B. Equations of motion

We pick two legs angles θ_1 and θ_2 which the two angles are appreciation to vertical to the dimension ground. Here, θ_H = θ_1 - θ_2 is the relative hip joint point, θ_3 is the vertical angle with torso. It is important to observe that unbalanced masses requires two individual equation of motions, one for walking around left stance leg and other walking around right stance leg. Walk lopsided of each improvement make unmistakable bearings, and two conditions developments have handled this issue. We choose the stance leg introductory advance as the left leg, which transforms into the swing leg of the second step and other is the right stance leg. The distinction in different masses between two legs have then again happened.

Let $q = \begin{bmatrix} x & z & \theta_1 & \theta_2 & \theta_3 \end{bmatrix}^T$ be the generalized coordinate vector. Where we can see there are 5-DOF of the robot.

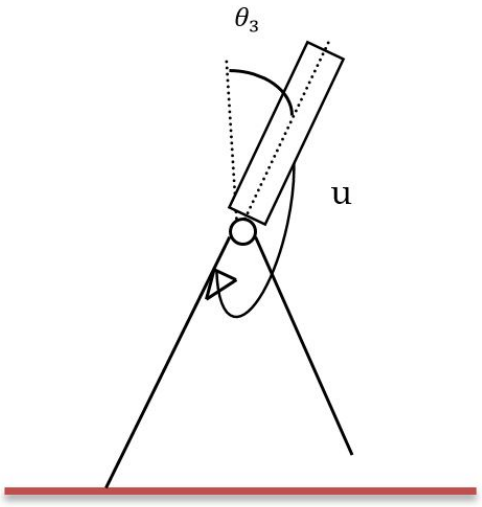

Fig. 2. Control model of the robot

The equations of motion can be derived using the Lagrangian dynamics. The underactuated biped robot with unbalanced masses equation of motion then becomes

$$\boldsymbol{M}(\boldsymbol{q})\ddot{\boldsymbol{q}} + \boldsymbol{h}(\boldsymbol{q}, \dot{\boldsymbol{q}}) = \boldsymbol{S}\boldsymbol{u} + \boldsymbol{J}^{\mathrm{T}}\boldsymbol{\lambda} \tag{1}$$

where left side indicated that $\boldsymbol{M}(\boldsymbol{q})$ is 5x5 inertia matrix, $\boldsymbol{h}(\boldsymbol{q}, \dot{\boldsymbol{q}})$ is the centrifugal matrix and gravitational force. The right hand side indicated that Su is control input vector. $\boldsymbol{J}\epsilon R^{2\mathrm{x}5}$ is a Jacobian matrix and $\boldsymbol{\lambda}$ is ground reaction force.

The details of the left-hand side for left stance leg are as follows.

$$\boldsymbol{M}_L(q) = \begin{bmatrix} M_{11} & 0 & M_{13} & M_{14} & M_{15} \\ 0 & M_{22} & M_{23} & M_{24} & M_{25} \\ M_{31} & M_{32} & M_{33} & M_{34} & 0 \\ M_{41} & M_{42} & M_{43} & 0 & M_{45} \\ M_{51} & M_{52} & M_{53} & 0 & M_{55} \end{bmatrix},$$

$$\boldsymbol{h}_L(q, \dot{q}) = \begin{bmatrix} h_{11} \\ h_{21} \\ h_{31} \\ h_{41} \\ h_{51} \end{bmatrix}, S = \begin{bmatrix} 0 \\ 0 \\ -1 \\ 0 \\ 1 \end{bmatrix}$$

,

$$M_{11} = m_1 + m_2 + m_b + m_h,$$
$$M_{13} = M_{31} = (am_1 + L(m_2 + m_h + m_b))cos\theta_1,$$
$$M_{14} = M_{41} = -bm_2cos\theta_2,$$
$$M_{15} = L_h m_b cos\theta_3,$$
$$M_{22} = m_1 + m_2 + m_b + m_h,$$
$$M_{23} = M_{32} = -(am_1 + L(m_2 + m_h + m_b))sin\theta_1,$$
$$M_{24} = M_{42} = bm_2 sin\theta_2,$$
$$M_{25} = -L_h m_b sin\theta_3,$$
$$M_{33} = a^2 m_1 + L^2(m_2 + m_h + m_b),$$
$$M_{34} = M_{43} = -bLm_2 cos(\theta_1 - \theta_2),$$
$$M_{35} = LL_h m_b cos(\theta_1 - \theta_3),$$

$$M_{45} = L_h^2 m_b,$$
$$h_{11} = -\dot{\theta_1}^2(am_1 + L(m_2 + m_h + m_b)sin\theta_1 + b\dot{\theta_2}^2 m_2 sin\theta_2 - b\dot{\theta_2}^2 m_2 sin\theta_2,$$
$$h_{21} = 4g(m_1 + m_2 + m_h) - \dot{\theta_1}^2(am_1 + L(m_2 + m_h)cos\theta_1 + d\dot{\theta_3}^2 L_b m_b cos\theta_3,$$
$$h_{31} = -g(am_1 + L(m_2 + m_b + m_h))sin\theta_1 - b\dot{\theta_2}^2 Lm_2 sin(\theta_1 - \theta_2),$$
$$h_{41} = bm_2\dot{\theta_1}^2 Lsin(\theta_1 - \theta_2) + gsin\theta_2,$$
$$h_{51} = -L_h m_b \dot{\theta_1}^2 Lsin(\theta_1 - \theta_3) + gsin\theta_3.$$

The other dynamic equation with right stance leg can be solved in a similar way

The velocity constraint condition for stance leg end is given by

$$\dot{x} = 0, \dot{z} = 0. \tag{2}$$

The Jacobian matrix $J \in \Re^{2\times 5}$ in Eq. (1) then becomes

$$J = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \end{bmatrix} \tag{3}$$

J is the constant vector and $J\ddot{q}$ = 0 holds. The Lagrange undetermined multiplier $\lambda \in R$ Eq. (1) can be solved as

$$\lambda = (JM^{-1}J^T)^{-1}(JM^{-1}(h - Su)) \tag{4}$$

C. Combined hybrid system

The hybrid system used when the two legs masses are different In this system consists one walking steps has two phases: a continuous phase and a discontinuous impact phase. In these walking, there are two different phases: a continuous swing and a separated collision phase. This type of system called a combined hybrid system. The two separate impact or collision equations necessary because of the two different masses in the two legs. The robot can continue walking in trajectories and its flows Combined hybrid dynamic system.

D. Impact or collision equation

The inelastic impact or collision equation with left stance leg described by

$$M(q)\dot{q}^+ = M(q)\dot{q}^- + J_I(q)^T\lambda_I \tag{5}$$

$$J_I(q)\dot{q}^+ = 0_{2\times 1} \tag{6}$$

Where $J_I(q) \in \Re^{2\times 5}$ is the Jacobian matrix determined by the horonomic constraint condition immediately after impact and λ_I is the Lagrange undetermined multiplayer vector that describe the impulse.

Let $(\bar{x}, \bar{z})$ the end position of swing leg.

Then we can $(\bar{x}, \bar{z})$ specify by

$$\begin{bmatrix} \bar{x} \\ \bar{z} \end{bmatrix} = \begin{bmatrix} x + Lsin\theta_1 - Lsin\theta_2 \\ z + Lcos\theta_1 - Lcos\theta_2 \end{bmatrix} \tag{7}$$

After Eq. (7) time derivative then becomes

$$= \begin{bmatrix} \dot{x} + L\dot{\theta}_1 cos\theta_1 - L\dot{\theta}_2 cos\theta_2 \\ \dot{z} - L\dot{\theta}_1 sin\theta_1 + L\dot{\theta}_2 sin\theta_2 \end{bmatrix} \tag{8}$$

Rearranged the Eq. (8) then the Jacobian matrix becomes

$$J_I(q) = \begin{bmatrix} 1 & 0 & Lcos\theta_1 & -Lcos\theta_2 & 0 \\ 0 & 1 & -Lsin\theta_1 & Lsin\theta_2 & 0 \end{bmatrix} \tag{9}$$

The Lagrange multiplyer $\lambda_I \in \mathbb{R}^2$ after solve the Eqs. (5) and (6)

$$\boldsymbol{\lambda}_I = -\boldsymbol{X}_I(\boldsymbol{q})^{-1}\boldsymbol{J}_I(\boldsymbol{q})\dot{\boldsymbol{q}}^- \tag{10}$$

Where

$$X_I(q) := J_I(q)M(q)^{-1}J_I(q)^T \tag{11}$$

. By putting the Eq. (11) into Eq. (5), we get

$$\dot{q}^+ = (I_5 - M(q)^{-1}J_I(q)^T X_I(q)^{-1}J_I(q))\dot{q}^- \tag{12}$$

where $\dot{q}^+$ means velocity vector immediately after impact or collision.

We can solve another impact or collision equation with right stance leg by a similar procedure.

III. Control system

In the robot model, the torso as like an inverted pendulum, which is stabilized is needed for stable walking motion. In this research, a PD controller is used for stable gait generation of the robot where using only one actuated.

The legs are assumed to keep the vertical which follow the condition θ_1=θ_2=0 and $\dot{\theta}_1$=$\dot{\theta}_2$=0. With the controller mentioned the above equation for the torso, θ_3=0, θ_d=0

The control input system developed by following PD controller,

$$u = K_p(\theta_d - (\theta_3 - \theta_1)) - K_d(\dot{\theta}_3) - (\dot{\theta}_1)) \tag{13}$$

Where θ_d is desired angle, K_p and K_d are proportional and derivative gain. u is the torque applied between the torso and stance leg. This controller behaves as like damped spring which is acting against the stance leg. Fig. 3 shows the control system of the underactuated biped robot where using only one actuator.

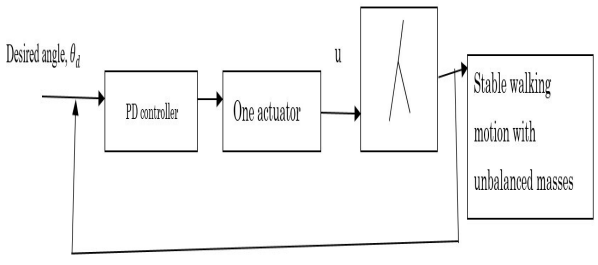

Fig. 3. Control system diagram for the biped robot

IV. Simulation Results

A. Typical walking gait of biped robot with unbalanced masses

The underactuated biped robot with unbalanced can be walking started from the initial condition

$$q(0) = \begin{bmatrix} 0 \\ 0 \\ -\alpha/2 \\ \alpha/2 \\ 5\pi/180 \end{bmatrix}, \dot{q}(0) = \begin{bmatrix} 0 \\ 0 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

Table 1: Parameter Settings

a	0.5 [m]
b	0.5 [m]
L =	1.0 [m]
L_t	0.8 [m],
α	$30\pi/180$ [rad]
g =	9.81 $[m/s^2]$
m_1	5.0 [kg]
m_2	10.0 [kg]
m_h	15.0 [kg]
m_t	3.0 [kg]
K_p	490
K_d	20

Fig. 4 shows the plot of walking as a sequence of stick diagram of the biped robot when the robot walks on level ground. In this diagram, displacement 1 step each leg cycle has been shown. The red color identifies the right leg and blue color line indicated the left leg. The physical parameters showed Table 1 chosen for the underactuated robot with unbalanced masses walking. Where one leg carry double mass then other leg and hip mass also heavy m_h = 15.0 [kg]. In this case, the robot can stably walk on the level ground without fall down. The robot changes the movement each 2-period. α is desired inter leg angle at impact, the acceleration of gravity is g, Total leg length, L. The K_p and K_d are proportional gain and derivative gain and the value of K_p = 490 and K_d = 20 are used for this robot controller. The torso is controlled Or maybe delicately, with the goal that jerk at collision is trailed by an articulated forward influence and recuperation.

These parameters used for Fig.5 to Fig.10 and there are 2-period walking generated for Angular position, velocity, ground reaction force, control output, control input. The Fig.7 and 8 show that the torque input and output of the motor intercept are the same levels, which is very significant because here used only one motor and also unbalanced masses. Fig. 10 shows that the total mechanical energy, kinetic energy, and potential energy, where we can see every walking step it needs low energy and keep it the same level. We can see the two legs carry the different masses which are almost double one leg to another and hip joint carry heavy mass, torso mass m_t = 3.0 [kg] and generate 2-period steady gait on the level ground. For the period-2 gaits describe the progress of collision time has converged after two points. In other description, after some iterations, the state variables replicate

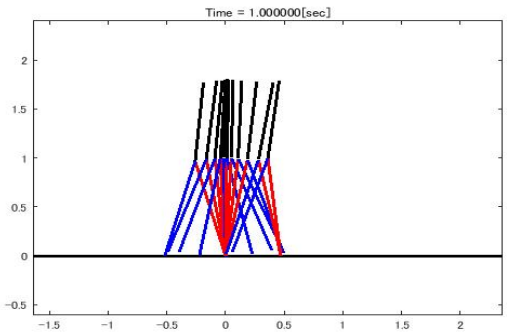

Fig. 4. The plot of walking as a sequence of stick diagram of the biped robot

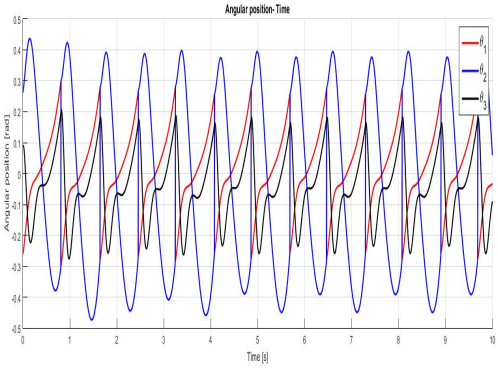

Fig. 5. Angular position for period-2

themselves after two continuous heel-strikes on the ground.

B. Gait analysis

Fig. 11 shows that the 2-period stable gait for three desired angles where used two negative and one positive values. The negative values step period is almost the same and for positive value after some disorder then step period walk 50 steps. Looking at Fig.12, it can see that when positive value used

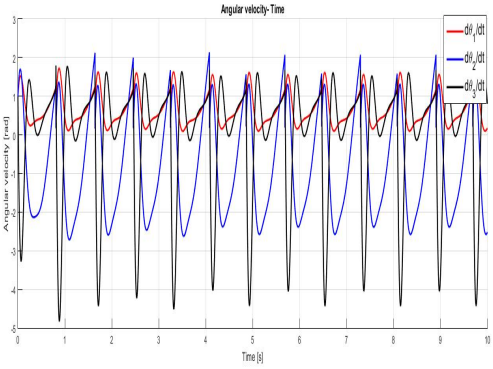

Fig. 6. Angular velocity for period-2

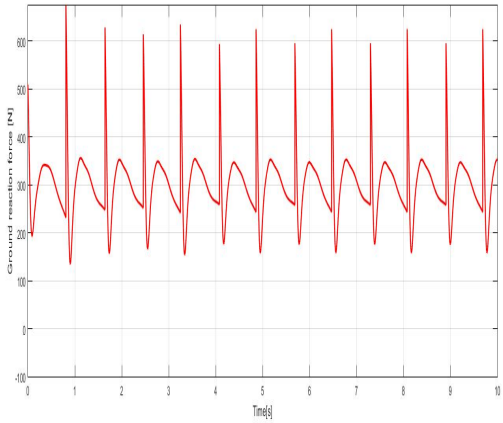

Fig. 7. Ground reaction force versus time for period-2

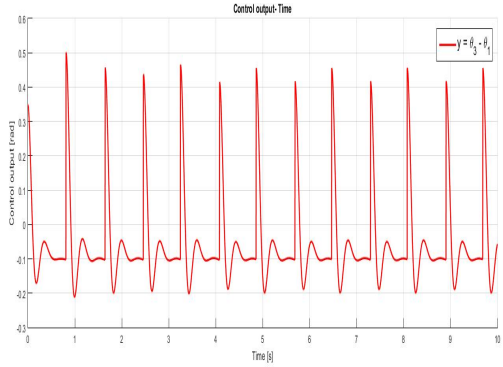

Fig. 8. The plot of output use to define the Controller versus time for period-2

for the desired angle than the walking speech low but when two negative values used then the walking speed is high and almost similar. In this case, the robot leg carries light mass instance leg which defined prosthesis leg and heavy mass carry in swing leg which defined physiological leg. In this simulation prove that light prosthesis leg design or modeling possible even other leg carry heavy mass. In this simulation shows robot can steady walk without unstable or fall-down.

Fig. 13 shows the step length for 3 different slope angles

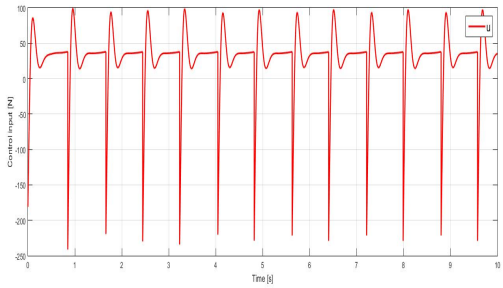

Fig. 9. The plot of applied torque input versus time for period-2

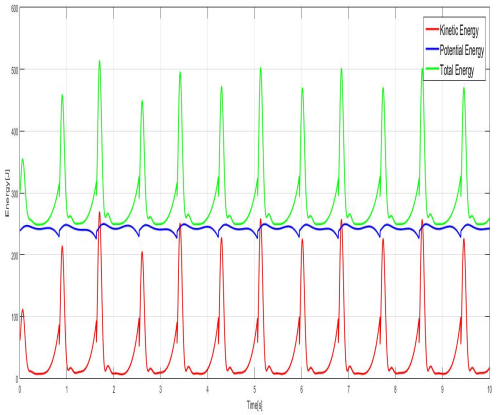

Fig. 10. Total Mechanical energy, kinetic energy and potential versus time for 2-period walking

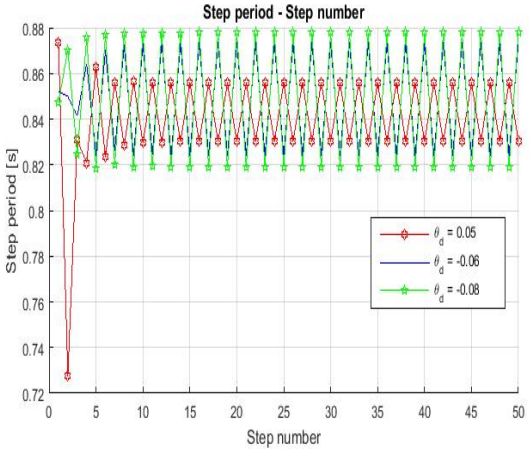

Fig. 11. Step period for different desired angle

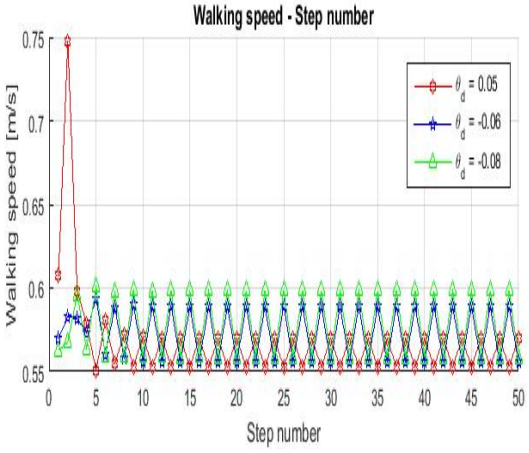

Fig. 12. Walking speed for different desired angles

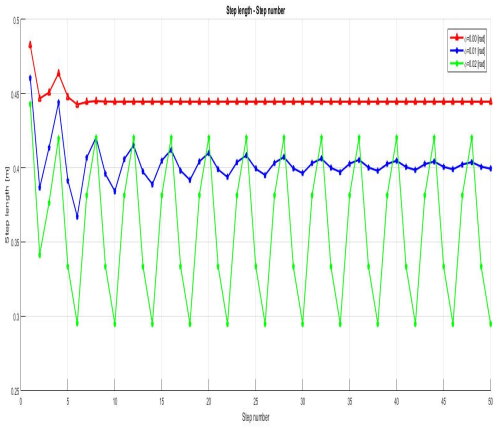

Fig. 13. Step length for different slope angles

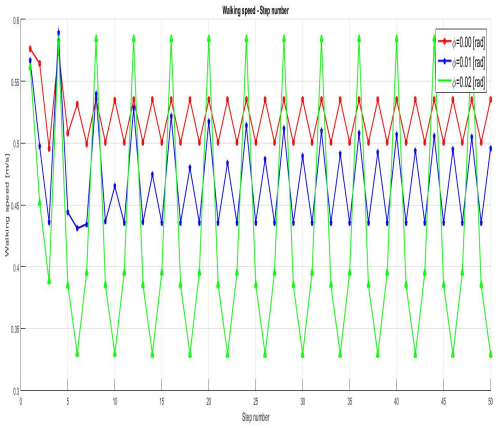

Fig. 15. Walking speed for different slope angles

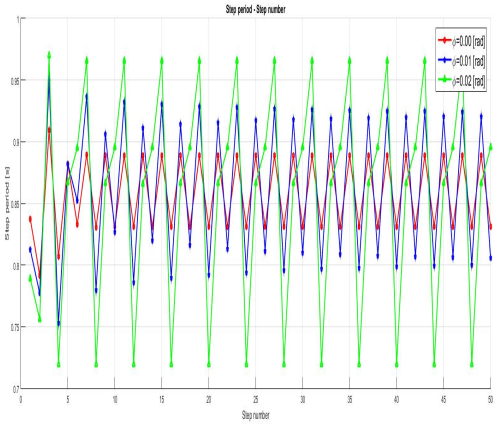

Fig. 14. Step period for different slope angles

when slope angle $\phi = 0$ [rad] then 1-period step length walking happened. Then if we used $\phi = 0.01$ and $\phi = 0.02$ the 4-period walking can generate the robot. Fig. 14 shows the step period for 3 different slope angles when slope angle $\phi = 0$ [rad] than walking step period is low. Then when we increased the slope angles $\phi = 0.01$ and $\phi = 0.02$ the 4-period walking step period can generate the robot. Fig. 15 demonstrates the walking speed of three different types of slops when slope angle $\phi = 0$ [rad] then 2-period walking cycle can generate. On the other hand, when the slope angle increased $\phi = 0.01$ and $\phi = 0.02$ then walking speed is high and 4-period walking cycle generated by the robot.

V. Conclusion

In this paper, the underactuated biped robot with unbalanced masses using one actuator was introduced. Then we have numerical simulation tested by different slope ground and desired angles. It was indicated that changing the different slope and desired angles of generated 2-period and 4-period stable gait for walking speed, step length, step period. The numerical simulations showed stable gait generation carrying with light and heavy masses is possible for the robot. The upper body robot walks are able to give accurate and simple behavior of the biped system. This model also a better understanding of human movement analysis who have central nervous system damage such as injury, stroke.

VI. Future Work

In the future, we should investigate more analysis of underactuated with unbalanced masses and develop the more advanced control system for biped robot upper body model with unbalanced masses. We will use the two actuators and control system for the upper body robot with unbalanced masses. Also, consider the different type of mathematical and simulation model the robot such as adding knees, semicircular feet and study different desired angles, downhill gentle slope and leg masses ratio [9].

***Abstract*—This paper presents artificial intelligence BONGO humanoid robot which is totally made with minimal cost in Bangladesh. The full meaning of BONGO is Bangla Robot. BONGO is a multilingual edifying robot arranged and impelled robot perspective in Bangladesh. This robot can appreciate Bangla and English the two lingos and prepared to talk with people and give the proper reaction to any sorts of the request. This robot sends irregular state voice and picture update advancement that why BONGO can know the front of the all inclusive community and it can talk with people by various sorts of explanation. For instance, Welcome to people and handshake with them, move the head etc. This robot can recognize an item as one of a kind individual. At that point, It will Be coordinating with our capacity organizers picture record. We use a unique mark hashing picture method to identify an image uniquely. Moreover, BONGO can be prepared to walk around shown by people directly. These days we are attempting to greater improvement of BONGO.**

***Index Terms*—BONGO; Sophia; humanoid robot; Bangla Robot, ASIMO.**

I. Introduction

The humanoid robot works as like Sofia [1] is particularly difficult however trying for building up the nation in Bangladesh. The confinement of monetary help and not accessible all materials for making a robot. The accomplished outcome is especially confused, yet we are endeavoring to research and make the BONGO robot as like human conduct. The BONGO robot media announced by the voice of America [2]. This robot likewise shapes like as Honda humanoid robot ASIMO [7].

Humanoid robot arrangement isn't equivalent to a customary present day diagram. A humanoid robot needs personality and character since it buries acts earnestly with individuals. Moreover, the layout procedure should fluctuate from that of machines, for example, vehicles and planes since it moves self-rulingly by seeing its condition. As the enhancement of human-PC participation additionally, interface design attributable to the advancement of the PC business, humanoid robot arrangement should be considered extensively and be recognized as another arrangement asks about the zone. The Sophia is a social humanoid robot made by Hong Kong-based association Hanson Robotics. Sophia was established on April 19, 2015 [1] and appeared at South by Southwest Festival (SXSW) in mid-March 2016 in Austin, Texas, United States [3]. She can appear more than 62 outward appearances. Sophia has been anchored by media around the globe and has shared in some conspicuous gatherings. While examiners around the world have been roused by the refinement of an expansive number of Sophia's responses to their request, the fundamental piece of Sophia's critical enunciations is acknowledged by masters to be somewhat scripted. KAIST configuration, control and built up their humanoid robot name KHR-2 [4]. The BONGO robot has some potential utilization of the distinctive sort of place, for example, security robot, instructive robot, amusements robots, Intelligent robot, military robot, human correspondence robot and so forth. The BONGO recently achieved the champion award of innovation challenge category on an international competition Ureckon 19 uem, kolkata [5].

II. Architectures of BONGO

Human-like shape and improvement, lightweight, moderate size, and kickback free actuator, independent structure, low power use As shown by above arrangement thought, we sketched out a youth assessed robot which resembles a human shape and has satisfactory joints to copy a human in Fig. 1. The BONGO robot front view and side view photos appear in Fig. 2. We used the front ultrasonic sensor for perceiving impediment in front of the robot. For autonomous development, all controllers, tangible gadgets, engines, and batteries, etc are set up inside BONGO. The BONGO robot full body and hand developed of Aluminum. BONGO has

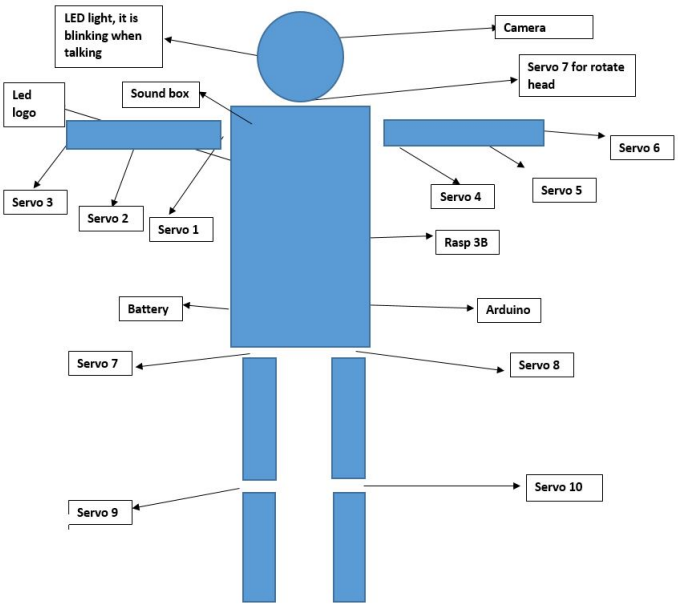

Fig. 1. Model of the BONGO robot

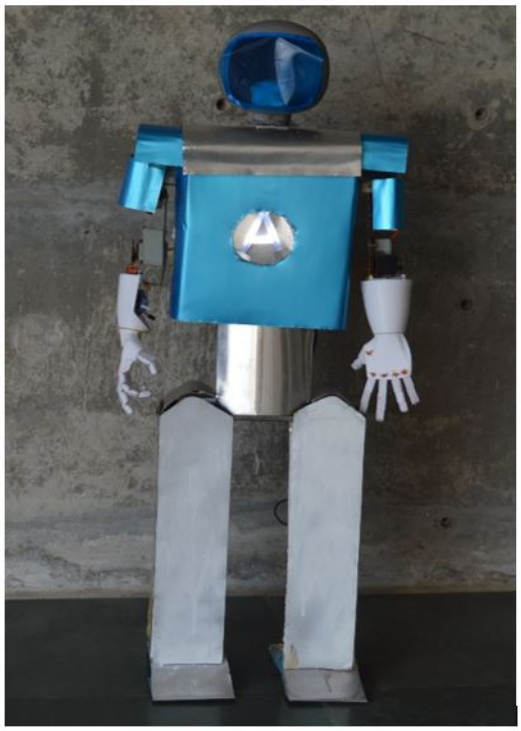

Fig. 2. Humanoid BONGO robot

Height and weight is 4.6 fit and 20 kg separately. We make the leader of the robot by a 3D printer. The body parts made by an aluminum sheet. We utilized the legs for the development of the robot. Later on, we will utilize legs for strolling the robot.

Fig. 5. Camera

III. METHODOLOGY

A. Hardware components

1) Microcontroller: The microcontroller shows in Fig.3. It controls any fringe device. like servo motor, DC motor, Ultrasonic sound Sensors and so on. We control here 18 Servo motors, 2 Ultrasonic sound Sensors, and some LED.

2) Servo motor: Servo motor to a blunder detecting input control which is utilized to remedy the execution of a framework. Fig. 4 shows the picture of the servo motor. Servo or RC Servo Motors are DC machine furnished with a servo system for exact control of the precise position. The RC servo engines, as a rule, have a revolution confine from 90° to 180°. A few servos additionally have turn farthest point of at least 360°. In any case, servos don't turn constantly. Their pivot is limited in the middle of the settled points. We are utilizing servo Motor here for control robot hands.

3) Camera: The camera shows in Fig. 5 which is a picture sensor gadget. So we utilized the camera to take face or protest picture. This photo perceives or process by the microprocessor.

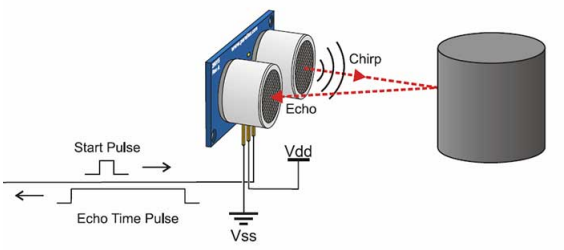

Fig. 6. Ultrasonic Sensor

Fig. 7. Raspberry Pi 3B

4) Ultrasonic sensor: Ultrasonic sensors show in Fig.6 which is a high-recurrence sound sensor. At the point when any protest results in these present circumstances Sensor. It detecting by the question and it sends information to the microcontroller. The BONGO detect an obstacle in front of the sensor.

5) Raspberry Pi 3B: The Raspberry Pi 3 device is the third epoch Raspberry Pi. It dislocates the Raspberry Pi 2 design B in February 2016. Contrasted with the Raspberry Pi 2 it has A 1.2GHz 64-bit quad-center ARMv8 CPU 802.11n Wireless LAN. Fig.7 shows the Raspberry Pi 3B device. Bluetooth 4.1 and Bluetooth Low Energy (BLE). We interface the camera with raspberry pi for preparing the picture to recognize human and items.

6) Arduino Uno R3: Arduino Uno device is a microcontroller board serving on the ATmega328p. We utilize this microcontroller to control servo and drove light. We have associated the Bluetooth module with it. Fig.8 shows Raspberry the Raspberry Pi 3B.

The Fig.9 shows hard ware block diagram of BONGO. The camera and Raspberry Pi 3B input connected with Andrino device and sound box, microphone is output device which used for robot communicate with people. The Arduino device input and output connected to the ultrasonic sensors and output with LEDs and Servo motors.

B. *Software tasks*

We used the Android operating System on android studio with the programming language Java. There are two main parts used for the BONGO robot. One part is Artificial Intelligence and another control of Microcontroller. The Artificial Intelligence part describes voice recognition. The robot also

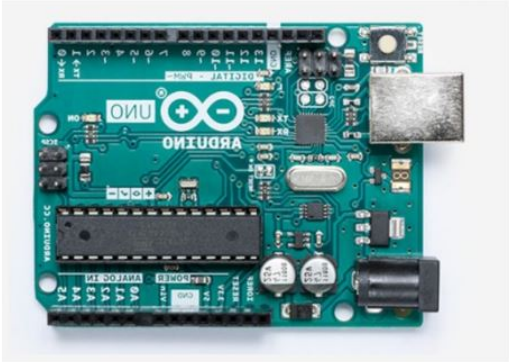

Fig. 8. Arduino Uno R3

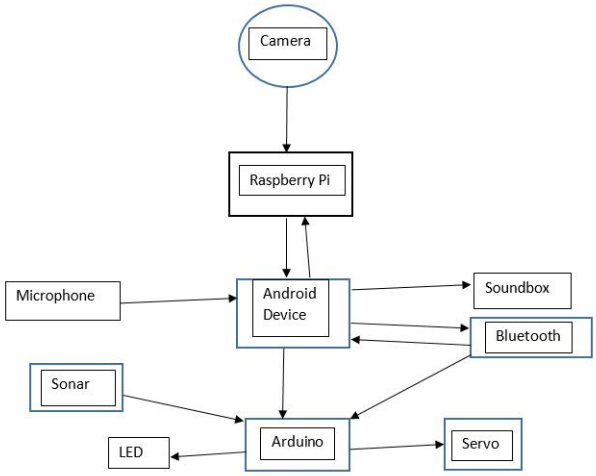

Fig. 9. Hardware block diagram

able to answer any types of questions. Microcontroller control movement of the robot, the handshake of the people, move head, hands and it can control by the microcontroller.
