May 3-5, 2019
Dhaka, Bangladesh

2019 1st International Conference on Advances in Science, Engineering and Robotics Technology (ICASERT 2019)

Proceedings of

2019 1st International Conference on Advances in Science, Engineering and Robotics Technology 2019 (ICASERT 2019)

May 3-5, 2019
Dhaka, Bangladesh

Table of Contents

Design of CMOS On-Chip Transformer Coupled Matching Network for Millimeter-Wave Amplifiers with Optimal Chip Area 1
Md Sazzad Hossain, Minoru Fujishima, Takeshi Yoshida, Shuhei Amakawa and Md. Mamunur Rashid

Enhancement of Global Bandwidth of Internet Users Employing Internet Exchange Point Leveraging VPN Technology 7
Al- Nahian Bin Emran, Aman Ullah Juman and Gazi Zahirul Islam

Comparison of Performance of Cognitive Radio Network under Single and Multi-User Scenario 12
Md Abul Kalam Azad, Md. Imdadul Islam, Muhammad R. A. Khandaker and Jugal K. Das

Impact of SUs under FC in Co-operative Cognitive Radio Network in PUEA Environment 17
Fahmida Hossain, Anzuman Yeasmin Snigdha and Imdadul Islam

Sleep-based DBA Algorithm for Energy Efficiency by End Points Collaboration in EPON 22
Kamrun Nahar Runa, Monir Hossen and Shuvashis Saha

Server Placement for Serving VIP Clients in Case of Link Failure 28
Sadia Sharmin, Shafayat Ahmed, Md. Saidur Rahman and Sourav Kumar Mondal

DDoS Mitigation and Intrusion Prevention in Content Delivery Networks using Distributed Virtual Honeypots. 34
Md. Mahmudur Rahman, Shanto Roy and Mohammad Abu Yousuf

Merging the communication protocols 6LoWPAN-CoAP and RPL-CoAP (Simulation and performance analysis using Cooja simulator) 40
Faria Hossain, Arif Mahmud, Faija Juhin and Tasnim Ara

A Low Cost Dual-Band Patch Antenna Array for Future 5G Communication Applications 46
Md Eshtiuk Hossain, Prosen Kirtonia and Mst Fateha Samad

Differentially Fed Compact Triple-band Antenna for Implantable Medical Devices 50
Prosen Kirtonia, Mst. Fateha Samad, Md Kamal Hosain and Md Eshtiuk Hossain

Design & Analysis of a Micro-strip Patch Antenna for RFID, WiMAX and X-band Applications 54
Mst. Dilshad Jahan, Chinmoy Das and Nayan Sarker

Traffic Load Based Efficient Energy Management Technique for 5G Small Cell Networks . 60
Syed Zahidur Rashid, Atikur Rahaman, Abdul Gafur, Yaheya Solaiman and Erfanul Hoque Bahadur

GDPR Compliance: Implementation Use Cases for User Data Privacy in News Media Industry 66
Ahmedur Rahman Shovon, Shanto Roy, Arnab Kumar Shil and Tanjila Atik

Applying Model-Free Reinforcement Learning Algorithm in Network Slicing for 5G 72
Mostafa Zaman Chowdhury, Md. Tanvir Hossan and Yeong Min Jang

Throughput Analysis of Compressive Sensing in Cooperative Opportunistic Radio Network 76
Shohely Tasnim Anindo, Teethiya Datta and Sk. Shariful Alam

Design of a High Voltage Closed Loop Charge Pumping System with a self-regulation mechanism 82
Alif Md. Asif Khan, Tahmida Islam, Md Wasif Absar, Md Rubel Sarkar and Md Shariful Islam

Effects of Wave Function Penetration on Gate Capacitance and Threshold Voltage of p-Channel Double Gate Junction Less Transistor 88
Md. Mohsinur Rahman Adnan and Mohammad Shahidur Rahman

Design of CMOS On-Chip Millimeter-Wave Transformer Coupled Balun and Power Divider-Combiner with Optimal Amplitude and Phase Imbalance 93
Md Sazzad Hossain, Minoru Fujishima, Takeshi Yoshida, Shuhei Amakawa and Md. Mamunur Rashid

Designing an Electro-Mechanical Ventilator Based on Double CAM Integration Mechanism 99
Md. Rakibul Islam, Mohiuddin Ahmad, Md. Shahin Hossain, Muhammad Muinul Islam and Sk. Farid Uddin Ahmed

Performance evaluation of an optical drop filter based on simple homogenous photonics crystal resonator 104
Md. Aminur Rahman and A.K.M Ehtesanul Islam

A High Speed and Low Power 32nm FinFET Dynamic Latch Comparator Design 108
Mir Muntasir Hossain and Satyendra N. Biswas

MOSFET-like Carbon nanotube Field Effect Transistor based Full adder design 112
Bappy Chandra Devnath and Satyendra N. Biswas

A Novel Approach to detect the Compound Level of Fertilizer and Pesticide in the Soil. . 116
Abu Shufian, Riadul Islam and Md. Mominur Rahman

Performance Analysis of EWOD Lens with Minimum Response Time and Optimized Damping Oscillation 122
Sumaiya Rahman and Mst. Fateha Samad

Impact of Increased Quantum Confinement on Gate Capacitance and Threshold Voltage of P-Channel Junctionless Transistor 127
Md. Khairul Alam Titu, Sajid Hasan and Md. Mohsinur Rahman Adnan

Design and Analysis of Dual-Core D-Shape Photonic Crystal Fiber Biosensor 132
Mohammad Al Mahfuz, Md. Nazmus Sakib, Mohammad Hasibul Hasan Hasib, Akash Bosu and Md. Roniuzzaman

An Efficient Soft Error Tolerant Approach to Enhance Reliability of TCAM 136
Rumana Afrin, Muhammad Sheikh Sadi and Jan Jrjens

An investigation on the surface states evolution of polycrystalline silicon nanowires for gas sensing application 142
Mohammad Mojammel Al Hakim, Afrida Arshad, Sharmin Shoma and Urmila Saha

Design and Analysis of high Efficient Latched Comparator 148
Dona Basak and Satyendra Nath Biswas

Performance comparison between Graphene Nano-Ribbon FET & conventional CMOS based on Arithmetic Logic Unit (ALU) 153
Md. Omar Faruque, Tanvir Hasan and Safayat-Al Imam

Numerical Assessment of the Backward Facing Step for NACA 0015 Airfoil using Computational Fluid Dynamics 156
Asif Kabir, Md. Saadbin Chowdhury, Md. Jahirul Islam and Mehran Islam

A Spatiotemporal Analysis and Forecasting of Electricity Generation-Mix in Bangladesh . 162
Sujoy Barua, Anik Nath, Fahim Shahriyar and Nur Mohammad

Compensation of Frequency Fluctuation in a Single Area Power System Using LQR-VC . 167
Fariya Tabassum and Dr Md Sohel Rana

Low Power Consuming Solar Assisted Vapor Compression Refrigerator To Preserve Emergency Medicines And Vaccines In Rural Areas 172
Akbar Hossain, Shovan Saha, Md Arifur Rahman and Mahbub Alam Himel

Robust Control of Terminal Voltage of an Isolated Electric Power Generating Unit 178
Fariya Tabassum and Dr Md. Sohel Rana

Design & Implementation of a Microcontroller Based Automatic Power Factor Rectification System for Different Loads 183
Md. Mayen Uddin, Abdullah Al Mahmud and Naeemul Islam

IMPROVED LOAD FREQUENCY CONTROL OF TWO-AREA POWER SYSTEM ... 189
Abdullah Al Mamun, Mohammad Mostafizur Rahman, Anowar Hosen, Sanjita Akter and Md. Mijanur Rahman

A Comparative Study of Various Methods of Phasor Measurement Unit Algorithms 194
Zahidur Rahim Talukder, Kazi Nishat Tasnim and Md. Shamim Reza

Water Cooled Chiller Based HVAC System Used in a Linear Generator for Oceanic Wave Energy Conversion 200
Selim Molla and Omar Farrok

Generation of Electrical Power by using High Graded Permanent Magnet Linear Generator for Wave Energy Conversion 206
Md. Samiul Bashir and Omar Farrok

Improved Bangla Language Modeling with Convolution 211
Shuvendu Roy

Denoising Sequence-to-Sequence Modeling for Removing Spelling Mistakes 215
Shuvendu Roy

Extracting RDF Triples from Raw Text 220
Yeasmin Ara Akter and Md Ataur Rahman

Bangla Spell Checking and Correction Using Edit Distance 224
Muhammad Ifte Khairul Islam, Rahnuma Islam Meem, Faisal Bin Abul Kasem, Aniruddha Rakshit and Md. Tarek Habib

Filtering Political and Sports News of Social Media from Textual Information 228
Lutfun Nahar and Zinnia Sultana Sultana

Sentiment Analysis & Emotion Extraction: a review of research paradigm 234
Lutfun Nahar

Topic Classification from Text Using Decision Tree, K-NN and Multinomial Nave Bayes . 242
Md Ataur Rahman and Yeasmin Ara Akter

Survey on Text-Based Sentiment Analysis of Bengali Language 246
Nayan Banik, Md. Hasan Hafizur Rahman, Shima Chakraborty, Hanif Seddiqui and Muhammad Anwarul Azim

Doly: Bengali Chatbot for Bengali Education 252
Md. Kowsher, Farhana Sharmin Tithi, M Ashraful Alam, Mohammad Nurul Huda, Mir Md. Moheuddin and Md. Golam Rosul

Threat and Abusive Language Detection on Social Media in Bengali Language 258
Puja Chakraborty and Md. Hanif Seddiqui

Adheetee: A Comprehensive Bangla Virtual Assistant 264
Syed Mohidul Islam, Most Fowziya Akther Houya, Syed Mynul Islam, Salekul Islam and Nahid Hossain

A Bangla Spell Checking Technique to Facilitate Error Correction in Text Entry Environment 270
Tanni Mittra, Sadia Nowrin, Linta Islam and Deepak Chandra Roy

Question Bank Similarity Searching System (QB3S) Using NLP and Information Retrieval Technique 276
Md Raihan Mia and Abu Sayed Md. Latiful Hoque

Textual Question Answering for Semantic Parsing in Natural Language Processing 283
Jaydeb Sarker, Mustain Billah and Md. Al Mamun

Information Retrieval System in Bangla Document Ranking using Latent Semantic Indexing 288
Md. Nesarul Hoque, Rabiul Islam and Md. Sajidul Karim

Face2Anime Generating Anime from Real Human Image with Adversarial Training 293
Shuvendu Roy

Forecast Upcoming Traffic States by Exploiting Nearest Junctions and Big Data 298
Md. Akter Hossain and Mohammed Nazim Uddin

Pest-Inspector: An Insect Detection System by Learning Data Representations 304
Md. Akter Hossain, A. H. M Tareq and Mohammed Nazim Uddin

Kinect 3D Reconstruction Fusion Mapping with C# Algorithm By RGB-D Sensor 310
Shoumik Rahman Mehedy, Ashikur Jhalak and Rashedur M. Rahman

Detection of Lung Cancer from CT Scan Images using GLCM and SVM 316
Mehdi Hassan Jony, Fatema Tuj Johora, Parvin Khatun and Humayan Kabir Rana

Single Image Haze Removal with Non Linear Complex Diffusion Process 322
Sharmin Sultana, Nazifa Akter, Rahat Hossain Faisal and Md. Mostafijur Rahman

Underwater Image Enhancement Based on Fusion Technique via Color Correction and Illumination Adjustment 328
Shahjadi Silma Subah, Md. Ashfaqul Islam and Md. Mohyminul Islam

Automatic Examinee Validation System using Eigenfaces 333
Nuruzzaman Faruqui, Mohammad Abu Yousuf and Md. Fazlul Karim Patwary

Prediction of Potato Disease from Leaves using Deep Convolution Neural Network towards a Digital Agricultural System 340
Md Al-Amin, Tasfia Anika Bushra and Md Nazmul Hoq

Human Identification Based on Color Stimuli 345
Md.Mahmudul Hasan, Nafiul Hasan, Md. Mohaiminul Islam and Mahojabin Suhi

Design of a Convolutional Neural Network Based Smart Waste Disposal System 349
Md. Samiul Haque Sunny, Debopriya Roy Dipta, Shifat Hossain, Hossain Mansur Resalat Faruque and Eklas Hossain

Brain Tumor Classification Using Convolutional Neural Network 354
Sunanda Das, O.F.M. Riaz Rahman Aranya and Nishat Nayla Labiba

Improved Segmentation Approach for Plant Disease Detection 359
Md. Arifur Rahman, Md. Mukitul Islam, Gazi Mohammad Shahir Mahdee and Md. Wasi Ul Kabir

An Automated Approach to Detect Breast Cancer Tissue Using Ultrasound Images 364
Dr. T M Shahriar Sazzad, Misbah Ul Hoque, A.K.M. Ashek Farabi, Ismail Hosen and Mursheda Akter Somi

An Automated Dermatological Images Segmentation Based on a New Hybrid Intelligent ACO-GA Algorithm and Diseases Identification Using TSVM Classifier 368
Md. Humayan Ahmed, Romana Rahman Ema and Tajul Islam

Design and Development of a Hand Gesture Based Virtual Mouse 374
Kabid Hassan Shibly, Samrat Kumar Dey, Md. Aminul Islam and Shahriar Iftekhar Showrav

Non-parametric development of the ranked tree structure for the accurate facial landmarking localization. 379
Supratip Ghose and Habibur Rahman

A Vision Based Three-layer Access Management System with IoT Integration 384
Nafize Ishtiaque Hossain, Ali Reza Galib, Raihan Bin Mofidul and Dhiman Kumar Sarker

Computer Vision and Smoke Sensor Based Fire Detection System 389
Nahid Chowdhury, Dewan Ruhul Mushfiq and Ehtesham Chowdhury

Implementation of Principal Component Analysis on Mask and Non-mask Face Recognition 394
Md. Sabbir Ejaz, Md. Rabiul Islam, Md. Sifatullah and Ananya Sarker

Brain Tumor Detection Using Convolutional Neural Network 399
Tonmoy Hossain, Fairuz Shadmani Shishir, Mohsena Ashraf, Md Abdullah Al Nasim and Faisal Muhammad Shah

BFAGC: A Bias-Free Adaptive Gamma Correction Method for Image Enhancement 405
Nazifa Akter, Sharmin Sultana, Rahat Hossain Faisal and Md. Mostafijur Rahman

Automatic Attendance System: A Face Recognition Approach 411
Manukumar Rudresh, C. Lalnunchama, Arun Kumar, Vijay Bhaskar Semwal and Vinay Anand Tikkiwal

A Dynamic Face Recognition using HAAR & CNN: A Transfer Leaming Approach 415
Amaan lqbal, Kunal Kumar, Arun Kumar, Vijay Bhaskar Semwal, and Vinay Anand Tikkiwal

Heart Failure Risk Prediction and Medicine Recommendation using Exploratory Data Analysis 419
Sumaya Habib, Maisha Binte Moin, Sujana Aziz, Kalyan Banik and Hossain Arif

Chapman-Kolmogorov Relation Based Median String Algorithm for DNA Consensus Classification 425
Mohammad Shibli Kaysar and Mohammad Ibrahim Khan

Performance Analysis and Benchmarking of Clustering Algorithms with gene datasets ... 431
Meskat Jahan

Linear Regression Models for Total Body Water Measurement Based on Bioelectrical Impedance Analysis 436
Mst. Farzana Khatun, Dr Md Sohel Rana and Dr Ajay Krishno Sarkar

Improved Piecewise Constant Approximation Method for Compressing Data Streams 442
Atik Mahbub, Farhana Haque, Habibul Bashar and Mohammad Rezwanul Huq

Mathematical Models for Fat Free Mass Measurement Based on Bioelectrical Impedance Analysis 448
Tahasin Ahmed Fahim and Dr Md Shamim Anower

Statistical Approach for Classifying Sentiment Reviews by Reducing Dimension using Truncated Singular Value Decomposition 453
Asmaul Husna, Habibur Rahman and Emrana Kabir Hashi

Building Predictive Models for Infant Mortality Rate in Bangladesh 458
Mst Lucky Sultana, Mst. Irin Sultana and Md Mahmudul Hasan

Design of Twenty-One Level Modular Multilevel Converter Using a Three-level Submodule Block 464
Ashraf Siddiquee, Shirajum Munira and Md. Shamim Reza

Comparative Study of Enhancing Stability of a Wind Farm connected to the Grid using PID Controller based STATCOM and Capacitor Bank 469
Ajmayen Fayek, Shah Md. Salimullah, Md. Shakhawath Hossain, Rakib Hossain, Md. Shadman Hasan Shakib, Ariful Islam Anik and Moynul Hossen Khan

Load Scheduling of a Refrigerated Warehouse with Homogeneous Compressors Under Dynamic Pricing 473
Shah Md. Nehal Hasnaeen, Shohanur Rahman and Md. Forkan Uddin

Compensation for Voltage Disruption in a Smart Grid during Cyber-Attack 479
Md. Abdur Rahman and Dr Md. Sohel Rana

Fuzzy Logic based Optimization for Electric Vehicle Charging Station in Bangladesh 484
Ashish Kumar Karmaker and Md Raju Ahmed

Modeling and Design of a Fuzzy Logic Based PID Controller for DC Motor Speed Control in Different Loading Condition for Enhanced Performance 489
Mirza Muntasir Nishat, Fahim Faisal, Mahdi Rahman and Md Ashraful Hoque

A Systematic Approach to Design Optimal Controller of Single Phase VSC for Distributed and Renewable Energy Application 495
Md Khurshedul Islam, Farhina Haque and Naeemul Islam

Implementation of Finite Control Set Model Predictive Control on 7-level Flying Capacitor Multilevel Inverter Using Space Vector 501
Nasir Jubair Islam, Md.Selim Sarker, N.M.Merazul Islam and Md.Shamim Reza

Design and Comparative Analysis of Dual-stage Servo controller in Hard Disk Drive 507
Alamgir Hossain and Md Arifur Rahman

Intelligent Speed Control of DC Motor using ANFIS D Controller 512
Tanjim Tarannum

A New Topology of Input Switched Single Phase AC-DC Buck Boost Converter for High Performance 517
Khadiza Akter, Sairatun Nesa Soheli and Md. Nafiul Islam

A Novel 36-Pulse Star Rectifier with Passive Injection Circuits at DC Link 521
Md. Abdul Malek, Md. Abu Bakar Siddik and Md. Shoaib Akther

Experimental Results of a locally developed BLDC Motor Controller for electric tricycle . 527
Fahim Bhuiyan, Nazmus Sakib, Mohammad Rejwan Uddin and Khosru M Salim

HOMER Optimized Off-grid Hybrid Energy System: A Case Study on Rohingya Relocation Center in Bangladesh 531
Ferdous S. Azad, Istiak Ahmed, Syed Raihan Hossain and Rashedul Amin Tuhin

Improved Differential Strobe Terminal Based Open-loop Control of Smart Power Factor Metering System 536
Shahriar Rahman Fahim, Sakib Shahrear Avro, Subrata K. Sarker, Md. Rokunuzzaman and Sajal K. Das

Converter based Frequency Adjustment and Protection of Grid-Tied Wind Farm 542
Kanij Ahmad, Nur Mohammad and Muhammad Quamruzzaman

Design of a cost effective Smart Autonomous Power and Switch Controlled Led Street Light 547
Monir Hossain, Md. Tawhid Islam Opu, Mohaiminul Islam Ratul and Navila Rahman Nadi

Analysis of Air Foils and Design of Blades for a Low-Speed 250W Vertical Axis Wind Turbine Suitable for Coastal Areas of Bangladesh 553
Mahtab Murshed, Md. Yeasin Arafat and M. Abdur Razzak

Genetic Expression Analysis To Detect Type Of Leukemia Using Machine Learning 559
Umid Dey and Md Sajjatul Islam

Sensor-Less Solar Irradiance Estimation and Maximum Power Point Tracking Using Artificial Neural Network 565
Arif Rubayet and M. M. Atiqur Rahman

Electricity Theft Detection to Reduce Non-Technical Loss using Support Vector Machine in Smart Grid 570
Rafia Nishat Toma, Md Nazmul Hasan, Abdullah Al-Nahid and Bo Li

A Machine Learning Approach to Protect Electronic Devices from Damage Using the Concept of Outlier 576
Sunanda Das, Muhammad Sheikh Sadi, Md. Ahsanul Haque and Md. Milon Islam

Ulcer Detection in Image Converted from Video Footage of Wireless Capsule Endoscopy . 582
Abdullah Al Mamun and Md. Sohag Hossain

Feature-Based Mobile Phone Rating Using Sentiment Analysis and Machine Learning Approaches 586
Abdullahil Kafi, M. Shaikh Ashikul Alam, Sayeed Bin Hossain, Siam Bin Awal and Hossain Arif

Unsupervised Content-Based Image Retrieval Technique Using Global and Local Features 592
Md. Farhan Sadique, Bishajit Kumar Biswas and S.M. Rafizul Haque

Bangla Handwritten Character Recognition: an overview of the state of the art classification algorithm with new dataset 598
Md Nazmul Hoq, Nadira Anjum Nipa, Mohammad Mohaiminul Islam and Sadat Shahriar

Personality Detection from Texts using Convolutional Neural Network 604
Md. Abdur Rahman, Asif Al Faisal, Tayeba Khanam, Mahfida Amjad and Md Saeed Siddik

An Empirical Study of Cervical Cancer Diagnosis using Ensemble Methods 610
Enamul Karim and Nafis Neehal

Bangla Document Categorisation using Multilayer Dense Neural Network with TF-IDF. . 615
Manisha Chakraborty and Mohammad Nurul Huda

Neural Network based Software Defect Prediction using Genetic Algorithm and Particle Swarm Optimization 619
Safial Islam Ayon

Artificial Neural Network Inducement for Enhancement of Cloud Computing Security 623
Md. Raihan Uddin, Md. Taslim Arefin and Kh. Mohaimenul Kabir

Non Functional Requirements Classification with Feature Extraction and Machine Learning: An Empirical Study 629
Md. Ariful Haque, Md. Abdur Rahman and Md Saeed Siddik

Design and Development of Question Answering System in Bangla Language from Multiple Documents 634
Samina Tasnia Islam and Dr. Mohammad Nurul Huda

Using Boosting Approaches to Detect Spam Reviews 638
Sifat Ahmed and Faisal Muhammad Shah

Performance Analysis of Different Decision Tree Based Methods for Identifying Drop Out Students 644
Nafisa Tasnim, Mahit Kumar Paul and A.H.M. Sarowar Sattar

Students Academic Performance Evaluation Method Using Fuzzy Logic System 650
Abdul Aziz, Md. Asaf-Uddowla Golap and M. M. A. Hashem

Using Social Networks to Detect Malicious Bangla Text Content 656
Tanvirul Islam, Nadim Ahmed and Subhenur Latif

Classification of Bengali Questions Towards a Factoid Question Answering System 660
Syeda Tamanna Alam Monisha, Sourav Sarker and Md Mahadi Hasan Nahid

Evidential SVM for binary classification 665
Md. Eusha Kadir, Pritom Saha Akash, Amin Ahsan Ali, Mohammad Shoyaib and Zerina Begum

Sentiment Analysis of Bengali Texts on Online Restaurant Reviews Using Multinomial Naive Bayes 671
Omar Sharif, Mohammed Moshiul Hoque and Eftekhar Hossain

Clinical Human Gait Classification: Extreme Learning Machine Approach 677
Prithvi Patil, K.Shusheel Kumar, Neha Gaud and Vijay Bhaskar Semwal

A Performance Improved Kretschmann Configuration Based Surface Plasmon Resonance (SPR) Sensor 683
Tauhidul Haque and Hasan Khaled Rouf

Leakage Detection in Water Pipeline Using Microcontroller 687
Muhammad Arman Uddin, Mohammed Mohibul Hossain, Samin Yeasar Seaum, Akil Ahmed and Hasibul Hasan Sabuj

Smart Gas Furnace 691
Md. Mominur Rahman, Abu Shufian, Farzana Akter, Md. Tarikul Islam Juel and Riadul Islam

DOORMOR: A Fully Functional Prototype of a Search and Rescue Robot 696
Fahim Faisal and Farhana Sharmin

VADet: An Arduino based automated vehicle accident detection and messaging system .. 702
Nazir Ahmmed, Nusrat Jahan Jenny, Most Fowziya Akther Houya, Anika Ibnat Binte Alam and Md. Adnan Arefeen

ParkEasy: An Embedded Model to Mitigate Car Parking Problems Using IoT Technology 707
Samrat Kumar Dey, R. M. Rubayet Shamim, Md. Atiqul Islam and Md. Mahbubur Rahman

DESIGN AND IMPLEMENTATION OF BOILER AUTOMATION SYSTEM USING PLC 714
Md.Iquebal Hossain Patwary, Shafayat Hossain, Rubel Ahmed, S.M. Tahsin Labib, Sohan Ul Alam and Md.Ashikul Islam

Face Recognition System Based on Raspberry Pi Platform 720
Md Asaduz Zaman Mamun, Nafis Mustakim, Noushad Hossain, Mohammad Mustafizur Rahman, Nadimul Islam and Zayed Hossain Sayem

Automatically Controlled Energy Conservation System for Corporate Office Based on Microcontroller. 724
Koushik Ahmed, Joydip Paul, Md. Mominur Rahman, Abu Shufian, Md Shahnewaz Tanvir and Md. Mohaimanul Islam Sagor

Affordable Smart ECG Monitoring Using Arduino & Bluetooth Module 730
Mohammed Mahmudur Rahman, Muhammad Armanul Hoque, Md Azizul Hoque Rimon and Md. Redwan Sammir

Six tiers multipurpose Security Locker System Based on Arduino. 734
A. Z. M. Tahmidul Kabir, Nirmol Debnath, Utshaw Rafin Akther, Tawsif Ibne Alam and Fukrul Hasan

Design and Implementation of a Vault Security System 739
Md. Mahadi Hasan Moon, Debashish Kumar Ghosh and Nafiz Ahmed Chisty

Design and Implementation of Remote Controlling and Monitoring System for Automatic PLC Based Packaging Industry 745
Raihan Bin Mofidul, Md. Shahadath Hossain Sabbir, Amit Kumer Podder and Mohammad Shaifur Rahman

Development of an Automated Low-cost Book Scanner and Translator 750
Sabila Nawshin, Samir Kumar Das, Najia Hossain, Joyita Das Mela, Abu Shafin Mohammad Mahdee Jameel and Salekul Islam

A Strategic Routing Analysis for Agro Sensor Communications in Mobile Ad hoc Networks 755
Sampad Banik, Md Munjure Mowla and Iftekhar Ahmad

Return Loss and Gain Improvement for 5G Wireless Communication Based on Single Band Microstrip Square Patch Antenna 761
Mohammad Faisal

Performance Evaluation of SDN Controllers in Wireless Network 766
Saiful Islam, Md. Ariful Islam Khan, Sanjida Tasnim Shorno, Sumonto Sarker and Md. Abubakar Siddik

Low-Cost Underwater Wireless Communication System Development Using Piezo-Ceramic Transducer 771
Md Ragib Shaharear, H.A.Shakhawat Hossen Prayash, Md Farhanul Islam and Tuhin Dey

Mobility Aware Cache Management in 5G Future Generation Wireless Communication System 775
Mayeesha Fairooz Ahmad and Mohammad Arif Hossain

An Intelligent Assistive Tool for Alzheimer's Patient 781
Kazi Shahrukh Omar, Afia Anjum, Tahrima Oannahary, Md. Rezaul Karim Rizvi, Diana Shahrin, Tasmiah Tamzid Anannya, Sanjida Nasreen Tumpa, Md Mahboob Karim, Md Fazle Rabbi and Muhammad Nazrul Islam

A Prototype of Automated Vault Locker Solution for Industrial Application 787
Shafayet Hossain, Mazid Ishtique Ahmed and Md. Niaz Mostakim

The Third Tab (3T): Assistant for Visually Impaired People 793
Sohal Islam, Kazi Arham Kabir and Md. Jakaria Rahimi

A Case Study on a Proposed Adaptive and Energy Efficient Street Lighting System for Chittagong City 798
Saif Hannan, Goutom Barua Milton, Md. Humayun Kabir and Mohammed Jashim Uddin

Detection of Safe Angle for Water Vehicles due to Vulnerable Swing 803
Md. Shahidul Islam and Sarfaraz Newaz

A Comparative Study of Walking Assistance Tools Developed for the Visually Impaired People 809
Mahfuza Khanom, Muhammad Sheikh Sadi and Md. Milon Islam

Performance Evaluation of a Wearable 2.45 GHz Planar Printed Meandering Monopole Textile Antenna on Flexible Substrates 814
Md. Mamun Ur Rashid, Ashiqur Rahman, Liton Chandra Paul and Ajay Krishno Sarkar

Intelligent Path-finder for the blind. 820
A. Z. M. Tahmidul Kabir, Nirmol Debnath, Mohitosh Pramanik and Tawsif Ibne Alam

A multi-controlled semi-autonomous wheelchair for old and physically challenged people . 825
Md.Eftekhar Alam, Mohammed Abdul Kader, Umme Hany, Rumana Arjuman, Aisha Siddika and Md.Zakaria Islam

Towards Developing an Intelligent Wheelchair for People with Congenital Disabilities and Mobility Impairment 831
Tasneea Hossain, Md Sabbir-Ul-Alam Sabbir, Asma Mariam, Toki Tahmid Inan, Muhammad Nazrul Islam, Khairul Mahbub and Muhammad Tawsif Sazid

Wearable Visual-MIMO for Healthcare Applications 837
Tae-Ho Kwon, Ki-Soo An, Partha Pratim Banik, and Ki-Doo Kim

RoboFI: Autonomous Path Follower Robot for Human Body Detection and Geolocalization for Search-Rescue Missions using Computer Vision and IoT 841
Ahmed Imteaj, M A Isfar Jubair Chowdhury, Mohammad Farshid and Abdur R Shahid

Development of Microcontroller based Light Following Emergency Evacuation Chair 847
Delowar Hossain, Hasan Alam, Ajmain Ar Rafi, Kamruzzaman Rakib and Umma Hany

A Prototype of Heavyweight Carrying Robot for Garments Industry in Bangladesh 852
Md. Mizanur Rahman, Sanjoy Kumar Sana, Md. Rokib Hasan, Sadia Kamal, Junaed Jahin and Thajid Ibna Rouf Uday

Q-Learning Based Particle Swarm Optimization Algorithm for Optimal Path Planning of Swarm of Mobile Robots 858
Syed Irfan Ali Meerza, Moinul Islam and Md. Mohiuddin Uzzal

Offloading SLAM for Indoor Mobile Robots with Edge-Fog-Cloud Computing 863
Victor Kathan Sarker, Jorge Pea Queralta, Tuan Nguyen Gia, Tomi Westerlund and Hannu Tenhunen

Simulation of Ferrofluid Based Soft Actuator Using Magnetic Field Optimization Approach 869
Tasnova Tanzil Khan, A. M. Harsha S. Abeykoon, Tanujjal Bora and Golam Fahad Mullick

Design of a Prototype of a Ferrofluid Based Soft Actuator 875
Tasnova Tanzil Khan, Tanujjal Bora, A. M. Harsha S. Abeykoon and Golam Fahad Mullick

Stable walking of an underactuated bipedal robot with unbalanced masses using one actuator 880
Mohammad Farhan Ferdous and Jannat Binta Alam

Artificial Intelligence Humanoid BONGO Robot in Bangladesh 886
A S M Ahsanul Sarkar Akib, Mohammad Farhan Ferdous, Milon Biswas and Hossain Mohammad Khondokar

Design & Implementation of Voice Command Based Bipedal Surveillance Robot 892
Himel Das, Himel Chakraborty and Md. Sarwar Uddin Chowdhury

Development of Myoelectric Robotic Hand using 3D Printer 897
Sivapong Nilwong, Delowar Hossain, Eneo Petoku and Genci Capi

Revised Scheme for Antimagic Graph Labeling for Splitting Graph and Shadow Graph Associated with Cycle 901
Zareen Tasneem, Farissa Tafannum and Md Mahbubur Rahman

Icons For the Mass: An Approach Towards Text Free Smart Interface 906
Eshtiak Ahmed, Md. Mahade Hasan, Mirza Omar Faruk, Muhammad Farhad Hossain, Md. Arifur Rahman and Ashraful Islam

Efficient Compression Scheme for Large Natural Text Using Zipf Distribution 910
Md. Ashiq Mahmood and K.M. Azharul Hasan

Design and Optimization of AlGaAs/InP Multi-junction Solar Cell 916
Md. Masud Rana, S. Md. Firoz Khan and Md. Shafin Shafayat

Cows Urine is a prominent source of electrolyte for Microbial Fuel Cell 921
Md. Abdul Halim, Rituparna Kundu, Md Ibrahim, Md. Rasel Mollah, Hasan Md. Bokhari and Islam Md. Aminul

An Intelligent Street Light System Based on Piezoelectricity Generator with Noticeable Zebra Crossing Point and Bus Stand. 925
A. Z. M. Tahmidul Kabir, Nirmol Debnath, Mirza Tanvir Sadik, Sakhwat Hossain Lisun and Fukrul Hasan

Electrical and Morphological Characterization of Zinc-Doped a- Fe2O3 Thin Films at Different Annealing Temperature 931
Arman Ibn Shahjahann

Fabrication of Digital Sol-Gel DIP Coating System with Smart Beaker Carrier 935
Sarafat Hussain Abhi, Md. Shoaib Akther and Dr. Md. Faruk Hossain

Enhancement of Sensitivity for Surface Plasmon Resonance Biosensor with Higher Detection Accuracy and Quality Factor 939
Mohammad Hasibul Hasan Hasib, Jannati Nabiha Nur, Kamrun Nahar Shushama, Imteaz Rahaman, Md. Masud Rana and Mohammad Al Mahfuz

Design and Implementation of Solar Power Wireless Battery Charger 944
Abu Shufian, Md. Mominur Rahman, Koushik Ahmed, Riadul Islam, Mahmodul Hasan and Toufiqul Islam

Offshore Wind Energy Estimation in the Bay of Bengal using Satellite Wind Measurement 949
Navila Rahman Nadi, Ferhat Bingl and Merete Badger

Electrical Energy Harvesting from the Foot Stress On Foot Overbridge Using Piezoelectric Tile 957
Tarik Bin Abdul Akib, Hasanuzzaman Mehedi and Md. Nazmuschayadat

Aspects of Numeral Value of Cu2ZnSnS4 (CZTS) Absorber Layer Fabricated in Sol-gel Process by Dip Coating Technique 962
Sabiha Dilruba, Tabassum Perveen Ananna, Afrina Sharmin and Zahid Hasan Mahmood

A Statistical Estimation of Solar Power for Energy Mix in Bangladesh 966
Sujoy Barua, Zainal Abedin, Anik Nath and Chitra Biswas

A Comparative study on Waste-to-energy (WTE) technologies for municipal solid waste (MSW) management in Chittagong, Bangladesh. 970
Md. Rashidul Islam, Jobair Al Rafi and Md. Sajjad Hossain

Modeling and Performance Analysis of an Γ-Model Based DFIG Wind Turbine with Duel Crowbar Protection 976
Mehedi Azad Shawon, S. M. Imrat Rahman and Naheed Hossain

Electrical Properties of CSS Deposited CdTe Thin Films for Solar Cell Applications 982
Nipu Kuamr Das, Sheikh Alimur Razi, Kazi Sajedur. Rahman, Mahmud Abdul Matin Bhuiyan and Nowshad Amin

Layer thickness effect on power conversion efficiency of a P3HT:PCBM based organic solar cell 986
Raian Islam, Murad Abrar, Farhatul Hassan and Sifat Adnan

An Efficient CZTS Solar Cell from Numerical Analysis 989
E.M.K. Ikball Ahamed, Ashoke Kumar Sen Gupta, Muhammad Qamruzzaman and M. A. Matin

Modelling a Solar Charge Station for Electric Vehicle with Storage Backup 994
Muhammad Ali, Safayat Mohammad and Md. Minhajur Rahman

Comparison of Different Hybrid Renewable Energy Systems With Optimized PV Configuration to Realize the Effects of Multiple Schemes 998

***Abstract*— Transformer coupled matching network is one of the alternative topologies for millimeter-wave integrated circuit design. Its impedance (inter-stage) transforming network (ITN) have been examined by planar and stacked topology with dimensional changing where planar transformer gives comparatively better performance than the stacked one. One-to-one-turn transformer-coupled ITN has been evaluated by the physical properties on optimum dimensional changing. Where ITN parameters and its properties function have been set below self-resonant frequencies (SRF) at 60 GHz & 79 GHz amplifiers. The quality factors (Q_f)and insertion losses (IL)of transformer ITN are $Q_{f@60GHz}$>20, insertion loss IL_{60GHz}<4dB and $Q_{f@79GHz}$>22, IL_{79GHz}<3dB at their center frequency. Also, parasitic inter-winding capacitances between primary and secondary coil are minimum because of the phasor angle between these two-coil voltage goes near to 0°. At millimeter-wave, the parasitic resistances of transformer coupled ITN are coming down <3Ω form tee-type equivalent circuits of impedance matrices. Extracted Optimal values of capacitances, resistances and inductances help to increase mutual coupling co-efficient as well as a good quality factor. Proposed planar and stacked small transformers have been utilized on ITN matching section of two millimeter-wave amplifiers on 55nm CMOS process. Supplying with 0.9V, mm-wave transformer coupled amplifiers have been designed layout area to 0.77 mm^2 with 34.51 dB peak gain at 60 GHz and 0.46 mm^2 with 17.15dB peak gain and both contain 24GHz 3dB bandwidth. As a result, it is confirmed that transformer coupled planar and modified stacked transformer are effective for shrinking layout area and high gain wideband 3dB BW in millimeter-wave regime.**

Keywords—Millimeter-Wave Transformers; Matching Networks; Impedance Transforming Network (ITN); Stacked & Planar Transformers; Transformer Coupled Balun & Power Divider; Millimeter-Wave Amplifiers.

I. INTRODUCTION

Millimeter-wave amplifiers are one of the key element for transceiver design. There are several topologies of mm-wave amplifiers with different circuit techniques. The single ended design technique suffers from poor noise performance and high area consumption due to the bulky passive devices. But differential technique can solve several problems behind this. Some previous Inductive-Capacitive (L-C-L) coupling, multi-section coupled lines, metal insulator metal (MIM) capacitor transmission line face a larger layout area and comparatively more insertion loss due to matching with ITN and input-output side matching network. Compared with those coupling [1] [2] [3], Transformer coupling network with cross coupling neutralizing capacitor (CCC) (fig.1) is one of the circuit technique for a good mutual coupling, impedance matching, minimize insertion loss, single to differential conversion, power distribution and combination. It helps to reduce layout area, minimizing insertion loss, a good quality factor and impedance matching with optimal mutual coupling co-efficient and lessen parasitic inter-winding capacitance and evaluation of lower resistances and optimal capacitances of each coils which have been considered for designing mm-wave devices. Along with other passive components, an arbitrary transformer coupled network is also used for impedance matching with a fixed material property changes. A center-trapped transformer coil can be easily set with differential ended active element. The design of several type of transformer is a one part of this paper.

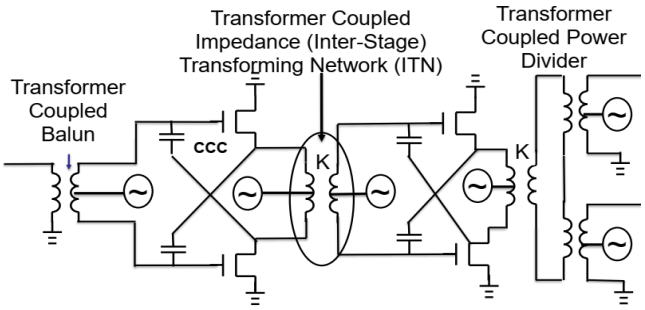

Fig. 1. Transformer coupled ITN with differential amplifier

Regarding the HFSS & Cadence layout of each coils, their relative location, geometric dimension, substrate shielding, transformation ratio, physical properties above. Similarly Transformer coupled balun and power divider provide much smaller amplitude & phase imbalance within larger bandwidth and consume less layout area rather than other topologies. Transformer practical circuit is little bit different from ideal equivalent circuit due to real time application. It contains several characteristics due to substrate capacitance (C_{SUB}), intra metallic capacitance (C_{Intra}), oxide capacitance (C_{OX}) which add several factors to degrade performance of passive elements and amplifier circuits (eqn. 1).

$$f_{prac}(L_P, L_S, R_P, R_S, C_P, C_S) = f_{ideal}(L_P, L_S, R_P, R_S, C_P, C_S) + Z_{SUB} + Z_{Intra} + Z_{OX} \quad \text{------ (eqn. 1)}$$

Maintaining optimal performances of mm-wave transformer and the physical properties evaluation with dimensional changing is one of the way to set a high-quality and small area on-chip transformers. In a brief, the goal of

this paper is the physical properties analyzing with On-Chip CMOS transformers with planar and stacked design. And finally realizing on-chip transformer coupled matching network for passive elements, millimeter-wave amplifiers design with higher gain, wideband 3dB BW and shrinking layout area at 60GHz and 79GHz on U and V band.

II. LITERATURE REVIEW

100 GHz 90nm CMOS amplifier uses constant planar transformer topology containing 11GHz 3dB BW, 11 dB gain, layout area is 0.87mm^2, 1.2V satisfying a good coupling co-efficient and set impedance transformation ratio by changing coil turns where higher SRF is important to minimize the loss [4]. Using a single steak of planar design reduces SRF and quality factor. Not even various dimensional planar and stacked topology have been described here. 60 GHz 65nm CMOS wideband differential driving amplifier measure wideband and high gain performance with multi-section coupled lines (Peak Gain: 20dB, 3dB BW: 10~15 GHz, 0.70mm^2) which faces quality factor degradation due to using RF grounded. Firstly, they regard transformer face defected ground effect on mutual coupling, increasing resistance and inductance and that will degrade the performance of amplifier at higher frequency [3]. From this paper, the loss has been minimized with higher SRF and having a good quality factors for transformer coupled inter-stage transforming network design. Transformer based 90nm CMOS at 60GHz amplifier (peak gain: 22dB, 0.27mm^2) stacked rectangular transformer has been visualized as coupled line segments. Topology is four-stage differential amplifier with 22dB gain at 60GHz. Here transformer is divided into three parts which includes two coupled lines and inductive lines to the terminals [5]. Here, physical properties with dimensional change of transformer isn't clarified using geometrical dimensional equation. Although it's tough to re-generate a general basement for transformer optimization but analysis aiding with some physical properties would be helpful to solve the different patterns.

III. PROPOSED MILLIMETER-WAVE TRANSFORMER COUPLED MATCHING NETWORK

A. *Millimeter-Wave Transformers*

Transformer is a passive element having primary and secondary impedance (L_p, L_s), primary & secondary resistance (R_s, R_p) and capacitance (C_p, C_s), parasitic coupling co-efficient, mutual coupling co-efficient (k_{imag}), turn ratio (n), quality factor (Q) and transformer efficiency (fig.4). Depending on whether the lateral or vertical magnetic coupling is used, transformer structures have two categories: planar and stacked. Several circuits (e.g., differential circuit) prefer transformers with a symmetrical layout.

Planar transformer topology (fig.2) contains top metal and thickness of 55nm CMOS process. There are many variations in planar transformer realization. Planar transformer usually occupies a large area. In multilayer process, several top metal layers can be strapped together to reduce resistance. The tradeoffs are a large terminal-to-substrate capacitance and a smaller self-resonant frequency [6]. But in mm-wave transformer coil has been chosen from top (TNA, Al, 2.8um) metal 12 only for a horizontal transformer design. The planar transformer is octagonal shaped having a space between primary and secondary coil maintaining design rules.

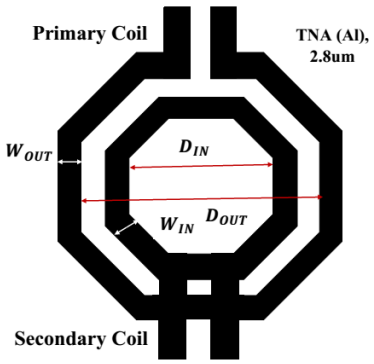

Fig. 2. Octagonal Planar Transformer with Top metal (TNA, Al, 2.8um)

A stacked transformer using two metal layers is shown in (fig.3) with utilizing vertical and lateral magnetic coupling, ideally self-inductance and coupling co-efficient are high. Millimeter-wave stacked transformer coil has been chosen from primary top (TNA, Al, 2.8um) metal 12 and Secondary metal 11 (LDA, Cu, 3.3um) without any vias (TWA) in a vertical design. The stacked transformer is octagonal shaped having a space between primary and secondary coil maintaining design rules. From fig.3, if the number of metal (below metal number-10) increases both in planar and stacked topology, it creates different properties. If several metals are used for stacked transformer, resistance decreases but capacitance increases. So, several mutual Intra & Inter metallic coupling inductances will generate and it will deteriorate the self-resonance frequency and insertion loss will be high enough because of using more thick metal. Because of some physical properties imbalances of multi turn planar and stacked transformer, achieving good quality factor, optimal mutual coupling and higher SRF, 1:1 turn is the reasonable choice of millimeter wave application arenas with their acute dimensional changing.

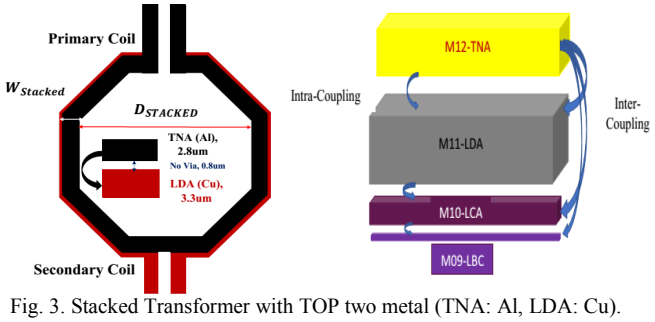

Fig. 3. Stacked Transformer with TOP two metal (TNA: Al, LDA: Cu).

B. *Ideal ITN Circuit Optimization*

Millimeter-wave Transformer based circuit can be represent into Tee & Pi type fourth order band pass filter and giving prime focus on mutual coupling co-efficient, self-inductances variation with an optimized goal, the matching section can be illustrated perfectly. Here, Primary, secondary & mutual inductance is gradually noted by $L_A = L_P - L_C$,$L_B = L_S - L_C$, $L_C = k_{imag}\sqrt{L_P L_S}$ and these two coils with 6 port networks (Port1_P, Port2_P, Port1_S, Port2_S, V_{ds}, V_{gs}). The Z parameters can be defined by eqn.2. From HFSS & Cadence MOMEMTUM cell, practical model of transformer with center trapped 6 port S-parameters has been extracted from simulation environment. The center trapped signal lines have related to supply source (gate & drain voltage).

$$\begin{bmatrix} V_P \\ V_S \end{bmatrix} = \begin{bmatrix} j\omega L_P & j\omega L_C \\ j\omega L_C & j\omega L_S \end{bmatrix} \begin{bmatrix} I_P \\ I_S \end{bmatrix} \quad \text{(eqn. 2)}$$

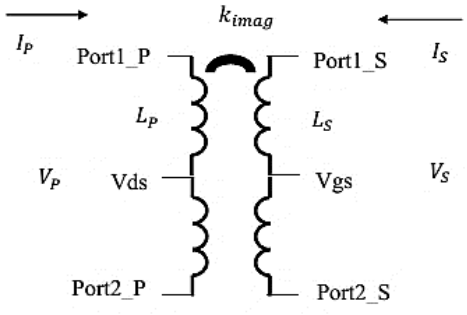

Fig. 4. Ideal circuit model of transformer

From 6 port S parameters MOM cell, V_{ds} & V_{ds} port have been taken ground initially to evaluate four port S matrices. Using theory of mode transformation [7] four port S matrix has been orthogonally transformed into even-even, even-odd, odd-even & odd-odd matrices, and odd-odd has been shown here (eqn.3).

$$S_{oo} = \begin{bmatrix} S_{o1o1} & S_{o1o2} \\ S_{o2o1} & S_{o2o2} \end{bmatrix} = \frac{1}{2}(S_{11} - S_{21} - S_{12} + S_{22}) \quad \text{(eqn. 3)}$$

Here, transformer Tee type equivalent circuit (fig. 5) has been represented from practical design cell. In Tee type transformation, it contains resistance (R_P, R_S), leakage inductance (L_{lecp}), self-inductance (L_A, L_B) and mutual inductance (L_C). Mutual Coupling Co-efficient k_{imag} will be calculated from Z matrices (eqn.4).

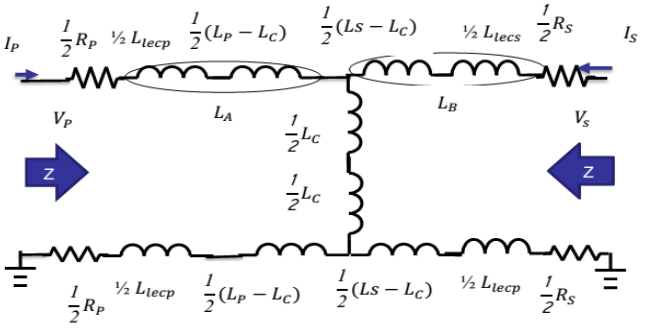

Fig. 5. Tee Type equivalent ideal transformer circuit

$$Z_{11} = a_{1t} + jb_{1t} = \frac{V_p}{I_p} = R_P + j\omega L_P;\ V_s = 0$$

$$Z_{12} = a_{2t}' + jb_{2t}' = \frac{V_p}{I_s} = j\omega L_C;\ V_p = 0$$

$$Z_{21} = a_{1t}' + jb_{1t}' = \frac{V_s}{I_p} = j\omega L_C;\ V_s = 0$$

$$Z_{22} = a_{2t} + jb_{2t} = \frac{V_s}{I_s} = R_S + j\omega L_S;\ V_p = 0 \quad \text{(eqn. 4)}$$

Extracted Parameter could be expressed in eqn.5,

$$L_A = \frac{im(Z_{11})}{\omega} + L_{lecp};\ L_B = \frac{im(Z_{22})}{\omega} + L_{lecp} \quad \text{(eqn. 5)}$$

$$R_P = a_{1t};\ R_S = a_{2t}$$

$$L_P = L_A + L_C;\ L_S = L_B + L_C;\ L_C = k\sqrt{(L_P L_S)}$$

$$k_{imag} = \sqrt{\frac{im(Z_{12} \text{ or } Y_{12}) * im(Z_{21} \text{or } Y_{21})}{im(Z_{11} \text{or } Y_{11}) * im(Z_{22} \text{or } Y_{22})}}$$

Pi type transforming network (fig.6) behaves as like band pass filter with RLC network. From Pi type equivalent circuit, mutual coupling co-efficient (k_{imag}) can be determined from two port Y matrices (eqn.6). And from here, parasitic capacitance (C_P, C_S) along with resistance (R_P, R_S) and self-inductance (L_P, L_S) can also be calculated from following equations and extracted parameters have been taken match with tee type transformation one.

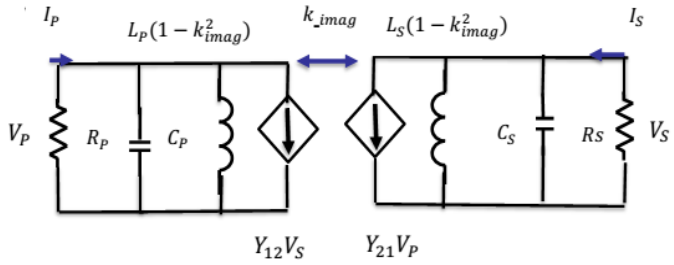

Fig. 6. Pi type equivalent ideal transformer circuit

$$Y_{11} = \mathbf{a_{1y} + jb_{1y}} = \frac{I_P}{V_P} = \frac{1}{R_P} + j\omega C_P + \frac{1}{j\omega L_P(1-k_{imag}^2)};\ V_S = 0$$

$$Y_{12} = \mathbf{a_{2y}}' + \mathbf{jb_{2y}}' = \frac{I_P}{V_S} = \frac{k}{j\omega L_S(1-k_{imag}^2)};\ V_P = 0$$

$$Y_{21} = \mathbf{a_{1y}}' + \mathbf{jb_{1y}}' = \frac{I_S}{V_P} = \frac{k}{j\omega L_P(1-k_{imag}^2)};\ V_S = 0 \quad \text{(eqn.6)}$$

$$Y_{22} = \mathbf{a_{2y} + jb_{2y}} = \frac{I_S}{V_S} = \frac{1}{R_S} + j\omega C_S + \frac{1}{j\omega L_S(1-k_{imag}^2)};\ V_P = 0$$

Primary & secondary inductance (L_p, L_S), Parasitic resistance and capacitance (C_P,C_S,R_P,R_S) and quality factor (Q_P, Q_S) have been expressed by these following equations.

$$L_P = \frac{-k_{imag}}{\omega b_{1y}'(1-k_{imag}^2)};\ C_P = \frac{1}{\omega}\left(b_{1y} - \frac{b_{1y}'}{k_{imag}}\right);\ R_P = \frac{1}{a_{1y}}$$

$$L_S = \frac{-k_{imag}}{\omega b_{2y}'(1-k_{imag}^2)};\ C_S = \frac{1}{\omega}\left(b_{2y} - \frac{b_{2y}'}{k_{imag}}\right);\ R_S = \frac{1}{a_{2y}}$$

$$Q_p = \frac{\omega L_p}{R_p};\ Q_s = \frac{\omega L_s}{R_s}$$

Cross coupling neutralized techniques for CCC means to cancel out the Gate-Drain Capacitance between a transistors at high frequency and increase transistor maximum frequency (f_{max}). And insertion loss (IL) can be calculated by maximum available gain (MAG) (eqn.7),

$$IL = -10\log_{10}(G_{max}) \quad \text{(eqn.7)}$$

$$G_{max} = 1 + 2(x - \sqrt{x^2 + x}), \text{ Where}$$

C. *Practical ITN Circuit Optimization*

Planar and stacked designed transformer coupled ITN coils ware taken into vertical & horizontal view (fig. 7). In the oxide layer, these two types of coils have been set in an un-similar thickness but same dimensional area and same width. And the larger self-resonance frequency (SRF) and

good quality factor (Qf) have been determined from their simulated S matrices. So, from simulated result, stacked transformer SRF is lower than the planar one. On the other hand, stacked quality factor is better than planar transformer but doesn't have wideband characteristics. For wideband amplifier application, the trans-impedance of planar transformer give the broadband characteristic remain in 1GHz - 200GHz where stacked transformer contains in 1GHz – 70 GHz both having same structural area (fig. 8 & 9).

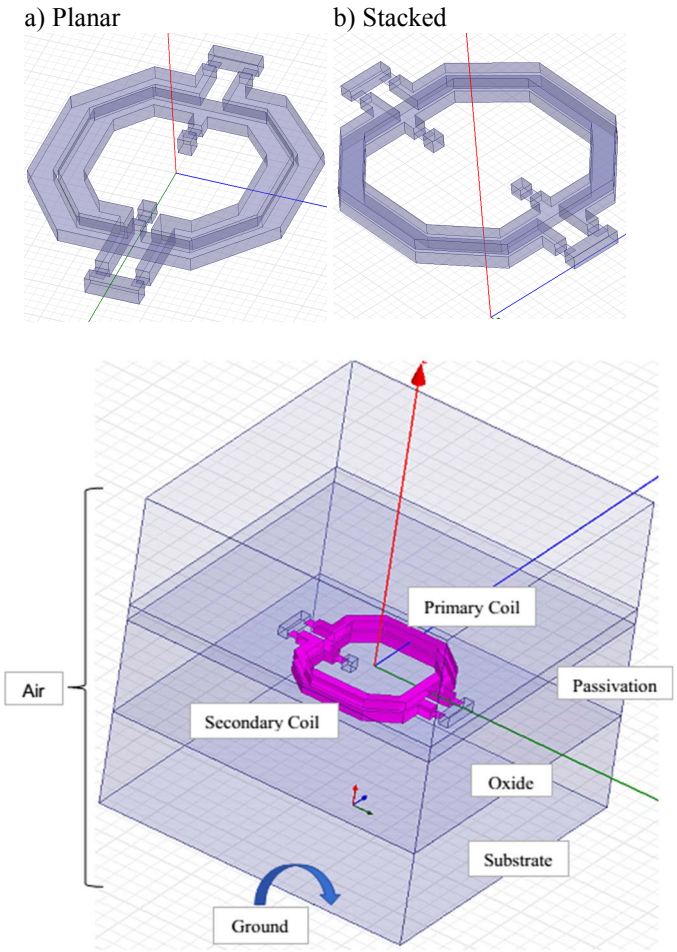

Fig. 7. (a & b) Planar and Stacked Transformer practical cell and final HFSS designed transformer cell

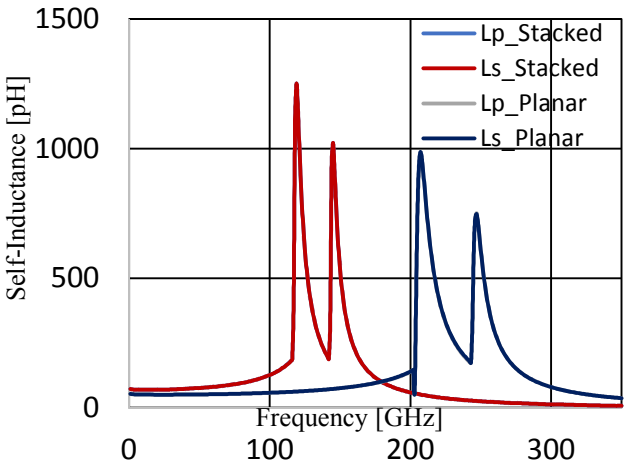

Fig. 8. Self-resonance frequency (SRF) of practical transformer cell

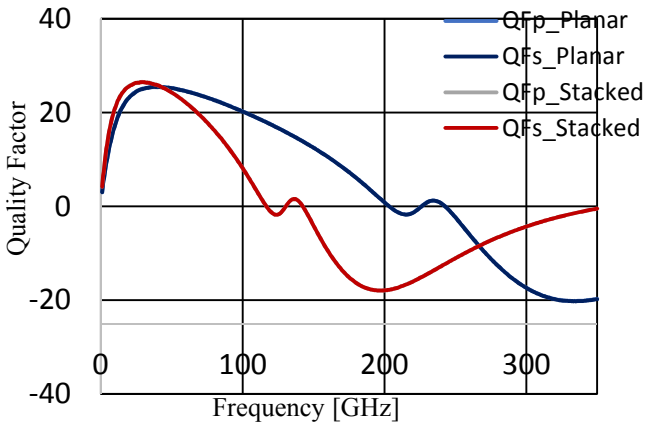

Fig. 9. Quality factor of practical transformer cell

Based on fixed dimensional planar and stacked transformer cell physical property, a geometrical boundary has been optimized. Upon this boundary and checking chip design rules, several planar and stacked transformers has been evaluated for amplifier design in mm-wave region. From (fig. 10, 11 and 12), a decision could be finalized with planar transformer because of its continuous good quality factor, lower insertion loss and higher SRF. On the other hand, a smaller stacked transformer can perform same characteristics as like planar beyond the edge of design rule. Such as 40um stacked one give same SRF as like 70um planar one.

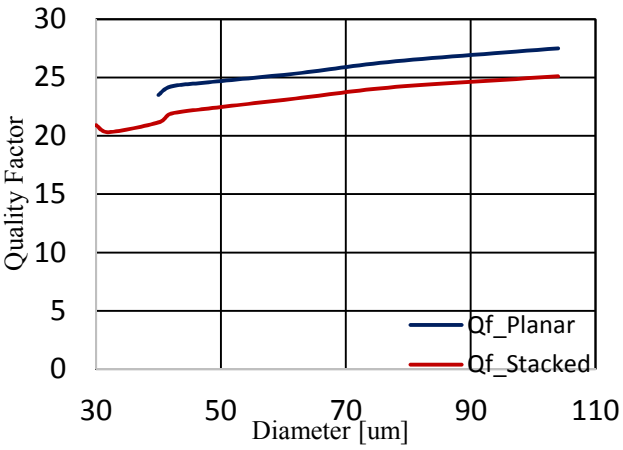

Fig. 10. Optimized practical transformer cells quality factor

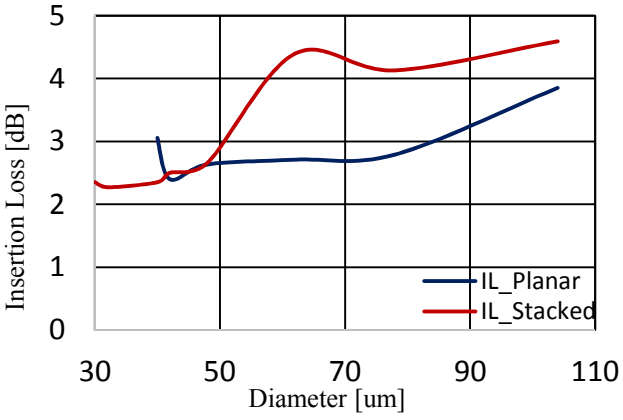

Fig. 11. Optimized practical transformer cells insertion loss

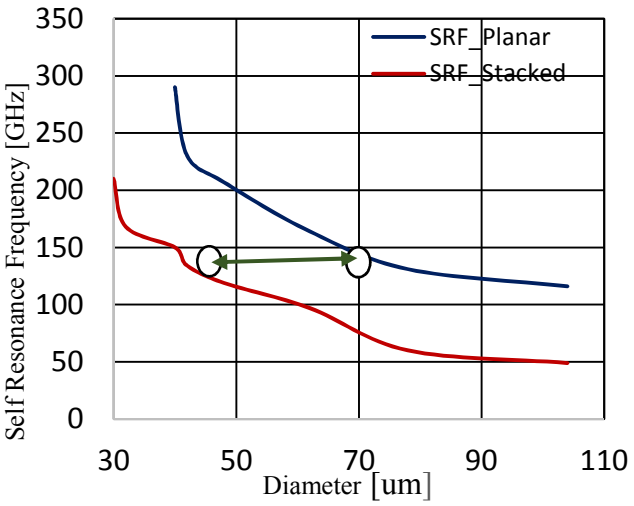

Fig. 12. Optimized practical transformer cells Self-resonance Frequency

IV. RESULTS OF TRANSFORMER COUPLED TECHNIQUE ON MILLIMETER-WAVE AMPLIFIERS

Transformer coupled ITN has been set with no ground wall and ground floor but XPWA to fix a good quality factor. Although forward (FC) and backward (BC) connector create a little bit more insertion loss into the circuit, but this phenomenon might be slightly change coupling co-efficient. And two differential pair transistors with fingers {(32X2), (64X2)} have been attached with periodical changing of material diameter and width of planar and stacked transformer (fig.13).

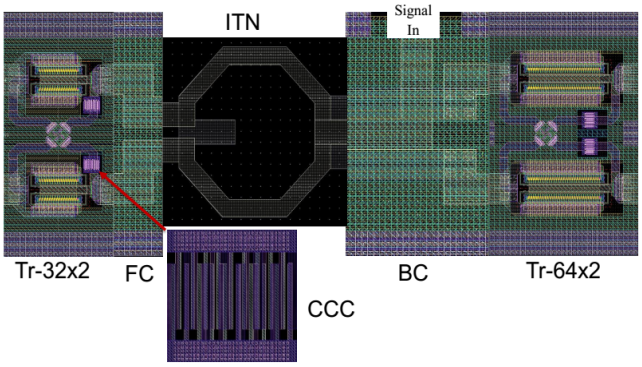

Fig. 13. Layout of two stage single amplifier with transformer coupled ITN

A. Transformer Coupled Amplifier at U and V Band

Here fig. (14 & 18), transformer coupled amplifier schematic at 60GHz and 79 GHz have been designed with Q_{f60GHz}>20dB, optimal IL_{60GHz} < 4dB and Q_{f79GHz}>22dB, IL_{79GHz} < 3dB and both amplifier satisfied optimal K_{imag}~0.4. Parasitic inter-winding capacitance angles are nearly to 0^0 which means minimum capacitance shows between two windings and $V_{CC} = 0$. Planar transformers are being geometrically designed to sustain itself at higher self-resonance frequency. But smaller stacked will provide good performance as like planar under a certain design rules. From (fig. 15 & 19), total layout area has been estimated into 1673 um^2 × 460 um^2 = 0.77 $mm^2$and 3dB BW 24GHz in U with a 34.51 dB peak gain (fig.16) at 60GHz. Again at 79GHz amplifier layout size is 1006 um^2 × 455 um^2 = 0.46 $mm^2$and 3dB BW 24GHz in V band with a 17.15 dB peak gain (fig.20). Transformer coupled amplifier at 60GHz and 79GHz comparison diagram have been viewed here (fig. 17 & 21). And these transformer coupled amplifiers have been compared with other transformer coupled and several topologies in case of peak gain, 3dB BW and less layout area. Here, a smaller dimensional stacked transformer with diameter and width changing provide similar characteristics as planar one in the millimeter-wave application.

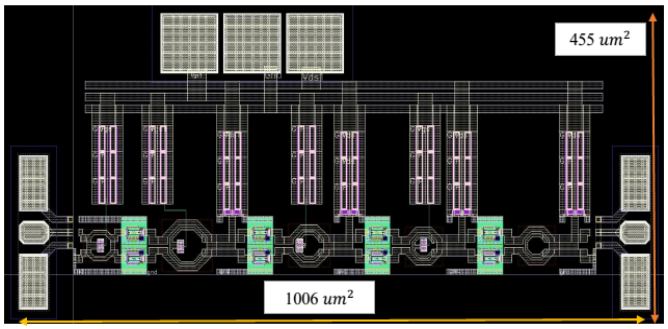

Fig. 19. Layout of 79 GHz Transformer coupled amplifier

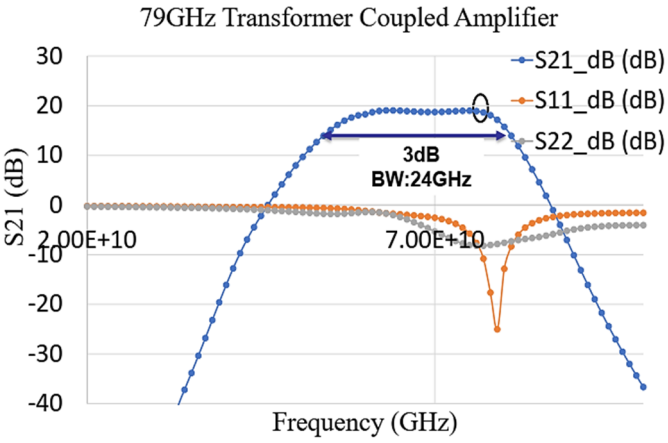

Fig. 20. 79 GHz Transformer coupled amplifier gain

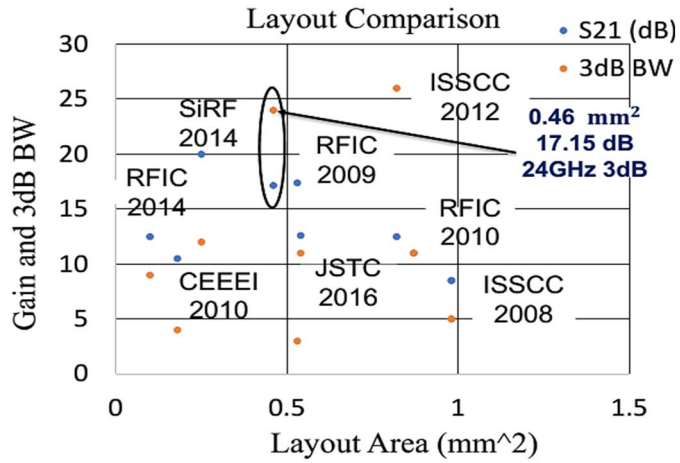

Fig. 21. 79 GHz Transformer coupled amplifier comparison diagram

VI. CONCLUSION

In this simulated work on cadence, high-quality and small-area on-chip transformers are proposed and optimized for differential amplifier. Proposed transformers are used as passive matching circuits and have advantage to compare with traditional matching circuits to reduce chip area. For millimeter-wave amplifiers, transformer-coupled planar and stacked type inter-stage transforming network (ITN) has been evaluated. As a result, wideband trans-impedances of fourth-order ITN is realized with a good quality-factor and low insertion-loss transformer by miniaturizing parasitic inter-winding capacitance and resistance with high self-resonant frequency.

ACKNOLEDGEMENT

The author would like to thank the member of Frontier Integrated System Laboratory, AdSM, Hiroshima University, along with MIE Fujitsu Semiconductor Inc. Japan, for cadence 55nm DDC CMOS IC design platform and their design rules.

***Abstract*—Not all internet service providers provide the same amount of bandwidth to their users. Based on bandwidth allocation, location and price service providers capped their users' bandwidth. As a result, we observe bandwidth limitation among the users. In this paper, we will implement a technique to bypass bandwidth and firewall restriction using virtual private network where we will use common IXP route to avoid the initial level of the bandwidth cap. In this project, we show that internet speed of international route i.e. global bandwidth can bypass, if there are multiple ISPs use a common IXP and at least one of those ISP provide robust global bandwidth. Usually, regional ISPs use common IXP to route their local traffic within the region. We utilize IXP to bypass global bandwidth cap of users who have better local bandwidth allocation. We show that using our proposed method global internet speed of a user can raise several times effectively.**

Keywords—IXP, VPN, BDIX, Global Bandwidth, Local Bandwidth, ISP

I. INTRODUCTION

It is undeniable that the Internet is a ground-breaking technology in this century. We can hardly think of a day without using the internet. There's hardly any sphere in human life left where the internet hasn't brought any change yet. From the outer space to the deepest trench of the world, the internet has brought the world to our finger's end. For the greater welfare of mankind, the Internet should reach every people's hand at their greatest conveniences. But there are too many deficiencies in our system that has been a hindrance to spread the internet at a convenient cost. Pointing out all of the deficiencies of the internet is not the main focus of this paper. In this paper, we came up with a solution to make the Internet handy. In our country Internet bandwidth is not well distributed with a well-maintained pricing list. Pricing of packages varies from one ISP to another which is making conundrum to the users. Peoples are not getting proper bandwidth by paying money which they yearn. Somewhere they are getting fair service for internet packages by paying decent amount of money and somewhere they cannot think of getting the same service with the same amount of money. So, focusing on the pricing variations, we will try to find a convenient solution to get superior global speed by using the Internet Exchange Point (IXP).

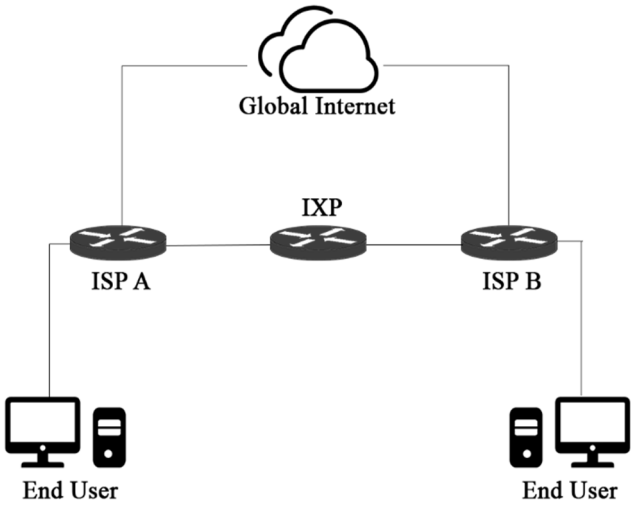

Fig. 1. Basic schematic diagram of an IXP

Internet exchange point was invented to affect the speed of the internet and give a whole new infrastructure of communication. A typical IXP schematic diagram is shown in *Fig. 1*. Here IXP servers as a common exchange point of the internet where Internet Service Providers (ISPs) are interconnected via IXP. ISPs are also connected to each other through global internet cloud [1]. An IXP interconnects ISPs in a region or country, allowing them to exchange domestic Internet traffic locally without having to send those data across multiple international gateways to reach their final destination [13], [14].

As IXP ensured us better local traffic, our goal is to use local traffic speed to get over with global bandwidth syndication and ensure a thorough distribution and maximized speed of global traffic with a decent amount of money. The details of the protocol will be explained in 'System Design and Implementation' section i.e. section IV.

TABLE I. AN ESTIMATE OF INTERNET USERS AND THEIR GROWTH

Year	Number of users	Population	% Penetration
2000	93,261	131,280,739	0.1 %
2005	345,372	142,929,979	0.2 %
2010	5,609,821	151,616,777	3.7 %
2014	15,271,441	159,077,513	9.6 %
2015	19,420,674	160,995,642	12.1 %
2016	21,439,070	162,910,864	13.2 %

The rest of the paper is organized as follows. We first discuss the background in section II then elaborate related works and motivation in section III. Section V contains performance evaluation and comparison. Constraints and recommendations are discussed in section VI. Finally, section VII concludes the paper.

II. BACKGROUND

Bangladesh is passing through some massive technological changes. From nineties' VSAT communication system to today's Internet accessibility through submarine cable, our country's communication pattern faced many challenges and successfully overcame those obstacles by adopting 3G, Wi-Max and LTE technologies. After introducing the submarine cable system, the number of local ISPs grew up drastically. Before the introduction of IXP, local traffic has to travel to other countries to reach its final destination. As such prior infrastructure was not able to provide a cost-effective service. The internet penetration of Bangladesh is one of the lowest in the world, only greater than North Korea, Myanmar and Sierra Leon which are exceptional cases [12]. In one of the press releases, the CEO of Grameenphone enlighten us with impressive information. He forecasts that by the year 2020, the total number of internet user of Bangladesh will be nearly 20 million. An estimate of internet users and their growth is shown in *Table I* [3], [4]. We can see in the year 2000, only 0.1% of the total population were using the Internet. By the year 2016 the number of Internet users increases to 13.2% which is 132 times of the year 2000. The BTCL, WiMAX operators, mobile operators and numerous ISPs are trying to reach every corner of the country to expand their services to make the internet a daily useful companion.

As Internet Exchange Point has profound impact over local traffic, we propose a method where local traffic can be used for elevated global traffic by creating a third wheel [2]. The third wheel will use Virtual Private Network (VPN) or proxy server. If a user has higher local bandwidth than global bandwidth, our method can establish an elevated global traffic route by counting little extra money to VPN providers.

For example, one internet provider is serving their customer with 1 Mbps Global bandwidth along with 20 Mbps of local bandwidth for 500 BDT. On the other hand, another provider is providing his customer with 5 Mbps of global bandwidth and 30 Mbps of local bandwidth for the same amount of money. In this case, we observe both ISPs are providing sufficient bandwidth for local traffic, but their global bandwidth is not satisfactory yet. Again, there is a huge difference in global bandwidth between two ISPs. Now the first customer who is currently getting 1 Mbps global bandwidth from his ISP could get up to 5 Mbps global bandwidth from the second ISP using their VPN server.

III. RELATED WORKS AND MOTIVATION

Bangladesh Telecommunication Regulatory Commission (BTRC) has been working deliberately for making internet handy to everyone. BTRC had taken a quintessential step to make a revolutionary change in existing infrastructure since the day Bangladesh was connected to the international submarine cable 'SeaMeWe-4'. As a result of simultaneous effort, Bangladeshi ISPs had been connected to its own IXP known as Bangladesh Internet Exchange (BDIX), thereby Bangladeshi users enjoying tremendous internet speed for local traffic. Without IXP local traffic has to travel to other countries to reach its final destination. So IXP has been a revolutionary technology in the world of communication as it changed the whole communication pattern of the Internet. There has been a lot of researches and projects for deployment of IXP.

"Internet Exchange Point: A Context of Bangladesh" is one of the finest research paper based on IXP. In this paper, the authors described the role of IXP and also explained how a whole infrastructure of a county could be changed through the setup of IXP [1]. The authors also enlightened us how a cost-effective model could be achieved by deployment of Internet Exchange Point. In 2004, Russell Southwood published an outstanding article upon the request of the International Telecommunication Union (ITU) and the International Development Research Centre (IDRC) that addresses two issues of direct relevance to most developing countries [5]. One of the factors inhibiting the growth of Internet usage in these countries is the high cost of bandwidth and the usage of this international bandwidth to exchange data at a local and national level. The other being: the need to setup an IXP to accelerate the growth of local traffic and save incurring international bandwidth cost.

The author of [6] focuses on the problems and opportunities for IXP deployment in Africa. The paper includes two distinct case studies for Kenya and Bangladesh focusing on their local Internet traffic, cost of bandwidth and IXP deployment issues. Another paper titled "Economics of Internet Exchange Points" by Mouhamet Diop published in 2009 gives an in-depth analysis of Internet transit, internet peering ecosystem and the economic impact of an IXP in a country. The paper also discusses various issues concerning the creation and operation of an Internet Exchange and tries to come up with an appropriate business model for it [7].

IV. SYSTEM DESIGN AND IMPLEMENTATION

In this section we will delineate a general IXP system then we will describe and implement our proposed method elaborately.

A. Apparatus and Mechanism of Internet Exchange Point

Internet Exchange Point acts as a switch that routes traffic among its associated ISPs. It saves the bandwidth cost and time of large intermediate portion of internet flow from source to destination. It is mandatory that all intended ISPs must be connected thorough a common IXP. In *Fig. 2* Tier 1 providers

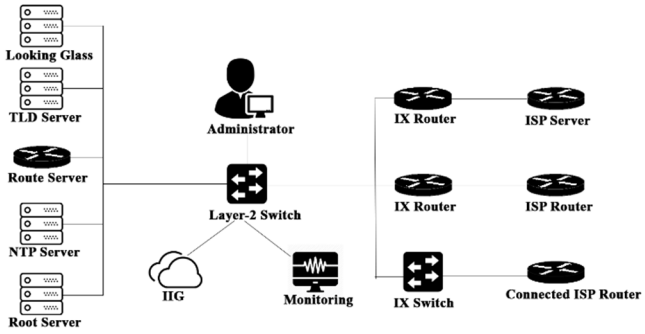

Fig. 3. Schematic diagram of an IXP

are the backbone of international traffic. Tier 2 is a thorough distributor of international traffic to Tier 3 by peering agreements. Tier 3 buys internet bandwidth from Tier 2 and provides internet connectivity to corporate and residences. Throughout the whole journey of traffic, IXP reduces the usage of global bandwidth by filtering out local traffic which previously uses the global route. Thus, the usage of international bandwidth reduces dramatically. If we investigate the top 20 websites searched by Bangladeshi users, we can see our Bangladeshi websites such as Prothom Alo, Kalerkantha, Jugantor, Bdjobs etc. are ruling in top 20. *Table II* shows top 20 websites which are surfed most of the time by Bangladeshi users [7]. The traffic of local websites need not travel through Tier 1 as this traffic will consume only local bandwidth using IXP. Thus, the Internet system using IXP could provide a faster connection in our country which could be implemented by any other country of the world.

For the establishment of an IXP, we require some elements such as root server, route server, NTP server, looking glass etc. [9]. These are illustrated in *Fig. 3*.

B. *Implementation Requirement*

The first and foremost requirement is both ISPs must be connected to the common IXP. For the third wheel that helps us to accelerate the global bandwidth, we need a VPN or proxy server. For our project, we rent a Linux VPS (Virtual Private Server) from the company 'Xeon BD' where we installed a VPN server. We have determined the result using our method after connecting to VPN server. Speedtest.net [11] is the website that we use to measure the acceleration of bandwidth with a Singaporean server named 'Singtel'.

C. *Implementation with an IXP in the middle*

Our aim is to maximize the global bandwidth leveraging VPN technology utilizing local bandwidth. A user who is getting poor global bandwidth from his current ISP can be benefitted by an IXP to boost up his global bandwidth. For that the user must be subscribed to another ISP that is providing higher global bandwidth from his current ISP and both ISPs must be connected to each other through the common IXP. Thus, a user getting a higher global bandwidth provided by his new ISP sitting in the network of his old ISP's and ISP to ISP traffic through IXP utilizes local bandwidth. The user has to take the services of a VPN or proxy server from the new ISP. If new ISP does not provide these services, then the user has to setup the VPN server by himself. When a user accesses the internet via a VPN server, he acts as a DHCP client to the VPN server. After connecting VPN server traffic between current ISP to VPN server (new ISP) will use user's local bandwidth portion. Now user's global traffic will be routed through the VPN server. *Fig. 4* illustrated the scenario.

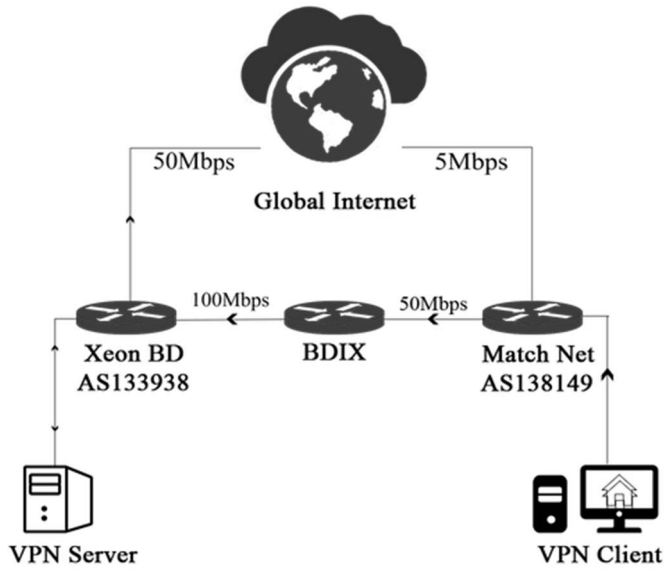

Fig. 4. A typical network of the proposed method with an IXP in the middle

TABLE III. DATA COLLECTED FROM DIFFERENT ISP

No	ISP Name	Package Specification	Package Cost	Obtained Global Internet Speed
01	Match Net	5 Mbps (Global Bandwidth) 50 Mbps (BDIX Bandwidth)	500 BDT	3.94 Mbps
02	ICC Communication	4 Mbps (Global Bandwidth) 30 Mbps (BDIX Bandwidth	700 BDT	3.96 Mbps
03	Explore Online	10 Mbps (Global Bandwidth) 100 Mbps (BDIX Bandwidth)	500 BDT	9.68 Mbps
04	Stargate Communication	2 Mbps (Global Bandwidth) 70 Mbps (BDIX Bandwidth)	500 BDT	2 Mbps

TABLE IV. DATA COMPARISON BEFORE AND AFTER USING PROPOSED METHOD

No	Source ISP	Obtained Global Internet Speed (Previous data)	Obtained Global Internet Speed (Applying VPN over IXP)	Improvement
01	Match Net	3.94 Mbps	30.55 Mbps	7.75 times faster
02	ICC Communication	3.96 Mbps	27.48 Mbps	6.94 times faster
03	Explore Online	9.68 Mbps	41.43 Mbps	4.27 times faster
04	Stargate Communication	2 Mbps	16.14 Mbps	8.07 times faster

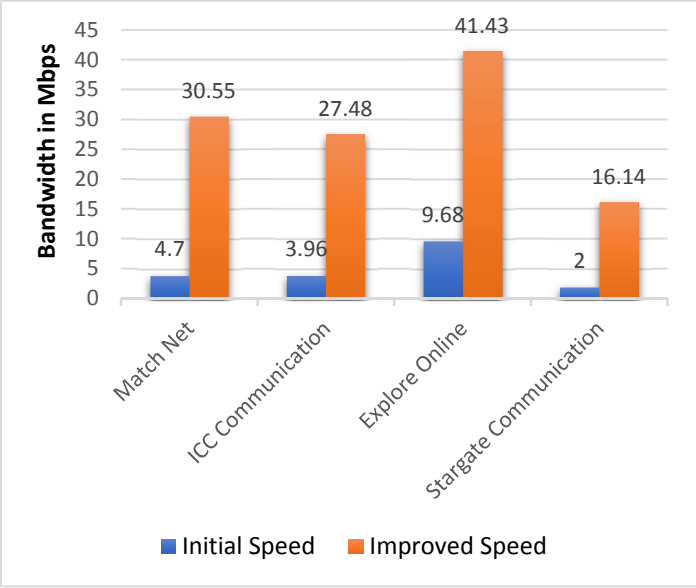

Fig. 5. Improvement of global bandwidth

Initially, we were taking internet services from an ISP named 'Match Net' located at Kolabagan, Dhaka that providing global bandwidth 5 Mbps along with 50 Mbps local bandwidth. To implement our technique, we rent a Linux VPS from another data center named 'Xeon BD' located at Mohammadpur, Dhaka. Xeon BD provides us 50 Mbps global bandwidth along with 100 Mbps local bandwidth for 400 BDT.

In VPS we installed the SoftEther VPN server which supports multiple types of VPN. In the server, we enabled L2TP, IPSec, SSTP, and OpenVPN. As VPS does not contain built-in DHCP server, we utilize virtual NAT function where we enable SecureNAT. Whenever a client connects the VPN server, the server will provide a private IP address from SecureNAT pool. In client end, we use SoftEther VPN Client application which uses SSTP (Secure Socket Tunneling Protocol) by default to connect VPN server.

V. PERFORMANCE EVALUATION AND COMPARISON

In this section, we will evaluate the performance of our proposed method and numerically determine the improvement of global bandwidth sitting at different locations of different ISP's in Dhaka City.

Table III shows different internet package information provided by some renowned ISP of capital city Dhaka. The data of the last column i.e. Obtained Global Internet Speed of *Table III* is measured by us using Speedtest.net website with the help of a Singaporean server 'Singtel'. We have gathered information of four ISPs' namely Match Net, ICC Communication, Explore Online and Stargate Communication. Their global bandwidth ranges from 2-10 Mbps, local bandwidth ranges from 30-100 Mbps, package cost ranges from 500-700 BDT and our measured global speed ranges from 2-9.68 Mbps.

Table IV shows the improvement of global bandwidth after using our method. To acquire higher global bandwidth, we connected our VPN server which hosted on Xeon BD from primary ISPs' user end. Again, we have tested global bandwidth by using Speedtest.net. It is noted that Xeon BD is providing a pleasing global bandwidth of 50 Mbps which is substantially larger than other ISPs'.

Examining *Table IV*, we can easily realize the differences in global speed using and without using an IXP and can perceive the effects of our proposed method. Now sitting at each of the primary ISP's network we are getting an enlarged global bandwidth which is around 4 to 8 times higher than the allocated bandwidth. *Fig. 5* summarizes the output of the

system graphically. The blue bars represent the global bandwidth which is given by the ISPs and the orange bars represent the results after employing our method.

Analyzing cost benefit, we can show that the bandwidth price will be significantly reduced after implementing VPN technology. According to the *Table III* and *Table IV*, we roughly estimate that after employing VPN, our cost increases around 1.75 times while speed increases 6.75 times. Thus, we must acknowledge the tremendous benefit of employing IXP leveraging VPN technology.

VI. Constraints And Recommendations

There are some constraints and limitations to implement the project using our intended method. Our method will work if and only if the ISPs are belong to a common IXP. For example, if one ISP only belongs to BDIX and another one only belongs to NOVOCOM NIX then the method will be void. Another thing is that local bandwidth of all ISPs must be good enough otherwise a bottleneck would occur. Lastly, users who want to experience an elevated global bandwidth must have to buy a VPN server from the ISP that providing a robust global bandwidth.

VII. Conclusion

The Internet has been a tremendous gateway for acquiring knowledge as well as a constant companion for entertainment. Our goal is to provide a method that can overcome bandwidth syndication, capping of bandwidth and provide every user a pleasant experience of using Internet with a maximized global bandwidth without paying large amount money.

In this article, we effectively illustrated a project that boosted global bandwidth using IXP. So our method can be used to resolve the syndication problem, deficiencies of internet speed and give comfort to the users for the next generation communications. In future, we will implement the project in a more flexible way so that any non-technical person can easily setup the system.

***Abstract*—In this paper, we analyze the performance of single user and multi-user communication model in LTE CRN links. The performance of the two models is compared in terms of outage probability and symbol error rate (SER) under small-scale fading including combining schemes. The impact of the number of antenna elements on combining schemes and two different fading environments have been investigated in terms of the above performance metrics. The performance of the communication system deteriorates under multi-user scenario because of inclusion of interference but the multi-user model represents more realistic scenarios of wireless links. We found that SER and outage probability of multi-user model comparable with single user case under multiple antennas. The analytical results are also verified by simulation with high confidence level.**

Keywords— LTE CRN, relay gain, outage probability, SER and MRC.

I. INTRODUCTION

Cognitive radio network (CRN) technologies have emerged with a handful of potentials to address spectrum scarceness in wireless communication systems [1]. CRN is often termed as *brain-empowered wireless communications* since the underlying technology enables unlicensed users gain control of the underutilized frequency band licensed to other users. However, with minor abuse, CRN has been adopted in long term evolution (LTE) systems, in which the primary users (PUs) can set up direct links with the evolved node B (eNB) but the secondary users (SUs) need one or more PU(s) as intermediary nodes. The SUs' ability to establish links with the home evolved node B (HeNB) directly remains unaffected.

In [1], the secrecy outage performance of a co-operative cognitive radio network is determined under Rayleigh fading channels. The system model in [1] consists of a secondary source, a decode-and-forward (DF) relay, a secondary destination and a passive eavesdropper. The outage probability is determined taking both signal to noise ratio (SNR) and transmission rate as the random variable. The secrecy outage performance is plotted against 'interference to noise power ratio in dB' under maximal ratio combining (MRC) scheme considering both power control and no power control. Similar analysis can be found for single hop links under multiple antenna systems in [2]. In cooperative cognitive radio, the concept of two-hop wireless links has also been introduced. For example, the outage performance of amplify-and-forward (AF) relay with multiple co-channel interference is considered in [3] under Nakagami-*m* fading channels. In [3], the product of fading factor and transmitted power is considered as a random variable following the pdf of Nakagami-*m*. The analytical expressions of outage probability have been derived using both pdf and cdf of Nakagami-*m* along with the end to end SNR. Finally, the outage probability is plotted against the threshold SNR taking the number of interferes in the first and second hops into consideration. It has been shown in [3] that the outage probability increases with increase in both threshold SNR and the number of interferers of any hop, both analytically and through simulations. In co-operative cognitive radio, more energy consumption is unavoidable to ensure accuracy of detection. Hence a tradeoff is desirable between these two parameters. In [4], a new scheme known as the energy-aware optimal relay selection (EAORS) is used, where the number of active relay station is optimized. The authors consider the weighted normalized sum of energy corresponding to transmission and sensing as the objective function. Finally, the variation of weighted energy consumption is plotted against the number of SU relays taking transmission distance, SNR and modulation schemes as parameters.

Another new cooperative CRN is proposed in [5] where primary transmitter (PT) sends message to primary receiver (PR) directly but the secondary transmitter (ST) and receiver (SR) listen to the message. When PR receives the message successfully and send the ACK then ST and SR listen to it and remove the message from buffer. If PR fails to decode the data packet, then SR will decode the data packet and redirect it to ST. If ST is able to decode it then the secondary system (SS)

will work in co-operative mode. The long-term average throughputs (LATs) and outage probability is considered as the key parameters in determining the performance of the network. The combination of above four nodes is found under a different protocol in [6]; where the authors derived closed-form solution of bit error rate (BER) and outage probability for PS and SS. A similar co-operative model has also been considered in [7] under Rayleigh fading channels where two SUs are used in co-operative mode to send the message in secondary destination. Another new concept of co-operative CRN is found in [8]. Several SUs closely located form a mesh connection in a CRN called coalition, used in co-operation mode to enhance throughput of the system. A five-stage algorithm is applied to reduce average probability of false alarm and to increase average throughput. Both performance metrics have been plotted against the number of users and a comparison is made with non-cooperative CRN.

However, all these works deal with the performance of CRN or dual hop wireless links under either SNR, signal to interference (SIR) or signal to interference and noise ratio (SINR) model. To the best of our knowledge, none of these works presents the relative performance of two models together.

In this paper, we analyze the performance of two models in terms of outage probability and symbol error rate (SER) under small scale fading and combining schemes. The impact of the number of antenna elements on combining schemes and two different fading environments (e.g., Chi-square and Nakagami-*m*) have been investigated in terms of the above performance metrics. Extensive simulation results demonstrate that the single user based model shows the best performance as compared with the multi-user model. Changing the modulation scheme, combining scheme and number of antenna elements in the multi-user model can provide comparable results under the single user model.

The rest of this paper is organized as follows. Section II deals with system model of CRN under single and Multi-SU Scenario with the concept of dual hop wireless link with full mathematical and statistical explanations. Section III provides results based on the analyses of section II, and finally, section IV concludes the paper.

II. System Model

We consider a dual-hop LTE CRN network consisting of a macro eNB, home eNBs (i.e., femto BS), PUs and SUs, as shown in Fig. 1. The performance of a traditional CRN depends on the utilization of traffic channels by SUs under the constraints of misdetection and false alarm. In LTE networks, however, the situation is more complicated where the macro and femto cells coexist. Here a SU can communicate with femto BS directly but depends on Pus for communicating with the macro BS, as shown inFig.1. Thus the PUs work as repeaters and the concept of dual-hop wireless links is used to measure the performance of the network. In this paper, we consider three models of the dual hop wireless links to observe the relative performance of LTE networks where PUs help the SUs to reach thee NB of the macro cell. We begin the analysis with the most simplified scenario, in which a single SU communicates with the eNB with the aid of a PU. Then we consider a multi-SU scenario where multiple SUs communicate with the eNB simultaneously. In the multi-SU scenario, each SU experiences interference from other users' transmission. Hence we analyze the performance of SNR based link model for the single SU scenario, and both SINR as well as SIR based models for the multi-SU scenario in the dual-hop LTE CRN links.

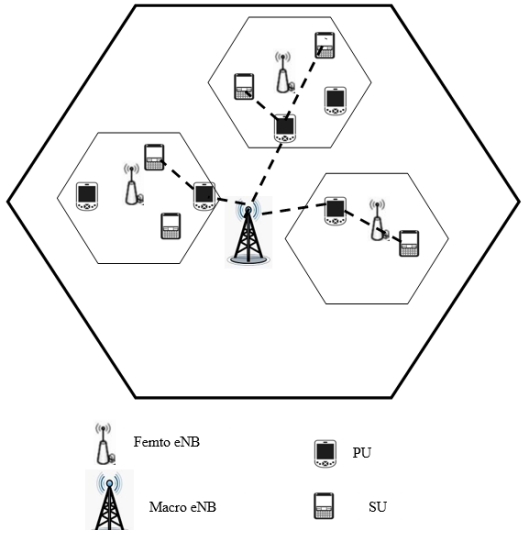

Fig.1. Multi-user model of cognitive radio network

A. SNR Method for the Single SU Scenario

The link between the SU and the macro eNB is established through a PU which acts as a relay. The PU performs an amplify-and-forward (AF) relaying operation for simplicity reasons. Therefore, 2-hop wireless link of AF relaying is applicable in this case. Let us assume that the SU transmits the symbol S to PU; the PU amplifies it by a factor β, and then sends it to eNB. The other parameters involved in this model are defined as:

$S \rightarrow$ Symbol transmitted by the SU,
$P \rightarrow$ Transmit power
$\gamma_1 \rightarrow$ SNR of the link between the SU and the PU,
$d_1 \rightarrow$ Distance between the SU and the PU,
$g_1 \rightarrow$ Path gain between the SU and the PU,
$\gamma_2 \rightarrow$ SNR of the link between the PU and the eNB,
$d_2 \rightarrow$ Distance between the PU and the eNB,
$g_2 \rightarrow$ Path gain between the PU and the eNB.

The signal received at the PU when S is transmitted by the SU can be expressed as [9-10],

$$r_{PU} = \sqrt{Pd_1^{-\varepsilon}}\, g_1 S + n_1; \quad (1)$$

Where P is the SU's transmit power, n_1 is the complex additive white Gaussian noise (AWGN) at the PU, and ε is the path-loss exponent. The PU performs linear operation on the received signal r_{PU} and transmits the amplified signal to the eNB. Thus the received signal at the eNB is given by

$$r_{eN\beta} = \sqrt{Pd_2^{-\varepsilon}}\, g_2 \beta r_{pu} + n_2$$

$$= \sqrt{Pd_2^{-\varepsilon}}\, g_2\beta\left\{\sqrt{Pd_1^{-\varepsilon}}\, g_1 S + n_1\right\} + n_2$$

$$= P\sqrt{(d_1 d_2)^{-\varepsilon}}\, g_1 g_2 S\beta + \sqrt{Pd_2^{-\varepsilon}}\, g_2\beta n_1 + n_2 \quad (2)$$

;where $n_2$is the complex AWGN at the eNB.

Now, the SNR of the link between the SU and the PU is given by

$$\gamma_1 = \frac{\left(\sqrt{Pd_1^{-\varepsilon}}\, g_1\right)^2}{n_1^2} = \frac{Pd_1^{-\varepsilon} g_1^2}{n_1^{/}}; where, n_1^{/} = n_1^2,$$

and the SNR of the link between the PU and the eNB is given by

$$\gamma_2 = \frac{\left(P\sqrt{(d_1 d_2)^{-\varepsilon}}\, g_1 g_2 \beta\right)^2}{n_2^2}$$

$$= \frac{P(d_1 d_2)^{-\varepsilon} g_1^2 g_2^2 \beta^2}{n_2^{/}}; \text{where}, n_2^{/} = n_2^2. \quad (3)$$

Thus the effective SNR experienced by thee NB in the second phase can be expressed as

$$\gamma_{eq} = \frac{\left\{P\sqrt{(d_1 d_2)^{-\varepsilon}}\,(g_1 g_2)\beta\right\}^2}{\left(\sqrt{Pd_2^{-\varepsilon}}\, g_2\beta n_1\right)^2 + n_2^2}$$

$$= \frac{P^2 (d_1 d_2)^{-\varepsilon} g_1^2 g_2^2 \beta^2}{Pd_2^{-\varepsilon} g_2^2 n_1^2 \beta^2 + n_2^2} \quad (4)$$

Rearranging the terms in (4), we obtain

$$\therefore \frac{1}{\gamma_{eq}} = \frac{Pd_2^{-\varepsilon} g_2^2 \beta^2 n_1^{/} + n_2^{/}}{P^2 (d_1 d_2)^{-\varepsilon} g_1^2 g_2^2 \beta^2}$$

$$= \frac{n_1^{/}}{Pd_1^{-\varepsilon} g_1^2} + \frac{n_2^{/}}{P^2 (d_1 d_2)^{-\varepsilon} (g_1 g_2 \beta)^2}$$

$$= \frac{1}{\gamma_1} + \frac{1}{\gamma_2}. \quad (5)$$

Similarly,the effective SNR in the downlink i.e.,eNB to SU link, through the PU as a repeater can be modeled.

B. SINR Method for the Multi-SU Scenario

In this subsection, we analyze the more complicated scenario of multiple SUs communicating with the eNB simultaneously. The actual communication is done in two phases: (i) in the multiple access (MAC) phase, both SU and eNB transmit their symbolsS_1 and S_2, respectively, to the PU, (ii) in the broadcast (BC) phase, the PU amplifies the combined received signal by a factor of β and transmits the amplified signal to the eNB and the SU discussed in [11]. In this case, S_2 creates interference to the SU, while S_1 creates interference to the eNB. Hence the SINR based link model is more appropriate in the context of practical network compared to the SNR model presented in the previous subsection.

In the MAC phase, the received signal at the PU is given by

$$y_{pu} = \sqrt{Pd_1^{-\varepsilon}}\, g_1 S_1 + \sqrt{Pd_2^{-\varepsilon}}\, g_2 S_2 + n_1, \quad (6)$$

Where $n_1$is the complex AWGN at the PU with mean zero and variance σ_p^2. The SNR between SU and PU of the transmitted signal S_1 is given by

$$\gamma_1 = \frac{\left(\sqrt{Pd_1^{-\varepsilon}}\, g_1\right)^2}{n_1^2} = \frac{Pd_1^{-\varepsilon} g_1^2}{n_1^{/}}, n_1' = \sigma_p^2.$$

In the BC phase, the PU broadcasts the amplified signal to both the SU and the eNB. Thus the received signal at the eNB is defined as

$$y_{eN\beta} = \sqrt{Pd_2^{-\varepsilon}}\, g_2 y_{pu}.\beta + n_2$$

$$= \sqrt{Pd_2^{-\varepsilon}}\, g_2\beta\left\{\sqrt{Pd_1^{-\varepsilon}}\, g_1 S_1 + \sqrt{Pd_2^{-\varepsilon}}\, g_2 S_2 + n_1\right\} + n_2$$

$$= P\sqrt{(d_1 d_2)^{-\varepsilon}}\, g_1 g_2 \beta S_1 + Pd_2^{-\varepsilon} g_2^2 \beta S_2 + \sqrt{Pd_2^{-\varepsilon}}\, g_2\beta n_1 + n_2 \quad (7)$$

Wheren_2 is the zero-mean complex AWGNat the eNB with variance σ_e^2. Therefore, the SINR of the transmitted signal S_1 at thee NB is given by

$$\gamma_{eNB} = \frac{\left(P\sqrt{(d_1 d_2)^{-\varepsilon}} g_1 g_2 \beta\right)^2}{(Pd_2^{-\varepsilon} g_2^2 \beta)^2 + \left(\sqrt{d_2^{-\varepsilon}} g_2 \beta \sigma_p\right)^2 + n_1'}$$

$$= \frac{P^2 (d_1 d_2)^{-\varepsilon} g_1^2 g_2^2 \beta^2}{P^2 d_2^{-2\varepsilon} g_2^4 \beta^2 + Pd_2^{-\varepsilon} g_2^2 \beta^2 n_1^{/} + n_2^{/}}, \quad (8)$$

Where$n_2' = \sigma_e^2$. Rearranging the terms in (8), we have

$$\therefore \frac{1}{\gamma_{eN\beta}} = \frac{P^2 d_2^{-2\varepsilon} g_2^4 \beta^2 + Pd_2^{-\varepsilon} g_2^2 \beta^2 n_1^{/} + n_2^{/}}{P^2 (d_1 d_2)^{-\varepsilon} g_1^2 g_2^2 \beta^2}$$

$$= \frac{d_2^{-\varepsilon} g_2^2}{d_1^{-\varepsilon} g_1^2} + \frac{n_1^{/}}{Pd_1^{-\varepsilon} g_1^2} + \frac{n_2^{/}}{P^2 (d_1 d_2)^{-\varepsilon} (g_1 g_2 \beta)^2}$$

$$= \left\{\left(\frac{d_2}{d_1}\right)^{-\varepsilon}\left(\frac{g_2}{g_1}\right)^2\right\} + \frac{1}{\gamma_1} + \frac{1}{\gamma_2}$$

$$= \frac{1}{\gamma_I} + \left(\frac{1}{\gamma_1} + \frac{1}{\gamma_2}\right)$$

$$= \frac{1}{\gamma_I} + \frac{1}{\gamma_{eq}}, \quad (9)$$

,where $\gamma_I \triangleq \left(\frac{d_2}{d_1}\right)^{\varepsilon}\left(\frac{g_2}{g_1}\right)^{-2}$. It can be clearly seen from (9) that the effective end-to-end link experiences an additional drop in SNR due to the amplification of the interference at the relay node (i.e., PU).Note that we consider a flat fading channel environment in this paper so that the combined equivalent SINR can be considered as a random variable. Let us now assume that for successful decoding at the receiving end, the required SINR threshold is $\gamma_{t\square}$. Thus we have

$$\gamma_{eq} = \frac{\gamma_1 \gamma_2}{\gamma_1 + \gamma_2 + c} \geq \gamma_{th}$$

$$\Rightarrow \gamma_1 \geq \frac{\gamma_{th}(\gamma_2 + c)}{\gamma_2 - \gamma_{th}}$$

,

Where c is a random variable that represents the combined SINR. Accordingly, the probability density function (PDF) of γ_{eq} is given by

$$f_{\Gamma_{eq}}(\gamma_{th}) = \int_{\gamma_{th}}^{\infty} \frac{d}{d\gamma_{th}} \left\{ \frac{\gamma_{th}(\gamma_2 + c)}{\gamma_2 - \gamma_{th}} \right\} f_{\Gamma_1}\left(\frac{\gamma_{th}(\gamma_2 + c)}{\gamma_2 - \gamma_{th}} \right) f_{\Gamma_2}(\gamma_2)\, d\gamma_2$$
$$= \int_{\gamma_{th}}^{\infty} \frac{\gamma_{th}(\gamma_2 + c)}{(\gamma_2 - \gamma_{th})^2} f_{\Gamma_1}\left(\frac{\gamma_{th}(\gamma_2 + c)}{\gamma_2 - \gamma_{th}} \right) f_{\Gamma_2}(\gamma_2)\, d\gamma_2 \quad (10)$$

and the cumulative distribution function (CDF) of γ_{eq} can be derived as

$$F_{\Gamma_{eq}}(\gamma_{th}) = 1 - \int_{\gamma_{th}}^{\infty} \left\{ 1 - F_{\Gamma_1}\left(\frac{\gamma_{th}(\gamma_2 + c)}{\gamma_2 - \gamma_{th}} \right) \right\} f_{\Gamma_2}(\gamma_2)\, d\gamma_2 . \quad (11)$$

Now the SINR outage probability of the link is defined as

$$P_{out}(\gamma_{th}) = 1 - F_{\Gamma_{eq}}(\gamma_{th}) \quad (12)$$

In this paper, the combined SINR is considered as a random variable that follows Rayleigh and Chi-square distribution with v degree of freedom.

C. Combining Scheme

In CRN, several MSs can be used as repeaters to achieve diversity gain. While diversity is a powerful technique to overcome the effects of flat fading by combining multiple independent fading paths, diversity typically entails some penalty in terms of rate, bandwidth, complexity, or size. In practice, both selection combining (SC) and MRC significantly reduce the impact of fading. However, both SC and MRC offer different levels of performance against complexity. The concept of virtual MIMO with combining schemes can be used at the receiving end for multi-user systems. In this section, we consider the SC and MRC schemes under the virtual MIMO setup.

Under SC, we aim at deriving the cdf,
$\gamma_{sc} = \max(\gamma_1, \gamma_2, \gamma_3, \cdots, \gamma_N)$,
where $\gamma_1, \gamma_2, \gamma_3, \ldots, \gamma_N$ are the SNR provided by repeater 1, 2, 3, …, N, respectively.
The probability,

$$P(\gamma_i \le \tau) = \int_{-\infty}^{\tau} f_{\Gamma_i}(\gamma_i) d\gamma_i = \Psi_i(\tau). \quad (13)$$

Therefore,

$$P(\gamma_1, \gamma_2, \gamma_3, \ldots, \gamma_N \le \tau) = \prod_{i=1}^{N} P(\gamma_i \le \tau) = \prod_{i=1}^{N} \Psi_i(\tau).$$

Thus the cdf of γ_{sc} is defined as

$$F_{\Gamma_{sc}}(\gamma_{sc}) = \prod_{i=1}^{N} \Psi_i(\gamma_{sc}). \quad (14)$$

Under the MRC scheme, we can use upper bound of SNR of dual hop link as considered in [12-13]. Accordingly, the received SNR at the i-th node is defined as

$$\gamma_i = \frac{\gamma_{SR_i}\gamma_{RD_i}}{\gamma_{SR_i} + \gamma_{RD_i}} \le \min(\gamma_{SR_i}, \gamma_{RD_i}) = \gamma_{u_i} \quad (15)$$

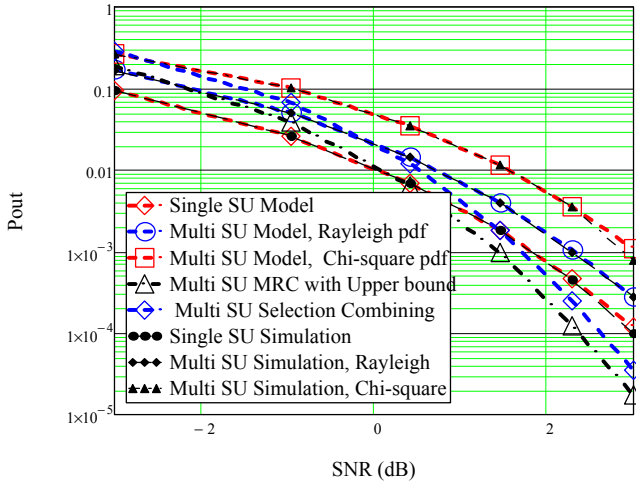
where γ_{u_i} is the upper band of the end-to-end SNR of i-th relayed link.
Therefore, the combined SNR of the virtual MIMO system $\gamma_{mrc} = \sum_{k=1}^{N} \gamma_{uk}$ is the random variable with Chi-square pdf with N degree of freedom such that

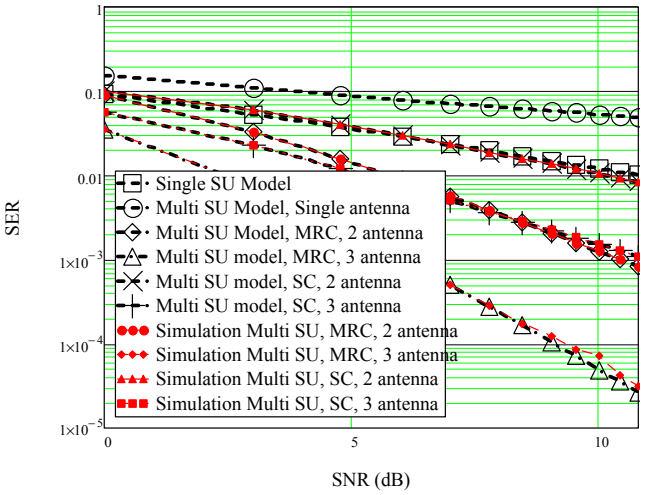
$$f_{\Gamma_{mrc}}(\gamma_{mrc}) = \frac{1}{(N-1)!} \frac{\gamma_{mrc}^{N-1}}{\gamma_{av}^{N}} \exp\left(-\frac{\gamma_{mrc}}{\gamma_{av}} \right), \quad (16)$$

;where γ_{av} is the average value of γ_{mrc}.

III. Results

In this section, we evaluate the performance of the proposed analytical results through numerical simulations.





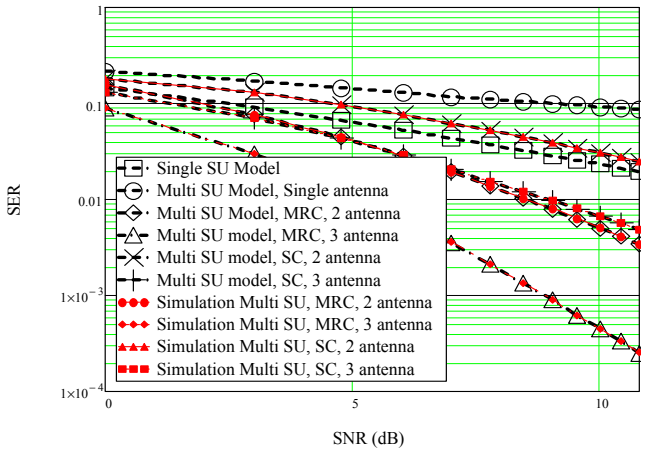


Fig.2. Comparison of outage probability of analytical and simulation work.

Here, we consider two antenna elements at the receiving end for both MRC and SC schemes under Rayleigh fading environment. Fig.2 shows the variation of outage probability against instantaneous SNR of the received signals for five different cases. Results in Fig. 2 reveal that the single user model yields the better performance at low SNR since the model ignores the interferences. However, as the SNR increases beyond 0.1dB, the MRC under multi-user case (upper bound) becomes comparable with this model. On the other hand, the performance of the SC scheme seems a little bit worse than that of the MRC scheme, but better than the other two fading models. The performance of the Chi-square pdf case depends on the degree of freedom v. For v = 2, the Rayleigh and Chi-square fading become comparable under multi-user model but for larger value of v the performance of the Chi-square fading environment deteriorates heavily. In this paper we use Monte

Carlo simulation generating 10^6 random variable of Rayleigh and Chi-Square distribution to evaluate outage probability. The analytical and simulation results are found very closed.

(a) QPSK modulation

(b) 16-QAM modulation

Fig.3. Comparison of SER for different modulation schemes.

Finally, Fig.3(a) and 3(b) show the SER performance of the models against SNR in dB for QPSK and 16-QAM modulation schemes, respectively. Similar to the previous figures of this section, the performance of the single user case is better than the multi-user case, provided SC and MRC schemes (multi-user case model) show better performance than single user case when the number of antenna elements $N = 3$. If the relative performance of SC and MRC are compared for the same number of antenna elements, the MRC performs far better than the SC under the multi-user model as visualized in Fig.3.

IV. Conclusions

Recent literature deals with performance of CRN or dual hop wireless links under either SNR or SINR model. This paper presents the relative performance of both models in a simpler manner. The SINR model or multi user case represents the real-life scenario of wireless link between the two models considered in the paper, and provides desired results using adaptive modulation schemes and combining schemes of LTE. Here we consider Rayleigh and Chi-square pdf random variables in both hops of a dual-hop link. The dissimilar fading models, for example, the first hop under Rayleigh fading and the second hop under Nakagami-*m* fading, can also be used in future to get the scenario of dense urban areas.

***Abstract*— In this paper we determine the performance of a co-operative Cognitive Radio Network (CRN) under Additive White Gaussian Noise (AWGN). The impact of the number of received samples on probability of detection (P_D) and false alarm (P_{FA}) are shown graphically to determine the optimum number of samples for perfect detection. Next we show the impact of number of SUs under FC on the performance of co-operative CRN and determine the optimum value of threshold signal to noise ratio (SNR) at FC to combat the effect of PUEA. Analytical results are verified by simulation and found confidence level above 99%.**

Keywords—false alarm, misdetection, NP theorem, threshold SNR, FC

I. INTRODUCTION

This In MAN (Metropolitan Area Network) or WAN (Wide Area Network) limited number of channels are allocated to a huge number of users. The channel allocation is done using MAC sub-layer. Sometimes all channels are found busy but most of the time few channels are found idle or unused. In conventional mobile cellular network, there is no explanation about these unused channel. CRN gives the real explanation of these unused channel. Several works are done on CRN and few of them are mentioned in this paper. In [1] the analytical and simulation results of probability of detection and false alarm of a co-operative cognitive radio network are compared under both AWGN and Rayleigh fading environment. The research work of [2] extends the performance of a CRN using the combination of membership functions of SNR, SIR (signal to interference ratio) and SINR (signal to noise plus interference ratio) which improves the detection hypothesis at the expense of process time and complexity of Fuzzy model. Authors of [3], revealed the threshold gain of the adaptive beam former along the line of sight (LOS) between the transmitter and the receiver. The paper [4], introduces a new CSS scheme in the presence of a malicious PUEA based on multi-level hypothesis testing (MLHT),generalizing from binary hypothesis testing to MLHT, they partition the decision space to four decision options and apply minimum Bayes cost criteria to determine the channel status. The Simulation results are provided to indicate the performance improvement of the proposed MLHT method against PUEA, compared with the conventional method. The research work of [5] states the issue of delay caused by a band-selection decision process that directly affects the security and performance. The model cluster-based distributed cooperative spectrum sensing is proposed here that cluster heads (CHs) exchange control information with other CHs and ordinary nodes, significantly reduced the delay, sensing, convergence, routing, in band-selection process. The simulated results show the improved performance of cognitive radio networks in terms of delay, packet loss ratio and bandwidth usage as compared to cluster-based cooperative spectrum sensing model. The opportunity for primary user emulation attacker is minimized as the overall delay is reduced. According to the concept of [6], a proposed algorithm is projected to distinguish primary user signal from others, through an energy-efficient localization mechanism and channel parameter variance, which is simulated in MATLAB environment and it is found to be an effective mechanism to authenticate primary user and mitigate the primary user emulation attack. As explained in [7], a detection method according to the characteristics of wireless channel. Using the multipath delay characteristics of the fading channels, PUEA can be detected by the secondary users (SUs). Simulation results illustrate that the proposed PUEA detection method achieves high detection probability in terms of low false positive probability. Authors of [8] stated an adaptive and realistic PUE attack detection technique is proposed in this paper inspired by the physical features widely used as the fingerprint of variant electronic devices. It leverages the PU transmission features that attackers are not able to mimic. In this work, the transmission power is selected as one of the hard-to-mimic features due to the intrinsic discrepancy between PUs and attackers, while considering constraints in real implementations. Their experimental results verified the effectiveness and correctness of the proposed mechanism. Authors in [9] propose a PUEA detection method that exploits the radio channel information to detect the PUEA in the cognitive radio network. In the proposed method, the uniqueness of the channel impulse response (CIR) between the secondary user (SU) and the signal source is used to determine whether the received signal is transmitted by the primary user (PU) or the primary user emulator (PUE). Numerical results show that the proposed PUEA detection method performs well although the difference in channel characteristics between the PU and PUE is small. The research work of [10] provides a survey for resource allocation in underlay CRNs as for conventional wireless networks, the main target of resource allocation (RA) is to efficiently utilize the available resources that lead to spectrum under-utilization, and in this regard cognitive radio networks (CRNs) have received great attention due to their potential to improve the spectrum utilization. Finally [11] introduces cognitive radio network in order to dynamic the spectrum therefore to increase the spectrum efficiency, decreasing costs and increasing number of wireless users, cognitive radio network solved bad utilizations and in advance it improved more characteristics for the spectrum. For large value of degree of freedom, the Chi-square pdf becomes Gaussian pdf, which makes the analysis of CRN easier. Above concept motivates us to work in this paper. In this paper, our main contribution is to estimate the threshold SNR at FC to make the probability of false alarm and misdetection below 4% at the same time to ensure the probability of detection above 96%. Finally the probability of PUEA is also

dropped below 4% under fine tuning of threshold SNR both analytically and simulation.

The rest of paper is organized like: section II provides basic theory and statistical analysis of detection of presence or absence of PU, section III gives analytical and simulation results based on analysis of section II and finally, section IV concludes entire analysis.

II. SYSTEM MODEL

A. Basic of two Hypothesis model

The received signal of the SU on a traffic channel, $x(n)$, is expressed under two hypothesis model like,

$$x(n) = \begin{cases} w(n) & ; H_0 \\ s(n) + w(n) & ; H_1 \end{cases} \quad (1)$$

where $w(n)$ is additive white Gaussian noise (AWGN), H_0 is the hypothesis of the absence of PU signal and H_1 denotes the hypothesis of the presence of the PU signal. To determine the detection performance we first note that the test statistics $T(x)$ as,

$T(x) = \left(\frac{1}{N}\right)\sum_{n=0}^{N-1} x[n]$; is Gaussian under each hypothesis. The means of the $T(x)$ is,

$$E(T(x); H_0) = E\left(\frac{1}{N}\sum_{n=0}^{N-1} w[n]\right)=0 \quad (2)$$

Similarly, $E(T(x);H_1)= A$ for hypothesis H_1

The variance of test statistics,

$$var(T(x); H_0) = var\left(\frac{1}{N}\sum_{n=0}^{N-1} w[n] \; ; H_0\right)$$

$$= \frac{\sigma^2}{N}$$

$$= var(T(x); H_1) \quad (3)$$

Therefore, $$T(x) \sim \begin{cases} N\left(0, \frac{\sigma^2}{N}\right) \text{under} H_0 \\ N\left(A, \frac{\sigma^2}{N}\right) \text{under} H_1 \end{cases} \quad (4)$$

We have the probability of false alarm as,

$$P_F = P_r\{T(x) > \gamma \; ; H_0\} = Q\left(\frac{\gamma}{\sqrt{\sigma^2/N}}\right) \quad (5)$$

Next the probability of detection becomes,

$$P_D = P_r\{T(X) > \gamma \; ; H_1\} = \frac{1}{\sqrt{2\pi}} Q\left(\frac{\gamma - A}{\sqrt{\sigma^2/_N}}\right) \quad (6)$$

The relation between P_F and P_D is expressed as,

$$P_D = Q\left(Q^{-1}(P_{FA}) - \sqrt{\frac{NA^2}{\sigma^2}}\right) \quad (7)$$

B. Co-operative spectrum sensing

To improve the detection accuracy the received signal, several SUs are combined at FC to take the decision about presence of PU like fig.1. Fusion rule may be AND logic, OR logic, MRC scheme etc. If N SUs send the signal to FC; where each SU sends M samples then the number of samples received at FC is MN. In energy detection, the detection random variable becomes, , follows Chi-square pdf. When

$$Y = \sum_{k=1}^{MN} |x(k)|^2$$

MN is large enough then Chi-square pdf approximated by Gaussian pdf. If each sample $x(n)$ follows $N(0, 1)$ then mean and variance of Y is found in [4].

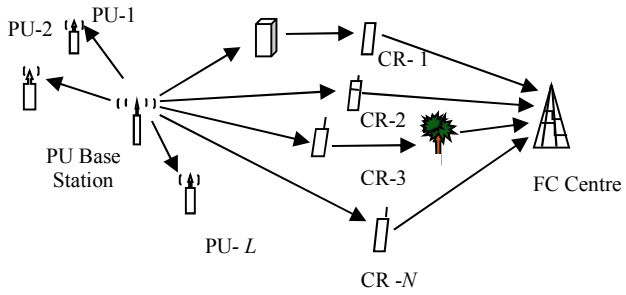

Fig. 1. Cooperative spectrum sensing

C. Co-operative spectrum sensing

PUEA presents a serious threat on the performance of CRN; which actually imitate the PUs to confuse the SUs. The real scenario of PUEA is shown in fig.2 can be expressed with three hypothesis model like,

$$Y \sim \begin{cases} H_0 : only\ noise \\ H_1 : PU + noise \\ H_2 : PUEA + noise \end{cases} \quad (8)$$

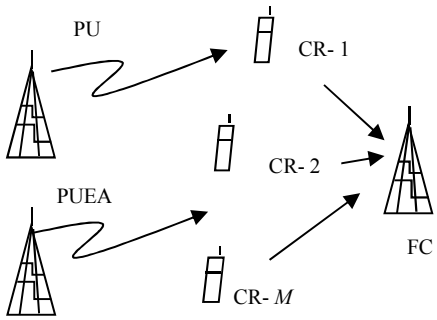

Fig. 2. Primary user emulation attack in cognitive radio networks

The PUE attackers or malicious user creates signals of similar power of PU, hence in energy detection technique it is difficult to recognize a PUE attacker. In feature-based detectors the attacker will emulate the corresponding feature of the PU but dynamic change of feature can be a remedial measure, which is beyond the scope of the paper.

D. Simulation algorithm

This subsection provides Monte Carlo simulation in determining P_f and P_D. The steps of algorithm are:

1. Input variables under H_0: $N\rightarrow$ number of users under FC, $M\rightarrow$ number of samples/symbol, $m\rightarrow$ number of random variable in simulation, $n\rightarrow$ length of random variable to take average, $T\rightarrow$ average of n random variable, $\mu_0 = MN\rightarrow$ the mean of T, $\sigma_0^2 = 2MN\rightarrow$ variance of T, $\gamma\rightarrow$ SNR, $\gamma_{max}\rightarrow$ maximum SNR.
2. Take an array of length m with initial value of each elements 0, as T = zeros(m,1);
3. Generate n random number with normal pdf of mean μ_0 and variance of σ^2 :
   x = sqrt (σ^2)*randn(n,1)+μ_0 and take mean of x.

4. Repeat step 3,m times and store the mean of x each time in an array T like:

for i = 1:m
{
$x = sqrt(\sigma^2)*randn(n,1) + \mu 0$
T (i) = mean (x);
}

5. Select the range of SNR, γ as γ = *0 : interval:* γ_{max};Find the number of elements of the array T greater than $\gamma(i)$ for each value of SNR,$\gamma(i)$ designated as:γ_{num}; The probability of false alarm under simulation is the ratio of length of γ_{num} and m.

for i =1: length (gamma)
{
γ_{num} = *find (T>gamma (i));*
PFA_sim(i) = length (γ_{num})*/m;*
}

6. Evaluate the analytical probability of false alarm, $PFA_th = 0.5*\text{erfc}((\gamma-\mu_0)/(\text{sqrt}(2*\sigma_0^2/n)))$;
7. Under hypothesis H_1 the variables are:The mean SNR$\rightarrow \bar{\gamma}$, $\mu_1 = MN(\bar{\gamma}+1)$, $\sigma_1^2 = 2NM(\bar{\gamma}+1)^2$. Repeat step 1 to 5 under the variables of hypothesis H_1 and determine the probability of detection from step 5.
8. Evaluate the analytical probability of detection, $PD_th = 0.5*\text{erfc}((\gamma-\mu_1)/(\text{sqrt}(2*\sigma_1^2/n)))$;
9. Under hypothesis H_2 the variables are: The mean SNR$\rightarrow \bar{\lambda}$, $\mu_2 = MN(\bar{\lambda}, +1)$, $\sigma_2^2 = 2NM(\bar{\lambda}, +1)^2$.
10. Repeat step 1 to 5 under the variables of hypothesis H_2 and determine the probability of detection from step 5.
11. Evaluate the analytical probability of detection, $PD_th = 0.5*\text{erfc}((\gamma-\mu_2)/(\text{sqrt}(2*\sigma_{12}^2/n)))$;

III. RESULTS

First of all we plot the probability of false alarm against threshold SNR in dB (normalized with respect to μ_0) taking the number of samples as a parameter. The P_f decreases with increase in threshold SNR and attains to 0 at -1dB or above. The decrement of P_f occurs at higher value SNR for larger number of samples. Fig.3 shows the graphs for M = 10, 15, 20 and 25 samples. Similar analysis is shown in Fig.4 for the case of probability of misdetection (P_{md}). The increment of P_{md} is found at larger value of threshold SNR. Comparing fig.3 and 4 we found that taking threshold SNR/μ_0 within 0 to 5 dB we can ensure both P_f and P_{md} below 5% only for M>20. A tradeoff is necessary between proper detection (or spectrum sensing) of signal and the number of samples (related to process time).The results of fig.3 and 4 are for non-co-operative spectrum sensing case.

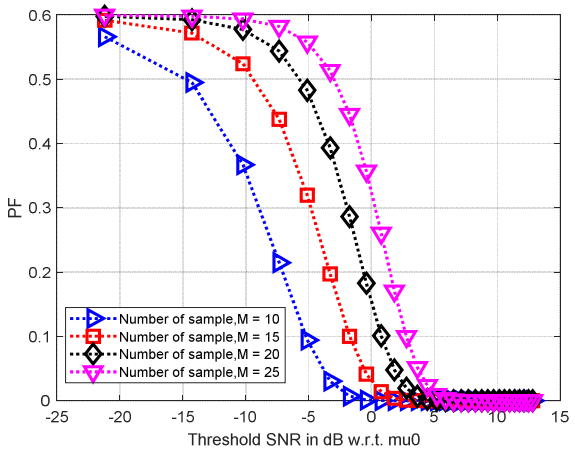

Fig. 3. Variation of probability of false alarm against the threshold SNR in dB

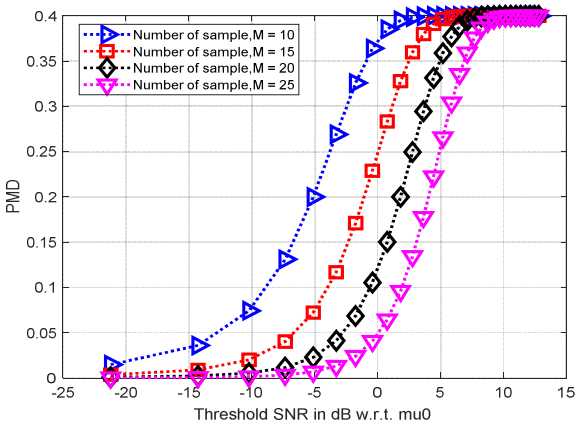

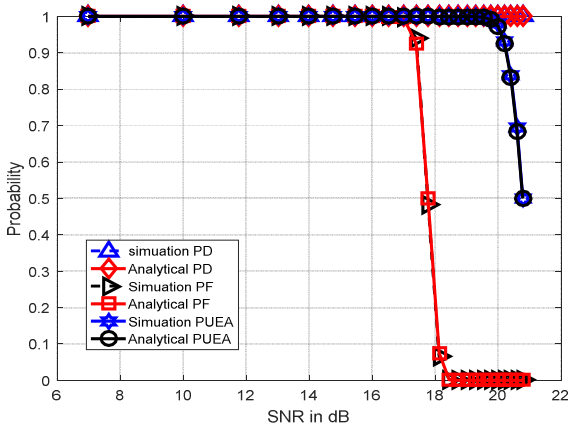

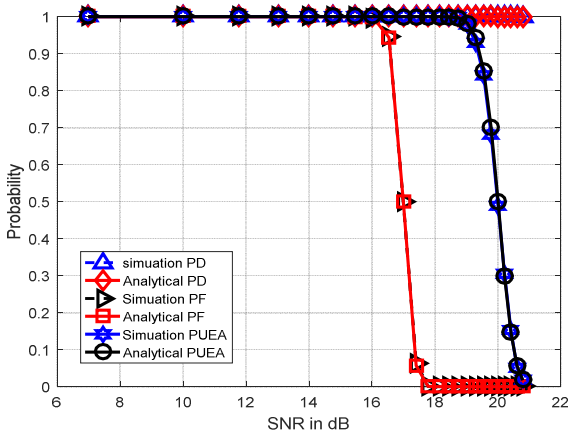

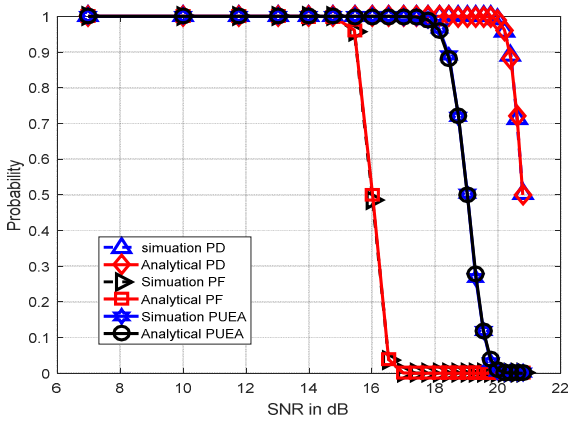

Fig. 4. Variation of probability of misdetection against the threshold SNR in dB

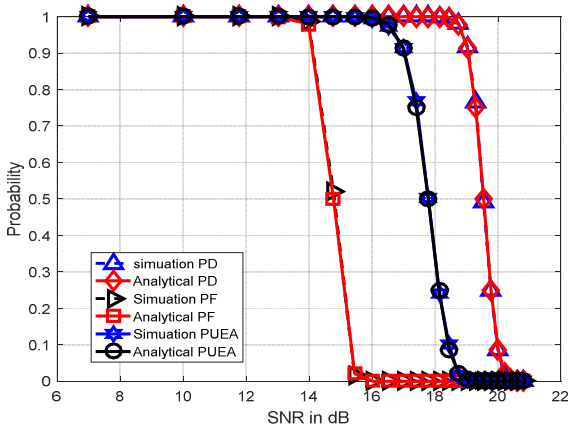
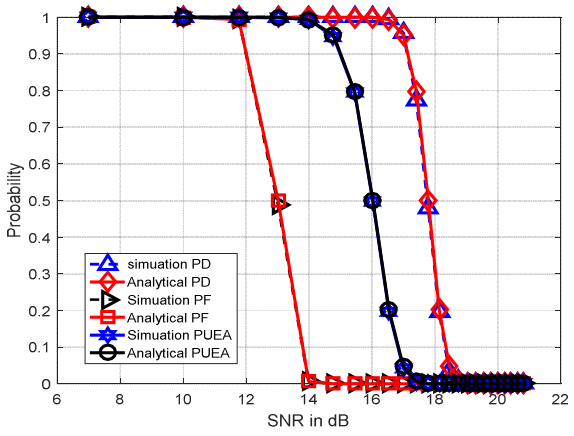
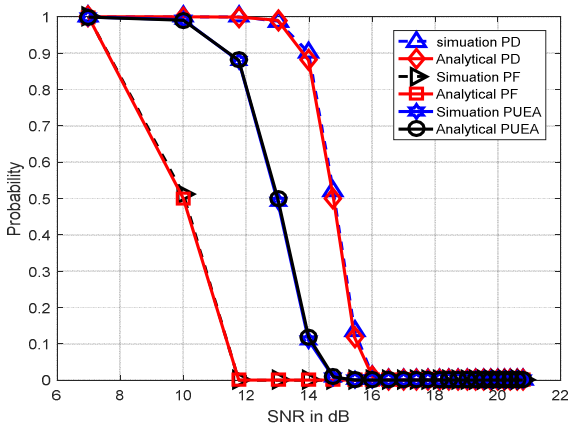


(a) $N = 6$



(b) $N = 5$



(c) $N = 4$

(d) $N = 3$

(e) $N = 2$

(f) $N = 1$

Fig. 5. Impact of users under a FC with PUEA

Next part of the result section deals with co-operative spectrum sensing case. A large number of co-operative SU under a FC improves the SNR at FC to take the correct decision. Fig. 5 (a) – (f), shows the comparison of analytical and simulation results under three hypothesis model: H_0 (no user), H_1 (only PU), H_2 (only P_{UEA}). Each figure provides three pairs of graph on P_D, P_F and P_{PUEA} under both analytical and simulation cases. Our simulation provides very closed results with that of analytical (the confidence level is above 98%). Because of power consumption, the presence of attacker will be small even transmitting power is also smaller compared to PU. Here we assume $P(H_3) = 0.2$ and $P_{PUEA} = P(H_3).P\{\gamma \geq \gamma_{th}\}$.The relation among the number of users N under FC, P_{PUEA} and threshold SNR is shown in table I. Both the simulation and analytical result reveals that P_D is very closed to 100% and P_F to 0% for $N > 4$.

TABLE I. IMPACT OF SUs ON CO-OPERATIVE CRN

Number of SU under FC (N)	Threshold SNR (γ_{th}) in dB	P_{FA} in %	P_D in %	P_{PUEA} in %
1	14.2	1.4	96.3	8
2	16.8	0.68	98.6	2
3	18.4	0	99.2	1.2
4	19.6	9	100	0.5
5	21.3	0	100	0
6	22.4	0	100	0

When both PUEA and PU exist simultaneously then $\gamma >> \gamma_{th}$ and SU can easily recognize the occupancy of the traffic channel, therefore we ignore the fourth hypothesis of [4].

IV. CONCLUSION

In this paper we evaluated performance of CRN based on probability of detection, probability of primary user emulation attack and that of false alarm varying threshold SNR. We determine the appropriate threshold SNR to maintain P_f below 4% and P_d above 96% under both non-cooperative and cooperative CRN. In future we will evaluate the performance of the same network under different types of small scale fading environment instead of awgn case. Even the concept of PUEA under four hypothesis model can be analyzed under Chi-square pdf.

***Abstract*— Ethernet passive optical network (EPON) offers large bandwidth that requires less power consumption. The EPON systems require dynamic bandwidth allocation (DBA) algorithm to share a medium for different users with fairness and quality of services. In energy efficient DBA (EE-DBA) algorithm, the optical network units (ONUs) enter the power saving mode in lower traffic condition. However, the main limitation of the existing EE-DBA algorithm is that it requires to keep optical line terminal (OLT) in active state for all the time. That is why some energy is wasted in the OLT side. For mitigating the excess energy consumption by the OLT, we propose a sleep-based DBA (SB-DBA) algorithm for EPON system. In the SB-DBA scheme, both the OLT and ONUs enter into the power-saving mode for reducing overall energy consumption in the network. Simulations are used to evaluate the performance of the SB-DBA scheme. Comparative analysis of simulated results proves that the energy consumption of the proposed SB-DBA scheme is less than the existing EE-DBA scheme with similar end-to-end packet delay.**

Keywords— SB-DBA, EE-DBA, power-saving mode, energy efficiency.

I. INTRODUCTION

Ethernet passive optical network (EPON) is one of the promising access network architecture that can effectively reduce the energy consumption. The EPON system has three major components, namely optical line terminal (OLT) which forms the base station, optical network units (ONUs) perform as the terminating unit of the network, and the optical splitter which splits the downstream optical signal into multiple ONUs.

The energy savings for EPON is sub categorized into two classes; such as energy savings for OLT and energy savings for ONUs. In the energy savings for ONUs category, each ONU is entered into the power savings mode when there is no data packet to transmit. In the energy savings for OLT category, the OLT is entered into the power savings mode when there is no data packet to receive. Actually, power saving method in EPON depends on the availability of upstream and downstream data traffic [1]. In the EPON systems, based on the principle of multi-point control protocol (MPCP) the OLT knows the time of data transmission for ONUs. This paper uses the predefined time slot of each ONU and then additional sleep control signal is not required.

In reference [2], a new green bandwidth allocation (GBA) framework has been introduced where hybrid sleep mode for ONUs and batch mode transmissions for the OLT and ONUs are used. The sleep mode for ONU is determined emerged on the maximum delay whereas in batch mode transmission, the ONU can reduce the overhead time during the switching. A batch mode transmission at the ONUs and OLT is still the outlay of the Quality of Service (QoS) losses due to packet delay. To overcome this problem, a new analytical model has been presented in [3], in which the downstream packet delay is analyzed at the ONU sleep time by considering the limited service discipline with the overlapped time window in upstream transmission.

In an analytical model, the ONU receiver running speed and the expended energy is not sufficient condensed. To overcome this problem in reference [4], the authors studied the downstream burst transmission (DBT) for energy saving.. So, the receiver data processing follows the on and off control. The pre-scheduled data is arrived in the downstream buffer because it enters the power on mode. The downstream data packets are destined for other ONUs by entering the power off mode. In a sleep-controlled rule, the handshaking between the OLT and ONUs is involved. In reference [5], a sleep-controlled rule using semi-Markov chain method has been proposed. This proposed scheme doesn't necessitate the handshaking to attain high energy savings efficiency and high bandwidth utilization. However, the absent of downstream data traffic is detected for ONU in the scheduling cycle followed by the ONUs into sleep mode.

In a sleep-controlled rule, the semi-Markov chain model for the receiving ONU is defined only in the downstream traffic whereas any downstream traffic is not lost because of ONU's sleep time. A sleep-aware dynamic bandwidth allocation (SDBA) algorithm for maximizing energy efficiency has been proposed in reference [6]. Here, reflecting the multiplication of the polling cycle as much as possible for enlarging the ONU sleep time. The ONU is allowed for sleep for allocating the enough bandwidth to transmit traffic.

In a minimum sleeping period of an ONU, to decrease the contrary effects of frequent mode switching a sleep mode aware (SWA) algorithm has been proposed which consists of two kinds of ONUs such as legacy ONUs (L-ONUs) and next generation ONUs (NG-ONUs). The L-ONUs are assigned for

large sleep overheads and the NG-ONUs are employed for small sleep overheads. This algorithm also uses a novel sleep period prediction scheme. As a result of frequent switching process, the ONUs cannot have plenty sleep time and the energy efficiency is narrowed even under light traffic loads. To exceed this problem in [7], the authors signified the energy efficiency dynamic bandwidth allocation (EE-DBA) algorithm. In this scheme, two predefined sleep times are used such as maximum and minimum sleep times. The maximum sleep time is calculated for OLT when the accumulated packet and delay can assure the shortcoming of buffer status and end-to-end packet delay. The power saving mode is not allowed for ONUs when there is no sleep time.

In the EE-DBA scheme, the OLT always stays at the active mode rather than considering if there exist any Report message or not, consequence into the devour of power of OLT at all the time. To overcome this problem, in this paper, we propose a sleep-based DBA (SB-DBA) algorithm for the EPON systems. In the proposed SB-DBA scheme, we use sleep time for both OLT and ONUs based on the upstream and downstream data traffic. So, both the ONUs and OLT can reach the power saving mode simultaneously for minimizing the energy consumption of the EPON systems. A ONU steps into the power saving mode when there are no data packets in the buffers of that ONU. Similarly, the OLT also steps into the power saving mode when there is no Report message from an ONU. Performances of the proposed SB-DBA scheme are evaluated in terms of total energy consumption and energy savings ratio by numerical simulation. The simulation results confirm that the performance of the proposed SB-DBA scheme outperforms the existing EE-DBA scheme.

The paper organization is as follows. Section 2 explains the principle of the proposed SB-DBA scheme. Section 3 presents the performance analysis for numerical simulation. In section 4 and 5, the simulation results are explained and concluded the paper, respectively.

II. Principles of the Proposed SB-DBA Schemes

In this section, we 1st we explain about the principle of the existing EE-DBA scheme then the principle of the proposed SB-DBA scheme. Fig. 1 shows a basic network architecture of EPON system where *N* ONUs and single OLT are connected through a passive splitter in tree topology.

A. Proposed SB- DBA algorithm

In the existing EE-DBA scheme [8], the OLT is always in awake mode whether there is Report message or not from the ONUs to receive. Such continuous active state of the OLT leads to the misuse of power which is the major drawback of

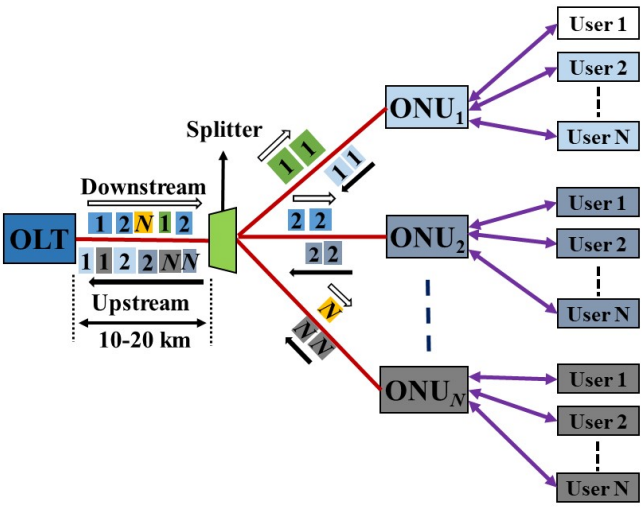

Fig. 1. Tree based EPON architecture.

the existing EE-DBA scheme. For solving such problem, in the proposed SB-DBA scheme, we encourage the OLT to enter into power savings mode in addition to the ONUs.

Figure 2 shows the data transmission scenario of the proposed SB-DBA scheme using two ONUs and single OLT. Based on the DBA principle the packet distributions in the Figure prove that the downstream and upstream transmissions

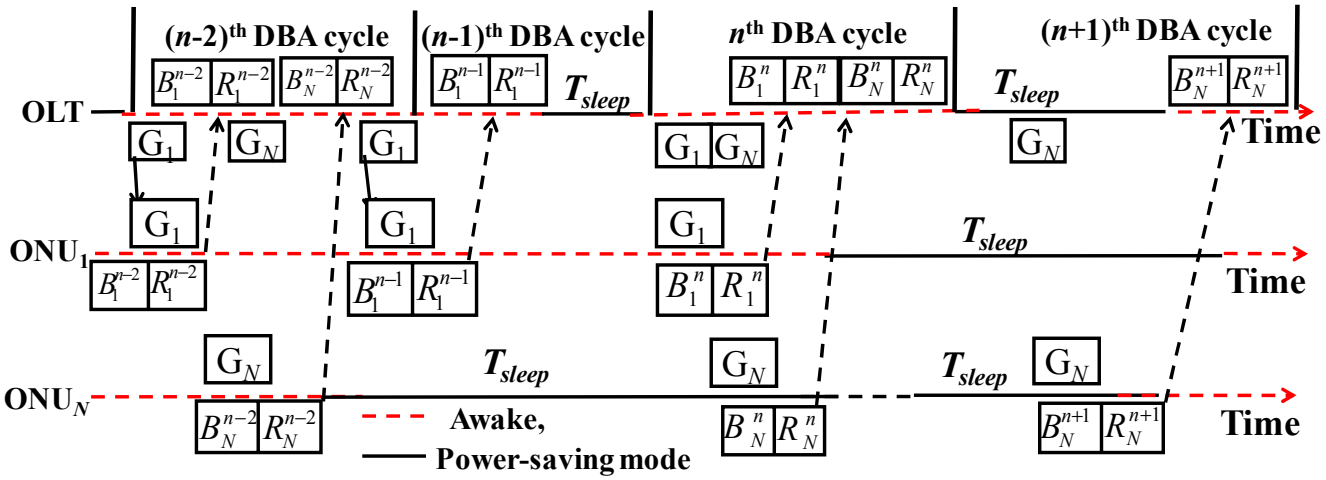

Fig. 2. Illustration of awake and power saving modes of the proposed SB-DBA scheme.

have no fixed bandwidth. Here, ONUs transmit the Report message to the OLT and the OLT checks the circumstance and delivers Gate messages to the ONUs and receives the upstream data packets. So, an ONU enters into the awake mode if it has data packets in the buffer. In contrast, the ONU ignites the power saving mode if there is no data packet in the buffer. From the Fig. 2, it is clear that the OLT may receive the data packet from the two ONUs or one ONU or none of the ONUs. If the OLT receives the data packet from both the ONUs, then the OLT remains in fully awake mode this case is illustrated in the $(n\text{-}2)^{th}$ DBA cycle of the Fig. 2. If the OLT receives the data packets from one ONU, then the OLT does not remain in awake mode for whole the DBA cycle. In this condition, sometime the OLT is in awake mode and sometime in power saving mode. If the OLT does not receive any Report message from both the ONUs, then the OLT conforms into fully power saving mode.

B. Methodology of the Proposed SB-DBA Scheme

Figure 3 shows the flowchart of the proposed SB-DBA algorithm. In the initial phase of individual DBA cycle, OLT checks the current buffer status of all the ONUs based on the received Report messages. If the condition $W_R = W_{max}$, where, W_R is the requested window size of an ONU in a time cycle, and W_{max} is the maximum window size of an ONU, is satisfied, then the ONU is fully awake mode and so the OLT also remains in awake mode because the ONU transmits the data packets and the OLT has to receive those data packets. In this condition, awaken time period for the ONUs and OLT are calculated using the following equation.

$$Awake\ \ time\ = \frac{W_R}{W_{\max}} \times 100\ \% \tag{1}$$

If the ONU has no data packet in the buffer, then it remains in sleep mode and the OLT also enters into the power saving mode.

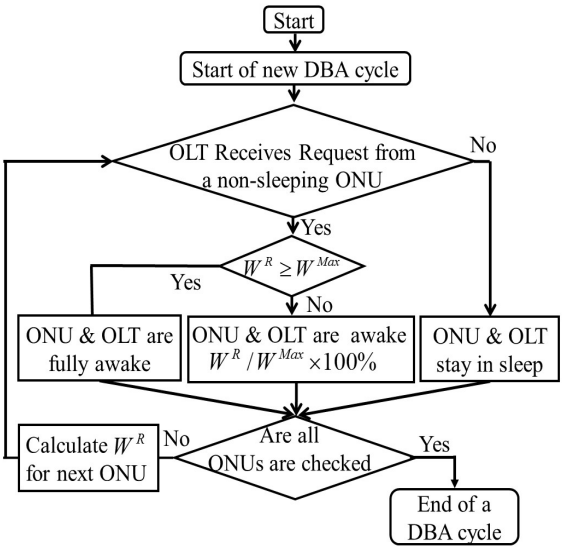

Fig. 3. Flowchart of the EE-DBA scheme.

III. PERFORMANCE ANALYSIS

The main features of the proposed SB-DBA scheme are making the EPON system energy efficient by employing active and power saving modes for both the OLT and ONUs. In this section, we provide detail analysis of the energy consumption in both active and sleep mode condition mode in the proposed SB-DBA scheme.

A. Energy Consumption in Active Mode

Let, W_{max} is the maximum window size for each ONU then following equation is used to calculate the W_{max}.

$$W_{\max} = (T_{cycle} - N * T_g) / N \tag{2}$$

where, T_{cycle} is the maximum cycle time, N is the number of ONUs, and T_g is the guard time.

If W_R is the requested window size by an ONU. Then equation (3) is used to calculate the W_R^i of an ONU *i.*

$$W_R^i = n^i (E_o + P_l) + R_l \tag{3}$$

where, E_o is the Ethernet overhead, P_l is the packet length, R_l is the length of Report message, and n^i is the number of packets in the buffer of an ONU *i.*

Following formula is used to calculate the active time of an ONU *i* T_{act}^{ONUi} in a time cycle.

$$T_{act}^{ONUi} = \begin{cases} 0 & \text{if } W_R = 0 \\ W_R & \text{if } W_R \leq W_{\max} \\ W_{\max} & \text{if } W_R > W_{\max} \end{cases} \tag{4}$$

Then, the active time of the OLT T_{act}^{OLT} in a time cycle is calculated as follows:

$$T_{act}^{OLT} = \sum_{i=1}^{N} T_{act}^{ONUi} \tag{5}$$

Equation (6) is used to calculate the total energy consumption in active mode by the OLT and ONUs in a time cycle *j*.

$$E_{act}^{Total(j)} = \left(T_{act}^{OLT} + \sum_{i=1}^{N} T_{act}^{ONUi} \right) P_a \tag{6}$$

where, $E_{act}^{Total(j)}$ is the total energy consumption in active mode in a time cycle *j*, and P_a is the power consumption by the OLT or ONUs in active mode.

B. Energy Consumption in Sleep Mode

As equation (4) is used to calculate the active time of an ONU *i* in a time cycle then following equation is used to calculate the sleep time of an ONU *i* T_{sleep}^{ONUi} in a time cycle.

$$T_{sleep}^{ONUi} = T_{cycle} - T_{act}^{ONUi} \quad (7)$$

Then formula (8) is used to calculate the total sleep time of all the ONUs and OLT in the EPON system.

$$E_{sleep}^{Total(j)} = \left(\sum_{i=1}^{N} T_{sleep}^{ONUi} + (T_{cycle} - T_{act}^{OLT}) \right) P_s \quad (8)$$

where, $E_{sleep}^{Total(j)}$ is the energy consumption in the sleep mode of a time cycle j, and P_s is the power consumption by the OLT and ONUs in the sleep mode.

Total energy savings in a time cycle is calculated using formula (9).

$$E_{saving}^{Total(j)} = (N+1) T_{cycle} P_a - E_{sleep}^{Total(j)} \quad (9)$$

where, $E_{saving}^{Total(j)}$ is the total energy savings in the proposed SB-DBA scheme in a time cycle j.

IV. Simulation Result

In this section, we have compared the system performance of the proposed SB-DBA scheme with the existing EE-DBA scheme in terms of energy consumption, energy savings in terms of percentage and packet delay of the EPON system. All performance analyses were done numerically for different range (0 to 1.0) of non-uniform normalized offered load (NOL)with cycle time variation from 1 ms to 3 ms and the data rate in the range of 0.5–2 Gbps. In the simulations, we have considered a tree topology based EPON with 16 ONUs and one OLT. We also have considered the power consumption in active and sleep modes of OLT and ONUs are 3.85 W and 1.7 W, respectively [8]. The simulation parameters are summarized in Table I.

Table I Simulation Parameters.

Symbol	Description	Quantity
N	Number of ONUs	16
T_{cycle}	Maximum cycle time	1 – 3 ms
T_g	Guard time	5 µs
E_o	Ethernet overhead size	576 bits
R_l	report message size	304 bits
P_l	Maximum Packet length	1500 bytes
R_n	Transmission data rate	0.5 to 2 Gbps
P_a	Power consumption of OLT/ONU in active mode	3.85 W
P_s	Power consumption of OLT/ONU in sleep mode	1.7 W
D	OLT and ONUs distance	10 – 20 Km

Fig. 4 presents a comparative results of the energy consumption vs. NOL for the OLT between the proposed SB-DBA and the existing EE-DBA schemes for 2ms cycle time and different data rates of 1 and 2 Gbps. From the results it is clear that the energy consumption by the OLT in the proposed SB-DBA scheme is far better than the existing EE-DBA scheme. Actually, the existing EE-DBA scheme requires

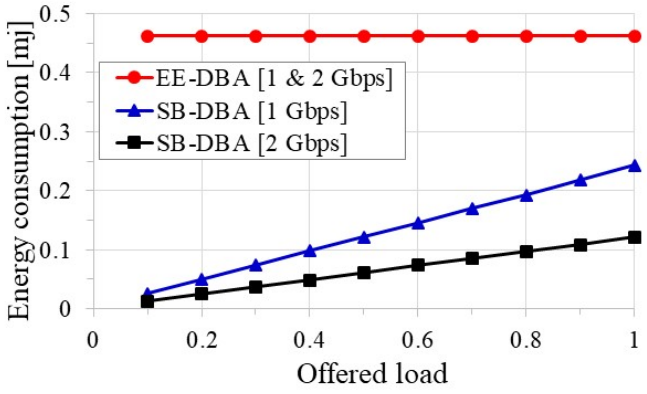

Fig. 4 Comparison of energy consumption for the OLT and maximum time cycle of 2 ms.

almost constant energy consumption for any value of offered load and data rate. The main reason of this result is that in the EE-DBA scheme energy saving technique has not been considered for the OLT. In contrast, the proposed SB-DBA scheme provides less energy consumption for the OLT than the existing EE-DBA scheme for any value of the NOL and data rate. Moreover, with increase of data rate the energy consumption in the proposed scheme is reduced. In the proposed SB-DBA scheme, at the NOL of 1.0 the maximum values of the energy consumptions are 0.24 and 0.12 mj for 1 and 2 Gbps data rates, respectively. Whereas, the energy consumption in the existing scheme is 0.462 mj for any value of NOL and data rate.

Fig. 5 represents a comparison of the percentage of energy savings for the OLT among the proposed SB-DBA and the existing EE-DBA schemes for data rates of 1 and 2 Gbps. The proposed scheme shows the highest energy savings for the OLT whereas the existing scheme has no energy savings. At the data rate of 2 and 1Gbps, the SB-DBA scheme saves 97% and 95% energy, respectively, at the lowest NOL of 0.1.

Fig. 6 compares the overall energy consumption, i.e., summation of energy consumptions by OLT and ONUs, between the proposed SB-DBA and existing EE-DBA schemes for 2 ms cycle time. The proposed SB-DBA scheme provides less energy consumption than the existing EE-DBA scheme for any value of NOL and data rate. This is because

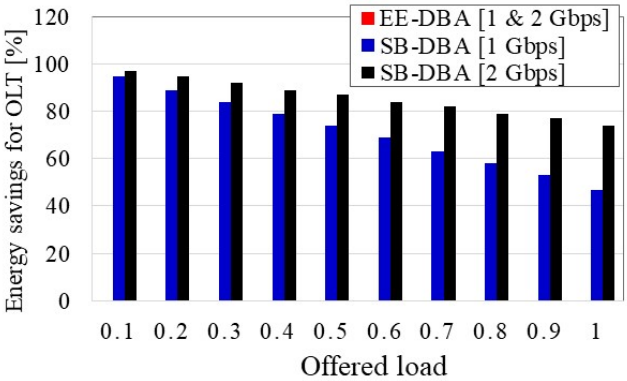

Fig. 5 Percentage of energy savings for OLT and 2 ms cycle time.

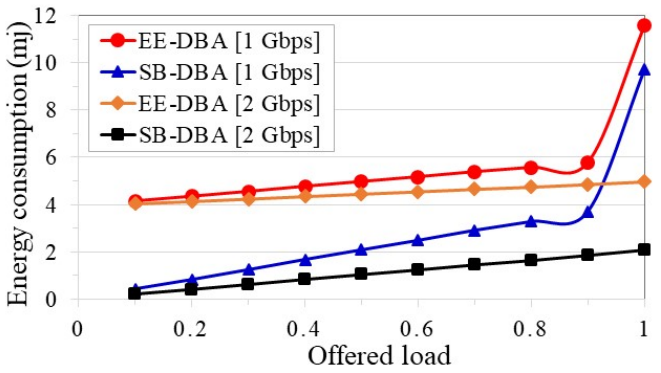

Fig. 6. Comparison of overall energy consumption.

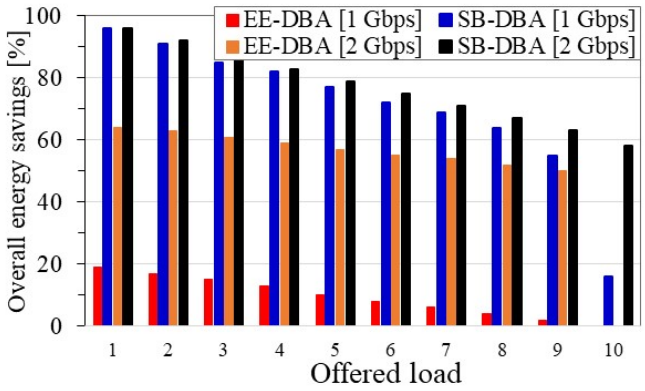
that the proposed scheme considers the energy saving technique for both the OLT and ONUs. The maximum values of energy consumptions in the proposed scheme for 1 and 2 Gbps data rates are 9.8 and 2.1 mj whereas those of the existing scheme are 11.5 and 5 mj at the maximum NOL of 1.0. So, it is clear that the performance improvement in the proposed scheme is more significant at higher data rates and lower NOL.

Fig. 7 provides a comparison of the percentage of overall energy savings between the proposed SB-DBA and existing EE-DBA schemes for different data rates of 1 and 2 Gbps. At the data rates of 1 and 2 Gbps the proposed SB-DBA scheme saves the highest energy that is 98% whereas that of the existing scheme are 19%, and 64%, respectively, at the lowest offered load of 0.1.

From the analysis of above-mentioned results, it is found that the proposed SB-DBA scheme provides better performance than the existing EE-DBA scheme. However, the end-to-end packet delay of the proposed SB-DBA scheme is almost similar to the existing EE-DBA scheme. Figs. 8(a) and 8(b) show the comparison of end-to-end packet delays for the proposed SB-DBA and existing EE-DBA schemes for 2 ms cycle time and data rate of 1 Gbps. Here, we see that the delay of the proposed scheme is similar to that of the existing scheme.



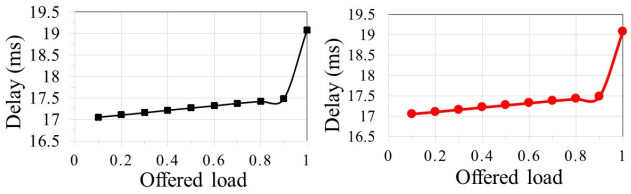


Fig. 7 Percentage of overall energy savings.

(a) SB-DBA (b) EE-DBA

Fig. 8 End-to-end packet delay of SB-DBA and EE-DBA schemes.

V. Conclusion

In this paper, we have proposed a new DBA scheme called sleep-based DBA (SB-DBA) scheme for reducing the energy consumption in the PON system. The performances of the proposed SB-DBA scheme are evaluated in terms of energy consumption, percentage of energy savings and end-to-end packet delay. The proposed SB-DBA scheme provides better energy efficiency than that of the existing EE-DBA scheme while maintaining the same delay performance. The proposed DBA scheme provides 98% energy savings for the 2 ms time cycle for the data rate and offered load of 2 Gbps and 0.1, respectively, whereas the existing EE-DBA scheme provides 64% energy savings.

***Abstract*— Designing and operating a reliable network which is robust against network failures is crucial for internet service providers. Especially, a network must be sufficiently connected even if link failures occur. Since link protection is costly, it is important to place the servers in such a way that a network suffering from link failures can still provide connectivity to some special clients. In this paper, we focus on the placement of servers assuring that special clients named as VIP clients remain connected to the servers even if links fail. We first set some criterion for serving the VIP client so that they get priority in case of link failure. We then propose an approximation algorithm that considers the trade-off between path length and alternative paths from the servers. We compute scores for various server placement combinations and try to provide the best suitable placement of servers. We have experimented with different types of synthetic graphs and tested our approach in case of link failures. Results indicate the effectiveness of our approach to maintain a sustainable network.**

Keywords — Link protection, Connectivity, Server Placement, VIP Clients, Average Distance, Approximation algorithm.

I. INTRODUCTION

Network Service Providers always want to provide service which is reliable and stable. When any link drops, the network may be disconnected or has to get connected via different route. This is called link failure. Critical links are those links whose failures drastically destroy the connectivity and must be protected. Such a failure prevents a large number of users from access to the servers. In case of link failures if there are no alternative paths from server to the client then connection is disrupted and can happen due to failure of routers, cutting of fibers, congested connection lines and so on. Moreover there are some clients among the network whom we can identify as valuable or VIP clients and failure to provide service to these clients can have severe damage to a country or society. For example banks, hospitals, universities, civil defense, security service and so on. Therefore, this clients need to be taken special care while serving network connections and given back-up in case of failure.

Moreover our working approach of placing service providers across a network for serving valuable clients can serve various other applications. Like where one shopkeeper can set up his food court considering school and universities as VIP clients, a pharmacy can be set up considering availability of hospitals around and how easy it is to get to the pharmacy from the hospitals etc.

A. Related Work

Designing a fully robust network is not simple. In this section, we are going to overview some of the recent approaches regarding network connectivity and link failure.

In 2004 Markopoulou et. al showed that 70 percent of unintentional failures, excluding failures caused by maintenance, are single-link failures [1]. The problem of determining a set of edges to meet a required edge connectivity or vertex-connectivity by adding edges to a graph was addressed in [2], [3], [4]. Approaches for determining a set of edges to meet a required diameter by adding edges to a graph was described in [5], [6].

From the viewpoint of link protection, researchers have investigated the smallest number of links to be protected so that the diameter of a network resulting from failures of non-protected links is less than or equal to a threshold in [7] and [8]. It was proved that this problem is NP-hard [7], and an algorithm was presented to solve the problem in polynomial time when the number of failed links is restricted. Imagawa and Hiroyoshi [9] defined and analyzed to find the links to be protected so that, even if any non-protected links fail, the number of the nodes connected with a server in the resulting network is not less than a threshold. Irie, Kurimoto and Miwa showed an approach to find the links to be protected so that, even if any non-protected links fail, all connected components include specified servers in a resulting network [10].

B. Notations

A graph $G = (V, E)$ consists of V, a nonempty set of vertices (or nodes) and E, a set of edges. Each edge is an unordered pair of vertices. An edge between two vertices u and v is often denoted by (u, v). We also denote the set of vertices of a graph G by $V(G)$ and the set of edges of G by $E(G)$. Path is a non-empty graph $P = (V, E)$ of the form $V = \{x_0, x_1, ..., x_k\}$ and $E = \{(x_0, x_1), (x_1, x_2), ..., (x_{k-1}, x_k)\}$, where the x_i are all distinct. The number of edges in a path is called its length. Two vertices u and v of graph G are said to be connected if there is a path in G whose end vertices are u and v. In a graph G, the distance between two vertices u and v, denoted by $d(u, v)$, is defined to be the length of a shortest path joining u and v in G. The diameter of G , denoted by $D(G)$, is the maximum distance over all pairs of vertices in G.

II. Our Approach

In our work, instead of protecting links or selecting critical links or minimizing cost of protecting links we concentrate on serving significant clients more reliably by placing servers in a robust way. In a network, all clients are not of same significance. We propose an algorithm for deploying a pair of servers in a network for serving the VIP clients more reliably. We focus on the properties for optimal selection of servers for a client. Our algorithm considers some trade-offs between fitness scores of server pairs and time complexity. We experimented on various types of networks like dense, sparse, small and large and demonstrate the effectiveness or our algorithm by dropping random links.

A. Evaluation Criteria for the Fitness of Server Pairs

We consider the following three criteria for deciding a server pair for serving VIP clients.

- **Number of alternative paths from a server to client:** If a server has multiple routes to a client, then if any edge drops which we say link fails, then it can still provide connectivity to that client using alternative routes. More the alternative paths, greater the chance of surviving link failures.
- **Distinct paths from a server pair to a client:** If the paths from server pairs to a specific client has less number of common edges then the chance of sustaining link failure is increased. So while choosing between multiple server pairs the pair with distinct routes to the clients will get advantage.
- **Distance from server to client:** Sometimes it is worth choosing long distance paths for distinct and multiple alternate paths rather than having short and less disjoint path. So while placing servers this is also taken in consideration.

B. Algorithm

Suppose we are given a network, considering it as a Graph G(V,E), there is a set of VIP clients C. We will select a pair of server according to our algorithm which will ensure better connectivity to those VIP clients.

First we need to find all the routes to the VIP clients from all other nodes of the network. But finding all the routes between two nodes in a graph is an NP-hard problem [11]. Therefore, instead of computing paths from all other nodes to VIP clients, in our experiments we selected only nodes with higher degrees. Because it is more likely that the higher degree nodes will have better chances of providing routes to the VIP clients as they are more likely to have alternate paths. Algorithm 1 illustrates the server placement procedure using all path listing procedure $allpaths$ and server ranking procedure $evaluationval$.

Algorithm 1 Algorithm for Server Placement

Input: A graph $G = (V, E)$, VIP client set C.
Output: Server Pair Set V'

```
V' ← φ
Bestval ← −1
int e ← 0
for i ← V, i ∉ C do
    for j ← V, j ∉ C do
        e ← evaluationval(i, j)
        if e > Bestval then
            V' ← (i, j)
            Bestval ← e
        end if
    end for
end for
return V'
```

In Algorithm 2, we take all server pair combinations and calculate the evaluation value for each pair. Calculating evaluation value is done considering the selected priorities. The evaluation function takes two server nodes, VIP clients and the graph as inputs. It calculates combinations of paths to a VIP client and generates an evaluation value.

Algorithm 2 Evaluation Value Computation ($evaluationval(i, j)$)

Input: A graph $G = (V, E)$, VIP client set C, Server pair (i, j).
Output: $Evaluation\ Value$

```
D ← |E(G)| − log(|E(G)|) + 1
Evaluationval ← 0
for each k ∈ C do
    for allpaths(i, k) do
        for allpaths(j, k) do
            Evaluationval = Evaluationval + D − commonedge − log(averagedistance)
        end for
    end for
end for
return Evaluationval
```

The evaluation value calculation is quite simple. We prioritize having alternate paths over distance and common paths using Algorithm 3. For every combination of paths, their evaluation value keeps adding to overall evaluation value calculation of the server pair candidate. This is ensured with the help of a constant D. Algorithm 3 is nothing but Breadth First Search (BFS) operation. We will use BFS approach to find all the paths from a particular node to another node.

The number of common edges is subtracted for particular path pair to a VIP client. It can be noted that for certain path pair highest number of common edges possible is the number of total edges in the network.

Again, we considered distance for the server pair candidate using the concept of **average distance** into action. We took the path length of both of the server to VIP node

Algorithm 3 Find All Paths ($allpaths(i, j)$)

Input: A graph $G = (V, E)$, pair(src, des).
Output: All paths from src to des, $src \in V, des \in V, src \neq des$

```
1: Allroutes ← φ
2: bool * visited
3: int * path
4: int * pathindex ← 0
5: for each v ∈ V do
6:    visited[v] ← false
7: end for
8: for each u ∈ adj[i] do
9:    visited[u] ← true
10:   path[pathindex] ← u
11:   pathindex + +
12:   if (u == j) then
13:      Add path to Allroutes
14:   else
15:      for each v ∈ adj[u] do
16:         if (visited[v] == false) then
17:            Proceed from v
18:         end if
19:      end for
20:   end if
21: end for
22: return Allroutes
```

considering common edges only once and call it average distance. The logarithm value of this average distance is subtracted because the larger the graph gets the impact of distance minimizes. Logarithm works perfectly to reflect the situation. The calculated average distance can be highest upto the logarithm value of the total number of edges in the network. So to obtain a positive value for every possible alternate pair of paths we added a constant value D with the evaluation value.

$$D \leftarrow |E(G)| - \log(|E(G)|) + 1 \tag{1}$$

In our experiments, we did not take all the alternative paths but only the paths with shortest distance and second & third shortest length paths into consideration for reducing complexity.

Algorithm 1 selects the server pair with highest evaluation value after trying all possible server pairs.

III. Time Complexity and Optimization

In this section we go through the time complexity of our algorithm and optimization techniques.

A. Time Complexity

Lets assume the given resources of a network graph G are,

- n : number of vertices.
- m : number of edges.
- c : number of VIP clients

Now in our algorithm we need to find all the routes between server candidates to the VIP clients. This is a time consuming operation and is of order $O(n!)$.

The main algorithm needs to check all possible pair of servers which takes $O(n^2)$ time. So, overall the algorithm becomes
$O(n^2) * O(c * (n!^2))$ = $O((n^3) * (n!^2))$

B. Optimization

Our proposed algorithm takes exponential amount of time, which is not suitable for practical applications. Therefore we employ some optimization techniques to improve the situation.

1) Reduce Candidate Nodes: Finding all the routes from the network to a VIP client takes an incredible amount of time. So for general purpose we try to cut down number of candidate nodes. From the evaluation criteria we know that the more the number of alternative paths the greater the chance of being selected as server to ensure a robust network. Therefore we look for the candidate nodes which have the highest degree or close to the highest degree. This prohibits a significant amount of nodes from being a candidate for server nodes. This speeds up the algorithm to a greater extent and in general shows reasonable result which we present in later sections.

2) Reduce number of routes: If we have to find all the routes, then it will take exponential amount of time. For this problem, we try the shortest and close to the shortest routes only. It helps to reduces computation time. For computing the shortest route from a server candidate to a VIP client, we use famous shortest path finding algorithm of Dijkstra [12].

3) More Number of Servers: Our main approach is to select optimum server positions for 2 servers. If the network is bigger and need more servers to serve the purpose, then we divide the network into subnetworks of smaller size and run our approach for all those subnetworks.

Suppose, we have a network of 10000 nodes and 100 VIP clients in it and need to place 20 servers. Then we divide the network into 10 subnetworks of 1000 nodes and then run our algorithm for each of the subnetworks.

IV. Performance Assessment

In this section, we discuss the performance assessment of our proposed algorithms.

A. Performance Assessment Method

Our performance assessment approach consists of three consecutive steps :

- Randomly dropping some links.
- Checking connectivity of the graph of resulting network.
- If disconnected already, checking if all the VIP clients are connected to at least one server.

1) Random Link Failures: To test the effectiveness of our solution we randomly drop some links from a sample network graph. We do this step by step. Slowly we increase the percentage of failed links from 5% to 100% and check

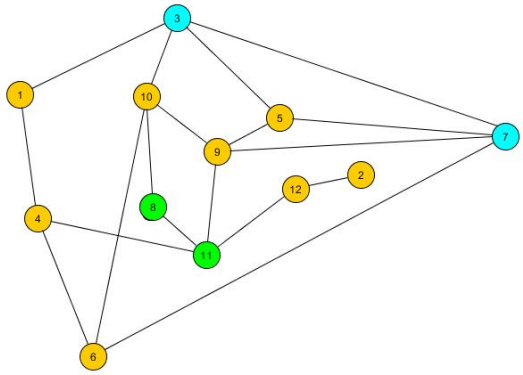

Fig. 1. A sample network graph with two VIP client node 8 and 11

if the servers previously chosen by our proposed algorithm can provide connectivity to all the VIP clients.

In Figure 1, green colored nodes are VIP clients and blue colored nodes are chosen as servers by our algorithm. Number of edges of this graph is 18. There are 2 VIP clients: node 8 and node 11. Node 3 and node 7 are chosen as servers.

2) Checking Connectivity of Resulting Network: In this step, we check for disconnectivity in the resulting network graph after random link failures. In a connected graph, each node must be reachable from all the other nodes. In Figure 2, VIP client nodes are 8 and 11, our previously selected servers are node 3 and 7. Let random failures occur for links $(3, 5), (3, 7), (4, 6)$ and $(4, 11)$. We can see, as number of connected component is 1 and the graph is not disconnected. There is still a route between previously selected server node 3 and VIP client node 8, represented by a bold edge in figure..

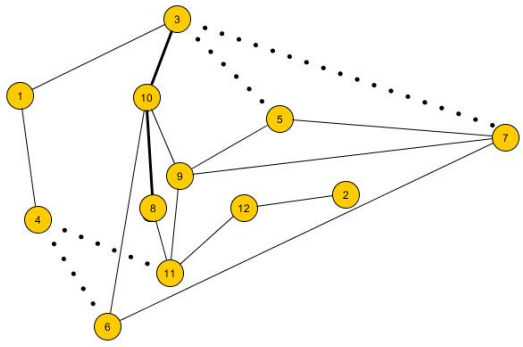

Fig. 2. An existing route between proposed server node 3 to VIP client node 8

3) Checking Service Reachability to VIP Clients: If the resulting network graph is disconnected after random link failures, then there is a possibility that any one or more of the VIP clients are no more receiving service from any server. This can happen if there is any VIP client left out in such a subgraph that has no server node in it. For this scenario, we check reachability from server nodes to all VIP clients. If any VIP client has connection with at least one server, we can declare that the client is getting uninterrupted service. We use BFS (Breadth First Search) for this reachability test.

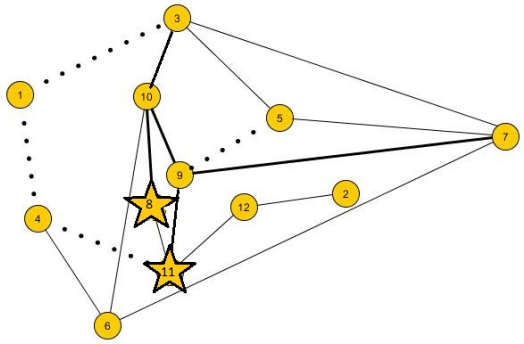

Fig. 3. All VIP clients have reachability to servers

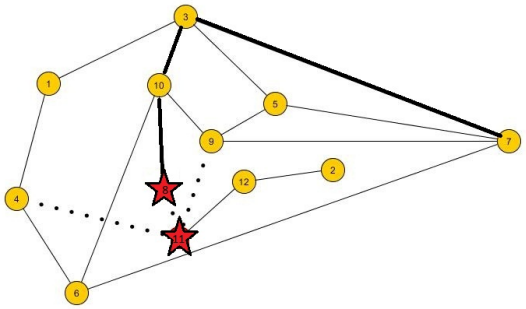

Fig. 4. VIP client 11 has no reachability to any server

In Figure 3, we can see that VIP clients are 8 and 11, selected servers are 3 and 7. 8 and 11 both have server connectivity. But for same network graph with different set of failed links, we can see in Figure 4, VIP client 11 is not reachable from any server.

B. Performance Evaluation for Variable Network Size and Density

In this section, we present the results of our simulation experiments done on sparse and dense graphs of variable sizes. In a sparse network there are more chances of disconnectivity and server failures. The result of our experiments agrees with this claim.

1) Small Networks: Our small networks consist of 10 to 99 nodes and 2-5 VIP clients. We increase the percentage of edge drop by 5% in each iteration and simulate our test 10 times. The results show that the success rate drops with the change of density of edges in the graph but the drop is significantly lower if the maximum degree is higher i.e. the graph is dense.

2) Large Networks: The large random networks consist of 100 to 1000 nodes. We increase the percentage of edge drop by 5% in each iteration and simulate our test 10 times. Results show the drop of success rate with the increase of edge drop in the graphs.

For networks with number of vertices 1000 and 10 VIP clients Figure 5 shows that success rate drops rapidly with

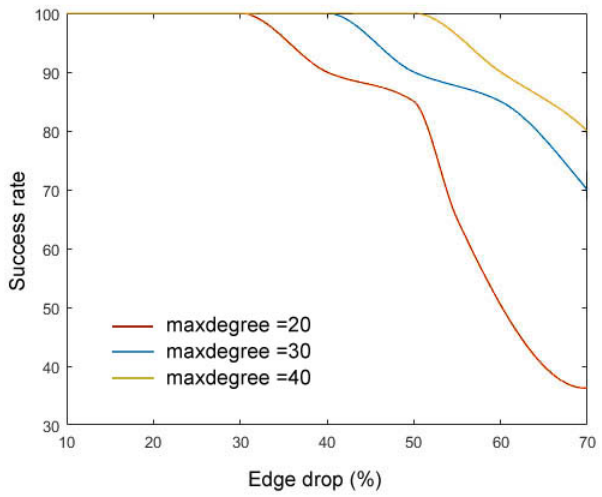

Fig. 5. Success Rate vs Edge Drop (%), Number of Vertices =1000, VIP Clients=10

increasing link failures for networks with nodes having smaller maximum degree. On the other hand networks with maximum degree 40 provide connectivity to all VIP clients even with 50% random link failures.

3) Computation Time for Different Network Size and Density: The server selection for a dense network should take more time than for a sparse network. Again, computation on large network takes much more time than for a small network. The following table shows the time taken by our algorithm to select required number of servers in networks of variable size and density.

TABLE I

PERFORMANCE EVALUATION REGARDING TIME NEEDED FOR VARIABLE NETWORK SIZE AND DENSITY

Number of Vertices	Maximum Degree	Number of Edges	Computation Time(s)
50	10	123	11.06
	15	190	11.347
	20	317	12.184
100	10	290	31.009
	20	546	31.173
	30	802	32.055
500	10	1132	979.487
	20	2547	968.113
	30	3755	967.567
1000	20	4460	4202.850
	30	6848	4208.063
	40	9377	4210.78

In Table I we can see that for the same number of nodes with the increase of edge density, the computation time doesn't change that much. But with the change of network size, time increases moderately fast. With respect to the complexity of the algorithm we can say our optimization approach has quite a success for large graphs.

C. Performance Evaluation for Variable Number of VIP Clients

In the following set of experiments, we present the results of our simulation experiments done on network graphs of variable sizes with variable number of VIP clients.

1) Small and Large Networks: We have run simulation on small and large networks that consist of 10 to 1000 nodes. The percentage of edge drop is increased by 5% in each iteration and each test is run 10 times. Number of VIP clients are varied from 5 to 15. Table II presents the results for the networks with 1000 vertices.

TABLE II

PERFORMANCE EVALUATION FOR 1000 VERTICES' NETWORK

Number of VIP Clients	Edge Drop(%)	Success Rate(%)
5	40	100
	50	90
	60	85
	70	70
	80	45
10	30	100
	40	90
	50	85
	55	70
	60	40
15	20	100
	30	90
	40	80
	45	70
	50	45

From Table II we can see that the success rate drops rapidly when we have to serve more VIP clients. Figure 6 shows it graphically. Here the network has 1000 nodes and maximum degree is 20. When the number of VIP clients is 1% of the total network size, the selected servers serve them

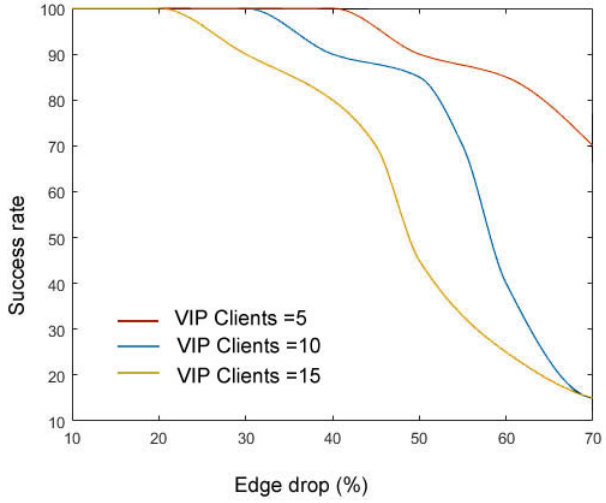

Fig. 6. Change of Success Rate vs Edge Drop (%) Varying Number of VIP Clients and Network Size=1000

2) Computation Time for Different Network Size and Density while varying the number of VIP Clients: The following table presents time taken by our algorithm to select servers in networks of variable sizes and densities.

TABLE III
PERFORMANCE EVALUATION REGARDING TIME NEEDED FOR VARIABLE NUMBER OF VIP CLIENTS AND NETWORK SIZE

Number of vertices	Number of VIP clients	Computation time (s)
10	2	0.204
	3	0.439
	4	0.464
50	5	11.068
	10	23.158
	15	40.051
100	5	42.229
	10	83.713
	15	135.37
500	5	712.063
	10	1406.290
	15	2074.17
1000	5	2138.56
	10	4202.85
	15	6223.172

Table III shows the increase of computation time with the increase of the number of VIP clients for fixed sized networks. For large networks computation time increases significantly with the increase of Number of VIP clients than for smaller networks.

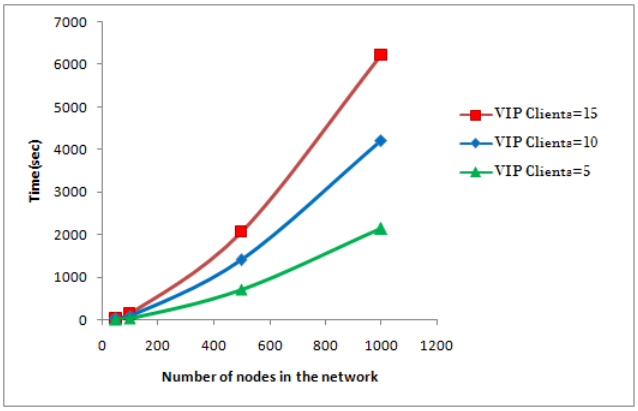

Fig. 7. Computational time needed for different networks with varying the network size for fixed number of VIP Clients

Figure 7 organizes the computational time needed to select servers for the same number of VIP clients while increasing the network size, which tends to be a polynomial function of the number of nodes in the networks.

V. CONCLUSION

Protecting links is always costly and selection of the links to protect is hard. Placing the servers in right positions is important so that clients having significance in a network always finds an alternate route in case of link failures. We have defined the criteria for selecting servers for serving VIP clients, provided an algorithm that can place a server pair in quite a large network and still give a reasonable choice. We have also shown how the algorithm reacts with various change of properties of the network. Moreover we have experimented our solution by link failures at random basis and shown its robustness for keeping the VIP clients connected to the service providers. We have analyzed to reduce the complexity of our algorithm, set various criterion to optimize it.

Last but not the least experiments with larger, weighted networks are yet to be explored. Moreover we have experimented with synthetic graphs only. Performance of our strategy in case of real network will also help to strengthen our claim.

***Abstract*—Content Delivery Networks(CDN) is a standout amongst the most encouraging innovations that upgrade performance for its clients' websites by diverting web demands from browsers to topographically dispersed CDN surrogate nodes. However, due to the variable nature of CDN, it suffers from various security and resource allocation issues. The most common attack which is used to bring down a whole network as well as CDN without even finding a loophole in the security is DDoS. In this proposal, we proposed a distributed virtual honeypot model for diminishing DDoS attacks and prevent intrusion in securing CDN. Honeypots are specially utilized to imitate the primary server with the goal that the attack is alleviated to the fake rather than the main server. Our proposed layer based model utilizes honeypot to be more effective reducing the cost of the system as well as maintaining the smooth delivery in geographically dispersed servers without performance degradation.**

keywords- Network Security, Virtual Honeypot, Distributed Denial of Service (DDoS), Intrusion, Prevention, Mitigation.

I. Introduction

Denial-of-Service (DoS) attack can be a variety of attacks that are used to stop the system from functioning briefly or indefinitely to prevent authentic users from accessing it [1]. Pinging the system with a load of spam requests results the system to be overloaded and eventually crash due to the process power of the system is restricted. It is accomplished through diverse ways, botnets and buffer overflow vulnerability are the foremost famed among them.

The scale, frequency and sophistication of denial-of-service (DoS) and distributed denial-of-service (DDoS) attacks will continue to grow as businesses and other organizations move more and more online. Using malware to remotely control thousands of computers and direct them to overwhelm a specific target with bogus requests, DDoS attacks cause a CDN network to come slow or unavailable to users, potentially resulting in lasting damage to reputation, productivity and profitability. Apart from data loss, the DDoS attacks cost them a lot of time and money. Although there are many ways of preventing such attacks, new DoS attacks are being constantly introduced as a result of hacking advances.

Honeypot is a system [2] that imitates the primary system by attracting potential intruders who want to gain unauthorized access. It is used to assess the movements and footprints of hackers and to correct protection of the system to avoid future attacks [3]. Generally, it consists of a computer, applications and data that acts and behaves like a decoy. Here we address a method how distributed virtual honeypot pillared with a verification system is used to safeguard a CDN network with greater efficiency and lower cost. A basic architecture of secure CDN network is presented in **Figure 1**.

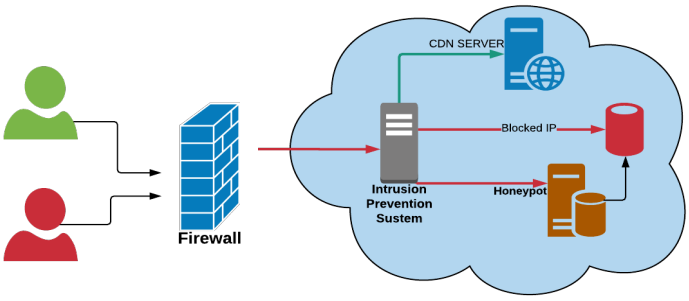

Fig. 1. DDos attack mitigation using Distributed Virtual Honeypot

The primary objectives of our work are as follows:

- To make a honeypot model for mitigating DoS attacks and prevent intrusion in Content Delivery Network.
- To propose an algorithm that offers more efficiency in detecting intrusion in the system.
- To use simulation to apply our proposed model.
- To compare results with existing system.

II. Literature Overview

A. Background

A firewall is designed to keep the attackers away from the network, while honeypots are designed to trick the hackers into attacking the system. CDN systems are very useful to control and optimize all network services that find the shortest distance for its users . On the other hand, servers can sometimes be a prime target for DoS or DDoS attacks in such architectures.

Several protective models with honeypots have been suggested for DDoS.

Tiwari, R., Jain, A.[4] clarified honeypot innovation and its weaknesses in the honeypot framework and proposes an appropriated framework which cure the current insufficiency in the centralized control system to enhance network security. A.Zakari and A.A.Lawan.[5] they identified three requirement for using honeypot that is deceptiveness, robustness and intelligence.

Y. Yang, H.Yang, and J.Mi [6] mentioned the distributed deployment for honeypot system. It widens the network area and mark the package to identify real attacks sources and has certain expansion ability. Hrishikesh Arun Deshpande [7] contributed by using virtual honeypot in preventing distributed denial of service attacks.

Nishat, Doh and Chae [8] suggested a technique against DDoS attacks that uses SDN-based CDNi networks to safely provide services with a multi-defense strategy. They combine ALTO servers to track a very large network to provide a bird's eye view. It also mark path map in the ALTO server to trace the request packets and has a protection switch to protect the main servers. But they have not mention how the legitimate user will get more efficient service.

Concerning DoS assaults on CDN, I might want to feature the research embraced and the thoughts proposed to manage this appalling attack. Resmi, An and Chezian, R.M.[9] proposes interruption prevention and discovery in Content Delivery Networks. There has additionally been research beforehand attempted into the utilization of honeypots to relieve DoS attack in IoT frameworks[10]. Though at the present point, this examination stays theoretic with just theoretic models being proposed.

To diminish DDoS attacks Sherif M. Khattab et al [11] proposed roaming honeypots. Here a pseudo-random schedule changes the location of the current active server and the honeypot, shared between the servers and the authorized client. Therefore legitimate clients always send their service request to active servers whereas attack request may reach the honeypot. The source address of any request that hits a honeypot is black listed so that all future requests from this source are subsequently dropped.

Quang Duy La et al [12] proposes game theoretic model in which both the attacker and defender endeavor to mislead one another. The defender utilizes honeypots to mislead and trap the aggressors. This research is an expnasion of the work done by N. Garg et al [13] that examines the viability of utilizing honeypots for double dealing in systems following an game theoretic methodology.

As made reference to beforehand these works have been limited to theoretic models. With this in mind, we deploy a honeypot based security system for a CDN in this paper, to block DDoS attacks from malicious attackers and also collect information on the attacker so that future attacks might be prevented.

III. Distributed Honeypot System

A. Honeypot in CDN

Honeypot is the second layer in our CDN security. A honeypot's most huge esteem depends on the data that it acquires and can quickly caution on. Information that enters and leaves a honeypot permits security staff to assemble data that isn't accessible from an IPS. An aggressor's keystrokes can be logged amid a session, regardless of whether encryption was utilized to set up it. Additionally, any endeavors to get to the system can trigger quick alerts. Sometimes many attackers can get into the main server without being detected by the Intrusion Prevention System(IPS). At that time they cannot really find the real server rather they will be observed by our decoy server honeypot that analyses their motive and blocks them if they fall in the danger zone . Otherwise if the analysis found to be safe then they can access the CDN server. The system flowchart diagram is shown in **Figure 2**.

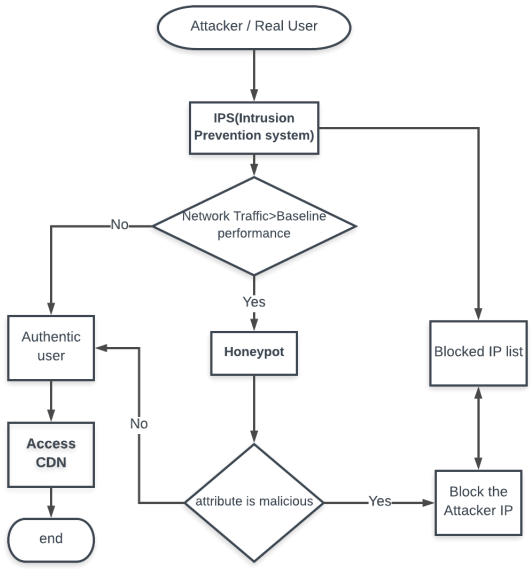

Fig. 2. System flowchart

As honeypot presents honey data as a decoy for the attackers, it is used for both intrusion detection and prevention purposes.

a) Intrusion Detection System: Intrusion Detection System (IDS) causes data frameworks to manage attacks. This is refined by gathering data from an variety of frameworks and system sources. The data gathered is broke down for conceivable security issues. An IDS assembles and breaks down data from different zones inside a system to distinguish conceivable security break [14].

b) Intrusion Prevention System: In our proposed system, we have maintained an intrusion prevention system (IPS) which is a cyber attack prevention technology that analyses the flow of network traffic to detect and prevent vulnerability. Vulnerability feats usually take the form of malicious inputs

into a target application or service used by attackers to disrupt and control an application or machine. Following a successful exploit, the attacker can slow down the target application (resulting in a denial-of-service state).

In IPS, we detect statistical anomaly samples of network traffic at random and compares them to a pre-calculated baseline performance level. When the sample of network traffic activity is outside the parameters of baseline performance, the IPS takes action to handle the situation. It sends these to the next part of our system honeypot which will analyze and find if it is false positive .

B. Distributed Honeypot in CDN

Content Delivery Network is the largest distributed server for smooth content sharing. It is distributed geographically along with proxy server and backup database to provide end-users high availability and high performance. Distributed servers are kept for distributing contents e.g. a University campus where students access to their personal data and class material resources through it. Therefore, assuming that there is a central or primary server that hosts the primary Honeypot and the network traffic attributes database, all other servers will host secondary honeypots as the initial target of attackers. As a result the edge servers will act as the monitoring agent that continuously monitor the data and provide feedback to the central control system through secure channel.

Following is the system architecture of our distributed server in **Figure 3**.

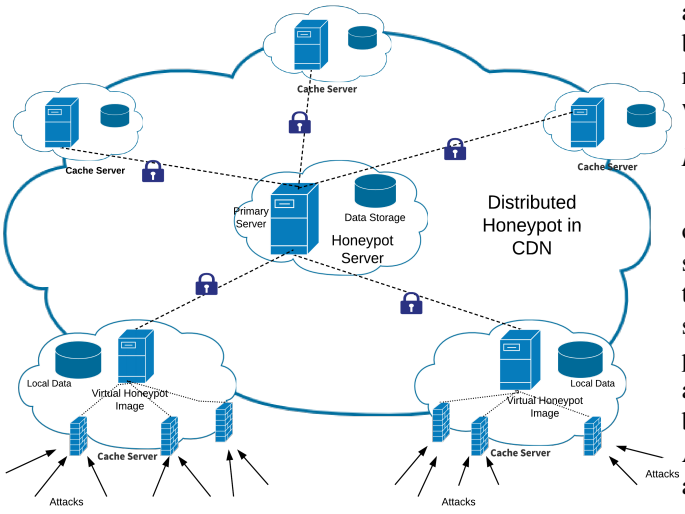

Fig. 3. System Architecture of distributed virtual Honeypot in CDN

Distributed honeypot based systems have two layer architecture in general as: Control agent and Monitoring agent. Details regarding the agents and secure communication management are provided in the following:

a) Control agent: The primary server acts as the control agent in CDN keeping the primary log file synced with other local log files residing in edge servers. The honeypot hosted by the primary server works in the second layer keeping the monitoring agents in the first layer of malicious attacks.

b) Monitoring agents: All the honeypots residing in the edge servers act like the monitoring agents. As users will be initially granted access to resources in the edge caching servers, the malicious user have the same access mechanism. Therefore, monitoring agents are the first layer to face any sort of intrusion or attacks.

c) Secure communication between agents: The communication between the control agent and the monitoring agents is secured using secure socket layer (SSL). If one monitoring agent reports anomalies, then it will be synced with the primary honeypot hosted by control agent. Later the same report will be synced with all other edge servers for further rule changing purpose in firewalls.

C. Virtual Honeypot using image

A virtual honeypot is a software that imitates an endangered system to draw in intruders and concentrate their behaviors. Honeypot proprietors can assemble data about attackers and their activities that can help recognize organize vulnerabilities and take activities to secure feeble focuses. The data can likewise be utilized to figure out what IP locations and requests ought to be blocked. Virtual honeypots are hosted in virtual machines (VMs) which may exist in numerous arrangements on a solitary PC or apparatus to copy different frameworks and vulnerabilities. As honeypot is comparatively costly and in a distributed framework like CDN it will increase the total cost for maintenance of the system, virtual honeypots seem to be a better solution and easier to implement. Virtual honeypots are less expensive to convey and more secure than equipment based systems. As Content delivery Network comprises of numerous intermediary topographically disseminated server so we utilized virtual honeypot so that attack can be halted.

D. Cache Servers

Cache server or proxy server is the distributed server of Content delivery Network because of its smooth content sharing. Due to dispersed nature of cache server it is vulnerable to various attacks. Actually it is the copy of the primary server which resides in edge servers. Therefore, if any attack is performed in any location then its regional users will be greatly affected. In our architecture, every cache server is protected by Virtual honeypots hosted in virtual machine containers. Also these honeypots will act as monitoring agent which will analyze the traffic and make decision whether or not a request will gain proper access to cached contents. As a result the actual user will get instant and reliable service and malicious intruder will be detected at once.

Now an overall in-detailed data flow diagram of our architecture is shown in **Figure 4**.

E. Algorithms

Initially user request will come at the monitoring agent which is the edge server. Then they will generate local log if it

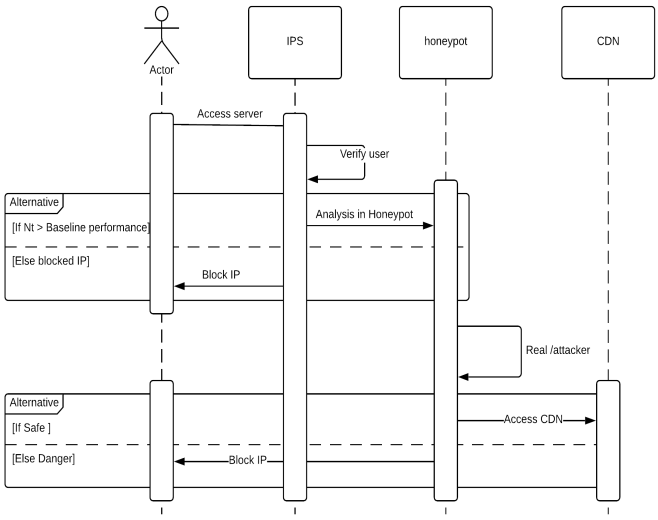

Fig. 4. Data Flow Diagram

is authentic user or attacker. Afterwards this information will be synced with primary server [Control Agent]. The complete process is presented in **Algorithm 1**.

Algorithm 1: Algorithm for attack mitigation using Honeypot

```
System Initialization;
while TRUE do
    Real user or attackers send request to access CDN;
    /* AT Edge Server                                  */
    if IP in Blocked list of Local Log then
        Reject Access;
    end
    if Network traffic > Baseline Performance[depends
     on the system] then
        Send Anomaly request to Monitoring
         Agent[Honeypot] for Analysis;
    end
    /* AT Monitoring Agent                             */
    if Analysis found safe then
        Grant access to use CDN;
    end
    else
        IP stored to the blocked list in Local Log;
        Updated List is synced with The Control Agent;
    end
end
```

IV. Implementation and Evaluation

A. DDoS Attack Simulation

In this test we will conduct trials using Ubuntu operating system and Python script for deploying attacks on our server, this attack testing will conduct a direct attack to the server so that in the presence of this test will go into the trap honeypot. The following **Figure 5** is demonstrate the script is running and it will flood our bandwidth with unnecessary bad traffic.

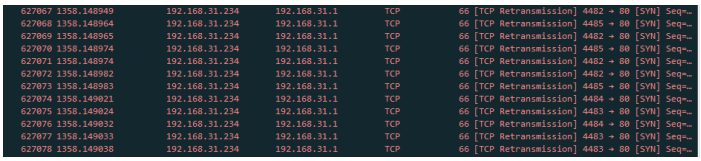

Fig. 5. Python Script for DoS attack

The **TABLE I** shows that we will make a real server that will act as a CDN server with port 80 and another IP address will be an intruders address from where we will perform attack and will make the system unreachable to the users.

TABLE I
Attacker IP and Server IP

IP Address	User Computer	Operating sytem	PORT
192.168.31.1	Real Server	Ubuntu	80
192.168.31.234	Client Intruder	Ubuntu	80

1) Normal Traffic: Network traffic or data traffic is the amount of data moving across a network at a given point of time. At first we measured the normal traffic movements **Figure 6** in our system and analyzed different parameter values.

TABLE II
Statistics of Normal Traffic

Measurement	**Captured**	**Displayed**
Packets	15196	15196 (100.0%)
Time span, s	58.391	58.391
Average pps	260.2	260.2
Average packet size, B	821	821
Bytes	12472428	12472428 (100.0%)
Average bytes/s	213 k	213 k
Average bits/s	1,708 k	1,708 k

We have captured the traffic for almost 60 seconds and found the statistics given at **TABLE II**. Here the average bytes/s was 213k and average packet/s was 260.20.

2) DDoS Attack Traffic: Not at all like other cyber criminal intrusions, DoS and DDoS attack don't attempt to penetrate a system rather they are regularly part of a bigger attack. They try to create force so that bandwidth allocated to the real user are used up by fake request **Figure 7** and create panic towards the users. Here is a statistics of the DDoS attack traffic performed on our system in **TABLE III**.

From the above table we found that here the average packet/sec was 3223 and the average byte 1154k which is far more than normal traffic.

The comparison between two traffic given in the following **Figure 8**.

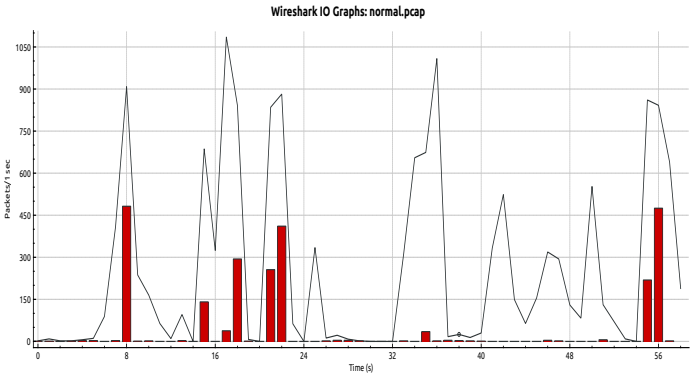

Fig. 6. Normal Traffic in server

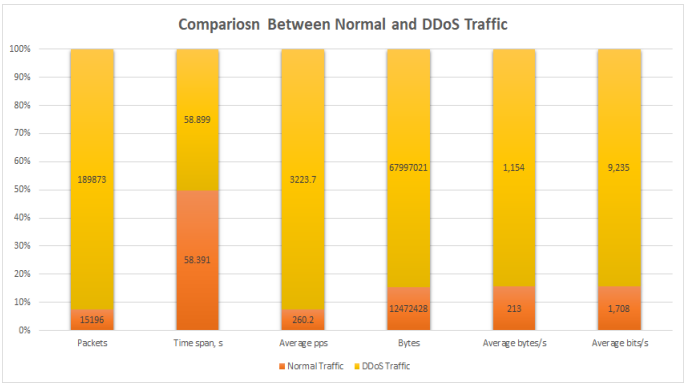

Fig. 8. Comparision between DDoS and Normal Traffic

TABLE III
STATISTICS OF DDOS TRAFFIC

Measurement	Captured	Displayed
Packets	189873	189873 (100.0%)
Time span, s	58.899	58.899
Average pps	3223.7	3223.7
Average packet size, B	358	358
Bytes	67997021	67997021 (100.0%)
Average bytes/s	1,154 k	1,154 k
Average bits/s	9,235 k	9,235 k

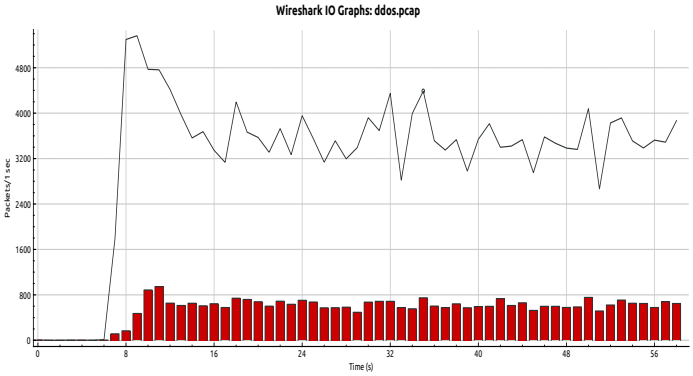

Fig. 7. DDoS Traffic in server

Now we will add honeypot and make a port open so that intruder try to find that way and want to perform their task. When any malicious attacker will find that open port and want to do something then our honeypot will show his IP address and we can block that IP address.

B. Intrusion Detection by Honeypot

In our Distributed Virtual honeypot model every edge server contains monitoring agent(Honeypot) that analyzes traffic if it is malicious and sent by the IPS then after analyzing, it will be added to the blocked IP list or sent to the server for their service .

This is the interface **Figure 9** of honeypot being deployed to our server. It is a Ruby script from where we can select various tool.

Fig. 9. Honeypot tool

Now we will go to the network tool by selecting second option. We will see that different network tools are on the list. From these we will choose honeypot . After choosing honeypot we will find two option for auto configuration and for manual configuration . We will go for manual configuration and give our preferred options like :

- Port number
- Any message want to show
- Log file generated by intrusion
- Alert option for intrusion

After enabling honeypot, we will try to DoS attack attempt on our server. We will use python script that creates many requests, that will try to flood the server.

Next for each intrusion detected by our honeypot we will get intruders information **Figure 10**. We will save the IP address in the blocked list of monitoring agent and later on this will be synced with the control agent of our main server.

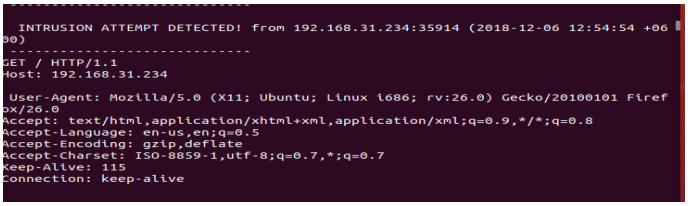

Fig. 10. Attacker IP address Detected by Honeypot

This blocked list will be helpful for detecting the blacklisted IP at the first place by the IPS and it will smooth our CDN services.

V. Discussion

A. Significance and Application

Presently, the most difficult issue is to keep up the unwavering quality and speed of a system. Content Delivery Network(CDN) is worked for quick service and smooth conveyance of assets to its clients. Sometimes its asset conveyance is being hampered by different Denial of Service attacks which spent the data bandwidth of the clients and make them sit tight for their services. As a result we implemented a distributed measure that will mitigate these DDoS attacks and serve the user in their best way. We have used two levels of security for better intrusion detection. And virtual honeypot adds numerous advantages, mostly they can essentially enhance our security pose along with IPS in CDN.

Unlike IPS, IDS can not block attacks rather it can give warning to the administration. Therefore, this changes the situation when we find the blocked IP wanted to access the contents then it will be rejected at the first attempt. If somehow any false positive IP were found then it will be analyzed by honeypot and it will take necessary action. Reduced cost is another advantage while implementing the model. As the edge servers are hosted in virtual machine containers, it will reduce the total cost tremendously which is much less than implementing traditional honeypot system in CDN.

B. Scope and Limitations

In our architecture we have taken a baseline performance that determines the traffic characteristics and then we give access to our main content server. The system may find limitations as it needs to study different baseline performance according to various networks.

C. Future Work

Future work will be maximizing more security by making our honeypot adaptive that is able classify the intrusion and anomaly patterns and modify firewall rules accordingly. Adaptive systems provide quicker response to malicious attacks and severe risks including zero day attack.

VI. Conclusion

The consistent advancement of DDoS attacks have rendered them one of the best weight to the present Internet transmission capacity. In spite of the fact that variety of DDoS attack prevention, mitigation, and traceback techniques methods have been proposed by analysts in the most recent decades, their relative take-up has been negligible at mammoth. In this paper, a mitigation strategy is exhibited for counteractive action of DDoS attacks on a CDN server by Distributed Virtual Honeypot while the proposed system does not influence the activity from genuine users, it effectively blocks traffic from the attack sources by watching their network traffic and sends those for more assurance to the honeypot where it analyze the packet if they are false positive or not. Thus our technique will maintain the real users bandwidth and blocks the false users. Moreover, the utilization of virtual honeypot could be reached out for different kinds of attacks as a research based honeypot to gather points of interest.

Acknowledgement

The research work was partially supported by Green University of Bangladesh research fund.

***Abstract*— IoT can prolong the internet communication to heterogeneous types of objects those are used within embedded technology to join with the surrounding through the active support of internet technology. The exploration and application of the Internet of things technology is certain to quicken the industrial promotion and revolution, at the same time, to securely promote the growth of the national economy, to constantly improve the comprehensive national power. A number of research works is going on these IoT nodes which consume limited resources and the development of communication protocols can be considered as the vital one. This paper is concentrated on finding out the best protocol for communication between IOT nodes after merging these three protocols RPL, CoAP and 6LoWPAN depending on different criteria and, therefore, the study can be useful in personal and home application, healthcare, utilities and services, enterprise application and industrial automation. Based on the results, it can be stated that the combination of RPL and CoAP performs better than the combination of 6LoWPAN and CoAP in terms of received packets for varying number of nodes, simulation time and communication range.**

Keywords— CoAP, Cooja, IoT, RPL, 6LoWPAN

I. INTRODUCTION

The amount of connected entities has already gone beyond the total amount of human being few years ago and it is predicted to reach 50 billion by the end of 2025 [1]. As more and more devices are being introduced in our regular life, has created immense pressure on internet connectivity in term of storage and routing. These devices are constantly communicating with each other and also with the server through the internet. Therefore, the necessities of application specific communication protocols have risen up and will continue too in future days to come.

Communication protocols are similar to traffic directors that maintain organized communication with each other. Protocol has the responsibilities to develop, maintain communication and without protocols, the nodes of various networks might get connected but won't be capable to interact with each other. Therefore, if one machine wants to receive or send data to another machine, both of them should use similar protocol for completing the task [2]. As a result, choosing an appropriate communication protocol is one of the vital concerns now a day.

This paper is concentrated on finding out the best protocol for communication between IOT nodes after merging these three protocols RPL, CoAP and 6LoWPAN depending on different criteria and, therefore, the study can be useful in personal and home application, healthcare, utilities and

services, enterprise application and industrial automation. Hence, the paper is schematized as the following methods:Section II describes IoT and Communication protocols;Section III illustrates Literature review; Section IV defines the sample communication scenario using these merged protocols; Section V explains results based on comparison among these protocols; and the paper is concluded in section VI.

II. IOT AND COMMUNICATION PROTOCOLS

Internet of Things (IoT) denotes the dynamic connectivity of physical devices with limited resources with the support of internet infrastructure. It helps to develop interaction between these entities and also every internet supported objects and networks [3]. IoT can prolong internet communication to heterogenous types of objects those are used within embedded technology to join with the surrounding through the active support of internet technology [4]

Based on the necessities and regular application IoT has already been included in the national five-year development plan outline of China [5]. The exploration and application of the Internet of things technology is certain to quicken the industrial promotion and revolution, at the same time, to securely promote the growth of the national economy, to constantly improve the comprehensive national power [6].

A number of research works is going on these IoT nodes which consume limited resources. Development of communication protocols can be considered as the vital one. At present, three communication protocols have become popular and therefore, we have chosen them to simulate using cooja simulator. The basic features of protocols are explained below in brief:

The 6LoWPAN concept originated from the idea that the Internet Protocol could be applied to the smallest devices, [8] and those low-power devices with limited processing capabilities. The standard has the liberty of choosing frequency band and the elasticity to complete over several communications stages, counting Ethernet, Wi-Fi and 6LoWPAN protocol. This protocol plays a most imperative role in IoT wireless communication as it stands for IPv6. It is demonstrated by auxiliary addresses with diverse lengths, low bandwidth, star and mesh topologies, battery supplied devices, low cost, large number of devices, unknown node positions, high unreliability, and long idle periods during the communications [7].

RPL is one of the distance vector routing protocols for network layer and it is developed to function with little energy and lossy systems using IPv6. Besides, message confidentiality and reliable message delivery are cared by RPL. It has been pre-arranged in such a technique that link layer appliances can be castoff when available and appropriate; yet, in their absence, RPL can custom its own mechanisms[8]. RPL is popular for many reasons, for example, it can develop its own route very fast, share the routing information to other nodes and have the capability to get adapted dynamically with the network topology [9].

CoAP is considered as one of the most recent application layer protocols founded by IETF to be utilized for intelligent objects. In addition, it is a trivial protocol for low resource consumed smart devices and can be embedded into buildings, vehicles. It is also considered as the substitution of HTTP protocol to be used in application layer of IoT devices [10]. As a result, the data reception from the sensor has become more convenient. In addition, this protocol has the multicast feature, a little overhead though and very effective in M2M interaction. CoAP nodes are divided into two types namely server and client from the architecture viewpoint. Server nodes are installed in sensors while client nodes are embedded into controller [11].

III. LITERATURE REVIEW

Currently, a number of research works is going on these communication protocols. Different types of simulators are being used for different applications. The papers [12] studied the performance of COAP protocols for different platforms like Contiki, TinyOS, POSIX, lwIP etc. C, JAVA, JAVA script and python were implemented as programming languages and several library functions were used, for example, ibcoap, FreeCoAP, smcp, CoAPthon, Californium etc. [13] used the COAP protocol for healthcare monitoring application. The paper [14] made the comparison between REST and SOAP architecture using the previously described three protocols to be used for building management system. Besides, the benefits of BMS were explained along with the methodologies that are needed, were analyzed. [15] also worked with the development of protocol stack.

This paper [16] described the strong points and limitations of RPL protocol. It also pointed out the vulnerability and proposed an intrusion detection technique in support of it to reduce the attack. The paper [17] found out the importance of RPL, COAP and 6Lowpan as the communication protocol for IOT to be used to develop smart city. The paper [18] proposed a new model for cross layer network infrastructure on NS-3 platform. It also addressed the congestion problem and solved with back pressure

algorithm. The paper [19] studied the three protocols on the development of sensor networks and their viability was evaluated for industrial purpose. However, no much study has been attempted on cooja simulators or on contiki nodes. Most importantly, these protocols were not merged, simulated and our study can be considered as the newest one.

IV. COMMUNICATION SCENARIO

In this chapter, the communication between the IOT nodes will be illustrated using RPL, CoAP and 6LoWPAN protocols. Besides, these protocols will be merged and their network architecture will be briefly explained.

IPv6 Low power Wireless Personal Area Network (6LoWPAN) is functional on adaptation layer that allows the consumption of IPv6 over low power wireless and User Datagram Protocol (UDP) header compression. As seen in Fig. 1, the 6LoWPAN stack is both highly scalable and reliable. The modular structure of the design makes possible for ARM to accommodate most of the requirements. The combination of 6LoWPAN stack and 6LoWPAN border router Access Point (AP) enables developers to use the extremely flexible and multipurpose mesh communication for most applications.

As in Fig.2, DIO carries information that allows a node to discover an RPL Instance, learn its configuration parameters and select DODAG parents. A DIS solicits a DODAG Information Object from an RPL node. Destination Advertisement Object (DAO) propagates destination information upwards along the DODAG.

As shown in figure 5, CoAP cooperative model is related to HTTP's client/server model and CoAP employs a two layers structure. The bottom layer is Message layer that has been designed to deal with UDP and asynchronous switching. The request/response layer concerns communication method and deal with request-response message [10].

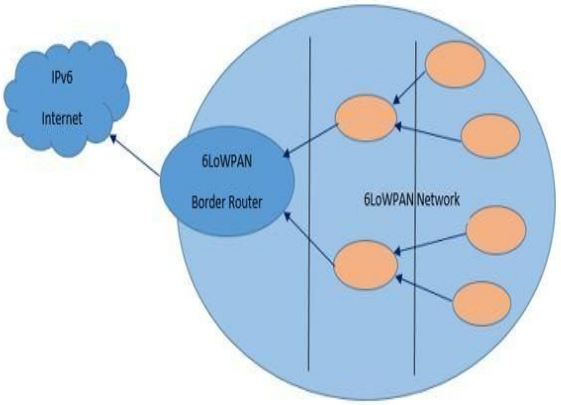

Fig. 1. Network architecture of 6LoWPAN [20]

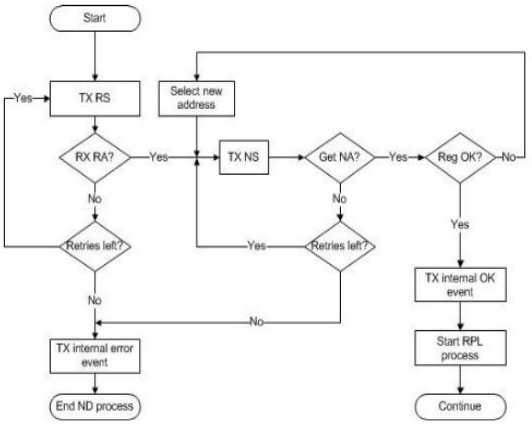

Fig. 2. Functional systen of RPL [10]

Fig. 3. Network Architecture of RPL [10]

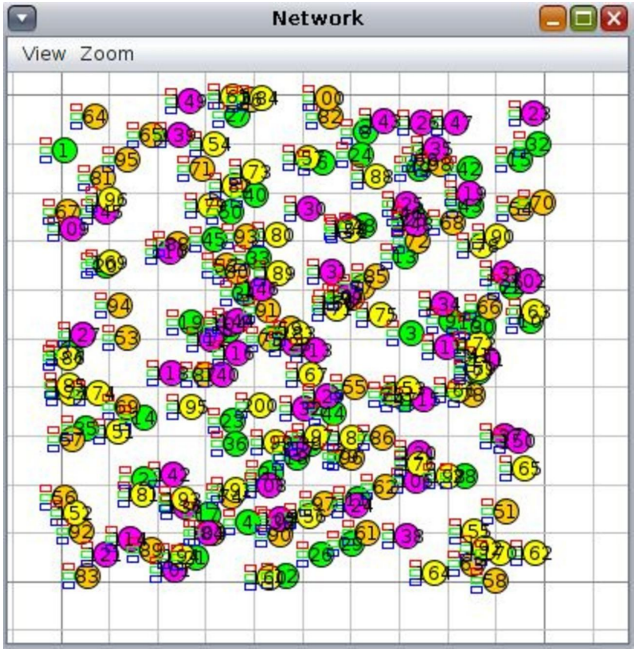

Fig. 4. 6LoWPAN and CoAP are communicating on cooja platform

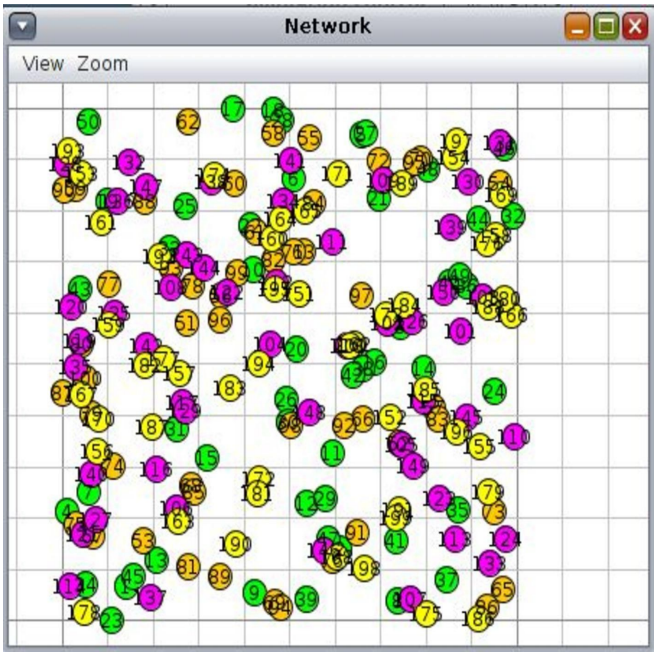

Fig. 5. RPL and CoAP are communicating on cooja platform

As can be seen from Fig. 4,the server and the client nodes are communicating with each other using 6LowPAN and CoAP protocols together.Here,Purple and yellow nodes are UDP client and server under 6LoWPAN protocol and green,orange nodes are UDP client and server under CoAP protocol.

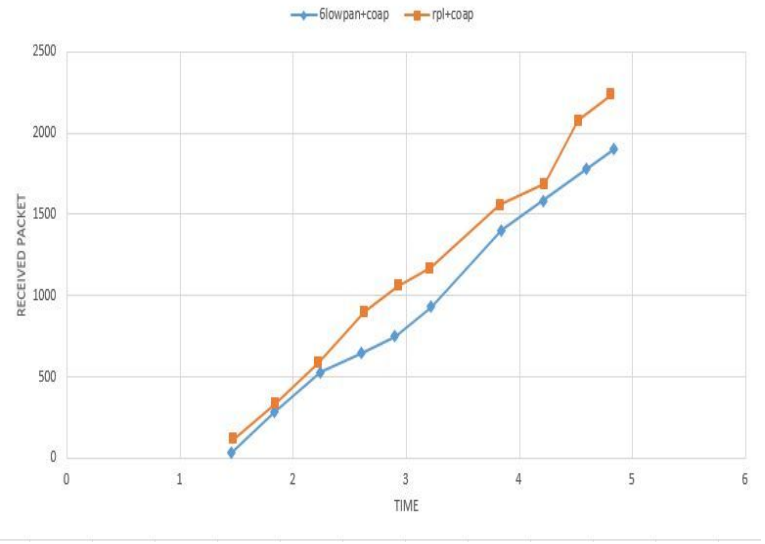

Fig. 6. Comparison of received packet for 50 nodes

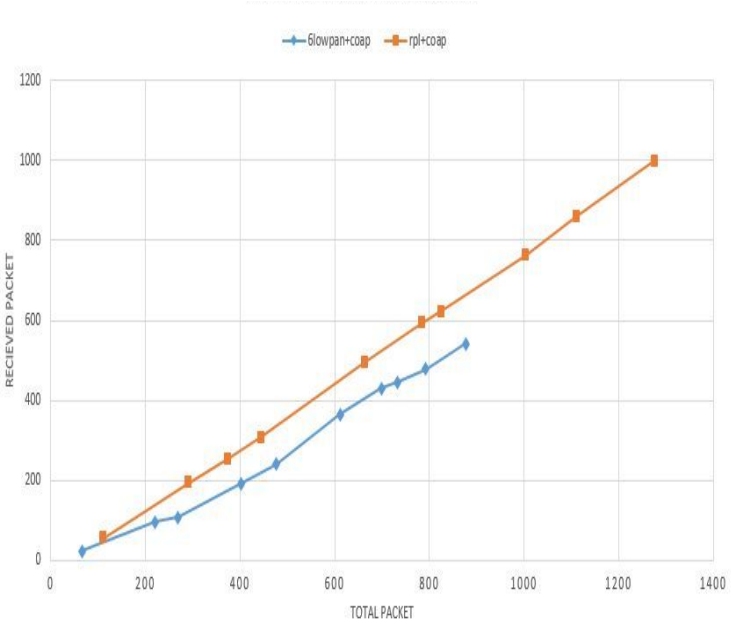

Fig. 7. Comparison of received packet for 70 nodes

As shown in Fig. 5, the server and the client nodes are communicating with each other using RPL and CoAP protocols together.Here,Purple and yellow nodes are UDP client and server under RPL protocol and green,orange nodes are UDP client and server under RPL protocol.

V. IMPLEMENTATION AND RESULT

The performance of merged (6LoWPAN and CoAP, RPL and CoAP) protocols will be compared depending on different criteria like received packet, number of nodes, time simulation and number of IOT nodes on cooja platform. Cooja is chosen to simulate contiki nodes which consume low resources like energy, bandwidth to communicate with each other on Ubuntu operating system. At present, this simulator is very popular among the network researchers since accurate behavior of the system can be examined and simulations of large networks are possible before embedded them into devices [21].

As seen in Fig. 5 ,the X-axis indicates the transmission time and Y-axis indicates number of received packets.The number of nodes has been taken as 50 for this simulation.It can be observed that 6LoWPAN and CoAP combination are bit slower than RPL and CoAP combination.For example, in 4.8 minutes 6LoWPAN and CoAP combination received 1900 packets out of 1977.However,at the same time RPL and CoAP combination received 2236 packets out of 2326.

As in Fig. 7, the X-axis indicates the total packets and Y-axis indicates number of received packets the number of nodes has been taken 20. 6LoWPAN and CoAP combination received 564 packets out of 877 and on the contrary RPL and CoAP combination receives 998 packets out of 1224.However 6LoWPAN and CoAP combination are slower than RPL and CoAP combination.

In Fig. 8, the X-axis indicates the transmission time and Y-axis indicates number of received packets.RPL-CoAP can receive more packets than 6LoWPAN-CoAP combination. In certain periods of time(12.51 minutes for both case) 6LoWPAN and CoAP combination received 641 packets on the other hand RPL and CoAP combination receives 1046 packet.

As seen in Fig. 9, Transmission range has been expanded from 10 meter to 60 meters.It can be seen from Fig. 6 that transmission rate of 6LoWPAN and CoAP is very slow. Noticed that, in 12.31 minute 6LoWPAN and CoAP combination received 841 packets.On the contrary RPL and CoAP combination received 3,545 packets for the same amount of time.

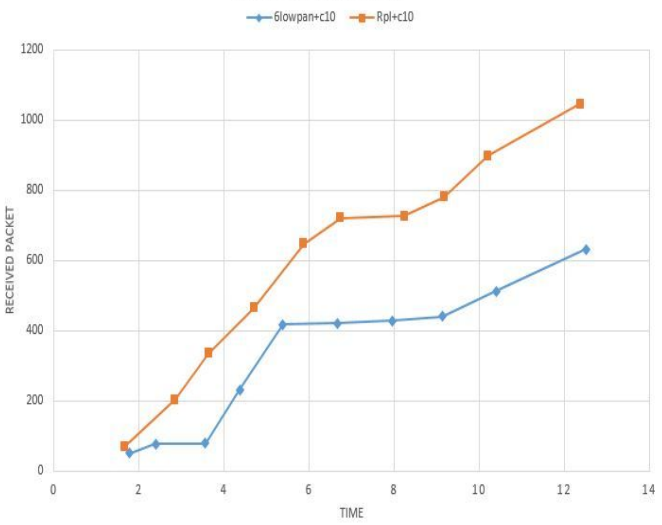

Fig. 8. Comparison of received packet for 10 meter range

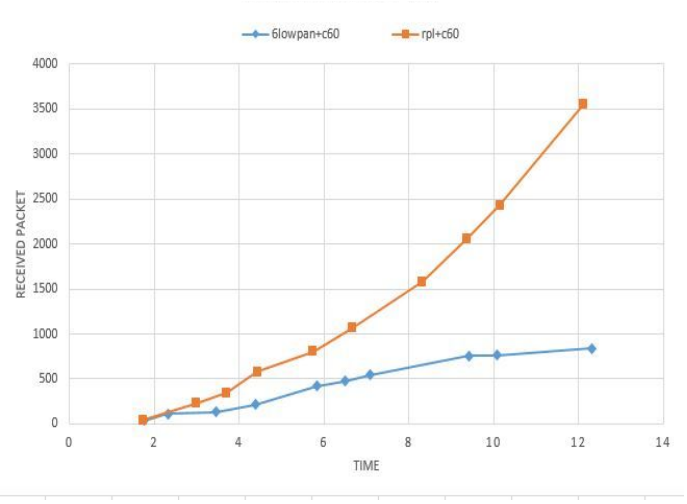

Fig. 9. Comparison of received packet for 60 meter range

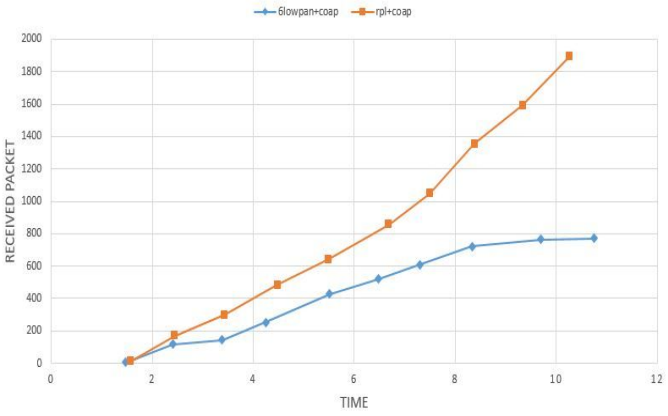

Fig. 10. Comparison of received packet for 100 meter range

Communication range has been changed in Fig. 10 for 100 meters.It can be find that in 10.74 minutes, 6LoWPAN and CoAP combination receives 771 packets but at the same time RPL and CoAP combination receives 1894 packets.

VI. Discussion

IoT is the concept in which the virtual world of information technology mixes flawlessly with the real world of things, it is one of the important topics in the current networking research.Since small devices which are embedded into IoT, are connected via the internet, consumption of power, memory, energy, routing, bandwidth, etc. are the vital issues.In this paper, mainly focused on investigating a better solution of finding out the best communication among these merged protocols 6LoWPAN and CoAP, RPL and CoAP.

In previous paper [], IoT protocol stack along with different protocols used at different layers have been studied for the efficient communication among IoT nodes through the Internet and focused on investigating a solution of finding out the best communication among three protocols 6LoWPAN, RPL and CoAP individually.But in this paper, find out the best communication after merging these protocols 6LoWPAN and CoAP, RPL and CoAP.

In this paper, the performance of merged protocols were examined depending on different criteria like different transmission range, different transmission time with number of data packets. After the analysis, it can be stated that packet transfer rate of 6LoWPAN and CoAP combination is slow and the combination of RPL and CoAP is more efficient in terms of packet reception. We are also hopeful to implement this protocol in real testbed and not so much deviations are expected though.

Abstract— A dual-band, 4×2 microstrip patch antenna (MPA) array for future 5G communication applications is proposed in this paper. The single element antenna of the proposed array configuration is a dual band patch antenna with dimension of 8×8 mm². This proposed single element antenna has resonance frequencies of 29 GHz and 40.5 GHz, and achieves 5.69 dBi and 4.54 dBi gain at the center frequencies respectively. The attained -10dB impedance bandwidth of the single element antenna is 10.34% and 12.34% at two operating frequency bands. Using corporate fed and series fed, the proposed 8-element MPA array is designed from this single element. The dimension of the proposed array antenna is 38 × 15 mm^2 and low-cost FR-4 material is used as the substrate. The proposed array antenna resonates at 29.5 GHz and 38 GHz, and provides 8.4 dBi and 9.3 dBi total gain at the resonance frequencies respectively. Thus, improved bandwidth and better radiation performance over required frequency bands, high gain and use of low-cost material makes the proposed antenna perfect for 5G communication/wireless communication applications.

Keywords- Antenna array, corporate fed, fifth generation (5G), millimeter-wave, dual-band.

I. INTRODUCTION

There are various generation of Mobile communication technology from 0*G* to 4*G* is introduced with the improvement of wireless communication system. The current generation of cellular communication system is 4G which is ineffective to solve the problems of poor coverage, crowded channel, poor quality, dropped connection and flexibility that unable to fulfill the consumer's requirements [1]. To fulfill these tradeoff, investigation and development of Fifth Generation (5*G)* of wireless communication have been started and it's expected to commercialize in 2020 [2].

5*G* is capable to provide a data rates of at least one gigabit per second for tens of thousands of users simultaneously, improved security features, large bandwidth, increase the energy efficiency and higher resolution for cells. So, 5G will provide support for interactive multimedia such as, virtual reality, autonomous driving etc. [3][4].

Modern/5G communication system requires the antennas with high standard of data transfer, small size, low cost of fabrication, more bandwidth which increases the demand of microstrip patch antenna. The limitation of low impedance bandwidth, low gain, and low efficiency of patch antenna can be overcome by using ARRAY configuration of a single element patch antenna. Also, the dimensions of the mobile phone rapidly decreasing that lead to the evolution of compact antenna structures. Multi-band characteristics, compact structure has emerged the patch as a promising candidate for handheld devices [5].

5G will use millimeter bands and probably require the generalization of the implementation of small-cell radio transmitter though no standard will be available until 2019 [6]. Fifth Generation (5G), here millimeter wave radio frequencies can provide the basic ground. Millimeter wave have unexploited spectrum (3GHz-300GHz) to fulfill the new generation needs. The range of spectrum for 5G application is 20-90GHz and different frequency bands will be allocated for different countries and different applications [7]. Recently, the 28 GHz and 38 GHz bands have been approved for mm-wave 5G operation in the USA by FCC [8].

Microstrip patch antenna is used in wireless and mobile communication because of its small size, low cost of fabrication, capability of supporting multiple frequency bands, and array configuration for the better gain. Each and every element of the array configuration has to be fed properly to make the array a perfect radiator. Single or multiple line feeding can be used in array. Series feeding network is single line feeding and multiple line feeding is called corporate feeding network [9].

In this work, a slotted microstrip patch antenna is designed which resonates at 29 GHz and 40.5GHz with total gain of 5.69 dBi and 4.54 dBi and impedance bandwidth of 3 GHz and 5 GHz at the resonance frequencies. FR-4 material has been used as substrate and thickness of the substrate is 0.8 mm. Then, for enhancing the gain 2×1, 4×1, and 4×2 patch antenna arrays is designed using corporate fed and series fed connection. Finally, an eight-element array antenna is developed which resonates at dual frequency bands dedicated for 5G communication and provides better radiation performance.

II. ANTENNA CONFIGURATION AND DESIGN

A. Single Antenna Element Design.

The schematic representation of the dual band single element patch antenna is shown in Fig.1. The dimension of the antenna is 8×8 mm², and designed on low cost FR-4 substrate with a dielectric constant (ε_r) of 4.4, loss tangent (tan δ) of 0.02 and thickness of 0.8 mm. It consists of a rectangular patch of dimension 3.25 ×2.3 mm² and microstrip feed line of 1 ×2 mm² having characteristic impedance equal to 50Ω. An E-shaped slot is truncated from the conventional rectangular patch to achieve dual-band characteristics and increase current flow path. Then the size of the slot is optimized to adjust the frequencies and achieve desired gain.

The detailed dimensions of optimized design of single element patch antenna are given in TABLE.I.

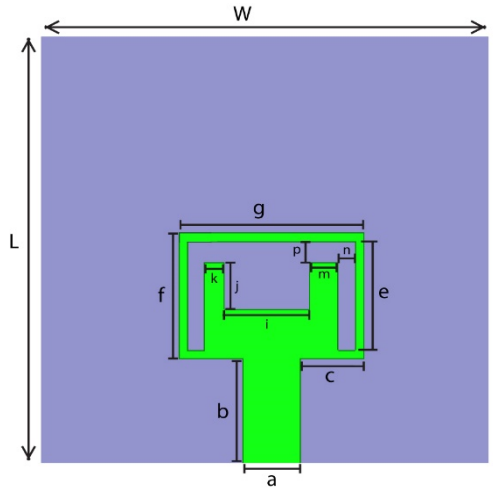

Fig.1 Single Element Patch Antenna.

TABLE.I. DETAILED DIMENSION OF THE SINGLE ELEMENT DESIGN

Parameter	Value(mm)	Parameter	Value(mm)
W	8	g	3.25
L	8	k	0.35
a	1	i	1.5
b	2	j	0.86
c	1.125	p	0.47
e	2	m	0.5
f	2.3	n	0.3

B. Array Antenna Design.

To ameliorate the total gain value array configurations are used. Here 4×1, four elements and 4×2, eight elements array antennas are designed. The schematic representation of 4×1, four element array antenna is shown in Fig.2.

The elements are connected using corporate fed in this configuration. Multiple fed lines are used to connect the elements, and match the impedance of the feeding line and antenna. The dimension of the 4×1, four element antenna array is 38 × 16 mm². The detailed dimensions of optimized fed line and distance between elements are given in TABLE.II.

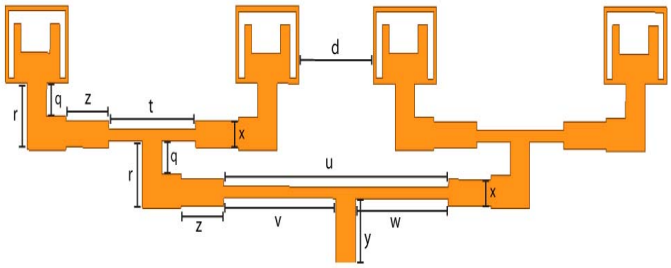

Fig.2 4×1 Array Configuration.

TABLE.II. DETAILED DIMENSION OF THE 4×1 ARRAY DESIGN

Parameter	Value (mm)	Parameter	Value (mm)
u	11.6	t	4.5
v	5.8	r	2
w	4.8	q	1
x	0.8	d	3.85
y	2.05	z	2.2

Finally, the proposed 4×2, eight elements antenna array is found by adding single element using corporate fed and series fed, which is shown in Fig.3. The size of proposed 4×2, eight elements antenna array is 38 × 15 mm². In the proposed 4×2 antenna array design, the dimensions of the fed line and single element are same as TABLE.I and TABLE.II . Here, series fed connections are used to add four antenna elements with previously described 4×1 antenna array to achieve dual-band characteristics and improved gain. The proposed antenna array is designed and simulated using Ansys HFSS software.

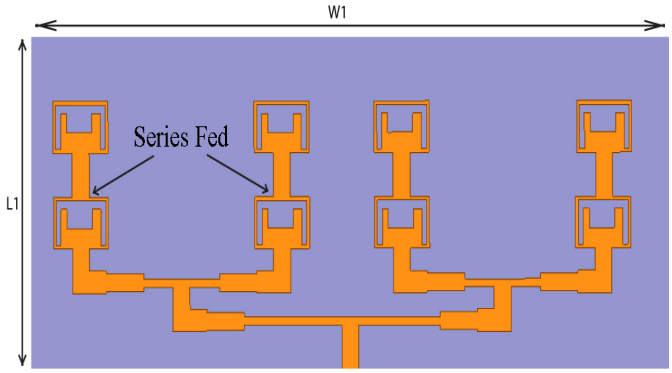

Fig.3 Proposed 4×2 Array Antenna

III. SIMULATION AND RESULTS

A. Simulation of Single Antenna Element.

Reflection coefficient shows the return loss due to mismatch in impedance of fed line and antenna. So, the lower value of reflection coefficient is preferred and -10 dB is the standard value for calculating impedance bandwidth. The proposed single element design has a return loss of -25.03 dB and -29.7 dB with VSWR of 1.11 and 1.06 at the resonating frequencies respectively which is shown is Fig.4. The achieved -10dB impedance bandwidth of this single element antenna is 10.34% and 12.34% at two resonating frequency bands which covers two 5G communication band.

The single element design provides total gain of 5.69 dBi and 4.54 dBi at two resonating frequencies respectively which are illustrated in Fig.6 using radiation pattern in E-plane and H-plane. The simulated 3d polar plots of gain at resonance frequencies are delineated in Fig.7 and Fig.8. This design provides directive radiation pattern and maximum gain at a specific direction and angle. In the

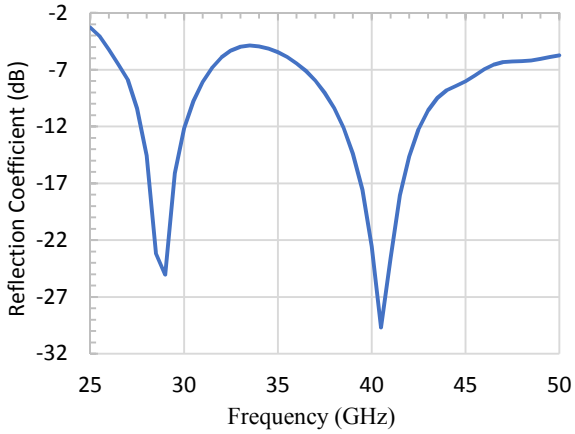

Fig.4 Reflection Coefficient of Single Element Antenna.

simulation, the radiation efficiency of single element antenna is found 79.26% and 87.13% at 29 GHz and 40.5 GHz respectively.

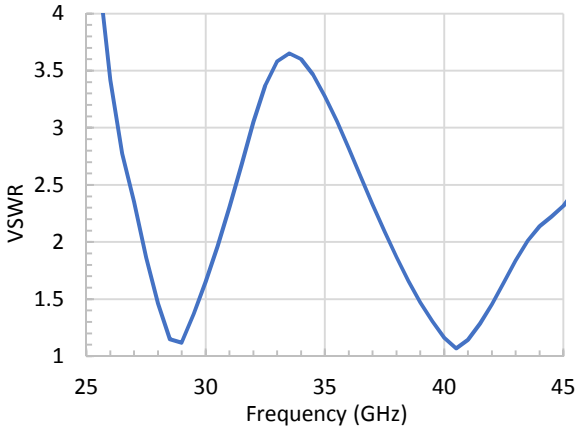

Fig.5 VSWR of Single Element Antenna

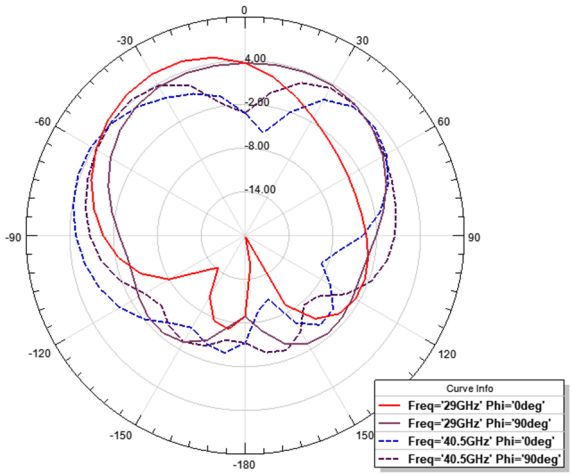

Fig.6 Gain of Single Element Antenna in Radiation Pattern

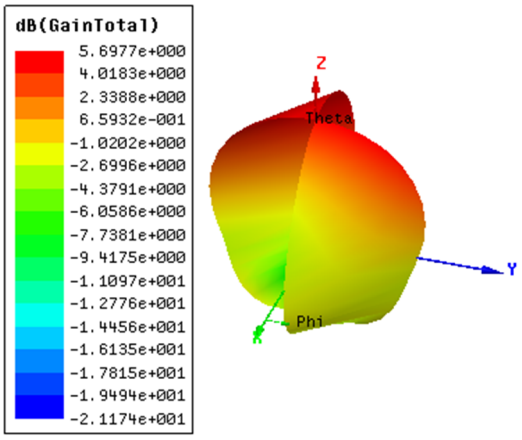

Fig.7 Simulated Gain of Single Element Antenna in 3d Plot at 29 GHz.

B. Simulation of Proposed Array Antenna.

Here, Fig.9 shows the simulated return loss of 4×1, four elements and 4×2, eight elements array antenna. Both are evident that they operate over two desired frequency bands allocated for 5G communications. The designed 4×1, four element array antenna resonates at 30 GHz, 32 GHz, 34.5 GHz, 38 GHz and provides return loss of -17 dB, -20.5 dB, -15.5 dB, and -18.7dB respectively. Thus, the simulated resonance frequency of proposed 4×2, eight elements array antenna is 29.5 GHz, 32 GHz, 35 GHz, and 38 GHz, and provides return loss of -18 dB, -17.9 dB, -16.1 dB, and -17.6 dB at the resonating frequencies respectively. Among the operating frequency bands, two bands are extensively used for 5G communication research.

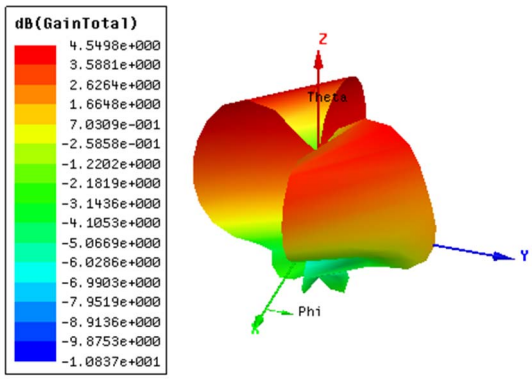

Fig.8 simulated Gain of Single Element Antenna in 3d Plot at 40.5 GHz.

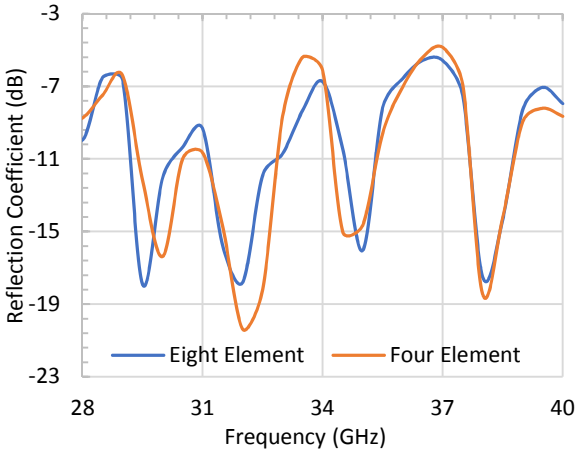

Fig.9 Reflection Coefficients of 4-Element and 8-Elements Array Antenna.

The achieved -10dB impedance bandwidth of 4×1 antenna array is 4.1% and 3.6% at resonance frequencies of 30 GHz and 38 GHz respectively. Here, the proposed 4×2 antenna array attains -10dB impedance bandwidth of 4.5% and 3.6% at the resonance frequencies of 29.5 GHz and 38 GHz respectively. The radiation pattern of the total gain in E-plane and H-plane of 4×1 antenna array at the resonating frequencies is shown in Fig.10. The total gain of 4 element array antenna is found 8.1 dBi and 8.8 dBi at the operating frequencies respectively.

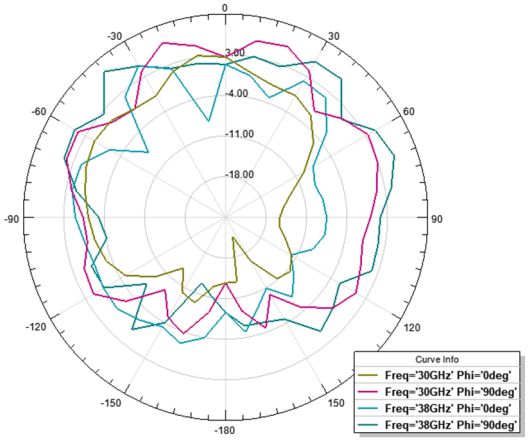

Fig.10 Gain of 4×1, 4-Element Array Antenna.

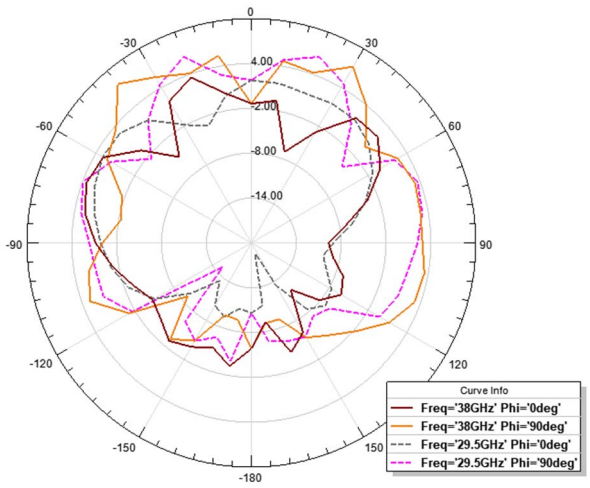

Fig.11 Gain of proposed 4×2, 8-Element Array Antenna.

The gain of the proposed 4×2, eight element array antenna is illustrated in Fig.11 using radiation pattern. Total gain of this proposed 4×2, eight element array antenna is achieved 8.4 dBi and 9.3 dBi at resonance frequencies respectively. The radiation efficiency of the proposed array configuration is 98.3% and 98% at the center frequencies respectively. Here, Table.III and Table.IV contain the performance comparison of single element design and proposed array design with similar existing works to limn the improvement in outcomes of the proposed antennas.

TABLE. III. PERFORMANCE COMPARISON BETWEEN PROPOSED SINGLE ELEMENT ANTENNA AND SIMILAR EXISTING WORKS

No	Dimension (mm²)	Resonance Frequency (GHz)		Gain (dBi)		Bandwidth (GHz)	
		F1	*F2*	*F1*	*F2*	*F1*	*F2*
[7]	7 × 3	28	38	3.75	5.06	3.34	1.395
[10]	19 × 19	10.15	28.1	5.51	7.54	.278	1.085
Proposed	8 × 8	29	40.5	5.69	4.54	3	5

TABLE. IV. PERFORMANCE COMPARISON BETWEEN PROPOSED ARRAY ANTENNA AND SIMILAR EXISTING WORKS

No.	Dimension (mm²)	Resonance Frequency (GHz)		Gain (dBi)	
		F1	*F2*	*F1*	*F2*
[11]	(64-elements)	-	38	-	6.5
[12]	130 × 74	29	32	5.39	4.92
Proposed	38 × 15	29.5	38	8.4	9.3

IV. CONCLUSION

A compact array antenna operates at two frequency bands which are dedicated for 5G communication is proposed in this work. A dual-band single element patch antenna is designed to make the desired MPA array configuration. Here, different array configurations are used using different feeding technique to achieve the desired radiation performance. The material used in this design is low cost FR-4. The proposed MPA antenna encloses two 5G communication frequency bands (28GHz and 39.5GHz) entirely and provides improved gain of 8.4dBi and 9.3dBi. Low cost, operation over two bands, wide bandwidth and high gain with compact structure ensures that the proposed antenna has great potential for 5G mobile communication applications.

***Abstract*— A compact triple-band antenna for biomedical telemetry applications is presented in this paper. The proposed antenna operates at MedRadio band (402-406 MHz) and ISM bands (902-928 MHz & 2.40-2.48 GHz) whose resonance frequencies are 402 MHz, 914 MHz, and 2.43 GHz. A meandering slotted patch over the silicon substrate of standard 0.275 mm thickness and a sorting pin is used to achieve the desired results and size. The performances of the proposed antenna are evaluated and studied in free space, in a skin phantom cube and inside the fat of a six-layer phantom model using Ansoft HFSS software. Differential feeding is utilized in the design and the volume of the presented antenna is only 46.475 cubic millimeter excluding superstrate. The simulated bandwidth of the proposed antenna is 11.7%, 0.77%, and 2.88% at the resonant frequencies respectively. Finally, the specific absorption rate is determined at the center frequencies in the phantom model for the assessment of patient safety. Compact structure, bio-compatibility, improved realized gain and operation over three different biomedical frequency bands enables the antenna to be used with implantable medical devices with great possibilities.**

Keywords*— Biomedical Telemetry, Implantable antenna, Low profile, Miniaturization, Triple-band.

I. INTRODUCTION

The use of biotelemetry system in the implantable medical devices (IMD) like pacemaker, defibrillator, glucose monitor etc. are increasing gradually because of thriving demand in continuous monitoring of physiological parameters, diagnosing diseases of patients, and treating some diseases [1]. In a biotelemetry system, implantable antenna is the major element for transmitting and receiving physiological signals. In this perspective, an implantable antenna must be stable in terms of performance and biocompatible for assuring patient safety. Moreover, it has to be compact in structure as the IMDs are very small in size [2].

Various types of antenna such as PIFA [3], slot antenna, patch antenna [4], spiral antenna [5] etc. have been proposed in last few years for biotelemetry applications. These implantable antennas are operated with radio-frequency coupling strategy which is a great alternative to traditional inductive coupling coils. There are few radio frequency bands including MedRadio bands (402-406 MHz, 413-419 MHz, 426-432 MHz, 451-457 MHz) [6], ISM bands (433-434.8 MHz, 902-928 MHz, 2.4-2.48 GHz, and 5.725-5.875 GHz) which have been dedicated to biomedical telemetry applications by the Federal Communications Commission (FCC). Antennas for biotelemetry applications can operate at single or the multiple numbers of frequency bands from the bands mentioned above.

In literature, some work has conducted on multiband antennas. For instance, a differentially fed dual band implantable antenna operating at MICS band (402-405 MHz) and ISM band (2.4-2.48 GHz) has been proposed in [7]. The simulated -10dB bandwidth of that antenna was 12.6% at MICS and 5.7% at ISM band respectively. However, the volume of this antenna is 691.515 mm^3 which is comparatively large. Another differentially fed dual band implantable antenna is reported in [4]. This antenna also operates at MICS and ISM band mentioned above. After using the shorting pin and meandering slots the obtained volume of that antenna was 642.62 mm^3.

The important requirements while designing an antenna for biomedical application are patient safety and stable radiation performance. For assuring patient safety, the assessment of biocompatibility usually done through specific absorption rate (SAR) calculation at the resonant frequencies. The SAR of the antenna at the operating frequencies must follow the maximum allowable standard. The maximum value of the average SAR should be equal to 1.6 W/kg for 1-g tissue model as IEEE C95.1-1999 standard [8]. According to IEEE C95.1-2005 standard the maximum average SAR should be equal to 2 W/kg [9]. Moreover, after implantation, the surrounded environment (e.g. human/animal tissues) influences the performance of the antenna. So, the performance of the antenna must be optimized by considering tissues in the surrounding environment. Thus, the antenna performance needs to be evaluated in free space and in different tissue models to figure out the change in antenna performance in different conditions.

In this work, a compact triple-band antenna is proposed. The antenna is simulated in free space, in a skin phantom, and in six-layer phantom model to find the resonance frequencies and realized gain. Finally, SAR of the antenna is determined for assuring patients safety and biocompatibility of the proposed implantable antenna.

II. ANTENNA CONFIGURATION

In this paper, a patch antenna is proposed because of low cost, easy fabrication, compact size, and flexibility of design. The dimension of the proposed design is 13×13×0.275 mm^3 excluding superstrate. The schematic representation of the proposed antenna is shown in Fig.1. A silicon layer of 0.275mm thickness with the dielectric constant of $\in_r$=11.9, loss tangent of tanδ = 0.0012 is used as the substrate layer. In this design, a meandering slot, shorting pin, and rectangular slots are applied to minimize the dimension of the antenna and find the desired output.

Firstly, a meandering slot is truncated on the center of the patch to increase the current path between the feed and the radiating patch hence to reduce the antenna size significantly. Secondly, two rectangular slots are mangled to adjust the resonating frequencies and antenna size by increasing current patch or altering patch current distribution. Thirdly, a sorting pin of 0.4 mm is used for altering the reactance of the antenna which is required to further miniaturization of the antenna and reduce the resonant frequencies. For achieving the lower value of the axial ratio, two slots are made on the ground which can be adjusted to obtain circular polarization.

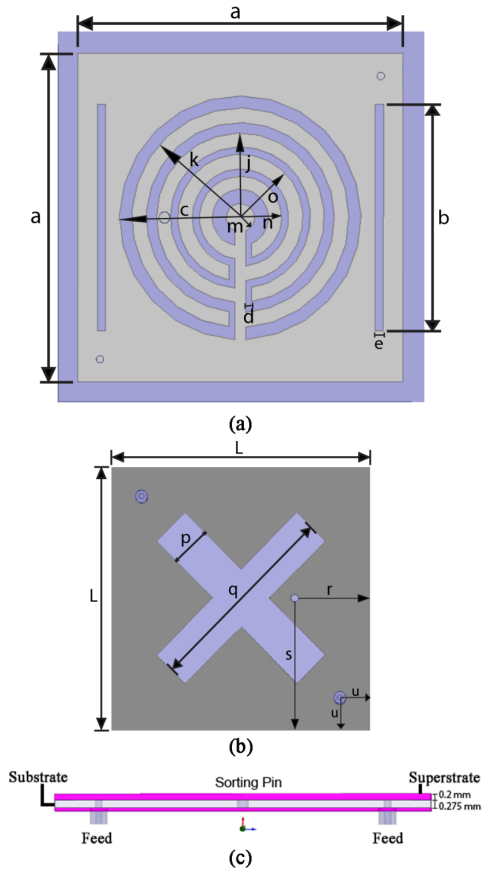

Fig.1. Schematic Representation of Proposed Antenna a) Patch, b) Ground, and c) Side View.

For avoiding the short circuit between metallic ground/patch and tissue after implantation, a separation layer is used which is called superstrate layer. A thin layer of silicon-di-oxide with the dielectric constant of $\in_r$= 4.0, loss tangent of tanδ = 0.006 is used as a superstrate. The thickness of the superstrate is 0.1 mm. Superstrates are attached all over the metallic patch/ground to reduce the losses by human/animal tissues and improve the radiation performance [7].

The size of the slots, the location of sorting pin is optimized by iterative simulation to obtain desired resonance frequencies and radiation performance. The feeding ports are connected to 50 Ω coaxial cable. Iterative simulation of the antenna with different feeding position is done to obtain impedance matching of antenna with the feed line. Proper impedance matching is needed to reduce return loss and increase the efficiency of the antenna. After the optimization and adjustment of size, the optimal geometric parameters are obtained which are listed in TABLE.I.

A. *Simulation in free space.*

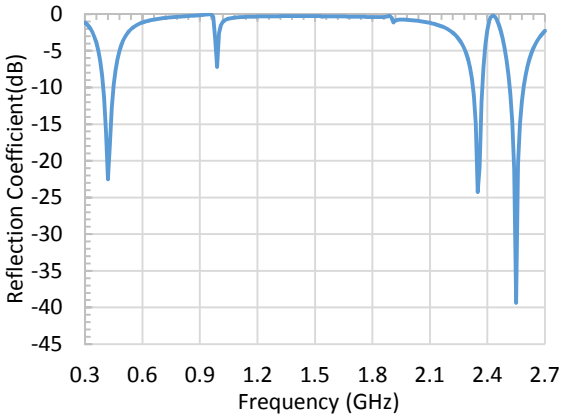

Fig.2. Reflection Coefficient in Free Space.

The return loss response of the proposed antenna in free space is illustrated in Fig.2. In free space, the antenna resonates at 0.42 GHz, 0.99 GHz, 2.35 GHz and 2.55 GHz which are shown in Fig.2. The proposed antenna is optimized following the phantom model simulation result because of purpose of implantation. It is simulated in the free space to observe the antenna performance and effect of phantom model on the antenna only that's why the antenna is not tuned in desired frequency bands. The simulated radiation efficiency of the antenna is found 94.84%, 98.49%, and 95.91% at 0.42 GHz, 2.35 GHz, and 2.55 GHz respectively in free space.

B. *Design of Phantom Models.*

The performance of an implantable antenna should be determined inside the phantom model for estimating the antenna performance after implantation. Antenna performance depends on surrounded or radiating environment. Moreover, for analyzing the biocompatibility of the designed implantable antenna, it is required to simulate the antenna in phantom models also. An antenna generally shows different characteristics in the different environments like air, fat, skin, tissue, multi-layer model etc.

Depending on requirements, the antenna must be simulated inside single/multi-layer skin model or human

body model. Here, a skin phantom cube and a six-layer model is designed to simulate the proposed antenna. Although the body model of an animal or human is very complex, here, a simple six-layer model is considered for simulation of the design. Human/animal body tissues show different dielectric characteristics in different frequency and an average value is used in the design of the models as the proposed antenna operates over multiple frequency bands. Geometric representation and detailed dimension of skin model and six-layer phantom model are shown in the Fig.3 and dielectric properties of the tissues of the models are given on Table.II.

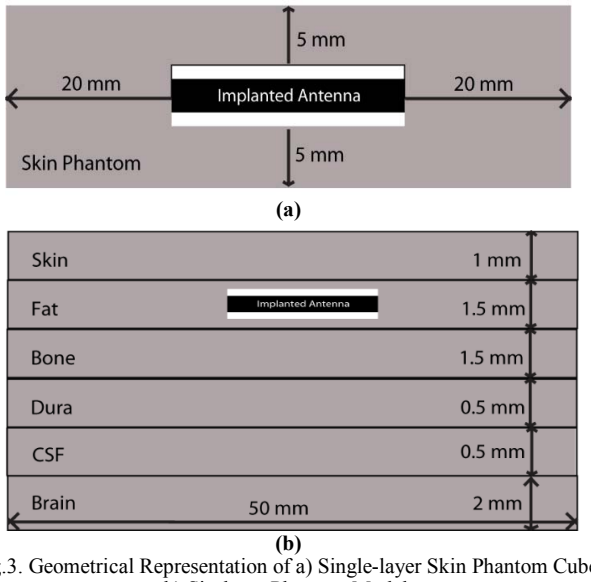

Fig.3. Geometrical Representation of a) Single-layer Skin Phantom Cube, b) Six-layer Phantom Model.

TABLE II. THE DIELECTRIC PROPERTIES OF DIFEERENT TISSUES [10]

Tissues	Permittivity	Mass Density	Conductivity(S/m)
Skin	40.2	1080 kg/m^3	0.8
Fat	15	920 kg/m^3	0.35
Bone	4.9	1180 kg/m^3	0.15
Dura mater	44.39	1030 kg/m^3	0.966
CSF	68.61	1110 kg/m^3	2.419
Brain	50	1050 kg/m^3	1

C. Antenna Performance in Phantom Models.

The proposed antenna is optimized in a single layer skin phantom cube, and the optimized design is simulated in free space and six-layer rat head model later. The resonance frequencies of the proposed design are found 402 MHz, 914 MHZ, and 2.43 GHz in the simulation inside skin phantom cube. Value of S_{11} parameter at the resonant frequencies (402 MHz, 914 MHZ, and 2.43 GHz) are -24.74 dB, -16.27 dB, and -14.52 dB respectively as shown in Fig.4. The VSWR at resonance frequencies are 1.12, 1.37, and 1.50 respectively. The achieved -10dB impedance bandwidths of the antenna are 11.7%, 0.77%, and 2.88% at 402 MHz, 914 MHZ, and 2.43 GHz frequency respectively. Simulated radiation efficiency of the proposed antenna in the skin phantom cube is attained 80.32%, 60.10%, and 88.18% at 2.43 GHz, 914 MHz, and 402 MHz respectively.

In the simulation inside the six-layer model, the optimized design resonates at 360 MHz, 2.13 GHz, and 2.3 GHz. The simulated data of the reflection coefficient are plotted and shown in Fig.4 with the comparison of single layer model results.

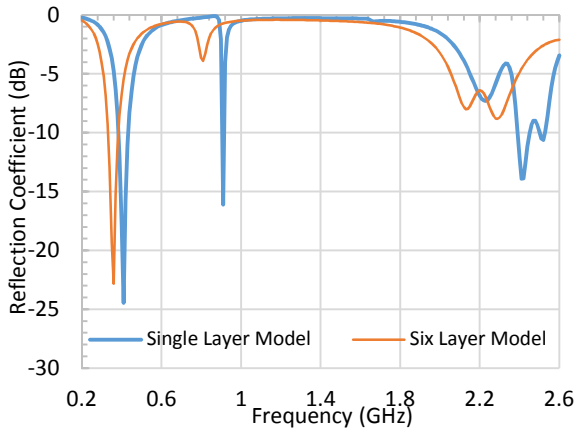

Fig.4. Reflection Coefficient of the Proposed Antenna in Skin Models.

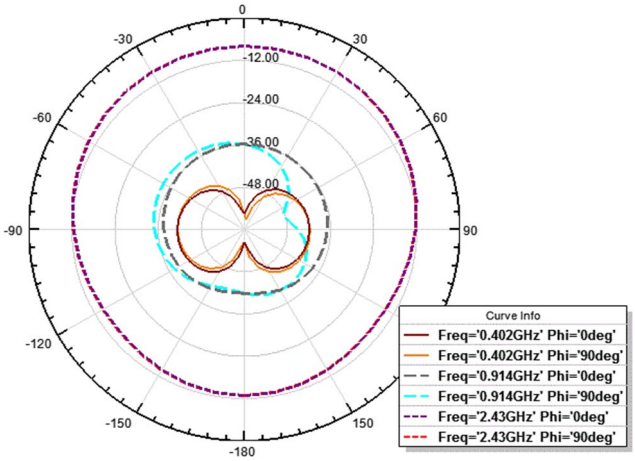

Fig.5. Realized Gain of the Proposed Antenna in Skin Cube

The peak realized gains of the proposed antenna inside skin phantom cube are attained of -41.30 dBi, -33.35 dBi, and -7.90 dBi at 402 MHz, 914 MHZ, and 2.43 GHz respectively which are illustrated in Fig.5. The angles at which the peak realized gains are found are -90-degree, -50 degree, and 0 degree. In the simulation inside the fat of six-layer model, the peak realized gain of the antenna are -16.01 dBi, -11.52 dBi and -42.9dB at resonance frequencies found in the simulation in six-layer model respectively.

The maximum value of current distribution over the patch of the proposed antenna is found at 2.45 GHz. Current distribution of the antenna is represented at Fig.6. High value of current on the patch can cause heat there which must be avoided. Here, the value of Jsurf over the patch is sustainable, and superstrate layers are applied over the patch and ground.

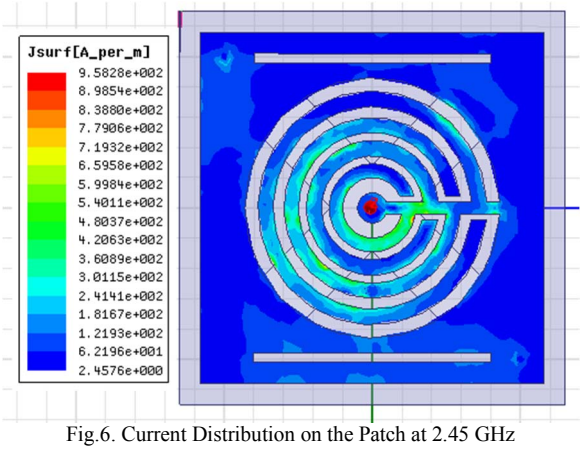

Fig.6. Current Distribution on the Patch at 2.45 GHz

A performance comparison between the proposed design and similar existing works are delineated in Table. III to limn the performance improvement of the proposed antenna.

TABLE III. COMPARISON BETWEEN PROPOSED AND SIMILAR EXISTING ANTENNA

No.	Vol. (mm^3)	Implant Tissue	Resonating Frequency (MHz)	-10 dB impedance bandwidth	Gain (dBi)
[7]	691.515	Skin	400 2400	12.6% 5.7%	-30 -
[4]	642.62	Skin	402 2400	7.4% 6.6%	-36.7 -27.1
This work	46.475	Skin Fat	402 914 2430	11.7% 0.22% 2.88%	-41.30 -33.35 -7.90

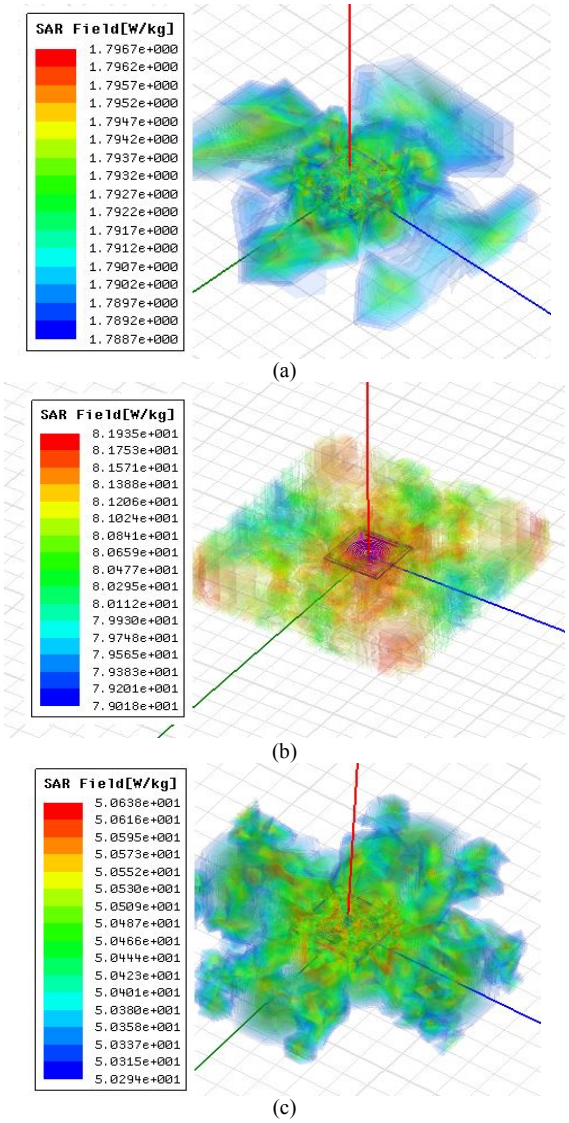

Fig.7. The Value of Specific Absorption Rate at a) 402 MHz, b) 914 MHz, and c) 2.43 GHz.

D. Biocompatibility Analysis.

Specific absorption rate analysis is the factor to evaluate the radiation effect of the antenna on the human/animal body to determine the safety level. The proposed patch antenna transmits and receives the electromagnetic energy wirelessly while working with an implantable device. A portion of the electromagnetic energy which is transmitted/received interacts with the tissue around the implantable antenna and assessment of that absorbed energy is called biocompatibility analysis. Maximum allowable specific absorption rate and conditions discussed in previous section [9][10]. The specific absorption of the proposed antenna is simulated at the resonating frequencies, assuming 1W power is radiated by the antenna and mass of the skin phantom cube is 1g. After the SAR analysis of the proposed antenna at the resonance frequencies, the maximum specific absorption rate is found 81.93 W/Kg at 914 MHz. So, the radiated power of the antenna must be less than 19.53 mW to satisfy the maximum allowable specific absorption rate of 1.6 W/Kg for 1g tissue. The results of the specific absorption rate analysis at the resonance frequencies are shown in Fig.7 respectively.

IV. CONCLUSION

A differential fed compact in size triple-band antenna is designed in this paper. The volume of the proposed antenna is 46.475 mm^3 without superstrate and the antenna resonates at three frequency bands which are dedicated for biomedical applications (MedRadio and ISM band). The -10dB impedance bandwidth of the antenna fully encloses one MedRadio (401-405 MHz) and one ISM band (2.40-2.48 GHz), and partially covers another ISM band (910-917 MHz). Due to implantation purpose, the performance of the designed antenna is assessed in free space and inside phantom models. The SAR is calculated for ensuring biocompatibility and patient safety. Before concluding about the antenna performance and patient safety, an extensive experimental study is needed as the results of this paper is totally simulation-based.

***Abstract*— This work deals with the design and simulation of patch antenna that provides resonance at frequency 9.968 GHz and applicable for RFID, WiMAX, and X-band applications. The antenna has a -10 dB impedance bandwidth of 300 MHz ranging from 9.8 GHz to 10.1 GHz. The prospect of this design is to obtain a small size, light weight and low-cost miniaturized antenna with good antenna characteristics and ease of integration using feed-networks. The basic theory and design are analyzed, and the simulation results are obtained using computer simulation technology (CST) Microwave Studio. The proposed antenna provides excellent VSWR of 1.208 and a gain of 5.960 dB. The simulated directivity, return loss (S11) and radiation efficiency are 6.015 dBi, -20.49 dB and 98.14% respectively. The simulation and PCB design of the proposed antenna are carried out using FR4 (lossy) substrate. The experimental radiation pattern is investigated using wave and antenna training system (WATS 2002) module. Finally, the simulated radiation pattern is compared with the experimental one.**

Keywords*— Patch Antenna, Microstrip, RFID, X-band, VSWR.

I. INTRODUCTION

Now-a-days, technology is rapidly switching and make many things easier day by day. Since the innovative thinking of a person is increasing day-by-day, new methods for wireless communication have been evolved. As the lower frequency band are almost occupied and due to spectral crunch wireless technology are switched to the higher frequency band. Higher frequency band means there is a greater chance to achieve higher bandwidth as a result multi-gigabit data speed can be achieved according to the user demand [1]. Since the performance of an antenna directly affects the overall communication system performance, so an accurate antenna design, especially at a higher frequency band, is a very essential task. Huge research has been done in the area of antenna design at the industrial, scientific and medical band (ISM), high frequency (HF) band, ultra-high frequency (UHF) band and centimeter band [1]. It should be great concern that the designed antenna should be low profile antenna that means the antenna have light weight, lower substrate thickness, and lower dimensional parameters with acceptable antenna performance metrics. At present low profile antennas with good performance characteristics are a suitable candidate for any wireless technology especially at wireless-fidelity (Wi-Fi), worldwide interoperability for microwave access (WiMAX), and X-band applications like satellite communications [2,4]. On the other hand, if we consider both commercial and military applications wideband, multiband and low profile antennas are great demand for a modern wireless communication system that influenced the research on antennas in many directions. The researcher is exploiting various types of antennas like as L-shaped, F shaped, inverted F-shaped, and E-shaped microstrip patch antenna for different applications like WLAN, GPS, GSM, mobile radio, wireless communications [2,3]. The microstrip patch antenna is a very good candidate and can perform very well in WiMAX and X-band satellite communication due to its ease of fabrication, low profile and acceptable performance [2,4]. The patch of a microstrip patch antenna is generally made of metal like copper or gold. But, the surface of the dielectric substrate feed line and the radiating patch are basically photo etched. Just for its fringing fields, the patch is electrically bigger than its physical size. The rectangular microstrip patch antenna is a very simple design considering its geometric structure but the electromagnetic field is complex. Calculating all the parameters need thorough analysis and accurate calculation. The main advantage of a microstrip patch antenna is its light weight and simple design. But the drawbacks are the narrow frequency bandwidth, deceptive feed radiation, poor polarization purity, limited power capacity, tolerance problem and the excitation of surface waves [5]. To design microstrip patch antenna substrate plays an important role to achieve good antenna performance. Because higher the substrate thickness lowers the antenna resonance frequency but higher the antenna gain, directivity, and bandwidth. In addition, if the dielectric constant (permittivity) of the antenna substrate is decreased then antenna resonance frequency and bandwidth are increased. So it is necessary to adjust antenna dielectric substrate thickness as well as substrate permittivity according to the technology requirements [8].

II. LITERATURE REVIEW

We have reviewed some of the previous antennae works as well as we have discussed their antenna size, shape, operating frequency band, gain, return loss etc. In Section V we have compared our resultant values with some of the reviewed works. The literature review table is shown in "TABLE.1

III. OBJECTIVES AND ORGANIZATION OF THIS RESEARCH WORK

The main contributions of this paper are mentioned below:

A. A microstrip patch antenna is proposed having resonance frequencies of 9.968 GHz, and 12.3 GHz to 13 GHz for wireless applications such as X-band, WiMAX, and RFID applications. The simulation of the proposed antenna is carried out using CST Microwave Studio and the simulated Gain, S11 (Return loss), VSWR, and the radiation pattern is presented.

B. The proposed antenna is implemented in hardware and the experimental radiation pattern is measured using WATS 2002 module. Finally, a comparison between simulated and experimental radiation pattern is reported in this research.

The rest of the paper is organized as follows. In Section IV, the design of microstrip patch antenna is designed. Simulation results on the return loss (S_{11}), voltage standing wave ratio (VSWR), directivity, radiation efficiency for the proposed antenna are presented in Section V. Finally, Section VI provides concluding remarks.

IV. ANTENNA DESIGN METHODOLOGY

Our research work is primarily focused on designing a microstrip patch antenna. The proposed antenna is formulated based on the empirical formula that helps to obtain desired geometry. This equation based designed results in the larger size of the antenna. As well as in most cases they may not provide excellent results. Hence, in order to achieve better results, further adjustments are required. After designing an antenna, we emphasized on antenna design with irregular geometry.

A. Antenna Design

Computer Simulation Technology (CST) Microwave Studio is used for antenna simulation and optimization. Commercially available FR4 substrate of thickness 2.5 mm is used on which the total structure is mounted. Dielectric constant (ϵ) is chosen 4.3 while loss tangent is 0.025. The opposite side of the substrate contains the copper plate that acts as a ground plane. This enhanced the directivity of the antenna to the desired level. Copper metal is also used as the radiating element. The thicknesses of both the radiator and ground plane are 0.313 mm. Plan view of the centimeter wave microstrip patch antenna is shown in "Fig. 1". Here, the proposed dual-band antenna is designed and optimized with first resonance frequency band at f_{r1} = 9.868 GHz and second resonance frequency band at f_{r2} = 12.3-13 GHz on

FR4 substrate. The overall ground plane dimension of the proposed antenna is 40 × 39 mm^2.

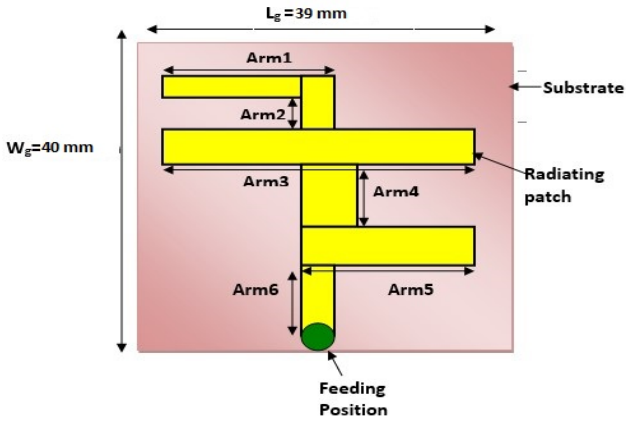

Fig. 1. Schematic diagram of the proposed antenna.

The antennas are designed based on the "(1)" – "(4)". In order to obtain the antenna's higher order Transverse Electromagnetic Modes (TEM) whose attributes are very closely matched with the fundamental mode, a technique is introduced to calculate the proposed antenna's length and width. This technique is commonly known as size extension method [10]. According to the size extension method, the extended patch antenna width 'W' and length 'L' can be expressed as below:

$$W = \frac{(2N+1)}{\sqrt{(2\varepsilon_r+1)/2}} \times (\frac{\lambda}{2}) \quad (1)$$

$$L = \frac{(2N+1)}{\sqrt{\varepsilon_{eff}}} \times (\frac{\lambda}{2}) - 2\Delta L \quad (2)$$

where λ is the proposed antenna's operating wavelength, ε_r is the relative permittivity (dielectric constant) and N is a positive valued integer number (in this antenna design we assume N =1). The physical dimensions of the microstrip patch antenna would look electrically wider for the fringing field effect. The extended length of the patch ΔL on each side is a function of antenna width to substrate height ratio (W/h) and the effective dielectric constant ε_{eff} [8]. So, ΔL and ε_{eff} are obtained by the following equations

$$\Delta L = 0.412h \frac{(\varepsilon_{eff}+0.3)(0.264+W/h)}{(\varepsilon_{eff}-0.3)(0.8+W/h)} \quad (3)$$

Where, effective dielectric constant,

$$\varepsilon_{eff} = \frac{\varepsilon_r+1}{2} + (\frac{\varepsilon_r-1}{2})(1+12\frac{h}{W})^{-\frac{1}{2}} \quad (4)$$

The initial length and width of the two antennas are obtained by taking 10 GHz resonance frequency. The optimized dimensional parameter values of the proposed dual-band antenna are shown in "TABLE. II".

TABLE II: GEOMETRICAL PARAMETERS OF ANTENNA STRUCTURE

Arm name	Length(mm)
Arm1	20.645
Arm2	5
Arm3	33.29
Arm4	8
Arm5	19.145
Arm6 (Feed line)	4
Patch thickness	0.313
Lg (Substrate Length)	39
Wg (Substrate Width)	40
h (substrate thickness)	2.5

"Fig. 2" and "Fig. 3" shows the front and back view of the hardware implementation of the proposed antenna. The hardware design of the antenna is done using toner transfer process.

Fig. 3. Back view of the proposed antenna hardware.

B. Antenna Performance Metrics

The performance of an antenna depends on several performance metrics. These metrics are S-parameter, Voltage Standing Wave ratio (VSWR), Half Power Beam Width (HPBW), antenna bandwidth, gain, directivity, and radiation efficiency. In this research work, the antenna designs are evaluated by the following metrics:

- *Scattering parameter (S-parameter):* S-parameters represent the amount of power reflected back from the antenna. It is also called return loss (RL). RL is related to reflection coefficient (Γ). "Equation (5)" and "(6)" are used to represent reflection coefficient and return loss of an antenna respectively.

$$\Gamma = \frac{Z_L - Z_{in}}{Z_L + Z_{in}} \quad (5)$$

$$RL = -20\text{Log}(\Gamma) \quad (6)$$

where Z_L is the load impedance (antenna impedance) and Z_{in} is the input impedance (or source impedance Z_S).

- *VSWR:* VSWR indicates impedance mismatch and higher the impedance mismatch, higher the value of VSWR. For effective radiation, the ideal value of VSWR is 1. But a VSWR value less than 2 is acceptable.

$$VSWR = \frac{1+|\Gamma|}{1-|\Gamma|} \quad (7)$$

- *Directivity (D):* The antenna directivity is defined as the ratio of the radiation intensity in a given direction from the antenna to the radiation intensity averaged over all directions.

$$D = \frac{4\pi U(\theta,\phi)}{P_{rad}} \quad (8)$$

Where D is the directivity (dimensionless), P_{rad} is the total radiated power in Watt, $U(\theta,\phi)$ radiation intensity (W/sr).

- *Gain (G):* Gain is closely related to the antenna directivity and can be defined as the ratio of the radiation intensity in a given direction to the radiation intensity that would be obtained if the power accepted by the antenna were radiated isotopically.

$$G = \frac{4\pi U(\theta,\phi)}{P_{in}} \quad (9)$$

- *Radiation Efficiency (η_{rad}):* Antenna radiation efficiency is related to the antenna gain and directivity.

$$\eta_{rad} = \frac{G}{D} \quad (10)$$

V. Simulated and Experimental Results of the Proposed Antenna

The designed antenna provides resonance at frequencies at = 9.868 GHz and second resonance frequency band at = 12.3-13 GHz. The excitation signal to the antenna is supplied by a 50Ω waveguide port using CST simulation software. From the "Fig. 4" it can be seen that the return loss at first resonance frequency is -20.49 dB and at the second resonance frequency is -10 dB. The proposed antenna provides 3 dB impedance bandwidth at first resonance frequency is 300 MHz ranging from 9.8 GHz to 10.1 GHz and -8 dB bandwidth at the second resonance frequency is 1 GHz ranging from 12.2 GHz to 13.2 GHz. The simulated VSWR curve of the proposed antenna is shown in "Fig. 5".

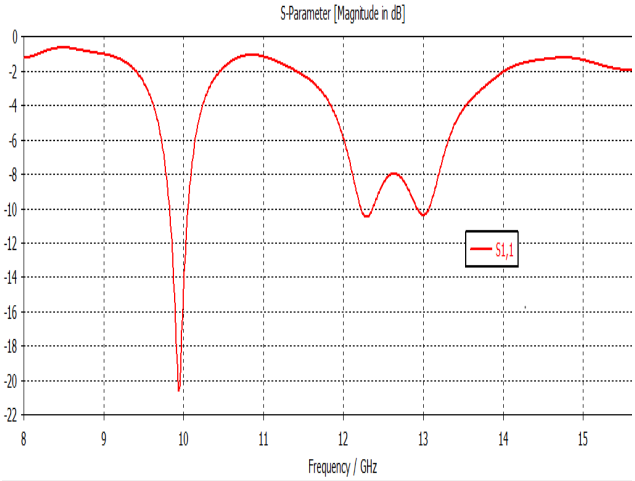

Fig. 4. Simulated return loss of the proposed rectangular patch antenna.

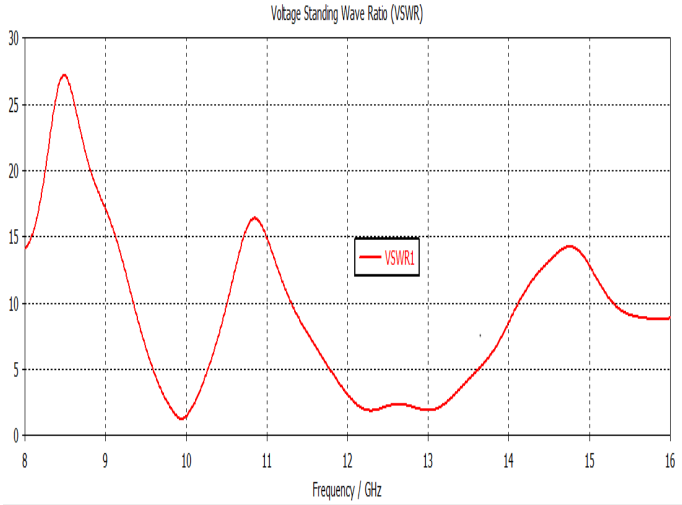

Fig. 5. Simulated VSWR of the proposed rectangular patch antenna.

From "Fig. 5" it is evident that at both the resonance frequencies the numeric value of VSWR is less than 1.5 that is effective for any wireless communication.

The gain and directivity of the proposed antenna at resonance frequency 9.968 GHz is 5.960 dB and 6.015 dBi respectively which is suitable for WiMAX, RFID, and X-band wireless applications. The 3D gain and directivity of the proposed antenna are shown in "Fig. 6" and "Fig. 7".

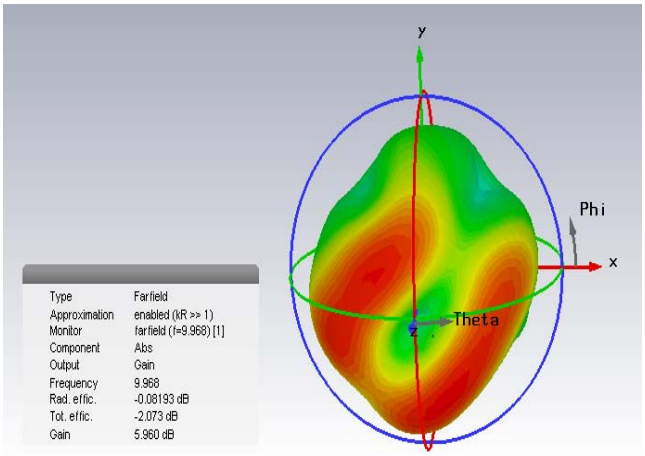

Fig. 6. 3D radiation pattern (Gain) of the proposed antenna.

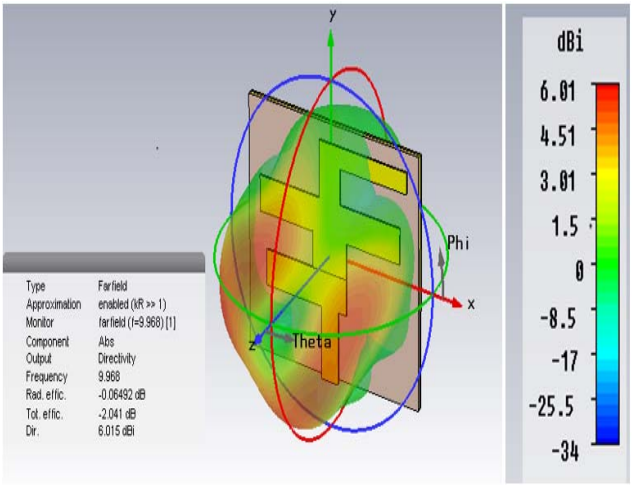

Fig. 7. 3D radiation pattern (Directivity) of the proposed antenna.

In a practical scenario, the VSWR is 1.1 to 2.5 and S-parameter range is less than -10 dB respectively although the ideal value of VSWR is unity. In our designed antenna the VSWR is less than 1.5 and S-parameter is less than -10dB. "Fig. 8" & "Fig. 9" shows the polar plot of radiation pattern (both gain and directivity) of the proposed antenna which indicates that the side lobe level is -7.6 dB, main lobe magnitude is 5.8dB and 3dB angular width is 40 degree at resonance frequency 9.968 GHz.

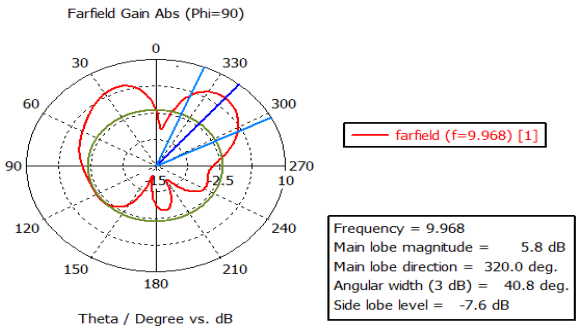

Fig. 8. The polar radiation pattern of Gain of the proposed antenna.

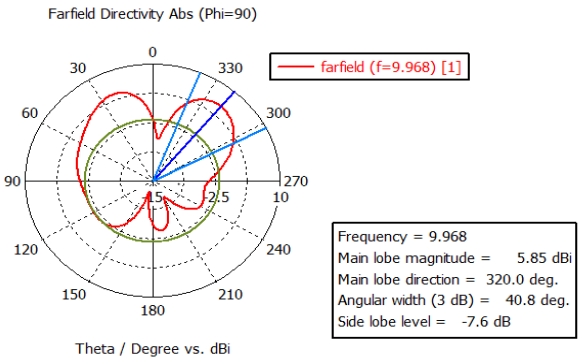

Fig. 9. The polar radiation pattern of directivity of the proposed antenna.

The antenna radiation efficiency is related to the gain and directivity and it can be written as $\eta_{rad} = G(dB) - D(dB)$. So, the antenna radiation efficiency at 9.968 GHz is almost 98 %. "Fig. 10" shows that experimental radiation pattern of the proposed antenna using WATS 2002 Module. To compare with the simulation radiation pattern shown in "Fig. 8" & "Fig. 9" is slightly different with the experimental result shown in "Fig. 10".

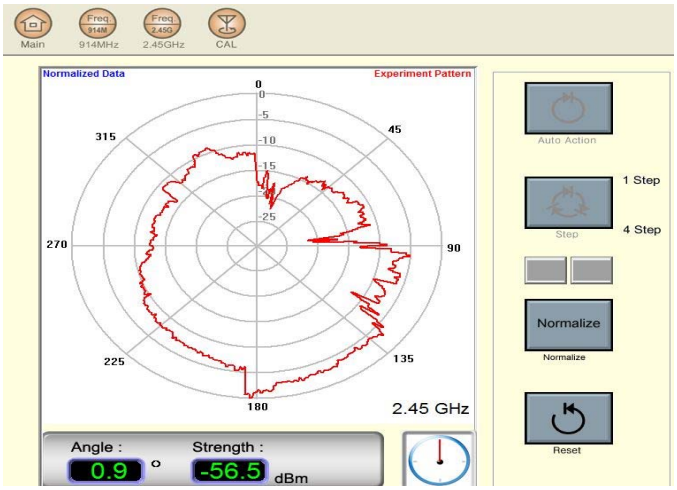

Fig. 10. Experimental radiation pattern of the proposed antenna using WATS 2002 Module.

The variation of the resonance frequency, VSWR, gain and return loss due to the variation of antenna arm length (Arm3) are shown in "Fig. 11".

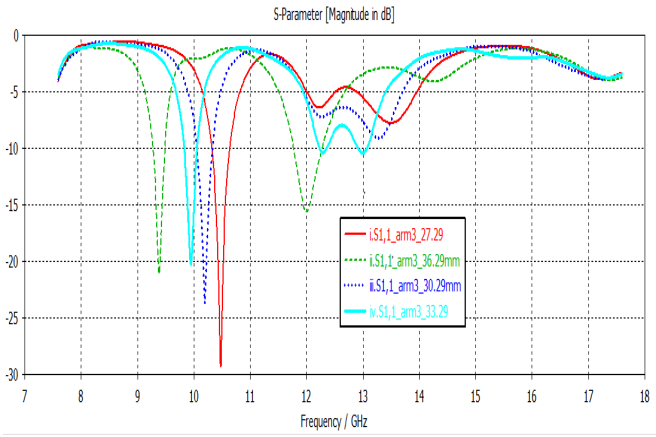

Fig. 11. Effect of length variation of Arm3 on the Resonance frequency and S-parameter.

TABLE III: EFFECT OF LENGTH ADJUSTMENT OF ARM 3

Length of Arm3(mm)	Resonant frequency (GHz)	Return loss (dB)	Gain(dB)	VSWR
33.29	9.97	-20.49	5.96	1.21
30.29	10.21	-23.33	6.18	1.15
27.29	10.49	-26.99	6.86	3.02
36.29	9.39	-21.05	6.61	1.19
	12	-15.56		1.40

From the "TABLE. III", it is seen that when the length of Arm3 decreases then resonance frequency as well as gain increases. It is noted that when Arm3 decreases from 30.29 mm to 27.29 mm the resonance frequency is sifted 10.21 GHz to 10.49 GHz and gain increases from 6.18 dB to 6.86dB. Also, we observed that when the length of Arm3 is increased to 36.29 mm then gain is slightly decreased but resonance frequency shifted to upper frequency than others. When the Amr3 is 36.29 mm, the proposed antenna provides two band; one at 12 GHz and other at 9.39 GHz. So, at this length of Arm3, the designed antenna acts as dual-band antenna. The S_{11} parameter, gain, VSWR at resonance frequency 12 GHz and 9.39 GHz becomes -21.05 dB, -15.56 dB, 6.61dB, and 1.40, 1.19 respectively.

TABLE IV: COMPARISON OF THE PROPOSED ANTENNA WITH THE LITERATURE

Reference Antennas	Size in mm^2	Operating Bands in GHz	Bandwidth in GHz	Gain (dB)
[12]	40×60	3.85,5.80,8.12	3.869,4.034	2.6
[8]	83 × 83	0.91	0.86	7.55
[11]	98 × 98	2.45, 5.8	2.42-2.49,5.59-5.93	4.1
[13]	178.04×178.04	0.8425, 0.92	0.025, 0.025	4.5, 5.5
[15]	38 × 33.5	5.8	0.11	4.9
Our Proposed antenna	**40 × 39**	**9.968, 12.3-13**	**0.30. 1.0**	**5.96**

The overall simulated results of our designed antenna are compared with the various reference antennas are presented in "TABLE IV". From the comparison table, we can see that our proposed design has better gain with less weight & dimension than some other existing antennas.

VI. CONCLUSION

In this contribution, we have analyzed and studied the characteristics of a rectangular microstrip patch antenna. The antenna is simulated on FR4 (lossy) substrate in CST simulation software and all the possible results are obtained using CST software. The proposed design is implemented in hardware and measure the radiation pattern using WATS 2002 module. The physical dimension of our designed antenna is 40×39 mm^2. The antenna provides high gain, high directivity, lower side lobe level and the standard amount of VSWR and S-parameter. Due to the variation of the length of Arm 3 provides the variation of resonance frequency with a variation of S-parameter, gain, VSWR and bandwidth. The proposed antenna provides all the required features within the simplest design possible. The results obtained from the designed microstrip antenna is useful in X-band, RFID and WiMAX applications. In the future, an array antenna will be designed using the proposed antenna to achieve higher gain and directivity.

Abstract—There will be high energy wastage and CO_2 emissions will be increased in 5G network because of dense deployment of small cell base stations. This paper brings an efficient energy management technique for 5G green small cell network which switches on as such number of antennas from the array as needed. This is done by monitoring and counting the amount of data traffic within the area of the small cell. It is shown that the proposed scheme is capable to improve energy saving significantly. We have found that the scheme consumes up to 96.875% less energy than without energy management technique. Besides, the emission of CO_2 is reduced by 2.3166kg per day when the small cell is operated by a diesel power source and for all kinds of power sources on average CO_2 emission can be reduced by 1.612 kg per day.

Keywords— Energy efficiency; 5G Green network; CO_2 emissions; massive MIMO; Small cell network.

I. INTRODUCTION

It has been reported that [1], the mobile data traffic is globally increased nearly 11-fold within 2013 to 2018. Now it is reached to 15.9 exabytes per month approximately. The only reason for it, is the gradually increasing number of devices that are mobile connected. Currently it is about 1.4 per capita. Hence, the demand of mobile data is growing very rapidly. So to say, the one and only solution to solve such demand is deploying small cells. It is a matter of concern that, there is high data traffic density in 5G small cell network(SCN). To improve the capacity also, deploying dense small cell is mandatory. Actually it not only helps to improve the capacity, but also it helps to reuse the radio resources. Again, it helps to reduce the base station transmit power. Thus, it helps to fulfill the demand of next generation network by improving both spectral efficiency and energy efficiency.

In accordance with [2] and [3], one of the promising solutions of 5G networks to cope with the sustaining trend of ever growing mobile data traffic is to deploy dense small cell base stations. A small cell is a low-cost radio Base Station which operates at low-power and provides better cellular coverage. The cell radius of the small cell can range from tens of meters to a few hundred meters. Because of a short distance between the Base Station and the user equipment(UE) the transmit power is reduced significantly in small cell network.

Small cell can be deployed in places of high user density, i.e. stadiums, pedestrian malls, exhibition centers, airports and so on. But, at off-peak time like as, nights, the user density is decreased noticeably. So, we do not need to activate all the antennas of the array at that time.

To develop a green network, the energy consumption of base stations must be reduced. Because 56% power consumption of cellular network is from base stations [4]. This great amount of power consumption increases the amount of CO_2 in the environment. Although, the amount of CO_2 emitted from cellular network industry is relatively meager, it will be increased in the next generation mobile network. Because, there will be a very large number of base stations in the network. Therefore, developing a green network is dependent on decreasing the power radiation from the future small cell base stations which will be densely deployed.

For boosting the network throughput and to save energy at low traffic hours, it is highly required to develop efficient cell management technique and user access mechanisms for the dense deployments of small cell networks. Because, the active hardware not only consumes power, but also increases the amount of CO_2 in the environment.

Data traffic is varied because of the mobility of the user. Hence, the demand of the antenna changes continuously. So,

obviously there should be some techniques to manage the cell for saving energy.

II. LITERATURE REVIEW

Different techniques are brought to achieve energy efficiency. In [5], we have seen that, the coverage areas of some stations are adjusted and other base stations are turned off. They achieved 40% less power consumption in the sleeping base stations. In another study [6], the base stations are switched to different sleep modes step by step, where less power is consumed to deeper sleep modes. They could save 92% energy in empty network. In the study of [7], we have seen that, they did the load analysis. On that basis, they have chosen sleep mode technique and thus found energy efficiency. They achieved nearly 22% and 38% improvement in network throughput without and with delay respectively.

In [8], the authors divided the geographical area into different grids. To give satisfactory service to all the users at the peak hours, they selected maximum number of small cell base stations in every grid. On the other hand, required number of base stations are kept on and others are turned off in the idle periods. They saved up to 53% and 23% energy in the dense and uncrowded area respectively.

19% energy efficiency is achieved in [9] compared to a scheme where the Base Stations run with a set number of antennas. In this study the authors used a game theoretic framework. In another study [10], the authors proposed minimum 40% energy efficiency and QoS improvement. They used the combination of an adaptive discontinuous transmission and antenna optimization.

This paper deals with an unaccustomed traffic load based energy management technique where the base stations decide how much antennas will be activated according to the total number of user equipment. In every 3 seconds the base station will count the number of users in its monitoring area(M_A) and required number of antennas will be activated. So, this scheme is reducing the wastage of energy by small cell base station. As a result, the small cell base stations can form an adaptive, stable and energy efficient small cell network. The energy saving attributes and CO_2 reduction characteristics of the technique are then estimated and compared with a scheme with no energy management.

The remainder of this paper is organized as follows: The model of the system is defined in Section III. The energy management technique is described in Section IV. Section V presents the results and analysis. Comparison with similar research works is shown in Section VI. Finally, the work is concluded in Section VII.

III. MODEL OF SYSTEM

A. Network Architecture

Basically, there will be four kinds of small cell in future 5G network, namely, femto-cell, pico-cell, micro-cell and metro-cell. We have worked with pico-cells. Pico-cells can be deployed both indoors and outdoors, i.e., stadiums, pedestrian malls, exhibition centers, airports and so on. Here, each pico-cell contains 128 (16*8 array) massive MIMO antennas in its array. For applying beamforming technology, a dedicated antenna will be allocated for each user. So, the maximum number of users that can be supported by the cell is 128. The energy consumption of each antenna is approximately 1.5625Wh [11]. Hence, the energy consumption of all the antennas is 200Wh. The monitoring radius of the cell is 50 meters or less [12]. A pico-cell base station is located at the center of figure 1.The User Equipments (UE- the dots in the figure) are arbitrarily distributed within and out of the monitoring area. The monitoring area(M_A) is depicted as the circle shown in figure 1. The user equipments that are within the monitoring area will only be served by the base station.

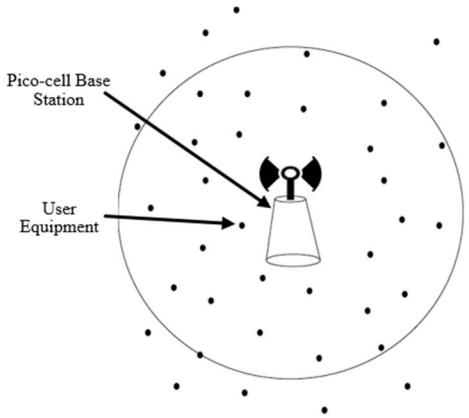

Fig. 1: Proposed Model

B. Model of Path Loss

By using WINNER II model, which is given in [13] the path loss between the small cell base station and the UE is calculated. Assuming the SCNs with high population density such as train stations or airports, we have chosen model B3 as shown below:

$$PL_{LOS} = 13.9\log_{10}(r) + 64.4 + 20\log_{10}(f_C/5) + SF_{LOS} \quad (1)$$

$$PL_{NLOS} = 37.8\log_{10}(r) + 36.5 + 23\log_{10}(f_C/5) + SF_{NLOS} \quad (2)$$

$$P_{LOS} = 1 \quad ; \text{if } r \leq 10 \quad (3)$$

$$P_{LOS} = \exp(-(r-10)/45) \quad ; \text{if } r > 10 \quad (4)$$

where path loss for line of sight (LOS) is PL_{LOS} (in dB) and the path loss for non-line of sight (NLOS) is PL_{NLOS} (in dB). Again the parameter r represents the distance between the small cell base station and the user equipment, f_C represents GHz level of carrier frequency. The shadow fading for LOS and NLOS are SF_{LOS} and SF_{NLOS} and valued them 3 dB and 4 dB respectively. Finally, the probability of having LOS propagation condition is represented as P_{LOS}.

Here, different path losses will be resulted for line of sight and non-line of sight communications. Obviously, the path loss for non-line of sight will be more, and in 5G, it will be a mandatorily considerable factor. Because, as it is known that penetration is increased with increasing frequency.

IV. ENERGY MANAGEMENT TECHNIQUE

The small cell has a circular monitoring area M_A with a radius of R. Here, the monitoring radius is 50 meters. The distance between the base station and the UE is $D_{c,x}$. The small cell base station will estimate the distance of a UE by measuring the power because main cause of power attenuation is path loss which is a function of distance as given in equation (1), (2), (3) and (4). The path loss can be shown by a function, f(D).

While transmitting data, a UE_x sends a reference signal, P_{ref} periodically. The small cell base station, receiving this signal will record the receive power $P^{(r)}_{c,x}$, which is similar to recording the $D_{c,x}$ due to the relationship given below [5]:

$$P^{(r)}_{c,x} = P_{ref} - f(D_{c,x}) \quad (5)$$

Where $P^{(r)}_{c,x}$ and P_{ref} are in dBm corresponding to $f(D_{c,x})$ in dB.

In this way, the small cell base station measures whether the UE_x is within its monitoring area. If the UE_x is within the monitoring area, it will forward the UE_x into its monitoring list. And finally, the base station counts the number of users in its cell area.

Here, the users that are within the cell area will only be supported by the base station. The period of measuring reference signal by the base station sent by the user equipment is considered to be 3 seconds. It is thought-out that the number of users will not be changed significantly within the cell area within this period.

A. Working Principle by Pseudo Code

By using the equation (5) the base station calculates the path loss and then by using equations (1), (2), (3) and (4) the base station will calculate the distances of the UEs. After that it will count the total number of user equipments in the cell area. And then, it will activate antennas according to the number of users. Because of keeping the blocking probability low, the number of active antennas are more than the number of users. So there are some extra active antennas for the upcoming possible users. It will continuously do the same thing in every 3 seconds.

The algorithm of the model's working principle is illustrated below in the pseudo code:

Here, estimated_time_duration denotes the period for which the pico-cell is deployed.

```
time1 := starting_time()
FOR time() time_i ε estimated_time_duration do
  time2 := time()
  IF time_difference(time2, time1) is equal to 3 seconds
    scan energy_database from buffer memory
    calculate distance and push to distance_database
    IF distance[i] is less than range
      push the user in user database
      calculate total permitted waiting user number
      IF user number is 0
        provide array (2*2)
      ELSE IF user number is 1 to 2
        provide array (2*4)
      ELSE IF user number is 3 to 5
        provide array (2*6)
      ELSE IF user number is 6 to 10
        provide array (2*8)
      ELSE IF user number is 11 to 19
        provide array (3*8)
      ELSE IF user number is 20 to 27
        provide array (4*8)
      ELSE IF user number is 28 to 35
        provide array (5*8)
      ELSE IF user number is 36 to 43
        provide array (6*8)
      ELSE IF user number is 44 to 51
        provide array (7*8)
      ELSE IF user number is 52 to 59
        provide array (8*8)
      ELSE IF user number is 60 to 67
        provide array (9*8)
      ELSE IF user number is 68 to 75
        provide array (10*8)
      ELSE IF user number is 76 to 83
        provide array (11*8)
      ELSE IF user number is 84 to 91
        provide array (12*8)
      ELSE IF user number is 92 to 99
        provide array (13*8)
      ELSE IF user number is 100 to 107
        provide array (14*8)
      ELSE IF user number is 108 to 115
        provide array (15*8)
      ELSE user number is 116 to 128
        provide array (16*8)
      END IF
    END IF
  ELSE difference (time2, time1) not equal 3 seconds
  time2 := time()
  END FOR
```

V. RESULTS AND ANALYSIS

For showing the effectiveness of our proposed scheme, we have compared it with the scheme without energy management technique. We have analyzed this technique with respect to a pico cell. We considered 128 (16*8 array) massive MIMO antennas in a pico cell. In a cell with no energy management technique, all the antennas are kept on at all the time. But our technique will activate as such number of antennas which are actually required by the surrounding user equipments. We have gained a good amount of energy saving and CO_2 emission is also minimized.

The number of active links during a day are approximated on rational basis. In figure 2, horizontal axis represents hours of a day and vertical axis represents number of active links. We can see from figure 2 that, the number of active links may become zero during off-peak hours. There is considerable variation in the number users during a day because of user mobility.

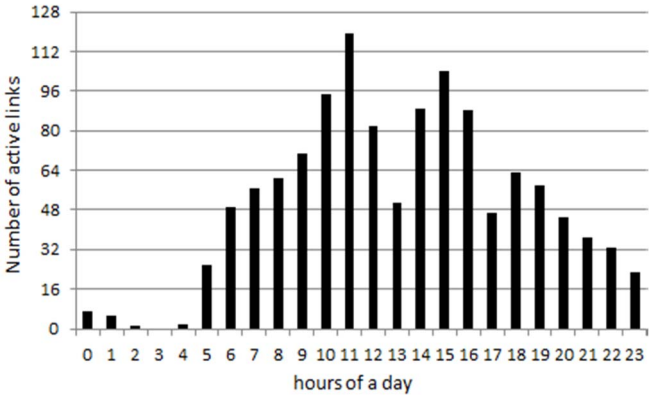

Fig. 2 Number of active links against hours of a day

In figure 3, horizontal axis represents hours of a day and vertical axis represents required number of antennas. Here, the comparison between the proposed scheme and the scheme without energy management is shown. In the fixed topology, 128 antennas are kept on continuously. On the other hand, the number of active antennas are adapted according to the number of users in the proposed scheme. Antennas will be activated according to the pseudo code described in Section III. We can see from figure 2 that in most of the time of a day, the number of user is less than its maximum value. That's why it ensures energy saving significantly.

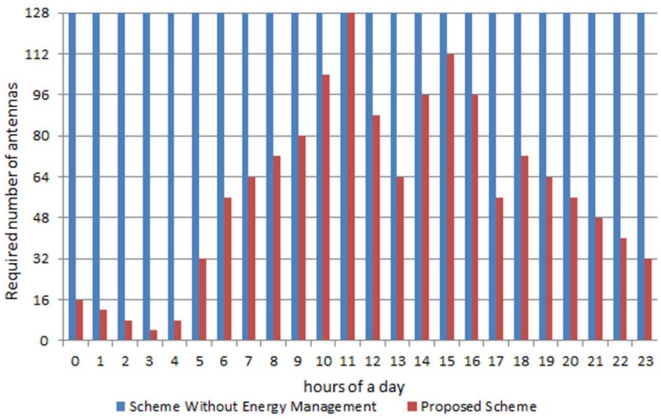

Fig. 3: Required number of antennas against hours of a day

In figure 4, horizontal axis represents hours of a day and vertical axis represents required energy in Watt-hour. Here, the energy consumption of the base station during a day is shown. The base station consumes 200Watt-hour of energy in every hour if there is not any energy management. But, the energy consumption is varied during a day with the variation of the number of users in the suggested scheme. A very small amount of energy is consumed during off peak time. A big amount of energy is saved and energy wastage is reduced by a great amount therefore. Thus maximum energy saving during off-peak time and average energy saving during a day are calculated by,

$$ES_{OPT} = (CE_{WNEM} - CE_{WEM}) / CE_{WNEM} \quad (6)$$

$$ES_{AVG} = (\sum CE_{WNEM} - \sum CE_{WEM}) / \sum CE_{WNEM} \quad (7)$$

Here, CE_{WNEM} and $\sum CE_{WNEM}$ are representing cell energy consumption at off-peak time and total cell energy consumption during a day respectively with no energy management. CE_{WEM} and $\sum CE_{WEM}$ are representing cell energy consumption at off-peak time and total cell energy consumption during a day respectively with energy management. We can notice from figure 4 that, our proposed scheme can achieve 96.875% energy saving during off-peak time and 54.167% energy saving on average during a day.

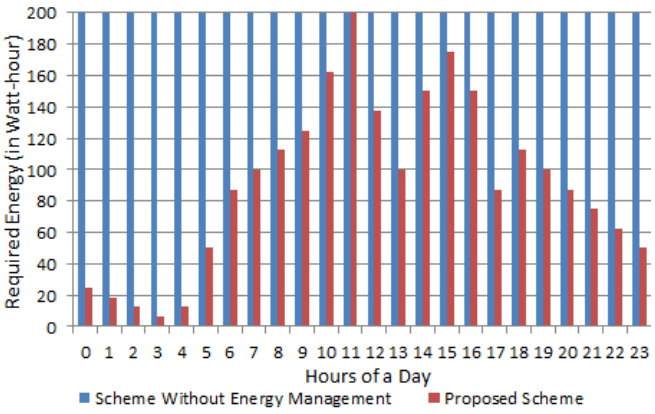

Fig. 4: Required Energy (in Watt-hour) against hours of a day

In figure 5, horizontal axis represents hours of a day and vertical axis represents the amount of CO_2 in kg. Here, amount of CO_2 emission in the proposed scheme is compared with the scheme without energy management.

Because of dense deployment of small cell base stations, the CO_2 emissions will be considerably increased. So, it will be a threat to the environment and to reduce the amount of CO_2 emitted from base station is a major challenge to develop a green network. In India the CO_2 emission from a base station is 0.000891kg for 1W of power radiation when a diesel engine is used as the power source. Maximum CO2 reduction during off-peak time and average CO_2 reduction during a day are calculated by,

$$CR_{OPT} = (CE_{WNEM} - CE_{WEM}) / CE_{WNEM} \quad (6)$$

$$CR_{AVG} = (\sum CE_{WNEM} - \sum CE_{WEM}) / \sum CE_{WNEM} \quad (7)$$

Here, CE_{WNEM} and $\sum CE_{WNEM}$ are representing CO_2 emission at off-peak time and total CO_2 emission during a day

respectively with no energy management. CE_{WEM} and $\sum CE_{WEM}$ are representing CO_2 emission at off-peak time and CO_2 emission during a day respectively with energy management. Without energy management technique, the amount of CO_2 emitted from the base station is 4.2768kg per day. But, only 1.9602kg CO_2 will be emitted by proposed scheme per day. Hence, this technique is offering a good amount of CO_2 reduction.

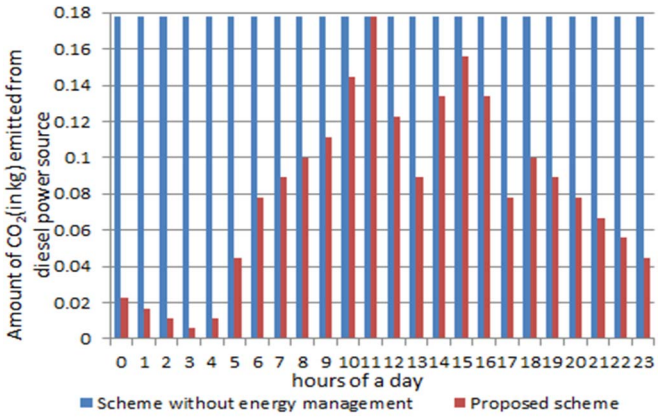

Fig. 5: Amount of CO_2 (in kg) emitted from diesel power source against hours of a day

In the United States of America, the average amount of CO_2 emitted per KWh is about 0.62 kg. Without energy management technique, the amount of CO_2 emitted from the base station is 2.976kg per day. But, only 1.364kg CO_2 will be emitted by proposed scheme per day. Thus this technique is helping to develop a green network.

VI. Comparison Table

Research Works	Approach used	Outcomes
Our Proposed work	Switching antennas according to user number by proper coding.	Up to 96.875% less energy consumption in empty network and 54.167% energy saving on average.
Ref [6]	Base stations are switched to different sleep modes step by step.	They could save 92% energy in empty network.
Ref [7]	They did the load analysis and have chosen sleep mode technique.	Achieved nearly 22% and 38% improvement in network throughput without and with delay respectively.
Ref [9]	They used a Game theoretic framework.	19% energy efficiency is achieved.
Ref [10]	They used the combination of an adaptive discontinuous transmission and antenna optimization.	Achieved minimum 40% energy efficiency.

VII. Conclusion

This paper introduced an efficient energy management technique for small cell networks based on traffic load. It is evident that it can save significant amount of energy. Here, as such number of antennas will be activated as needed. It offers up to 96.875% less energy consumption in empty network and 54.167% energy saving on average than with no energy management technique. Besides, our proposed scheme can reduce the emissions of CO_2 from small cell base stations. CO_2 emission is reduced from 4.2768kg to 2.9602kg in the suppositional scheme per day when the small cell is operated by a diesel power source. For all kinds of power sources in average CO_2 emission can be reduced by 1.612 kg per day. Moreover, our proposed algorithm can be utilized for any massive MIMO antenna system. So, this technique is ancillary to develop an efficient, stable and green network.

***Abstract*—The paper presents implementation use cases towards the consequences of maintaining user data privacy after the adoption of GDPR; specifically in the news media industry. General data privacy regulation (GDPR) is a European Union general data protection regulation adopted in 2016 subjected to protect personal data of the citizens in the EU. Besides, it implies to particular restrictions and obligations for handling user data by different companies or organizations. However, although the rule is applicable only if EU citizens are involved, all the companies started adopting the preparation and practice to maintain compliance with GDPR. In this paper, we identify and present the system design and implementation use cases for the news media industry that is compliant with the new regulations. The use cases indicate and explain significant transformation required in user data management process according to the GDPR.**

Keywords- General Data Protection Regulation, GDPR and Compliance, Privacy/Policy by design

I. Introduction

In order to restrict the use of user data by media or service industry, General Data Policy Regulation (GDPR) has been introduced. GDPR defines some particular data usage policies based on certain criteria that must be fulfilled by the developers so that a system preserves it's user rights. GDPR came in front with a view to solving the issue regarding user data misuse without the consent of unaware European Union citizens. However, as every system has worldwide user access including EU citizens, all companies had to change their user data access policies across the world to follow GDPR compliance.

News media industries generally partake various user information by selling subscriptions to a wide range of users. Therefore, it raises the question of how they are managing all these data and using further for advertisement or latter analytics purpose. Now, GDPR is compelling the industry to expose how they are managing all the user data so that the whole process of reusing data remains transparent to users. In addition to that, while mailing offers or showing adds, they have to act carefully in order to avoid user's right violation.

As the data collection and maintenance depend on the user consent, there should be a proper way to communicate between the industry and user's end through an easy to access user dashboard. Applications require to be developed keeping in mind that users should be aware of where, when and how their data is collected and used for further analytics purposes.

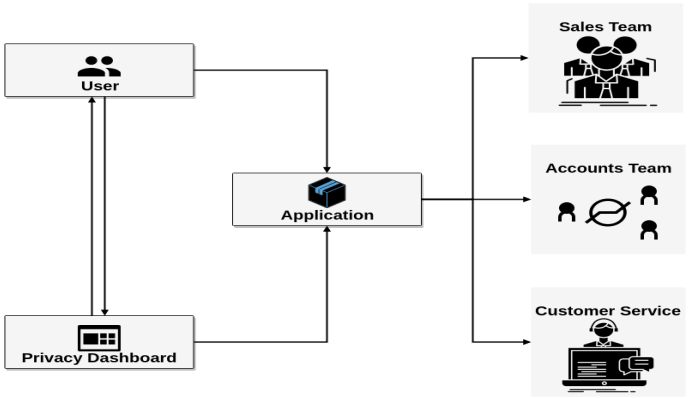

Fig. 1. Privacy by design and GDPR

Therefore, the industries end up enforcing transparent data usage policies that require user permission to use the data for future analysis. This also ensures that if the owner of data or user wants to delete his information, the industries will be responsible to erase that particular data entirely from their database. This is how GDPR is leading towards a policy/privacy by design solution that comes with options towards users for better accessibility, understandings, and management of their owned data. A simple policy/privacy by design with GDPR compliance is shown in **Figure 1**.

In this paper, we designed and developed a model framework that describes the initiation of a user dashboard. The dashboard is a better media of communication and understanding between the industry and the users. Users can read the policies provided by the company and therefore assign the data access rights through their consents. In addition to that, we provided the implementation use cases in the news media industry. We also identified the required transformation of the present system to meet the GDPR compliance.

The rest of the paper is as follows: **Section II** presents the issues and summary guidelines of GDPR compliance. **Section III** identifies and summarizes the implementation use cases of GDPR compliance. Then **Section IV** presents the design and workflow of the news media industry system followed by the consequence discussion in **Section V** and a few related work summaries in **Section VI**.

II. Background and rationale

A. Principle rules of GDPR

There are primarily six principles related to data subject rights that comprise breach notification (Article 33) [1], right to access (Article 15) [2], right to be forgotten (Article 17) [3], data portability (article 20) [4], privacy by design (Article 25) [5] and data protection officer (Article 39) [6]. The principles basically describes the rights a data subject should have on basis of new regulations. Therefore, if there is a data breach the owner of data must be notified as soon as possible. Data subject will need to have the right to know whether or not his particular portion of data is being used for any purpose; and somehow if he wants to erase his previous data, processor or service provider will not be able to store that information further. Another aspect is, the introducing of data portability where the data subject can move or transmit his data from one data controller to another. Privacy by design is not a jargon anymore, it is being applied to different sectors including big data analysis [7] to crisis management using social media [8]. Considering the regulations, controllers need to minimize the amount of data by deducting additional data as well as restricting the use of personal data during data processing (Article 23) [9]. In addition, controllers need to notify the data processing activities along with the local data protection act (DPA) in order to grab approval from the authority.

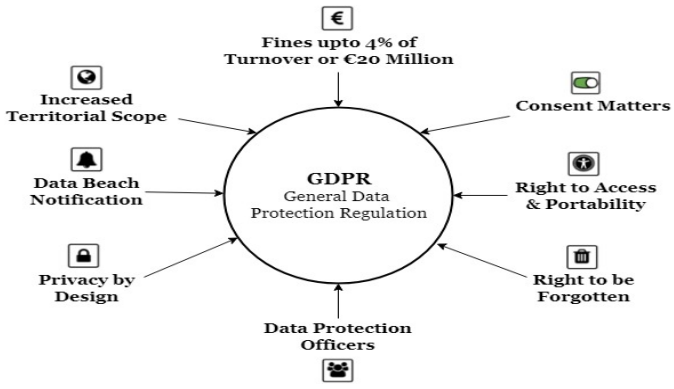

Fig. 2. General Overview of GDPR

Therefore, considering the rights of the data subject, controller or service providers have to perform minimum changes in their user policies and interfaces. Prior to the rules, in privacy program management (PPM) and privacy enterprise management (PEM), system engineering used to exclude consideration regarding user's data behavior. GDPR changed the view and directed it towards more data subject centric decisions to ensure privacy and protection for personal data.

B. Personal data protection

GDPR introduces the protection of data in personal level in the updated regulation policies applicable for only European Union citizens.

C. User consent centric Privacy by Design

Another principle introduced by GDPR is the privacy by design. It refers to the incorporation of the privacy practices from the initial design to the final specification of a system [10]. Privacy by default means that strict privacy settings will be automatically applied upon running or using the system for the first time. GDPR further emphasizes to provide enough protection mechanisms while the personal data of EU citizens is transferred to other countries and requires both a data controller and processor to take the liability.

D. Adoption to the new regulations

GDPR has far more influences over the policies and user experiences beyond regional boundaries. Although the rules are applied for ensuring the data protection across Europe, companies, and service providers have been taking initiatives to amend all the user policies as giant companies like Facebook and Google gave their commitment [11] [12]. But do every company need to take initiative for that? The answer is 'no'. The very first question that comes before deciding is whether or not the company sell products to individuals. Another question is whether or not the company keeps or collects personal data. If the answer to any between these two questions is- yes, the company need to measure whether their clients are from the EU or not. If the potential client is from the EU, the company must follow the regulations to avoid punishments. Since people across the world access to the news pages throughout the day, they register to access news articles and pay for subscription along with providing personal sensitive data. Therefore, news media must adopt the GDPR to establish synchronized user policies all over the world. While adopting, there are several things to keep in mind that include educating employees about the rules, revising user policies, reviewing personal data consent requests, managing and securing data, implementing privacy by design for data, performing data protection by hiring an officer, analyzing third-party risks, etc.

According to the new GDPR, users must have been informed about all the data practices to be done with their personal data. Also, users must have the opportunity to hold their right to give and at the same time to withheld their consent if they disagree to any of the usages of their personal data [13]. However, most of the time the privacy policies are written in an unclear and complicated way [14] and because of the policies being too long, users find it difficult and are unwilling to read the whole content [15].

GDPR aims to improve transparency [16] in terms of the information collected from the data subjects and encourages the use of visualization along with the requirement for using clear and simple language (Art 58, GDPR). To get compliant to this legislation, lately, the Usable Privacy Policy Project [17] in the US has given a try to represent the policy notices in a machine-readable way to display the relevant content in a more user-friendly manner.

Another important issue is to assess the users whether they have understood everything they read on the privacy notice

or not. In this paper distinct concepts of GDPR are discussed and which information must be given to the users while getting consent are extracted. Furthermore, a comparison was made with the old data protection directive 95/46/EC [18].

Some approaches are suggested here related to the notice:

- Firstly, all the data practices and their implementation procedures must be provided.
- A demo approach on how to read the document step by step can be included.
- Different colors and fonts can be used for different topics to keep the users attention.
- For critical legal notations, hyperlinks and pop-up windows can be provided containing illustration and examples related to those notations. These can be accomplished by using Akoma Ntoso mark-up.
- For assessing the proper understanding of the policies by the users, a consent form can be designed where clickable icons can be used to gather explicit consent.
- After taking the consent, same icon can be presented to the users and asked to connect different given icons according to its meaning.

This approach can seem to be annoying thus, needs to be refined further and tested on different categories of users.

III. Implementation use cases

According to the statement of [19], privacy is breached when personal information is available outdoor its supposed context. [20] prescribed some approaches to maintain privacy by utilizing data minimization which may limit the data controllers task of processing and collecting personal data. Giving users control over their own personal data to decide who they want to share those data and in what condition, can strengthen their privacy protection.

The natural persons whose personal data(PD) is processed by a processor or controller are identified as data subject(DS). GDPR compliant system should ensure the rights of Data Subjects(DS) which includes:

- **Right to be informed**: Provide the information listed in Art. 13 [13] if the personal data is supplied by data user. Otherwise, provide information listed in Art. 14 [13].
- **Access right**: Provide access to personal data and information listed in Article 15 [2].
- **Rectification right**: Allow rectification of incorrect personal data and the provision of supplementary data.
- **Right to be forgotten**: Allow erasing personal data when requested. Once deleted it should not be retained.
- **Right to restriction of processing**: Restrain processing of personal data under the situation stated in Art. 18 [21].
- **Notification obligation**: Notify any rectification or erasure or restriction of processing to each recipient stated in Art. 19 [22].
- **Right to data portability**: Allow data subject to transfer personal data as required to another data controller providing that Article 20(1) [4] is applicable.
- **Right to object**: Provide the option to object the processing if the conditions in Article 21 [23] apply. Respond and demonstrate legitimate grounds at earliest convenience.
- **Automated decision making**: Avoid taking decision merely on automated processing including profiling which produces legal effects Article 22 [24].

[25] show an effective methodology for analyzing privacy threats essentially aims on the basic privacy concepts such as non-repudiation, information disclosure, policy content awareness etc. It gives the engineers an initial knowledge about how an intruder might attack a system and helps them setting up effective safeguards while implementing the system.

The primary implementation approaches are as follows:

1) Appoint a data protection officer
2) Stick to a code of conduct
3) Acquire consent for data
4) Ensure 3rd party data processing is compliant to user consent
5) Provide set of policies to end users
6) Develop a dashboard where user can update the consent according to each policies
7) Categorize sources of personal data
8) Protect data subject right to erasure of personal data
9) Establish anonymized processes
10) Establish governance programs
11) Access restriction to approved processes

Our proposed implementation provides GDPR compliance in the following areas:

- Systems and data auditing
- Data maintenance
- Work-flows and data processing
- Policy dashboard configuration
- User consent preference
- User subscription management
- User personal data capture

IV. System Design and Development

User interface (UI) and user experience (UX) design require a user dashboard through which a user can easily gain access to the privacy related options and gives consent for further use of his data. The following paragraphs discusses the user dashboard requirements and functionalities that are required for privacy by design approach. Therefore, the whole management workflow of the news media industry is elaborated followed by the database design issue and miscellaneous.

A. System design for News Media Industry

In order to design a sustainable system with GDPR compliance, we needed to follow the primary implementation approaches mentioned in **Section III**. Therefore at first we identified the required interactions between the user and the system through the user dashboard and added contents for user consent according to that. A web media system basically contains advertisements, data analytics module, cookies, and the site contents- which is generally accessible to users after

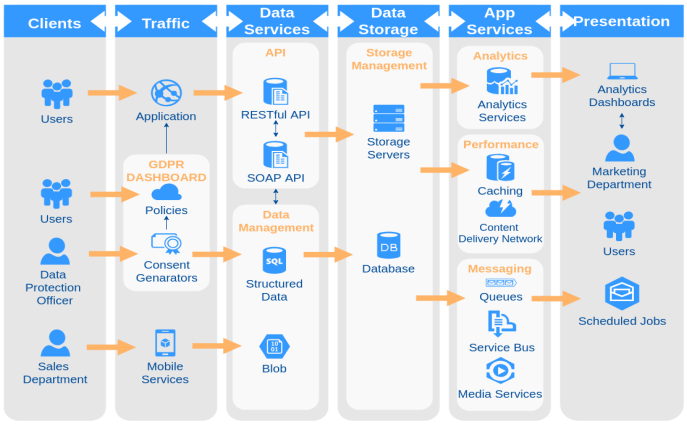

Fig. 3. System Architecture

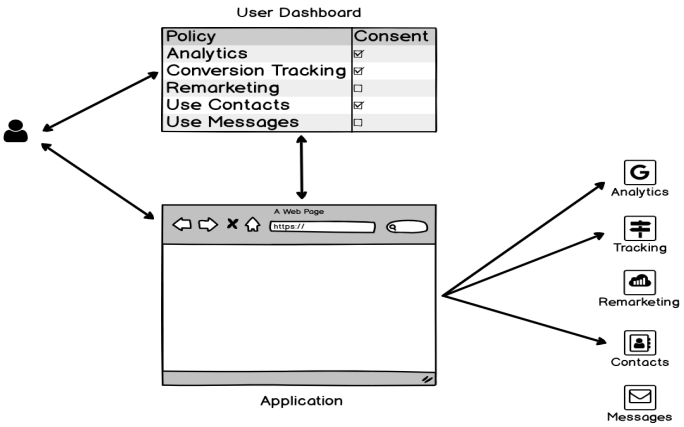

Fig. 4. Dashboard Functions

certain authentication process for users. Except those, the news media website also contains free site contents, newsletter, and other payment oriented monetary modules. The additional part here indicates the policy dashboard for users where user can put his preferences from which the system learns how to handle user data. As the owner of the data, it is completely up to the user whether or not the system can use his data for further analytics or business processes. According to the user consent input, the system stores the privacy data in an access control system through which other analytics module have permission or not to use user data in later cases. The design issues and processes are presented in **Figure 3**.

B. Dashboard Requirement and Functionalities

The user dashboard is the primary concern for the industry as it is the communication and understanding media for them with the users. The dashboard should include the user data policies along with the form that presents user consent options. The application checks initially the user preferences and then acts accordingly. For example, if the user gives his consent to use his data for only 2 options among 5 options, then the application will collect only those data and pass to other analytical machines for further use or analysis. In **Figure 4**, there are five policies for a user including analytics, conversation tracking, remarketing, use contacts, and use messages. A general user has given his consent for only analytics, conversation tracking, and contacts by ticking on the checkmark. Now the application collects data from the user accordingly and lets the data pass to other engines accordingly. Point to be noted that the system will also be responsible to convey the message towards the user on how his data is being used.

The user dashboard is required to have the following functionalities in general:

- Add or delete policies as needed for the application
- User can Check/Uncheck per policy (Give Consents)
- User can See and Update Consents in a dashboard

C. News media management workflow

Data management workflow for a news media includes from the data collection through application according to the user consents to the data transferring gateway to other applications. The application is always responsible for tracking any change that user dashboard provides and collecting the user data. Then the data is stored privately in secure storage lied in their own data centers according to various categories. Later the stored data is passed to other applications for further processing through privacy dashboard. **Figure 5** represents the data flow in a particular system.

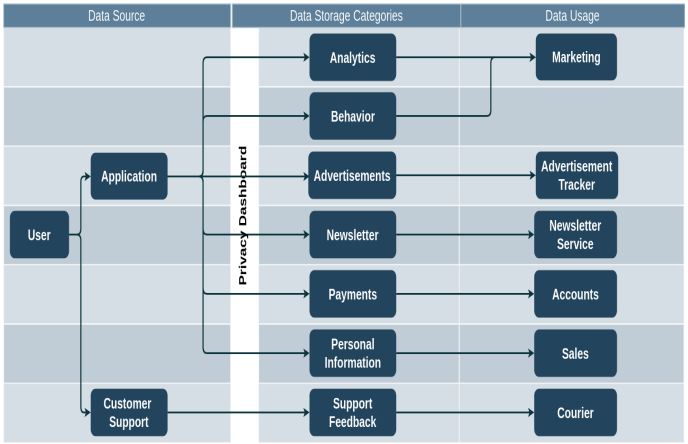

Fig. 5. News Media Corporation Data flow

D. Sample User Dashboard

A standard user dashboard contains the data usability policies and related options to users requesting for their permission in re-usability of user created contents. **Figure 6** represents a sample parallel user dashboard that is easily accessible to users. After reading the company policies, users become able to make the changes in remarketing and recommendation use cases that enforces credibility towards the reuse of user data.

The dashboard expresses whether or not a user is interested in receiving offers from the company through mail or phone. Also as the owner or creator of data, user is able to recommend whether the company will be able to use user data for future customer experience or for enabling personalized advertising

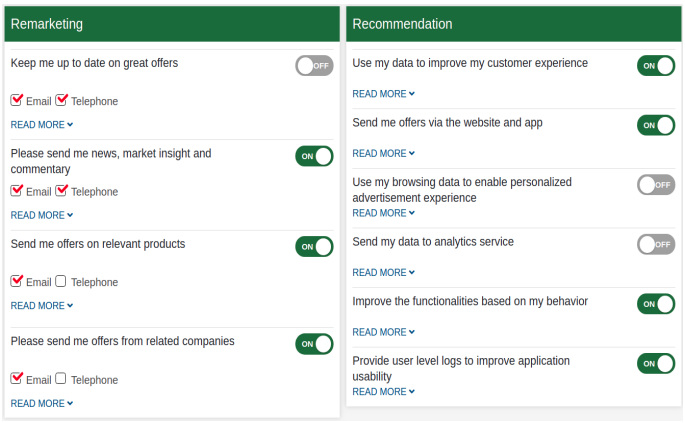

Fig. 6. Sample User Dashboard

experiences. Whether other third parties will be able to use data for behavior analysis or other analytic services- options are present within the dashboard for user permission as well.

V. Discussion

A. Penalty

[26] analyzes how the EUs GDPR will affect the IoT firms in terms of legal and preventive cost all over the world which deals with huge amount of personal information. According to the reference given by Ponemon Institute in 2016 [27], four personal data breach cases out of around twenty four thousands were analyzed to compare the estimated cost damage before and after GDPR. Assuming the average per capita cost of a data breach over the last four years as $150 and for each violation of GDPR costs 2% of a firms global turnover, the results of the analysis shows that in some cases a firms cost may be increased 3-18 times than before GDPR is applied based on the annual turnover of any firm for the past year. Vizio, an electronic product development company was charged with a $2.2 million fine after using content-aware apps to track user data without permission. The data of the users was collected intending to analyze personal TV habits info. If it would happen in current time with GDPR enforced, it would have been $292 million, more than hundred times larger penalty. In addition to that, users have full right to demand compensation for damages if experienced any material or non-material damage due to a violation of GDPR rules.

B. Liabilities of both service provider and consumer

Maintaining proper data privacy requires both parties to be aware of the data usage policies and regulations. Liability goes to both parties as users are responsible for getting familiar with the policies and put ticks on their preferable choices of data usage. On the other hand, service providers must follow user's preference and use data for further purpose thereby.

C. Issues

GDPR has several issues though. [28] enlightens some problems that can be caused when the new GDPR will be in force. The information flow within the digital market can be scattered because of the uneven national provisions. It will be infeasible for a cloud provider to have prior written consent from all of its data subjects before starting any processing task. Furthermore, to ensure highest level of security in every processing the CPs must carry out security assessments more frequently increasing the cost in a considerable amount and eventually the customers will have to bear that cost.

Also, cloud providers must optimize operational cost by adopting efficient privacy compliant practices while handling the data [29] as any information which can identify an individual including name, location, ID number, genetic, and biometric data etc. are considered as personal data.

VI. Related Works

In [28], the major changes in the new GDPR in cloud environment relating the field of healthcare are discussed. Much significance is given on the role of data controller and data processors in the GDPR and also their roles have been refined in some extent. The data subjects are now given more privileges which in turn increases the responsibilities of data controllers. A data controller must find a trustful processor that will maintain the compliance with the new principles such as the right for data access, data portability and also to be forgotten. To maintain appropriate security, both the controller and the data processor have to evaluate the risks associated with the processing of personal data and take feasible measures to eradicate those risks.

[30] focused to solve these problems by introducing the use of some widely used icon sets while preparing the privacy policy to facilitate the users task of decision making. Having the ability to present the legal information in a much clear, fast and effective way, graphical elements such as images icons etc. can improve the readers understanding capability.

The primary focus in [31] is to create a supportive environment for health and social care sectors and an analysis of the impact and related changes to the Information Governance Toolkit (IGTK) in the primary care sector in England considering the presence of new GDPR which will replace the UK data protection act,1998. The paper also describes the impact of introducing cloud computing in e-health, different risk factors and the maintenance of the security in the cloud. 8 principles of the data protection act,1998 are summarized and core 5 elements of information governance are discussed. [32] identified three major threats to security, that is tampering with data (Integrity), loss of data(availability), and unauthorized access to data (confidentiality). With these three under consideration, the risk of data security will be minimized.

The new GDPR that is in force from 25 May,2018; has imposed more obligations to regulate the privacy issue while collecting, storing and processing the personal data of EU citizens [16]. This paper aims at capturing the privacy requirements introduced by GDPR and providing general guidance to the engineers for developing GDPR-standard software. This paper further gave an overview on the roles and responsibilities of the liable authorities while developing a GDPR compliant

system via UML use-case diagrams. While implementing privacy policies within an organization several factors are too be considered such as directives, inspections, fine amount, and other profit and loss side effects [33].

VII. Conclusion

The primary concern of GDPR is to protect user personal data by enforcing the law. These days, all companies including Google, Facebook, and Amazon etc are following the rules and regulations. The news media industry is still adopting the new framework towards more user aware data usage policies. Processing of data is now more transparent towards users end. As the owner of data, users can change their preference at any time and become more aware of the policies on where and how the data is being used by other applications. This leads to privacy or policy by design that is more concerned about the security of personal data. Our paper discussed the design and developmental adoption to the new rules and regulations. Furthermore, we discussed the user dashboard in details so that other companies can follow the adoption with framework transformations that comply with the new regulations.

Abstract– A network slicing (NS) represents a form of isolated logical or virtual network architecture for a fixed physical network of 5G to support different radio access networks and adequately provide a specific service platform for the customers. The possible application of NS will find in the varying infrastructure of a network. Moreover, among several research challenges in NS, e.g., trouble to isolate the slices, mobility management, cooperation with other 5G technologies, and management of NS; the most challenging tasks are allocating resources of the slice efficiently and ensuring security. Reinforcement learning (RL) approach in NS for 5G helps encounter these critical challenges. It automatically reduces the latency and block suspected threat profile to ensure security in that slice. Additionally, the possible uses of allocated resources in SN improved sufficiently by applying RL technique. This paper will appropriately address to develop a policy-gradient based model-free RL approach to achieve optimal policy for NS with current values and action variables and accomplish optimal solutions for security improvement and detecting malicious nodes within the NS for 5G.

Keywords–Network slicing, reinforcement learning algorithm, policy-gradient approach, 5G.

I. INTRODUCTION

The term network slicing (NS) implies several logical or virtual networks of a core network and/or radio access networks (RAN) [1], whereas each slice of the network dedicates to serve a specific functionality (e.g., security, mobility support) and performance (e.g., latency, reliability, throughput) depending on the user requirement. The key objective to implicate NS to provide a platform for coexisted architecture in a fixed and compressed physical infrastructure to allow a flexible virtual network for the 5G mobile network alliance. It is required due to the considerable increase of RAN spectral efficiency in a significant number as well as the mobile networks need significantly scaling up and improve efficiency. NS take care of various services on mobile networks and makes it more flexible and programmable fabric. Additionally, it offers a control and management platform for the network infrastructure as well as allocated resources for optimal uses. Figure 1 describes the general architecture of sliced networks for 5G.

Meaningful discussion on NS is stronger than before due to the drawbacks of the existing networks, where typical networks deliver support various services from the same network region. The strategy of this network architecture naturally fails to make available a proper platform for internet-of-things devices, low latency, high throughput, high data rate, etc. Meanwhile, NS will provide valued support to 5G networks to deal with some unpredictable network applications, like haptic communications. Although it also enhances the potential scopes and benefits in automotive sectors. These support is required not only for radio frequency (RF) based application in 5G but also for several other technologies, which wants to merge with it. One of the technologies is based on optical wireless communications [2], which opens different futuristic scenarios, e.g., human bond communications [3]. Despite advantages and importance, NS is experiencing a few challenges (i.e., mobility management, cooperation with other 5G technologies, slices isolation and management) [1], which has caught the attention of the other researchers. Most challenging tasks are radio resource optimization and provide better solutions at the point of security of NS [4].

The radio resource slicing is typically defined as the NS in the wireless domain. The quality of service (QoS) of entire radio resource measures with slices. Resource slice isolation is a fundamental feature that ensures traffic from one slice never interfere to the other slice. Optimization of a radio resource slice decides the reconfiguration resolution of it. This optimization strategy can carry better QoS and ensures highest utilization of these potential resources. It enables the terminal between a network and terminal resource manager [4]. On the other hand, a cryptography protection algorithm is typically required for each slice of the networks from being hacked by anonymous nodes/networks and make these slices more accessible to multiple users [5].

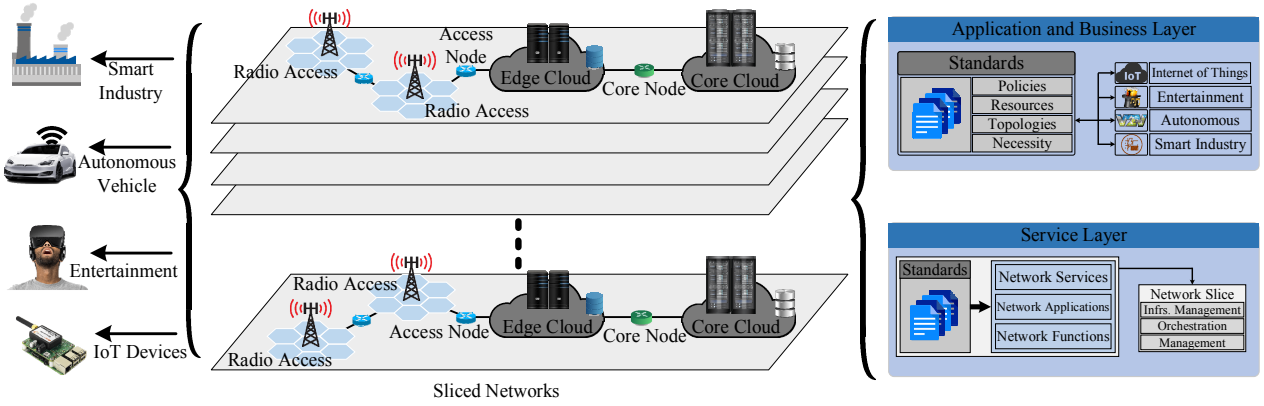

Figure 1. Overall architecture of sliced networks for 5G.

In this paper, we are deploying reinforcement learning (RL) approach, which can ensure proper resource slice optimization and security in the same slice. It is an artificial intelligence and unsupervised approach to carry out decisions about a critical environment (e.g., sliced networks) using the information from agents. Recent progress for artificial intelligence based network slicing has discussed in section II. Section III, explains briefly the innovation in our research approach. In the following section (section IV) we are discussing our proposed idea along with the simulation result. The way to reach the research destination has discussed in section V. The following two sections (i.e., section VI and section VII) illuminate the potential challenges and approaches for those challenges, respectively, before it ends up with conclusions in section VIII.

II. Related Works

NS in 5G is recent research concern. In [8], authors are introduced a possible solution for exchanging necessary data between vehicle-to-everything by slicing the core network and the radio access network resources. The article also includes the key contributions and configurations in the isolated treatment and guaranteed performance for same application scenarios of critical 5G cases. A complete integration of software defined networks and network function virtualization architecture for 5G sliced network, which is presented in [5]. For visualizing such cases, the authors also bring a practical example of the integration technologies to address its importance for the sliced network. At the end of their article, open research issues are enlisted. The overall characteristics of a distributed cloud infrastructure for NS are carefully analyzed along with the illustration of the optimization enhancement of the same network for 5G, has shown by the authors in [9]. However, possible deployment of a sliced network in specific application, e.g., ultra-dense cellular network and mobile edge computing based 5G wearable network architecture is discussed in [10]. In this article, the authors introduce the data driven network slicing management technique for proper resource sharing and energy-efficient application.

The extensive involvement of artificial intelligence in sliced networks is reasonably demanding to face existing challenges, especially in resource management and adequate security. However, the research progress is unsatisfactory enough in these regards and few of those discussions RL for a comprehensive solution. In [11], the authors present RL based slice admission policy to enhance the considerable profit of an infrastructure. Their proposed RL based policy shows up to 54.5% improved performance than the standards. In addition, authors in [12], agree that deep-RL is an essential part for resource management of each sliced. It helps those NS to provide better performance and services hasty. Here, deep-RL deals with several key issues, such as typically providing quality of experience and reduces the computational cost within the network resources. Eventually, deep-RL solves the optimal control policies in problems of RL with raw visual input. Conversely, the authors never discuss in their article about the measures like ensuring security by RL.

III. Innovation in Research

The possible and efficient utilization of the network resources can be solved by optimization approaches. The application of model-free RL structure can solve the optimization problems by analyzing the sliced networks into a finite set of discrete values [7], [13]. Moreover, the decision maker (or agent) helps predict new malicious attacks and achieve optimal or near-optimal performance of the sliced networks. RL can identify the dynamically changing strategies of malicious nodes in time progress. However, adding or removing flexibility of the sliced network puts the core network in a security risk. RL reliably detects the malicious node and convenient store this information until the formation or removal of sliced networks [14].

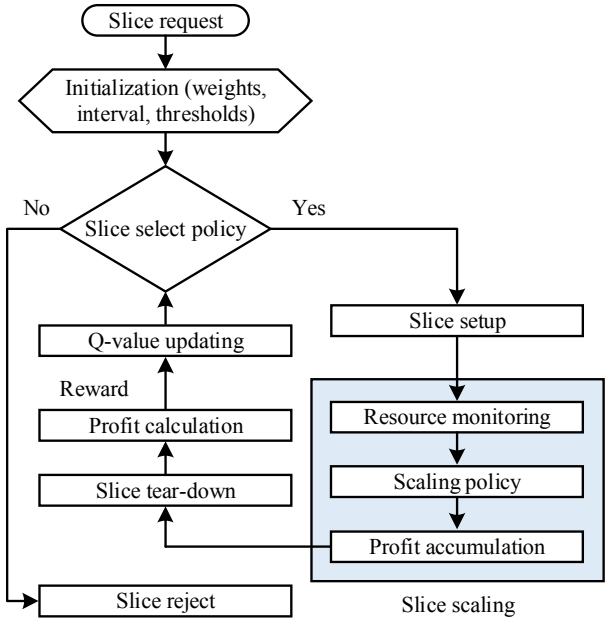

Figure 2. Model-free RL approach for 5G NS.

IV. Proposed Idea and Simulation Result

Applying a model-free RL approach to optimize available resources efficiently for the network slice as shown in Figure 2. The agent of this model typically depends on trial and error based feature for action selection. Without the extensive knowledge of transition and reinforcement function, this model can adequately provide necessary decision to evaluate the complex network scenarios like sliced network. The trial-and error learning experience helps to optimize the network by accurately mapping the available resources of the sliced network. However, with the several iterations of actions, the availability of the malicious node accurately identifies within the NS and adequately provides possible solution for security improvement with this identification.

Furthermore, the policy-gradient-based reinforcement learning algorithm [15] select an action from most significant reward to achieve precisely the optimal policy for NS with current values and action variables. This algorithm includes three distinctive methods, i.e., policy-based, value-based, and actor-critic methods.

The proposed algorithm has compared with two different algorithms, such as random algorithm and greedy-based algorithm. Under certain condition, random algorithm randomly allocates the sliced network resources. Figure 3 and Figure 4, show the total revenue and cost of energy with respect to the number of sliced network, respectively. In all cases, proposed algorithm almost always shows better performance than others algorithms.

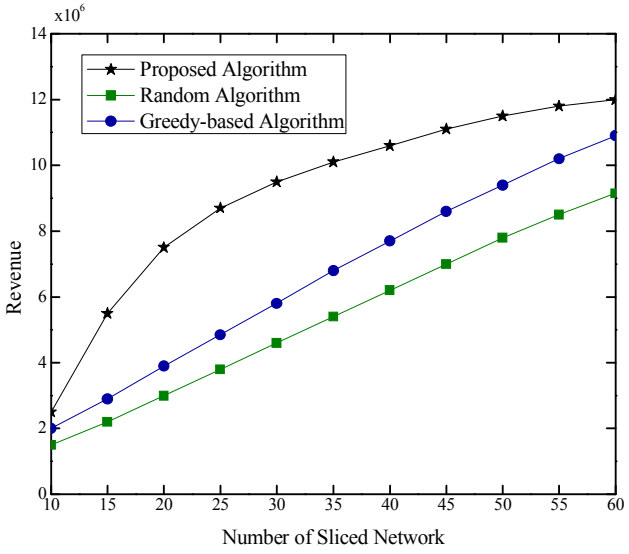

Figure 3. Comparison of total revenue with respect to the number of sliced networks.

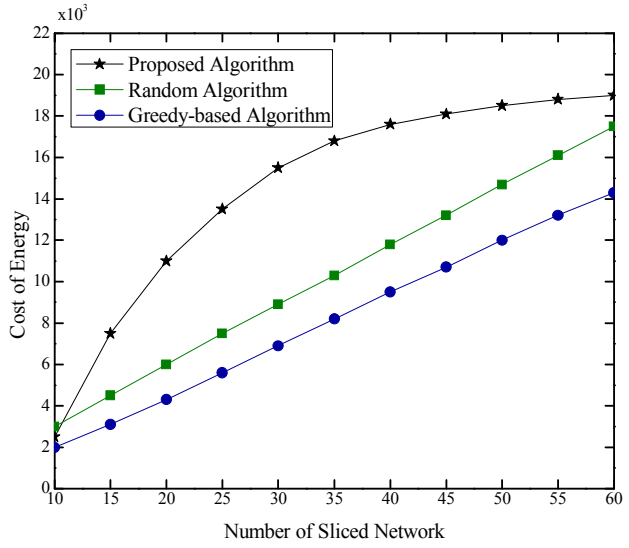

Figure 4. Comparison of total cost of energy with respect to the number of sliced networks.

V. Research Direction

The research timeline conveniently divides into three completed stages, which includes the literature review, modelling, functional analysis, and review the steps. The research review process will include constructive discussion and comparison with possible results found in the literature. The research timeline obtains as follows:

Stage 1: Literature review and initial developing an RL based efficient algorithm for optimizing resources and ensuring security in NS for the lightly dense traffic scenario.

Stage 2: The research will focus on the development of RL based efficient algorithm for dynamic, heavy, dense traffic

scenarios and achieve precisely the optimal policy for NS with policy-iteration based RL approach.

Stage 3: Progressively improve the performance of RL based NS for the next generation wireless communication system (i.e., 5G and beyond 5G) and mitigating the challenges for critical cases.

VI. Potential Challenges

The most significant reward for an action will obtain from a series of trial actions in trial-and-error learning approach of RL to accurately determine a distinct action for sliced network optimization. Moreover, it is not always a reliable way to determine an action, where the learning approach is typically based on the arbitrary choice. Simultaneously, the prolonged learning process also pushes the whole security system of the sliced network into a vulnerable situation.

On the other hand, both policy-based and value-based methods have some key limitations individually, such as an insufficient convergence process, significant variance to weights the performance of the policy, perform iterative computation from finite discrete actions, and difficult to determine the learning rate; whereas actor-critic method has better convergence process [16]. However, high variance at actor part does not provide any trouble to estimate policy gradient due to the assistance of critic part.

VII. Potential Approaches

The potential approaches for the research will address as follows:

Approach 1: Integrating imitation or hierarchical learning approaches with RL to progressively improve its learning speed for fast network optimization and also ensure network security.

Approach 2: Deploying policy-gradient-based actor-critic reinforcement learning algorithm to achieve optimal policy for NS. At this place, the actor generates successive actions, whereas a critic weights the performance of the policy with rewarding the action initiated by the actor.

VIII. Conclusions

The current NS has faced several challenges, including slices isolation, slices network management, mobility management, resource allocation for slices, maintain security in slices, which is required to solve to fulfil the demand for wireless capacity with 5G and beyond communications. In this paper, we have proposed a model-free RL for resource optimization and security enhancement. Additionally, policy-gradient based RL helps manage an optimal policy for NS. Detecting new malicious attacks with accomplishing optimal or near-optimal performance of NS will be the biggest novelty of this approach. However, it still faces some challenges, such as an insufficient convergence process, significant variance to weights, iterative computation from finite discrete actions, and slow learning progress, leads to a good research issue.

***Abstract*—Cooperation in opportunistic radio (OR) technology is one of the prominent alternatives to meet up spectrum inadequacy and to enhance Quality of Services (QoS) in wireless communication infrastructure. Opportunistic Users (OUs) are sensor nodes that utilize spectrum when transmission channel is unoccupied, OU senses spectrum and cooperatively takes their decision about data transmission, it provides better probability of detection (P_{d}) about whether Primary User (PU) is active or inactive and lower probability of false alarm (P_{f}). Though for cooperation sensing time increases, it provides better detection, reliable data transmission and maximized throughput. In this paper we have presented comparative studies among different cooperative decision fusion rules and their impact on throughput under different fading channels. The cooperation of different no. of nodes and effect of changing SNR on achievable throughput for OU data transmission are also studied. Finally, optimal tradeoff between sensing time and time frame under different channels and fusion rules are investigated for compressive sensing in opportunistic radio network (ORN).**

***Index Terms*—Cooperation, opportunistic radio, throughput maximization, decision fusion**

I. Introduction

Spectrum utilization has become a great issue as spectrum scarcity problem has been become a challenge for its limited resources. To use underutilized part of spectrum, ORN has become popular now a days [1]. In ORN, OU first senses spectrum then makes decision about data transmission depending on presence of primary users (PU) in spectrum bands. As soon as OU senses the presence of primary users, it vacates the channel within a certain amount of time [2]. Non cooperative sensing indicates that single opportunistic node senses spectrum and makes local decision about its own transmission and transmits data if primary user is found inactive. But in cooperative sensing, a group of sensor nodes make their decisions jointly by applying decision fusion rules among individual local decisions and the final decision is carried out for all nodes. For this, all local decisions are sent to a predefined node among the group of secondary nodes called decision Fusion Centre (FC). The decision is made by FC and FC sends cooperative decision to all nodes. So sensing time increases for cooperation and decision about P_{d} and P_{f} are distinguished more properly than that of no cooperation case. Thus throughput performance of cooperative compressive sensing is better than no cooperation case [3]. Sometimes for cooperation OU nodes are considered to be in defined topology [4]. In this paper, for simplicity no topology is defined for cluster of nodes. Compressive sensing based spectrum sensing is performed where signal detection classification and co-channel interference [5] are avoided.
Fading is fluctuation of signal strength in small period of time [6]. Fading occurs due to multipath propagation, Doppler spread, attenuation and noise of particular environment. There are some model of fading channels to reduce effect of fading [7], most of the cases real time fading follows these fading models. In this paper a study is performed for throughput maximization in cooperative ORN for different channels (AWGN as non fading channel and Rayleigh, Rician and Nakagami as fading channel). The relevance between sensing time and throughput for different channels are studied. More precisely, the objectives of this paper are to investigate maximized throughput in terms of optimal sensing time and time frame and to observe performance of different cooperation methods among OUs for different channels.
These paper has been organized in five sections. In section II cooperative wideband spectrum sensing is shortly discussed, in section III different cooperation rules and fading channels are discussed, in section IV simulation outcomes and finally in section V conclusion is discussed.

II. Spectrum Sensing and Throughput Preliminaries

A. Signal Model

Lets assume a signal $s(n)$, whose frequency band with carrier frequency f_{c} and bandwidth W and sampling frequency of the received signal is f_{s}. When the primary user is in data transmission state, the discrete received signal at the opportunistic user follows [2]

$$y(n) = s(n) + u(n) \tag{1}$$

which is considered as circumstance under hypothesis H_1 where $s(n)$ is transmitted signal and $u(n)$ is noise signal. When the primary user is not in data transmission, the received signal of opportunistic user follows

$$y(n) = u(n) \tag{2}$$

and this case is referred to as hypothesis H_0. Here γ is represented as the signal to noise ratio (SNR) measured at opportunistic receiver for presence of primary users.

$$\gamma = \frac{{\sigma^2}_{\mathrm{s}}}{{\sigma^2}_{\mathrm{u}}} \tag{3}$$

γ is measured at opportunistic receiver (or OU) under hypothesis H_1. Here σ_s and σ_u are variance of transmitted signal and noise signal respectively. Two probabilities are apparent for spectrum sensing: P_d, which is considered under hypothesis H_1, is the probability of correctly detecting the presence of primary signal; and P_f, which is considered under hypothesis H_0, is the probability of falsely declaring the presence of primary signal. For a good detection purpose, high P_d is desired while P_f must be kept as low as possible.

B. Energy Detection

Energy detection is performed after compressive sensing. Energy detectior is consists of filter, square law device and finite time integrator. The received signal of OU is compared with a threshold and decisions are made about the presence of PU. Later the values of P_d and P_f are used for throughput calculation. Lets assume that available sensing time is τ and N is number of samples (N is the maximum integer and is not greater than f_s, and for notation simplicity, we assume (N=τf_s). The test statistic for energy detector is given by

$$T(y) = \frac{1}{N}\sum_{n=1}^{N} |y(n)|^2 \tag{4}$$

Under hypothesis H_0, the test static T(y) is a random variable and its probability density function (PDF)- $P_0(x)$ is a Chi-square distribution with $2N$ degrees of freedom for complex valued case and with N degrees of freedom for real-valued case. If we choose the detection threshold as ϵ, the probability of false alarm is then given by

$$P_f(\epsilon,\tau) = P_r(T(y) > \epsilon|H_0) = Q\left((\frac{\epsilon}{{\sigma^2}_u} - 1)\sqrt{\tau f_s}\right) \tag{5}$$

and the probability of detection is then given by

$$P_d(\epsilon,\tau) = P_r(T(y) > \epsilon|H_1)$$
$$P_d(\epsilon,\tau) = Q\left((\frac{\epsilon}{{\sigma^2}_u} - \gamma - 1)\sqrt{\frac{\tau f_s}{2(2\gamma+1)}}\right) \tag{6}$$

Therefore, for a target probability of detection P_d, the probability of false alarm is dependant on the target detection probability as follows:

$$P_f = Q\left(\sqrt{2\gamma+1}\,Q^{-1}(P_d) + \gamma\sqrt{\tau f_s}\right) \tag{7}$$

On the other hand, for a target probability of false alarm, P_f, the probability of detection is given by

$$P_d = Q\left(\frac{1}{\sqrt{2\gamma+1}}(Q^{-1}(P_f) - \gamma\sqrt{\tau f_s})\right) \tag{8}$$

Finally, for a given pair of target probabilities (P_d, P_f), the number of required samples to achieve these targets can be determined by cancelling out the threshold variable ϵ. The minimum number of samples is given by

$$N_{min} = \frac{1}{\gamma^2}[Q^{-1}(P_f) - Q^{-1}(P_d)\sqrt{2\gamma+1}]^2 \tag{9}$$

C. Throughput of OU

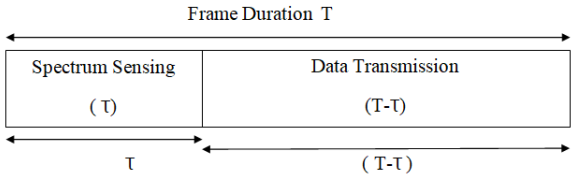

Fig. 1: Structure of single frame in Opportunistic Radio Network [8]

If a frame duration be T and sensing time τ then time required for transmission is (T-τ) as depicted in Fig 1, γ be the SNR found at receiver of OU for hypothesis H_1 when PU is active. f_s be sampling frequency and Throughput of OU, when PU is absent and $P(H_0)$ be probability of hypothesis H_0 after energy detection, throughput for a target probability of detection P_d is [2]

$$R(\tau) = C_0 P(H_0)(1 - \frac{\tau}{T})(1 - Q(\alpha + \gamma\sqrt{\tau f_s})) \tag{10}$$

where

$$\alpha = \sqrt{2\gamma+1}\,Q^{-1}(P_d) \tag{11}$$

Thus, it can be seen that the achievable throughput of the opportunistic network is a function of the sensing time τ.

III. Cooperation of OU

Fading channel: Channel models are utilized to reduce effect of fading [9]. Here, AWGN as non fading channel and among fading channels Rayleigh, Rician and Nakagami channel models are considered to observe throughput performance.
Cooperation: Cooperation is performed among OUs to make integrated decision [10]. For cooperation of different no. of nodes, sensing time increases so apparently time for data transmission decreases [4].

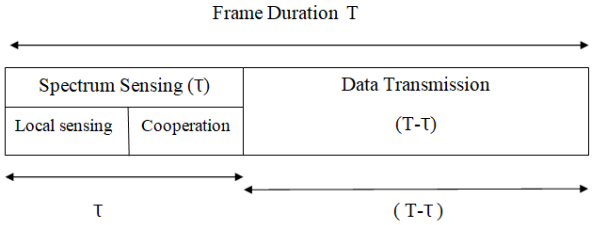

Fig. 2: Frame structure for cooperative sensing in Opportunistic Radio Network [4]

But for cooperation, detection is made better. For cooperative sensing, decision fusion operations are needed to make final decision by fusing individual decisions of sensor nodes. There are four fusion operations [11]. They are:

AND Operation: AND operation works as follows: if all decisions say that there is a primary user, then the final decision declares that there present a primary user. Mathematically

$$P_{d,AND} = P_{d,i}^{N} \tag{12}$$

where N= no of nodes, if $P_{\text{d,AND}}$=1, primary user is present.
OR Operation: OR operation is also simple decision operation like AND operation: if one of the decisions says that there is a primary user, then the final decision declares that there is a primary user. Mathematically,

$$P_{d,OR} = 1 - \Sigma(1 - P_{d,i})^{N} \tag{13}$$

$P_{\text{d,OR}}$=1 then the primary user is present; otherwise, there is no primary user.
Majority Operation: Majority operation is mainly based on majority of the individual decisions. If half or greater than half individual decisions decide that there is a primary user, then the final decision declares that there a primary user is present. Mathematically,

$$P_{d,MAJ} = \sum_{l=\lfloor \frac{N}{2} \rfloor}^{N} (\binom{N}{l} P_{d,i}^{l}(1 - P_{d,i})^{N-l} \tag{14}$$

Optimal Fusion Operation: In this operation sensor nodes are given weighted value to their decisions based on preference, performance and distance of nodes. Mathematically,

$$\Lambda = \sum_{i=1}^{n} [u_i \log \frac{P_{di}}{P_{fi}} + (1-u_i) \log \frac{1 - P_{di}}{1 - P_{fi}}] + \log \frac{P(H_1)}{P(H_0)} \tag{15}$$

if Λ=1, primary user is considered to be present. Decision of highest priority nodes are valued most.

IV. Simulation Outcomes

For analysis of throughput, The signal was taken 64 MHz wideband signal, BPSK modulated and divided into 32 sub bands. Each sub bands are sampled, coded and reconstructed via compressive sensing and energy detection is performed to estimate P_{d}. Probability for which PU transmission is inactive or absent under hypothesis H_0 is considered 0.9. Target probability of detection considered 0.98 and probability of false alarm 0.02. For achieving simple and fair decision under majority operation,odd no of nodes are considered for simulation. Cooperation of 5 nodes and 11 nodes are simulated to observe the effect of increasing no. of nodes on throughput. SNR was taken 10 dB and 15 dB to observe its impact.

A. Against Sensing Time:

Here time frame was kept fixed and it was 100 ms. Throughput are simulated for both 10dB and 15dB SNR for different channels (AWGN, Rayleigh, Rician and Nakagami channel) and different decision fusion operations (AND, OR, Majority and Optimal Fusion). Cooperation of 11 nodes are considered in every case.

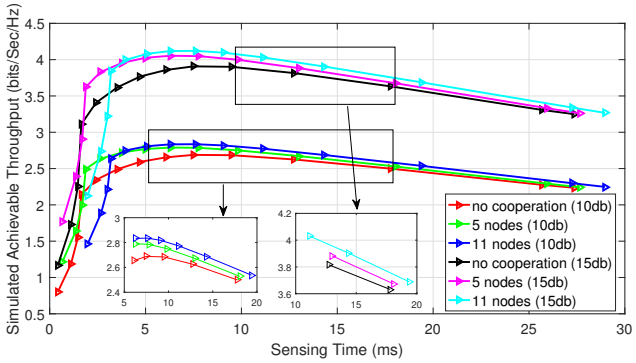

Fig. 3: Throughput Vs Sensing Time for AWGN channel for AND operation (SNR 10dB and 15 dB)

From Fig. 3, achievable throughput found for no cooperation and cooperation of 5 nodes and 11 nodes for AWGN channel AND operation. Here both achievable throughput for 10 dB and 15 dB SNR values are shown. From Fig. 3, it can be seen that, though sensing time for 5 nodes is greater than for no cooperation, and sensing time for 11 nodes are greater than sensing time for 5 nodes, throughput increases for 11 nodes than 5 nodes than no cooperation. Here though sensing time increases, cooperation of nodes provides better result because detection is made better than no cooperation. From simulation achievable throughput found 2.8354, 2.7893 and 2.6886 bits/second/Hz for cooperation of 11 nodes, 5 nodes and no cooperation respectively for SNR value 10 dB. For SNR 15 dB, achievable throughput found 4.1209, 4.0539 and 3.9075 bits/second/Hz for cooperation of 11 nodes, 5 nodes and no cooperation respectively. Again, throughput increases for increased value of SNR.

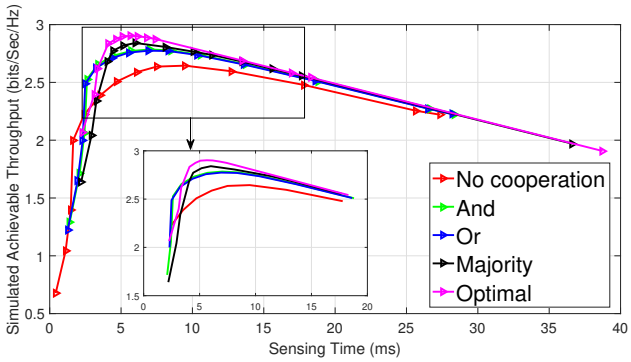

Fig. 4: Achievable Throughput Vs sensing time under Rayleigh channel for different decision fusion operations (AND, OR, Majority, Optimal)

From Fig. 4, simulated achievable throughput found for different fusion operations (AND, OR, Majority and Optimal Fusion) under Rayleigh channel. In every operations, cooperation of 11 nodes are compared with no cooperation case. Maximum achievable throughput for no cooperation found 2.6886 bits/sec/Hz. For AND, OR, Majority and Optimal Fusion operation maximum achievable throughput found 2.8354, 2.8008. 2.8600 and 2.9345 bits/sec/Hz respectively for SNR

10 dB. Optimum sensing time can be determined for different operations. In no cooperation maximum throughput found when sensing time is about 8 ms but for optimal fusion operation optimum sensing time is about 5 ms. Optimal fusion operation provides better throughput than others under same condition in Rayleigh channel.

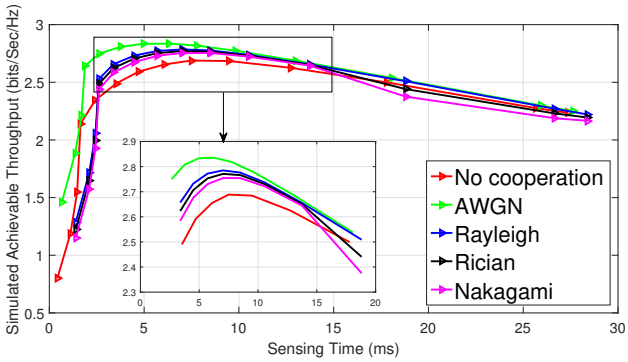

Fig. 5: Achievable Throughput Vs Sensing Time under AND operation for different channels (AWGN, Rayeigh, Rician and Nakagami)

From Fig. 5, simulated achievable throughput found for different channel under AND operation. All these throughput found for different channels are also compared with no cooperation in AWGN channel. The results are taken for SNR 10 dB and cooperation of 11 nodes. Maximum achievable throughput for no cooperation found 2.6886 bits/sec/Hz and for AWGN, Rayleigh, Rician and Nakagami channel maximum achievable throughput found 2.8354, 2.7850, 2.7711 and 2.7543 bits/sec/Hz respectively for 10 dB SNR. From this figure, optimum sensing time can be determined for different channels. In no cooperation maximum throughput found when sensing time is about 8 ms but for cooperation of AWGN channel optimum sensing time is about 5 ms, though cooperation requires more sensing time than no cooperation situation, after achieving cooperative decisions throughput maximization requires less timing than no cooperation case. AWGN channel provides better throughput than others under same condition in AND operation. After 14 ms sensing time, throughput of Rician and Nakagami channel degrades sharply than Rayleigh and AWGN for their fast fading nature.

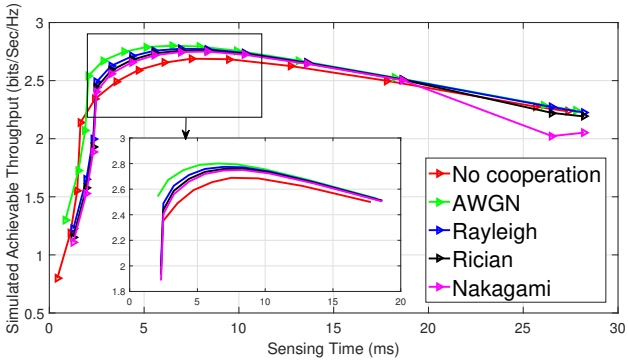

Fig. 6: Achievable Throughput Vs Sensing Time under OR operation for different channels (AWGN, Rayeigh, Rician and Nakagami)

From Fig. 6, simulated achievable throughput found for AWGN, Rayleigh, Rician and Nakagami channel under OR operation. Here also AWGN channel provides better throughput and Nakagami channel provides comparatively inferior performance. Performance of OR operation is almost same as AND operation. Maximum achievable throughput for no cooperation found 2.6886 bits/sec/Hz and for AWGN, Rayleigh, Rician and Nakagami channel maximum achievable throughput found 2.8008, 2.7743, 2.7588 and 2.7502 bits/sec/Hz respectively for 10 dB SNR. But here performance of Nakagami channel degrades more than no cooperation case after about 18 ms sensing time.

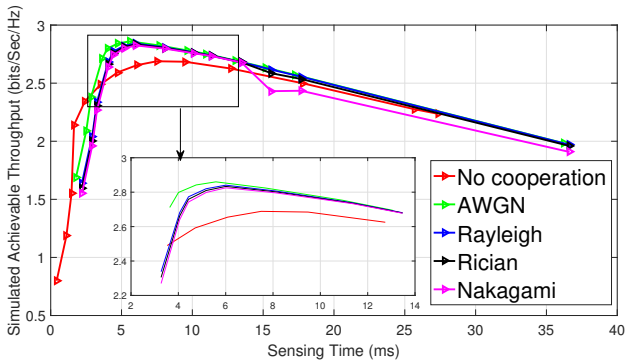

Fig. 7: Achievable Throughput Vs Sensing Time under Majority operation for different channels (AWGN, Rayeigh, Rician and Nakagami)

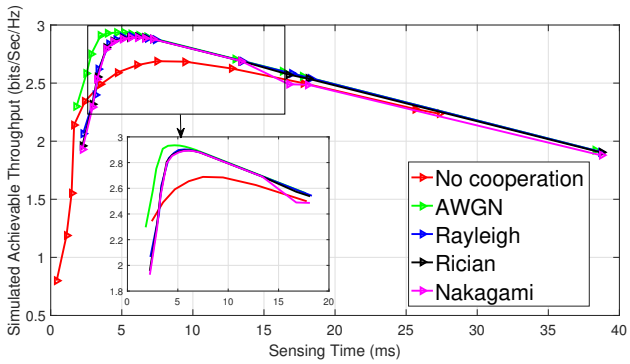

Fig. 8: Achievable Throughput Vs Sensing Time under Optimal Fusion operation for different channels (AWGN, Rayeigh, Rician and Nakagami)

From Fig. 6,7 and 8, performances for different channels for fixed decision fusion operation found. In every case AWGN channel provides better throughput then Rayleigh channel then Rician and finally Nakagami channel.

B. Against Frame length

Simulated achievable throughput against varying time frame for different channels and different fusion operations are analyzed. Here time frame varied from 50 ms to 200 ms and for each case sensing time kept fixed and it is 7 ms. The comparisons are made for different channels when fusion operation is fixed and among different fusion operation under

fixed channel.

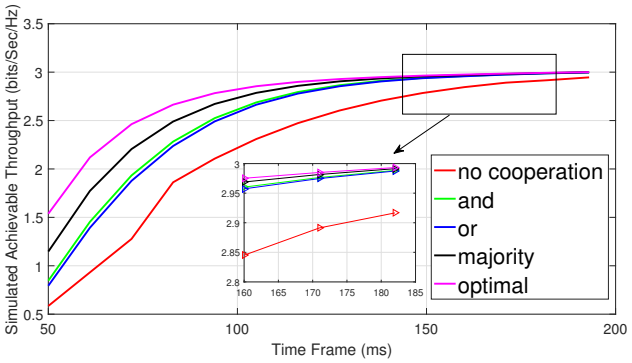

Fig. 9: Achievable Throughput Vs Time Frame under Rayleigh channel for different decision fusion operations (AND, OR, Majority, Oprimal Fusion)

From Fig. 9, simulated achievable throughput found under Rayleigh channel for AND, OR, Majority and Optimal Fusion operation. Here cooperation of 11 nodes for 10 dB SNR for different operations are compared with no cooperation state. Sensing time kept constant 7 ms and time frame varied from 50 ms to 200 ms. Increasing time frame length, throughput also increases. After 150 ms of time frame increasing rate of throughput gets slow for all decision fusion operations. Here Optimal Fusion operation provides better performance than others. From zoomed portion, it can be seen that for increasing time frame from 160 to 200 ms, throughput for Optimal Fusion operation and other operations also increases in slower rate. As in every cases optimal fusion operation provides better throughput than others. For changing time frame, achievable throughput for different channels under Optimal Fusion operation are analyzed.

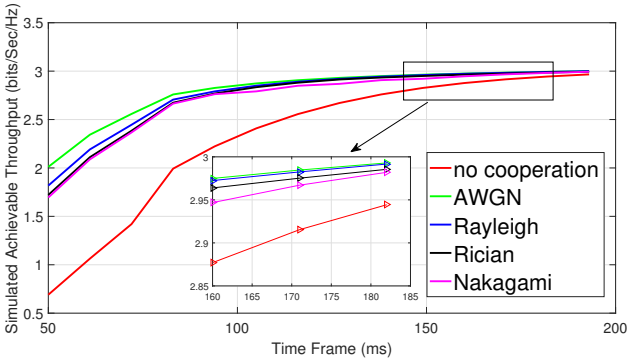

Fig. 10: Achievable Throughput Vs Time Frame under Optimal Fusion operation for different channels (AWGN, Rayeigh, Rician and Nakagami)

From Fig. 10, simulated achievable throughput found for different channel under Optimal Fusion operation. All these throughput found for different channels are also compared with no cooperation case under AWGN channel. The results are taken for SNR 10 dB and cooperation of 11 nodes. Here frame length varied from 50 ms to 200 ms. From Fig. 10, it can be seen that, increasing time frame also increases throughput as time for data transmission increases. From Fig. 10, AWGN channel provides better throughput among four then Rayleigh channel among two other fading channels. After time frame 75 ms, rate of increase of throughput gets slow for AWGN, Rayleigh, Rician and Nakagami channel. So for optimal fusion operation and for cooperation of 11 nodes optimal time frame can be set between 70-80 ms.

In ORN, QoS like throughput increases with the increase of cooperation of no. of OU. Among four fusion operations (AND, OR, Majority and Optimal Fusion), optimal fusion operation provides better throughput. In AND operation, decision is finalized when each nodes provides positive results about the presence of opportunistic nodes. If every nodes decide that there is a presence of PU, detection will be made. In OR operation, if any of nodes decides the presence of other node, detection will be made. As here P_{f} is greater, so performance of OR operation is less than AND operation. In Majority operation decision is made according to decisions of majority. So it provides better performance than AND and OR operation. In Optimal Fusion operation, decisions of nodes are prioritized according to their distance or performance. As a result, reliable nodes decision is valued most. Thus optimal fusion operation provides best result among four fusion operations.

Among Channels AWGN channel provides better throughput compared to others. AWGN channel is ideal noise channel. But in practice, there is real time noise present and that affects achieving maximized throughput like ideal cases. Rayleigh channel is slow fading channel where Rician and Nakagami are fast fading channel. When there is line of sight propagation component present between transmitter and receiver, Rician channel can be utilized, if there is multiple echo component present, Nakagami channel can be modeled. As in cognitive radio network for cooperative compressive sensing for estimating throughput for opportunistic users, there is no dominant line of sight component present and fading is slow. So Rayleigh channel can be modeled for these purpose compared to Rician and Nakagami fading channel.

Throughput performance against time frame provides optimum time frame for each situations. Above 150 ms time frame, increase in throughput gets slower and almost gets saturated. Optimal sensing time found around 5 to 8.7 ms for different decision fusion operations. Optimal sensing time varies from channel to channel and from fusion scheme to scheme.

V. Conclusion

In this paper, cooperation of different no. of opportunistic nodes in ORN are studied in terms of achievable throughput, sensing time and variable frame length. A comparative study on throughput performance has been carried out for different decision fusion operations and different fading channels. Trade-off between optimal sensing time and achievable throughput for variable frame length are presented for defined simulation setup for compressive sensing in cooperative ORN. Future contribution in performance analysis can be made by

estimating computational burden and throughput maximization can be made by evaluating mini slot sensing, other spectrum sensing approaches etc.

***Abstract*— This paper proposes a complete design and simulation of a charge pumping system using a voltage regulator. The system has been implemented using a 6 stage Dickson Charge Pump with an operating frequency of 582 MHz and a maximum pumped-up voltage of 5.32 volts. The voltage level can be fixed to lower user-defined values utilizing the proposed regulatory components in the system. The generated output voltage of the charge pump is compared with a reference voltage produced from a low leakage on-chip Voltage Regulator thus forming a closed loop system. This feedback system allows the user to get the preferred output voltage from the Charge pump system. In this work, the targeted output voltage is 2.65 volts. The whole system is designed using CMOS 180nm process technology.**

Keywords—Charge Pump, Voltage Regulator, Bandgap Voltage, Biasing Current, Comparator, CMOS technology

I. INTRODUCTION

A Charge pump is an electronic circuit used for on-chip generation of higher voltages by transferring charges among capacitor networks utilizing clock phases. For certain applications such as writing or erasing data in non-volatile memories like flash memories or EEPROM, generating actuation voltages for MEMS devices, producing higher voltages in high gain photo-detectors and LED drivers, etc. charge pump is used.[1] [2]. Charge pump has specific applications in analog circuits for running analog switches and generating voltages to provide high dynamic range. [3]

There has been some considerable works in the past on the design and analysis of efficient charge pumps. A novel voltage regulation scheme using variable clock frequency for high voltage charge pump was proposed in [4] suited for neural implants. Two modified charge pump topologies were proposed in [5] which have higher efficiencies due to the elimination of reversion loss in conventional cross-coupled charge pump topologies. A novel tripler charge pump using switched bootstrapping technique with higher efficiency and faster startup was presented in [6]. For low power applications several design modifications were put forward in [7]-[10] and some comparative analysis of different charge pumps were conducted in [11]-[13].

With an endeavor to model state of the art analog circuits and investigate their performance we propose a design of a regulated system capable of controlling the pumping mechanism of the charge pump.

In this paper, Section II describes the different building blocks used for designing the whole system, Section III highlights the design trade-offs in Charge Pump, Section IV shows the simulation results of the proposed integrated circuit and Section V concludes our paper as well as discusses the future scope of our work.

II. FUNCTIONAL BLOCKS & DESIGN ARCHITECTURE

The diagram below shows the orientation of functional blocks and design architecture. Here, a clock system provides the frequency for charge pump stages and operational amplifier is used to turn the clock on or off. A reference voltage is needed for the comparator which can be generated from Bandgap reference and Voltage regulator circuit. A brief explanation regarding the operation of those blocks and connectivity is shown in following sections.

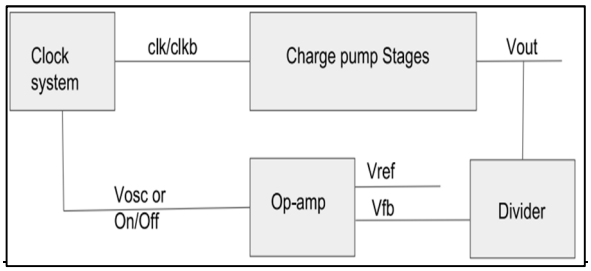

Fig. 1. System Overview of Proposed Charge Pump System

A. Charge Pump

For pumping up the voltage from the supply, charge pump uses multiple stages of capacitors which are charged and discharged by means of switches based on periodic input signals. At first stage the capacitor is charged to the supplied voltage and then at the next stage this stored charged along with the supplied voltage is applied to the load. The supplied voltage across the load increases proportionally by the number of stages used in the charge pump. In our design we have used a six stage Dickson Charge Pump and its output voltage is governed by the following equation:

$$V_{out} = V_{in} + N\left[\left(\frac{C}{C+C_s}\right).V_{\emptyset} - V_D\right] - V_D - \frac{NI_{out}}{(C+C_s)f} \quad (1)$$

where,

N=no of stages,

C= capacitor connected at each node,

Cs=stray capacitance of the device,

V_D=voltage drop across the gate drain connected MOSFET,

Vφ=voltage swing at each node due to capacitive coupling from the node.

I_{out}= Current with load.

The following figure shows the unit block of 6 stage Charge Pump.

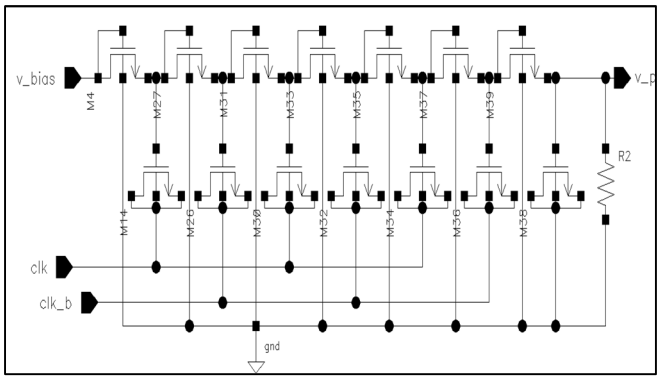

Fig. 2. Charge Pump stage.

B. Clock Generation

In order to generate the clock signals for the charge pump, voltage controlled oscillators (VCO) were used as it gives the advantage of controlling the oscillating frequency unlike the ring oscillators. The oscillating frequency of the VCO is related to the input voltage by the following equation:

$$f = \frac{I_D}{NC_{tot}V_{DD}} \quad (2)$$

where, N=No of stages & C_{tot}=sum of input and output capacitance of each stage. The figure below shows voltage controlled oscillator.

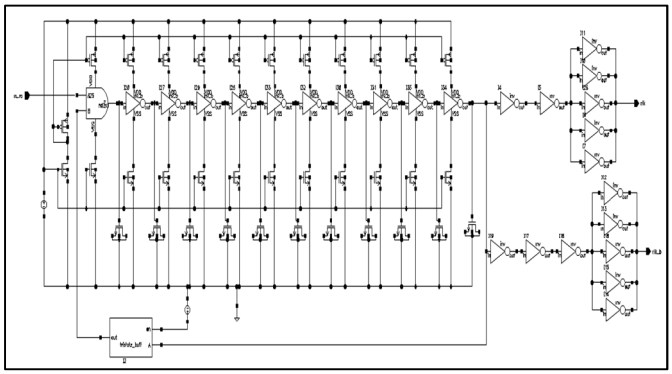

Fig. 3. Voltage Controlled Oscillator.

A frequency control pin has been used to regulate the oscillation frequency. Current in the branches directly varies with the frequency. By using current mirroring technique, same current is provided to all the branches ensuring a much stable operation. The output buffers are used to increase the driving strength and the tri-state buffer is used to make the edges of the clock sharper. Normally, generated oscillations had lower slew rate, but the tristate buffer improved the output.

C. Biasing Current Generator

To generate fixed amount of current to the bandgap voltage reference circuit, voltage trimmer and the operational amplifier of the system, a current generator independent of supply voltage variation has been used. Figure below shows a beta multiplier circuit where the circuit operation is controlled by the enable pin. Beta multiplier circuit has two stable operating points and one of them is when zero current flows in the circuit. Hence to operate the circuit at the desired operating point a startup circuit has been used. The output current for the circuit can be calculated from the following equation:

$$I_{REF} = \frac{2}{R^2 KP_n \frac{W_1}{L_1}}\left(1 - \frac{1}{\sqrt{k}}\right)^2 \quad (3)$$

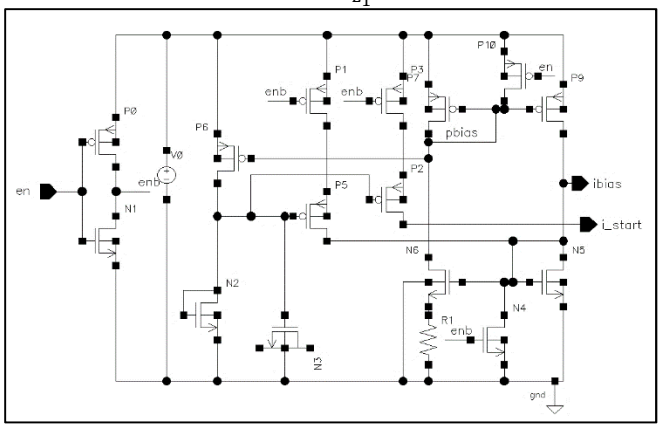

Fig. 4. Biasing Current Generator

As, this type of bias current generator has issues regarding high leakage current, multiple enabling input has been introduced. This helps the MOSFETS in the main generator circuit to be at totally OFF state during non-operating stages thus ensuring very less amount of leakage flowing through the circuit. Also, it allows us to eliminate the floating voltage from gates and keeping them at known values.

D. Bandgap Voltage Reference Circuit

This circuit is used to generate a constant voltage which is resistant to supply voltage, temperature and process technology variations. Combining the CTAT (Complementary to Absolute Temperature) behavior of the Bandgap energy of silicon and the PTAT (Proportional to Absolute Temperature) behavior of the thermal voltage a temperature resilient voltage reference circuit is designed.

If V_{BE} is considered as Base to Emitter voltage for BJT then,

$$\Delta V_{BE} = V_{BE_1} - V_{BE_2} = V_t \ln\left(\frac{I_1}{I_{S_1}}\right) - V_t \ln\left(\frac{I_2}{I_{S_2}}\right) \quad (4)$$

Again, $$V_{R_2} = \Delta V_{BE} = V_t \ln\left(\frac{I_1 I_{S_2}}{I_2 I_{S_1}}\right) \quad (5)$$

$$I_2 = \frac{\Delta V_{BE}}{R_2} = \frac{V_t}{R_2}\ln\left(\frac{I_{S_2}}{I_{S_1}}\right)) \quad (6)$$

Now, $$V_{ref} = V_{BE2} + V_{R2} + V_{R0,R1}$$

$$V_{ref} = V_{BE2} + V_{R2} + I_2 R_0 \quad [R_o = R_1]$$

Using (4), (5), and (6), it can be written as,

$$V_0 = V_{BE_1} + (1 + \frac{R_1}{R_2})V_t \ln(\frac{I_{S_2}}{I_{S_1}}) \quad (7)$$

The above derived equation is used to set the values of resistors in the circuit.

A differential amplifier was used in the Bandgap Reference circuit to keep same voltages on both sides of the circuit. Differential amplifier causes much noise, especially in Bandgap circuits. In this circuit, an extra low pass filter improved the effect of noise on the circuit.

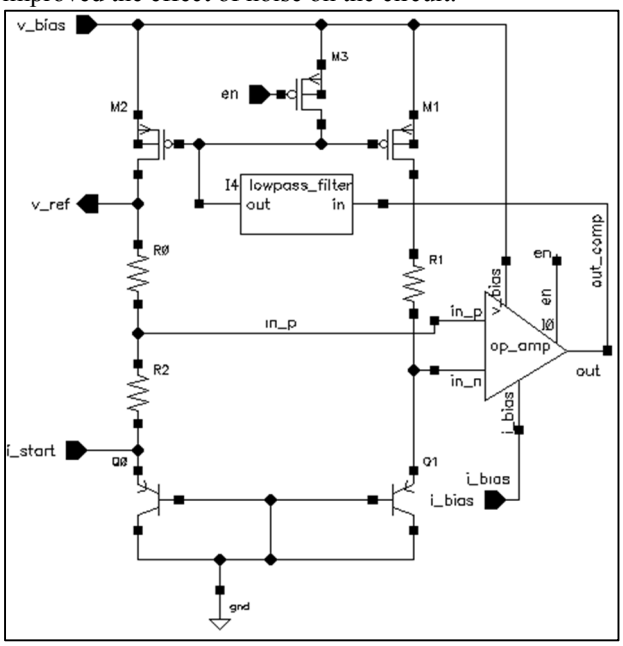

Fig. 5. Bandgap Reference Voltage Generator

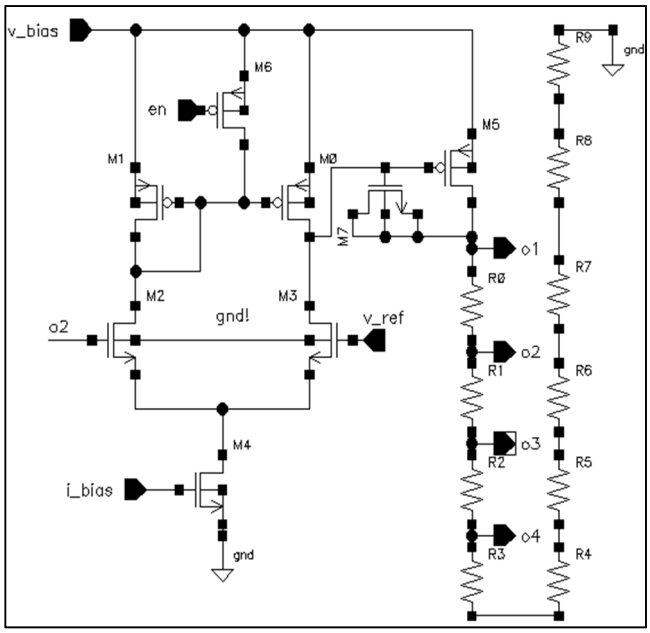

Fig. 6. Voltage Trimmer Circuit

E. Voltage Trimmer Circuit

In order to get different voltage levels from the output of the voltage reference circuit, a voltage trimmer is used. It adds flexibility of using the system at multiple voltage levels. The comparator keeps the voltage level of the two inputs at the same value where its output is eventually trimmed at different voltage levels. User can choose any suitable voltage as the reference value from this Voltage Trimmer circuit.

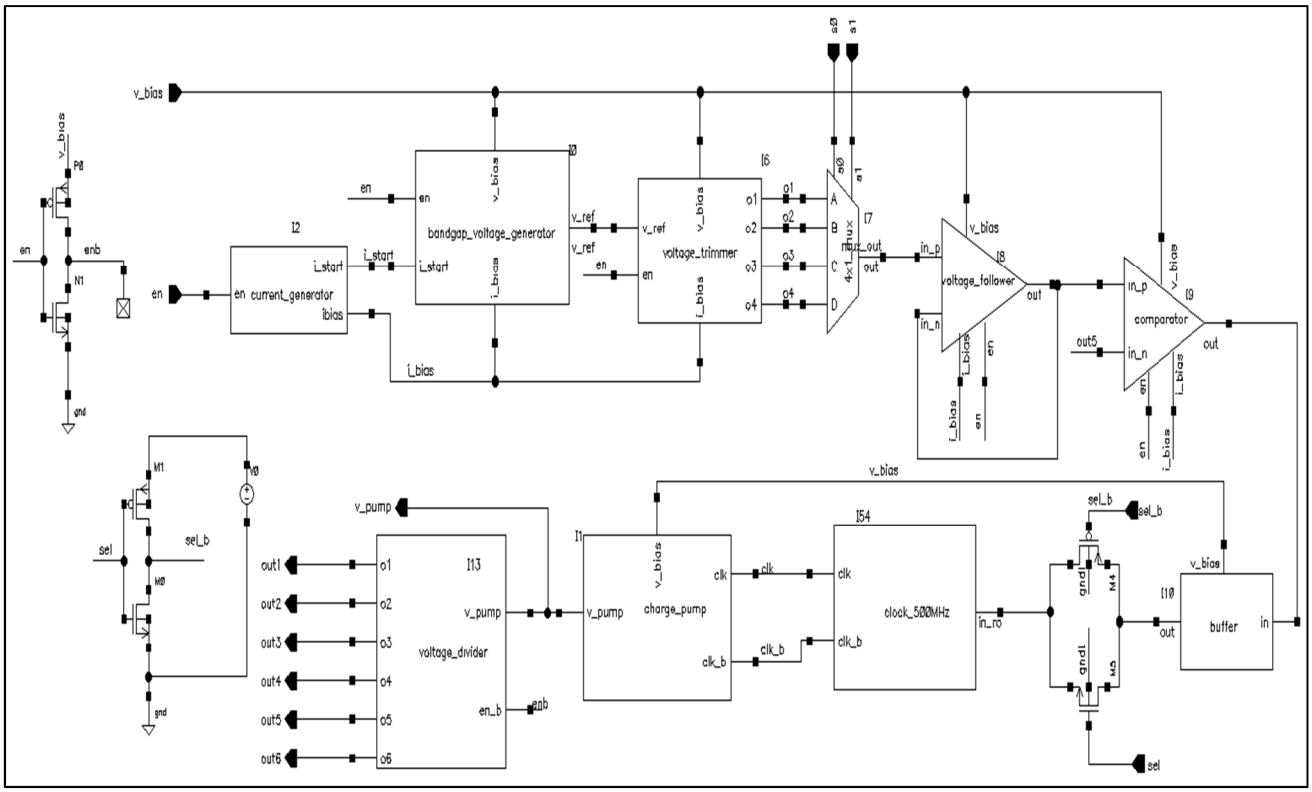

Fig. 7. Top Level schematic of High Voltage Charge Pump System

F. *Top Level of System*

The figure above shows the schematic of the proposed system. The output voltage of the Charge Pump goes into a Voltage Divider to generate a comparable voltage for the comparator. Another input of the Comparator is a user defined value which comes from the output of the Voltage Trimming circuit. Initially feedback voltage from the Voltage Divider is lower than the reference voltage which compels the comparator to give a logic high at its output enabling the oscillators. With the non-overlapping clock signals created by the oscillator, Charge Pump starts pumping up the voltage. The pumped up voltage results into an increased feedback voltage which when surpasses the value of the reference voltage generates a logic low at the output of the comparator. As a result the oscillator is turned off and the charge pump will consequently stop pumping up the voltage until the feedback voltage is lower than the reference voltage. In that case the comparator will give logic high and enable the charge pump again. From this process a fixed scalable voltage can be achieved from the system

III. Design Tradeoffs in a Charge Pump

The behavior of a charge pump usually depends on a few decisive parameters which have been discussed in detail in the following section.

A. *Effect of stage capacitance*

Increasing the value of stage capacitance increases the storage capacity of the pump and thus increases the output voltage and current. On the contrary much delay is added to the circuit and thus makes the circuit slower. Almost 400ns of time was recorded to get a stable voltage level while using capacitors of 20pF. But the settling time has increased comprehensively when capacitors' values were increased to 80pF.

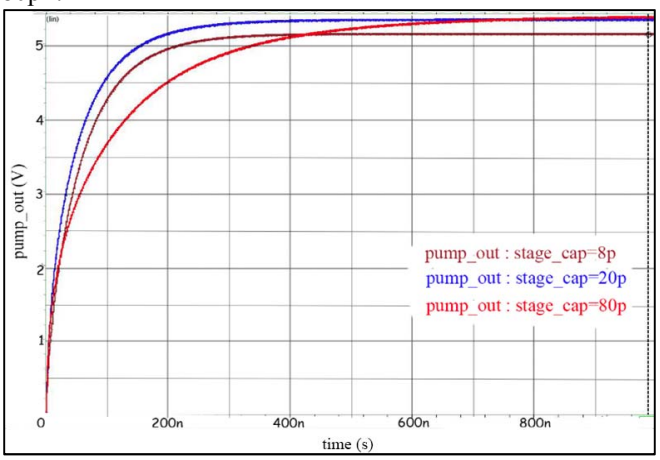

Fig. 8. Effect of stage capacitance for charge pump

Decreasing the value of the stage capacitors reduces the maximum output voltage to 5.13v.

B. *Effect of load capacitance*

The load capacitor when reduced to a lower value makes the ripples more distinct in the signals. In fig. 9, the effect of varying the output capacitor has been shown. Adding more load capacitance to the circuit can smoothen the output curve at a greater scale but at the expense of adding more delay to the output which has been illustrated in fig. 9. Here the load capacitance was increased from 10pf to 50pf which consequently delayed the signals reaching their maximum value.

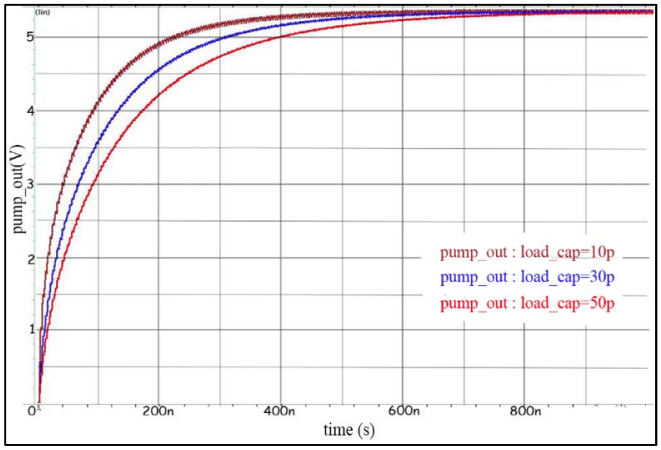

Fig. 9. Effect of load capacitance for charge pump

C. *Effect of load Resistance*

Reducing the load resistance increases the current across the load and consequently reduces the output voltage. The load resistance also has an inverse effect on the ripple of the signals. At resistance value of 2.8k, current increased to 1.45mA and voltage decreased to 4.3V. Load resistance was increased from 2.8k to 20.8k which dropped the current to a value of 270uA but the voltage increased to 5.61V. Also the ripples were minimized.

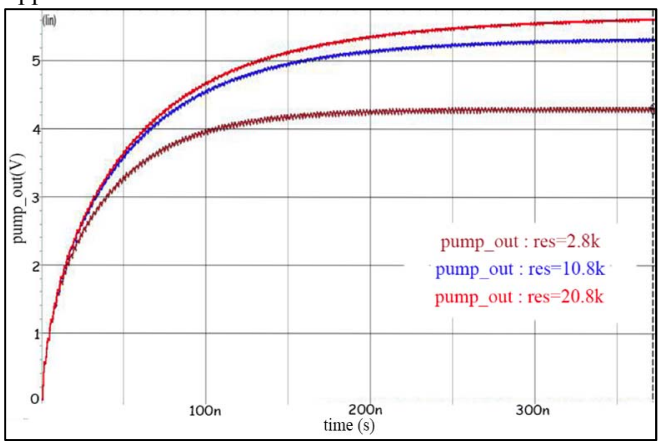

Fig. 10. Effect of load resistance on output voltage

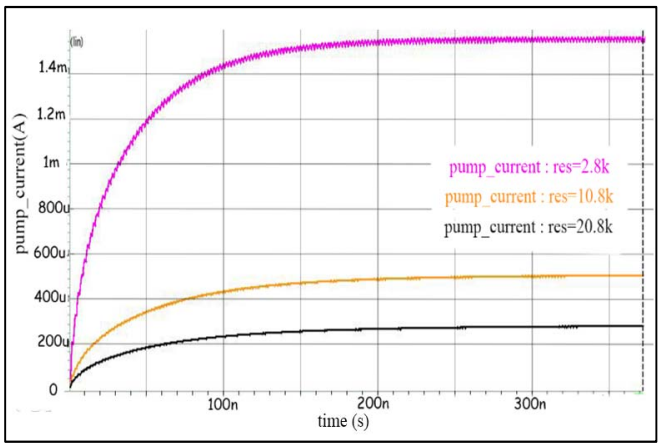

Fig. 11. Effect of load resistance on output current

D. Effect of Frequency

Frequency is always a dominant factor for a charge pump. When the time period was increased from 800ps to 2ns, the output takes almost 185ns to become stable. It also has an inverse effect on the ripple of the signals which can be seen in the figure below.

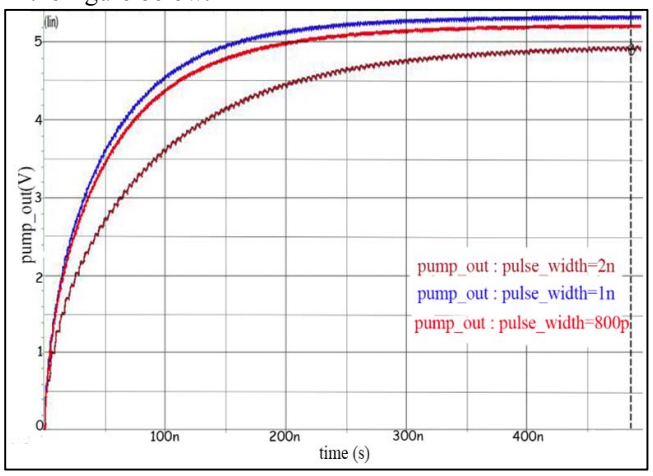

Fig. 12. Effect of frequency on output voltage

Increasing the frequency too much hinders the proper charging and discharging of the stage capacitors thus resulting into fewer charge accumulation and degrading the performance of the charge pump. It is shown from the fig. 12 that, output voltage got degraded and also ripples were added at the frequency of 500 MHz. Frequency also effects the output current in the same manner. Fig. 13 shows the effect of frequency on output current.

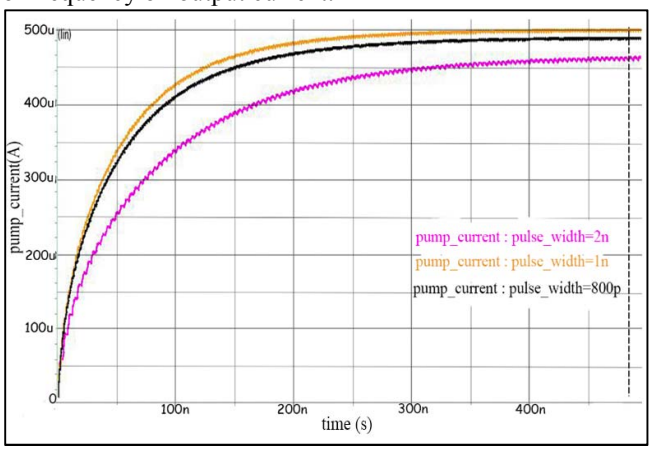

Fig. 13. Effect of frequency on output current

IV. Simulation Results

This section discusses the simulation results of the different blocks considering multiple conditions. It validates the authenticity of the proposed system.

In fig. 14. voltage profile at different nodes of the Current Generator is shown. The enable signal is used to start the current generator circuit and a startup circuit is used to inject voltage into the current sinking NMOS network turning them ON. The current generator circuit has been used to generate a current of 44uA. It is observed that, current flowing through startup circuit is about 25uA for a short period of time until a stable current supply has been ensured.

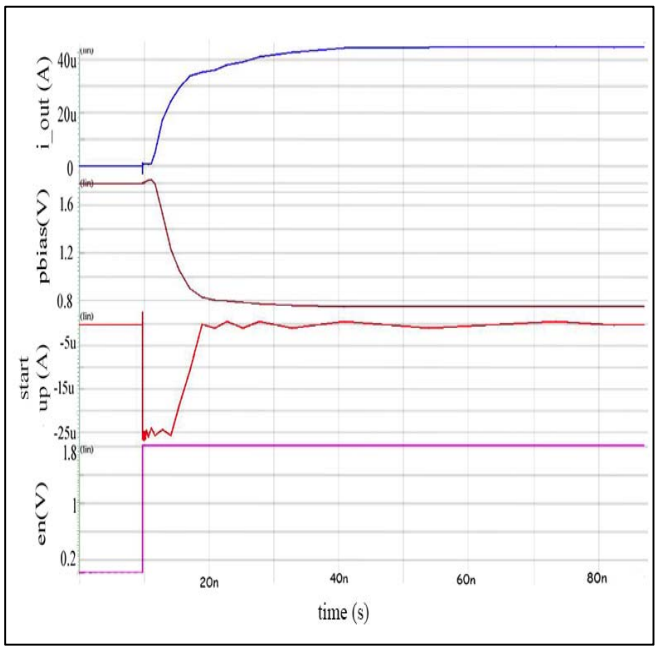

Fig. 14. Waveform of biasing current and startup current obtained from Current Generator

Fig. 15. represents results for Bandgap Reference Generator. When the enable signal is given, the startup circuit injects voltage into the reference circuit which initiates its operation. The operational amplifier used helps stabilizing the voltage on both sides of the circuit and a constant voltage of 1.24V is generated. The graph below shows an almost accurate temperature independence of the circuit. For a temperature sweep of -40 to 149 degree Celsius the circuits shows a voltage variation of 0.009V which is shown in fig. 16.

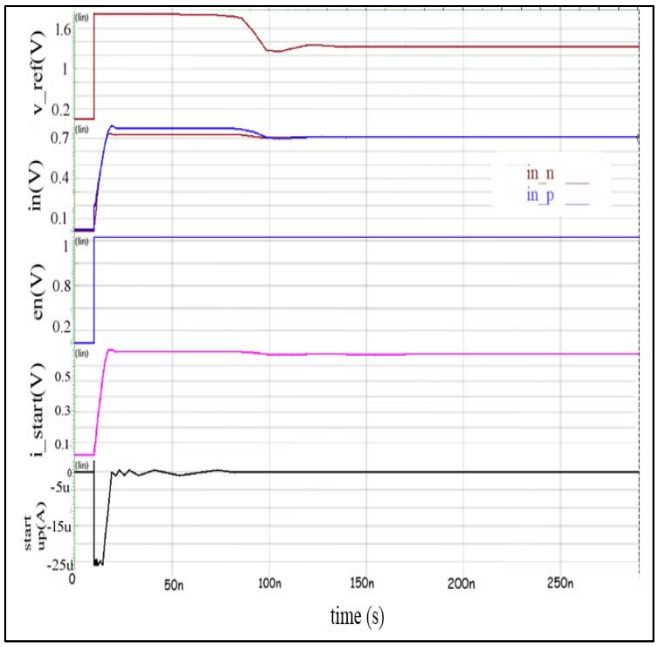

Fig. 15. Transient analysis of Bandgap Reference voltage

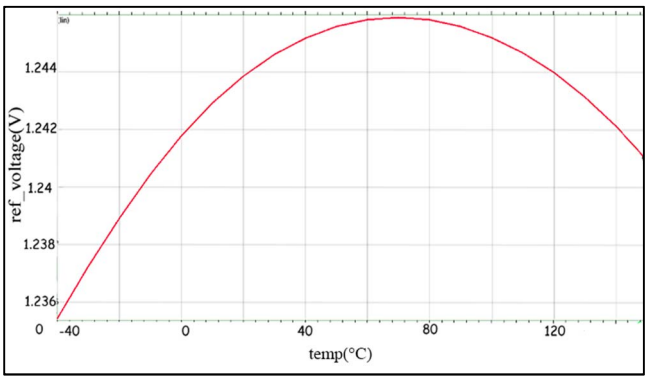

Fig. 16. DC analysis of Bandgap Reference voltage sweeping temperature

It states that, Reference Generator is independent of temperature variation. Once again very low leakage is ensured as startup circuit only draws current while enabling the main circuit.

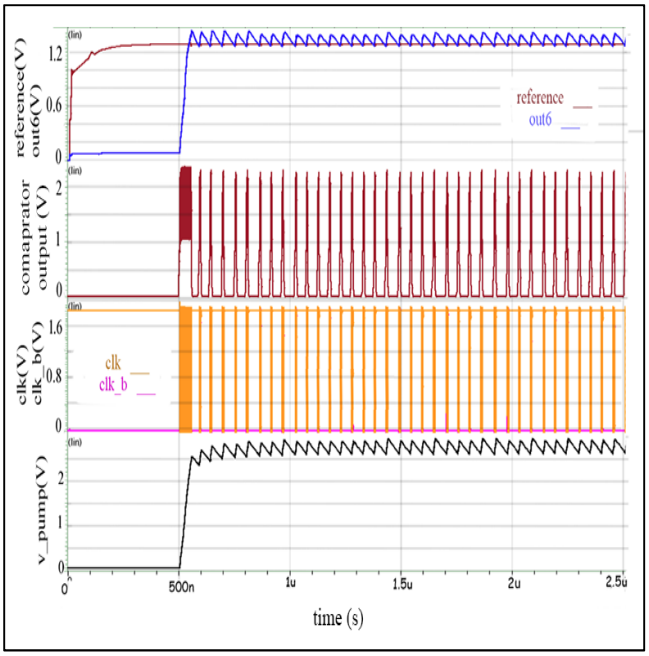

Fig. 17. Output wave shape of Charge Pump along with self-regulated mechanism

In order to control the clocks of the charge pumps we have used the voltage from the bandgap reference and a divided value of the pumped up voltage. When the derived output voltage of the charge pump goes below the reference voltage the clocks are switched on to activate the charge pump and the voltage is pumped up to a desired value of 2.64 volts.

V. Conclusion

The paper reported a low leakage biasing circuit by introducing multiple enabling inputs and flexible operation of the system at multiple voltage levels by using a voltage trimmer. All design and simulation are done under Cadence – Virtuoso environment. The results of the developed system were analyzed under different conditions which validate the purpose of the proposed method. Further work will include the improvement of the charge pump for lower voltage and higher frequency. Higher frequency introduces more noise. So the effect of noise will be a concern for future work.

***Abstract*—Wave function penetration phenomenon had been studied for a p-channel Double Gate Junction Less Transistor in terms of Capacitance-Voltage (C-V) characteristics. It has been found that the gate capacitance differs visibly for the two cases (i.e. with and without penetration) only in the accumulation mode of device operation. As a result, it is safe to assume that the occurrence of threshold condition is independent of this phenomenon for the studied device, which had been established by extracting threshold voltage from the simulated C-V curves.**

***Index Terms*—Junction Less Transistor, Self-Consistent Schrödinger-Poisson Solver, Wave Function Penetration, C-V characteristics, Threshold Voltage.**

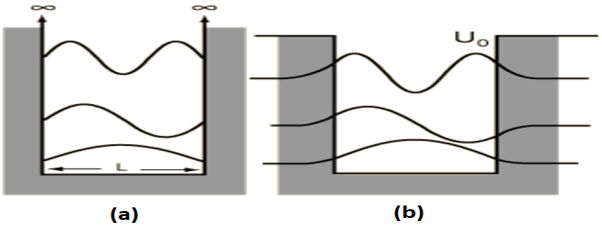

Fig. 1: Wave Function Penetration (WFP) effect in Double Gate Junction Less Transistor (DGJLT). The structure is basically a quantum well with 1D confinement. Being a finite potential well, it is safe to assume some penetration into gate oxide occurs as shown in (b), instead of ideal case with infinite barriers as depicted in (a). [9]

I. Introduction

The need for quantum mechanical modeling of Field Effect Transistor (FET) devices' characteristics was first described and practically implemented by Stern [1]. To model the ultra-small devices with micro-to-nanometer range feature lengths, Stern employed self-consistent methodology which solved Schrödinger and Poisson equations iteratively till a complete description of charge distribution and potential profile inside the FET structure was found. With the scaling of FET devices to ever decreasing sizes, self-consistent modeling has become a popular method to model their electrostatics now-a-days. In his model, Stern assumed that the FET structures were quantum confined i.e. well (1D) or wire (2D) with infinite potential barriers surrounding the channel [1]. As a result, the carrier wave function was assumed going to zero abruptly at channel-oxide interface. But this is not really a valid scenario as the potential barrier arising from the difference in band structure of channel and oxide materials' is actually only a few electron volts high [2]. As a result, assuming no penetration of carrier wave function into the gate oxide of the device gives an incomplete picture of the charge distribution and potential profile inside the FET structure [2]. So, in order to obtain a more complete description of charge distribution, potential profile and other electrostatic properties like gate capacitance and threshold voltage, a few previous works [2], [3], [4] have allowed carrier wave function to penetrate into gate oxide. All of them studied Inversion Mode (IM) MOSFET, so there is a scarcity of such modeling for other FET devices in literature.

Recently, a new FET device called the Junction Less Transistor (JLT) has been proposed [5]. While IM-MOSFET has its carriers conducting at channel surface just below the channel-oxide interface [3], the JLT device's carrier conduction mostly happens at or near the channel center [5], which is the furthest point from channel-oxide interface inside the device structure. Specially during sub-threshold and near threshold operation, the bulk conduction mechanism of JLT can not be ignored [5]. As a result, it is quite possible that considering wave function penetration effect while self-consistently modeling JLT electrostatics is not so important as in the case of IM-MOSFET modeling.

Indeed, a recent study of Capacitance-Voltage (C-V) characteristics of n-channel Double Gate (DG) JLT device has demonstrated that the occurrence of threshold condition in n-JLT is independent of penetration into gate oxide by carrier wave function [6]. The study also showed that wave function penetration phenomenon has no effect on the gate capacitance in full and partial depletion modes of n-JLT operation [6]. Even though definite proof of theory now exists for n-JLT, no such study was carried out for p-JLT yet. As the results for deep submicron n- and p-MOSFETs were found to be different in [2], it is necessary to carry out a similar study for p-JLT. So, the present work aims to first simulate the p-DGJLT C-V characteristics both allowing and disallowing wave function penetration and then study gate capacitance and threshold voltage to find out if they are as affected as in the case of n-JLT by the occurrence of this phenomenon.

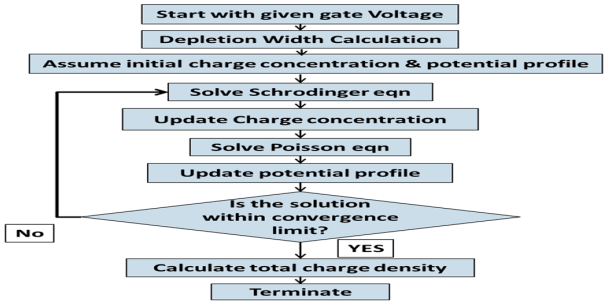

Fig. 2: Self consistent solver [1].

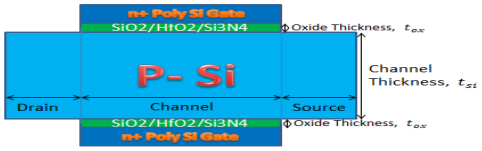

Fig. 3: Double Gate Junction Less Transistor (DGJLT) structure.

II. Simulation Details

A MATLAB based 1D Schrödinger-Poisson solver had been created following the steps described in [1] to simulate the C-V curves, and is depicted in Fig.2. Necessary modification for the physics of JLT as described in [7] had been used in building the simulator. Necessary parameters of gate insulator (i.e. K value, conduction band offset and band gap) were obtained form [3]. The valance band offset was calculated by subtracting the conduction band offset from the bandgap offset. DOS and Quantization effective masses of holes and degeneracy information of Si were obtained form [2]. The effective mass of hole in oxide is assumed to be $0.5m_0$, m_0 being electron's rest mass [2]. Whenever wave function penetration had to be ignored the channel-oxide valance band offset was set to a very high value (e.g. 4000 eV), following [4]. The threshold voltage was extracted depending on the work of [8], which suggests that when mobility variation is ignored, the position of the maximum peak of $|\frac{dC_{gate}}{dV_{gate}}|$ vs. V_{gate} curve gives the threshold voltage V_{th}. For p-channel JLT, absolute value $|\frac{dC_{gate}}{dV_{gate}}|$ had been plotted to observe the change only, ignoring its direction. The range of uncertainity for all reported threshold voltage values is limited to within ± 0.1 V.

III. Results

The studied structure is shown in fig.3. The channel is made of p-Si while the gate is made of n+ poly Si. The parameters are chosen as doping density, $N_A = 10^{19}/cm^3$, channel thickness, $t_{si} = 10nm$, oxide material, SiO_2 and Effective Oxide Thickness (EOT), $t_{ox} = 2nm$ and have been maintained for all simulations unless otherwise specified.

To find the effect of changing oxide material, along with SiO_2, other gate oxides used were HfO_2 and Y_2O_3. Fig.4 shows the C-V curves. The $|\frac{dC_{gate}}{dV_{gate}}|$ vs V_{gate} curves are shown in Fig.5.

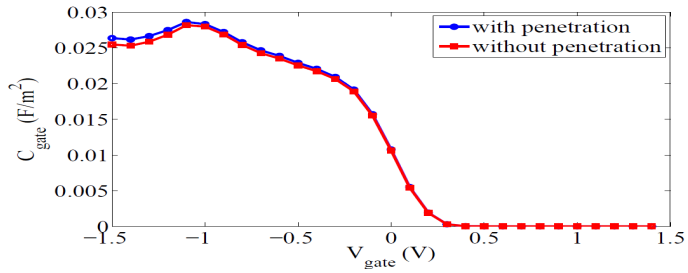
To find the effect of changing channel thickness, it was varied to 6, 8 and 10 nm. Fig.6 shows the C-V curves. The $|\frac{dC_{gate}}{dV_{gate}}|$ vs V_{gate} curves are shown in Fig.7.

To find the effect of changing oxide thickness, it was varied to 1, 1.5 and 2 nm. Fig.8 shows the C-V curves. The $|\frac{dC_{gate}}{dV_{gate}}|$ vs V_{gate} curves are shown in Fig.9.

To find the effect of changing channel doping density, it was varied to $10^{19}/cm^3, 5*10^{18}/cm^3$ and $10^{18}/cm^3$. Fig.10 shows the C-V curves. The $|\frac{dC_{gate}}{dV_{gate}}|$ vs V_{gate} curves are shown in Fig.11.

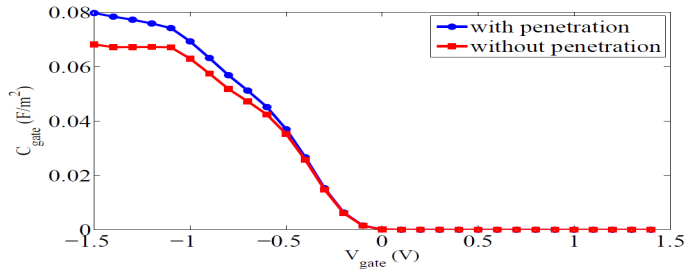
For the defined device structure, the metal to semiconductor work function (also known as the flat-band voltage) [7] is $-1.1V$. In the C-V curves, saturation behavior occurs beyond this voltage. This is also the voltage beyond which gate capacitances differ due to penetration. So, from observing the results it can be said that regardless of penetration the gate capacitances are visibly same in the C-V curves up until the accumulation mode of operation (i.e. saturation behavior) [7].

The maximum peak in the $|\frac{dC_{gate}}{dV_{gate}}|$ vs. V_{gate} curves occurs at same V_{gate}=V_{th} regardless of penetration.



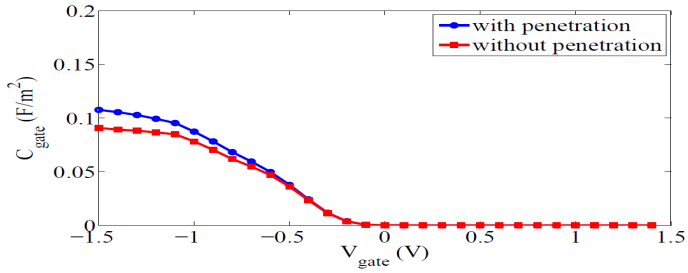
IV. Conclusion

In p-JLT, initially a space charge region arising from the acceptor doping covers the whole channel. As a gate voltage is applied and gradually increased in positive direction, the depletion region reduces and free holes start to gather at the channel center. With sufficient holes gathered at the channel center to nullify the depletion charges, a string like path of neutral-Si from source to drain is created [5]. After this threshold condition has occurred, applying a suitable drain to source voltage will make conduction possible. As channel center is the furthest point inside the device form channel-oxide interface so it is expected that wave function penetration into gate oxide should have no effect on threshold voltage, which has been proven from the results of this work.



Moreover, the C-V curves show the wave function penetration to have no perceivable effect on gate capacitance in full or partial depletion mode of device operation. The gate capacitance is defined as,

$$C_{gate} = \frac{q\delta(p - N_A^-)}{\delta V_{gate}}$$



where, q=charge of a hole, qp=mobile charge arising from holes(+ve) and qN_A^-=depletion charge arising from acceptors (-ve). In this equation, only the mobile charge, qp is variable. This term is affected by wave function penetration only when the holes are present near channel-oxide interface. Only then the probability of holes tunneling into gate oxide takes on a moderate value. This does not happen in full or partial depletion mode of operation. Only beyond flat-band, when all of p-JLT channel is available for conduction [5], then the mobile charge term is affected by wave function penetration. So, the observations in this work comply with both theoretical notions and the results for n-JLT.

***Abstract*— Millimeter-wave passive elements are one of the vital part to distribute power through integrated circuitry. And transformer coupled passive devices are used not only for signal transmitting but also making chip area smaller. A transformer coupled planar and stacked type both could be used for balun and power divider-combiner design. This type of balun provide small amplitude imbalance ~2dB and 180^0 phase imbalance between 57-120 GHz bandwidth (BW) and successively shrinking the layout area of $0.0061mm^2$. On the other hand, transformer coupled two way power divider-combiner (PD-C) occupies $0.0088\ mm^2$ (7.5 Times Smaller than Wilkinson PD-C) with amplitude variation ~1.87dB and phase angle variation 3^0 with larger BW (50-120 GHz). Again four way PD-C occupies $0.0122mm^2$ (5 Times Smaller than Wilkinson PD-C) having amplitude variation ~2dB and phase angle variation 2.8^0 with a larger BW 50-120 GHz. Proposed stacked small transformers with a center trapped baluns and power divider-combiner have been implied on two millimeter-wave amplifiers on 55nm DDC CMOS.**

Keywords—Millimeter-Wave Transformer; Transmission Line; Transformer Coupled Balun; Transformer Coupled Power Divider-Combiner; Two-way and Four-Way Power Divider-Combiner.

I. INTRODUCTION

Millimeter-wave passive elements are one of the vital part in integrated circuit design. Transmission line (TX-Line) and capacitors have been used for coalesce with other active section. Balun and power divider-combiner are the key elements for power distributing and combining in-phase or out-phase. Along with several type of baluns [1] [2] [3] [4] and power divider-combiner [5] [6], proposed transformer coupled balun and power divider-combiner (PD-C) have been designed with twelve metallic stack of 55nm DDC CMOS. Initially transmission line has been designed with ground floor, ground wall and signal line (fig.1). Withdrawing the signal line part of TX line, the transformer coils have been added with signal I/O. A center-trapped transformer balun coil has been attached with differential ended active element. In fig. 2, a transformer coupled balun and PD-C have been inserted for signal distribution and matching network setting.

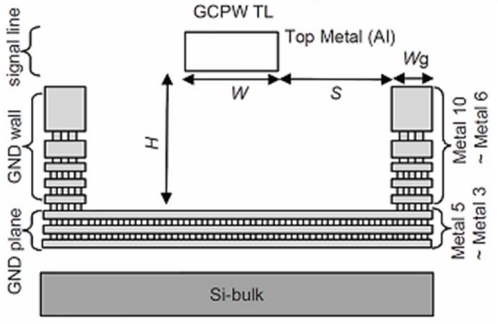

Fig. 1. Cross view of TX Lines

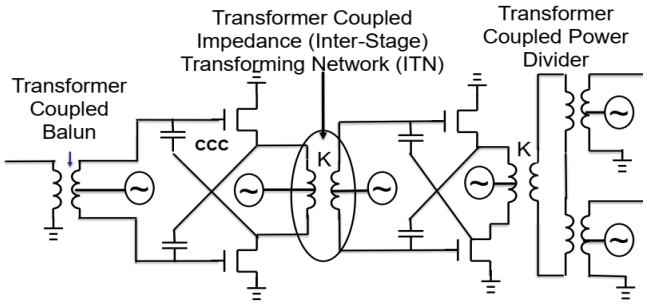

Fig. 2. Transformer coupled ITN with differential amplifier

II. REVIEW OF SOME TEST DESIGN

Millimeter-wave amplifier contain several passive elements for satisfying the property of lower insertion loss, good input and output matching, higher gain and output power, low noise figure, good figure of merit etc. For L-C-L coupled circuit, MIM capacitor, Transmission Line, MOM capacitor, Inductor and resistor are the passive elements for design circuitry. Balun, power divider and combiner also contain transmission lines to mitigate its properties. An ideal balun is a three-port device with a matched input and differential outputs. It is most succinctly described all by the required (ideal) S-parameters (eqn. 1).

$$\angle S12 = -\angle S13 = \angle S21 = -\angle S31$$

$$\mathrm{dB}(S12) = \mathrm{dB}(S13) = \mathrm{dB}(S21) = \mathrm{dB}(S31)$$

$$S_{11} = -\infty$$

$$\text{Amplitude Balance} = 20\log_{10}\left|\frac{S_{31}}{S_{21}}\right| \quad \text{(eqn. 1)}$$

$$\text{Phase Balance} = \text{ang}\left(\frac{S_{31}}{S_{21}}\right)$$

$$\mathrm{IL}_{\mathrm{power}} = 20\log_{10}(|S_{12}|^2 + |S_{13}|^2)$$

A. Ratrace and Marchand Balun

Transmission line with HFSS designed simulation (1-500 GHz) has been converted into RLGC .dat file, fixed for a

center frequency (60GHz & 79GHz) and then inserting the values of R, L, G, C into these equation. The propagation constant, $\gamma = \sqrt{((R + j\omega L)(G + j\omega C))}; \beta = \text{imag}(\gamma); \lambda = 2\pi/\beta$. Rat-race balun also behaves as differential signals $(0^0, 180^0)$ having $\frac{\lambda}{4}$ and $\frac{3\lambda}{4}$ signal line length and layout area 0.138mm^2. The schematic and layout area is comparatively large than capacitively coupled transmission line balun, Marchand balun & transformer coupled balun (fig.2). Marchand balun is TX line type balun, which has left ported input and right ported output with equal length of transmission lines. Marchand balun behaves as differential signals $(0^0, 180^0)$ having separately $\frac{\lambda}{4}$ signal line length and layout area 0.169mm^2. Transformer type balun is considerably good from rat-race and marchand balun in case of keeping lower Amplitude and phase imbalance and layout area is also smaller than marchand and ratrace balun. And it sustains larger BW of 180^0 phase differences.

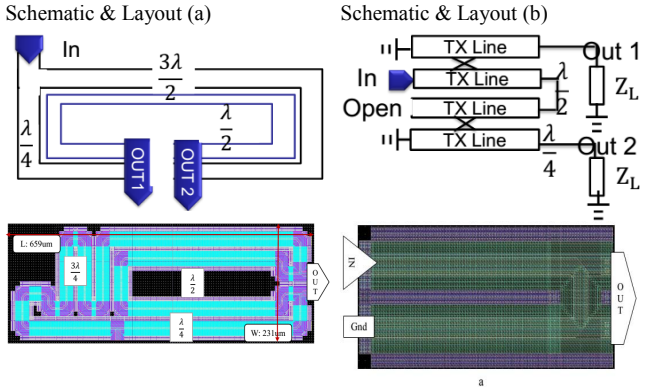

Fig. 2. Schematic and Layout of Ratrace Balun

B. *Wilkinson Power Divider-Combiner*

Power Divider-Combiner (PD-C) is a specific class of circuit that can achieve isolation between the output ports while maintaining a matched condition on all ports. Network theorem of this divider can't satisfy all three conditions at the same time. It satisfies the first two (matched and reciprocal properties) but can't satisfy last one ideally (Loss-less) in eqn. 2.

$$[S] = -\frac{j}{2} * \begin{bmatrix} 0 & 1 & 1 \\ 1 & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix} \quad \text{(eqn. 2)}$$

$S_{11}, S_{22}, S_{33} = 0$, These terminals are matched.

$S_{23}, S_{32} = 0$, Output terminals are isolated.

$S_{21} = S_{31}$, Equal power need to be achieved.

$$S_{21} = S_{31} = -3\text{dB} = 10\log_{10}\left(\frac{1}{2}\right), \text{ Ideal wilkinson PD} - \text{C yields}$$

Wilkinson PD-C is widely used for power splitting or combining due to its input/output matching and high isolation characteristics. However, it often requires multiple $\lambda/4$ transmission lines as shown in fig 3, leading to a large circuit area especially at the GHz RF frequency. Recently, several papers have reported Wilkinson PD-C designs with size reduction, by using slow-wave structures [7], lumped/quasi-lumped elements [8], and general π-network structures [9]. However, these circuits still require a large area at the GHz frequency and cannot be easily extended for general N-way Wilkinson power splitting or combining.

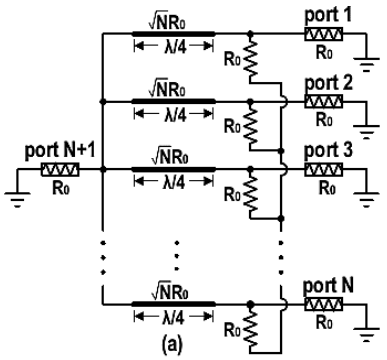

Fig. 3: N-way Wilkinson power divider-combiner (PD-C)

However, S parameter of two way PD-C has been extracted from Momentum cell simulation and converted into ABCD matrices. RLGC parameters has been extracted from these equations to set 100 Ω TX line for 4-Way power divider & combiner. As well as 50Ω, 71Ω resistances TX line value can be evaluated from HFSS model. For two-way PD-C at $Z_0 = 71\Omega$ in the output section. And theoretically the output port signal phases $\angle S_{21} = \angle S_{31}$ and $\text{dB}(S_{21}) = \text{dB}(S_{31})$ are come to represent. And for four-way power divider and combiner $Z_0 = 100\Omega$ is to be settled at the output section. But the signal line width of 100 Ω TX line is so narrow to design whether the capacitance decreases literally and change the performance of propagation constant. Besides it increase the layout area larger with insertion loss (fig. 4).

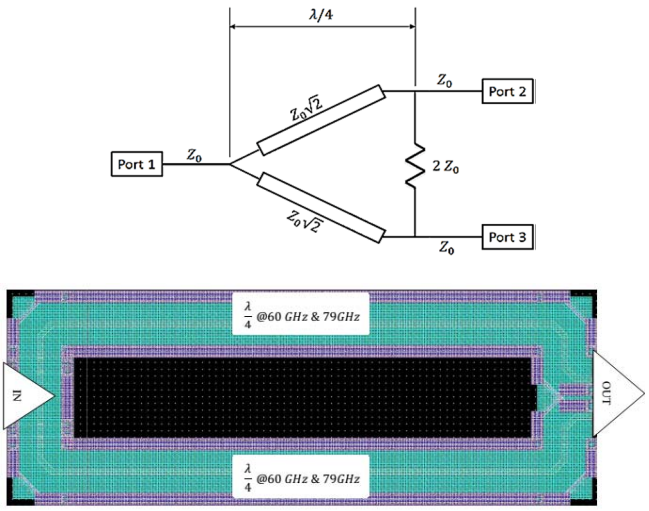

Fig. 4: Schematic & Layout of two-way Wilkinson PD-C

III. PROPOSED MILLIMETER-WAVE TRANSFORMER COUPLED BALUN AND POWER DIVIDER-COMBINER

A. *Ideal Transformer Coupled Balun*

In classical transformers, there are two electrically separate windings of wire coils around the transformer's core and it's behave as a voltage Balun. The primary winding receives the input signal, and the secondary winding puts out

the converted signal. The core that they are wound on air core or a magnetically neutral material like a porcelain support, also it contains a material which is good magnetic conductor like ferrite in modern high-frequency (HF) balun. The electrical signal in the primary coil is converted into a magnetic field in the transformer's core. When the electrical current through the primary reverses, it causes the established magnetic field to collapse. The collapsing magnetic field then induces an electric field in the secondary winding. Transformer coupled Balun behaves as 3 ports (fig.5), the input signal divided into two phases such as in phases (0^0) and in opposite phase (180^0) differential ports signal and then it applies through a differential circuit. The secondary coil has been taken center trapped for gate signaling. And the layout area is so smaller than others balun structural design.

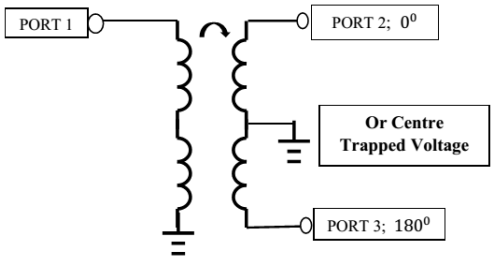

Fig. 5: Ideal Transformer Coupled Balun

B. *Practical Transformer Coupled (Flipped HFSS) Balun*

In transformer coupled practical cell, both flipped or planar topology has been used for 180^0 phase difference and same amplitude signal distribution. Here, flipped transformer coupled balun has been designed with top two metal.

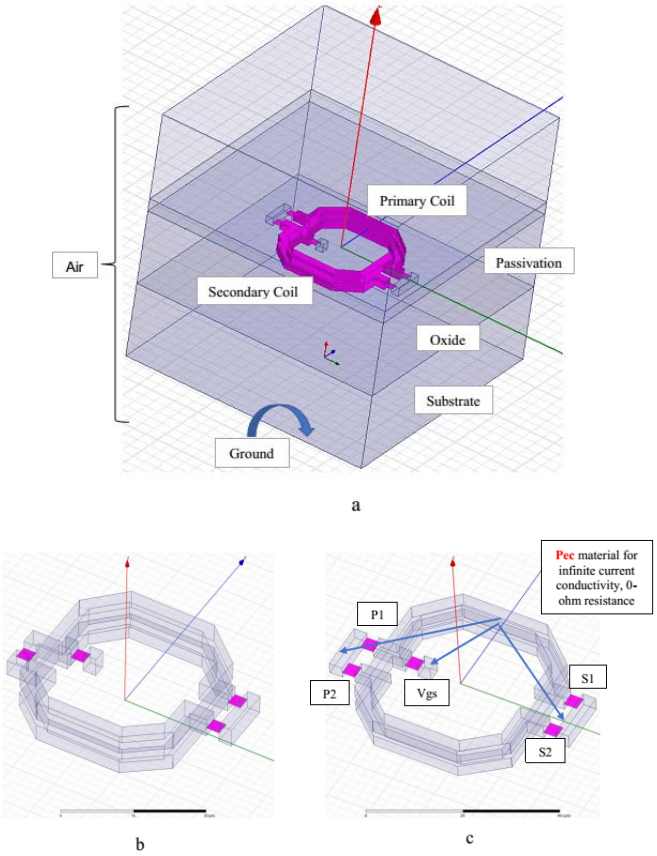

Fig. 6: (a) mm-Wave transformer (b) 4-Port Transformer Balun (c) 5-Port Transformer Balun

Primary coil has been set as Al Metal (2.8 um, TNA) and Secondary coil has been set as Cu metal (3.3 um, LDA). Figure (6a) behaves as mm-wave transformer balun with ground, substrate, oxide, passivation and in air medium. It has two coils: Primary & Secondary with 5-ports (4-port containing source and 1 port is for gate signal). Figure (6c) represents the 5-port transformer coupled balun and fig (6b) represents 4-port transformer coupled balun having short connected primary port.

C. *Practical Transformer Coupled (Flipped Cadence) Balun*

Here, flipped transformer coupled Balun (fig. 7) has been designed with top two metal. Primary coil has been set as Metal 11 (Cu, LDA) and Secondary coil has been set as Metal 12 (Al, TNA). XPWA layer has been used for improving quality factor. From TX Line in fig.2, Ground floor contain metal 3 to metal 5 (LAC, LAD, LAE) with via 4 & 5 (NAD, NAE) on 55nm CMOS. And ground wall contain metal 6 to metal 11 (LAF, LBA, LBB, LBC, LCA, LDA) with via 6 to via12 (NAF, NBA, NBB, NBC, NCA, NDA, TWA). From transformer coupled balun, it's five port S parameters having port 1 (P_1), port 2 (P_2), port 3 (S_1), port 4 (S_2) and port 5 (V_{gate}). For checking balun properties, port 2 (P_2) and port 5 (V_{gate}) have been grounded. And it gives in phase 0^0 and out of phase 180^0 signal at the secondary output section. In figure 13 & 14 below transformer balun property is shown. At 60GHz and 79GHz the phase angle variation is $\angle S21 - \angle S31 = 180^0$, V to W band: $50 - 110\text{GHz} = 180^0$. Here in table (8), transformer coupled balun properties have been compared with another topology.

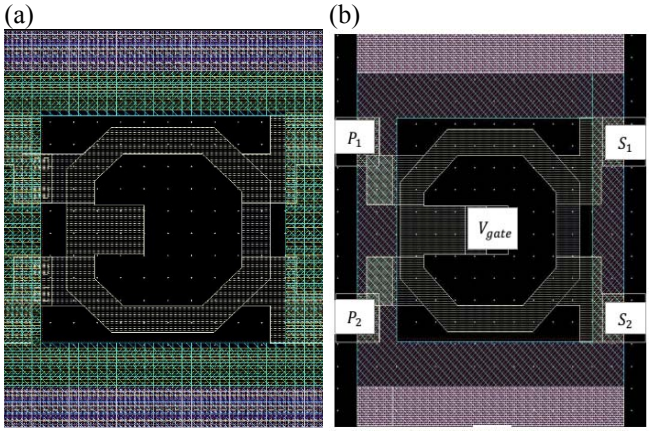

Fig. 7: Layout & Momentum Cell of Flipped Transformer Coupled Balun

D. *Ideal Transformer Coupled Power Divider-Combiner*

Transformer coupled PD-C (fig.8) is same as wilkinson type devices. It represents transformer-based coupling 2, 4, 8…n way dividing and combining with symmetric length and width of primary & secondary coil. Based on different parallel combining of transistor, the length of signaling can be distributed equally. From transformer coupled PD-C, equal power and in same phase signal will transmit through output terminals at OUT1+ & OUT2+.

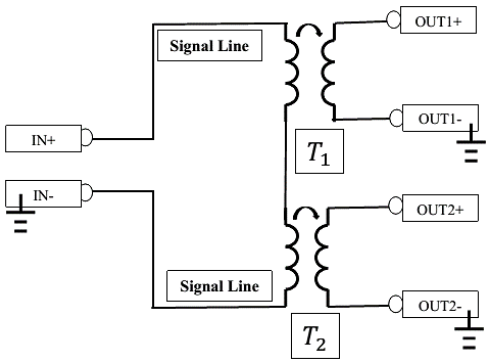

Fig. 8: Ideal Transformer coupled power divider and combiner

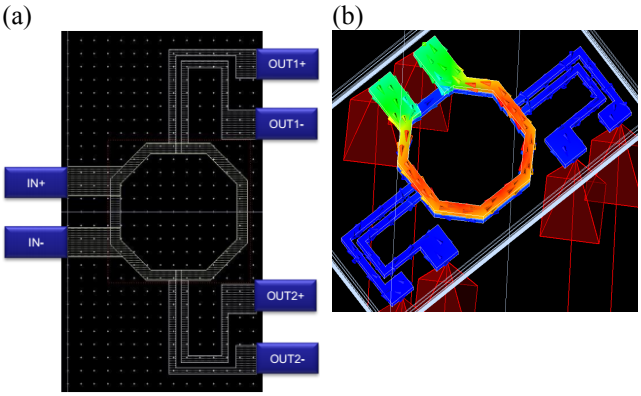
E. *Practical Two-Way Transformer Coupled Power Divider-Combiner*

In transformer coupled two-way PD-C with current flow animation (fig. 9), the primary input and secondary output have two-way current distribution section (Out1 & Out2). Primary section top metal (Al, TNA), thickness: 2.8um and Secondary Section metal 11(Cu, LDA), thickness: 3.3um. The layout area of transformer Coupled PD-C ($72\text{um} \times 123\text{um} = 0.0088\ \text{mm}^2$) which is 7.5times smaller than Wilkinson PD-C ($157\text{um} \times 435\text{um} = 0.0683\text{mm}^2$).



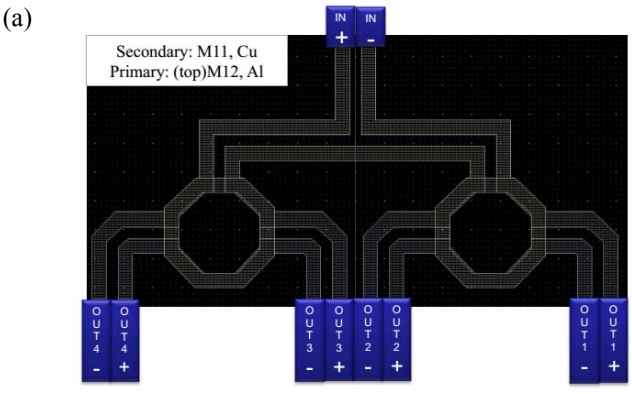


Fig. 9: Two-way transformer coupled power divider-combiner, Layout (a) Current Flow Animation (b)

F. *Practical Four-way Transformer Coupled Power Divider-Combiner*

Four-way transformer coupled PD-C with current flow animation (fig. 10), the primary input and secondary output have four-way current distribution section (Out1, Out2, Out3 & Out4). Primary section metal (Al, TNA), thickness: 2.8um. Secondary section metal (Cu, LDA), thickness: 3.3um.

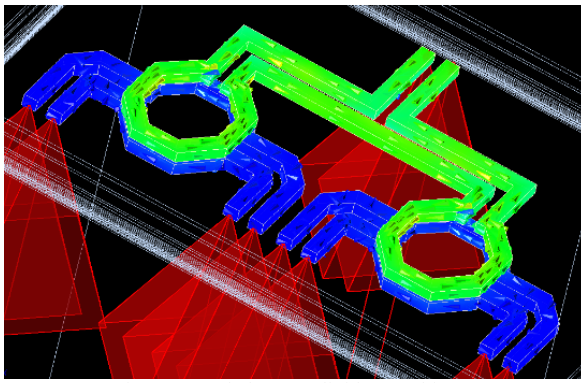

Fig. 10. Four-way transformer coupled power divider-combiner, Layout (a) Current Flow Animation (b)

The layout area of transformer four-way Coupled Power Divider-combiner ($72\text{um} \times 169\text{um} = 0.0122\ \text{mm}^2$) which is 5.5times smaller than Wilkinson PD-C ($157\text{um} \times 435\text{um} = 0.0683\text{mm}^2$). Depend on the signal line position of Balun at the end port, this transformer coupled PD-C output section can be set at longer different symmetric length. Two Way & Four Way PD-C are almost same amplitude & phase angle between $50\text{GHz} - 120\ \text{GHz}$. Finally, it can be said that these transformers coupled PD-C are basically designed for two major purpose, (1) layout area minimizing & (2) signal line matching without using matching network between this bands. S parameter characteristics of four-way transformer coupled PD-C has been shown below here. Here, four-way transformer coupled PD-C (fig. 10) works between 1-150GHz and at 79GHz, phase variation is $\angle S21 \sim \angle S31 \sim \angle S41 \sim \angle S51 = 2.8^0$ and amplitude variation is $\text{dB(S21)} = \text{dB(S31)} = \text{dB(S21)} = \text{dB(S31)} \sim 2\text{dB}$.
Transformer type PD-C is considerably good from wilkinson in case of keeping lower amplitude and phase imbalance and layout area is so small. It sustains larger BW of 0^0 phase differences.

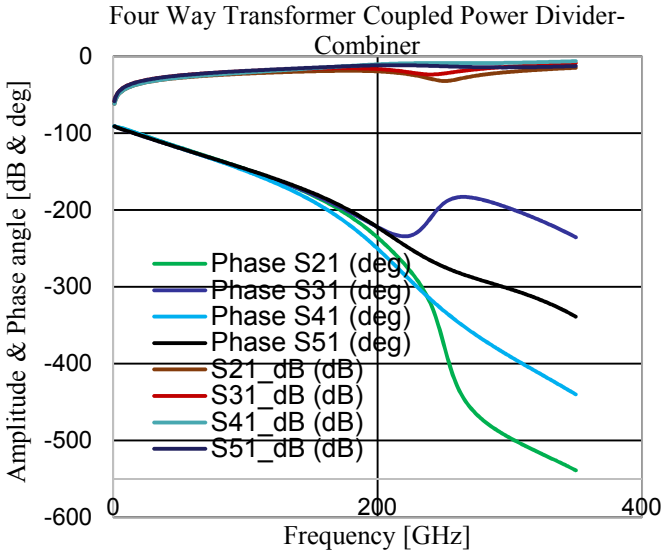

Fig. 11. Four-way transformer coupled power divider-combiner, Amplitude & Phase Differences (a) Return loss (b)

IV. RESULT AND DISCUSSION

From fig.12 & 13, HFSS simulation result, the S parameter property of transformer balun $\angle S21 - \angle S31 = 180^0$ and amplitude are kept same $[\text{dB(S21)} = \text{dB}(\angle S31)]$ between

30GHz to 250GHz. And it has amplitude imbalance (AI): ~1 dB between 30-250 GHz and phase imbalance (PI) < 2^0. Similarly, from cadence simulation it contains 180^0 phase difference and BW limit to 1-120 GHz, amplitude imbalance (AI): ~2 dB between 1-120 GHz and phase imbalance (PI) < 3^0.For transformer coupled balun, HFSS data comparatively give better performance than momentum (cadence platform) design. From fig. 14, the amplitude differences have been compared with transformer, ratrace (lower AI BW zone: 77-89 GHz, lower PI BW: 60-90GHz, return loss<-20 dB) and marchand (lower AI & PI BW: 72-80 GHz, return loss<-15 dB) balun. Here, ratrace balun gives low insertion loss through all BW than other types of balun while layout area is so large. On the other hand, marchand and transformer balun take less chip area but comparatively transformer coupled balun occupies more less area. It provides a bit more insertion loss at low frequency (1-50GHz) however it takes less area than marchand.

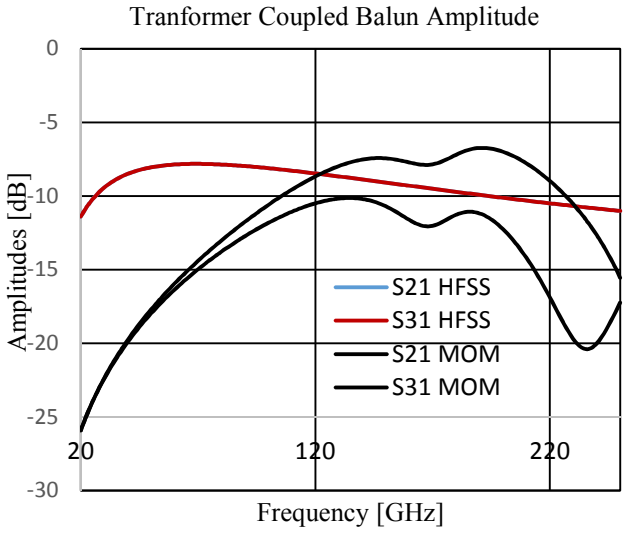

Fig. 12. Amplitude variation of HFSS and Momentum results

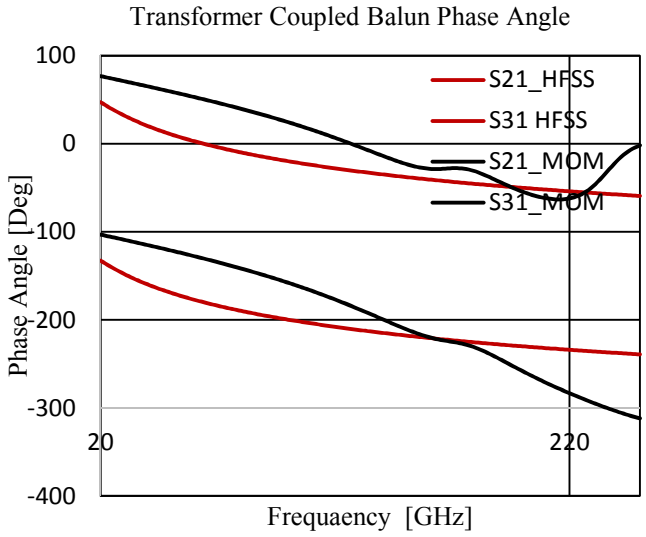

Fig. 13. Phase variation of HFSS and Momentum results

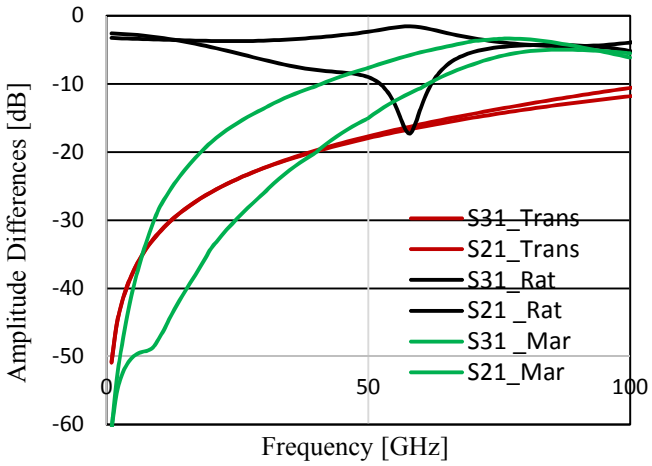

Fig. 14. Amplitude difference of different kind of baluns

In fig. 15, transformer balun provide better performance in phase difference within a large BW than other type of baluns. Transformer coupled balun amplitude imbalance ~2dB and Phase differences perfectly in 180^0 with larger bandwidth (50-120 GHz) occupying area 0.0061 mm^2 which is 23 times smaller than ratrace & 3 times smaller than marchand balun. In table 1, several balun properties have been illustrated and compared.

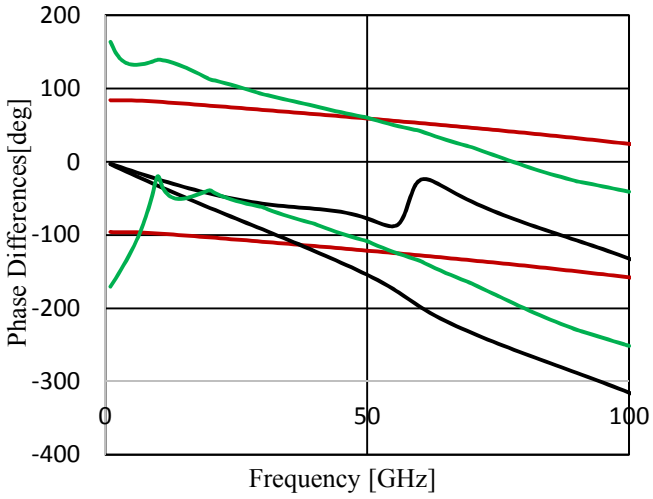

Fig. 15. Phase difference of different kind of baluns

TABLE I. Balun Properties Comparison [10]

Ref.	Topology	Tech.	Freq. (GHz)	AI (dB)	PI (Deg)	IL (dB)	Surface (mm^2)
Lee, 04	Marchand	GaAs	26-55	<1	$<5^0$	<2	0.51
Din, 08	Marchand	0.18um Bi-CMOS	45-75	<0.5	$<6^0$	<2.5	0.09
Din, 05	Ratrace	0.13um Bi-CMOS	57-71	<0.6	$<10^0$	<3.2	0.28
Ham, 05	Line-based	InGaP/GaAs	15-45	<1	$<5.5^0$	<7	0.04
Fel, 07	Transformer	0.13um CMOS	55-65	<3	$<10^0$	3	0.05
Leite, 12	Transformer	0.13um Bi-CMOS	60-120	<1	$<3^0$	<3	0.03
This Work	**Transformer**	**55nm CMOS**	**57-120 30-250**	**~2 ~1**	**$<3^0$ $<2^0$**	**7~11 5~7**	**0.0061**

From fig. 16, the amplitude differences have been compared with transformer and wilkinson PD-C and in comparison with phase differences wilkinson gives better performance than other types but the layout area is so large (fig.17). On the other hand, transformer PD-C take less area but transformer coupled two–way PD-C occupies less area 0.0088mm^2 which is 7.5 times smaller than Wilkinson PD-C and amplitude variation is $\text{dB(S21)}\sim\text{dB(S31)} = 1.87\text{dB}$. Transformer coupled PD-C provides a little bit more insertion loss at low frequency (1-60GHz) although it takes more less area. From fig. 17, two-way transformer coupled power divider-combiner provides 0^0 between 50-120GHz, phase variation is $\angle\text{S21}\sim\angle\text{S31} = 3^0$.

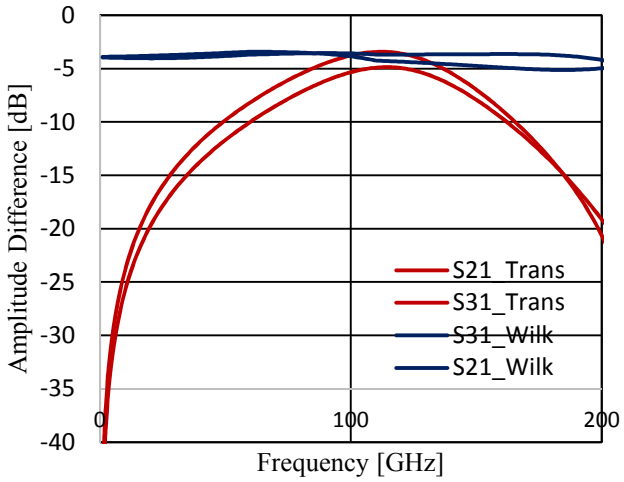

Fig. 16. Amplitude difference of different kind of power divider-combiner

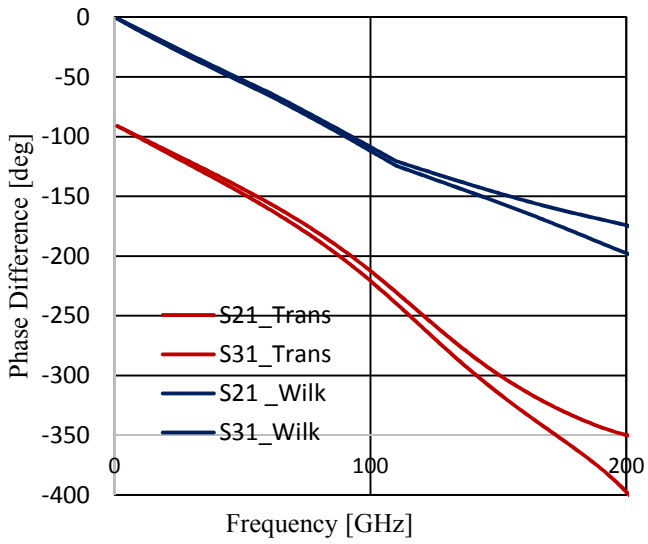

Fig. 17. Phase difference of different kind of power divider-combiner

V. CONCLUSION

Transformer coupled passive elements such as balun and power divider-combiner are comparably good choice for mm-wave circuit design. It contains smaller chip area and easy to integrate with active parts. Considering the total chip layout area shrinking, Transformer coupled devices provide a good performances than others. A small stacked transformers having center trapped balun, power divider-combiner have been designed with 55nm DDC CMOS process. The originality of these paper is maintaining an mm-wave smaller layout design with optimal phase and amplitude imbalance avoiding some pitfalls in low frequency regime.

ACKNOLEDGEMENT

The author would like to thank the member of Frontier Integrated System Laboratory, AdSM, Hiroshima University, along with MIE Fujitsu Semiconductor Inc. Japan, for cadence 55nm DDC CMOS IC design platform and their design rules.

***Abstract*—This paper proposes a simplified structure of microcontroller based mechanical ventilator integrated with a Bag-Valve-Musk (BVM) ventilation mechanism. Here, an Ambu bag is operated with computer-aided manufacturing (CAM) arm that is commanded via a microcontroller and manual switches by sending a control signal to the mechanical system and according to this control signal, the mechanical computer-aided manufacturing (CAM) arm simultaneously compresses and decompresses the Ambu bag. It is a self-inflating bag and like a one-way valve around its inlet and outlet corner. By compressing the Ambu bag it delivers air and by relaxing, it takes air from the environment through a mechanical scavenger. The control signals are designed with three modes named adult mode, pediatric mode, and child mode based on the respiratory rate. The device is in assist controlled mode by dint of fixing the tidal volume for all unique control signals. The control signal is visualized by a platform known as BIOPAC student's lab system. The proposed device is portable, compact, low weight, and efficient performable. It can be supplied around the rural area hospitals for immediate medication with cost efficiency and risk avoidance. Anyone can operate it as no need to study or training of ventilation rules like ICU ventilator. The proposed system is safe, riskless, and repairable. The angle, volume, and respiratory measurement have found 95%, 92%, and 90% accuracy respectively. By applying this portable ventilator system immediate attention can be taken up in rural or general hospitals and in ambulances.**

I. INTRODUCTION

In this era of modern science, the uses of microcontrollers are increasing day by day. Integrating with it the automation systems are improving. A manual resuscitator generally known as Bag-valve-musk (BVM) ventilator is used in the mechanical ventilating system. Manual compression, as well as relaxation of an Ambu bag, is inaccurate and painful for the operator with an unknown volume of air. Reducing this specific problem an automation system is necessary for well delivery of air for the person who is unable of taking a breath. Ambu stands for Artificial Manual Breathing Unit. It was invented in 1956 by German engineer doctor Holger Hesse and his partners. In 1559 an Italian professor of anatomy named Matteo Realdo Colombo recounted a method called tracheotomy's method [1].

For attainment a better output, an approximate mechanism is maintained for controlling Ambu bag. In this paper, a specific mechanism is used to get the required output from the system. A normal adult (18 years aged or more) person generally takes 12-20 breath within a minute where a child (1- 12 month aged) has 30-60.

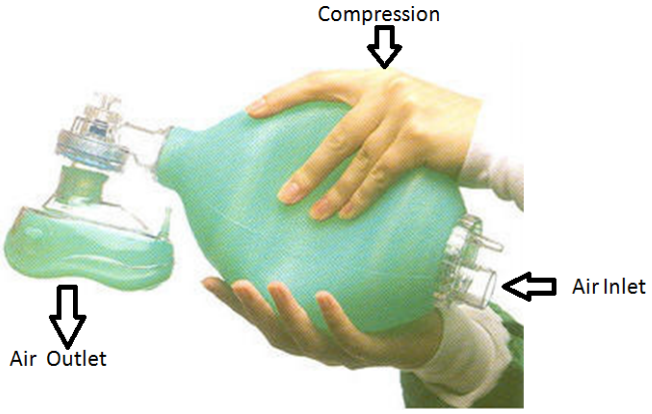

Fig. 1. Manual operation of the Ambu bag system.

It is clear that the respiratory rate of a child is faster than an adult. Out of them, pediatric (6-11 years aged) persons have the respiratory rate (RR) of 18-25 per minute. Authors in [2] describe the detection and monitor of a metabolite of pneumonia at the early stage. A silicon Ambu bag is chosen for its auto relaxation property. This property takes zero energy for relaxation and thus automation system makes flexible. At an emergency condition in ambulance sometimes need 90 percent or more oxygen for the patient recovery. So portability and low power consumption is a great fact for patient care.

With the rapid growth of medical technology, the configuration architecture of the ventilators is becoming complex day by day due to the integration of mechanical, electrical, electronic, and computational technologies [3]. Authors in [4] describe a roller-chain method where this chain compression makes a force on an Ambu bag. This method is acceptable to some drawbacks. There is some possibility of breaking chain thus be dangerous in an emergency condition and need huge torque to compress it. In paper [4], another mechanism named Cam-arm mechanism (CAM) is shown. The cam-arm mechanism is better than the roller chain mechanism on account of its noise reduction property. Our prototype is designed on the basis of two handmade CAM-arm functions that use optimal torque with noise reduction, low power consumption, portability augmentation, and better output. Lung-protective ventilation is treated as a simple supportive therapy and also as a prophylactic therapy to attenuate patient self-inflicted lung injury [5].

The paper is organized as follows: Section II describes the materials and methodology. This section describes the framework of the proposed method; the existing system, proposed system, CAM arm mechanism, BVM mechanism, corresponding mathematical formulation, and circuit diagram. Section III gives hardware implementation and its relative advantages and disadvantages. Section IV gives the results and discussion of the proposed system. Finally, section V concludes our paper with some future directions.

II. Materials and Methodology

A. Flowchart of the Proposed Research

The basic framework of the proposed research work is shown in Fig. 2.

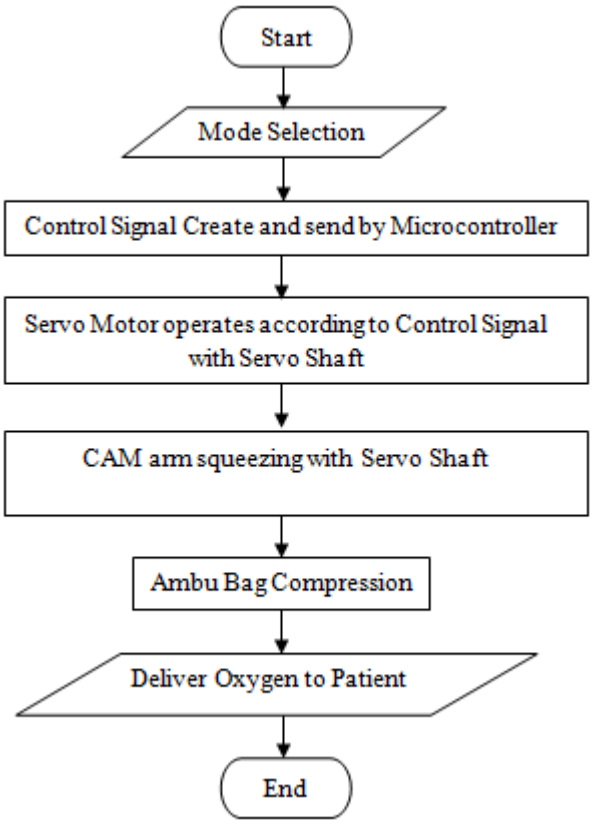

Fig. 2. Basic flowchart of the proposed work. The flowchart represents three modes at a time (Adult mode, pediatric mode, and child mode).

B. Existing System

There are several existing systems of operating an Ambu bag. Such as Ruler chain mechanism, CAM mechanism, Rack and pinion mechanism, Lead screw Mechanism. They have some advantages and disadvantages. Another existing ventilator system is integrated with the vocal alarming system to reduce noise that generates from ventilators in the hospital [6]. Ruler chain mechanism is preferred in previous for its availability and high torque gain with DC motor. When it operates, noise generates that can cause sound pollution in the care environment. Tele-controlling mechanism exists and integrated with the system [7, 8]. After that, another mechanism preferred called CAM mechanism eradicates the noise or additional sound. Actually, this mechanism does not generate any noise like ruler chain mechanism. Rack and Pinion mechanism makes the platform of gear for more precise controlling. Lead screw mechanism uses a threaded screw to operate a mechanical arm with a nut that compresses and relax the Ambu bag simultaneously. Authors in [9] show the hyperbaric oxygen therapy using mechanical ventilator where the pressure is proportional to volume.

C. Proposed System

Our proposed system is based on CAM principle having some additional feature of controlling precisely with portability, battery operated, reduced size and noise removal. Several modes selected for control operation such as child mode, pediatric mode, and adult mode. These modes are selected according to the lung capacity and breath-rate of the subject as well as inspiration and expiration (I:E) ratio. All of these parameters are generally depend on the age of the subject. The automation requires a microcontroller, some mechanical switches, and two servos. Servos are positioned face to face oppositely with the 180-degree angle. The shafts of the motor are attached with a mechanical pulley that rotates according to motor direction. A nonflexible cot wire connects one arm and one pulley and same to the second one. When the motor rotates, the torque creates tension in the cot wire through the pulley that results in pulling a mechanical arm to compress an Ambu bag.

D. Computer-Aided Manufacturing Arm Mechanism

A CAM (Computer-Aided Manufacturing) arm is a rotating or sliding piece in a mechanical linkage that is used especially to convert rotary motion into linear motion which is shown in Fig. 3. The main reason for selecting a cam arm is the servo system as it has a high torque of approximately 15 kg-centimeters. The arm is nonflexible, hard and weight bearable. The cam function is graphically shown in Fig. 4.

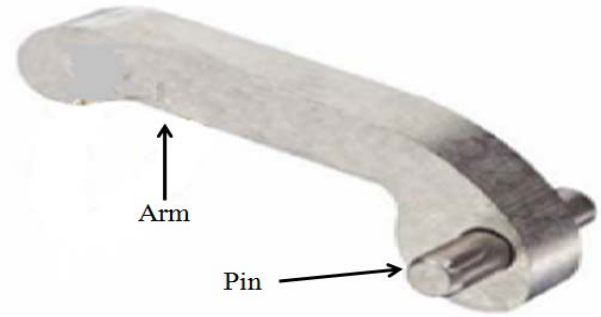

Fig. 3. Basic CAM arm with its pin attachment.

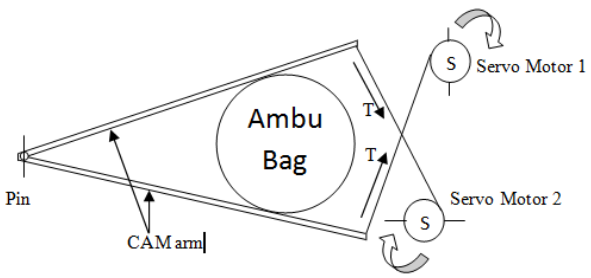

Fig. 4. CAM function with the proposed system (T means tension).

E. Bag-Valve-Mask (BVM) Mechanism

The Bag-valve-mask was also known as manual resuscitator is a mechanical system that intelligently delivers air to a single direction when it is compressed and takes air from the environment when relaxation takes place [1]. In a proper way, BVM ensures air and oxygen from the environment to the patient. There are three inlets in the Ambu bag used in this project. One is for the environmental air inlet. The second one is for the connection pathway of oxygen reservoir and the third one is for the loss minimization. Out of that, there is a single pathway for emergency air circulation. There is a single outlet of the Ambu bag that is used to connect the patient for air inhalation. There is a one-way valve in the outlet of a BVM Ambu bag. Out of that, there is also a single air pathway at the outlet side of it for emergency exhalation. Some emergency patients need a high volume of oxygen approximately tends to hundred percent oxygen otherwise dangerous hypoxia occurs where hypoxia is the oxygen deficiency in the abiotic environment.

F. Mathematical Formulation

Child mode (1-12) month aged child has a tidal volume of (4-6) milliliter per kilogram. Pediatric mode (6-11) years an aged person has a tidal volume of (5-8) milliliter per kilogram. Adult mode (18 or more) years an aged person has a tidal volume of 7 milliliters per kilogram. So, for example generally, the tidal volume of 23 years and 61 kilogram weight adult person is equal to (7 ml/kilogram×61 kilogram) or 427 ml. In this way, we can calculate the general tidal volume of all aged person.

The diameter of the pulley is 4.3 centimeter, so the circumference of the pulley is 27 cm approximately. As we have two servos operating on 180 degrees or two right angles at a time, so the cot wire can oscillates within (27/2)×2 = 13.5×2=27 centimeters. Arm length is 40.50 centimeter. Relax angle or initial angle is 37.94 degrees or 5.1/7.7 radian and compress angle or final angle is 18.2 degrees or 2.45/7.1 radian for an adult. Now we want to find out the angle between two CAM arms because the output volume depends on the angle between two arms.

We know that the arc length of a circle is $S = r\theta$, where the angle θ is in radian and r is the radius. We have three circles, two pulleys which act like a circle and another imaginary large circle is considered where CAM arm is the radius of that large circle. As we have two pulleys, we take $S_p = S_{p1} + S_{p2}$ *where* S_{p1} is the arc from the first servo motor and S_{p2} from the second servo motor. For 180 degree or π radian rotation of pulley the imaginary circle covers a small arc Sa. So it can be said that S_a is equal to S_p, then $r_a\theta_a = r_p\theta_p$. Finally, we get Eq. (1).

$$\theta_a = \frac{r_p \theta_p}{r_a} \tag{1}$$

We know that as large as the radius of the pulley, it covers large arc S_a of the largest circle shown in Fig. 5 (left). Therefore, $r_p \propto \theta_a$ and we get Eq. (2).

$$r_p = k_1 \theta_a \tag{2}$$

Where k_1 is the proportional constant that depends on r_p and θ_a. Another proportional constant k_2 is found where θ_a is proportional to the output volume (V) of the Ambu bag results for compression on it by the mechanical CAM arm as written in Eq. (3).

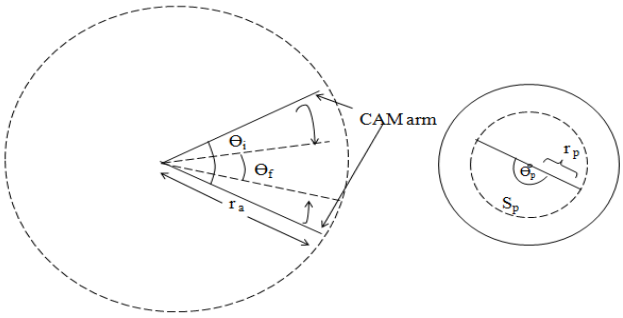

Fig. 5. (Left) Large imaginary circle to measure of $\theta_a = \theta_i - \theta_f$ and (Right) Pulley structure to calculate different angles.

$$\text{So, we can write } \theta_a \alpha V \quad \text{or } \theta_a = k_2 V \tag{3}$$

From Eq. (2) & Eq. (3), the relationship between pulley radius and oxygen output volume is obtained that is shown in Eq. (4).

$$r_p = k_1 k_2 V = kV \tag{4}$$

Since k is constant, therefore, the radius of the pulley is proportional to the volume output of the Ambu bag.

In the above analysis, θ_a is the difference between an initial angle and final angle, θ_i is the initial angle, θ_f is the final angle, V is the volume output that means the tidal volume, r_a is the radius of the large circle shown in Fig. 4(left) that means the length of the CAM arm, r_p is the radius of both pulleys. Here, S_a is the arc covered by the large imaginary circle described before.

G. Proposed Circuit Diagram

The circuit diagram consists of resistors, microcontroller, servo motors, switches, and power supplies. The input and output pins are set to the digital pin of the microcontroller. A 12-volt power supply is added to get high torque from the servo motor. The electronic circuit diagram of the proposed system is shown in Fig. 6.

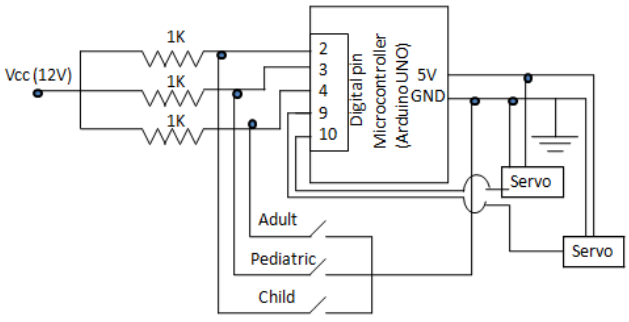

Fig. 6. Electronic circuit diagram of the proposed system

III. System Architecture and Hardware

A. System Architecture

This architecture shows the combination of all hardware part of the system that is stable with a hardware frame. Oxygen cylinder is used with a control opening. An oxygen tube is connected with an oxygen cylinder and Ambu system. Our environment contains about 23 percent oxygen. So we can take it through another inlet to reduce loss. The system architecture is shown in Fig. 7.

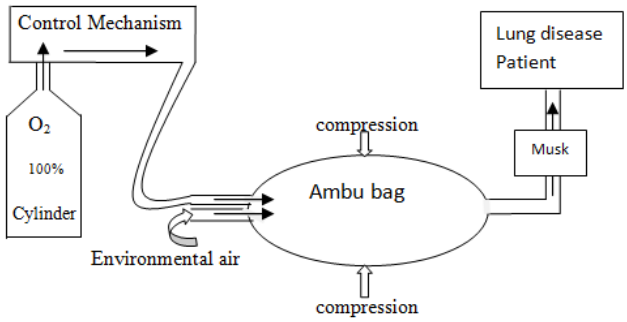

Fig. 7. The architecture of the proposed system making a way of oxygen delivery.

B. Hardware Implementation

The actual hardware implementation of this project is shown in Fig. 8. The hardware implementation is one of the most important as it is a challenge to reduce mechanical error. The hardware design consists of the following: microcontroller, wood frame, CAM arm made by PVC, servo motor, switches, pulleys, DC 12 volt battery, Ambu bag, jumper wires, etc. The top, front and right side view of the hardware implementations are given below in the figures respectively.

Fig. 8. Experimental setup with BSL SS11LA airflow transducer (right) and with a peak flow meter (left) of the proposed system.

C. Facilities and Advantages

There are some attractive facilities of the Ambu bag with this proposed system. Clinicians offer patients to use age wise different Ambu bag. Such as adult Ambu bag, the silicon Ambu bag is the self-inflating system. Here we need only to compress it. After compression when decompress it inflates itself. This is the most attractive feature of silicon Ambu bag. Ambu bag can be sterilized easily although it is non-autoclave-able. There are two emergency airways at the inlet and outlet side. Another attractive feature of Ambu bag with this proposed system is that instead of using three Ambu bag (such as for Adult, Pediatric and Child Ambu bag) one Ambu bag is used to perform different modes by controlling it with a microcontroller. The adult BVM system is about 1650 ml that is enough to deliver the minimal tidal volume to all aged patient using the control mechanisms. In the future, some more additional advantage can be integrated with this proposed system to improve it.

D. Drawbacks, Hazards, and Solutions

Misassemble of Ambu bag sometimes occurs for the cause of using an Ambu bag for so many days as the manufacturing material have fracture properties. To avoid this problem Ambu bag can be replaced. The second one is the Bacteria and Germ attack from the environment while filtering is not used. The third reason is the ventilation difficulty of the BVM system because of not replacing after long-term use. The fourth one is improper BVM selection. All of this problem can be solved by using proper hardware implementation and technique development. After all the entire germ attack is the main problem of an Ambu bag. Germ attack can be reduced by using a filter at the inlet of the bag and the filter may be changed every day after use per patient. However, in a developing country like Bangladesh has no in-house clinical engineer in any of the ICU which represents the inferior type of clinical engineering interaction with life support ventilator [3, 10].

IV. Results and Discussions

We have measured three of our output data with respect to the input. They are data of angle, data of tidal volume (TV) and data of respiratory rate (RR). The command angle is generally measured from the large circle that is shown in Fig. 4 (left) without any Ambu bag and the output angle is measured with the Ambu bag. This is why the Ambu bag is like a load in the system of the device. So we found the efficiency of the whole system while we got a different angle at with load and without load for the same input. The angle errors are shown in Table I. this angle error results for the insufficient torque of the servo motor.

In Table II, we have discussed the tidal volume output. All the separate command angles that described in Table I, we measured the command volume in the same way. Then after Ambu bag insertion, we found some variation in the output tidal volume. As our servo was DC servo with 180-degree angle highest rotation, this is the highest output for our hardware device, rather than we can get a more accurate result by changing the hardware structure. In Table III respiratory rates are discussed. We chose some respiratory rate according to the age of a patient named command respiratory rate or command RR and beside them, the observed respiratory rate is displayed. The negative percentage refers to the high observation than input command. The tidal volume graph of an adult, pediatric and child mode respectively collected from Biopac Student Lab system as a portion of spirogram is described by Fig. 9, Fig. 10 and Fig. 11 [11]. An adult person has a low frequency of RR than a pediatric boy or a child. On the other hand, adults have a high amplitude of air volume that is clearly notified from the output graph. The average peak to peak value describes the tidal volume that is found 395, 243 and 71 for adult, pediatric and child mode respectively. For some experimental result, we have used some standards displayed in the command. We can alter the command standards and add several modes more to find out more accurate results that would reduce errors. These are our final outputs.

TABLE I. MEASUREMENT OF INITIAL ANGLE AND FINAL ANGLE FOR DIFFERENT MODES

Mode	Command angle (degree)	Initial angle (degree)	Final angle (degree)	Output (difference of angle)	Error
Adult	19	37.9	19.7	18.2	4.71 %
Pediatric	16	37.9	23.1	14.8	6.91 %
Child	10.5	37.9	27.8	10.1	5.66 %

TABLE II. MEASUREMENT OF OUTPUT VOLUME AND ERORR CALCULATION FOR DIFFERENT MODES

Mode	Command volume (ml)	Output volume (ml)	Volume error
Adult	430	395	8.13 %
Pediatric	260	243	6.53 %
Child	65	71	-8.85 %

TABLE III. MEASUREMENT OF RESPIRATORY RATE CALCULATION FOR DIFFERENT MODES

Mode	Command RR (breath/minute)	Output RR (breath/ minute)	RR error
Adult	20	21	- 5 %
Pediatric	30	34	- 13.33 %
Child	60	67	- 11.67 %

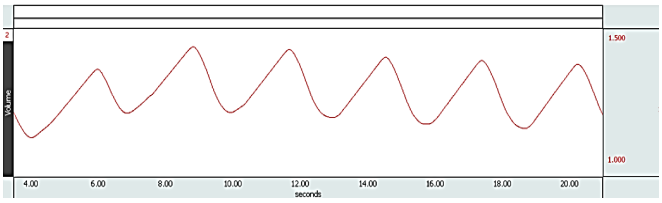

Fig. 9. Spirogram of tidal volume for an Adult male collected from BSL integration with our device. (Tidal volume is 395 ml approximately found)

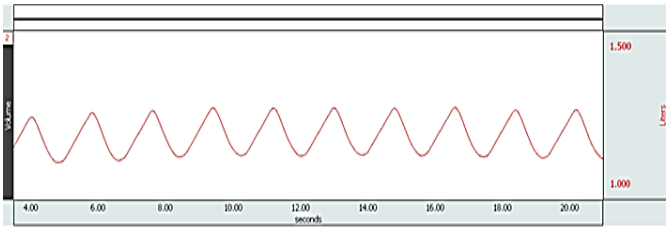

Fig. 10. Spirogram of tidal volume for a pediatric boy collected from BSL integration with our device. (Tidal volume is 243 ml approximately found)

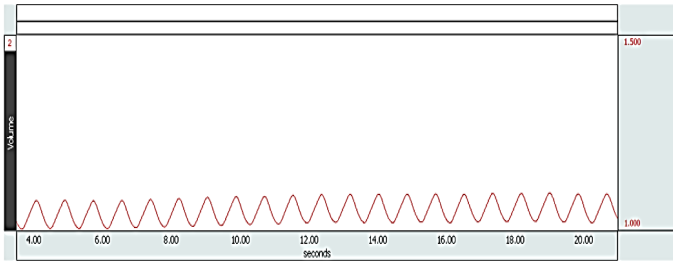

Fig. 11. Spirogram of tidal volume for a child collected from BSL integration with our device. (Tidal volume is 71 ml approximately found)

The command values of angles in Table I are found by the calculation in the programming section of the microcontroller and the output value of angles are the measured value. Based on these angles and structure of Ambu bag, the command volume and respiratory rate are identified and output of them are the measured parameters that are collected from Biopac BSL software [11]. Between the calculated and measured value, the efficiency or error is found out easily while the measured values are the outputs.

V. CONCLUSIONS

Our goal is to implement such a ventilator system that is stable, portable, high efficient, low powered or battery operated, easy to use, riskless, repairable and reusable. Although we could not fulfill all facilities we want, we efficiently show the output at so near to the exact output values. In the future, we can develop another technology to find out the tidal volume and respiratory rate automatically using sensors that will be implemented with the ventilator system and according to the physiological parameters, the control signal that means tidal volume can be generated. After all mechanical ventilator is a growing technology in this world now for the automation basics like telemedicine applications. Smart ventilators may be a large field for both in clinical cure or research field in the near future.

***Abstract*— In this paper we proposed a novel drop filter structure based on Photonic Band Gap (PBG) for the 1550nm communication wavelength. The filter is designed and then simulated using Finite Element Method (FEM) and Plane Wave Expansion Method (PWEM) method. The filter shows 91% efficiency at the mentioned wavelength. We also analyzed how the target wavelength can be varied by changing various aspects of the structure. The design utilizes all homogeneous method which is easier to fabricate and introduce in photonic integrated circuit.**

Keywords—Photonic Integrated Circuit, drop filter, photonic band gap (PBG), photonic crystal

I. INTRODUCTION

Photonic crystal (PC) structure gained tremendous popularity in the last decade. Though the one dimensional photonic crystal (1DPC) was proposed in 1887, after the introduction of 2D (2DPC) and 3D Photonic(3DPC) crystal in 1987 the potential of PC structure were fully realized [1 ,2]. Due to the lack of computational power in the early stage not many structure was analyzed. As the computational power increased analysis of different structure is easier than ever before.

Electromagnetic wave can be controlled by manipulating periodic dielectric structure. Most commonly used design to guide EM wave is metallic pipe waveguide and dielectric guide [3]. They are used mostly in the infrared, visible or microwave range. Waveguide which are based on total internal reflection are restricted by heavy losses in the bends. But by creating defect or engineered structure in a Photonic band gap (PBG) material, EM wave can be confined as such it does not show high radiation losses in the bend. A linear defect in a PBG material can be used as a waveguide. This type of waveguide work as the defect results in a guided band in-between TM band gap. So, the conventional optical fiber use index guiding whereas the PBG structure use band gap confinement to confine light. Band gap confinement works better as this minimizes losses, nonlinearities, and any other unwanted properties of the material [4].

In all optical computing, photonic integrated circuit or an optical communication system PCs can be used extensively due to their longer life period, better confinement, high speed and small size [5-10]. In a dense wavelength division multiplexing system (DWDM) due to the high spectral selectivity, low loss and high quality factor of PC structure, the conventional strip based micro-ring resonator can be replaced by PCs [11-14].

PBG structure can be classified broadly as homogeneous and heterogeneous structure. In a heterogeneous structure, different sections use different reflective index or the reflective index of the material can be actively changed (in case of electro-optic/ magneto-optic/ acousto-optic materials) [15,16]. Hetero structure is useful on its own ground but it is difficult to fabricate. On the other hand, homogeneous structure has material with single reflective index which is easy to fabricate.

Many different structure based on PBG have been proposed, analyzed and fabricated. L-shaped bends, T shaped power splitter, [18,19] X shaped, quasi square, tri quarter square etc. [20]. from the above structures it is various category of filter like that band pass, add/drop or device like demultiplexer in WDM system are studied extensively. In most of the filters, they showed various way to manipulate the filter characteristics. Tuning the wavelength changing the add/ drop frequency, increasing the transmission coefficient can be done by changing dielectric constant, radius of the rod, changing lattice constant etc.

In this paper we have investigated a drop filter design created by introducing linear gap in the structure to create the waveguide and then creating a simple structure in the gap to create resonant structure, which performs as a drop filter in the 1550nm range. The next section introduces the structure used in the simulation. In section 3 we describe the simulation result. Section 4 describe the working principle of the structure. Section 5 summarize the finding in the paper.

II. GEOMETRY OF THE FILTER STRUCTURE

The drop filter is designed to be operated in the 1550nm wavelength range. A square dialectic rod lattice with a lattice constant of 'a' and dielectric rod with radius "r=.2*a" is chosen for the structure. To design the filter, first the photonic band gap of the square lattice was determined to find out the range of frequency the filter can be used for. Using the lattice parameter and r=.2*a, relative permeability ε_r = 16, relative permittivity, μ_r= 1 using Plane Wave Expansion Method (PWEM) dispersion diagram was determined (Fig. 1). While calculating different band it was also considered the material in-between the dialectic rod is air.

For transverse electric (TE) polarization the dispersion diagram shows there is a complete photonic gap for the range $0.2451 \leq a/\lambda \leq .3871$. The complete photonic gap (PBG) can be seen in Fig. 1 as yellow region. Inside this region the square lattice will not pass any TM polarized EM wave. (there is no allowed mode in this range of frequency). This is the primary concept in band gap confinement. By creating line defect in perfect lattice structure guided mode can be crated in between the photonic band gap. Two waveguide made out of line defect was created to pass TM polarized light. The EM excitation travel in the air in between the lattice structure. The proposed filter structure (Fig. 2) is created in-between the waveguides.

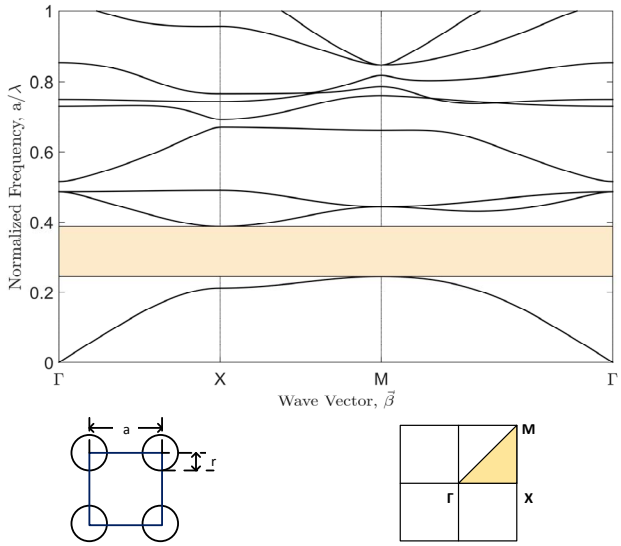

Fig. 1. Top: Dispersion diagram of a square lattice (n=4) and r=.2*a. The yellow region shows a complete photonic band gap for TE mode. Bottom left: The square lattice Bottom right: Irreducible Brillouin zone (IBZ) showing the key points of symmetry

The coupling rods (yellow square in Fig. 2) as the name suggests couples the EM energy from the top waveguide to the resonator cavity. In our design, we employed the simplest of structure by using only a single inner dielectic rod (red square) with a radius of 4*r . Here 'r' is the radius of the dielectric lattice rod

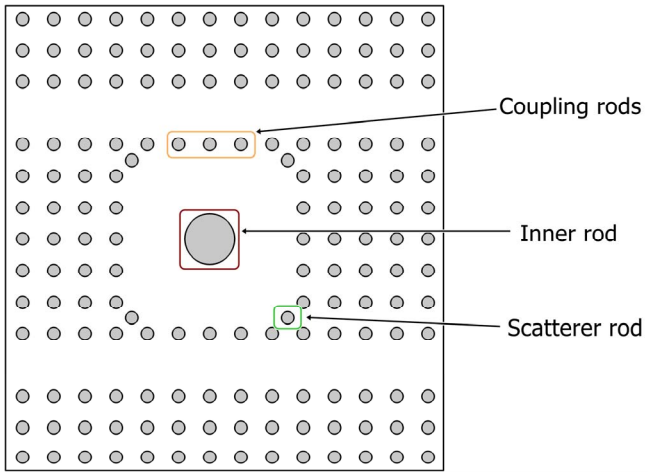

Fig. 2 Proposed resonent filter

PWEM is a popular medthod employed to determine the theoritical dispersion diagram of a periodic dielectric structure [21,22]. PWEM solves Maxwell's equation in Fourier space. Maxwell's equations for time harmonic case can be written as :

$$\nabla \times \left(\frac{1}{\varepsilon_r}\nabla \times \vec{H}\right) = k_0^2 \mu_r \vec{H} \quad (1)$$

$$\nabla \times \left(\frac{1}{\mu_r}\nabla \times \vec{E}\right) = k_0^2 \varepsilon_r \vec{E} \quad (2)$$

The equations assumed a) field strength is small b) material is macroscopic and isotropic c) material dispersion is ignored d) material is transparent e) structure does not vary with time f) there are no free charges or currents.

The above equations are written in the form of a eigen value problem. These equations can be written as a three dimentional (3D) eigen value problem in fourier space as a matrix so that it can be solved numerically.

$$[\vec{K}\times]\frac{1}{[\varepsilon_r]}[\vec{K}\times]\vec{u} = -k_0^2[\mu_r]\vec{u} \quad (3)$$

$$[\vec{K}\times]\frac{1}{[\mu_r]}[\vec{K}\times]\vec{s} = -k_0^2[\varepsilon_r]\vec{s} \quad (4)$$

Here $k_0^2 = \omega\sqrt{\varepsilon_0\mu_0}$, u and s corespond to the H and E field in fourier space .

By solving equation (3) and (4) the dispersion diagram was calcualted.

PWEM is the most popular method used to genarate the dispersion diagram but to simulate propagation mode and transmission or reflection spectra this method cannot be used. In order to simulate the poparating mode we employed a Finite Element Method (FEM) based solver, which produce the tranmission /reflection spectra and field pattern of the structure. A Perfectly Matched Layer (PML) was utilized around the srtucture to stop reflections at the boundary.

III. Simulation and Results:

The concerned filter is depicted in Fig. 3. The filter is made with array of dielectric rod with square lattice structure. The filter is composed of 4 port A, B, C and D. An electromagnetic excitation is introduced in port A and then observed at port B, C and D. By comparing the incident wave to the wave at B, C and D port the transmission spectra can be determined. Transmissivity is defined as the ratio of the square of the amplitude of transmitted intensity at the output ports. To that of an input port. The electromagnetic excitation was varied from 1530nm to 1595nm to generate the transmission spectra at different port.

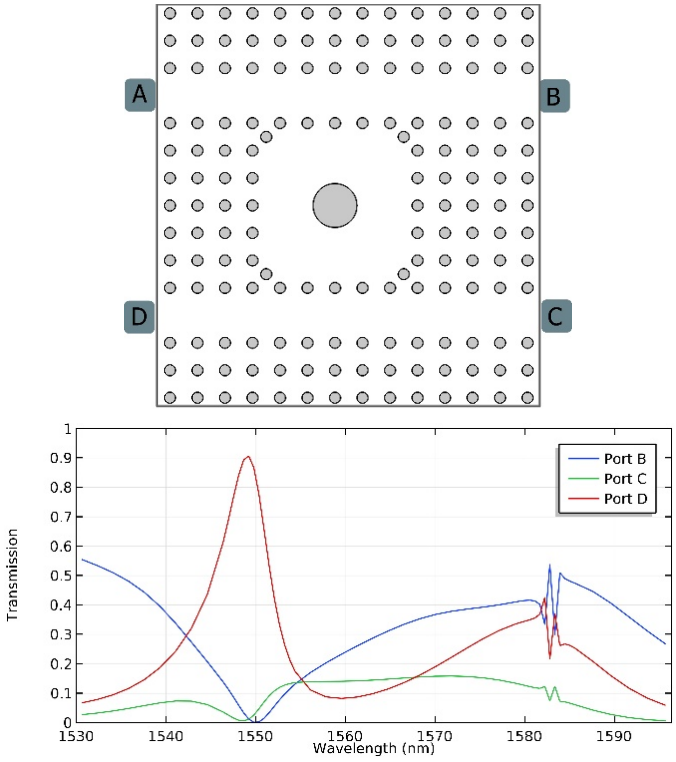

Fig. 3. Top: geometry of the filter Bottom: transmission spectra of the filter at B, C, D port.

Using the parameter mentioned on the previous section the transmission spectra can be seen in Fig. 3. The peak transmission was found 90.7% at a wavelength of 1549nm at port D. At the peak point transmittance at port B is 1.27% and at port C is 1.17%. Some power is also lost in port A. The back- reflection occurs mainly due to the coupling mismatch at port A [23]. The quality factor, $(Q = \lambda_0/\Delta\lambda)$ at 1549nm is 217. The bandwidth is calculated at Full Width Half Maximum (FWHM).

So it is clear that the drop port of the filter is Port D. For that purpose, for the rest of this paper we will focus our study on port D. By varying different parameter, the transmittance can be varied or the peak point can be shifted to another targeted wavelength. By varying the inner rod radius, the lattice rod radius or by changing the dielectric constant of the rods in general different attribute of the transmission spectra can be varied. Changing the inner rod radius results in the peak transmittance, which can be seen in Fig. 4. But it can also be seen that the peak value is blue shifted when the radius is reduced bellow 4*r and various artifacts appears when the inner radius is 4.4*r. Also with different simulation it was also found with a radius of less than 3*r or above 5*r the resonant structure completely loose its resonant property and the filter is no longer functions.

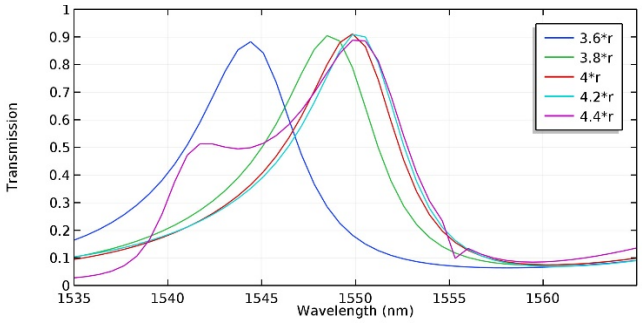

Fig. 4. Transmission spectra at port D while varying the inner radius

While varying inner rod by a small amount from 4*r does not change the output by much, changing the radius of the lattice rod shift the peak point to the right or to the left.

Effect of changing the radius of dialectic rod can be seen in Fig. 5. By increasing the radius of the dialectic rod the spectrum shifts to the right. Also the peak value of the transmission increase slightly when increasing the radius of the rod. But after increasing the radius up to a point the peak transmission levels off and then starts to decrease.

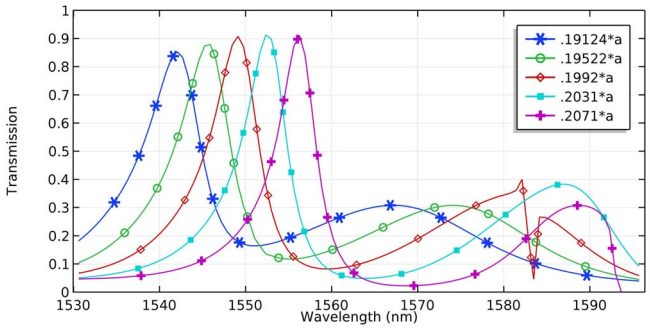

Fig. 5. Transmission spectra at port D while varying the radius of the dielectric rod

In Fig. 6. effect of changing the refractive index can be seen. By varying the refractive index from n=3.9 to n=4.4 the peak transmittance remains the same but the spectra red shifts. Changing the refractive index means changing the material itself. So by using different material the peak can be shifted without changing the peak transmittance.

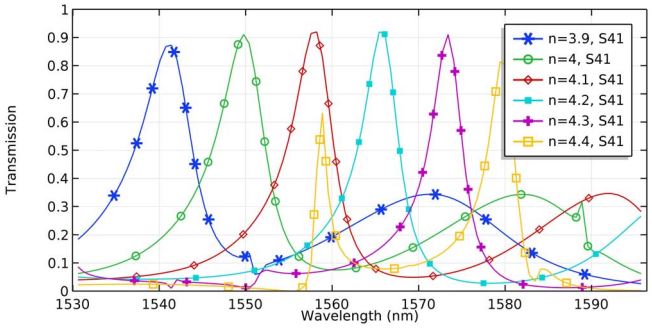

Fig. 6. Transmission spectra at port D while varying the refractive index.

IV. WORKING PRINCIPLE OF THE DROP FILTER:

The drop filter works by coupling a certain range of frequency in the cavity and rejecting the rest. The coupling is done by the coupling rod in the structure. Fig.7 shows the normalized electric field at the point of resonance. The color bar next to the figure show the scale of the relative electric field. Also in the figure the highest electric field is seen near the coupling rod. The input coupling rod couples the EM energy from A–B waveguide path. The coupled energy is then dropped to the C-D waveguide path. The light is confinement in the intended path which can be seen by the near zero electric field (dark blue part in Fig. 7).

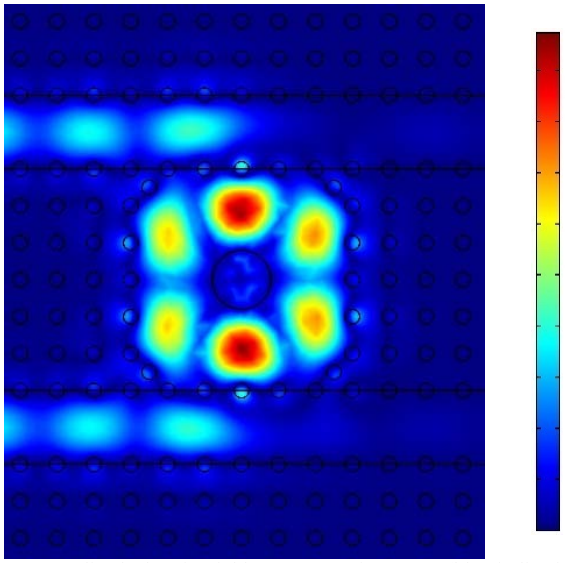

Fig. 7. Normalized Electric Field at resonant frequency (blue indicating no electric field and red indicate high electric field)

From the time average power flow diagram in Fig. 8 (Top) it can be seen when the power circulates clockwise around the inner rod the maximum power is dropped in port D. On the contrary when the structure couples power as such that the power flow on both side of the inner rod Fig. 8 (Bottom) the power flows at port B, C and port D. The coupling rod couples some energy which is divided between ports C and D. But most of the power flows through port B

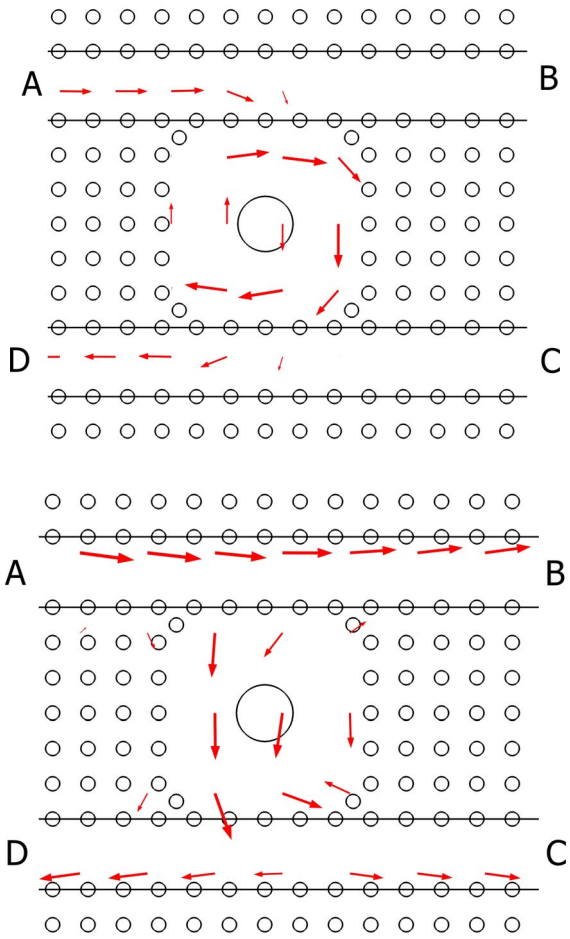

Fig. 8. Time average power flow of the filter Top: at peak resonant wavelength Bottom: at a non resonant wavelength (Length of the arrow represents relative time avgegare power flow in log scale)

V. Conclusions

In this study a simple homogeneous drop filter was simulated to show its various performance aspects. Plane Wave Expansion Method (PWEM) was performed to find out the photonic band gap of the lattice structure. Then using the parameter found in the study a novel structure was created which performs as a drop filter at a communication wavelength of 1550nm. From Finite Element Method (FEM) study the drop transmittance was found close to 91% at 1550nm which can be tuned to different wavelength by varying different parameter of the structure.

As this structure is very compact (8 µm x 9µm) it can also be included in photonic integrated circuit. As the dispersion diagram is normalized and due to the scalability of photonic band gap (PBG) structure the filter can be easily designed for lower or higher wavelength range.

***Abstract*—A comparator establishes the bridge to connect the realms of digital and analog circuits. Moreover, the need to fulfil the consistent demand of low power and high speed small-scale devices has brought the MOS transistor based circuit design near to the edge of feasible design limit. In recent times, with the advancement in fabrication technology, FinFET has emerged as the most competent alternative with the prospective to overcome the short channel effect challenges of MOSFET. In this paper, we have presented a dynamic latch comparator circuit using 32nm PTM model of FinFET and performed our simulations with LTspice and MATLAB. Our designed comparator has shown an impressive propagation delay time of only 7.25 ps and average power consumption of 45.64 µW at 0.8V dc supply. Also, its performance comparisons with other contemporary designs verified the supremacy of our proposed comparator. Moreover, it seems that in the upcoming years, FinFET has the potential to bring forth radical transformation in device modeling and supersede conventional MOSFET oriented design.**

Keywords—dynamic latch comparator, FinFET, PTM, low power, high speed

I. INTRODUCTION

Analog to Digital Converter (ADC) and Digital to Analog Converter (DAC) are the two cardinal doorways between the digital and analog world [1]. They have numerous applications in diverse field of areas like memory circuits, switching power regulators, data converters, oscillators, RF communication, etc. [2], [3]. The comparator is the core element for both of the converters. Due to the speed limitation and massive power requirement, static converters have been superseded by dynamic converters [4]. A dynamic latch comparator meets the essential requirements of circuit simplicity, high input impedance, smaller chip area, high frequency operation, reduced power dissipation, low supply voltage operation, noise immunity, lower offset, etc. [5], [6]. Over the years, many researchers have been working relentlessly to develop more and more efficient design of comparators. In [7], to acquire faster speed, an NMOS input comparator has been suggested; however, the power consumption increased dramatically. In order to increase the speed, auxiliary transistors have been included by B. Goll et al., although it enhanced the area and power requirement [8]. For lowering the power absorption and improving the speed performance, a delayed clock pulse based design is proposed in [9]. Although the gain amplified with the deferred clock pulse, but the kickback noise issue affected the circuit seriously. Other than voltage boost or additional transistors for conventional body driven comparators, an ultra-low voltage design has been proposed in [10] for further delay reduction, but still the delay remained high.

The ubiquitous usage of portable devices has escalated the demand of low power and high speed circuitry in recent years. For the last couple of decades, CMOS technology has solely dominated the circuit design industry. But as the technology is continuously shrinking, several short channel effects like the carrier's quantum mechanical tunneling through the gate oxide, sub-threshold leakage current due to drain induced barrier lowering (DIBL), higher threshold voltage in comparison with the drain to source supply voltage, mobility degradation of planar MOS transistors have inspired the researchers to explore for alternative possibilities [11], [12]. The double or multi gate structure which is most commonly known as FinFET (fin field-effect transistor), shown in fig. 1 [13], has successfully overcome the issues regarding short channel and emerged as the most promising alternative of conventional MOSFET. A FinFET has quasi planar structure which is very similar to planar MOSFET structure thus the fabrication process are analogous. A very thin silicon film is grown over the wafer and the gate wraps around the channel which facilitates the channel control from both front and back ends, and consequently, a better control is achieved over the threshold voltage and sub threshold leakage current [14], [15]. The channel of a FinFET is oriented vertically in contrast with the horizontal channel of MOSFET. Interestingly, the width of a channel is approximately twice the height of the channel plus the gate oxide thickness, which is known as width quantization; moreover, the effective width of a FinFET can be enlarged by raising the number of fins [16].

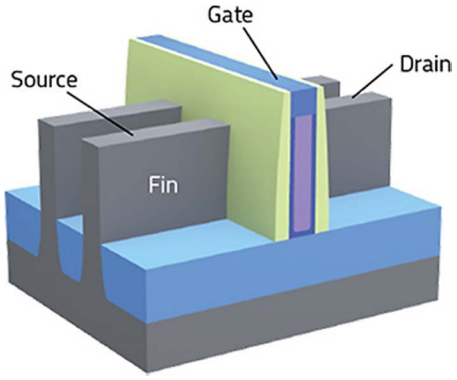

Fig. 1. FinFET architecture

In this paper, we have proposed a dynamic latch comparator using 32nm FinFET technology and excluding the preamplifier stage as it consumes significant amount of power. In section II, the circuit description of our proposed comparator together with propagation delay time and power consumption have been discussed. Simulation results and comparison with other research works are presented in section III. Lastly, section IV brings to an end with a brief conclusion.

II. Proposed Dynamic Latch Comparator

A. Circuit Description

In contrast with the amplifier chain type comparators, the dynamic latch comparators provide superior speed and low amount of power consumption attributes which particularly place them in a favorable position for designer's choice to implement flash A/D converters. Another distinct feature of latch type comparator is their immunity towards noise as once the decision is reached the output will hold that data indefinitely till next input.

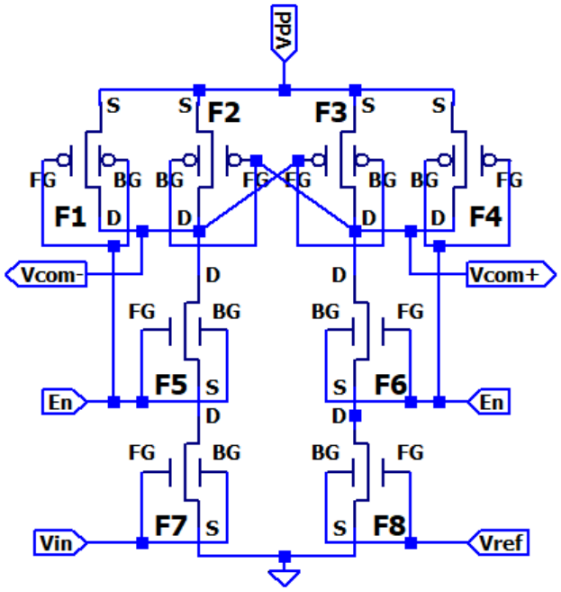

Fig. 2. Circuit design of the proposed dynamic latch comparator

In order to design the dynamic latch comparator, due to the small channel limitations of MOS transistor, FinFET has been introduced. The pFinFET and nFinFET have been designed by using the 32nm PTM (Predictive Technology Model) with LTspice. The schematic representation of our proposed dynamic latch comparator has been shown in fig. 2. The latch stage between F2 and F3 pFinFETs establish a cross coupled pair where the drain of one pFinFET is attached to the gate of another. The input and reference voltages are applied to the gate of F7 and F8 nFinFETs, respectively. The comparator performs its operation in two phases. The first phase is called the "Reset Phase" while the Enable (En) signal remains logic low. En is connected to the gate of F1, F4, F5 and F6. So, as the F5 and F6 nFinFETs are getting logic low, both of them enter into the cut off region, where as the F1 and F4 pFinFETs enter into the triode region or in simple words are turning on [17]. Now, through F4 and F1 both Vcom+ and Vcom- are charged to Vdd, and this voltage will be remained there as the discharging paths through F5 and F6 are disconnected. Input voltage (Vin) and reference voltage (Vref) might still be present, but during the reset phase their amplitudes are not compared. If F5 and F6 nFinFETs were not used then Vcom+ and Vcom- nodes would have never be remained charged at Vdd.

The next phase of the comparator is called the "Active Phase" where a logic high signal is applied through the En input. F5 and F6 nFinFETs will immediately enter into the triode region which means they will turn on. At the same time as both F1 and F4 pFinFETs are getting logic high to their gate, they will turn off as they would move into the cut off region. Initially, both Vcom+ and Vcom- would remain at Vdd. Now, depending on the voltage levels of Vin and Vref, the discharging path conductance of F7 and F8 would differ. If Vin is greater than Vref then the conductance of F7 would be higher than F8 thus will facilitate the discharge of Vcom- earlier than Vcom+. Once Vcom- is discharged to Vdd-Vtp level, where Vtp is the threshold voltage pFinFET, the gate of F3 pFinFET through the drain of F1 will receive logic low which will eventually turn on the F3 as the source of F3 is already connected to Vdd. So, Vdd volt will appear at Vcom+ node. Moreover, as the gate of F2 pFinFET is connected to the drain of F3, it will get logic high thus will remain into the cut off region. In this active phase the F2 pFinFET never gets the opportunity to turn on if Vin remains higher than Vref. Hence Vcom- will maintain the ground voltage. However, if the input signal is lower than the reference level then in that case the conductivity of F8 would be higher than F7 and Vcom+ would discharge swiftly than Vcom- and reach at ground voltage level. Now as the gate of F2 pFinFET will achieve logic low, it will turn on and the drain voltage would be Vdd which will be appeared on Vcom- node. Every time for the input signal to be compared with the reference signal, the dynamic latch comparator must have to be reset first and the subsequent process will be continued.

B. Propagation Time Delay

One of the most important parameters of logic circuit is propagation time delay (t_{PD}) by which a designed circuit's performance is declared as high speed or low speed. With the advancement of technology, it has always been demanded for higher switching speed thus resulting high frequency operation which could only be achieved by shorter propagation delay. Two basic measurements associated with t_{PD} are t_{PHL} and t_{PLH}. The time interval between the 50% point of input and 50% point of corresponding output that goes from logic high to low is t_{PHL} and similarly, time duration between 50% points of input and output while it goes form logic low to high is t_{PLH}.

$$t_{PD} = \frac{t_{PHL}+t_{PLH}}{2} \quad (1)$$

C. Power Consumption

Another major issue, on which the researchers have been working relentlessly decade after decade is the reduction of power consumption of a circuit. It is of the paramount importance for high frequency operation, otherwise each switching would consume huge amount of power that would eventually overheat the circuit, cost more, increase device size and deteriorate the circuit performance over time. There are two basic components as explained below on which the total power consumption of a circuit depends [18].

1) Static Power Consumption: During the operation, while all the inputs of a circuit are at a fixed voltage or logic level and the circuit is not in a charging state, due to the establishment of reverse bias junction between the substrate and the source/drain some leakage power will always be drained due to the flow of minority carriers is called the static power consumption.

2) Dynamic Power Consumption: When the transistors of a circuit switch from one logic state to the opposite, current flows from Vdd to GND for a brief period of time as both p-type and n-type transistors remain on simultaneously; moreover, some current is also passed to charge the internal nodes and output capacitive loads. Both of these factors

contribute to higher amount of power absorption which is called the dynamic power consumption. Majority of the power consumed by a circuit is due to the dynamic power for high speed devices.

Total Power Consumption = Static Power Consumption + Dynamic Power Consumption (2)

The average power consumed by a circuit is determine by the following equation

$$P_{avg} = \frac{E}{T} = \frac{1}{T}\int_0^T I_{dd}(t)V_{dd}(t)dt \quad (3)$$

III. Simulation Results and Discussion

The dynamic latch comparator presented in this paper is designed with LTspice simulation software. Moreover, the simulation data have been exported into MATLAB to plot all the waveforms with greater ease. Most importantly, the 32nm FinFET Predictive Technology Model (PTM) that we have used for our design was developed by Arizona State University which is available at their website [19].

In fig. 3, all the essential voltage amplitude and power consumption levels have been clearly demonstrated. The dc supply voltage (Vdd) is chosen as 0.8V for the 32nm FinFET process. The Enable (En) or clock signal is a periodic square wave which for a brief period of time of 0.1ns remains at 0V in order to provide the scope to both of the outputs, Vcom+ and Vcom-, to be charged at Vdd. This time could be varied depending on the application requirements. The input voltage (Vin) has been delicately set higher than the reference voltage (Vref) in one cycle and lower in another with respect to En in order to indicate the comparison for both cases. It is clearly evident from fig. 1 that Vcom+ is at logic high and Vcom- is logic low while Vin is greater than Vref and vice versa. From the average power consumption curve we can see the spikes of dynamic power consumption during momentary switching periods.

In Table I, the time delay and power consumption have been presented for different amplitude of dc supply voltages. It is very interesting to note that the t_{PHL} (high to low transition time of output) has increased with the increment of dc supply voltage. It is due to the higher capacitance of FinFET, obviously more time would be required while discharging from a higher stored charge level. On the other hand, t_{PLH} (low to high transition time of output) decreased with higher Vdd, as because it would take less time to charge the capacitance with higher voltage. Average power consumption definitely had to increase for higher supply voltage.

The comparison among our proposed system with other works has been included in Table II for convenience. It is clearly manifesting that the FinFET technology is superior in case of power consumption and propagation delay time than its CMOS counterpart.

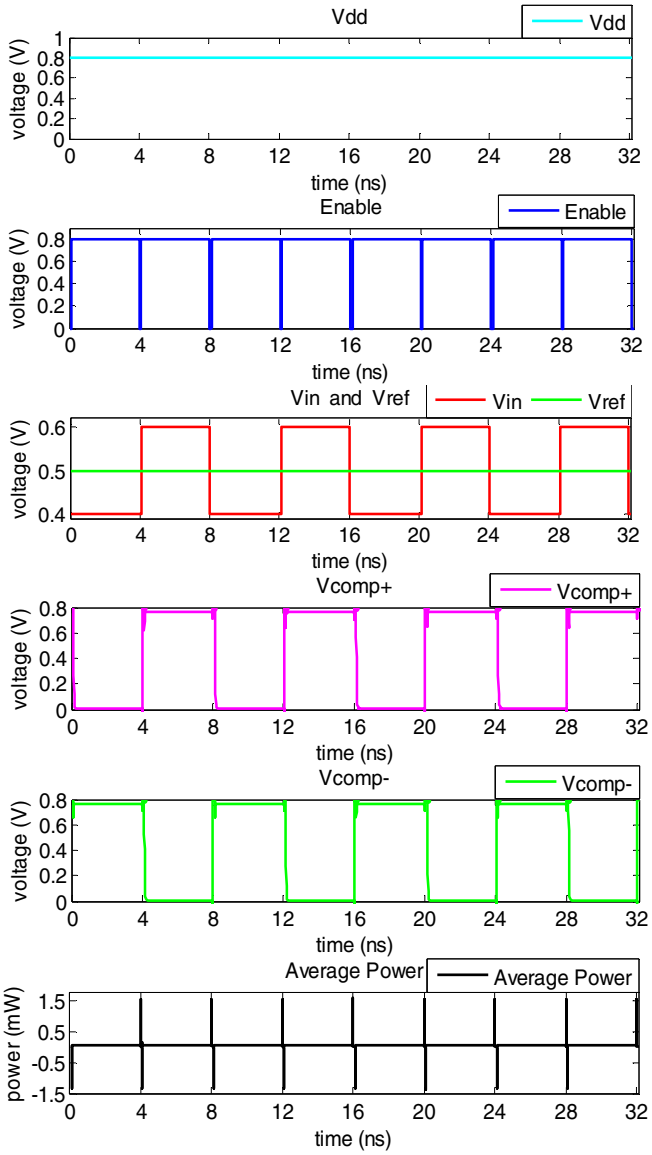

Fig. 3. Simulation results of the proposed dynamic latch comparator

TABLE I. Propagation Delay Time and Average Power Consumption with Different Supply Voltages

Supply voltage (V)	t_{PHL} (ps)	t_{PLH} (ps)	Propagation time delay, t_{PD} (ps)	Average Power (µW)
0.6	10.02	3.84	6.93	24.29
0.8	10.89	3.61	7.25	45.64
1	11.76	3.50	7.63	73.10
1.2	12.57	3.39	7.98	107.27

TABLE II. Performance Comparisons Among the Proposed and Other Dynamic Latch Comparators

Parameters	[20]	[21]	[22]	[23]	Proposed
Technology	CMOS	CMOS	CMOS	CMOS	FinFET
Channel Length	0.18µm	0.18µm	0.18µm	90nm	32nm
Supply Voltage	1.8V	1.8V	1.8V	1.2V	0.8V
Power Consumption	146.2 µW	460 µW	158.5 µW	225 µW	45.64 µW
Sampling Frequency	100 MHz	100 MHz	50 MHz	2 GHz	250 MHz
Propagation Delay	7ns	1.699ns	4.2ns	500ps	7.25ps

IV. Conclusion

In this research work, the design of a dynamic latch comparator, developed on 32nm FinFET PTM model, has been suggested and through simulations its performance has been evaluated. The proposed comparator circuit consumes less power and requires shorter delay time in comparison with other similar dynamic latch comparators as it is made with less number of transistors thus requires less chip area. FinFET based design results are so far remarkable and has opened the scope for researchers to explore the possibility and impacts on other essential circuit models.

***Abstract*— CMOS transistor of the commercial chip is currently at 7nm technology node. Fabrication engineer is now facing some complexities to further scale down the size of the transistor. Quantum mechanical phenomenon is occurred and significantly worsens the performance as well as it changes the overall properties of the transistor. So, researchers have developed several types of devices in order to overcome the shortcomings of CMOS. One of the devices is the Carbon nanotube Field Effect Transistor (CNFET). It is a suitable device because it can be scaled down up to 2nm and it overcome some limitations. One of the major advantages of CNFET is that the carrier faces theoretically zero resistance when passing through the carbon nanotube because that tube acts as a channel analogous to E-MOS. In this research, a new adder circuit is designed using 32nm CNFET model. The proposed circuit is based on Pass Transistor Logic (PTL) in order to reduce the number of transistors and silicon area. A comparative study is conducted by simulation. The results concluded that the proposed circuit performs better than other conventional adders in terms of power consumption and time delay.**

I. INTRODUCTION

MOSFET is widely used in the integrated circuit since late 1960. In order to improve the performance such as higher switching speed, low power consumption and high latency of a digital chip, more transistors are to be fabricated very tiny space. So, it is necessary to reduce the size of the transistor to fit a large number of them. If the size of the transistor is significantly scaled down, nonlinear properties of the transistor become prominent. We can see some nonlinear behavior of MOSFET such as channel length modulation, subthreshold leakage, drain induced barrier lowering (DIBL), Junction capacitance, etc. If the channel length of MOSFET is less than 10nm (theoretically) the quantum mechanical effect is to appear (Tunneling). It is realized that we cannot scale down of MOSFET less than an atom but the problem will arise before reaching that level. So, researchers are working to find out a new type of device.

Many devices are proposed [4] but the two devices are in the front. One is Nanowire FET (NWFET) and another one is CNFET as shown in figure 1 [4]. CNFET is made out with the CN tube as shown in figure 2, which is invented after 1990. CN tube is a graphite sheet which is rolled in a certain angle known as chirality angel. On the basis of chirality angles, the tube acts as a semiconductor or conductor. So, by using doping principle one can make a FET. Two types of CNFET

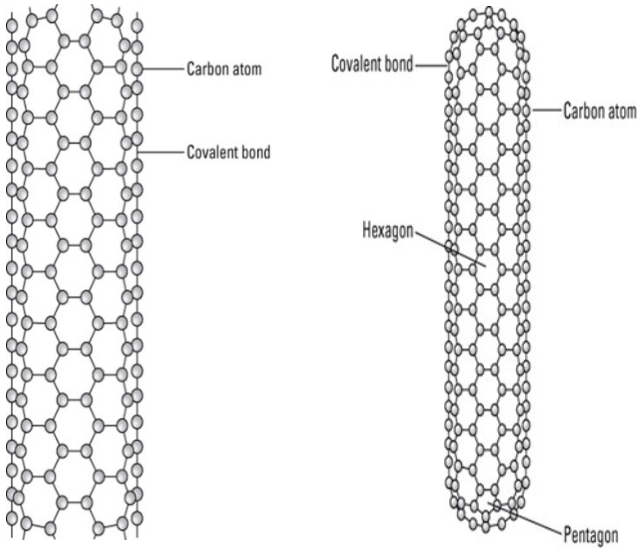

Figure 1: Carbon nanotube a) open, b) closed [google]

are existing: one is Schottky barrier CNFET and the other is Enhancement type CNFET [2]. Enhancement type CNFET is similar to the MOSFET. Different Logic circuits are designed using E-CNFET.

In this research, a new 1-bit full adder is designed using E-CNFET. Stanford university 32nm CNFET model is used [8]. Previous models of full adder circuits are discussed in section II, Section III describes the proposed model and simulation results are presented in section IV. Section V concludes the proposed research.

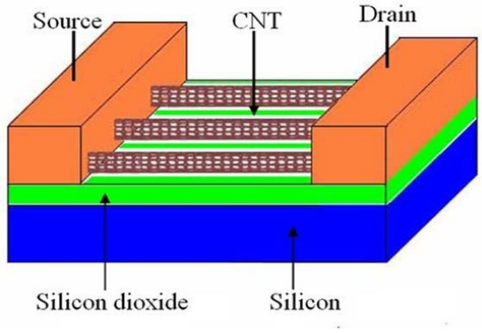

Figure 2: Carbon nanotube FET [google]

II. PREVIOUS WORKS ON FULL ADDER

CNFET is superior to MOSFET because of the ballistic transport of the carrier through the tube. Ballistic transport is basically the smooth traverse of electrons in a medium without encounters a scattering event. Theoretically, electron faces zero resistance during ballistic transport. As a result, the mobility of the carriers is theoretically infinite. For that reason, it is considered a prominent device in the near future.

In order to design an ALU, the adder is an important part. So many researchers proposed many adder circuits. Now we briefly discuss some published adder circuits

A. Majority function based full adder

Majority function based full adder means XOR-XNOR based full adder circuit. The capability of the majority function attracts the designer to use that function in their design [1]. Figure 3 shows the majority function based full adder [1].

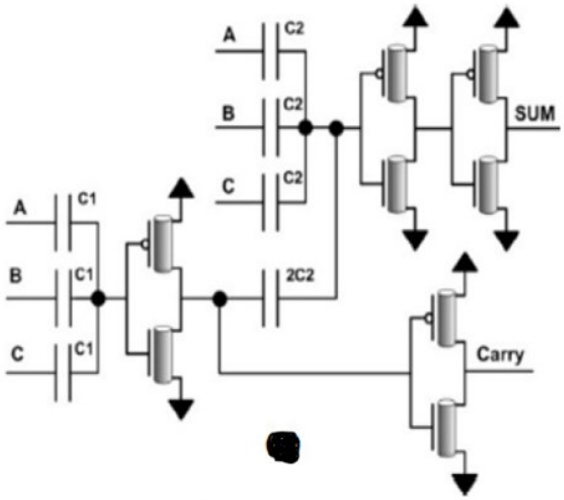

Figure 3: Majority Function based Full adder [1]

B. 24T Full Adder

This adder cell is proposed by A. Ghorbani and G. Ghorbani [1]. This adder is implemented with 24 CNFET and they claimed that the power of that adder is better than CMOS one. Figure 4 shows the 24T adder.

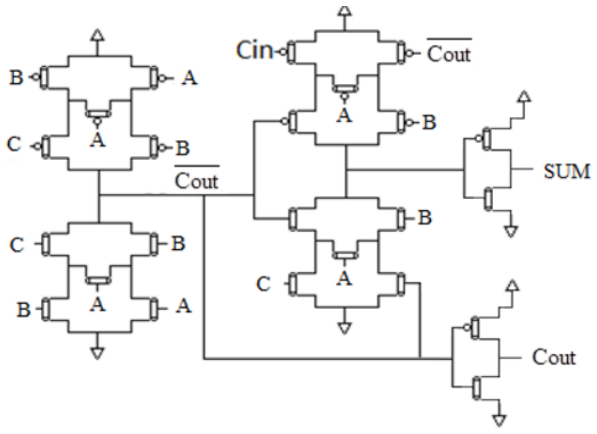

Figure 4: 24T Adder (A. Ghorbani and G. Ghorbani) [1]

C. TG Logic Based Full Adder

The advantage of TG logic-based circuit is the cell area is often very smaller [2]. The transistor count is smaller than CMOS logic. So, the TG logic-based system is power efficient compared with Conventional CMOS logic. Figure 5 shows the TG logic based Full adder [2].

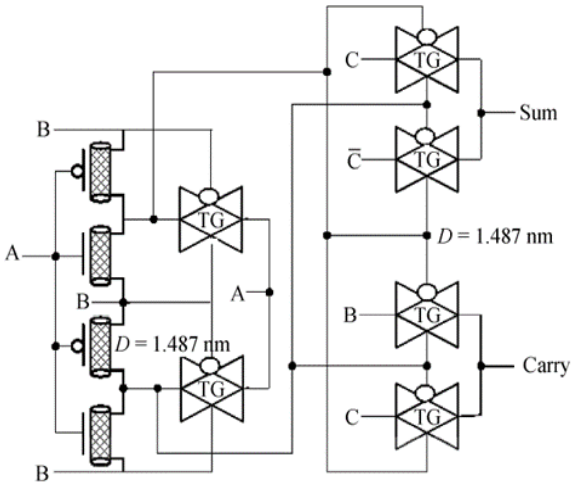

Figure 5: TG logic Based Full Adder [2]

D. Complementary logic based Full Adder

The advantage of CPL is that the complementary outputs are produced by in simple 4 transistor circuit [2]. The CPL full adder the sum and carry logic are structured separately on a more complex logic circuit [2]. In figure 6 the CPL full adder is showed.

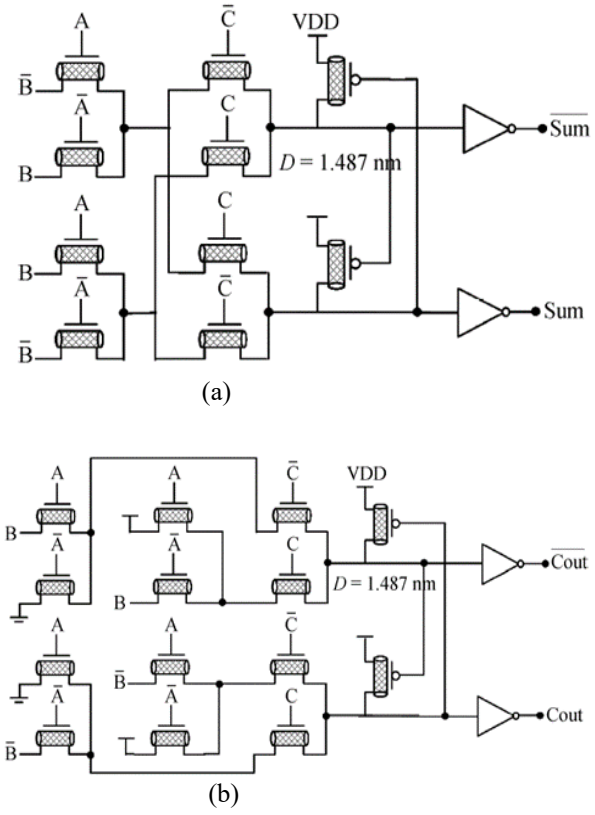

Figure 6: CPL full adder a) sum unit, b) carry unit [2]

III. PROPOSED FULL ADDER

The proposed adder is designed using PTL logic style. The goal is to design an efficient full adder which consumes less power, low silicon area, and better high-speed operation. So, we choose PTL, because it is a power efficient logic and the transistor count is also less. HSPICE is used for simulating our adder circuit. 10 transistors are needed for implementing the proposed adder. 4T XOR configuration is used for produce sum module and the carry module is generated using only 2 transistors. Figure 7 shows the schematic of our proposed adder.

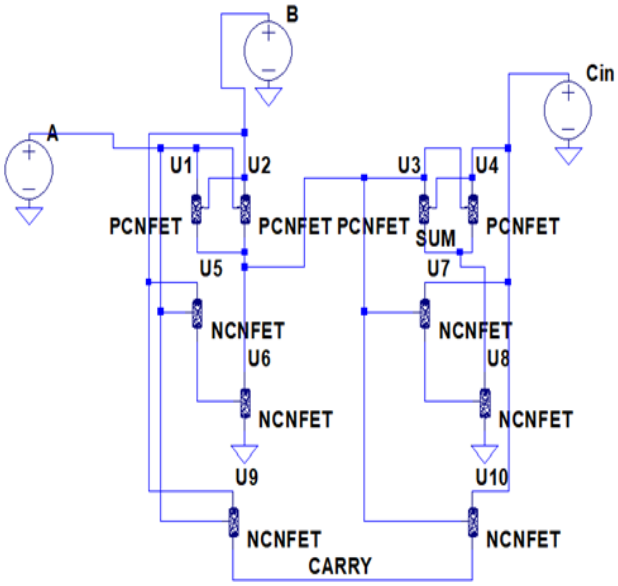

Figure 7: Proposed 10T Adder Using CNFET

TABLE I. PARAMETER LIST OF OUR PROPOSED CIRCUIT

Parameter Name	Value
Channel length	32nm
Channel width (PCNFET)	32nm
Number of the tube (PCNFET)	100
Channel width (NCNFET)	4nm
Number of the tube (carry NCNFET)	3
n1 and n2 (Chirality Vector)	(19,0)

IV. SIMULATION RESULTS

Table 1, displays the parameters, used in the simulation experiments in this research. The output of our adder circuit is given in figure 8. Some distortion is seen in the output. Here only one cycle is shown. The operating frequency of our circuit is 25MHz and the operating voltage is 0.9v.

To compare our findings with some published data [5-7]. The bar graphs of figure 9, 10 and 11 are given for comparing the performance among different types of adders. Figure 9 shows the Power, figure 10 displays the Time Delay and figure 11 depicts the PDP for adder circuits. From the calculated Power Consumption, Average Delay and the

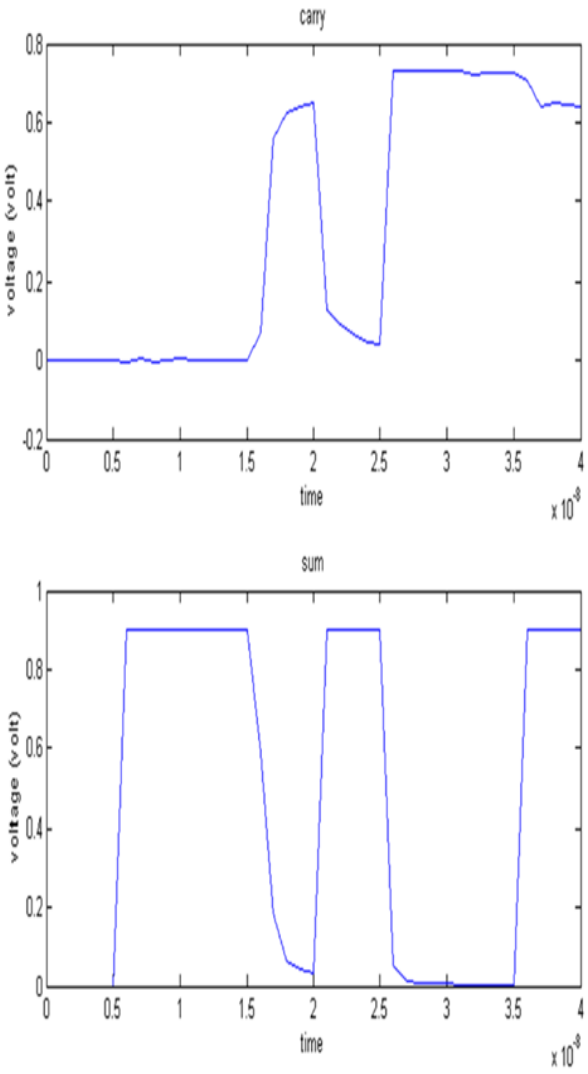

Figure 8: Output response of proposed 10T adder circuit

Power-Delay Product of the proposed adder, it is seen that the proposed circuit outperforms the other conventional models.

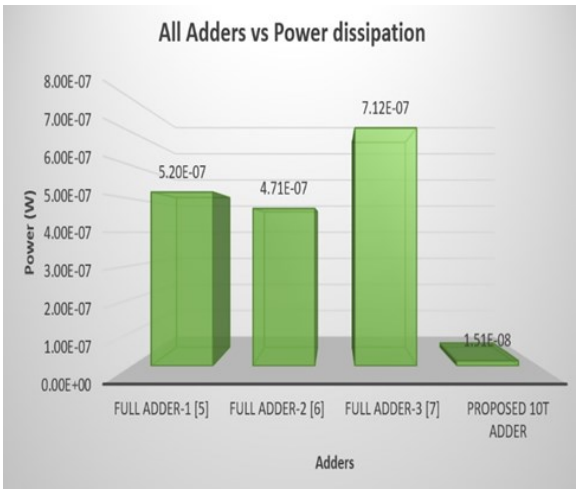

Figure 9: Bar Graph of Power dissipation of all Adders

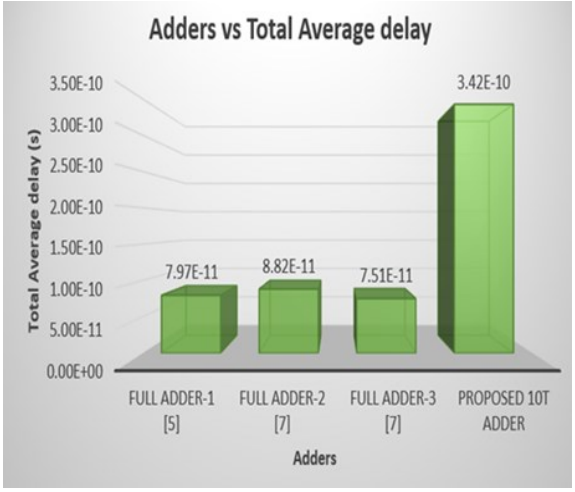

Figure 10: Bar graph of Average delay of all Adders

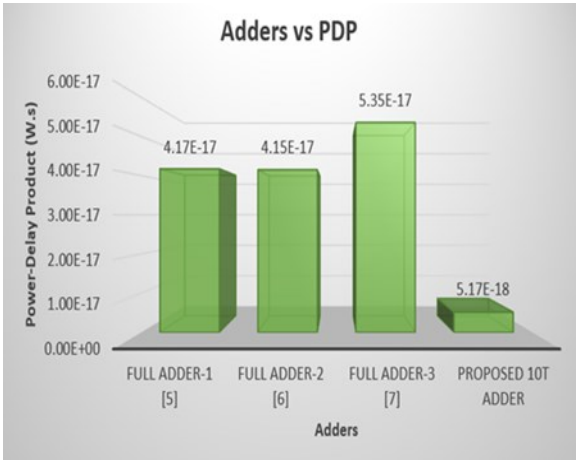

Figure 11: Bar graph of PDP of all Adders

V. CONCLUSION

A new adder is designed using a new type of device which is prominent now a day. We use the Stanford university model for obtaining a better result. From the comparative results, it can be concluded that the proposed circuit is superior in terms of power but slightly higher time delay. However, the proposed circuit is compact because it only needs 10 transistors. In terms of PDP, this circuit outperforms all other adder circuits.

***Abstract*—Fertilizers (Triple superphosphate) and pesticide (fungicide and insecticide) are one of the major products used to increase the productivity of crops. As time passes the amount of pesticide in crops is not maintained fixed. Pesticide does react with water and the level of pesticide decreases day by day. Hence, it is important to know the present level of pesticide in soil and crops. TSP and pesticide (fungicide and insecticide) are used in this project as a sample of fertilizer and pesticide, cause of its high demand in Bangladesh. To detect the amount of TSP and pesticide in the oil sample, the conductivity property of TSP and pesticide (fungicide and insecticide) are used. Three separate solutions of TSP and pesticide (fungicide and insecticide) is made with water then AC source is applied to the solution instead of DC to avoid electrolysis of the given solution. Through the op-amp and two comparators, the final result is accomplished. Those two comparators, comparator 1 and comparator 2 were used to find the presence of 30%, 50%,70% TSP and Pesticide respectively. As result suggest, the resistance of the solution decreases with the incremental frequency. The compatible frequency for AC source is selected as 40 KHz. The reference voltage of comparator 1 is 1.4v and comparator 2 is 5v.**

Keywords—co-axial cylinder electrode, triple super-phosphate, fungicide, insecticide, phosphoric acid, electrolysis, comparator.

I. INTRODUCTION

From the start of cultivation farmers all around the world are using different technologies to increase the productivity of their crops. Therefore, in old days farmer used organic pesticides. However, with time, science has given farmers so many tools for an easier and effective irrigation system. The pesticide is one of those creations of science. Farmer of our country used fertilizer in a different amount for the different type of crops. Without considering the future outcome, they use the same amount of fertilizer. Sometimes this uncalculated use of fertilizer disrupts soil fertility. As a result, foods health quality gets decreased. Though some method can be used to test the existing rate of fertility in soil however this method is not only costly but also difficult to operate. Although fertilizer level detection could be done by a simple electrical circuit at a low cost using pesticides resistivity property. It was observed that if water is added to the pesticide solution the resistivity of the solution is decreased. This decrease depends on the number of pesticides used. So using that a set of data were taken for the different amount of fertilizer. From those data, a certain voltage level was set in the comparator to show the output through a LED for a different level of fertilizer. If the voltage level of a sample is greater than the set voltage, then the LED will grow.

II. LITERATURE REVIEW

The fertilizer and pesticide detection process are not very commonly used in our country because of existing costly and difficult detection method. In the early days, for pesticide detection, one has to rely on a laboratory test. In the laboratory, a number of tests are conducted on a sample to identify existing materials on that particular sample. Nowadays scientists do chromatography and spectroscopy to identify chemical material on a sample [1]. The problem with this chemical test is it has to be done and individual with textual and practical knowledge. Therefore, these tests cannot be conducted by a farmer. Though there is some chemical detected method of pesticide whereas a few electrical approaches are noticed in this case. In the case of the chemical pesticide detection method, scientists preferred chromatography and spectroscopy as those are the most advanced and reliable detection method. There are some research works have been done to detection the pesticide level by an electrical method. In recent days, researchers have made a polymer coated signal IDT sensor to detect pesticide level researcher has used it in practical case but the problem with this sensor is there cost [2]. Moreover, these sensors are not still available for practical work. It is still in the developing stage. Another approach of testing soil fertility can be done by PH detection. But it does not give an idea about the pesticide level [3].

Using pesticide according to soil's need is not common in Bangladesh because of lack of pesticide detection. The scarcity of pesticide detector is because there has not been much work done in this sector. Therefore, for making a pesticide detector with demonstrating pesticide level required reviewing a large number of literature. As there was not any work directly related to this field so a large amount of modification was done to the available literature work in order to use it in our detection purpose. The basic theory was adopted from formalin detection process which worked on comparing resistance level of the sample solution and referred value of a different level of pesticide [4]. Furthermore, Electronic Nose for pesticide detection was reviewed to get an idea about present research work [5]. Effect of water PH on the chemical stability of pesticide was reviewed to get a more accurate output of our work [6].

III. METHODOLOGY

Conductivity is the ability to conduct current through any substance conductivity is directly connected to the resistivity of a substance. The low resistivity of a substance indicates a substance as highly conductive indicates the opposite. The resistivity of a substance can vary from time to time depending on many facts. For example, Resistivity of a copper wire varies with temperature increase and decrease [7].

The whole fertilizer, pesticide level detection process is working depending on the conductivity property of materials. If a pesticide is mixed with water the resistivity of the solution is decreased. This decrease depends on the amount of pesticide mixed in water. So in this project different voltage

level has been determined for a different level of pesticide. In the main circuit, a non-inverting amplifier is used to take voltage from an individual sample. Here a couple of comparators is used compare the voltage level of the sample solution and voltage level set for the different level of pesticide. Two LEDs are used to show the output of the corresponding comparator. This way using this method the presence of 30%, 50%, 70%, 100% pesticide in a sample can be determined. As two comparators are used in a circuit, as a result, the presence of any two levels of pesticide can be determined at a time.

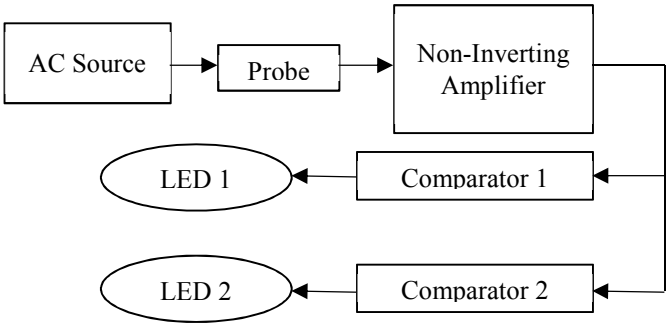

Fig. 1: Block diagram of pesticide detection

A. Working Methode

A set of data was taken for determining a different level of voltage for the different level of pesticide. Those voltage levels were set in the comparator for comparing sample voltage and default voltage set for the different level of pesticide. In comparator 1 a certain voltage level was set to detect the presence at any certain level of pesticide. In fig 2, Op-amp was used to measure the solution voltage gain using two probe method. In comparator 1, a certain voltage level was set to detect the presence at any certain level of pesticide. And in comparator 2, another voltage level was set for another level of pesticide. The comparator was used to show the result by comparing between the defaults voltages and sample voltage. Two LED was used to indicate the output result where one LED 1 shows one level of pesticide and another LED 2 shows the presence of another level of pesticide.

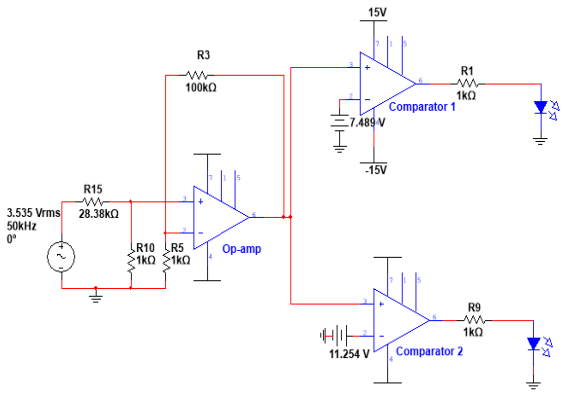

Fig. 2: Fertilizer and pesticide level detection circuit.

To make the solution, at first, TSP is mixed with a fixed amount of water. The amount of water is used here is 500ml. According to TSP's atomic molar mass 30%, 50%, 70%, 100% solution is made. A similar procedure is followed for pesticide (fungicide). And for insecticide 1 drop, 2 drops, 3 drops of sample are used for this detection process. The reaction of TSP and pesticide with water is given below:

$$Ca(H_2OPO_4) + H_2O \longrightarrow 2H_3PO_4 + CaO$$

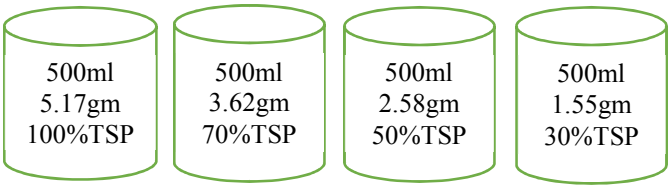

Fig 3: Reaction of TSP with water

Fig. 4: Reaction of pesticide (insecticide) with water

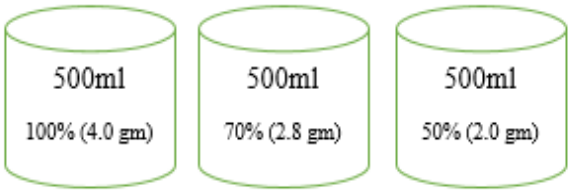

Fig. 5: Reaction of pesticide (fungicide) with water

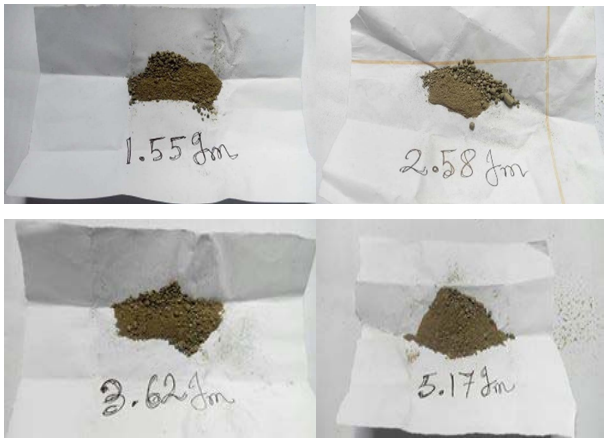

Fig. 6: Different amount of TSP according to their atomic masses.

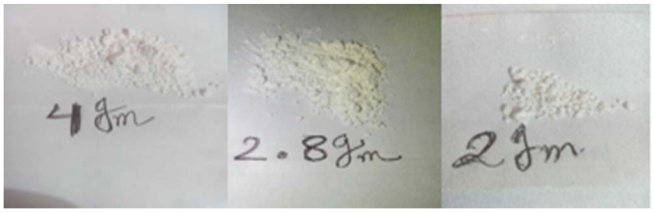

Fig. 7: Different amount of pesticide(fungicide) according to their atomic masses.

Fig. 8: Different amount of pesticide(fungicide) according to their atomic masses.

IV. Experiment Setup

A user-friendly and cost-effective circuit was used in this project for the purpose of detection. Basic electrical active devices like op-amp, comparator was used to finish the project. The AC source was applied to the solution. According to the solution resistance, the non-inverting op-amp will give an amplified output voltage. Then this output voltage was shorted to two comparators. Comparator-1 and Comparator-2 were used to detect 30%, 50%,70%, 100% TSP and pesticide respectively. Two DC voltages were assigned to the negative pin of each comparator. When the amplified AC voltage is more than the DC reference voltage the LED will glow. From the fig. 9, it can be inspected easily. In the main circuit, the op amp take gets a voltage gain from any kind of sample of pesticide using two probe method. From the op amp this voltage gain goes to the comparator 1 to compare the voltage gain with the default voltage set previously. If the sampled voltage is less than the set voltage for the presence of pesticide, then the LED 1 will not glow. That indicate the sample voltage level is lower than that of the presence of any level pesticide. On the contrary, if the LED does glow it indicated that the sample voltage is higher than the corresponding level and there is pesticide in the sample. This way four voltage levels are set for four pesticide level detection. The LED indicated the level of TSP or Pesticide present in a sample soil. In case of comparator 2 if the voltage gain of the sample is greater than the set voltage level than the LED 2 would glow indicating the pesticide level of corresponding circuit. As we are detecting different level of fertilizers and pesticides so different voltage levels were set in the comparators. If the voltage level of a sample is greater than the set voltage LED will glow. Two LED are used to show the output of corresponding comparator. Two comparators are used in a circuit, show the result by comparing between the default voltage and set voltage as a result presence of any two level of pesticide can be determine at a time. So we might have to test sample with all circuit to get accurate result.

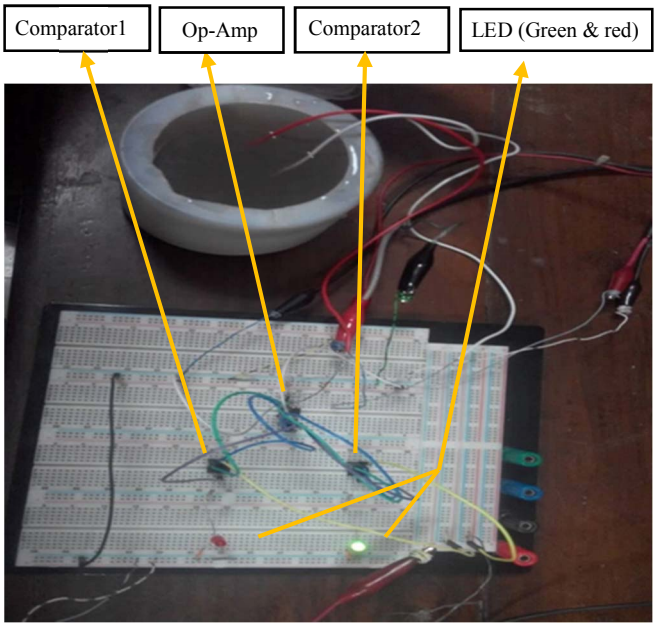

Fig. 9(a): Hardware implementation of the fertilizer and pesticide (detection circuit)

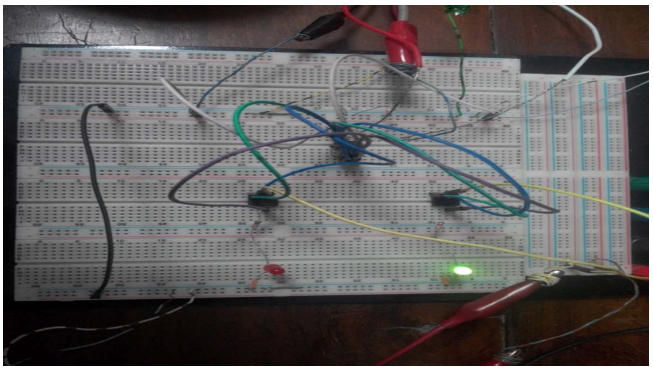

Fig. 9(b): Breadboard Setup (detection circuit)

Table 1: Components used to design the detection circuit

Components	Quantity
Op-amp (LM741)	4 pieces
Comparator (LM741)	16 pieces
Resistor	24 pieces
LED	8 pieces
Breadboard	4 pieces
TSP	1 kg
Urea	1 kg
Male to male jumper wire	40 pieces

Co-axial cylinder probe was used to detect the pesticide. Coaxial cylinder method is more accurate than two wire method.

Fig. 10: Co-axial cylinder probe (Lateral view).

Fig. 11: Co-axial cylinder probe (Top view).

V. Simulation Result

Before implementation of hardware part, simulation was done by National Instrumentation Multisim. The simulation shows that Led 1 is flickering and current is 2.513 mA and other 2 led is off so showing 0 A.

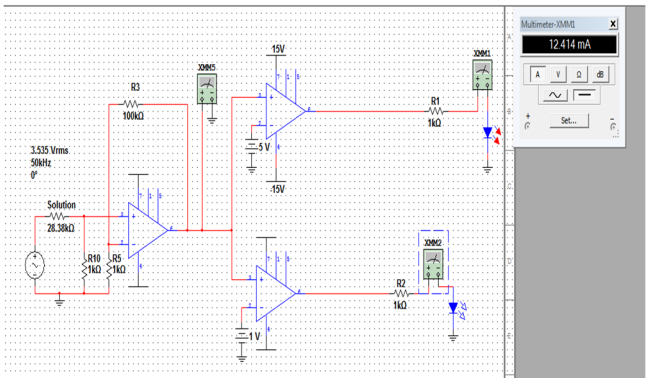

Fig. 12: Simulation for 30% level of the solution (TSP).

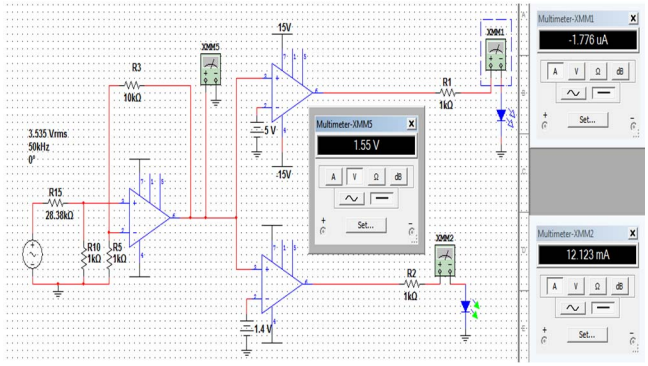

Fig. 13: Simulation for 50% level of the solution (TSP).

Fig. 12 and Fig. 13 are fertilizer solution (30% & 50%) simulation. Fertilizer solution has some resistance. For that solution resistance op-amp gives an output voltage. This output data is send to both comparators pin (3). Then the comparator which reference voltage is close to output voltage is changed by varying the power supply. And when the reference voltage matched with the output voltage of op-amp the corresponding comparator LED light turns ON.

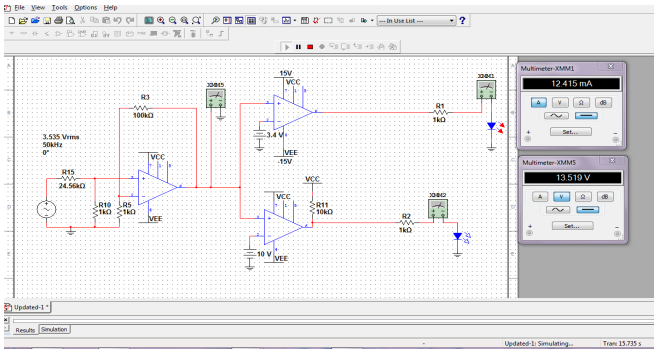

Fig. 14: Simulation for 1 drop (1ml) insecticide of the solution.

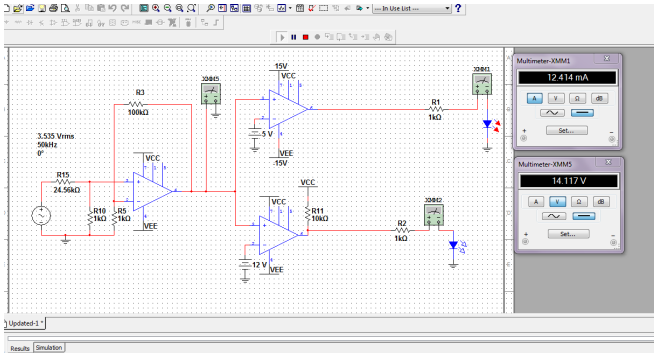

Fig. 15: Simulation for 2 drop (2ml) insecticide of the solution.

Fig. 14 and Fig. 15 are insecticide solution (1 drop & 2 drop) simulation. Insecticide solution has some resistance. For that solution resistance op-amp gives an output voltage. This output data is send to both comparators pin (3). Then the comparator which reference voltage is close to output voltage is changed by varying the power supply. And when the reference voltage matched with the output voltage of op-amp the corresponding comparator LED light turns ON.

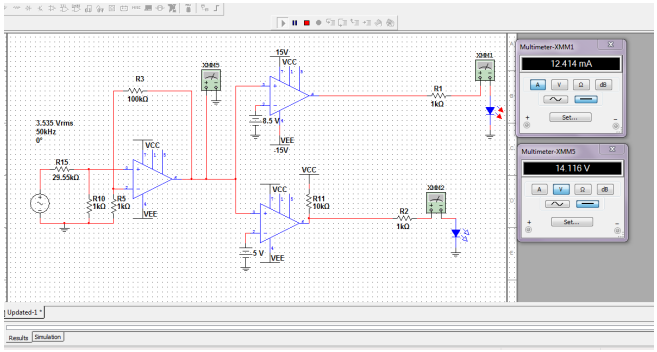

Fig. 16: Simulation for 50% (2gm) level of the solution (Fungicide).

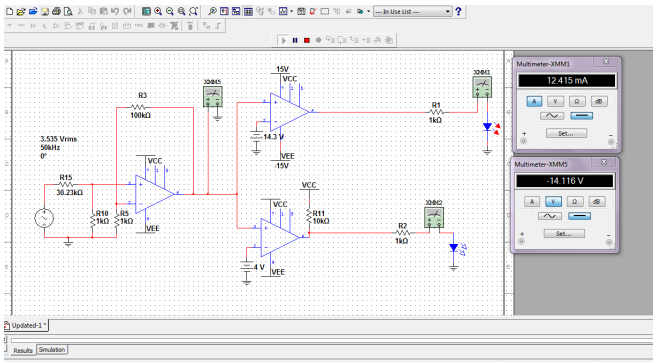

Fig. 17: Simulation for 100% (4gm) level of the solution (Fungicide).

Fig. 16 and Fig. 17 are fungicide solution (2gm & 4gm) simulation. These solution has some resistance (29.55 k-Ω & 30.23 k-Ω) . For that solution resistance op-amp gives an output voltage. This output data is send to both comparators pin (3). Then the comparator which reference voltage is close to output voltage is changed by varying the power supply. And when the reference voltage matched with the output voltage of op-amp the corresponding comparator LED light turns ON.

Table 2: Result of reference voltages

Vin	5V
The output voltage of the amplifier	2.5V
1st Comparator reference voltage (30%)	1.4V
2nd Comparator reference voltage (50%)	5V

In the case of a sample of 30% of a pesticide, the output voltage of op-amp was around 2.5V. As the reference voltage of 1st comparator was 1.4V which was less the output voltage of op-amp so the 1st LED was turned on. This 1st LED represents the presence of 30% of TSP pesticide in the soil. And the reference voltage of 2nd comparator was 5V which was for 50% of pesticide. It was higher than the voltage of op-amp which did not turn the 2nd LED. That means the presence of TSP pesticide in the soil is 30%. In the same way, we can also find the presence of a different level of TSP pesticides in the soil like 50%, 70%,100%.

Table 3: Referred voltages for a different level of solutions of TSP.

Level of solutions	Voltages (v)
30%	1.4 V
50%	5 V
70%	7 V
100%	11 V

The table given above is about the referred voltage of the different level of pesticide. One very important fact is that these referred voltages were measured from a solution of pesticide and water. If the sample was taken from field mixed with soil then the referred voltage seems to increase by 0.2~0.5 in each level. To get a better result it is observed that taking a sample of 5gm would be sufficient. The change in voltage level occurs due to the presence of other chemical compounds in the soil.

Table 4: Referred voltages for a different level of solutions of fungicide

Level of solutions (0.5 Liter water)	Reference Voltages (v)
1drop (1ml)	3.4V
2 drop (2ml)	5 V
3 drop (3ml)	10 V

Table 5: Referred voltages for a different level of solutions of insecticide

Level of solutions (0.5 Litter water)	Reference Voltages (v)
50%(2.0gm)	8.5V
70%(2.8gm)	9.5V
100%(4.0gm)	14.3 V

VI. Limitation & Future Enhancements

Every system has its limitations. This detection process has some limitations too such as it is only done for loamy soil. It can detect only two levels of TSP and pesticide at a time. In this process for each two level detection, one circuit is used. Presence of other chemical might affect the result.

As there has not been much work done in this domain in our country, so this would encourage new engineers to work in this domain. To take this work in the next stage what detection of all the level of pesticide can be done in one circuit. It would be challenging as using a couple of the number of the comparator and giving result through it would require using logic gate which leads to a challenge as logic gate do not work on AC voltage so a bridge rectifier has to be used in the process to convert the AC to DC. So using a more comparator would allow farmers to detect the different level of pesticide with one circuit.

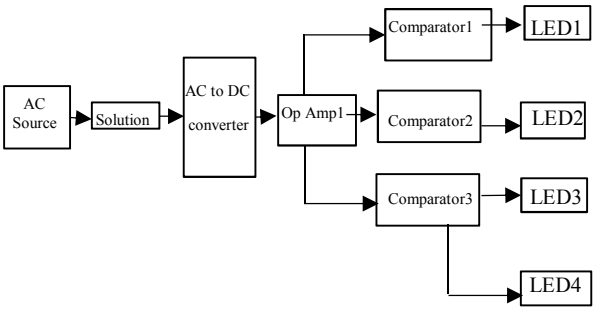

Fig. 18: Future proposed model (block diagram) which can detect 4 different levels of pesticide at a time.

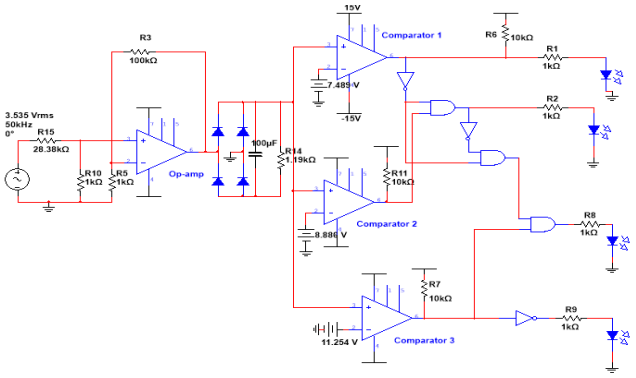

Fig. 19: Future proposed model circuit which can detect 4 different levels of pesticide at a time.

VII. Conclusion

This project was accomplished by detecting the amount of fertilizer presents in the given soil sample and pesticide in the water sample.However it not only indicates the presence of pesticide in sample but also it indicates the level of pesticide in the given sample. Conductivity property of TSP was used for the purpose of detection. This method of detection is very helpful for farmers and agricultural instructors as they can use this tool at a reasonable cost and use it easily. The wide availability of this project components is a major advantage in the case of manufacturing.

***Abstract*—This paper represents the performance analysis of liquid lens formed on the basis of electowetting principle. Electrowetting on Dielectric (EWOD) lens facilitates the conversion of lens from convex to concave without manual movement. The lens is designed with optimized dielectric layers and minimum damping oscillations. To characterize the performance of the lens, response time is considered. The simulation is conducted using the dielectric layer of polyvinylidene fluoride (PVDF) and hydrophobic layer of Teflon AF 1600, and the droplet of distilled water. The simulated optimized response time is approximately 28 ms with minimum damping oscillations for the high input voltage of 150 V and low viscosity of insulating fluid (0.01 Pa-s).**

Keywords—Electrowetting on dielectric (EWOD), response time, dielectric layer, damping oscillation, hydrophobic layer.

I. INTRODUCTION

The electrowetting on dielectric (EWOD) refers to a device where the movement of polar droplet is occurred electrically. This technique is applicable in modern technology because of no need of machanical movement [1]. Besides it also provides a huge range of tunability as well as faster frame rates and negligible power consumption [1]. Therefore, it is a perfect technique for the tunable focal lenses and miniature cameras [2]. Initially it was used only for industrial purposes but recently it applies for optical display, lab-on-a-chip (LOC) [3], optical switches with high rejection ratio, microscopy, remote sensing and even for biological applications including polymerase chain reaction, DNA replications [1]. Miniature cameras based on this technology can easily change from narrow to wide angle just by altering the electrical input.

Since decades high-speed focusing technology has been aimed for the above mentioned applications. However, the focusing speed of conventional optical systems is limited by the slow response time and requirement of moving parts manually [4]. To overcome this, the phenomenon of electrowetting was first invented by Lippman in 1875 [5]. This invention was an alternative to conventional lens with improved features of no moving parts as well as faster response time. Thus EWOD allows one bit of further flexibility in lens design.

Wide ranges of research have been conducted on EWOD lens. For instance, Ouyang et al. [6] showed an application of electrowetting principle where the shape and location of the droplet was adjusted which consecutively tunes the focal length and position of the lens. As possessing qualities such as tunability of focal length upto 20% along with low actuation voltage and low power consumption, it can be used as a lens. This idea clarifies the legitimacy of using EWOD devices as lens. Now-a-days, the research effort for EWOD lens is focused on the usage of lower viscosity's insulating fluid, optimized response time, and minimum damping oscillation. Moreover, Berge presented an experimental setup for liquid lens technology where more emphasis was put on the selection of suitable insulating fluid for centering of liquid lens [7]. The importance of the selection of proper insulating fluid with lower possible viscosity for stabilizing optical axis was shown here. Additionally, Park et al. [8] demonstrated a practical model of planner liquid lens where the range of input voltage was 0-200 V and in accordance with this, the confined Si-oil changed the droplet's shape. Here the tunability of focal length from 12 mm to 22 mm with a 3 mm diameter of liquid lens was tested. In another work, Supekeret [9] used parylene HT and Teflon as the dielectric, and found the response time ranging from 115-500 ms with DC driving voltage of 0-28 V. The effect of DC driving voltage function on the response time of EWOD lenses was observed. Similarly, the response time for the almost same setup was found approximately 36.5 ms where parylene C, LiCl, Si-oil were used [10]. Thus, it is clear that the modification of the materials can change the result.

In this work, a EWOD lens is designed and simulated. A new dielectric material with different layer configuration of lens is used to improve the system performance. Though Nb_2O_5 or CEP, both have higher dielectric constant, they are not convenient for biological applications because of their toxic property. Thus, polyvinylidene fluoride (PVDF) is chosen as a dielectric. The EWOD lens made by PVDF can also provide lower response time.

Though, in previous work, a multi-layer dielectric coating with PVDF was used on EWOD device to reduce the actuation voltage [11], a PVDF layer along with a hydrophobic layer (Teflon AF 1600) is used here for a EWOD lens to change the droplet's actual shape as well as lens's focal length and magnification. Hence the response time is minimized and the oscillation is optimized. The paper is organized as follows: Section II shortly describes the theory of EWOD lenses and presents the proposed design approach. Section III represents the simulation results and discussion with a comparative study of the existing works, and finally, Section IV concludes the remarks.

II. Theory of Liquid Lens and Design

A. Basic Principle of EWOD Lens

An EWOD device consists of a substrate layer as base, electrode's array, a dielectric & a hydrophobic layer [12]. A conductive liquid is used as a droplet of precise volume and density on the electrode's surface. This surface is surrounded by either air or an immiscible media (e.g. Si-oil) to prevent the volatilization of the droplet. The droplet indicates a lens characteristics because it owns a rotational symmetry around its principal axis. Theoretically, the relationship between the focal length (f) and contact angle (θw) by [14]:

$$cos\theta_w = cos\theta_0 + \frac{\epsilon_0 \epsilon_{rd} \epsilon_{rh} V^2}{2\sigma(t_{d1} \epsilon_{rd} + t_{d2} \epsilon_{rh})} \quad (1)$$

Where, θ_0 = initial contact angle, θ_w = actuated contact angle, ϵ_{rd} = dielectric constant of dielectric layer, t_{d1} = thickness of dielectric layer, ϵ_{rh} = dielectric constant of hydrophobic layer, t_{d2} = thickness of hydrophobic layer, σ = surface tension at the interface between two fluids, and V = applied voltage. In addition, the relationship between the focal length (f) and contact angle (θ_w) of an EWOD lens is given by [13]:

$$f^3 = \frac{3V}{\pi(1 - cos\theta_w(2 - \cos^2\theta_w - cos\theta_w)(n_0 - n_g))} \quad (2)$$

Here, V = volume of the droplet, n_0 = refractive index of oil, and n_g = refractive index of droplet. The relation shows that the contact angle decreases with the increase of applied actuation voltage and as the contact angle decreases, focal length increases consecutively [15]. Moreover, increased focal length implies more magnification i.e., zoomed in view whereas decreased focal length implies zoomed out view [16].

In terms of adaptive liquid lens, response time is an important factor. It includes both rise time and falling/settling time. Basically response time is the time required for a generic system to react to a given input. The following equation shows a relationship of the response time during droplet actuation.

$$V(t) = V_0\left(1 - e^{-\frac{t}{\tau}}\right) \quad (3)$$

Where, t = response time, τ = input rise time. Besides, in physical system, stored energy is dissipated through damping. So, it is required to optimize the damping oscillation as well as response time to achieve an optimized performance of a liquid lens.

B. Design Procedure

The proposed model is designed using two different fluids, such as polar and non-polar. Though both fluids contain similar density, however the polar liquid acts as a liquid lens. Here, distilled water is used as polar liquid and Si-oil is used as non-polar liquid. A single droplet of the polar liquid is placed inside of a glass tube, which is coated with an Indium Tin Oxide (ITO) electrode, a PVDF dielectric, and a 1wt % Teflon AF 1600 hydrophobic coating. In this work, the interior wall of the glass tube is made with a 200 nm thick layer of ITO which is an optically transparent and works as an electrode. Since the main focus is on the effect of dielectrics of EWOD device, so more emphasis is given on the properties of the dielectric layers and their thicknesses. The thickness of dielectric layer and hydrophobic layer are selected as 3 μm and 1 μm respectively. Additionally, non-polar liquid is filled on the top of the droplet to prevent the volatilization. Then, a DC driving voltage is applied between the droplet and the electrode for actuating the liquid lens. In order to design and simulate the proposed liquid lens, FEM software package of COMSOL Multiphysics 5.3 is used. The numbers of features for creating geometric primitives are provided in this software package. The schematic diagram of the design including all the parameters of liquid lens is shown in Fig. 1.

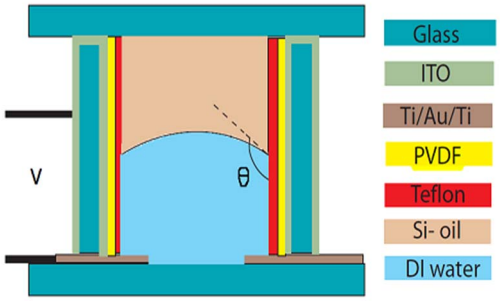

Fig.1. Schematic diagram of a EWOD liquid lens.

The solid structure of the design is obtained by taking the geometrical properties of 1.5 mm square and Bezier polygon (Fig. 2). Bezier polygon are basically a set of segment of polygon which has two rows divides as row 1 and row 2 (where, R = 1.55 mm and z = 0.76 mm). All properties of this polygon are chosen under the linear phase. Then the lens is filled by a polar liquid (distilled water) and a non-polar liquid (Si-oil) with the same density of 1000 kg/m3 at the temperature from 0 degree to 10 degree. The material properties for both polar and non-polar liquids are given as follows (Table I):

Fig.2. Geometrical structure of the liquid lens.

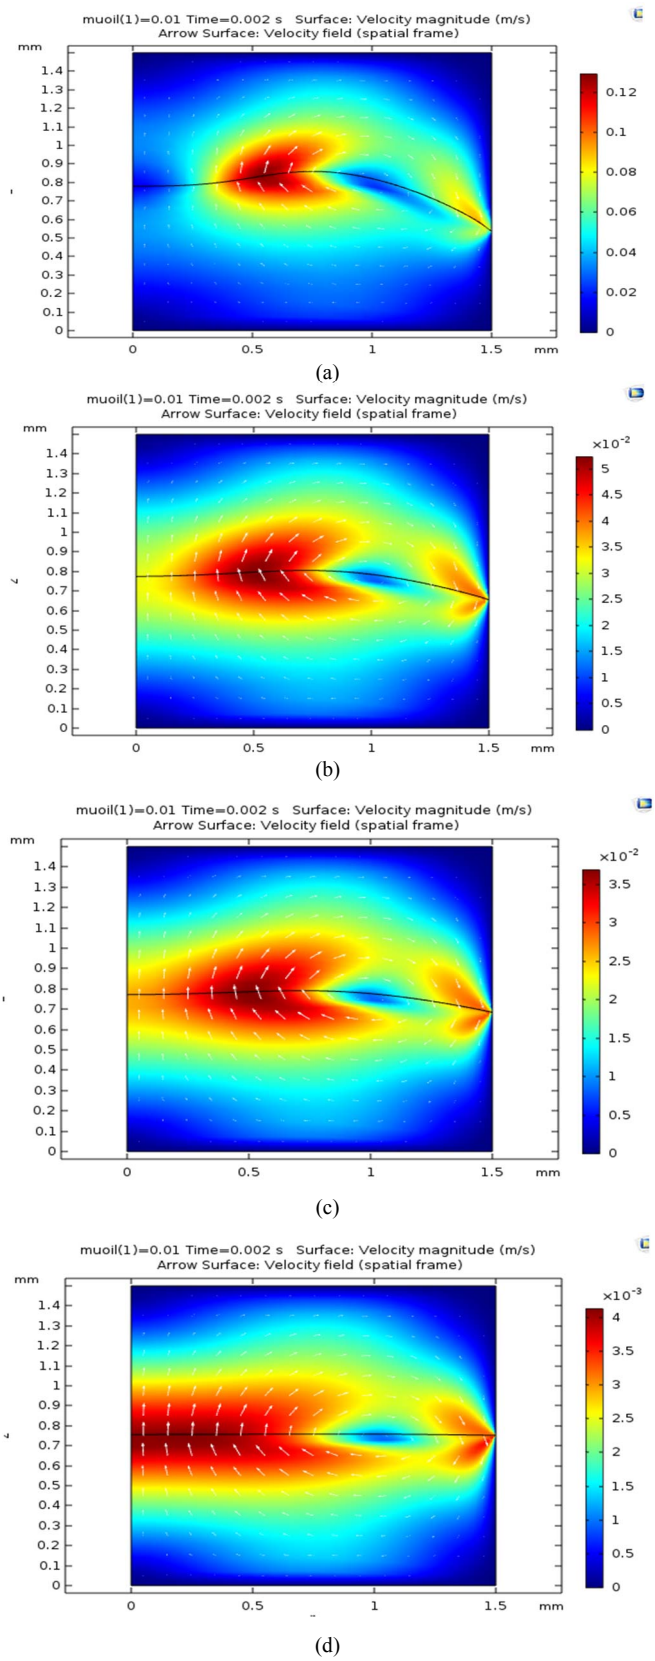
TABLE I. Material Properties of Liquid Lens Used in The Model.

Material	Properties	
	Density	***Dynamic Viscosity***
Conducting fluid (distilled water)	1000 [Kg/m^3]	1.57×10^{-3} [Pa-s]
Insulating fluid (Si-oil)	1000 [Kg/m^3]	muoil[a]

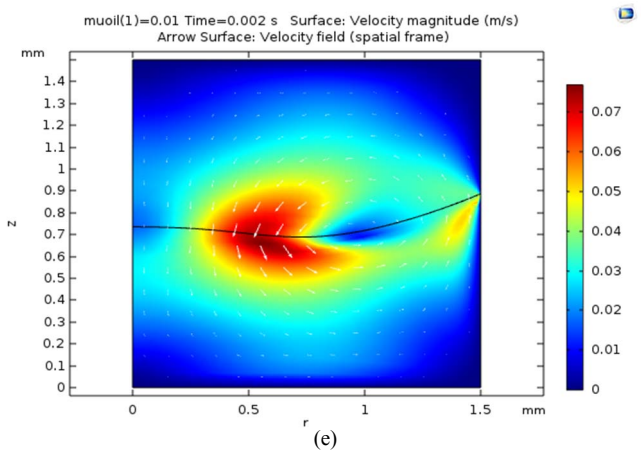
[a]muoil is varied from 0.01, 0.03, and 0.05[Pa-s].

Thus, for designing the model, firstly, the values of the parameters are defined in accordance with the geometry. The essential variable in this simulation is the contact angle, which varies directly with the applied voltage. The apparent contact

angle of the distilled water droplet on the Teflon coating is approximately 152 degree without any applied voltage. This angle is determined by the balance of forces at the contact points. In this work, the surface tension at the interface between two fluids is 0.049 N/m.



III. Simulation Result and Discussion

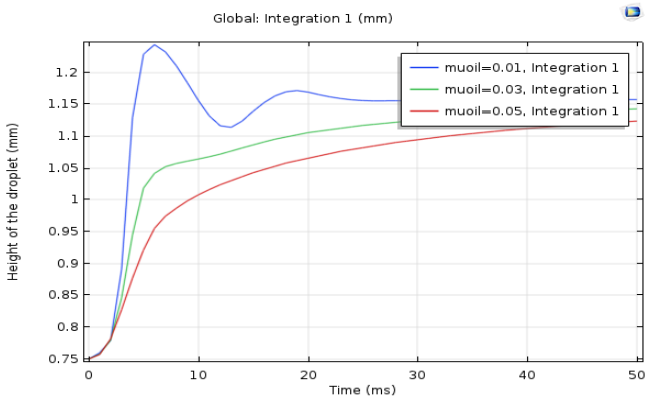


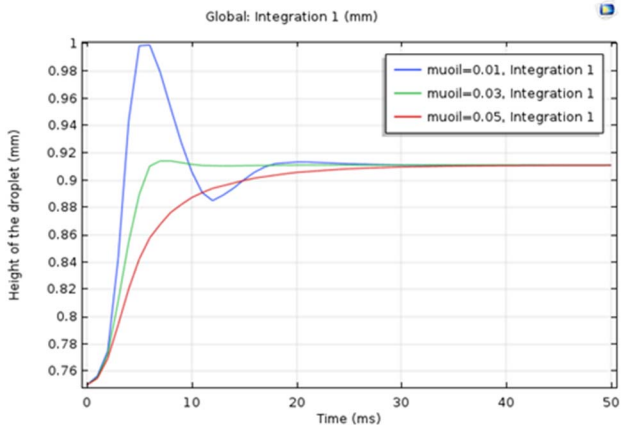
In this work, the FEM based COMSOL software is used in order to understand the temporal dynamics of our proposed lens. The simulation process is performed in two steps: (i) by adding a parametric sweep to the insulating fluid's viscosity and (ii) then defining the ranging of oscillation by adding a proper timing interval. It is desired to optimize the viscosity of the insulating fluid to achieve a faster response time. Thus, the range of viscosity is kept in between $10e^{-3}$, $30e^{-3}$, and $50e^{-3}$, whereas the time is taken in between 0, $1e^{-3}$, and $50e^{-2}$. The input voltage is switched from 0 V to 150 V. Therefore, the variation of the contact angles are achieved which is shown in Table II. It is clear that if the applied voltage increases, then the contact angle decreases, which justifies the theory. At higher voltage, the contact angle of the lens is significantly reduced. For example, at 120 V, the achieved contact angle is 91 degree or 1.59 rad.

TABLE II. VARIATION OF CONTACT ANGLES

Voltage [V]	0 V	30 V	60 V	90 V	100 V	120 V	150V
Contact angle [rad]	2.65	2.55	2.3	1.98	1.86	1.59	1.09

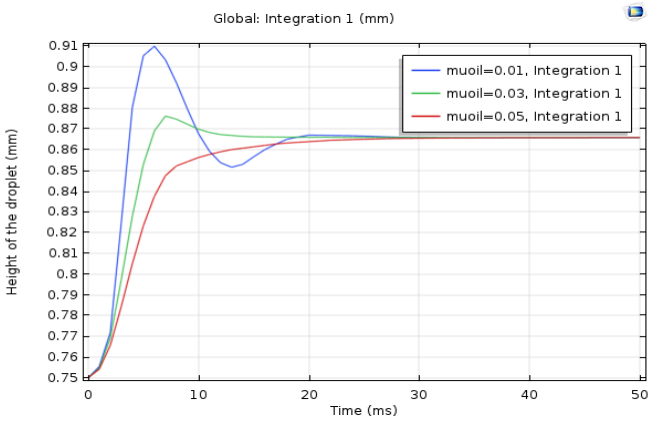
The total pressure withstood is found at a constant range as the water droplet in a Si-oil medium are confined into a chamber and driven together against a known pneumatic pressure until any advance forward. However, the velocity does not follow this consistency. The velocity of a fluid effectively describes everything about the motion of a fluid. At the initial condition, the internal force keeps the shape of the droplet fixed. When 0-60 V of the voltage is applied, then the velocity of fluid is observed as 0-0.12 ms^{-1}, indicating the convex shape of the droplet. Therefore, the droplet is started to change the shape and at the applied voltage of 90 V, the velocity of polar liquid is decreased which indicates a flat shape within a congested medium. The droplet exhibits a more flat shape with the reduction of velocity at 100 V. The absolute flat shape is obtained at 120 V of input potential. Furthermore, the highest velocity of 0.07 ms^{-1} is obtained at the applied voltage of 150 V. The velocity increases toward the center of the sealed chamber under the conditions of the laminar flow. This indicates the actuation of the droplet from flat to concave shape. All the numeric figures are obtained from COMSOL simulation. The fluid velocity as well as the change of curvature at different voltages is shown in Fig. 3.



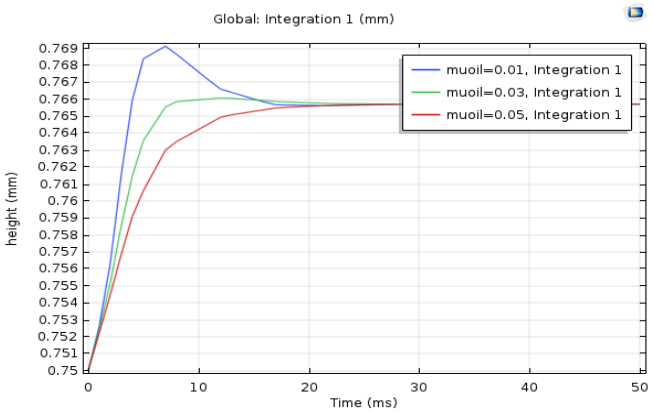


(e)

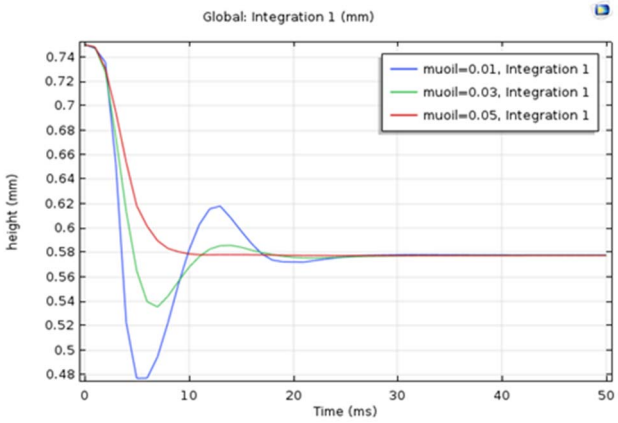
Fig. 3. The fluid velocity as well as the change of curvature at different voltages (a) 0 V, (b) 90 V, (c) 100 V, (d) 120 V, and (e) 150 V.



In addition, the plot of the response time at different actuation voltages is given in Fig. 4. It is clearly noticed that at minimum viscosity of 0.01 Pa-s, the achieved faster response time is approximately 36 ms. When the voltage is increased, the achieved response time is decreased. At the voltage of 150 V, the response time is obtained as 28 ms. The measurement of the response time is prepared with the help of Microsoft excel. Moreover, the damping oscillation at a particular voltage is be gathered by the output graphs obtained by the simulation software.



(a)



(b)

(c)

(d)

(e)

Fig. 4 : The response time at different actuation voltages of (a) 0 V, (b) 90 V, (d) 100 V, (d) 120 V, and (e) 150 V.

These simulation curves represent the change of the droplet height with respect to time from convex at 0 V (initial) to flat at 120 V to concave at 150 V with rising and settling time as well damping oscillations. Initially, the droplet exhibits a convex shape into the sealed chamber with a high damping loss. At 90-100 V, the droplet indicates a flat shape where the damping loss is partly minimized. Absolute flat shaped lens at 120 V is obtained with minimum damping oscillation to get distortion free imaging. And finally, at the highest applicable voltage of 150 V, the concave shape with a satisfactory amount of damping oscillation is achieved. Thus, the lens transformation from convex to flat to concave without any manual movement is attained using this principle.

This proposed design has better performance criteria in terms of response time. As in [9], the obtained response time was 500 ms at the maximum voltage of 28 V where the double layered (parylene HT and PTFE) EWOD lens was implemented. Moreover, the proposed design provides better performance than [10] too. The use of high dielectric material of PVDF provides a better response time of 28 ms, whereas the response time was 36.5 ms in [10]. Besides, our model has a good tolerance of voltage, it can withstand more than 150 V whereas the operation voltage limits was only 120 V in [10]. Thus the requirement of the lower possible response time is obtained by this proposed design.

IV. CONCLUSION

The principle of EWOD lens has been showed with the aid of simulation software COMSOL Multiphysics 5.3. System response time can be tuned from overdamped to underdamed with the reduced viscosity of Si-oil which indicates the change of the shape of liquid lens from concave to flat to convex without any mechanical parts. Moreover, our proposed model possesses a very good tolerance limit which allows it to perform at high actuation voltage with minimum response time and damping oscillation. Since the design of our EWOD lens is a simulated work, an experimental evaluation is needed to verify the simulation results and demonstrate the operation of the proposed EWOD lens. Although the fabrication procedure of the EWOD lens might be taken an additional cost, however this phenomenon can be very effective in the real time biological applications.

***Abstract*—In this work, by employing self-consistent solver we study Capacitance-Voltage (C-V) characteristics and the threshold voltage variation of p-type Rectangular Gate Junctionless Field Effect Transistor (RG-JLFET) and Double Gate Junctionless Field Effect Transistor (DG-JLFET). The self-consistent solver solves Schrodinger-Poisson equations with appropriate boundary conditions and takes wave function penetration and other quantum mechanical effects into account. We compare the effect of device parameter variation (such as channel thickness, oxide thickness and doping concentration) on threshold voltage control for both transistor structures. Physical explanations of the found results are also provided.**

***Index Terms*—Junctionless Field Effect Transistor, Threshold Voltage, Gate Capacitance, C-V curves, Self-Consistent Schrodinger- Poisson Solver, Multi-gate Transistors, Rectangular Gate, Double Gate.**

I. Introduction

The Junctionless Field Effect Transistor (JLFET) is a transistor without any physical p-n junction in the body region. The transistors have a heavily doped Silicon channel which in our case is p-type doping. The channel is covered by a thin Silicon Dioxide layer. In the outer most layers there is a Poly-silicon layer which is n-doped. This n-doped Poly-silicon acts as the gate of the transistor. We can see the cross-sectional view of the studied structures in Figure 1 & 2.

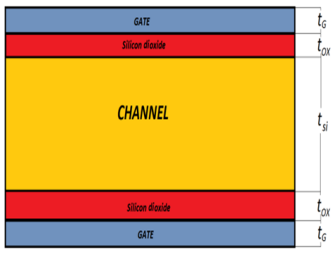

Fig. 1: A 1D cross-sectional view of Double Gate (DG)-JLFET. The cross-sectional view is perpendicular to the transport direction. For the devices, the channel thickness is 10 nm and the SiO_2 thickness is 2 nm.

The reason behind working on JLFET is that it has a huge advantage compared to regular MOSFETs against Short Channel Effects (SCEs). Also, the Multi-gate structures provide better performance against Short Channel Effects (SCEs)

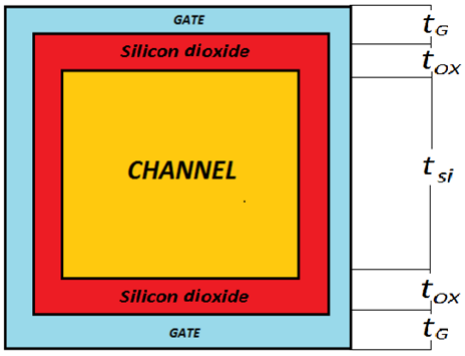

Fig. 2: A 2D cross-sectional view of Rectangular Gate (RG)-JLFET. The cross-sectional view is perpendicular to the transport direction. For the devices, the channel thickness is 10 nm and the SiO_2 thickness is 2 nm.

compared to single gate structure. Form [1] and [2], we know that the SCEs of a device is reduced if the gate length of the device is 6-10 times larger than its natural length (λ). Moreover, the natural length (λ) is related to its effective number of gates (n) in an inverse manner. If number of gates (n) is increased natural length (λ) will be decreased [1]. Then again with same Silicon thickness, the number of gates (n) is inversely proportional to the variation in threshold voltage ($\Delta V_{\rm th}$) [3]. In recent literature, there are already some works for p-doped JLFET on finding the threshold voltage using analytical models [4]. But most of them were done without considering any Quantum Mechanical (QM) effect. Previously, a comparative study on threshold voltage and Capacitance-Voltage (C-V) characteristics incorporating QM effects was done for the n-channel Double Gate (DG)-JLFET and Rectangular Gate (RG)-JLFET [5]. Because the electrostatic properties of n-MOSFET and p-MOSFET were found to be behaving differently [6], so it is necessary to do QM incorporated study for p-channel JLFET and compare the results with the study in [5]. In present work, a self-consistent solver incorporating QM effect like wave function penetration was used to evaluate the Capacitance-Voltage (C-V) characteristics for both DG-JLFET and RG-JLFET considering p-type doping. The threshold voltages have been obtained from the

Capacitance-Voltage (C-V) characteristics for both structures. And by varying the Silicon thickness (t_{si}), oxide thickness (t_{ox}) and doping concentration (N_a) of these structures, the variation in threshold voltage i.e. $\Delta V_{\rm th}$ have been obtained. The structure that had lower variability in threshold voltage ($\Delta V_{\rm th}$) was found out. Lower variability in threshold voltage means better control over channel potential. The device which had the lower $\Delta V_{\rm th}$ will have higher number of gates (n) and for that reason, it will also have lower natural length (λ) which eventually leads to better performance against Short Channel Effects (SCEs). In study [5] it was found that n-channel RG-JLFET was better in terms of SCE control over n-doped DG-JLFET. It is the target of this study to find out if the change in dopant type (p-doping) results in similar or different variation for increased confinement of JLFET device.

II. SIMULATOR MODEL

A coupled Schrodinger-Poisson equation was solved in order to compare the properties of both structures by self-consistent analysis [7]. To include the wave function penetration effects at the Si/SiO_2 interface open boundary condition had been used. In the case of DG-JLFET, the gates are placed on two sides of the channel. As a result, 1D Schrodinger-Poisson equation was solved for DG-JLFET. But for RG-JLFET, the gates are all around the channel (four sides) and because of that 2D Schrodinger-Poisson equation was solved for RG-JLFET.

A. Self-Consistent Analysis:

The Poisson's equation, as we all know, is,

$$\nabla(\varepsilon \nabla V) = -\rho \tag{1}$$

Here V is electrostatic potential, ρ = q[N_d-N_a+p-n] is charge density and ε is the permittivity of the substrate. N_d, N_a, p and n are donor density, acceptor density, hole concentration and electron concentration respectively. For the depletion region of p-type, ρ = q[-N_a + p] and if it is not depleted then, ρ = qp. Here, q represents charge of a hole.

The effective mass approximation can be found by the general form of Schrodingers equation and the equation is,

$$\left(\frac{-\hbar^2}{2m^*_{ds}}\nabla^2 + qV(r)\right)\psi(r) = E_j\psi_j(r) \tag{2}$$

Here, m^*_{ds} is the effective mass of holes. E_j and ψ_j are respectively the maximum energy and corresponding wave function of the j-th valance sub-band. Using (2) we determine the normalized ψ_j. Then in the j-th sub-band, the hole concentration is given by,

$$p_j = |\psi_j|^2 \int_{-\infty}^{E_j} g_j(E)[1 - f_{FD}]dE \tag{3}$$

Here, g_j(E) is the j-th sub-band Density-of-States (DOS) for valance bands and f_{FD}(E) is the Fermi-Dirac distribution function.

B. Finding the Capacitance and the Threshold Voltage:

The self-consistent analysis is converged and the coupled Schrodinger-Poisson is solved for the overall charge density. The equations are

In case of DG-JLFET :

$$Q = q\left[\sum\nolimits_j \int_0^{t_d} p_j dx - N_a t_d\right] \tag{4}$$

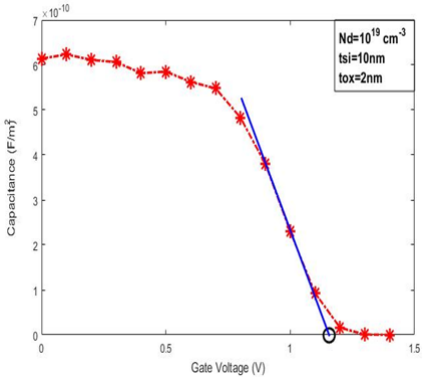
In case of RG-JLFET:

$$Q = q\left[\sum\nolimits_j \iint_0^{A_d} p_j(x,y)dxdy - N_a A_d\right] \tag{5}$$

Here, N_a is acceptor concentration, t_d is the depletion width and A_d is the depletion area. We calculate the gate capacitance per unit area (DG-JLFET) and per unit length (RG-JLFET) and it is expressed as,

$$C = \frac{dQ}{dV_{gate}} \tag{6}$$

To determine the threshold voltage we have to draw a suitable tangent at the partial depletion region of the C-V curve and then extend it toward the gate voltage (V_{gate}) axis [8]. At a certain point, the tangent intercepts the gate voltage axis and this is the voltage where charge contribution from free holes starts to dominate (figure 3). And this point is used to determine the threshold voltage of both structures [8].



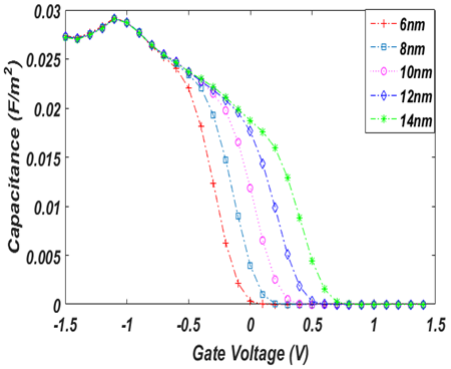


Fig. 3: Threshold voltage (V_{th}) extraction from C-V curve.

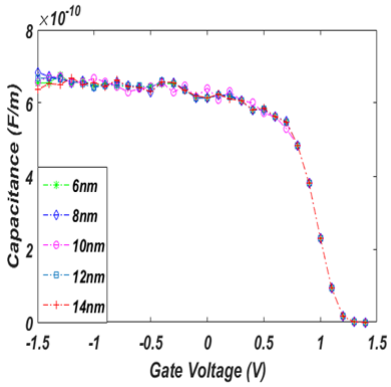


III. RESULT AND DISCUSSION

From our developed simulator, we have established C-V characteristics curves for both RG-JLFET and DG-JLFET. Figure 4 shows how the C-V characteristics of both structures are being changed by varying channel thickness (t_{si}). All three regions of operation of both structures have been shown in the figure. We get the full depletion region where the gate capacitance (C) is zero. When the mobile holes begin to gather then the capacitance (C) starts to rise. When it crosses a minimum value, then a channel is created. The partial depletion region can be found when the C is rising steadily to its maximum. At the Flat Band voltage V_{FB}, C reaches its maximum value for DG-JLFET $\left(C_{max} = \frac{2\varepsilon_{ox}}{t_{ox}}\right)$.

From the figure, we see that the maximum value does not depend on the Silicon thickness after a certain point. But in case of RG-JLFET, the capacitance rises steadily to maximum after full depletion. At V_{FB}, C reaches its maximum value $\left(C_{max} = \frac{\varepsilon_{ox} Perimeter_{gate}}{t_{ox}} = 4\varepsilon_{ox}\frac{t_{si}}{t_{ox}}\right)$ and in the Accumulation region it remains there (or very slowly increases). From the figure we can see that the capacitance (C) in DG is in 10^{-2} range but for RG-JLFET it gets to 10^{-10} as the term is multiplied by t_{si} where t_{si} is in the 10^{-9} range. We can see from the fig. 4(b) the maximum value of C changes for RG-JLFET as we vary the Silicon thickness, but this variation is very small compared to n-doped case from study [5].

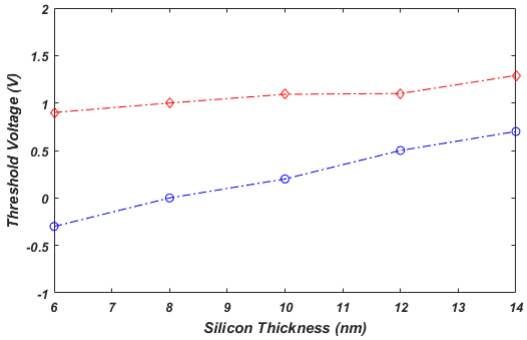
(a)

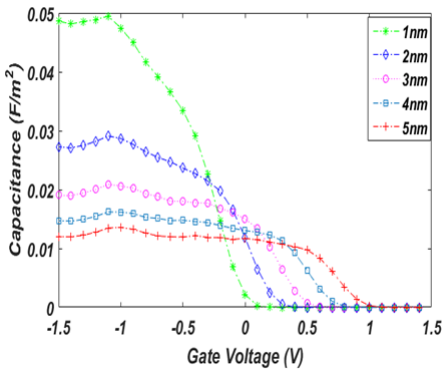
(b)

Fig. 4: C-V characteristic varying Silicon thickness (t_{si}) of (a) DG-JLFET and (b) RG-JLFET.

From fig. 5 for DG-JLFET, we see that as the t_{si} increases the threshold voltage also increases. There will be more acceptor charge in the channel with increased thickness. To create a channel at the center, more and more positive voltage is required at the gate to attract that extra charge to the surface as p-channel dopant acceptors are negative. But for the RG-JLFET, fig. 5 shows much smaller V_{th} variation than DG-JLFET as t_{si} varies. For RG-JLFET, the effect of varying channel thickness on threshold voltage is insignificant due to better control from gates on all side i.e. increased confinement.

Figure 6(a) shows the C-V characteristic of DG-JLFET, varying oxide thickness. From the figure, we can see that there are different maximum value for different oxide thickness for





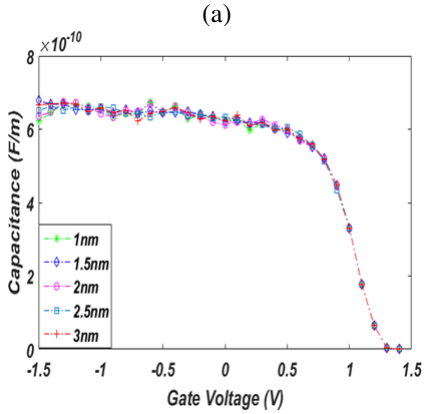


Fig. 5: The threshold voltage variation ($\Delta V_{\rm th}$) vs Silicon thickness for RG-JLFET (Red ◇) and DG-JLFET (Blue ○).

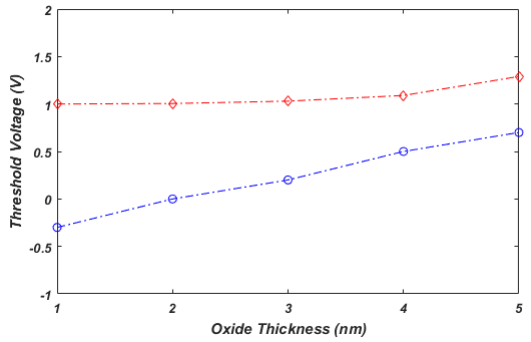
(a)

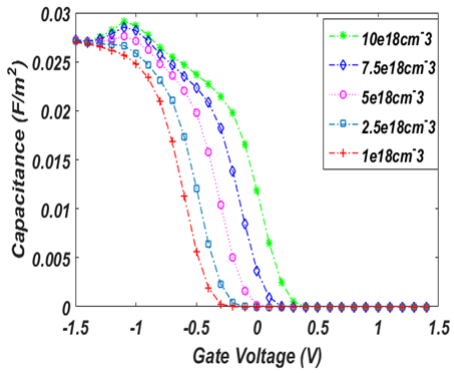
(b)

Fig. 6: C-V characteristic varying oxide thickness (t_{ox}) of (a) DG-JLFET and (b) RG-JLFET.

DG-JLFET. From figure 6(b) a similar scenario can be seen for RG-JLFET. The final value varied with varying oxide thickness. From figure 7, it can be seen that the V_{th} becomes more positive as the t_{ox} increases. This happens because the voltage drop across the oxide increases with the increase of t_{ox}. More positive V_{gate} is needed to create a channel. Here, in fig. 7, RG-JLFET again shows much better V_{th} control than DG-JLFET as t_{ox} varies.

But from fig. 8, it is noticeable that the final values of gate capacitance for both DG-JLFET and RG-JLFET remained almost same while N_a was varied.





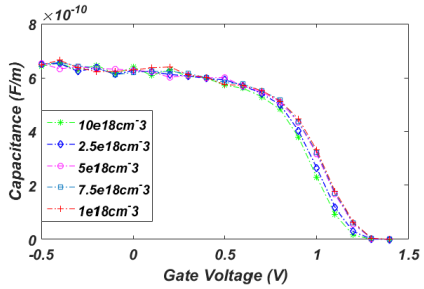


Fig. 7: The threshold voltage variation ($\Delta V_{\rm th}$) vs oxide thickness for RG-JLFET (Red ◇) and DG-JLFET (Blue ○).

(a)

(b)

Fig. 8: C-V characteristic varying doping concentration(N_A) of (a) DG-JLFET and (b) RG-JLFET.

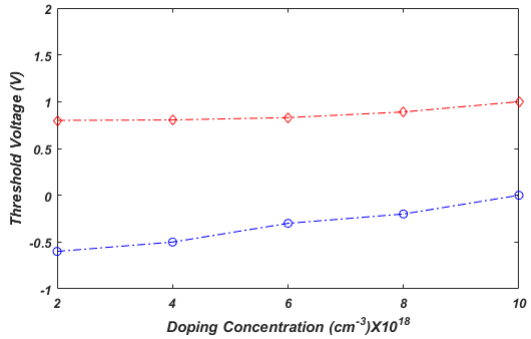

Fig. 9: The threshold voltage variation ($\Delta V_{\rm th}$) vs doping concentration for RG-JLFET (Red ◇) and DG-JLFET (Blue ○).

For each case, the V_{th} is calculated by the procedure which was stated in section II. But in fig. 9, it is clear that with the increase of N_a, V_{th} also increases. In this case, more positive voltage is needed at the gate to create a channel as there is more negative acceptor charge in the channel to be attracted so that the free holes can conduct in the center of the bulk. This is why V_{th} increases with the increase of N_a. Again RG-JLFET shows much better V_{th} control than DG-JLFET as N_a varies. Figure 5, 7 and 9 show that the variation in threshold voltage (ΔV_{th}) is greater in DG-JLFET than RG-JLFET with varying t_{si}, t_{ox}, and N_a. This is a confirmation of V_{th} being more sensitive in DG-JLFET than RG-JLFET with the change in t_{si}, t_{ox} and N_a. It means that DG-JLFET will have lesser control over channel potential than RG-JLFET. And the decrease in ΔV_{th} also proves that the natural length (λ) is lower and number of gates (n) is higher (which is obvious) in RG-JLFET then DG-JLFET which proves that RG-JLFET will be more efficient against Short Channel Effects (SCEs). All these observations are in line with the observations presented in study [5].

However, from figure 5, 7 and 9, it is evident that p-type RGJLFET has higher positive V_{th} then p-type DGJLFET. The reason is, to accumulate the free holes from the source and create a channel between drain and source at the body center, DG-JLFET has a one dimensional control (two-sided gate) whereas RG-JLFET has two dimensional control (four-sided gate). This is why to obtain the same amount of hole at the channel center, DG-JLFET needs more negative voltage at gate than RG-JLFET.

So higher quantum confinement means better control both in terms of accumulating holes at channel center and attracting acceptor dopant charges away from center towards the surface.

IV. Conclusion

For both JLFET devices structure threshold voltage (V_{th}) was calculated and compared by varying different parameters as Silicon thickness (t_{si}), oxide thickness (t_{ox}) and doping concentration (N_a). In that search, we found that with an increase of the given parameters, the V_{th} increases. In case of RG-JLFET, we show that threshold voltage variation ($\Delta V_{\rm th}$) is less than that of DG-JLFET. From this finding, we can conclude that RG-JLFET will perform better against Short Channel Effects (SCEs) and will have a better control over channel potential compared to DG-JLFET. Also we found that having better confinement resulted in a reduced need of negative gate voltage to achieve threshold condition for RG-JLFET compared to DG-JLFET. Thus, quantum confinement made controlling the occurrence of threshold condition easier for p-JLFET, similar to n-JLFET.

***Abstract*— In this paper, a simple D-shaped photonic crystal fiber (PCF) plasmonic biosensor is proposed and analyzed. The sensor performance is investigated by applying a mode solver based finite element method (FEM). The sensing layer and plasmonic metal (gold) layer both are deposited on the external upper plane surface for comfortable and easy fabrication. The sensor exhibits the maximum sensitivity of 8000 nm/RIU and 522 RIU^{-1}, and resolution of 1.25×10^{-5} RIU and 1.92×10^{-5} RIU using the wavelength and amplitude interrogation method, respectively, in the detection range between 1.45 and 1.48. Owing to the simple design and highly sensitive characteristics, the proposed biosensor can be precisely applicable for biomolecular analytes detection.**

Keywords— Surface plasmon resonance, Finite element method, D-shape Biosensor, Sensitivity.

I. Introduction

The devices that are associated with the detection of several analyte concentrations are well known as the biosensor. In optical sensing applications, surface plasmon resonance (SPR) bio-sensors are highly recommended. These sensors are most preferable and have been extensively applied to applications such as pharmaceutical diagnosis, antigen-antibody interaction, bio-imaging, food quality measurement, environmental observation, and so on [1]. In earlier SPR techniques, prism coupling based Kretschmann configuration with thin metal layer was introduced as the SPR sensors [2]. Because of bulkiness, excessive cost of optical and mechanical components, remote sensing limitations, and miniaturization roughness these types of SPR sensors are not preferable. To minimize these problems, in 1993 a fiber-optic based SPR sensor was proposed by Jorgenson [3]. The working principle of the PCF-SPR sensor described by the mutual interaction of surface electron and evanescent field. At a specific wavelength, the real part of the effective refractive index (n_{eff}) of fundamental core mode and surface plasmon polariton (SPP) mode becomes similar. Due to the effect of core-cladding evanescent field, emission of the electron occurs from the metal surface. As a result, the surface plasmon wave is created. Gold is preferred as the most attractive plasmonic material in SPR sensing [4]. Silver is another plasmonic metal [5] which faced oxidation problem. To measure the performance, it should be considered that the sensor shows more easy fabrication and highly sensitive characteristics. Huang proposed a *D*-shape SPR-PCF showing wavelength sensitivity of 6000 nm/RIU [6]. Therefore, excessive surface polishing increases fabrication difficulties. For external sensing purpose, Chakma *et al.* presented a sensor which showed the maximum amplitude and wavelength sensitivity of 318 RIU^{-1} and 9000 nm/RIU [7]. However, here the amplitude sensitivity is not so high in this sensor. Dual-core *D*-shape photonic crystal fiber has many excellent characteristics like flexible to design, easy to demonstrate, and light can be smoothly coupling with the metal surface.

In this paper, we proposed a highly sensitive SPR-PCF biosensor based on the gold coating on the upper planar surface. By applying the finite element method (FEM), numerical performances are investigated concerning wavelength sensitivity, resolution, amplitude sensitivity, the figure of merit (FOM), linearity, respectively. Varying structural parameters the sensing performances are also optimized.

II. Structure Design and Theoretical Basis

The schematic cross-sectional view of the proposed *D*-shaped PCF sensor is illustrated in Fig. 1. The PCF lattice designed with three hexagonal rings consisting of all circular air-holes. Two air holes are removed from the first ring to form a dual core. Most of the prior dual-core SPR sensors are demonstrated with circular PCF. In our design, we have efficiently applied the dual-core concept for *D*-shape PCF structure. Four air holes (two from the first ring and two from the second ring) are scaled down for the minimum gap between the sensing medium and core. Therefore, surface plasmons can interact with the metal surface easily.

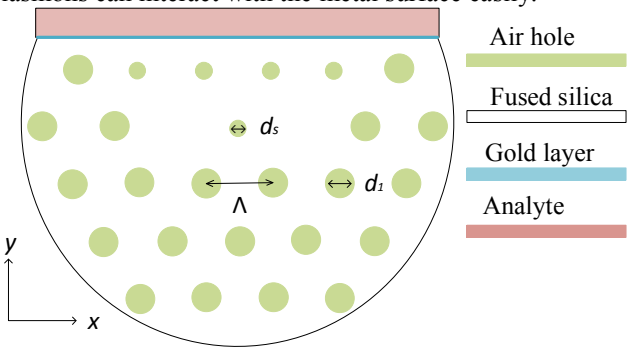

Fig. 1: Two dimentional view of the *D*-shaped PCF sensor with Λ = 1.9 µm, d_s = 0.25Λ, d_1 = 0.5Λ, and t_g=40 nm.

To form the *D*-shape, the top portion of the hexagonal PCF air-holes are removed. In this design, two adjacent air-holes center to center distance are symbolized as pitch (Λ), the diameter of smaller air holes is denoted as d_s, and d_1 denotes the diameter of larger air holes. Here, the parameters are fixed as, Λ=1.9 µm, d_s = 0.25Λ, and d_1 = 0.5Λ. The gold layer with the thickness (t_g=40 nm) is performed as the plasmonic material which placed at the plane surface of the sensor using chemical vapour deposition (CVD) method. Fused silica is selected as the background material. The Sellmier equation is used to calculate the complex refractive index (RI) of fused silica which is given by [7]. The dielectric constant of gold is obtained by the Drude-Lorentz model [7]. An analyte layer thickness of 1.5 µm was introduced during the simulation. The mesh parameters for the structure are introduced below. The structure contains total triangular elements of 17750 and mesh area of 97.76 µm2. Total vertex elements of 113 and edge elements of 1486. The average element quality of 0.9626 and the minimum element quality of 0.7694.

The modal analysis is carried out in *XY*-plane while the light is propagated in the *Z*-direction. *Y*-polarized propagation mode shows comparatively better light propagation intensity upon the gold surface. Hence, the evanescent incoming light can easily penetrate through the gold layer. So, we have considered *y*-component fundamental core mode for overall simulation purpose. The electric field, as well as resonance property, is given in fig. 2. Here, analyte RI is of 1.48. The real part of the RI of the *y*-polarized mode and SPP mode coincides at a wavelength of 1.30 µm. This wavelength is called the resonance wavelength. At that condition, we observe a sharp resonance peak that indicates the maximum energy transfers from fiber core to the plane surface.

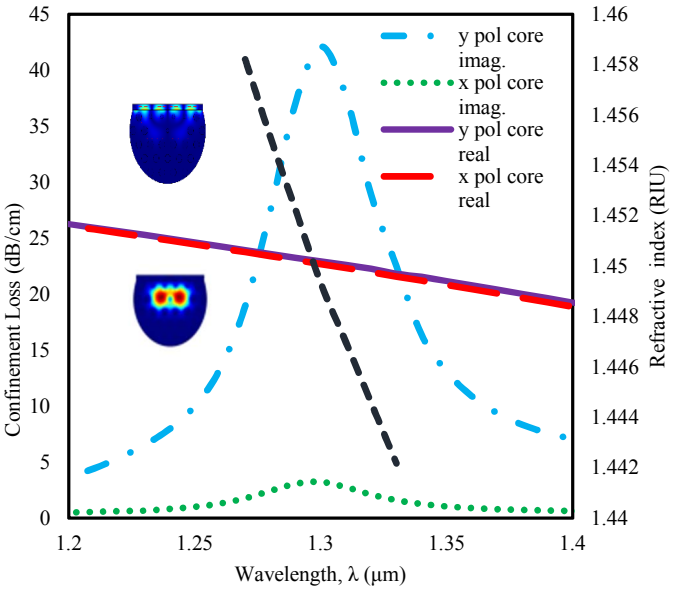

Fig. 2: Electric field distribution and dispersion relation of core mode and SPP mode with n_a = 1.48 and t_g = 40 nm.

Before assessing the characteristics of the PCF from a simulation, we checked fine and finer mesh numerical methods for to be sure about the precision which is shown in Fig. 3. From this figure, it is observable that the real effective refractive index for fine mesh element and finer mesh element are almost the same for a specific analyte RI. Therefore, we have considered finer mesh elements in our simulation to map the smaller air holes accurately.

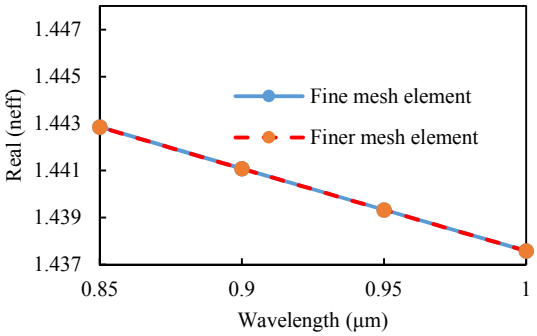

Fig. 3: Simulation for a different numerical method with fine and finer mesh elements.

III. SIMULATION AND PERFORMANCE ANALYSIS

A. Analyte variation and sensitivity

Confinement loss plays a significant role in sensing performance calculation which is obtained from the following equation [5]:

$$\alpha(dB/cm) = 8.686 \times k_o \, \mathrm{Im}(n_{eff}) \times 10^4 \qquad (1)$$

where *Im* (n_{eff}) is the imaginary part of the core mode index, k_0=2π/λ is wave number where λ is operating wavelength The variation of analyte RI profoundly influences the real part of the effective refractive index (n_{eff}).

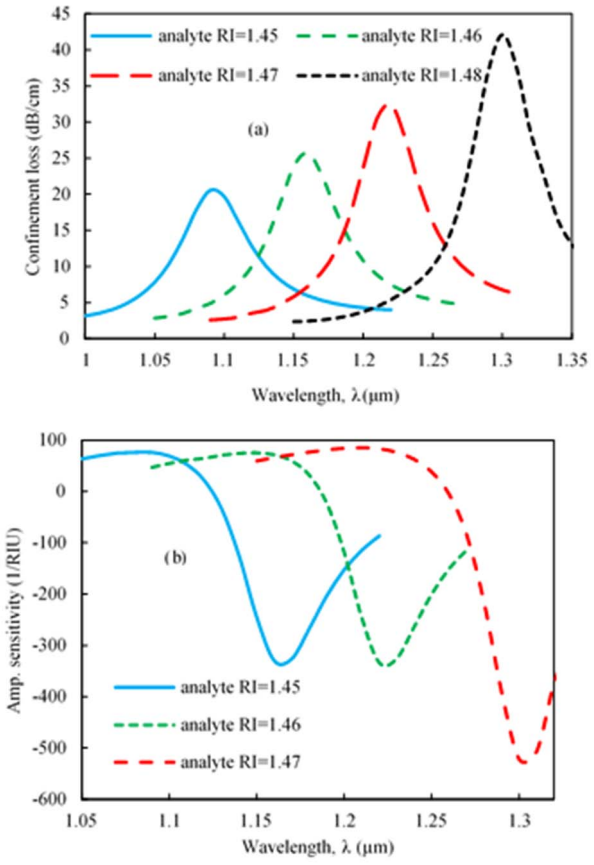

Fig. 4: (a) Analyte RI variation and loss from 1.45 to 1.48 and (b) amplitude sensitivity with Λ = 1.9 µm, d_s = 0.25Λ, d_1 = 0.5Λ, and t_g = 40 nm.

An unknown analyte can be easily detected with the small variation of RI with shifting of resonance point towards the higher wavelengths Fig. 4(a) shows resonance peak wavelength shift due to the variation of analyte RI from 1.45 to 1.48. For changing the value of n_a from 1.45 to 1.46, 1.46 to 1.47, and 1.47 to 1.48, the resonance wavelength is shifted from 1.08-1.15 µm, 1.15-1.23 µm, and 1.23-1.3 µm, respectively. Minimum confinement loss value of 20 dB/cm was found at 1.08 µm for analyte RI value of 1.45, and highest peak loss was observed at 1.30 µm is 45 dB/cm with the analyte RI of 1.48.

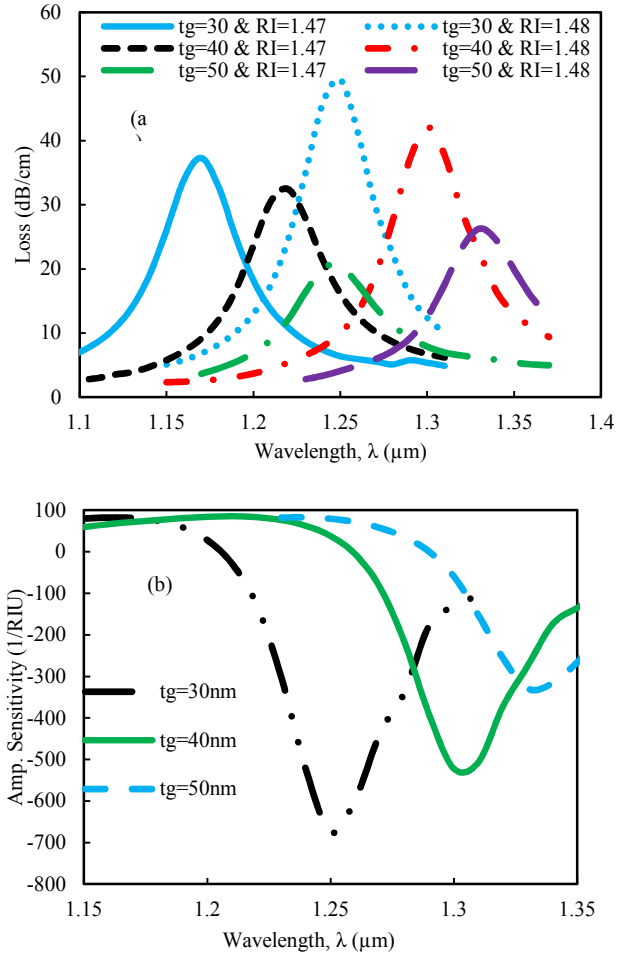

Fig. 5: (a) Gold layer thicknesses variation and loss for 1.47 and 1.48, and (b) Amplitude sensitivity with $\Lambda = 1.9$ µm, $d_s = 0.25\Lambda$, and $d_l = 0.5\Lambda$.

The PCF-based SPR sensor performance is measured in terms of sensitivity. The sensitivity of the proposed biosensor is obtained by using the wavelength, and amplitude interrogation method. The wavelength sensitivity can be calculated by the wavelength interrogation method using the following equation [5]:

$$S_\lambda(\text{nm/RIU}) = \Delta\lambda_{peak}/\Delta n_a \quad (2)$$

where $\Delta\lambda_{peak}$ denotes the wavelength peak variation, and Δn_a denotes the analyte RI change. The proposed sensor has a difference between peak and wavelength shift, $\Delta\lambda_{peak}$ of 70 nm, 80 nm, and 70 nm for RI variation Δn_a of 0.01, with changing of analytes RIs from 1.45-1.46, 1.46-1.47, and 1.47-1.48, respectively. Therefore, the theoretical wavelength sensitivities are computed of 7000, 8000, and 7000 nm/RIU, respectively. Another crucial parameter is the resolution of the sensor which shows how the sensor can detect a little change in the refractive index of an analyte. The following equation calculates the resolution [4]:

$$R\ (\text{RIU}) = \Delta n_a \times \Delta\lambda_{min}/\ \Delta\lambda_{peak} \quad (3)$$

Assuming $\Delta n_a = 0.01$ with $\Delta\lambda_{min} = 0.1$ nm, and $\Delta\lambda_{peak} = 80$ nm, the highest resolution of the *D*-shape sensor is found about 1.25×10^{-5} RIU. As a result, the proposed biosensor can be potentially detected analyte RIs variation of 10^{-5} order. To obtain the sensitivity, the wavelength interrogation method uses spectral manipulation which makes detection process complex but another process, amplitude variation can remarkably mitigate this problem by measuring sensitivity for a particular wavelength. The following formula defines the amplitude sensitivity [5]:

$$S_A = -\frac{1}{\alpha(\lambda, n_a)}\frac{\partial\alpha(\lambda, n_a)}{\partial n_a} \quad (4)$$

where $\alpha(\lambda, n_a)$ denotes the propagation loss and $\partial\alpha(\lambda, n_a)$ denotes the loss difference. Fig. 4(b) indicates the amplitude sensitivity curve for different analyte RIs. A maximum sensitivity of 522 RIU^{-1} is found at 1.30 µm wavelength with an n_a of 1.47. Besides, the amplitude sensitivity of about 330 and 333 RIU^{-1} are also found corresponding to the analyte RI of 1.45 and 1.46. Here, assuming 1% change of transmitted intensity, a maximum sensor resolution of 1.92×10^{-5} RIU is detected by the proposed sensor. The sensitivity of this proposed sensor can be comparable with the previously proposed work [5-8].

B. Gold Layer Variation and Sensitivity

Gold layer has a significant impact on sensing performance. The gold layer thickness (t_g) is tuned from 30 nm to 50 nm. Corresponding loss curve with analyte RI of 1.47 and 1.48 are given in Fig. 5 (a). We observed that increasing value of gold layer thickness increases loss depth. We also observed increment of gold layer thickness results a shifting of peak loss towards higher wavelength. The amplitude sensitivity of 700, 522, and 350 RIU^{-1} are obtained for the t_g of 30 nm, 40 nm, and 50 nm, respectively as illustrated in Fig. 5 (b). The physical reason for shifting of loss peak to the higher wavelength and decreasing of loss peak and amplitude sensitivity is of the reason for damping characteristics of gold. The frequency of the incoming light and the penetration depth are mutually proportional. Hence, the comparatively thin gold layer is the reason for better performance, and a thicker layer of gold decreases the sensitivity.

C. Linearity

A suitable sensor shows high linearity characteristics. Fig. 6 shows the linearity curve with analyte RI variation from 1.45 to 1.48. The following equation for linear line fitting can be written as y = 6.9x-8.916, where y represents the resonance wavelength, and x represents the analyte RI. The linear fitting characteristics of the proposed sensor shows the R-square value of about 0.9971 which indicates excellent linearity.

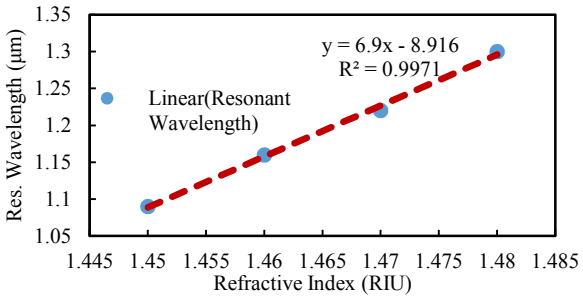

Fig. 6**:** Representation of line fitting properties of the sensor with varying n_a from 1.45 to 1.48.

Because of excellent line fitting properties, the suggested sensor can be a potential candidate for the liquid RI detection. The proposed *D*-shape PCF sensor can be practically implemented with the standard stack-and-draw fabrication process [15].

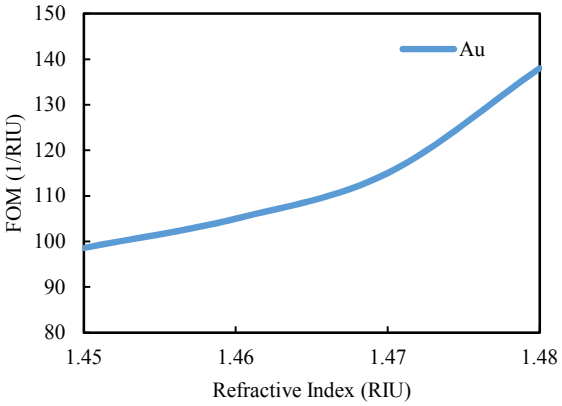

Fig. 7: FOM characteristics representation.

D. Figure of Merit

For the improved design, the signal to noise ratio (SNR) is an important parameter. The larger SNR can be the reason for smaller standard deviation with the variation of spectra. Moreover, the improvement of the SNR and spectral width will be a reason for a better detection range for the sensor, which can be formed with the term figure of merit (FOM). The FOM is obtained from [9]. During the simulation, the FOM of the designed sensor is obtained about 140 with a gold coating layer as shown in Fig. 7. Comparison with existing work has shown in Table 1.

TABLE 1: PERFORMANCE COMPARISON WITH THE EXISTING SENSOR.

Ref.	S_W (nm/RIU)	W_R (RIU)	S_A (RIU^{-1})	A_R (RIU)
Ref. [5]	4200	2.38×10^{-5}	300	3.33×10^{-5}
Ref. [7]	9000	----	318	1.11×10^{-5}
Ref. [8]	7700	1.29×10^{-5}	150	6.66×10^{-5}
Proposed Sensor	8000	1.25×10^{-5}	522	1.92×10^{-5}

IV. CONCLUSION

We proposed and numerically investigated the performances of a simple dual core *D*-shaped PCF sensor with the gold coating on its plane surface. The sensor with the gold layer is free from oxidation. The proposed PCF sensor requires less polishing effort, which potentially reduces fabrication difficulties. Sensing performance shows maximum wavelength interrogation sensitivity of 8000 nm/RIU and resolution of 1.25×10^{-5} RIU. Moreover, maximum amplitude sensitivity 522 RIU^{-1} and resolution of 1.92×10^{-5} RIU in the sensing range from 1.45-1.48. We believe that the proposed PCF can be considered as an ideal sensor for analytes refractive index detection because of its improved sensitivity and high linearity.

***Abstract*— Ternary Content Addressable Memory (TCAM) is a kind of extraordinary memory which is used to search operations in routers, firewalls, network address translators, and entire content in a single clock cycle. It is a special kind of memory which is used in highly reliable network applications. These systems require high reliability since a single error may interrupt any computation which may cause total system failure. However, TCAM is facing serious reliability challenges due to soft errors. The probability of soft errors in TCAM is increasing progressively due to alpha-particle, cosmic rays, high-vitality particles, and ionizing impacts of barometrical neutron. In order to minimize the risks of soft errors in TCAM, a new idea is proposed in this paper where the search key is constructed in a tricky way and the contents of the TCAM are ordered in a sequential pattern. The proposed method provides soft error tolerance with a low data overhead. Experimental study shows how the proposed method outperforms the existing method to tolerate soft error.**

Keywords— Soft Errors; Ternary Content Addressable Memory (TCAM); Memory Reliability; Error Correction Code; Don't Care Bits.

I. INTRODUCTION

Due to continuous downscaling of CMOS circuit, transistors are becoming very sensitive towards soft errors [1]. A little amount of charge can change the state level of a transistor, as a result of causing soft error [2]. Soft errors are matters of concern for electronic hostile systems and/or the systems which require high reliability [3], [4], [5]. TCAM which is one of the most essential components for networking devices and data transforming tool [6], are of high risks due to soft errors. TCAM is a vital tool for router, because TCAM helps to lookup entire routers, packet classification, and packet forwarding. It instantaneously compares the input data with the entire data saved in TCAM [7]. TCAM uses a special kind of data bit, named don't care bit (*), which has a binary value of 1 and 0 so that the data do not need to match exactly and it helps to speed up the networking process. If a smaller sized transistor is used in a high-speed memory of the networking device, it will be more susceptible to soft errors [8]. So, it is necessary to filter, encode, decode, and deliver data between sender and receiver without any soft error. Therefore, a soft error tolerant TCAM is extremely important as networking devices are used for dynamic communication setup [9]. However, TCAM dimensions and design practices are vital to face the challenges of soft errors. Due to increase of memory sizes, the chances of soft errors are also increasing [10].

The conventional TCAMs suffer from effective error correction techniques. Circuit or architectural solutions, which are generally aimed at increasing the critical charge, require modifications of the TCAM architecture; hence, these types of solutions incur a large amount of process cost. Several techniques involve the utilization of additional DRAM cells to tolerate soft errors. However, apart from the large cost overheads and the increased complexity of DRAM fabrication, the solution retains the possibility that incorrect data may lead to false miss or match results between two refresh intervals [11]. Error Ccorrection code (ECC), which is commonly used for RAMs [12], is another type of solution. However, at least 3 times larger memory bits are required than the original memory bits of the TCAMs to correct only 1-bit error per word when ECC is applied [9]. Therefore, further research are needed to prevent soft errors against multiple bit upset in TCAM.

In this paper, we have proposed a new methodology to improve the efficiency of TCAM. The proposed methodology is able to provide more reliable TCAMs for sequential data words. It will also help to speed up network device performance, with a low cost and information overhead, and circuit complexity.

Section II entails related work in this area. In Section III, the proposed methodology is illustrated. Test contemplates are introduced in Section IV. At last, conclusion is encompassed into Section V.

II. RELATED WORK

Several hardware and software methodologies are used to avoid soft error. Eftaxiopoulos, Axelos and Pekmestzi proposed a new methodology in [11] where, a special storage component was used to prevent soft errors. Here, two techniques were combined; one is a guard gate technique and another one is the usage of a pass transistor as a delay element. This methodology worked only for Single Node Upset (SNU) in case of Content Addressable Memory (CAM) and 75% soft error tolerance for TCAM. Moreover, this method needs two extra transistors to provide soft error tolerance for TCAM.

A Soft-error tolerant TCAM is proposed in [13] where an arbitrarily selected search key was used to estimate; and parallel TCAMs were used to detect single-bit flip error (here, the search key matches the last word). This method can only detect single bit upset and to correct this upset bit, it used a

backpack-SRAM. It also used an extra TCAM which is comparatively expensive.

A Bloom Filter based method is proposed in [14] to detect soft errors in TCAMs with a low power and data overhead. It can detect and correct single bit upset. The main disadvantage of this method is false positive. It happens when the Bloom Filter detect the presence of a data even though there was no data in the Bloom Filter.

Onawa, Matsunaga and Hanyur proposed a transistor /magnetic-tunnel-junction (MTJ) hybrid structure based asynchronous TCAM method in [15] which used 20 transistors and 4 MTJ device to detect single bit upset. This hardware-based method is much costlier than most other approaches.

A probabilistic approach to determine scrubbing interval is proposed in [16] where Compound Poisson (CP) process is used to count clustered random events. This method can detect and correct both single and multiple bit upsets, but CP model failing possibility is large due to independent assumptions in the experimental data.

A software-based error detection and correction technique was proposed in [17] which used three models to serve the purpose of capturing the underlying phenomenon of a sensor network and then guide the error detection to discover any anomaly observation. This method used two TCAMs which is highly expensive.

Therefore, we can notice that almost none of the existing techniques can work effectively in tolerating soft errors for TCAMs.

III. THE PROPOSED METHODOLOGY TO TOLERATE SOFT ERRORS

To prevent single bit and multiple bit soft errors, a new method is proposed in this paper. The proposed methodology does not need any extra TCAM or ECC-SRAM to detect and correct soft error. The several steps of the proposed methodology are illustrated as follows.

A. TCAM Encoding and Decoding

Suppose data bits are saved in TCAM with n words' length. Then total number of data words is 2^n. Now total data words are divided into $\frac{2^n}{4}$ groups sequentially. Each group contains 4 words and each word contains n data bits. In each word, nth and (n-1)th data bits are different for a group. Alternatively, 1 to n-2 data bits' are same for all words within a group. For generating search key in each group, the paper uses the following steps.

- First, all similar 1 to n-2 data bits are saved. Then, it ensures that in each group, the last 2 data bits are same for all groups' word. In case of all groups' first word, n-1th and nth data bit are "00" respectively. Similarly, in the second word, n-1th and nth data bit are "01"; in the third word, n-1th and nth data bit are "10"; and finally in the fourth word, n-1 and nth data bit are "11" respectively.
- Now for generating search key with don't care bit, any data word can be chosen within a group. Then the search key for each group is $S_1S_2S_3 \ldots S_{n-1}S_n$.
- $D_1,\ D_2,\ D_3 \ldots . D_{n-2}$ are similar data bits of each group and $D_{n-1},\ D_n$ are last two data bits which are different for each word within a group.
- Finally, it generates a search key including the don't care bits which are $S_1S_2S_3 \ldots S_{n-1} *$ and $S_1S_2S_3 \ldots *S_n$.

If first word's last two data bits "00" are chosen for search key, then the search key with don't care bit will be $S_1S_2S_30*$ and $S_1S_2S_3 \ldots *0$ respectively. For detecting and correcting soft errors, these two search keys need to fulfill the following conditions:

- For the first data word of each group, if $S_1S_2S_3 \ldots . 0*$ and $S_1S_2S_3 \ldots *0$ match with the data word, no error will occur. And if any error occurs in last data bit of first word then only $S_1S_2S_3 \ldots . 0*$ search key will match with the first data word. If the second last bit is erroneous, then it will match only with $S_1S_2S_3 \ldots *0$ search key. If the last and second last data bits are both erroneous then it will not match with any search key.
- For the second data word of each group, if $S_1S_2S_3 \ldots . 0*$ and $S_1S_2S_3 \ldots *0$ search keys match with the data word, the last data bit is erroneous bit. If the second last data bit is erroneous, it will not match with any search key. If both the last and second last bit are erroneous, it will match only with this $S_1S_2S_3 \ldots *0$ search key. Otherwise, stored data word is correct.
- For the third data word of each group, if $S_1S_2S_3 \ldots 0*$ and $S_1S_2S_3 \ldots *0$ both match with the data word, second last data bit is erroneous. If the first data bit is erroneous, it will not match with any search key. If both the last and second last bits are erroneous then it will match only with $S_1S_2S_3 \ldots . 0*$ search key. Otherwise, stored data word is correct.
- For the fourth data word of each group, if both $S_1S_2S_3 \ldots 0*$ and $S_1S_2S_3 \ldots *0$ search keys match with the data word, then the last and the second last data bit are erroneous. If the first data bit is erroneous then it will match only with $S_1S_2S_3 \ldots *0$ search key. If the second last bit is erroneous then it will match only with $S_1S_2S_3 \ldots 0*$ search key. Otherwise, stored data word is correct.

Similarly, we can choose 2nd, 3rd or 4th words' last two data bits "01", "10" or "11" respectively for generating the search keys. Then the search key with don't care bit for 2nd word will be $S_1S_2S_3 \ldots 0*$ and $S_1S_2S_3 \ldots *1$. For 3rd data word, the search keys will be $S_1S_2S_3 \ldots 1*$ and $S_1S_2S_3 \ldots *0$. And for 4th data word, the search keys will be $S_1S_2S_3 \ldots 1*$ and $S_1S_2S_3 \ldots *1$. To detect and correct soft errors, these two search keys need to fulfill the conditions which are shown in TABLE I.

TABLE I shows the conditions for detection and correction of soft error for various search keys. Green words represent correct data words which are saved in TCAM, and red words represent erroneous data words which are saved in TCAM. A checkmark (✓) shows correct match with the search keys and a cross-mark (**×**) shows false match among search keys and data words.

The proposed methodology to detect and correct soft errors is illustrated in Fig. 1, The first N sequential data words are saved in memory and then these are divided into four groups. Each group of the data words are then divided into two further groups. One is similar bits' data group and another one is dissimilar data bits' group. Then search keys, along with don't care bits, for all groups are generated.

TABLE I. CONDITIONS FOR DETECETING AND CORRECTING DATA WORDS BY USING VARIOUS SEARCH KEYS

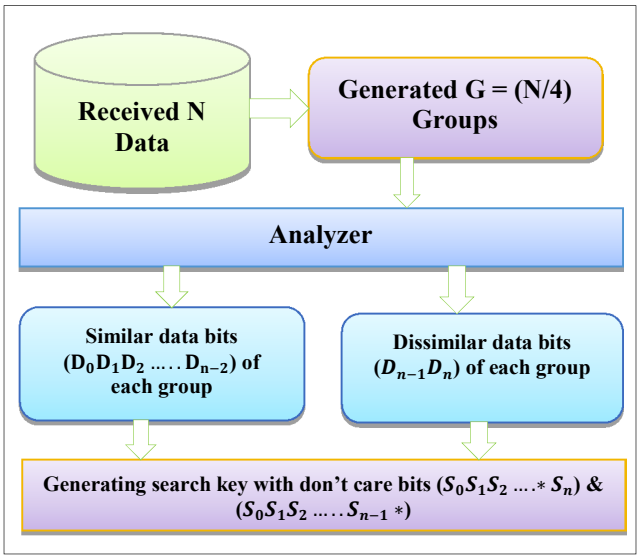

Fig. 1. A diagram of generating search keys with don't care bit.caption.

As shown in Fig. 2, the proposed method compares the search keys with the saved similar data bits of each group. If it matches, similar saved data bits are correct and if it does not match then an error is occurred in the saved data bits.

As a result, similar data bits are corrected by using search key and the different data bits are corrected by using search keys along with don't care bits. If search keys and data bits fulfill the conditions, the saved data bits are correct; otherwise an error is detected. In the next step, erroneous bits are corrected by using NOT operation. The correct data word is generated and saved in memory.

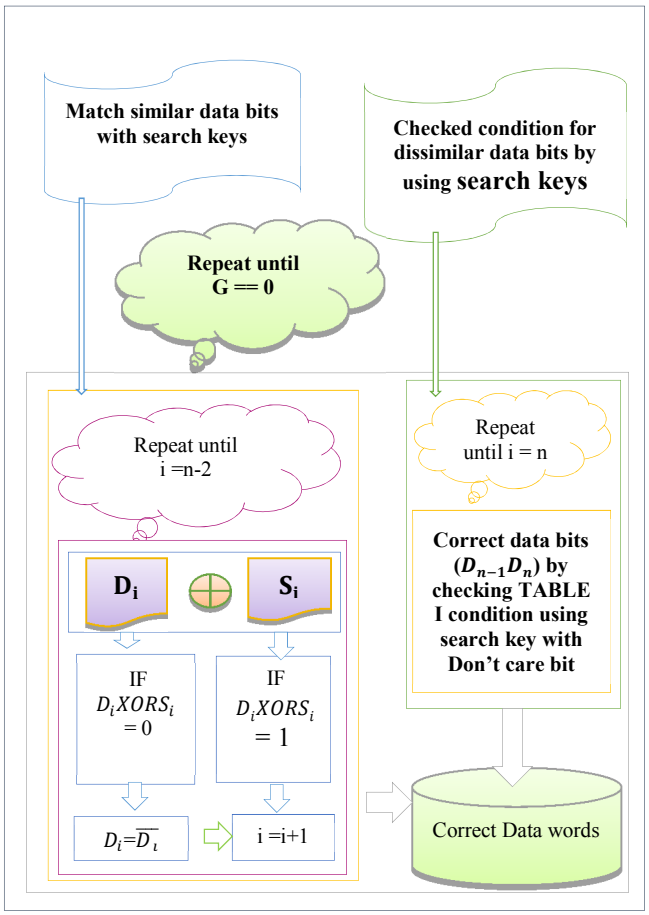

Fig. 2. The Flow diagram of the Proposed Methodology.

B. A Typical Example

Let us give an example of the proposed methodology. Suppose data words are saved in a TCAM with a word length of n=4. Then the number of data words which are saved in TCAM are $2^n=2^4 = 16$. In Table II, the saved data words in a TCAM are presented. Total data words are divided into $\frac{16}{4}$ =4 groups. For the first group, similar data bits are "00", for the second group, similar data bits are "01", for the third group, similar data bits are "10" and finally for the fourth group, similar data bits are "11". Within a group, for each word, the last two data bits do not match with each other. It is different for every word in a group. For generating search keys with don't care bits, we can choose any data word's last two bits. Here, we choose "11" as last two bits of search keys and the generated search keys for the first group are 001* and 00*1, for the second group search keys are 011* and 01*1, for the third group search keys are 101* and 10*1, and for the fourth group search keys are 111* and 11*1. Hence, if a single error or multiple soft errors occur in the data word, we can detect and correct these error(s) by using the conditions as shown in TABLE I.

In the next step, errors are injected in the saved data words. Few erroneous data words are shown in Table III. By using search keys 001* and 00*1, we can detect and correct erroneous data words within the data words that are saved in the first group.

TABLE II. DATA WORDS SAVED IN TCAM WITH A WORD LEANGTH OF 4

Data Word	Similar Data Bits in each Group	Dissimilar Data Bits in each Group	Search Keys with Don't care Bit

1111		11		1111

- In the first group, first two bits of the first and the fourth data words do not match with the first two bits of the search keys. Therefore, an error is detected in here. We correct the data bits "11" to "00" and "10" to "00". After that, the conditions of Table I is applied. Here, both search keys match with the first data word. So according to the conditions of Table I, the last two data bits of both second and fourth data words are erroneous bits and we correct these bits "11" to "00" by using inverse operation.
- Similarly, we checked other groups. In the third group, we got a mismatch. By using the conditions of Table I, we observed that both search keys are matched with the second data word. So, the last two bits of second data word are erroneous, and we correct those bits "10" to "01" by using inverse operation.
- In the fourth group, the third data word do not match with the search key. Here, the last data bit is an erroneous bit. It matched only with search key $S_1S_2S_3\ldots1*$. So, we correct the data bits "1" to "0" by using inverse operation.

In this way, we could detect and correct single or multiple bits' soft errors in the data words.

IV. EXPERIMENTAL ANALYSIS

The experimental analysis is done in three stages. The first one is experimental setup, the second is fault injection, and the third is results analysis.

A. *Exerimental Setup*

The following tools are used to implement the proposed methodology.

- Intel(R) Core ™ 2 Duo CPU T6570 @ 2.10 GHz
- 4 GB RAM
- C++ Language
- Code Block Equations

B. *Fault Injection*

The fault injection method which is *applied to* estimate the error detection and correction abilities of the proposed method is illustrated in Algorithm 1

Algorithm 1: Fault injection in TCAM

/* Input: D, n, where D is words saved in a TCAM, n each word length*/

1. Generating TCAM 1 from saved TCAM
2. Declare variable i, j and k
3. Initialize variable i, to zero
4. Initialize variable j, to zero
5. Repeat the step five until i less than or equal to D
6. Repeat the step six until j less than or equal to n
7. **IF** D [i][j] equal to zero **THEN**
8. Reset D [i][j] equal to one
9. **ELSE**
10. Reset D [i][j] equal to zero
11. **END IF**
12. Set k equal to j
13. Repeat the step thirteen until **k** equal ton
14. **IF** D [i][k+j] equal to zero **THEN**
15. Reset D[i][k+j] equal to one
16. **ELSE**
17. Reset D[i][k+j] equal to zero
18. **END IF**
19. Return TCAM 1

C. *Results Analysis*

Here 4*16= 64 bits' data are taken for analyzing the capability of the proposed method. After that, the error correction rate for the proposed method and KX-TCAM [7] are calculated. The error correction coverage for the proposed

method and KX-TCAM is shown in TABLE IV. Here, the first column represents the number of soft errors in words. From Table IV, we can observe that the proposed method has better error correction coverage than KX-TCAM.

TABLE IV. COMPARISON OF CORRECTION COVERAGE BETWEEN THE PROPOSED METHOD AND KX-TCAM

Corrupt bits in words	KX-TCAM	Proposed Method For sequential data words	Proposed Method For random data words
1	100%	100%	100%
2	100%	100%	100%
3	100%	100%	100%
4	50%	100%	100%
5	20%	100%	80%
6	0%	100%	66.7%
7	0%	100%	57.14%
8	0%	100%	50%

For sequential data words, the proposed method can detect and correct 100% single and multiple erroneous data bits. Alternatively, for randomly stored data words, the proposed method's error detection and correction rate is lesser than 100%. However, the proposed method has better coverage than the existing method because the existing method worked well only for some combination but not for all. Moreover, randomly selected search keys cannot detect and correct single or multiple bits of soft error. In Fig. 3, the comparison of the error correction rate between KX-TCAM and the proposed method is shown.

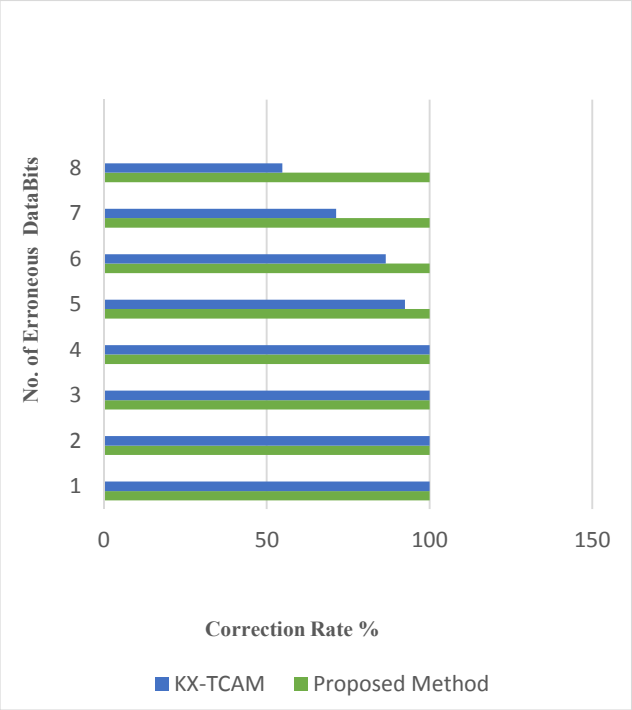

Fig. 3. Comparison of error correction rate between the Proposed Method and KX-TCAM

The comparison of coding efficiency between the Proposed Method and KX-TCAM is presented in TABLE V. Here, we can observe that for 64 bits' data word, KX-TCAM required 64 extra bits for detecting and correcting erroneous

TABLE V. COMPARISON OF CODING EFFICIENCY BETWEEN THE PROPOSED METHOD AND KX-TCAM

Error correction method	Data bits	Redundant bits	Correct error bits	Code word	Search key for MCU	Code Overhead (%)	Coding efficiency (%)
KX-TCAM	64	64	4	128	6	100	50
Proposed Method	64	40	64	104	2	62.5	38.46

bits whereas the proposed methodology required 40 extra bits for detecting 64 erroneous bits. KX-TCAM used 6 different search keys to detect and correct multiple cells whereas the proposed method used 2 different search keys. The fault tolerance capability of the proposed method is higher than the existing method. The code overhead of the proposed method is 62.5% whereas the existing method's code overhead is 100%. Fig. 4, illustrates the comparison of code overhead and coding efficiency between KX-TCAM and the proposed method.

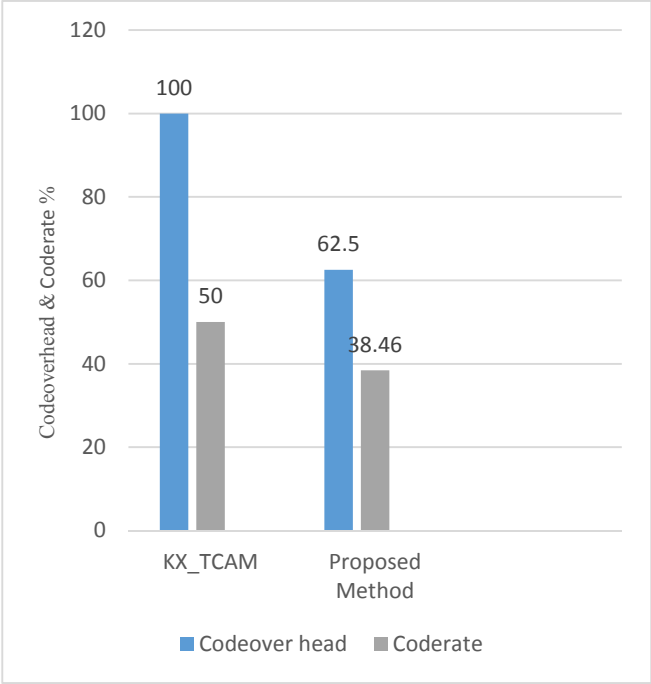

Fig. 4. Comparison of codeoverhead and coderate between KX_TCAM and Proposed method

Fig. 5 shows the comparison of memory requirement between KX-TCAM and the propose method. KX-TCAM used more storage space in memory than the proposed method.

Fig. 6 illustrates the comparison of execution time between KX-TCAM and the proposed method. The proposed method has a high-speed error detection and correction capability which helps to speed up the network.

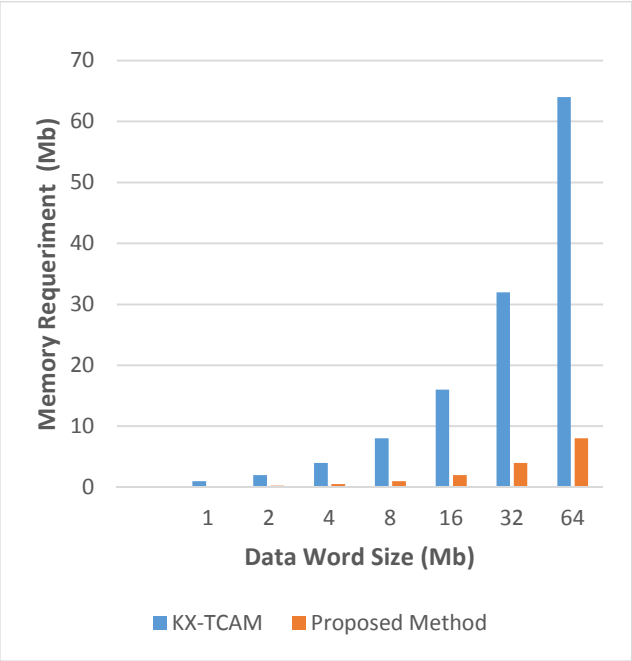

Fig. 5. Comparison of memory requeriment between KX_TCAM and Proposed method.

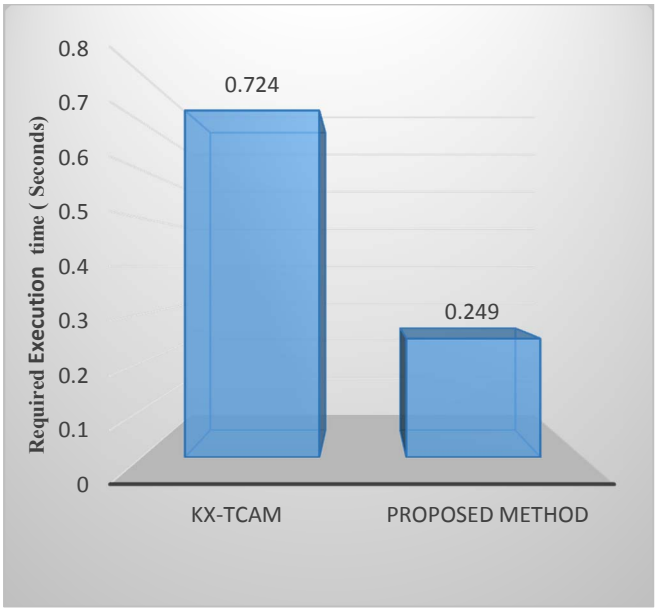

Fig. 6. Comparison of execution time requeriment between KX_TCAM and Proposed method.

V. CONCLUSIONS

This paper has proposed a novel idea to tolerate soft errors in TCAM. The proposed method uses a limited amount of memory space which helps to reduce the cost and time complexity than other existing methods. Moreover, its detection and correction rate is higher for both single bit error and multiple bit errors for a sequentially stored data words in TCAM. It also uses a simple code which can make the searching and forwarding speed of the network device faster with a lower time overhead. Although the proposed method works for sequentially stored data words only and this method do not work for randomly stored data words, the experimental analysis validates the effectiveness of the proposed method over existing dominant method.

Further scopes in order to extend this research is to develop a methodology which can detect and correct soft errors from both sequentially and randomly stored data words in TCAM.

Abstract- **We perform a feasibility study on the application of thin film polycrystalline silicon (polysilicon) nanowires for gas sensing application upon exposure into different gas ambient. The nano-sensors are developed in a relatively cheap reactive ion etching system using a low-density plasma based etch and mature 3 micron lithography. Systematic measurements in air, vacuum, hydrogen and isopropyl alcohol demonstrate promising gas sensitivity and impressive response/recovery times in room temperature. The modification of surface states in nanowires upon exposure into different gas ambient is confirmed through 3D numerical simulation. This investigation demonstrates the potential of polysilicon nanowires for detecting molecules in gas phase thereby reveals that the polysilicon nanowire sensor is promising for a simple, low cost, manufacturable route for gas-sensor fabrication.**

***Index Terms*— Thin films, nano-sensors, gas sensing, biosensors**.

I. INTRODUCTION

Smart nanosensors with the capability of detecting toxic gases from the environment and multiple biomarkers from physiological fluids have significant impact on the society. NO_x, O_2, NH_3, SO_2, CO, CO_2, and hydrocarbon detection has been the major concern for environmental protection [1]. The medical use of gas sensors is also a rapidly growing field [2-3]. The different compounds which have been identified in human breath, most of them are potential indicators (markers) of more than one type of diseases [2-5]: NO has been widely studied as a bio-marker for oxidative stress [4]; exhaled hydrocarbons of low molecular mass, such as ethane, n-pentane; ethylene, isoprene are markers for blood cholesterol levels [5].

Conventional gas sensing usually employs IR detection, UV spectroscopy, mass spectroscopy, or gas chromatography which are conclusive and highly reliable methods for detecting parts per billion (ppb) levels [6]. Even though these methods are precise, their physical size, cost and operation complexity prevent them from entering into everyday life use. The electrochemical metal oxide gas sensors although reduces the cost and complexity, most of the sensor devices developed so far requires high temperature operation [7]. Over the last two decades, enormous efforts actually have been made to lower the operating temperature of metal oxide gas sensors by adopting metal nanoparticles on metal oxide surface [8]. These efforts were successful in lowering the sensors operating temperature to a value close to 100°C, for some gases but operating temperature is still reasonably high [8].

Silicon nanowire-based gas sensors are currently in interests due to its promise for fast response in room temperature [9] which may ensure low power operation for incorporation into personal items like mobile phones that typical gas sensor does not offer. Within the framework that is readily amenable into standard CMOS technology, Si nanowire-based gas sensors would also allow signal processing and interconnects to be implemented on the same substrate in order to form smart sensor system which can simplify potentially complex and costly gas detection process [10]. However, silicon nanowire based gas sensors reported so far mostly exploited bottom up or top down processed single crystal silicon nanowires [11-13]. Bottom-up grown nanowires are not location controlled and hence, construction of functional device arrays challenging [11]. These shortcomings are eliminated in conventional top down approaches but have disadvantage of elevated budget associated with these advanced lithography techniques and costly SOI wafers [12-13].

Spacer etch process of thin film has been recently reported as a route towards low-cost nanowire fabrication [4-16]. Mature lithography and industry standard deposition/etch are the attractive features of this technology. This process can also enable low cost disposable diagnostics and portable, wearable or even implantable sensors due to the use of glass or plastic substrates. However, the sensor application of polysilicon nanowires is concentrated on the detection of analytes in aqueous environment, mainly within the context of biosensing (e.g., to detect biological species like DNA, proteins etc.) [14-16]. The surface states modulation of nanowires upon exposure of different gas ambient and hence, the detection of molecules in gas phase using polycrystalline silicon nanowires and are rare in the literature.

This article first time performs a feasibility study on the application of thin film polycrystalline silicon (polysilicon) nanowires (NW) for gas sensing application. Systematic measurements of nanowire conductance in air, vacuum, hydrogen and isopropyl alcohol demonstrate the potential of polysilicon nanowires for gas sensing. In addition, experimental investigation is augmented with numerical simulation to get insight into the surface states modulation of polysilicon nanowires in different gas ambient.

II. SENSOR FABRICATION AND CHARACTERISATION

The sensor fabrication and characterization were done in the Southampton Nanofabrication Center, University of Southampton, UK. 500 nm nitride and 100 nm oxide layers were deposited on (100)-oriented n-type silicon wafers which had a doping density of $10^{16}/cm^3$. Mature lithography (linewidth > 3 μm) was used to dry etch 100 nm oxide layer to create pillars. A low-pressure chemical vapor deposition (LPCVD) method was then used to deposit a 100 nm undoped amorphous silicon (α-Si)

film at 560°C and subsequently the film was doped by boron implantation (dose of $1.5\times10^{13}/cm^2$, energy of 25 keV). A special etch process with 12 sccm SF_6 and 12 sccm O_2 flow at a pressure of 30 mT was used to dry etch the α-Si film in an Oxford Instruments capacitively coupled RIE system. Such a spacer etch process leaves amorphous silicon nanowires around the oxide pillar sidewalls, which were later crystallized using thermal anneal. The physical structure of the nanowires (width, shape and surface morphology) was investigated by plan-view and cross-sectional scanning electron microscopy (SEM). Electrical characterisation of the nano-sensors was performed using an Agilent B1500A Semiconductor Parameter Analyser. The gas sensing measurements were performed utilizing the sealed chamber of a Lakeshore EMTTP4 probe station which was connected to a H_2 gas cylinder with a pressure control valve. Fig. 1 shows an optical microscopic image of the nanowire sensor.

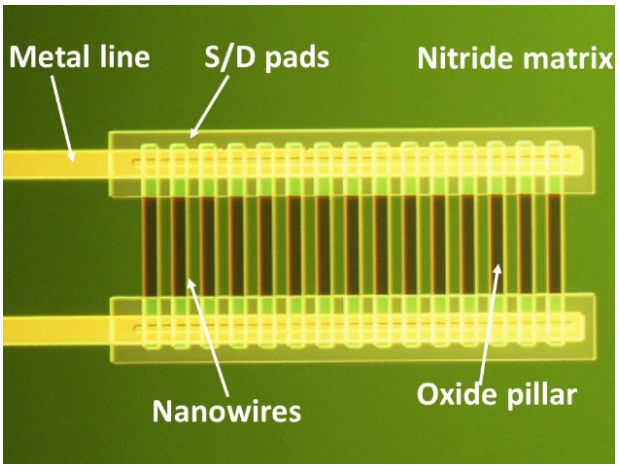

Fig. 1: Optical microscopic image of the polysilicon nanowire sensor.

III. 3D SIMULATION OF POLYSILICON NANOWIRES

Numerical simulations of nanowires were performed in the SILVACO TCAD platform installed in the VLSI lab of the East West University [17]. A p-type silicon nanowire 100 nm thickness and doping density was 6×10^{16} cm^{-3} (p-type) was created on a 500 nm Silicon Nitride (Si_3N_4) which was deposited on a 500 nm n-type Si substrate with substrate doping density $1\times10^{16}/cm^3$. A 20 nm thick aluminum material used as back gate and in the silicon nanowire, two heavily doped regions ($10^{20}/cm^3$, p-type) in the two sides of the channel were implemented to ensure ohmic contacts on the source/drain regions. There was 10 nm oxide on the polysilicon NW which was embedded in the sea of nitride layer. This specific type of NW and associated platform was chosen for 3D simulation to resemble our fabricated NWs which was fabricated targeting selective chemical functionalization on the NW only. During simulation, 2D coupled Poisson's drift-diffusion solver was used to model carrier transport in Polysilicon NW [17]. The Shockley-Read-Hall model for carrier emission and absorption was used to reflect the recombination phenomena within the device [17]. Moreover, the bandgap narrowing (BGN) effects in the heavily doped source/drain regions were included by Slotboom and de Graaf's analytical BGN model [17]. The polysilicon is modeled using a continuum of trap states consist of both donor-like and acceptor-like states distribution across the energy band gap [18]. Fig. 2 shows the 2D cutline view of the realized 3D structure in SILVACO platform.

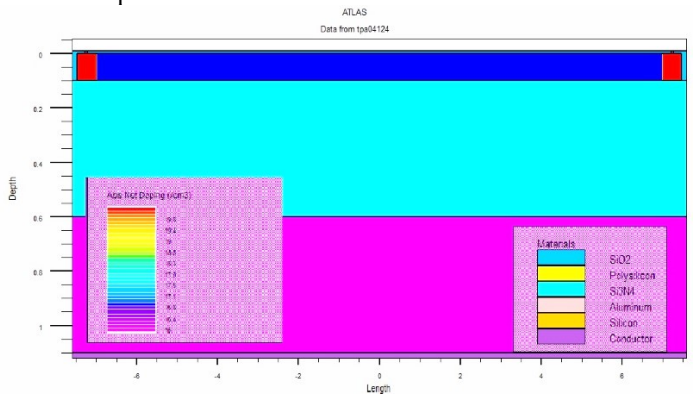

Fig. 2: 2D cutline view of realized polycrystalline silicon nanowire.

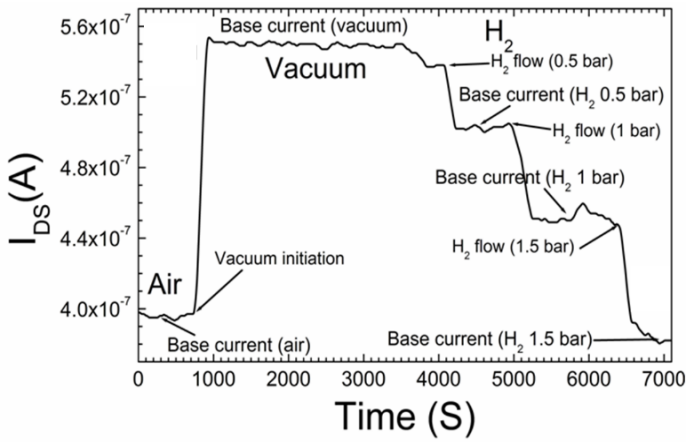

Fig. 3: The measured current response as a function of time for 58 µm long nanowires, sequentially in air, vacuum and different pressures of H_2 (5%) gases.

IV. RESULTS & DISCUSSION

To investigate the gas sensing capability of polysilicon nanowires, conductance measurements were made sequentially in different gases. Figure 3 shows the measured current response as a function of time for 58 µm long nanowires, sequentially in air, vacuum and different pressures of H_2 (5%) gases. The nanowires were supplied with bias voltages of V_{DS} = 5V and V_{GS}= -10 V. A systematic change of the nano-sensor current is observed when ambient gases are changed. The change of ambient from air to vacuum increases the nanowire current by 45 % and the typical response time (time required to reach 90% of the equilibrium value) is 101 seconds. A decrease in the NW current is observed when nanowires are exposed into H_2 gases. Numerically 13%, 10% and 16% decrease from the base current level are observed for H_2 gas pressures 0.5, 1.0 and 1.5 bar. The response times are 100, 127 and 120 seconds for gas pressures 0.5, 1.0 and 1.5 bar respectively. The nanowire response in Isopropyl Alcohol (IPA) gas is shown in figure 4 where the IPA vapour ambient is created by applying a drop of the solvent (5μl) to a tissue above a hole in a measurement box. The same nano-sensor chip that was used for H_2 gas exposure test has been used in this experiment. A significant response is observed where the NW current is increased by 450 % from the low base current

around 417 nA when the NW is exposed to IPA vapour. The response time of NW to IPA vapour is found to be 15 seconds. When the IPA vapour source is removed, the current returns to the base current level in air with a recovery time around 32 seconds.

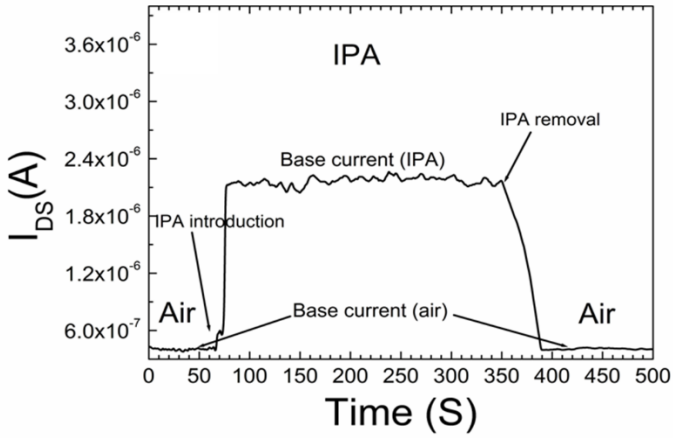

Fig. 4: The response of 58µm long polysilicon nanowire in Isopropyl Alcohol (IPA) gas.

The transfer characteristics of NW in air, vacuum, IPA and in H_2 gases at different pressures are shown in figure 5. During this measurement the substrate is used as gate and the 500 nm nitride layer is used as gate insulator. When the nano-sensor chip was exposed into different gas ambient, interesting changes in the sub-threshold characteristics can be observed. The sub-threshold slope of the nanowires remains unchanged after exposure into air, vacuum, H_2 gases which has a value around 2.6 V/dec. However, the change of ambient gas results in the shift of the sub-threshold characteristic. We have quantified this shift using the constant current threshold method at a current level of 4×10^{-8} A. A positive threshold voltage shift (ΔV_{TH}) of 2.47V is found when the ambient is changed from air to vacuum. However, the ambient change from vacuum to H_2 gas exhibits negative ΔV_{TH} shift with values of -1.14 V, -2.09 V and -3.16 V respectively for H_2 gases with pressures of 0.5, 1.0 and 1.5 bar. The introduction of the IPA gas results in the significant positive ΔV_{TH} of 10.48V with respect to air. It can also be observed that the ambient change associated nanowire's conductance change is strongly dependent on the substrate voltage (V_{GS}). The responses presented in figure 3 and 4 are measured for V_{GS} = -10 V which is actually in the saturation region of the characteristics and hence, there is plenty of room for response improvement by appropriate bias so that operating point falls inside the linear region of the transfer characteristics.

The nanowire conductance change (%) for different ambient as a function of substrate voltage (V_{GS}) is extracted through the numerical differentiation of figure 5 and presented in figure 6. Obviously, a phenomenological response of polysisilicon nanowire sensor can be obtained through appropriate bias which ensures the operating point to fall within the linear region of the sub-threshold regime. When the ambient is changed from air to vacuum, air to IPA and vacuum to H_2 gases with different pressures, promising conductance changes of 1560%, 3.6 × 10^5%, 70%, 90% and 97% can be obtained. These results are the testament of the gas sensing capability of polysilicon nanowire sensors at room temperature.

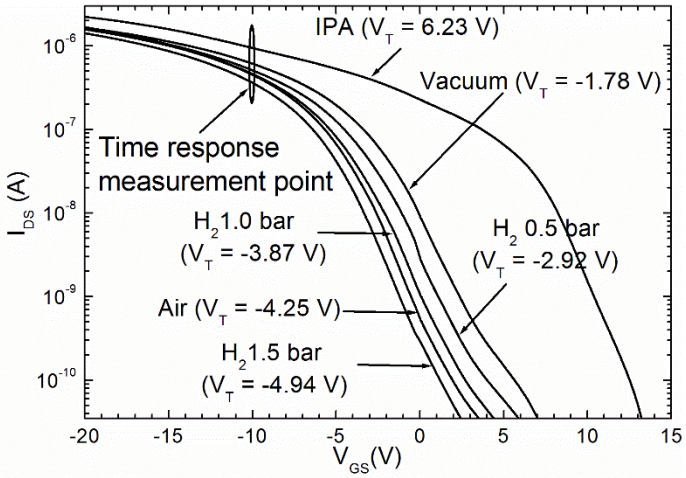

Fig. 5: The transfer characteristics of 58µm long polysilicon nanowire in air, vacuum, IPA and in H_2 gases at different pressures.

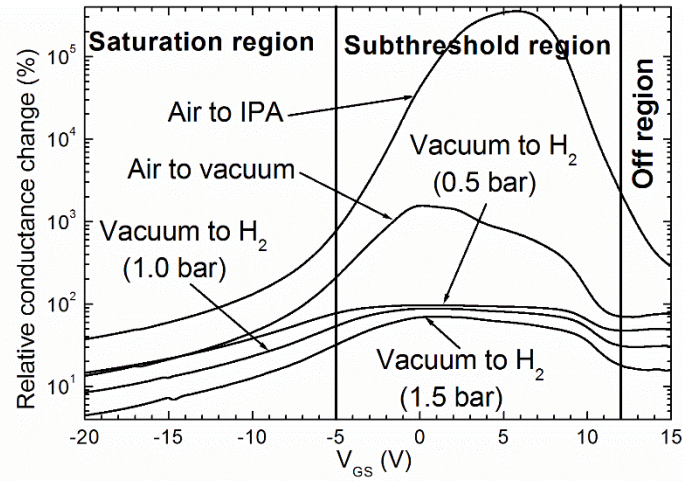

Fig. 6: The nanowire conductance change (%) for different ambient as a function of substrate voltage (V_{GS}) for 58µm long polysilicon nanowire.

Promising sensitivity of the fabricated polysilicon nanowire sensors for ambient like vacuum, H_2, volatile IPA gases are demonstrated in figure 3 to 6. It should be noted that the change of ambient from air to vacuum results in a significant increase in the response current of nanowires. Adsorption of gas molecules from atmosphere has been reported to influence the electrical properties of semiconductor nanostructures [19] which was found to be process dependent [19-21]. Reduction of nanowire conductance in p-type silicon nanowires from air to vacuum was observed by ref. [19]. Accumulation of holes in nanowire by adsorbed OH- ions was attributed to the enhancement of the nanowire conductance in air [19]. However, ref. [20] reported that the base conductivity of silicon wafer is not inherited in nanowires prepared by etch and p-type silicon nanowires showed significantly reduced conductivity in air due to surface charge associated depletion. Conductance increase of silicon nanowires in vacuum was also observed by ref. [21]. The fabricated polysilicon nanowires of this work show similar result like ref. [20-21] where reduced conductivity is observed in air due to surface charge associated depletion in air. As it is well known

that donor type states deplete the p-type nanowires by locally accumulating positive charges at the surface it can be decided that these atmosphere dependent surface charges in our work are most likely donor type.

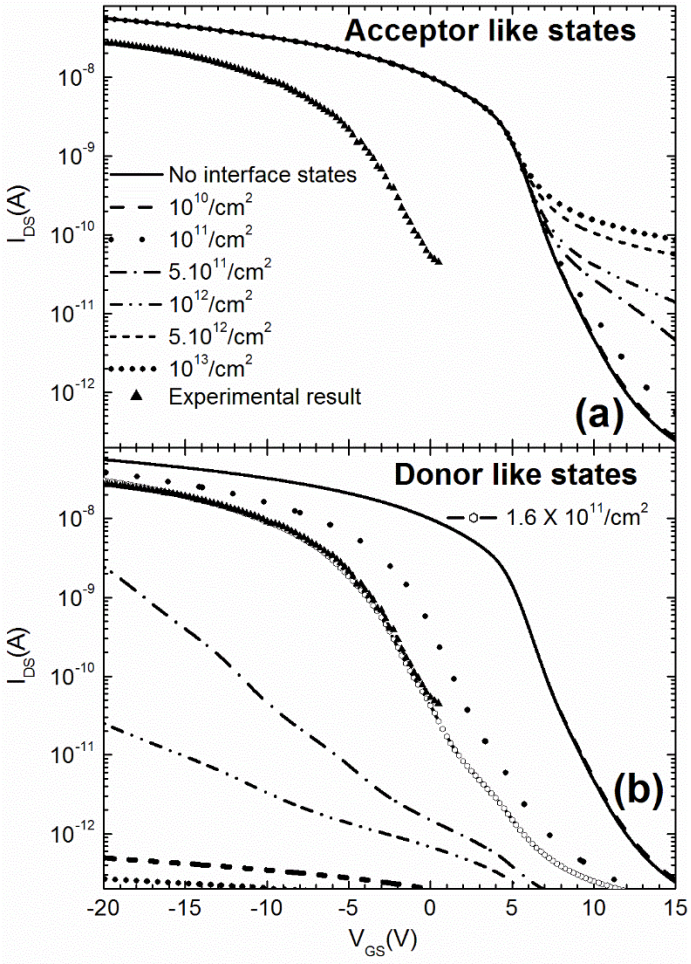

Fig. 7: The simulated and measured transfer characteristics for 14 µm long polysilicon nanowire in air for a nano-sensor block with different densities of a) acceptor like states and b) donor like states. V_{DS} value is 0.5V.

To get a deep insight on the surface/interface states of fabricated polysilicon nanowires in air, a 3D simulation of electrical characteristics of p-type polysilicon nanowires is done. For modelling polysilicon nanowires accurately, continuous trap states (both donor-like and acceptor-like) distribution model is used with parameters previously used in the literature for successful modelling of polyslicon thin film transistors [18]. For interface states, acceptor or donor type states with varying densities are invoked both in the top oxide/polysilicon and bottom nitride/polysilicon interface and tested. The simulated and measured transfer characteristics (I_{DS} as a function of V_{GS} for V_{DS} value of 0.5V) of the 14 µm long nanowire with different densities of acceptor like states is shown in figure 7a. It can be observed in figure 7a, acceptor like surface states and the reported continuous distribution of polysilicon defect states [18] are not enough to reproduce electrical characteristics of our polysilicon nanowires in air. The leakage current of p-type polysilicon nanowire is only affected by acceptor like surface states. The simulated and measured transfer characteristics of the 14 µm long nanowire with different densities of donor like states is shown in figure 7b. Obviously, polysilicon nanowire's sub-threshold and on current characteristics both are affected by donor type states. Acceptor like states are located at the upper half of the band gap whereas donor like states are located at the lower half of the band gap thereby showing different behaviour in different operation regime depending on the position of the fermi level.

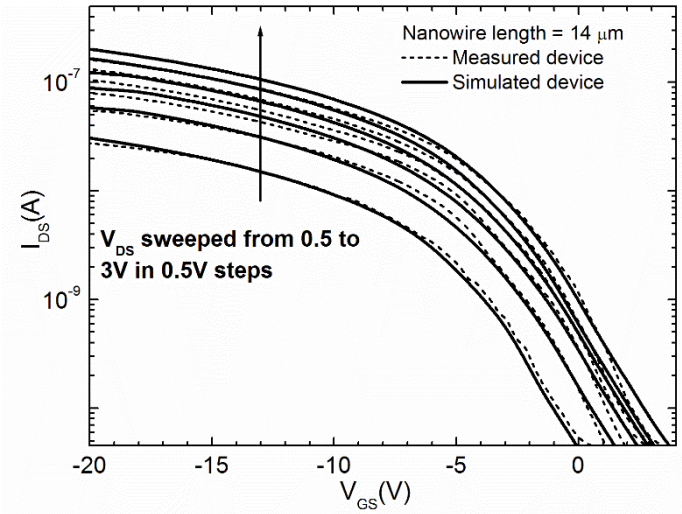

Fig. 8: Simulated and measured transfer characteristics for 14 µm long polysilicon nanowire in air. V_{DS} value is 0.5V.

The measured transfer characteristics (I_{DS} as a function of V_{GS}) for different V_{DS} values for the 14 µm long nano-sensor block is compared with simulation in figure 8. We are able to reproduce the measured sub-threshold characteristics of 14 µm long nanowires in air for the surface states density of $1.6 \times 10^{11}/cm^2$. This implies that the surface states of the fabricated polysilicon nanowires excluding grain boundary defects is around ~ $10^{11}/cm^2$. Similar results are reported for single crystal silicon nanowires reported by Jie et al ($4.3\times10^{11}/cm^2$) [19].

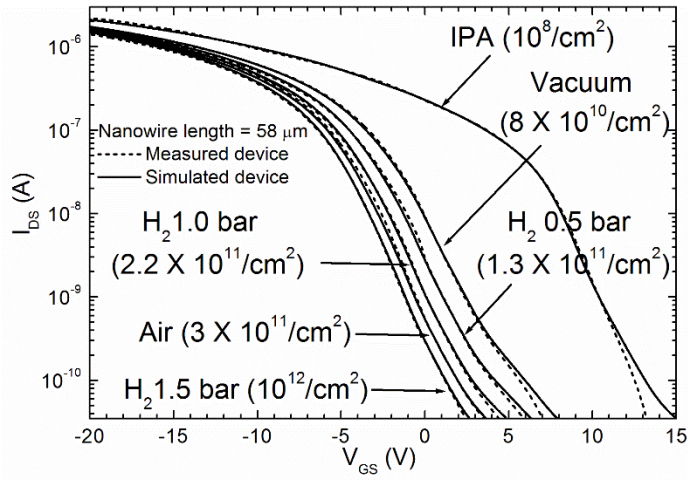

Fig. 9: Comparison of the measured transfer characteristics of the nano-sensor in different gas ambient with the simulated transfer characteristics for 58 µm long nanowires with different densities of surface states. V_{DS} value is 0.5V.

Figure 9 compares the measured sub-threshold characteristics of the nano-sensor in different gas ambient with the simulated transfer characteristics (I_{DS} as a function of V_{GS}) with different densities of surface states for 58 μm long nanowires. The donor type states in the top oxide/silicon interface for a density of $3 \times 10^{11}/cm^2$ is found to reproduce the measured sub-threshold characteristics in air which is similar to the density of $1.6 \times 10^{11}/cm^2$ that was used to reproduce the measured sub-threshold characteristics of 14 micron long nanowire in air (figure 8). This result implies that excluding the defect states contribution from grain boundaries, the surface states density of the fabricated polysilicon nanowires is around ~ $10^{11}/cm^2$. Donor type states with densities of $8 \times 10^{10}/cm^2$, $1.3 \times 10^{11}/cm^2$, $2.2 \times 10^{11}/cm^2$, $10^{12}/cm^2$ are able to reproduce the sub-threshold characteristics in vacuum and H_2 gases with pressures of 0.5, 1.0 and 1.5 bar respectively. Based on this result it can be concluded that $5 \times 10^{10}/cm^2$, $1.4 \times 10^{11}/cm^2$ and $9.2 \times 10^{11}/cm^2$ number of states are introduced when the ambient is switched from vacuum into H_2 gases with pressures of 0.5, 1.0 and 1.5 bar respectively and $2.2 \times 10^{11}/cm^2$ number of states is removed when the ambient is changed from air into vacuum. Donor type density of $1 \times 10^8/cm^2$ is able to reproduce the transfer characteristics in IPA, indicating that almost all of the surface states in air is effectively removed when the NW is exposed into IPA vapour. This result indicates the complex mechanism of IPA interaction with NWs that is reducing surface states and effectively working as passivation agent for NW surface states [22].

Table I

Comparison of the gas sensing figure of merit (i.e. conductance change, response/recovery times) of the fabricated polysilicon nanowire sensors with the literature.

Si NW size	Type/approach	Target	Conductance change	Response time	Recovery time	Ref.
Inorganic gas						
NA	Porous single crystal Si	H_2	18% at 5% H_2	-	-	23
			50% at 10% H_2	-	-	
d = 300 nm L = 5.25 μm	Single crystal Si NW synthesized by metal assisted chemical etch	H_2	60% at pure H_2	180 seconds	No recovery	24
d = 95 nm L = 58 μm	**Poly silicon nanowire by spacer etch (This work)**	**H_2**	**5% H_2 in air**	**100-120 seconds**	**101 seconds**	**This work**
			16% at 0.5 bar 32% at 1.0 bar 65% at 1.5 bar			
			5% H_2 in vacuum			
			70% at 0.5 bar 90% at 1.0 bar 97% at 1.5 bar			
Polar volatile organic compounds						
d = 30 to 70 nm L = 400 nm to 1 μm	Top down/bottom up grown single crystal Si NWs	Polar VOC (Methanol, Ethanol, Isopropanol)	50%	40 seconds	50 seconds	25
d = 95 nm L = 58 μm	**Poly silicon nanowire by spacer etch (This work)**	**Polar VOC (IPA)**	**3.6×10^5%**	**15 seconds**	**32 seconds**	**This work**

Table I compares the gas sensing figure of merit (i.e., response/recovery times and conductance change) of our polysilicon nanowire sensors with the only few reported silicon-based gas sensors for H_2 and polar volatile organic compound (i.e. IPA). To judge the capability of our nano-sensor to detect H_2 and IPA molecules fairly, we only consider pure silicon nanowires without any surface modifications. As can be seen from the table our polysilicon nanowire sensors exhibit much better response/recovery times in comparison to reported silicon based H_2/polar volatile organic compound sensors and demonstrate appreciable conductance change for H_2/IPA.

III. CONCLUSIONS

We have presented a thin film polycrystalline silicon nanowire sensor technology and have demonstrated room temperature gas detection using polysilicon nanowires. The nanosensors have been defined by spacer etch using low density plasma of SF_6/ O_2 gases from thin α-Si layer in a low cost reactive ion etch (RIE) equipment and well established 3 micron lithography. Comparative measurements in air, vacuum, hydrogen and isopropyl alcohol have demonstrated the potential of polysilicon nanowires as gas sensors in room temperature with remarkable gas sensitivity and impressive response/recovery times that are noticeably better than reported pristine silicon based nano-sensors. 3D numerical simulations of polysilicon nanowires have indicated the evolution of surface states in different gas ambient which is the testament of gas sensing ability of the polysilicon nanowires. The developed thin film polysilicon nanowire sensors show route towards simple, low cost, mass manufacturable nano-sensor fabrication which is compatible with glass or plastic substrates could open up opportunities in low cost disposable diagnostics and in portable, wearable or even implantable sensors.

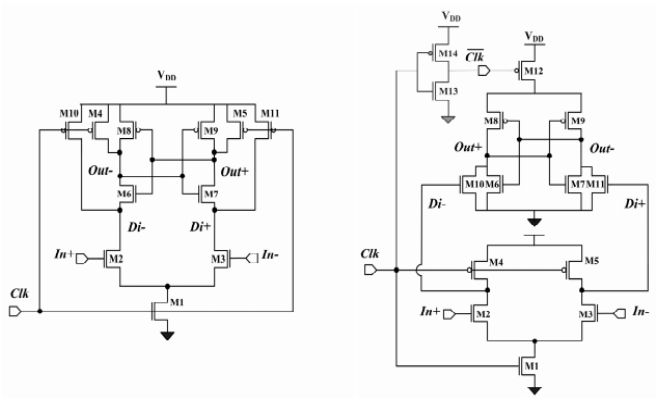
***Abstract*—Keeping pace with the new era, the necessity for comparator circuit with low power and high speed profile is increasing. In this research, a new latched comparator is proposed and compared with the conventional model. The proposed circuit is designed using PTM model. This circuit is proposed to overcome the difficulties mentioned in the conventional circuits. Different feature sizes (180nm and 32nm) transistor are considered. We have calculated power and delay and they are compared with previously proposed circuits for demonstrating the efficiency of the proposed model. Its power consumption is low compared with others and delay is decreasing with feature size. Also it has higher resolution and load drivability than those conventional approaches.**

Index Terms*— *Dynamic latched comparator, Feature size, Common mode voltage, Positive feedback mechanism.

I. INTRODUCTION



Comparator is one of the most widely used electronic devices after operational amplifiers in this modern era. Comparators are known as 1-bit analog-to-digital converter and for that reason they are mostly used in large abundance in analog to digital converter. Due to fast-speed, high input impedance and full-swing output, CMOS dynamic latched comparators are very attractive for many applications such as zero-crossing detectors, peak detectors, switching power regulators, analog to digital converters, memory sense amplifier, data transmission, and others. Nowadays, where demand for portable battery operated devices is increasing, a major emphasis is given towards low power methodologies for high speed applications. Also we have to minimize the power consumption by using smaller feature size processes. However, when we move towards power minimization, the process variations and other parameters will greatly affect the overall performance of the device. One such application where low power dissipation, low noise, high speed, less offset voltage are required is Analog to Digital converters for mobile and portable devices[3].

Dynamic comparators use positive feedback mechanism with one pair of back-to-back cross coupled latch in order to convert a small input-voltage difference to a full-scale digital level within a short time [1]. However, it has a larger input referred offset compared to linear amplifiers. The reason is that in addition to static V_{th} and β mismatch, it also suffers from dynamic offset due to imbalance of parasitic capacitors at internal nodes during evaluation [2]. A CMOS latch-type voltage sense amplifier was designed with a separated input and cross-coupled stage [7]. This topology has less stacking and can therefore operate at lower supply voltages. The double tail enables both a large current in the latching stage for fast latching independent of the V_{cm} and a small current in in the input stage for low offset .

Practically, there exist many papers, where some parameters of comparator such as speed, power consumption, offset voltage minimization etc. are analysed. Dynamic latched comparator and double tail comparators are modified by adding few transistors so that the positive feedback during the regeneration is strengthened, which results in remarkably reduced delay time. The simulated result is considered on 180nm CMOS technology with supply voltage of 1.2V and 0.6V [4]. However, input-referred offset voltage of 7.8mv and average power dissipation of 329µw at 500MHz frequency is found that is comparatively higher. Therefore, offset voltage compensation is very important to improve the performance of dynamic comparator. If the voltage gain of regenerative latch can be augmented to 22 V/V, it can demonstrate up to 24.6%less offset voltage and 30% less sensitivity of delay to decrease input voltage difference (17 ps/decade) than the conventional double tail latched comparator for same area and power consumption [6].In order to minimize input referred offset voltage a number of transistors are used that made the circuit more complex. Again, a comparator with a modified latch is proposed [7], which is different from the conventional circuit. This circuit shows an effective result at low power supply voltage (0.65V) as well as the conventional power supply (1V or 1.2V). Though the paper has shown that it gives rail to rail output, we have found a different result by simulation in LTspice. It can even detect a change of input signal within clock pulse but can not give rail to rail output as the capacitors take time to charge or discharge. However, we need an optimum design where power, speed, offset and size altogether gives an efficient result [5].

In this paper, a new dynamic latched comparator is proposed and simulated with various feature size. The circuit is simulated using LTspice at 180nm and 32nm PTM technology[9] for high performance application and 0.8V power supply. Following parameters are used for simulation using LTspice. PMOS parameters are: v_{thp}=-0.42V and v_{thn}=0.3999V for 180nm, v_{thn}=-0.4939V and v_{thp}=-0.4915V for 32nm. Clock frequency is considered as 0.33GHz for 180nm and 2.4GHz for 32nm because 180nm technology does not show desired result at high frequency such as 2.4 GHz .

II. CONVENTIONAL MODELS

(a) **(b)**

Fig 1(a) Conventional dynamic latched comparator [10]; (b) Double-tail dynamic comparator [8]

Though there are several advantages such as fast speed, ideally zero static power consumption, high input impedance and full-swing output, the dynamic latched comparator shown in Figure 1(a) has been most widely used [10]. However, in order to increase the drive current of the latch, it is inevitable to size up the tail transistor M1 since this comparator has only one tail transistor. If the size of tail transistor is increased, the drain currents of both input transistors M2 and M3 will increase during the evaluation phase (*clk*=V_{DD}). This means the reduction of the time duration for transistor M2 and M3 being operated in saturation region. *Di* nodes discharge from V_{DD} to ground in a very short period. Consequently, lower amplification of the input voltage difference will be made. And such a small *Vth* variation from mismatch between transistor M6 and M7 can yield high input-referred offset. In addition, since it shows the strong dependency on speed and offset with different common-mode input voltage V_{com} [10], it is less attractive in applications with wide common-mode ranges such as ADCs [8].

In order to circumvent these drawbacks, the comparator with separated input-gain stage and output-latch stage shown in Figure 1 (b) was introduced in [8]. This type of design made it possible for this comparator to operate at a lower supply voltage (V_{DD}) and have more stable offset voltage over wide common-mode voltage (V_{cm}) ranges. However, since it requires both *clk* and *clkb (inverted clk)* for its operation, high accuracy of *clkb* is required. Because the output-latch has to detect the voltage difference at *Di* nodes at very limited time. If a simple inverter replaces the *clkb*, *clk* has to be able to drive an additional large inverter (heavier clock load) in order to drive the largest transistor M12 in a small delay. If *clkb* is lagging the *clk*, it results in increased delay and if *clkb* is leading the *clk*, it results in increased power dissipation due to existing the short circuit current path from M12 to M10/M11 though M8/M9. And it can even increase the latch offset voltage if the device mismatch between M8 and M9 is significant. The comparator from [11] without offset calibration technique, shown in Figure 2, resolved the problem by replacing *clkb* with *Di* nodes. As a result, *clk* load was lessened and the input referred offset was reduced.

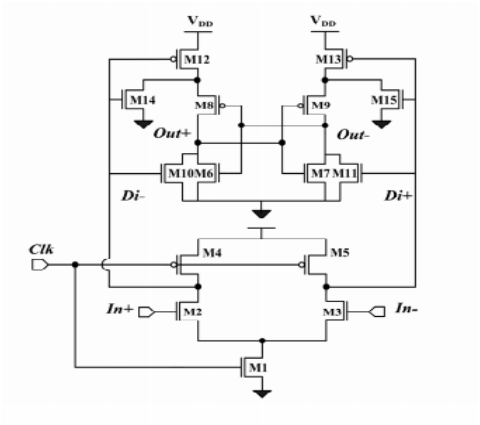


Fig 2: Dynamic comparator[11]

However, the improved offset has to trade off with the increased delay since the current drivability of the output load was weakened due to the fact that transistor M12 and M13 use *Di* node voltages as their *clkb* signal. That show slow exponential decay shape, and that the maximum drive current of each *Out* node was reduced to half of the single output tail current of M12 comparing with Comparator 1, since it was separated into two transistors M12 and M13

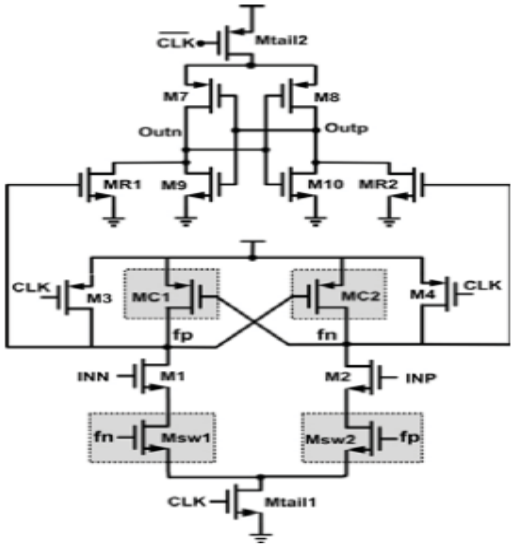

Fig 3: Dynamic comparator with reduced delay[4]

The above mentioned circuit of figure 3, improves the speed and reduces the delay and static power consumption of conventional dynamic and double tail comparator by adding two control transistor MC1 and MC2 as cross coupled inverter in input section. Two NMOS switches below two input transistors (MC1 and MC2), as a latch structure increases the voltage difference between fp and fn nodes within a very short time and passes that difference to intermediate stage transistors MR1 and MR2. This phenomenon furthermore improves the regeneration time of output latch stage, thus speed improves. It also enhances the effective transconductance (g_{meff}) of the latch, and delay is reduced. On the other hand, two NMOS switches M_{sw1} and M_{sw2} are included in order to avoid static power consumption due to current flow from V_{DD} to ground via two input transistors. However, it has shortcomings in case of offset mismatch and

kickback noise. When the input differential voltage is very small, threshold voltage and current factor mismatch of controlled transistors augment input referred offset voltage. Kickback noise is also increased in comparison with conventional double tail structure.

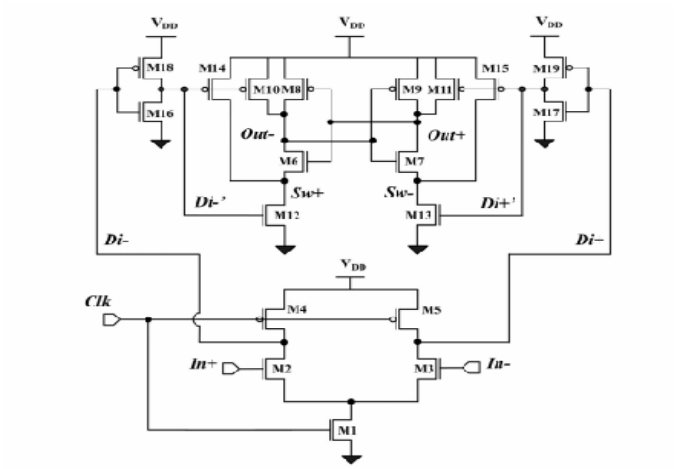

Fig 4: Dynamic comparator with reduced offset[6]

To resolve the problem of offset voltage another comparator circuit is proposed [6]. The given circuit offers lower input referred offset voltage and faster operation at the same area and power consumption. Two inverters are included between input and output stage for amplification of weak difference signal so that input referred offset voltage is attenuated by the voltage gain of that stage. On the other hand, pre-charge state voltage mismatch is overlooked by using M14 and M15 transistors which reset sw nodes. Therefore, V_{th} mismatch between M6 and M7 is removed. It has many stacked transistors and higher load drivability. The circuit was simulated on HSPICE on 90nm PTM technology with V_{DD}=1V.

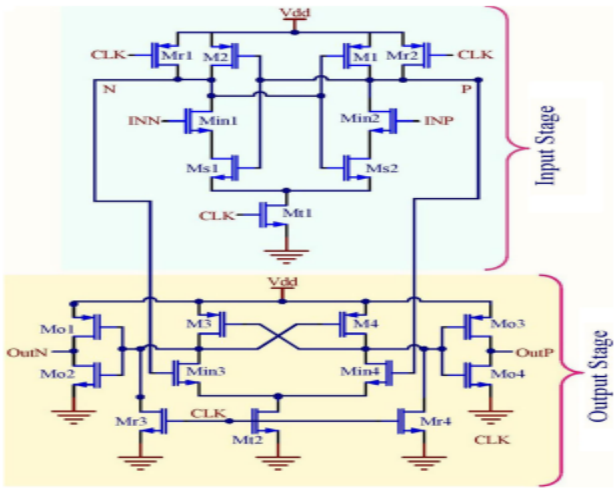

Fig 5: Dynamic comparator with optimized design[5]

To achieve a best possible design for double tail latch comparator power, speed, offset and size are optimized. The circuit is simulated on 180nm and power, delay is indicated. It depends on discharging of output capacitance to indicate rail to rail output swing.

III. PROPOSED DYNAMIC COMPARATOR

Fig .6 demonstrates the schematic diagram of the proposed dynamic comparator. During pre-charge (reset) phase when Clk = 0V, tail transistor M_{t1} and M_{t2} remains off while two PMOS transistors P3,P6 becomes on .It makes N4 and N3 switch on to pull both of the output to zero. During evaluation (decision making) phase when ClK=1, both M_{t1} and M_{t2} turns on and P3,P6 turns off. As a result, the capacitor at the gate of N3 and N4 starts to discharge according to the difference in input. Consider $V_{INP}>V_{INN}$, thus the drain of N1 discharges faster than that of N4.When drain voltage of N1 drops below V_{thn} the corresponding NMOS transistors N3 turns off gradually. At that time, voltage of OutN is still zero, so it turns on P1,makes Outp towards V_{DD}. On the other hand, N4 remains on before the gate volage falls off its threshold level. When the gate voltage of N4 drops below v_{thn}, N4 turns off. P2 was off before, therefore, the capacitor at OutN holds it to ground while OutP remains at V_{DD}. The case is vice versa for $V_{INP}<V_{INN}$.

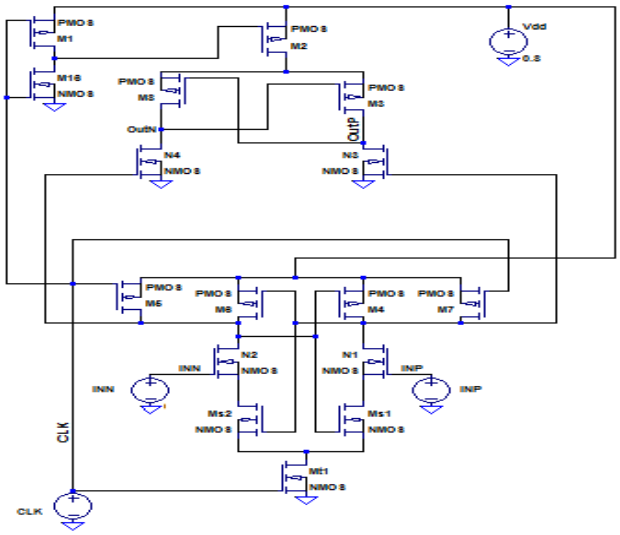

Fig 6: Schematic diagram of proposed comparator at 180nm CMOS Technology

IV. SIMULATION RESULTS

The circuit is simulated on LTspice using 180nm CMOS technology modeled with parameter (v_{thp}=-0.42V and v_{thn}=0.3999V. Fig. 7 is the simulated waveform for proposed circuit at 180nm CMOS technology. The same circuit is simulated with 32nm and the wave characteristics are shown in figure 8. Also, Fig. 3,Fig. 4 and Fig. 5 are simulated at 32nm and compared with proposed one.

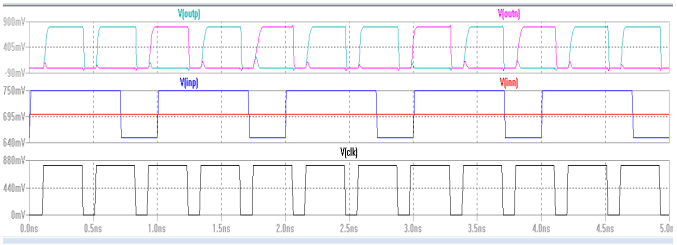

Fig 11:Simulation result of Fig .6 for 32nm CMOS technology at 2.4GHz

V. PERFORMANCE COMPARISON

In order to compare the proposed comparator with the referenced comparator given [4, 5, 6], the other circuits have been simulated in 180nm CMOS technology with V_{DD}=0.8V except Fig. 4. where supply is 1V. This is because, for Fig. 4 if the supply voltage becomes low, the top level of output alienate more from the V_{DD} level, which is not desired. Now, consider the circuits for 180nm.Maximum clock frequency is proportional to supply voltage. If the supply voltage is high ,we can use high clock frequency or vice versa. i.e. for Fig. 3 if V_{DD} is 1.2 V ,clock frequency can be elevated upto 2.5GHz. For V_{DD}=0.8V, here in Fig. 3 the maximum clock frequency is 1.69GHz.The same result is for proposed circuit where for Fig. 5 it is 1.66GHz. For Fig. 4 clock frequency is 3GHz with V_{DD}=1V. But, output can not reach to V_{DD} as high level. We need to enhance that frequency in order to get a good digital output. On the other hand, the ac performance tends to degrade if the number of transistor becomes larger due to parasitic capacitances. In our proposed circuit the number of transistor also has lessen compared to others. Time delay and power dissipation is also shown in Table I and it is clearly visible that for 180nm technology, our proposed design shows better performance.

Table II shows the same features for 32nm technology as we are moving towards smaller feature size. Clock frequency can be increased and we have used 2.4GHz. Power consumption and delay are analyzed with two threshold voltages to observe the variation. And again our proposed one gives less delay and power performance.

TABLE I. PERFORMANCE COMPARISON WITH REFERENCED COMPARATORS AT 180NM

Comparator structure	Ref. [4]	Ref. [5]	Ref. [6]	Proposed Comparator
Technology	180nm	180nm	90nm	180nm
No. of transistor	16	20	19	14
Supply voltage(V)	0.8V	0.8V	1V	0.8V
Clock frequency	Max 1.69GHz at 0.8V	1.66 GHz	3GHz	Max 1.69GHz At 0.8V
Delay at ΔV_{in}=50mv	Rise time:172.3ps	Fall time:49ps	Delay[ps]/log(ΔV_{in})=17	Rise time:97.41ps
Power dissipation at 0.33GHz and V_{cm}=0.7V	2.5908µW for simulation time 5ns	11.862µW for simulation time 5ns	162 µW at 3GHz and V_{cm}=0.6V	2.2929µW for simulation time 5ns

TABLE II. PERFORMANCE COMPARISON WITH REFERENCED COMPARATORS AT 32NM FOR 5NS SIMULATION TIME

Comparator structure	Dynamic Comparator[4]		Dynamic Comparator[5]		Dynamic Comparator[6]		Proposed Comparator	
	V_{thn}= 0.49V V_{thp}= -0.49V	V_{thn} = 0.35 V V_{thp} =-0.24 V	V_{thn}= 0.49V V_{thp}=-0.49V	V_{thn}= 0.35V V_{thp}= -0.24V	V_{thn}= 0.49V V_{thp}= -0.49V	V_{thn}= 0.35V V_{thp}= -0.24V	V_{thn}= 0.49V V_{thp}= -0.49V	V_{thn}= 0.35V V_{thp}= -0.24V

Delay at ΔV_{in}=50 mv	Rise time: 29.7 ps	Rise time 11.25 ps	Fall time: 12.34ps	Fall time 4.5 ps	Fall time: 11.37 ps	Rise time: 6.73 ps	Rise time: 28.10 ps	Rise time 7.86 ps
Power dissipation at 2.4GHz, V_{cm}= 0.7V	3.2542µW	2.6798µW	22.023 µW	26.11µW	54.27 µW	40.35 µW	3.0883 µW	2.3688µW

VI. CONCLUSION AND FUTURE WORK

In this paper, comprehensive analysis for clocked dynamic comparator is presented and analysed for various feature size. The present research is mainly concentrated on power consumption and delay of the proposed dynamic comparator. The comparator works perfectly according to the requirement and demonstrates better performance as compared to other referenced models. Moreover, the size of CMOS transistors as well as threshold value are varied and analysed their effect on the performance. The analysis shows clearly that the proposed

circuit reduces both the time delay and power dissipation in comparison with referenced others.

***Abstract*—. This paper presents the implementation and analysis of GNRFET and Conventional CMOS based 1-bit and multi-bit Arithmetic Logic Unit (ALU). The simulation results calculated using HSPICE have reported to show 2.79% reduction in Propagation Delay (PD), 57.59% reduction in Average Power Consumption, 61.98% reduction in Power Delay Product (PDP) and 66.44% reduction in Energy Delay Product (EDP) for GNRFET base 1-bit ALU as compared to Conventional CMOS based 1-bit ALU at 32nm technology**

Keywords—GNRFET, Power delay product, Energy delay product

I. INTRODUCTION

The advancement in IC technology rendering area optimized and fast ICs is primarily attributed to the MOSFET scaling theory. As the process technology reached the nanometer regime, silicon CMOS started developing short-channel effects which led to increased power dissipation. Much research has been conducted to find a potential replacement for Conventional CMOS. Graphene Nano-Ribbon Field-Effect Transistor (GNRFET) proved to be a potential replacement to traditional CMOS. Thus, analysis of the circuits built using GNRFET is necessary to demonstrate its merits. The driving engine for the exponential growth of digital information processing systems is scaling down the transistor dimensions. Although there are some improvements still at the end of the International Technology Roadmap for Semiconductors (ITRS) [1] roadmap industry needs more improved and fast switching devices compare to the current trend. With the introduction to new techniques in fabrication nano materials with carbon group are emerging in Field-effect transistors [2],[3]. They have very good electrical properties along with capabilities to be integrated. The most studied are carbon nanotube FETs (CNFETs) and graphene nanoribbon FETs (GNRFETs). Compared to cylindrical CNTs, GNRs can be grown through a silicon-compatible, transfer-free, and in situ process [4],[5]. Graphene [6] and carbon nanotube (CNT) [7] are the two carbon allotropes, which have become prominent contenders to substitute silicon in post-CMOS technology. With fast switching capability as 2D electron gas in graphene gives high velocity and concentration in carrier which makes large mobility and hence fast switching compared to traditional Si-based CMOS technology [8]. It makes the transistor current quite high as electrons are injected from the source and transit to the drain terminal [7],[8]. In this paper, an ALU has been designed with the emerging Graphene Nano Ribbon-based FET (GNRFET) at 32nm technology node. The results have been optimized by varying the number of graphene nanoribbons (GNRs). Lastly, the results are compared with a CMOS based ALU to get a realistic idea of its performance, as compared to the state of art technology. Delay, Power & Power-Delay Product (PDP) and energy-delay product (EDP) has been chosen as parameters of comparison between the aforementioned devices. The MOSFET type GNRFET model has been used for simulation purposes on the HSPICE platform.

II. GNRFET MODELING

This paper explores circuit-level simulations by using the SPICE models of MOS-GNRFETs from [10],[11]. We simulated the ideal cases of MOS-GNRFETs and Si-based CMOS technology. In MOS-GNRFET circuits, a contact resistance of 20 kΩ is added to all graphene-metal vias. The 32nm Si-CMOS libraries from Predictive Technology Models (PTM) are adopted as comparisons, and the GNRFETs are set to have matching dimensions. The impacts of supply voltage and process variation are evaluated on 1-bit arithmetic and logical unit and the performance of the design is evaluated. Table I defines the default values and their definitions.

TABLE I. DEVICE PARAMETER DEFINITIONS AND USED VALUES

Device Parameter	Description	Used values
L	Physical channel length	32nm
T_{OX}	The thickness of top gate dielectric material	0.95nm
nRib	The number if GNRs in the device.	6
N	The number of dimmer lines in the GNR lattice	12
dop	Source and Drain reservoirs doping fractions	0.001
T_{OX2}	Oxide thickness between channel and substrate/bottom gate	20nm
2*sp	The spacing between the edges of two adjacent GNRs within the same device.	2.0nm

III. ARITHMETIC LOGIC UNIT DESIGN

ALU is the heart of any processor. It performs basic arithmetic and logical operations. The ALU that have been implemented in this paper performs arithmetic operations such as addition & subtraction and logical operations such as AND & OR. In the 1-bit ALU shown in Fig. 1, the logical operations are performed by the 2 input AND & OR gate while the arithmetic operations are performed by the full adder-subtractor unit. The output 'S/D' of the full adder-subtractor unit indicates

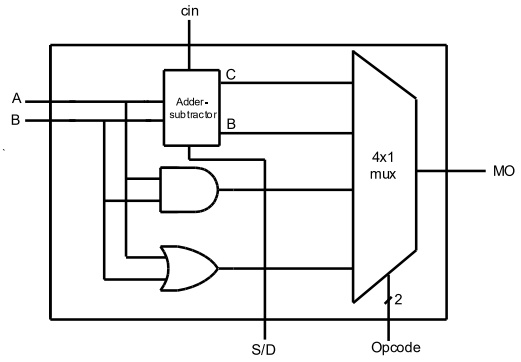

Fig. 1. *Block Diagram of 1-bit ALU.*

'Sum/Difference' bit as they are both the same in the case of addition and subtraction operations. The output 'C' of the full adder-subtractor unit indicates 'Carry' bit in case of addition operation and output 'B' indicates 'Borrow' bit in case of subtraction operation. The 2-bit opcode of 4x1 mux selects the result of either logical or arithmetic block which will be the output 'MO' of the ALU. The following Table II summarizes the select lines and operations performed by the ALU.

TABLE II. ALU OPERATION

Opcode		Operations
S_0	S_1	
0	0	ADD
0	1	SUB
1	0	AND
1	1	OR

IV. RESULT AND DISCUSSION

Timing diagrams of Fig. 2 and Fig. 3 represents the arithmetic operations of GNRFET and MOSFET based ALU. In arithmetic unit operation A, B & Cin are the three input pins and S_0 and S_1 are the opcodes. The unit operates addition when the opcode is in 00 combinations and works subtraction when it is in 01 combinations.

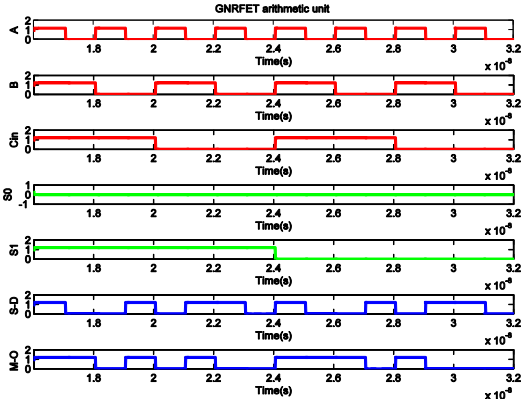

Fig. 2. *Arithmetic unit timing diagram for MOSFET*

The 1-bit ALU based on the University of Illinois (UIUC) MOS-GNRFET model is implemented and analyzed at 32nm technology. Another 1-bit ALU based on 32nm Berkeley Short-channel IGFET Model (BSIM4) for bulk CMOS is also implemented and analyzed for comparison, both having the same design. The ALU circuits are designed using static logic and simulated in HSPICE with a supply voltage of 1.2V. In logical unit operation, both opcodes are varied to get different logical operations. ALU performs AND operation where the output is high only when both inputs are high. In addition to different combinations, the unit performs OR operation with high output with one or more of its input is high. The resultant output performs different performance analysis with two sets of unlike structure. The results are compared at the nominal voltage of 1.2V and the number of nanoribbons is kept equal to 6 for making dimensions of GNRFET comparable to that of Si-CMOS. In this case, the delay of GNRFET based ALU is found to be 1.003ns whereas the delay of the Si-CMOS based is 1.031ns. Propagation delay has been taken between the 50% transition points of the input and output and hence calculated. Power consumption is another figure of merit for this ALU.

TABLE III. COMPARISON BETWEEN GNRFET AND MOSFET

Figure of Merit	GNRFET (32nm)	MOSFET (32nm)
Propagation Delay (PD)(s)	1.003×10^{-09}	1.031×10^{-09}
Average Power consumption (W)	6.498×10^{-06}	1.024×10^{-05}
Power delay Product (PDP)(J)	6.517×10^{-15}	1.056×10^{-14}
Energy delay Product (EDP)(Js)	6.537×10^{-24}	1.088×10^{-23}

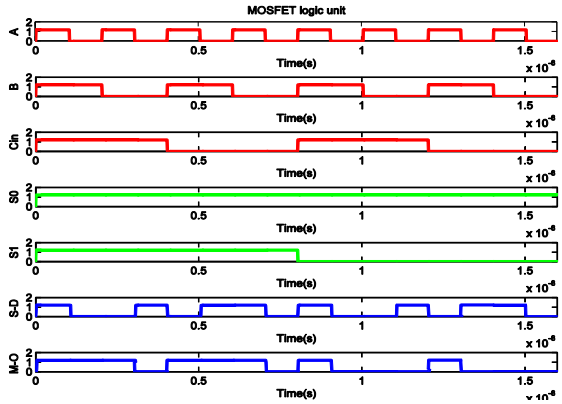

Fig. 3. *Logical unit timing diagram for GNRFET.*

The results show that GNRFET based 1-bit ALU has 2.79% reduction in Propagation Delay (PD), 57.59% reduction in Average Power Consumption, 61.98% reduction in Power Delay Product (PDP), 66.44% reduction in Energy Delay Product (EDP) as compared to Conventional CMOS based 1-bit ALU. As the simulation results have illustrated a substantial improvement in the performance of GNRFET based design over CMOS based design.

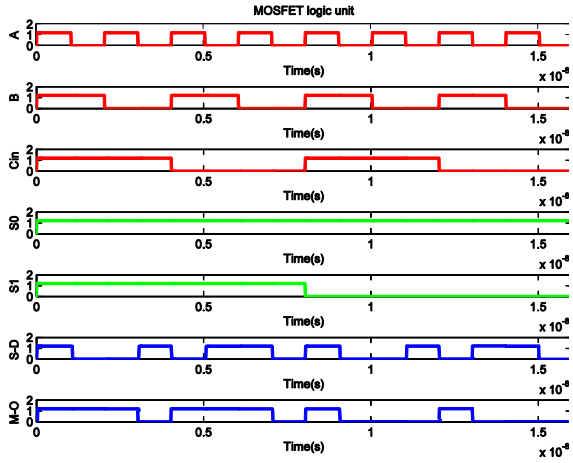

Fig. 4. *Logical unit timing diagram for MOSFET.*

so GNRFETs can be considered as potential candidates to replace conventional CMOS in the future.

TABLE IV. COMPARISON BETWEEN GNRFET(32NM) AND GNRFET(10NM) 1 BIT ALU.

Figure of Merit	**GNRFET (32nm) 1 bit**	**GNRFET (10nm) 1 bit**
Propagation Delay (PD)(s)	1.003×10^{-09}	1.002×10^{-09}
Average Power consumption (W)	6.498×10^{-06}	2.118×10^{-06}
Power delay Product (PDP)(J)	6.517×10^{-15}	2.122×10^{-15}
Energy delay Product (EDP)(Js)	6.537×10^{-24}	2.126×10^{-24}

Simulation results tabulated in Table IV shows that GNRFET (10nm) based 1-bit ALU has 0.09% reduction in Propagation Delay (PD), 67.41% reduction in Average Power Consumption, 67.44% reduction in Power Delay Product (PDP), 67.48% reduction in Energy Delay Product (EDP) as compared to GNRFET (32nm) based 1-bit ALU. From Table V, in case of GNRFET (32nm) based 2-bit ALU has 1.22% reduction in Propagation Delay (PD), 28.14% increase in Average Power Consumption, 27.28% increase in Power Delay Product (PDP), 26.38% increase in Energy Delay Product (EDP) as compared to Conventional CMOS based 2-bit ALU.

TABLE V. COMPARISON BETWEEN GNRFET(32NM) 2 BIT AND MOSFET(32NM) 2 BIT ALU.

Figure of Merit	**GNRFET (32nm) 2 bit**	**MOSFET (32nm) 2 bit**
Propagation Delay (PD)(s)	5.507×10^{-09}	5.574×10^{-09}
Average Power consumption (W)	2.874×10^{-05}	2.065×10^{-05}
Power delay Product (PDP)(J)	1.583×10^{-13}	1.151×10^{-13}
Energy delay Product (EDP)(Js)	8.716×10^{-22}	6.416×10^{-22}

V. CONCLUSIONS

The performance analysis of a single-bit and multi-bit ALU is done with two different transistor structures and technology node in this paper. In case of 1-bit ALU based on 32nm technology, the paper reports a small percentage of reduction in PD along with more than 60% of average power consumption with a significant amount of PDP reduction on GNR based device over the conventional one. Reduction of feature size (to 10nm for GNRFET) leads to small reduction in PD and significant amount of reduction in EDP, PDP and average power as compared to 32nm based GNRFET. But in case of 2-bit 32nm ALU GNRFET based design shows a small reduction only in PD as compared to conventional 32nm based CMOS design. So, in the case of the 1-bit combinational unit, the performance parameter of graphene-based architecture has the upper hand over the Conventional CMOS based unit.

***Abstract*—The objective of this work was to investigate the lift and drag characteristics of a NACA 0015 airfoil with backward facing step. For a free stream velocity of 30m/s, the point of separation was determined via CFD analysis for increasing angle of attack. A backward facing step was then introduced just prior to the point of separation which extended till the trailing edge. Computational studies were conducted with the goal of enhancing the aerodynamic performance of the airfoil by inserting several backward facing steps of gradually increasing depth. The CFD analysis was conducted for 30 m/s wind speed, with steps placed just prior to the point of separation for 18° angle of attack. The results produced show that as much as 26% reduction in drag is possible by introducing the step. But at the same time, about 12% reduction in lift was also observed. A wind tunnel test on a NACA 0015 was also conducted to verify the results from CFD analysis. Predominantly the goal of this thesis was to numerically determine whether or not the aerodynamic performance of an airfoil can be enhanced by introducing a backward facing step on the upper surface of the airfoil.**

I. INTRODUCTION

An Airfoil is a structure, piece, or body designed to obtain a useful reaction upon itself in its motion through the air. An airfoil may be no more than a flat plate, but usually it has a cross section carefully contoured in accordance with its intended application or function. Airfoils are employed on aircraft as wings to produce lift or as propeller blades to produce thrust. Both these forces are produced perpendicular to the air flow. Drag is a consequence of the production of lift/thrust and acts parallel to the airflow. Airfoil shapes are designed to provide high lift values at low drag for given flight conditions. The airfoil creates a situation where the velocity above the airfoil is higher than the velocity below the airfoil. According to Bernoulli's principle, a liquid or gas, areas with high relative velocity create lower pressure systems, and areas with low relative velocity create high pressure systems. So, the upper surface pressure is lower than the lower surface pressure. This pressure difference creates a resultant force. This resultant force has two components. The vertical component is known as lift and the horizontal component is known as drag. Fig 1.1 shows the forces acting on an airfoil.

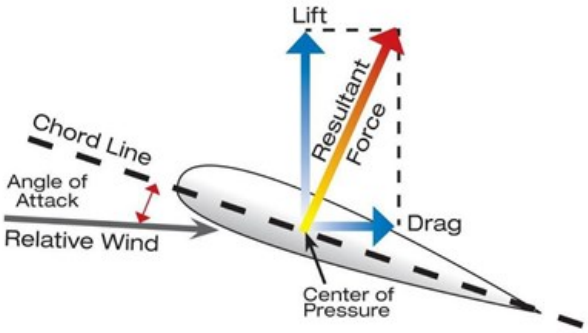

Fig. 1.1: Force vectors on an airfoil

The drag FD and lift FL are represented in terms of two dimensionless coefficients: the drag coefficient and Lift coefficient, defined as

$$C_D = \frac{F_D}{\frac{1}{2}\rho_\infty {U_\infty}^2 A} \quad (1)$$

$$C_L = \frac{F_L}{\frac{1}{2}\rho_\infty {U_\infty}^2 A} \quad (2)$$

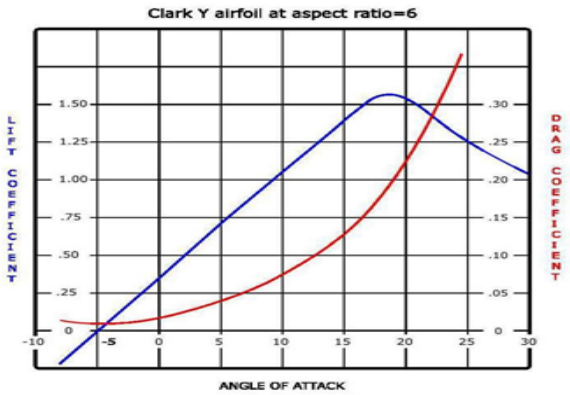

Fig. 1.2: Lift and drag curves for typical airfoil.

The lift generated by an airfoil depends on such factors as: Speed of the airflow, Density of the air, Total area of the

airfoil, Angle of attack. Fig 1.2 shows a lift and drag curve obtained in wind tunnel testing for different attack of angle.

The curve represents an airfoil with a positive camber so some lift is produced at zero angle of attack. With increased angle of attack, lift increases in a roughly linear relation. At about 18 degrees this airfoil stalls, and lift falls off quickly beyond that. The drop in lift can be explained by the action of the upper-surface boundary layer, which separates and greatly thickens over the upper surface at and past the stall angle. The thickened boundary layer's displacement thickness changes the airfoil's effective shape, in particular it reduces its effective camber, which modifies the overall flow field so as to reduce the circulation and the lift. The thicker boundary layer also causes a large increase in pressure drag, so that the overall drag increases sharply near and past the stall point. So, flow separation occurs over the airfoil top surface when the angle of attack (AOA) exceeds a certain value- the "stalling" angle of attack.

In other words, flow separation occurs when the boundary layer travels far enough against an adverse pressure gradient that the speed of the boundary layer relative to the object falls almost to zero. The fluid flow becomes detached from the surface of the object, and instead takes the forms of eddies and vortices. In aerodynamics, flow separation can often result in increased drag, particularly pressure drag which is caused by the pressure differential between the front and rear surfaces of the object as it travels through the fluid.

II. Literature Review

Boundary layer separation is a phenomenon that designers normally attempt to avoid, as it leads to a decrease in lift and an increase in drag. This separation may occur anywhere an adverse pressure gradient exists, such as on wings, airfoils, turbo machinery, and engine inlets. This problem is especially prevalent at low Reynolds numbers, when laminar flow is prevalent.

One of the earliest investigations of the flow features near surfaces structured with spherical dimples was made by Bearman and Harvey [1]. This study demonstrated the effectiveness of dimples as a technique of causing early boundary layer transition without the drag penalties associated with sand roughness. Unlike a smooth or roughed round ball the dimpled ball drag curve remains almost constant at the post critical Reynolds number. This confirms the dimples have a more beneficial effect on the drag reduction and laminar-turbulent transition than sand roughness.

Experiments carried out with the dimpled circular cylinder [2] have the shallow dimples cause the critical drag reduction event to occur at a lower Reynolds number than that for a smooth cylinder. It was concluded that the dimples affect the flow around a circular cylinder in a similar manner as the flow around a golf ball. Experimental studies of a cross-flow dimpled cylinder [3], [4] have revealed that the separation point is moved in the downstream direction. This results in a smaller wake region and a reduction in the pressure drag.

A two-dimensional groove is the limiting case of a closely spaced span wise array of dimples. The background relevant to the rectangular-shaped groove can be found in many existing publications. The data obtained by Zhak [5] have shown the laminar-turbulent flow transition inside rectangular cavity can occur via the specific mechanism of the Taylor-Görtler instability The available publications demonstrate that steps engraved into a solid surface generate 3D or 2D vortex flow structures that energize the boundary layer and reduce pressure losses over a wide range of Reynolds numbers. Besides Mahdi [6] and Asif [7] have all also used a wide range of Reynolds numbers for NACA 0012. As air flows over an indented surface treatment, such as a dimple or groove, a complex flow pattern develops. The flow inside the step is highly time dependent. This unsteadiness causes instability with a laminar boundary layer, causing the boundary layer to begin transition to turbulent flow. The turbulent flow promotes the mixing of high momentum flow in the boundary layer, which helps to combat the adverse pressure gradient.

Lake [8], Rouser [9], and Khalatov [10] have all previously used these techniques in the design of improved passive flow separation control techniques for cases of laminar separation. The indentations do not affect separation of a turbulent boundary layer, as the effects of mixing have already been realized through the turbulent nature of the flow. The effectiveness of the recessed technique depends on several factors, including the location of the indentation relative to the separation bubble, the geometry of the step, and the pre-recess boundary layer thickness. Although several studies have assessed the effectiveness of indented surface treatments for delaying boundary layer separation, definitive design guidelines have never been published. This study examined the previous literature with an eye towards determining the optimum placement, depth, and length of the steps. The best location for the grooves or dimples is just prior to the region of separation. So, our objective was to introduce a backward facing step just prior to the point of separation on the upper surface of a NACA 0015 airfoil and investigate its aerodynamic performance using Computational Fluid Dynamics (CFD) and verifying the CFD results by experimental approach.

III. Methodology

A. Formulation of the Flow Problem

The flow problem was set up as an airfoil fixed at a certain angle of attack with air flowing over it at a given free stream velocity. The objective was to study the aerodynamic performance of the airfoil using backward facing step that extends till the trailing edge of the airfoil. The configuration of a step is defined by its location on the airfoil chord and its depth expressed in the terms of airfoil maximum thickness. The employment of step to control the flow field around the airfoil comprises the passive flow control used in this study.

B. Parameter Range

There are several parameters which can affect the flow field around an airfoil. Both the airfoil and step profiles constitute the geometric parameters. The most important ones are the shape of airfoil (symmetric or cambered); chord length, which was taken as 19 cm; angle of attack; chord-wise location of the step; its length and depth on the upper surface. Fig. 3.1 shows a sketch of a sample airfoil configuration with backward facing step defining the main geometric parameters.

The flow parameters are the free stream velocity, density and viscosity grouped together as the Reynolds number (Re). For this flow problem the free stream velocity was taken as 30 m/s, density as 1.166 kg/m^3 and the viscosity as 1.8599×10^{-5} kg/s-m, which gave a corresponding Reynolds number of 357,341 while α was 18 degrees.

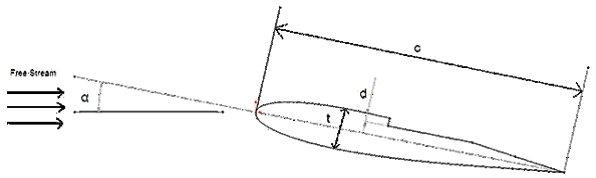

Fig. 3.1: Geometric parameters associated with airfoil with backward facing step

C. Computational Details

All of the computational work was done using commercial software packages. The airfoil profile was generated using SOLIDWORKS 2016. The profile was then imported into ANSYS 17.0 FLUENT. All the Pre-processing comprising generating meshes for all the airfoil configurations, quality control, setting up of the boundary conditions was done using FLUENT. FLUENT is a finite volume method based CFD tool which solves the governing equations of conservation of mass and momentum. Post processing including generation of plots and figures was done using FLUENT.

The problem was set up as a two dimensional flow problem in single phase. The Cartesian co-ordinate axes were fixed at the leading edge of the airfoil in each case. The computational domain comprises of four blocks for all base airfoil configurations, while the backward facing step configurations had six mesh blocks. Fig. 3.2 and 3.3 shows the grid distribution around a NACA 0015 airfoil. The flow was modeled as steady, incompressible in the flow domain comprising several blocks. The fluid chosen was air at 30° C and 1 atm pressure which were set as the reference values along with the free-stream velocity set corresponding to the flow Re for each simulation run for the preliminary cases of study. The inlet was set as "Velocity Inlet" which includes all the front, top and bottom edges of the flow domain. The x and y-velocities are "u", which is defined by the Reynolds number used and "v". "Spalart-Allmaras" one equation turbulence model was used in FLUENT for all computations. This computational model is well suited for modeling wall driven flows which transpire most commonly over aerodynamic bodies. All the exit boundaries combined were set as "Pressure Outlet". All the airfoil edges together were set as "Wall" with no-slip condition. The flow solver used the SIMPLE algorithm for pressure-velocity coupling. Least Squares Cell Based method was used for gradient computations. Pressure was set as second order, Momentum, and Modified Turbulent Viscosity were set as Second Order Upwind for Spatial Discretization computations.

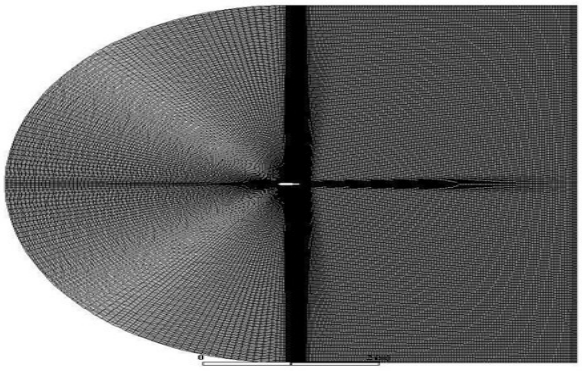

Fig. 3.2: Grid distribution around a NACA 0015 airfoil

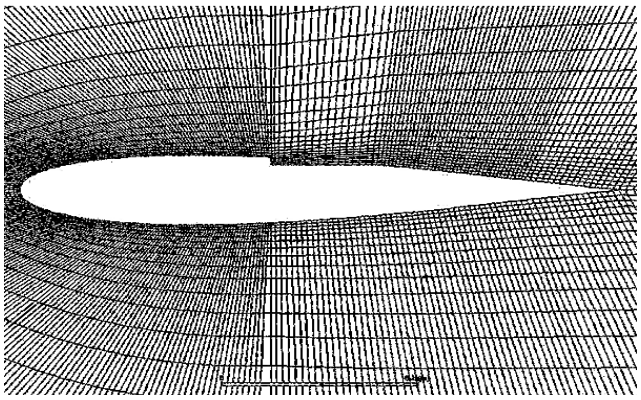

Fig. 3.2: Grid distribution around a NACA 0015 airfoil with backward facing step (close).

IV. Wind Tunnel Testing

A subsonic wind tunnel test on a NACA 0015 airfoil was conducted to validate some of the results obtained with numerical studies conducted as a part of this research effort. The experimental studies were conducted in the Fluid Mechanics and Machineries Laboratory located in the Department of Mechanical Engineering at Bangladesh University of Engineering and Technology. This section presents the approach followed for the wind tunnel testing of the NACA 0015 airfoil.

The airfoil was contained in a clear sided duct in 'closed ends' arrangement; thus airflow was only across the curved surfaces of the airfoil. Pressure taps were placed along the top and bottom surfaces of the airfoil. Each of pressure taps were numbered according to their placement. Pressure taps on the upper surface of the airfoil were numbered 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 and 16 while taps on the lower surface of the airfoil were numbered 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 and 32.

First the initial readings were taken from each tube of the manometer. Second readings were taken after the flow over the airfoil reached steady condition which was the final value in centimeter. The differences were converted into meter. Comparing the experimental data for a NACA 0015 airfoil at 18° AOA with the CFD result, we can see that our simulation result matches very closely to the experimental results. The slight deviation close to the leading edge may result from friction during the experimental procedure.

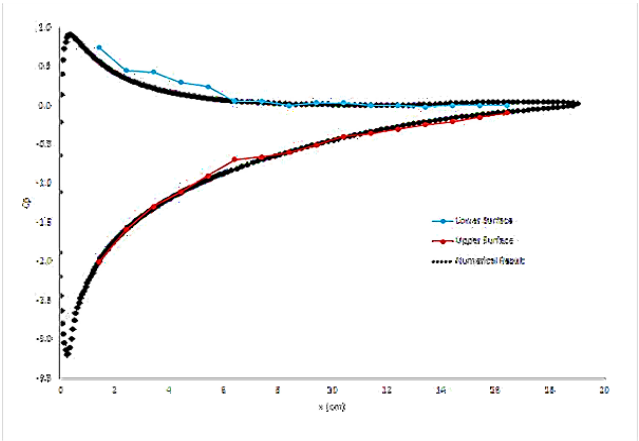

Fig. 4.1: Experimental results for 18° AOA, 30 m/s free stream velocity.

V. Results and Discussion

CFD analysis was conducted on a NACA 0015 airfoil with a chord length of 19 cm and a free stream velocity of 30 m/s. The temperature taken was 30° C which gave us air density, ρ = 1.166 kg/m3 and kinematic viscosity, μ = 1.8599 × 10-5 kg/s-m. This gave us a Reynold's number of 357,341 based on the chord length. Based on this Reynold's number, the turbulent Spalart-Allmaras model was chosen for the CFD simulation.

At first, for a base NACA 0015 airfoil, the point of separation was determined for increasing angle of attack from 8° up to 20° and found that for the above conditions, the stall angle was at 18°.The determination of the separation point was necessary because from the literature review, it was found that the best location for the abrupt change in geometry is just prior to the region of separation. So, a backward facing step was introduced just prior to the point of separation on the upper surface of the NACA 0015 airfoil and the lift and drag characteristics were investigated by CFD analysis.

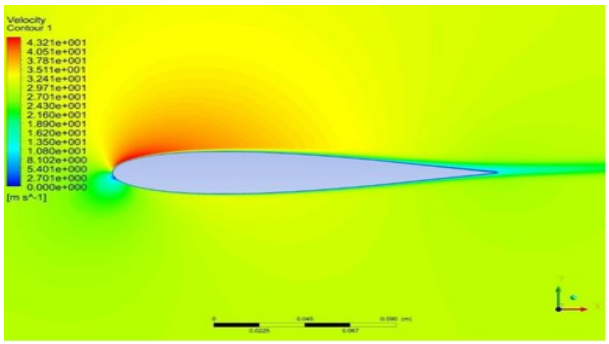

Fig. 5.1: Velocity contour of NACA 0015 at 8° AOA, 30 m/s free stream velocity

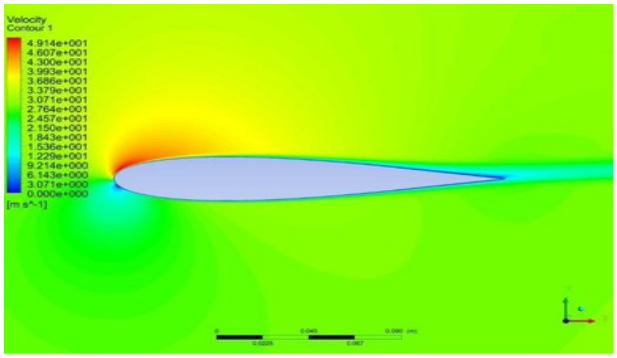

Fig. 5.2: Velocity contour of NACA 0015 at 12° AOA, 30 m/s free stream velocity

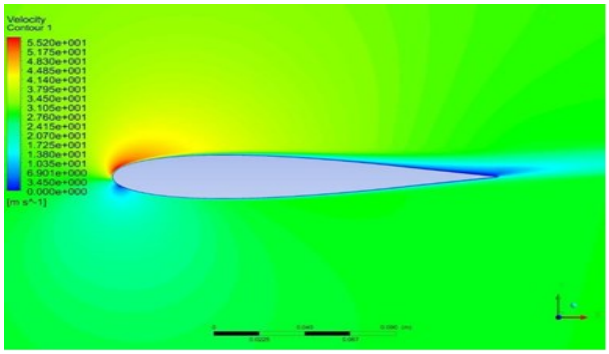

Fig. 5.3: Velocity contour of NACA 0015 at 16° AOA, 30 m/s free stream velocity

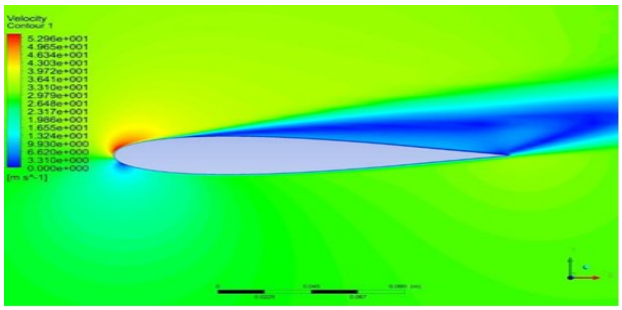

Fig. 5.4: Velocity contour of NACA 0015 at 20° AOA, 30 m/s free stream velocity

From 8° to 10° AOA, no separation can be observed. However, a separation can be observed near the trailing edge at 12° AOA. From here on, the separated region grows and slowly moves towards the leading edge as the angle of attack increases.

Near the trailing edge, a small separated region can be noticed at 14° AOA. The separation point can be located where the x-wall shear becomes negative. In this case, from the CFD analysis it was found to be at x/c = 0.83 from the leading edge.

Stall conditions were reached at 18° AOA. After which the flow over the upper surface of the airfoil becomes more separated. A very large increase in the separated region can be noticed when the angle of attack was increased from 18° to 20° due to exceeding the stall angle.

In order to place the backward step, the angle of attack was chosen to be 18° and the free stream velocity to be 30 m/s. For 18° AOA, the separation point was found at x/c = 0.47 from the leading edge. The step was placed at point prior to the separation point; at x/c = 0.42 from the leading edge.

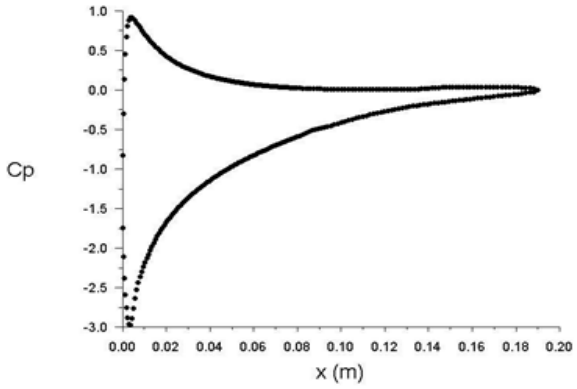

Fig. 5.5: Pressure distribution over NACA 0015 with step depth of 1 mm.

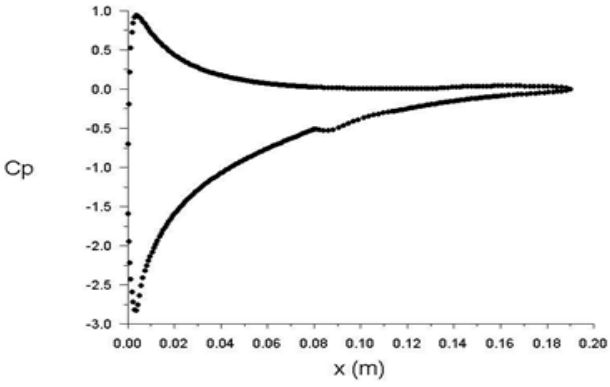

Fig. 5.6: Pressure distribution over NACA 0015 with step depth of 3 mm.

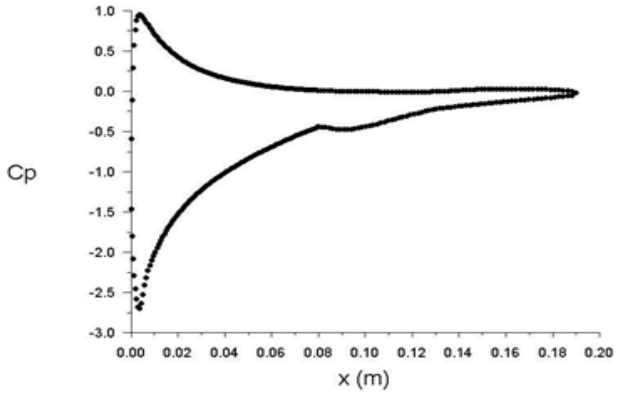

Fig. 5.7: Pressure distribution over NACA 0015 with step depth of 5 mm.

The pressure distribution curve follows similar trend to the base airfoil. But a small pressure drop can be noticed when the flow immediate to upper surface of the airfoil passes the step. This disturbance in the pressure distribution becomes larger with increasing step depth. A 4% reduction in lift and a 9% reduction in drag can also be observed due to the addition of the step on the upper surface.

For a step depth of 3 mm, a sharper disturbance can be observed in the pressure distribution curve. The pressure starts to drop sharply from location of the step at x/c = 0.42 until x/c = 0.44, and then the pressure sharply increases until x/c = 0.52; after which the curve follows similar trend to the base airfoil.

For a backward facing step of 5 mm depth, a higher pressure drop can be observed that starts from x/c = 0.42 and stops at x/c = 0.48, followed by a noticeable pressure increase until x/c = 0.68. From there the curve starts to follow similar trend to the base airfoil. The highest lift reduction at 12% and the highest drag reduction at 26% can be observed. With increasing step depth, the step length that extends till the trailing edge also increases.

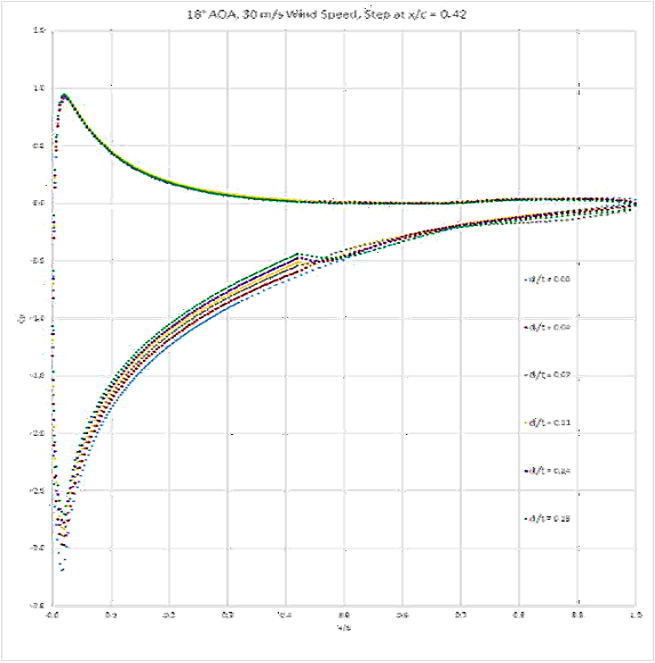

Fig. 5.8: Comparison of Cp for increasing step depths.

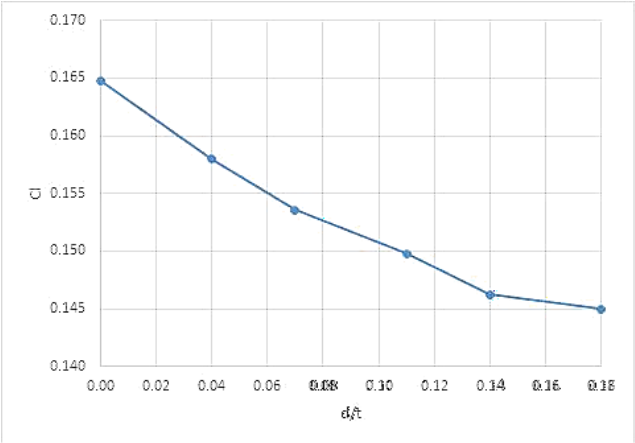

Fig. 5.9: Reduction in lift coefficient with increasing step depth.

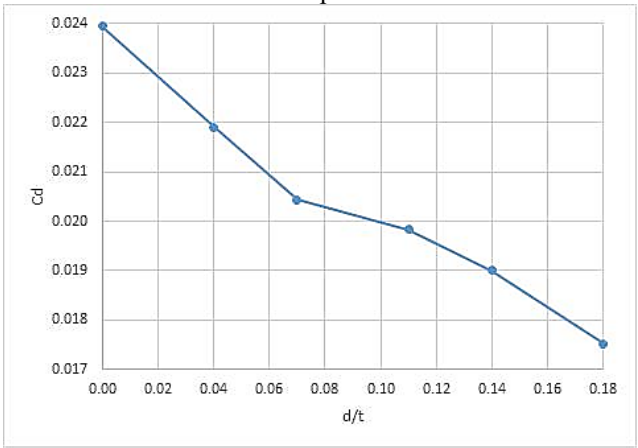

Fig. 5.10: Reduction in lift coefficient with increasing step depth.

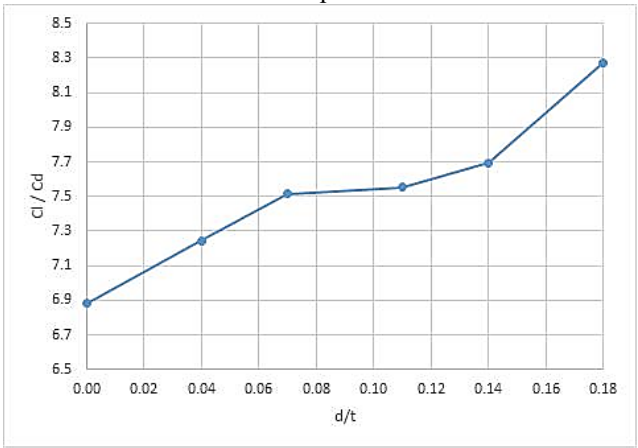

Fig. 5.11: Increase in lift to drag ratio with increasing step depth.

With the increase of the step depth, both the lift and the drag decreases. From fig. 5.9 and 5.10, it is evident that both lift and drag reduction is linear until d/t = 0.07 and becomes irregular as d/t increases. However, it is clear that the reduction in lift is much smaller than the reduction in drag. As a result, even though the lift is decreasing, for a larger decrease in drag, we get higher lift to drag ratio with increasing step depth. Similar to the trend that can be observed in fig. 5.9 and 5.10, it can be seen that the increase in lift to drag ratio is also linear up until d/t = 0.07 and becomes irregular as the d/t increases.

VI. Conclusion

The objective of this study was to investigate the aerodynamic performance of a NACA 0015 airfoil with backward facing step for a chosen velocity and angle of attack. The airfoil with a backward facing step on the upper surface was shown to have the potential to enhance the aerodynamic characteristics by reducing the drag coefficients and increasing the lift-to-drag ratios considerably. The findings of this study may be summarized as following:

- It is possible to enhance the aerodynamic performance of an airfoil by introducing a backward facing step extending till the trailing edge placed on the upper surface prior to the separation point.
- Drag coefficient can be reduced by the introduction of the step.
- Drag coefficient decreases with the increase of step depth.
- A drag reduction of up to 26% was observed in this study.
- However, lift coefficient also decreases with the increase of step depth. A lift reduction of up to 12% was observed.

Although the reduction in drag is much higher than the reduction in lift. As a result, lift to drag ratio actually increases with the increase in step depth.

VII. Recommendation

In this work, we have studied the aerodynamic performance of a NACA 0015 airfoil with a backward facing step extending till the trailing edge. The chord length was taken to be 19 cm, free stream velocity was chosen to be 30 m/s. The step was placed at x/c = 0.42 at 18° AOA. The depth of the step was varied from d/t = 0 to d/t = 0.18.

- The aerodynamic performance of an airfoil with a backward facing step can be investigated for different AOA.
- The backward facing step studied in this work was perpendicular to the chord. Steps of different angle can be studied to enhance the aerodynamic performance of the airfoil.
- The effect of different geometry for surface modification, for example, a circular step extending till the trailing edge, can be investigated.
- The aerodynamic characteristics of an asymmetrical airfoil with backward facing step should be investigated.

Further increase in step depth should be investigated. A backward facing step can be introduced at the lower surface of the airfoil.

***Abstract*—An analysis is presented to show time series data of electricity generation mix and forecasting by 2030 in Bangladesh. The comparative studies have been analyzed using spatiotemporal data of Germany, Australia and Bangladesh. The spatiotemporal data has been taken out from World Bank data bank for analysis. A Linear regression technique is applied for forecasting electricity generation mix from 2015 to 2030. The result shows the rise of renewable energy sources, coal and oil, and the diminution of natural gas gradually.**

Keywords— spatiotemporal, forecasting, electricity, energy mix, solar energy

I. INTRODUCTION

Power Generation mix refers to the combination of the various primary energy sources (fossil fuels, nuclear energy, renewable energy sources) used to meet electricity according to geographical region. For each region or country, the composition of the energy mix depends on the availability of usable resources domestically or the possibility of importing it. The Policy defines by historical, economic, social, demographic, environmental and geopolitical factors [1]. These differences can be appreciated by taking a look at the electricity generation and consumption information for a country.

World Energy Statistics presents comprehensive world electricity generation mix statistics on all energy sources: coal, gas, oil, electricity, renewable sources and waste. Coal is the highest source (39.3%) of electricity generation mix in the world.

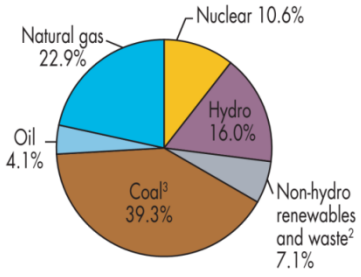

Fig.1. Global Electricity Generation Mix

TABLE 1. ELECTRICITY GENERATION MIX IN BANGLADESH

Gas	8810 MW (64.99%)
Furnace Oil	2785 MW (20.55%)
Diesel	880 MW (6.49%)
Power Import	600 MW (4.43%)
Hydro	230 MW (1.7%)
Coal	250 MW (1.84%)
Total	**13, 555 (100%)**

It is followed by natural gas which is contributed 22.9% in World electricity generation. Hydro (16%), nuclear (10.6%), Renewable energy excluded hydro (7.1%) and oil (4.1%) are respectively in the list of electricity generation mix in the world. Fig.1. shows the percentage of different sources of electricity generation [2].

In Bangladesh, the dominant electricity generation-mix or sources are largely reliant on gas and imported oil. Table 1 describes percentage share of electricity generation mix by sources [3]. The Contribution of gas and oil are significant which accounted for 60.99% and 20.55% respectively of the country's total power generation in 2017, while gas occupying 89.22%, and oil 3% [4]. Electricity generation mix changes over time in Bangladesh. By 2030, coal and nuclear power plant will be operation in which have the ability to generate a huge amount of electricity at a time [5]. So, power generation mix would be changed to renewable energy due to global warming. Even solar energy is potential in Bangladesh as a sub-tropical region [6] and govt. has already planned 2000 MW by 2021 [7].

An agriculture earnings based Bangladesh is one of world's most populated countries. Demand of energy creates with rapid urbanization and industrialization in Bangladesh. So, Bangladesh government should ensure electrical energy for the people that will be affordable and environmentally friendly. Energy sector in Bangladesh is reviewed, and it is hard to accomplish Millennium development goals (MDG) and Sustainable Development Goal (SDG) without improving energy sector [8]. Bangladesh government has already taken step to break the tax for investors in renewable energy [9]. Though Renewable currently play a small role in Bangladesh's fuel mix, despite domestic roof-top solar power units have brought electricity to over a million homes which are not on the grid. There are lots of opportunities in urban building to establish on grid solar power. Ensuring

electricity for all, Bangladesh government is establishing coal and uranium based power plants, as these are able to produce huge electricity energy at a time. Electricity market and cost of energy are hard to determine for power plant project. So, the competitive electricity market is optimized by game theory for revealing existence Nash equilibrium for network incommodity [10]. Last ten years, there is no any wind energy project in Bangladesh. This uncertainty of wind generation and market is managed proposing wind induced demand response (WIDR) using bi-level optimization frameworks [11]. The levelized cost of electricity (LCOE) including import and export is discussed in [12] for the each country. Next ten years, energy sector is expecting new generation-mix in electricity market carrying out the MDG and SDG towards development of Bangladesh.

In this paper, a spatiotemporal data of electricity generation mix of Bangladesh is analyzed and forecasted electricity generation sources for future indication using MS Excel and MatLab. And a comparative study has been done for showing how generation mix is varied with geography location and changed with time being in three different geography locations (Germany, Australia and Bangladesh). Linear regression is used for forecasting to indicate future electricity generation mix in Bangladesh. Linear regression can find linear relationship between two continuous variables. One is predictor and other is response or dependent variable. It looks for statistical relationship between two variables is said to be deterministic if one variable can be accurately expressed by the other [13]. In research, electric power generation mix is analyzed for long-term indication deploying model in Malaysia [14]. World Bank organization maintain data bank for such kind research and analysis [15]. The objective of this paper is to explore electricity generation sources which are an effective generation-mix towards the long-term energy security of Bangladesh considering geographic, demographic, environment, socio-economical factors for the national sustainable development.

TABLE 2: COUNTRY PROFILE OF AUSTRALIA, GERMANY AND BANGLADESH [14]

Country Profile (2016)			
	Australia (AUS)	**Germany (DEU)**	**Bangladesh (BGD)**
Population, total (millions)	24.21	82.35	162.95
Population growth (annual %)	1.5	0.8	1.1
Surface area (sq. km) (thousands)	7,741.2	357.4	147.6
Population density (per sq. km of land area)	3.2	357.4	1,251.8
Urban population growth (annual %)	1.6	1.1	3.3
CO_2 emissions (metric tons per capita)	15.37	8.89	0.46
Electric power consumption (kWh per capita)	10,059	7,035	310
Access to electricity (% of population)	100	100	75.92
Access to electricity, rural (% of rural population)	100	100	68.85
Access to electricity, urban (% of urban population)	100	100	94.01

II. METHODOLOGY

A. Country profile and Study

In this study, two countries are selected according to geographical location and development. As Developed countries their profile and status of electricity generation mix help to find result of developing country Bangladesh. Table 2 highlights information about the three countries which are indicated the present status of Australia, Germany and Bangladesh. Most of Points of table carry the information of electricity status phenomena over the countries that ease to do comparative study among them.

Bangladesh has topped the list of total population having 162.95m (m=Millions), 2nd to Germany (82.35m) and Australia (24.21m) is the last. As for population growth, it is the highest in Australia having 1.5%, Bangladesh is the second having 1.1% and Germany is the 3rd having 0.8%. Regarding population growth, land area determines the density of population of the country. Bangladesh is 1251.8 persons per sq. km of land area whereas Germany (357.4 person) and Australia (3.2 person) is the least number. Population of the country describes access to electricity and electricity 100% in both rural and urban but Bangladesh could not reach CO_2 emission of country. Australia and Germany access that point because of density of population in the country, rural and urban consumers consume 68.85% and 94.01% respectively.

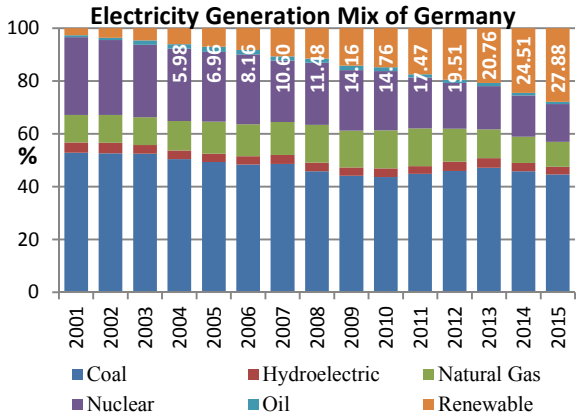

Fig.2. Percentage of Electricity Generation Mix in Germany

Electricity generation mixes of Germany in the period of 2001-2015 are shown in figure 2 where Coal is the largest percentage share of generation sources in the period of 15 years. There are two significant progresses reducing uranium sources and increasing renewable energy sources from electricity generation mix share over last 15 years (2001-2015).

The figure 3 shows percentage of the electricity generation of Australia about previous 15 years from 2011 to 2015. Australia is also highest percent source (80%-60%) using coal to produce electricity over the period. There is trend including natural gas in mix and renewable sources are

placing gradually over coal in last 10 years (2005-2015). There is no nuclear plant over this period significant of electricity generation sources in Australia.

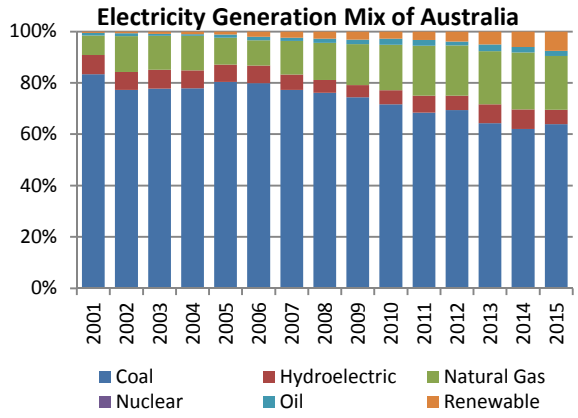

Fig.3. Percentage of Electricity Generation sources in Australia

The figure 3 shows percentage of the electricity generation of Australia about previous 15 years from 2011 to 2015. Australia is also highest percent source (80%-60%) using coal to produce electricity over the period. There is trend including natural gas in mix and renewable sources are placing gradually over coal in last 10 years (2005-2015). There is no nuclear plant over this period significant of electricity generation sources in Australia.

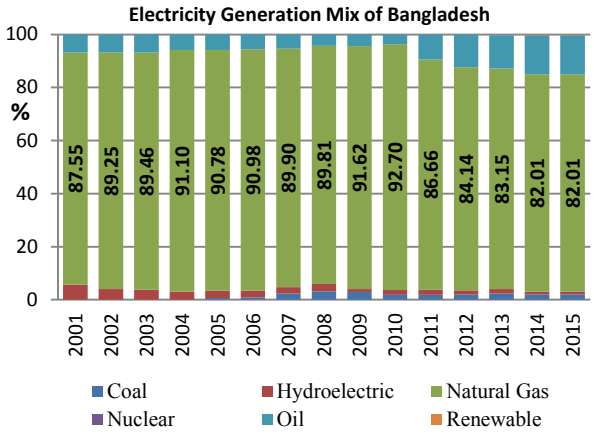

Fig.4. Percentage of Electricity Generation Mix in Bangladesh

Bangladesh fully depends on natural gas which is above 80% of electricity generation mix over the period of 2001 to 2015. Figure 4 shows the oil contribution in generation mix is gradually increasing 2010 to 2015. Coal started to share as electricity generation mix from 2005 and it would be increased more by 2030 [16]. Because of it has characteristic to generate huge amount electricity at a time. Nowadays, nuclear energy source is the most reliable to produce electricity in developed countries for producing burst amount of electricity at a time. But it would be in operation at Rooppur by 2023[17]. Renewable energy sources are the most preferable sources to produce energy. They are abundant and safe. But the figure 4 shows that from the year 2001 to 2015, Bangladesh get this very tiny amount share in electricity generation as sources. So there is lots of opportunity to build renewable energy plant, especially solar energy and bio energy are feasible for Bangladesh.

B. Theory of linear Regression

In statistical, linear regression is a linear approach to modeling the relationship with future value by using existing values and a set of statistical processes for estimating the relationships among variables or data. The known values are existing x-values (independent array or range of data.) and y-values (dependent array or range of data) and the new value is predicted by using linear regression. The equation (1) is for forecasting [18] [19]: $\bar{x}$ *and* $\bar{y}$ are mean value of *x* and *y*.

$$a = \bar{y} - b\bar{x} \quad \text{..... (1)}$$

$$\text{Here } b = \frac{\sum(x-\bar{x})(y-\bar{y})}{\sum(x-\bar{x})^2}$$

C. Data Analysis and Simulation

Data is collected for World Bank data indicator for analysis and Microsoft excel and MATLab are used for data analysis and evaluate the result. Forecast function is used to get future predictable electricity generation mix share in Bangladesh. There are remarks to simulate the data, these are: if input data is nonnumeric data, output generate error value. If they are empty or contain a different number of data points, function returns the error value.

III. RESULT AND DISCUSSION

A. Comparative Result

In the figures, Comparative studies have been observed between developed (Germany and Australia) and developing country Bangladesh to get forecasting electricity generation mix in Bangladesh. Forecasting is observed considering some factors like environment, global warming, and stability, socio-economic and geographical location.

Electricity generation mix from gas sources in Germany & Australia is pretty low which is between 10-20% for both countries. But Bangladesh share almost 90% of their electricity from gas, which did not come below 80 in past 15 years in figure 5. In figure 6, Electricity production source from coal, Australia is at the top, even though the production source is decreased 80% to 60% and Germany is keeping a constant as a mix around 50% in 2001-2015 and both countries are downwards trends. Whereas Bangladesh produces around 2% electricity from coal and it is upward trend as coal power plant has ability to produce big amount of power. Bangladesh has planned to generate large amount of electricity from coal by 2030. Next Figure 7 shows electricity production from nuclear source where only country exists, Germany which is decreasing their production from 30% to 12% in 2001-2015 time period. Bangladesh has started commission Nuclear power plant by 2024. Following figure 8 is displaying the electricity generation mix from renewable sources, where Germany made great advance from the initial 5% to 30% by 2001-2015. Even though Australia made slight improvement from 8% to 15% in 15 years, Bangladesh is yet to make visible improvement in this sector in spite of there are lots of opportunities on renewable energy in Bangladesh. Eventually, over the time period electricity generation mix changes and near future renewable energy, coal, uranium sources would be added accountable amount in electricity generation mix in Bangladesh.

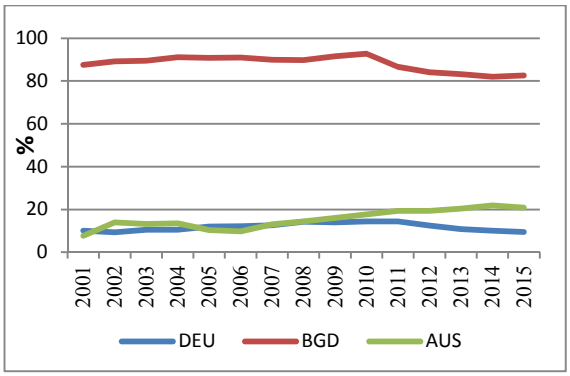

Fig 5. Electricity production from natural gas sources (% of total)

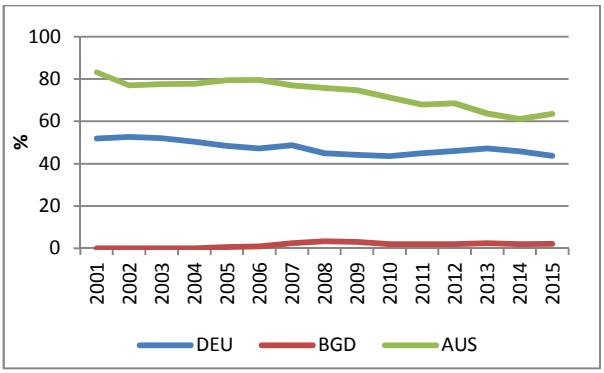

Fig.6. Electricity production from coal sources (% of total)

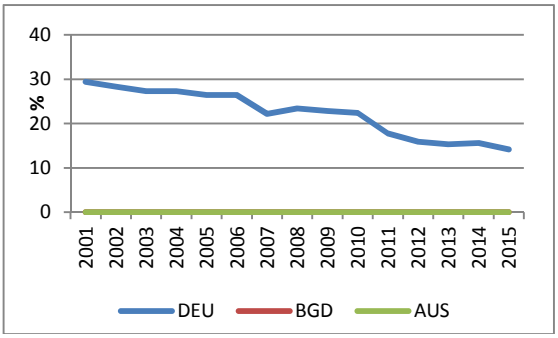

Fig.7. Electricity production from nuclear sources (% of total)

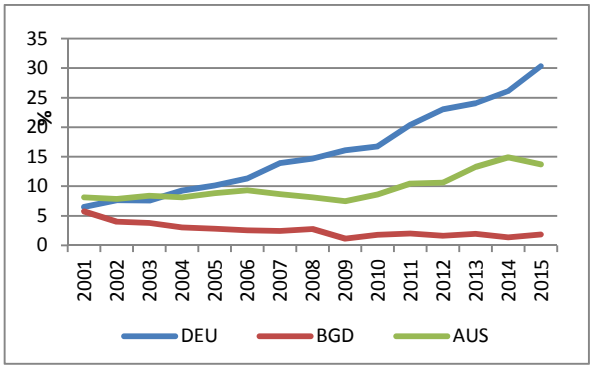

Fig.8. Electricity production from renewable sources (% of total)

B. Simulation Result

The simulation result shows forecasting of electricity generation mix 20016 to 2030 in figure 9. There is significant reduction of natural gas which reaches at 70% from 80% share in electricity generation over the period 2015-2030. Renewable energy share improve to 1.5% in 2030 and same as improvement of coal. So it is the position sign for country to reduce natural gas and improve renewable energy sources, and oil share is also gradually increasing but it should not be. As nuclear source was not in share, simulation function could not predict the future value. But as plan of Bangladesh, nuclear share would be added.

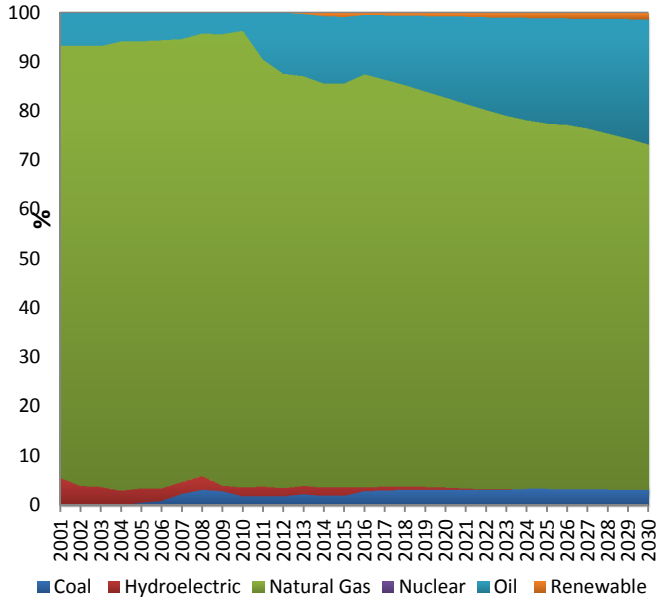

Fig.9. Electricity Generation Mix Forecasting in Bangladesh (2016-2030)

IV. CONCLUSION

In Bangladesh, the population is rapidly increasing and fossil fuel is depleting day by day. The consumption of electricity 310KWh per capita and 76% population get electricity in Bangladesh. Electricity demand is increasing demand day by day. Coal and Uranium will be added as a high percentage in electricity generation mix in Bangladesh. Both sources have the ability to produce a huge amount of electricity to fulfill the demand. Forecasting and comparative result have shown same output and prediction. Renewable sources will be mentionable share in electricity generation sources in Bangladesh according to forecasting result. End of the paper, it is clear that Electricity generation mix build prosper nation considering education environment, global warming, stability, socio-economic and geographical location.

***Abstract*—To maintain the power system stability frequency fluctuation should be eliminated within the shortest possible time. A new control scheme combining linear quadratic regulator (LQR) along with a vibration compensator (VC) is proposed in this paper for the robust control of frequency fluctuation due to load variation in a single area generating system. The proposed LQR controller is used for compensation of error deviation and the augmented VC to damp the frequency fluctuation. The performance of the proposed controller is compared with the automatic generation control (AGC) scheme, conventional proportional-integral-derivative (PID) and LQR controller to demonstrate its effectiveness.**

Keywords—Load frequency control (LFC), linear quadratic regulator (LQR), vibration compensator (VC), cost function.

I. INTRODUCTION

A reliable electrical power system is required for fulfilling the increasing demand of electricity. Stable power system is the main key to maintain the continuity and quality of the supply. With the varying demand of the consumers, the power is changing. Any change in real power affects mainly the system frequency. Maintaining constant frequency during supply is desired in order to maintain the stability and efficiency of the system. The conventional way of controlling the frequency of a generating unit is by using the load frequency control (LFC) loop [1]-[2]. It controls the system frequency by controlling the turbine input [3]. LFC plays an important role in maintaining constant frequency to ensure the reliability of electric power.

A complete mathematical model of LFC along with the necessary diagrams has been discussed in [4]. The step response of frequency deviation due to sudden load variation has been analyzed there and it was shown that using only the basic LFC loop to mitigate the frequency fluctuation was not wise. There was steady-state frequency deviation and the response of the basic LFC loop was oscillatory. The settling time was approximately 8 s and the overshoot was 54.8 % which is pretty large [4]. Settling time is a critical factor for maintaining power system stability and the power system should regain its steady-state condition as soon as possible after any parametric variation.

In literature, various techniques have been adopted to improve the performance of LFC to maintain nominal value of system frequency. One way to restore the frequency to its rated value quickly is to add an integrator with the basic LFC loop. The integral unit monitors the average error over a period of time and will overcome the offset. Thus as the system load changes continuously the generation is adjusted automatically to restore the frequency. This system is called automatic generation control (AGC). It is a feedback control system that regulates the output power of generators to maintain a specified system frequency. Mathematical modeling of AGC system and its step response of frequency deviation has been briefly discussed in [4]. It was shown that the response of AGC was certainly an improvement from the LFC but the AGC system also took a long time to be settled down. The settling time of the AGC was approximately 10 s [4].

Frequency deviation even for a small amount of time is very harmful for the stability of the power system, hence the settling time of the system is needed to be improved. In order to improve the system dynamics even more, a PID controller is proposed in [5]. Proposed controlled system had a negligible overshoot but settled down after approximately 5 s. The controller gains, K_P, K_I and K_D were tuned there by trial and error technique. By using more suitable values of K_P, K_I and K_D, with the help of advanced optimization techniques a better response can be obtained from the controller which was showed in [6]. It was shown that a PID controlled system with advanced optimization technique would settle down the frequency response much quicker and there were no steady-state error.

Moreover, optimal control techniques can be used for better performance. It deals with designing controls for dynamic systems by minimizing a performance index that depends on the system variables. Linear quadratic regulator (LQR), which is an optimal control method, was suggested in [7]. The response of the LQR controller was very satisfactory. The response settled down at approximately 0.7 s. Even though the settling time was reduced but there was a remarkable steady state error after the implementation of the LQR controller.

LQR is an optimal control regulator that tracks a reference trajectory more effectively as compared to traditional controllers like PID. It is a well-known method that provides optimally controlled feedback gains to enable the closed-loop stable and high performance design of system. For the effective control of system frequency an optimal control technique based on LQR is proposed here. Moreover, a vibration compensator (VC) incorporated with the LQR is used to improve the damping by reducing overshoot. The optimal LQR-VC is capable enough to

control the LFC loop effectively in order to minimize the settling time, tackle the overshoot issue and reduce the steady-state frequency deviation.

The remainder of the paper is organized as follows: modeling of the LFC system is discussed in section II. Control methodologies are discussed in section III. Implementation of controllers on LFC system is provided in section IV. Whereas, comparison among the proposed controller and the existing control techniques are discussed in section V. Finally the paper is concluded in section VI.

II. MODELING OF LFC

In electrical power system, nominal frequency depends significantly on the balance of produced and consumed active power. When active power imbalance occurs in any part of the system, it results in changes in the frequency of the entire system. Loads connected to electrical power system are very sensitive to the quality of electrical energy, mainly the frequency component. The relationship between system frequency and load is inversely proportional [8]. The alternation in frequency is sensed by LFC control loop.

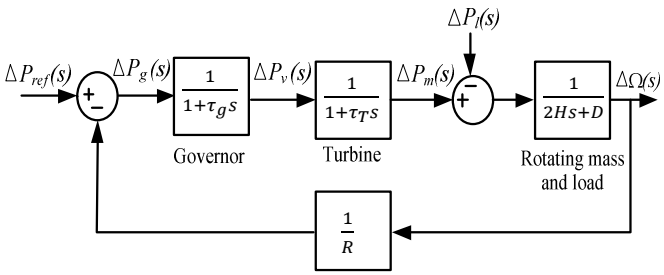

Fig. 1: LFC block diagram of an isolated power system.

The change in frequency and real power are sensed as a measure of the change in rotor angle δ. So the error Δδ needs to be corrected to eliminate the frequency fluctuation.

TABLE I. PARAMETERS OF AN ISOLATED SYSTEM [7]

Parameter	Value
Turbine time constant, τ_T	0.5 sec
Governor time constant, τ_g	0.2 sec
Governor inertia constant, H	5 sec
Frequency sensitive load coefficient, D	0.8
Change in load, ΔP_L	0.2 per unit
Governor speed regulation, R	0.05

This work is done by the primary LFC loop which consists of generator model, load model, prime mover model and governor model. Block diagram of the basic LFC control loop is shown in Figure 1 [7]. The LFC model parameters used for an isolated system are presented in (Table I) [7]. With the primary LFC loop, a change in the system load will result in a steady-state frequency deviation, depending on the

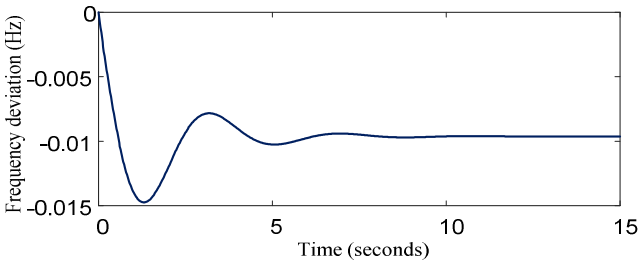

Fig. 2: Frequency deviation step response of LFC.

in a steady-state frequency deviation, depending on the governor speed regulation. The response is highly oscillatory and contains a steady-state error. So using alone the LFC loop to control the frequency is not wise and the response of the system is not satisfactory. Figure 2 shows the response of the LFC loop due to sudden load change of 0.2 p.u.

III. CONTROLLER DESIGN

A. Design of Integral controller

The integral controller is used along with the basic LFC loop to restore the frequency to its nominal value. This scheme is known as AGC. The block diagram of AGC for an isolated system is shown in Figure 3 [7]. The integral controller gain K_i must be adjusted for satisfactory response.

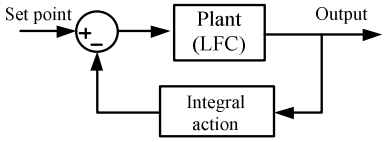

Fig. 3: AGC block diagram of an isolated power system.

B. Design of PID controller

The PID controller is used to improve the dynamic response as well as to reduce or eliminate the steady-state error. PID controllers being popular for its performance over wide range and simplicity, is largely used for controlling the LFC loop [5].

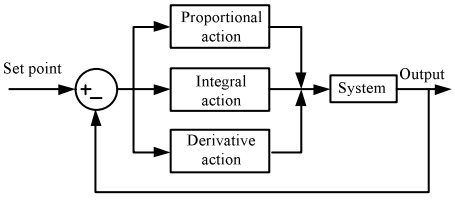

Fig. 4: Block diagram of PID controller.

A simple block diagram of a PID controlled system is showed in Figure 4 [5]. The transfer function of the PID controller is

$$G_C(s) = K_P + \frac{K_I}{S} + K_D s \quad (1)$$

C. Design of Vibration Compensator (VC)

Vibration compensator is used to improve system parameters like reducing steady-state error, reducing resonant peak, improving system response by reducing rise

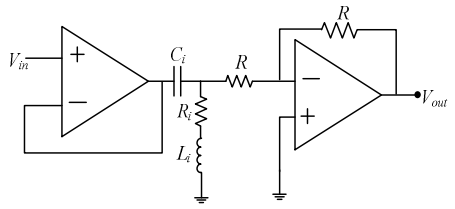

Fig. 5: Structure of the vibration compensator [9].

time. The VC as shown in Figure 5 is introduced in this paper to achieve better damping performance [9]. It helps to enhance the responsiveness and stability of the system. It is used to improve damping and thus reduce overshoot and improve settling time. The feedback loop for the LFC along with the VC is shown in Figure 6. By selecting the proper values of *Li*, *Ri*, and *Ci*, the damping of the LFC loop is improved. The general form of the damping compensator is [9].

$$M = \sum_{i=1}^{N} - K_i \frac{C_i s(R_i + L_i s)}{L_i C_i s^2 + R_i C_i s + 1} \quad (2)$$

where K_i, i = 1, 2,..., N, is the compensator gain of the corresponding mode.

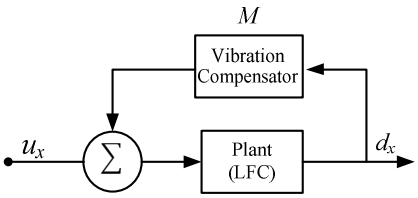

Fig. 6: Feedback loop of the vibration compensator for the LFC.

D. Design of (LQR)

LQR controller is a form of optimal control that provides optimally controlled feedback gains to enable the closed-loop stable and high performance design of systems. Its objective is to determine the optimal control law which minimizes a performance index [6]. In LQR, the system dynamics are described by a set of linear differential equations and the cost is described by a quadratic function and hence the name is linear quadratic regulator. The plant is described by

$$\begin{cases} \dot{x}(t) = Ax(t) + Bu(t) \\ y(t) = Cx(t) + Du(t); \end{cases} \quad (3)$$

where, x is called the state vector, $x(t) \in \mathbb{R}^n$, y is called the output vector, $y(t) \in \mathbb{R}^q$, u is called the input (or control) vector, $u(t) \in \mathbb{R}^p$, A is the state (or system) matrix of $n \times n$, B is the input matrix of $n \times p$. C is the output matrix of $q \times n$, D is the feedthrough (or feedforward) matrix (in case where the system model does not have a direct feedthrough, D is the zero matrix), of $q \times p$. $\dot{x}(t)$ is the first derivative of x(t). The problem is to find the vector $K(t)$ of the control law

$$u(t) = -K(t)x(t) \quad (4)$$

that minimizes the value of a quadratic performance index

$$J = \int_0^\infty (x^T Q x + u^T R u) dt. \quad (5)$$

Here Q is an $n \times n$ positive semidefinite matrix, also called the state weighting matrix, R is an $p \times p$ positive definite matrix known as control weighting matrix [10].

$$K = R^{-1} B^T P \quad (6)$$

where P is the unique positive definite solution of the algebraic Riccati equation (ARE) [9].

$$A^T P + PA + PBR^{-1} B^T P + Q = 0 \quad (7)$$

From the state-space representation of the plant values of A, B, C and D matrices can be found. By proper selection of the Q and R matrix the value of P and therefore K is determined which will place the close-loop poles of the system in the most perfect place using the LQR method with respect to the cost function. A simple block diagram of an LQR controlled system is shown in Figure 7.

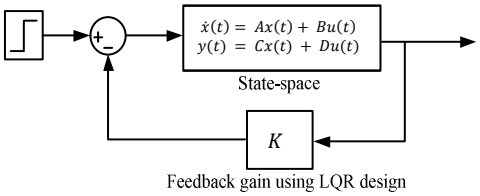

Fig. 7: Block diagram of an LQR controlled system.

IV. Implementation of Controllers on LFC

An isolated system with parameters given in TABLE I is considered and from Figure 2 it is seen that the frequency deviation step response of basic LFC loop is oscillatory and contains a steady state error.

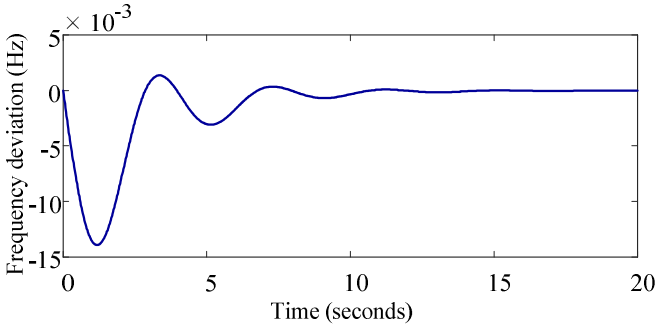

Fig. 8: Frequency deviation step response of AGC.

By using an integral controller and tuning the value of gain K_i=7 a response is obtained which has less steady-state error but both the overshoot and the settling time are quite

large. From Figure 8 it is seen that settling time is approximately 10 s. By using PID controller and tuning the values of K_P, K_I and K_D, a better response is obtained with negligible steady-state error and a smaller settling time.

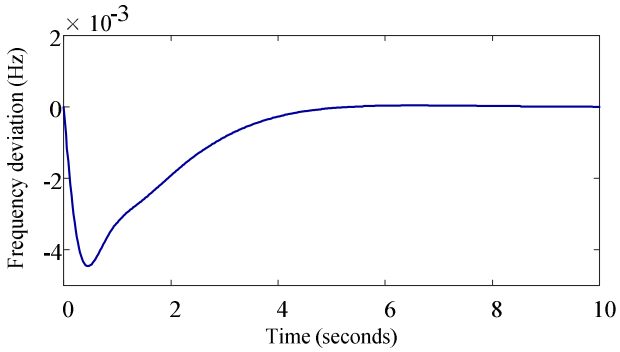

Fig. 9: Frequency deviation step response for PID controller.

When the values of controller gains are considered as $K_P = 30$, $K_I = 25$ and $K_D = 30$, then the response of the system is as shown in Figure 9 which has a settling time of approximately 5 s. The frequency deviation step response after using LQR controller is shown in Figure 10 which indicates a settling time of approximately 0.63 s but suffers from large steady-state error.

Figure 11 shows that when the proposed control scheme is applied to the same isolated system then settling time is reduced to a value of approximately 0.01 s with a negligible steady-state error and overshoot.

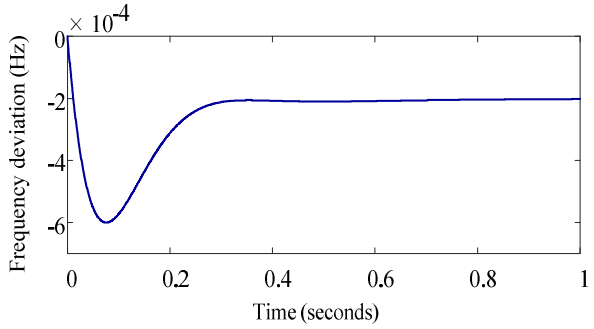

Fig. 10: Frequency deviation step response for LQR controller.

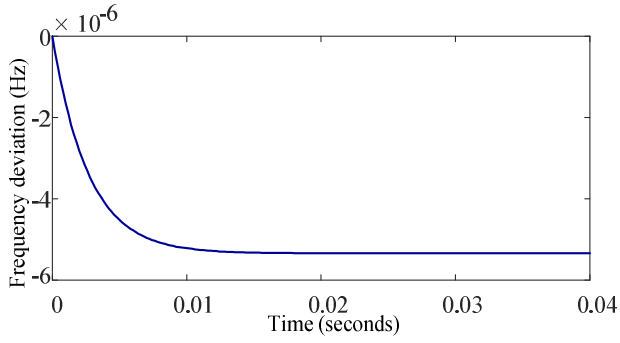

Fig. 11: Frequency deviation step response for proposed controller.

V. COMPARISON AND RESULT

A relative comparison among different control techniques for controlling the frequency of an isolated system is shown in Figure 12.

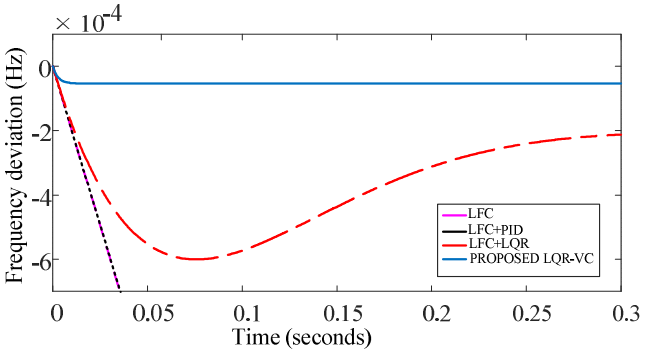

Fig. 12: Comparison among different control techniques.

From the comparison it is clear that by using proposed LQR controller along with a VC the best result is obtained compared to the existing control techniques. The response settles down after approximately 0.01 s which is approximately 60 times faster than the existing LQR control technique. So it can be concluded that proposed controller is certainly an improvement from the existing controllers. TABLE II summaries the results for different control techniques implemented on LFC and hence justifies that the proposed controller gives better result.

TABLE II. Performance parameters of different control techniques

Controller	Settling Time (seconds)	Overshoot (%)	Steady-State Error
PID	4.67	0.0001	1.0558e-07
LQR	0.63	0.02	2.0228e-04
Proposed LQR-VC	0.0105	0	5.3422e-05

VI. CONCLUSION

In this paper, design and implementation of an optimal LQR controller augmented with a VC is proposed to mitigate the frequency disruption of an electric power generating unit. The performance of the proposed controller is compared with the existing control techniques. The proposed controller eliminates the frequency fluctuation approximately 60 times faster than the existing LQR control method. The protective scheme is designed and applied in an isolated system but with some modifications it can be applied to the interconnected power grid.

***Abstract*—Solar Assisted Refrigerator (SAR) can be manufactured using elements like a solar panel, evaporator, expansion valve, compressor, and the inverter, etc. This paper gives an evidence to the concept of using solar energy to preserve emergency lifesaving medicines and vaccines at low temperature. The target storage temperature range was between -15°C and 30°C. The model refrigerator was designed and constructed totally by using local technology and placed in outdoor conditions to observe the effect of different weather conditions. By monitoring the temperature variation and compressor current after every one-hour, power consumption and the coefficient of performance (COP) were determined. The overall coefficient of performance (COP) was calculated 4.89 for the refrigerant "Iso-Butane(R600a)". The temperature and pressure profile have been observed using a highly accurate digital thermocouple thermometer and accurate pressure gauge to find out the heat transfer rate, suction and discharge pressure. Total power consumption per day was also calculated by observing the temperature and pressure profile. It proved that the SAR can be implemented in rural areas and the areas where grid-connected electricity is not available to preserve emergency lifesaving medicines and vaccines at low temperature. This could be a means to save millions of people's lives in the disastrous regions and at the refugee camps.**

Keywords—Solar Energy, Refrigerator, Refrigerant, Temperature and Pressure profile, Power Consumption, Heat loss, C.O.P, Storage, Rural Area, and Refugee Camps.

I. INTRODUCTION

Solar Assisted Refrigerator is a refrigeration system which works with the help of solar energy which is harvested from the sunlight. In hot climates and in those regions where grid-connected electricity is not available at all, people can use the SAR to preserve food so it does not rot. Alternatively, SAR can also be used to store vaccines at the proper temperature. When sunlight is not available, at that time the SAR can work using the power from batteries to run the refrigerator.

Solar energy has become very attractive for cooling purposes nowadays. It can provide a cheap and clean source of electricity all over the world for cooling and refrigeration purpose. Solar refrigeration technology collects the energy from the radiation of the sun and uses that energy for cooling purpose. This system is a lucrative choice for medicine and vaccine storage facility where an adequate amount of sunlight is available but has instability in electricity supply. It is also suitable for the areas which are located far from the grid. The solar system can be divided into two main categories, such as thermal driven and electrically driven systems. Photovoltaic panels are used as an electrically-driven system to produce electricity which is then used conventionally to run the refrigeration machine. The system consists of four basic components: PV modules, a battery storage system, charge regulator, and vapor- compression unit. In practical applications, solar PV refrigeration units are used in luxurious boats and/or in remote areas for food and vaccine preservation.[1]

Some research works are already done regarding Solar Assisted Refrigerator, but at that time the works had some limitations. In paper [2], researchers used solar panel, charge controller, battery for power storage and a DC powered cooling unit but it did not have sufficient battery back-up. On the other hand, in research work [3], the refrigeration system had enough amount of battery back-up for cloudy day protection. The problem of this both [2], [3] design was that there was no scope of running the system using AC power. If there was an option of running the system using AC power and had more battery storage then it would have been a better system. In paper [4], they used the MPPT unit but they did not keep any battery storage option. In paper [5], they worked based on Peltier device and that refrigerator has the ability to warm up the food too. Peltier device was used for cooling as a replacement of compressor which is commonly used in a traditional refrigeration system. The problem of using a Peltier device is that although it works well for cooling a small amount of food or medicine, it is not good for cooling a large load. Peltier device was also used by the researchers of paper [6] and their proposed refrigerator can only perform cooling for 1 hour 35 minutes from full charge condition which is not suitable for practical use.
The proposed Solar Assisted Refrigerator (SAR) is capable of solving all limitations of previous works and it is a very good solution for storing the medicine and vaccines at low temperature.

II. WORKING PRINCIPLES AND EXPERIMENTAL SETUP

The refrigeration cycle is very simple to understand. In figure 1, the refrigeration cycle is shown. Firstly, a cold liquid is passed around the object which needs to be cooled. This process will remove heat from the object. There is a throttling device that helps to reduce the temperature of the liquid. A throttling device is actually nothing but a capillary tube. For efficient throttling, an inlet liquid must be high pressured liquid. Throttling device essentially reduces the pressure of the

liquid. As the pressure decreases, the boiling point of the refrigerant comes down and it starts to evaporate. For the continuation of evaporation, the temperature drops down. If the temperature is measured at the inlet and the outlet of the capillary tube, a temperature drop will become noticeable. Then the evaporating refrigerant is passed through the evaporator tube of the refrigerator. After that, the refrigerant starts to absorb heat from the objects stored in the refrigerator. Thus, the refrigerant further evaporates and turns into pure vapor. This creates the required refrigeration effect.

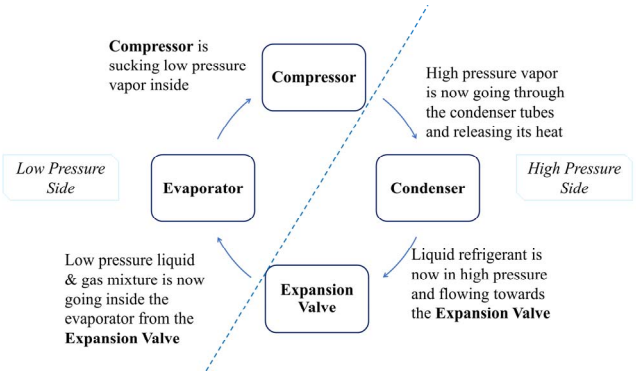

Figure 1: Refrigeration Cycle [8]

After absorbing heat from the refrigerator chamber, the refrigerant is in high temperature and low-pressure state. In order to repeat the refrigeration process, the pressure of the refrigerant has to increase. For this purpose, a compressor is used. The compressor increases the pressure of the refrigerant to its high-pressure state. Since it is compressing gas, the temperature of the refrigerator will also increase. After the compression, the refrigerant turns into a high pressure and high-temperature vapor. To transform the refrigerant from the vapor state to the liquid state, a heat exchanger is used. The heat exchanger is placed outside of the refrigerator and known as a condenser. It releases heat on the environment and as a result, the refrigerant will get condensed and turn into the liquid from its vapor state. Finally, the refrigerant will return to its beginning state and that is high-pressure liquid. This cycle is repeated again and again for running the refrigerator. This cycle is recognized as a vapor compression cycle.

In figure 2, a block diagram of the Solar Assisted Refrigerator is shown. The model is created using PV cell, charge controller, refrigerator, inverter and battery.

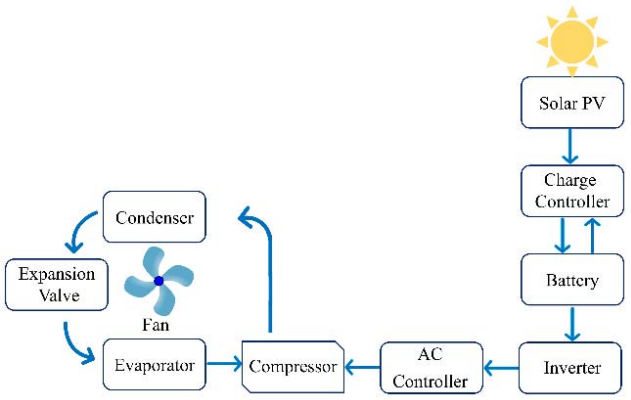

Figure 2: Block Diagram of the SAR [9]

At first, the PV cells will collect the irradiation from the sunlight and then produce electrical energy which is direct current (DC). This energy is stored in the battery and a charge controller is used to control the charging of the battery. An inverter is used to convert the direct current (DC) to alternating current (AC) for running the compressor. Since, the compressor is an AC compressor, an inverter is required for the SAR. The SAR can run by using the power from the battery storage or directly from the national grid as the compressor uses alternating current.

III. MATHEMATICAL MODELING

The Solar Assisted Refrigerator (SAR) was designed and constructed by using local technology and locally available materials the project was successfully implemented.

TABLE I

Description	Specifications
Outside Dimension	2.5 feet × 2 feet × 2 feet (H × W × L)
Refrigerant Type	Iso-Butane (R600a)
Charged Refrigerant Mass	120 grams (Approx.)
Compressor Type	Hermetically sealed
Compressor Oil Charge	200 ml (Approx.)
Power Source	220 Volt AC, 50 Hz
Total Weight	50 kg. (Approx.)
Compartment Type	1 Unit
Air Circulation	Forced Convective Fan
Calibration	Temperature Monitoring
Compressor Control	On/ Off Single Speed
Temp., Pressure & Humidity During Test	20°,102 kPa,60% RA [Based On 2017 January]
Antifreeze	Defrost*
Refrigerant Circuit (RC)	Total 4 'T' Connector Used for Compressor & Expansion Device

In table I, all specifications are given which are required for fabricating the SAR.

TABLE II

Four states				
	State 1	State 2	State 3	State 4
T	2.5°C	50.9°C	46.3°C	2.5°C
P	320 kPa Suction Pressure	1200 kPa Delivery Pressure [Provided by Manufacturer]	1200 kPa [No Loss Assumed]	320 kPa [Ideal Value is Assumed]
h	252 kJ/kg	279.3 kJ/kg	117.8 kJ/kg	117.8 kJ/kg
S	0.930 kJ/kgK	0.930 kJ/kgK	0.4245 kJ/kgK	S4 = 0.4436
X	1	1	0	x4 = 0.3

Here,

m' means mass in $\frac{kg}{h}$

h means heat in $\frac{kJ}{kg}$

1. Work Done by the Compressor = $m'(h_2 - h_1) = 3\ (274.3 - 252) = 82.3\ kW$
2. Cooling Load In the Evaporator = $m'(h_1 - h_4) = 3\ (252.0 - 117.8) = 402.30\ kW$

3. Heat Rejected by the Condenser = $m'(h_1 - h_3) = 3\ (279.3 - 117.8) = 484.6\ kW$
4. Heat Rejected = (Work Done + Cooling Amount) = $82.3 + 402.30 = 484.6\ kW$

$X_4 = \frac{117.8-55.2}{251.9-55.2} = 0.318 \cong 0.32$

$S_4 = S_f + X_4(S_g - S_f) = 0.2165 + 0.32(0.93 - 0.2165) = 0.4436$

Coefficient of Performance,

C.O. P = $\frac{Cooling\ Load}{Work\ Done} = \frac{402.3}{82.3} = 4.89$

A. Equipment Rating Selection

Before starting to build the Solar Assisted Refrigerator (SAR), the necessary calculation was done to determine the compressor power, pipe length for the compact condenser, evaporator and for the capillary tube. The rating of solar panel, battery and inverter size also calculated carefully and precisely.

B. Compressor Power Rating

The total volume of the chamber inside the SAR= 86.5 liter. Since the medicine weighs lighter than the same volume of water, the weight of 35-liter water is considered.

Q = Heat Energy
m = Mass
ΔT = Change in Temperature
W = Work
P = Power
H = Efficiency
ΔH_f = latent heat of fusion (kJ/kgK)
C_{p1} = specific heat of ice (kJ/kgK)
C_{p3} = specific heat of water(kJ/kgK)

Calculation for determining the heat required to transform -10°C ice to 0°C ice:

ΔT = 273 K – 263 K= 10 K

Q_1 = m×C_{P_1}×ΔT
=35 × 2.108 ×10
=737.8 kJ/s

Calculation for determining the heat required to transform 0°C ice to 0°C water:

ΔT = 273 K – 273 K= 0 K

Q_2 = m×C_{P_2}
= 35×335
= 11725 kJ/s

Calculation for determining the heat required to transform 0°C water to 10°C water:

ΔT = 283 K-273 K= 10 K

Q_3 = m×C_{P_3}×ΔT
= 35×4.2×10
=1470 kJ/s

Total Heat Energy,

Q=Q_1+Q_2+Q_3
= 737.8+11725+1470 = 13932.8 kJ/S
= $\frac{13932.8}{24\times60}$ kJ/m [For 1 day]
= 9.68 kJ/minute

C.O.P = 4.89

Efficiency, η = 30%

It is known that, C.O.P = $\frac{Q}{W}$

W= $\frac{Q}{C.O.P}$
= $\frac{9.68}{4.89}$= 1.98 kJ/minute

P = $\frac{W}{\eta} = \frac{1.98}{60\times0.3}$
= 0.10992 kw
= 109.92 watts

So, compressor power rating should be minimum 109.92 watts. Here, the power rating was calculated by considering the water, but for the medicine the C_P value is less than water. So, for the medicine, a less powerful compressor can be used. If less than 35 kg medicine is stored, then the compressor power rating will also decrease accordingly.

Considering the above-mentioned facts, a 110 watts compressor was chosen which can easily run the SAR without any trouble.

C. Pipe Length for the Compact Condenser, Evaporator and for the Capillary Tube

After calculation, it was determined that exactly fifty (50) feet evaporator pipe is sufficient for cooling the SAR. Ten (10) feet capillary tube and thirty (30) feet copper tube also used for condenser to get the optimum output from the SAR. The diameter of the copper tube was ¼ inch for both the compact condenser and the capillary tube.

D. Rating of Solar Panel and Battery

Solar Panel Selection:

The total energy required for the SAR = 133 watts

Total rating of the SAR= Total Connected Load × Operating Hours = 133×6 = 798 watt-hours [Compressor remains ON 15 minutes per hour] .[7]

So, 200-watt peak (Wp) PV panel was selected.

Battery Selection:

Power output of the PV panel = Peak Power Rating × Operating Factor = 200×0.75 = 150 watts

Actual power obtained (It is less than the Power Output due to low combined efficiency of the system) = Power output of the panel × combined efficiency = 150 × 0.85 = 127.5 watts

Energy produced by one 200 W_p panel in a day = Actual power output of the panel × 7 hours/ day = 127.5×7 = 892.5 watts-hour .[7]

Rating of the Battery = $\frac{\text{Total watt–hours rating of the SAR}}{\text{12 V battery}} = \frac{798}{12}$
= 66.5 ampere hours of reserve battery power

To preserve medicine at least for two days = 66.5 × 2 = 133 ampere hours of reserve battery power is required.

150 ampere hours of reserve battery was selected considering various losses.

E. Rating of the Inverter & Solar charge controller

Inverter Selection:

Total load = 133 Watts

Let's assume power factor is 0.8, so 1.18 VA = 1 Watt

Required inverter size = 1.18 × 133 = 156.9 VA

200 VA inverters was selected because 156.9 VA inverter is not available in the market.

Solar Charge Controller Selection:

Solar charge controller rating = $\frac{\text{Panel's wattage rating}}{\text{Voltage rating}} = \frac{133}{12}$
= 11.08 Ampere

So, 15 Amps solar charge controller was used.
To implement this SAR, walls with the thickness of four (4) inch was used along with several layers of polyurethane foam and 97% reflective aluminum foil.
A digital N-type thermostat was used for maintaining the precise temperature of the SAR. Furthermore, four pressure gauges were installed for analyzing the pressure profile.

Figure 3: Attachment of Evaporator Tube with the SAR chamber

Figure 4: Refrigerator Chamber with Wheels

Figure 5: Pressure Gauges

In figure 3 and figure 4, the evaporator and the refrigerator chamber are visible. Wheels were added with the SAR for easy portability of the system. Four (4) pressure gauges were used to find out suction pressure and discharge pressure. These gauges can measure up to 300 psi. Their picture can be seen of figure 5.
High accuracy digital thermocouple thermometer was used at the time of observing the temperature profile. On figure 6, the thermometer, along with the refrigerator can be seen. The thermometer probes can be seen on figure 7.

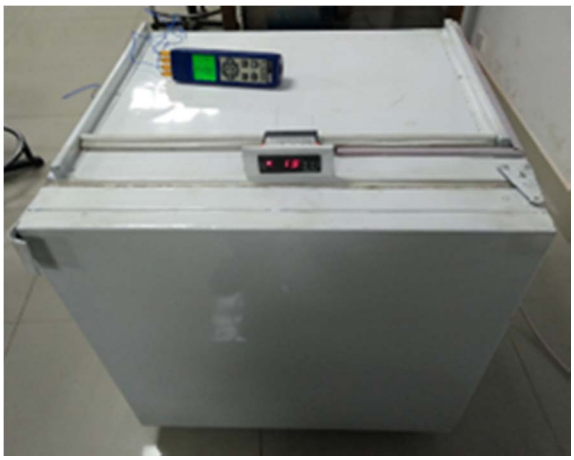

Figure 6: Top Side View of the Refrigerator

IV. Results Analysis & Critical Design Review

From figure 7 it can be seen that, T_1 was placed at the top of

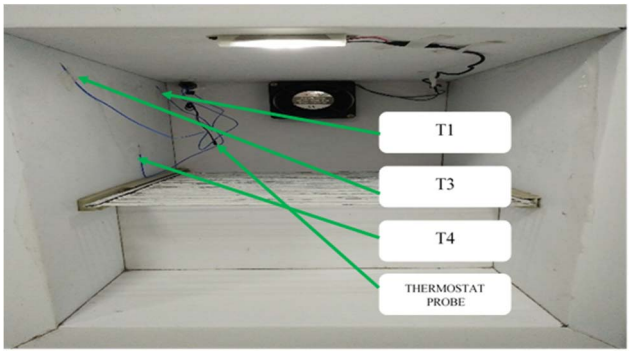

Figure 7: Themometer Probes Placed at Various Points Inside the Refrigerator Chamber

the left side wall near the back wall. T_3 was placed on the left side wall, close to the door. T_4 was placed at the bottom part of the same left wall. T_2 was placed at outside of the refrigerator.

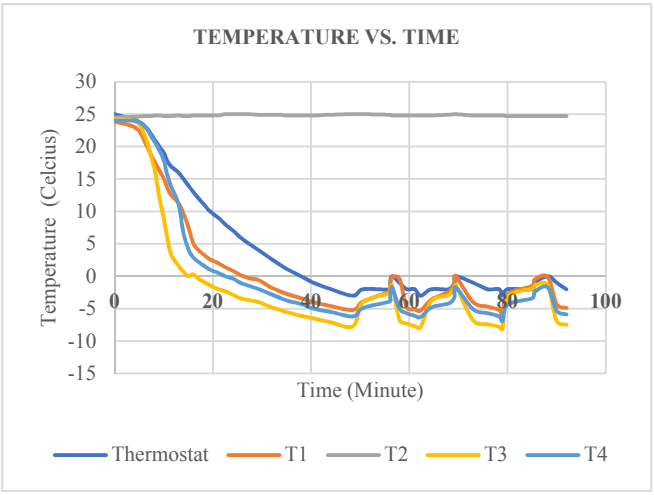

Figure 8: Temperature Versus Time

The figure 8 indicates that compressor remains off from 48.56 minutes to 56 minutes, 62.3 minutes to 69.16 minutes and 79 minutes to 85.55 minutes respectively. This graph indicates that outside temperature was almost 24.8°C and the desired set temperature was -2°C. At that condition, approximately 7 minutes to were needed to achieve the desired temperature -2°C to -1°C. It is the evidence that the heat loss is very low for this Solar Assisted Refrigerator.

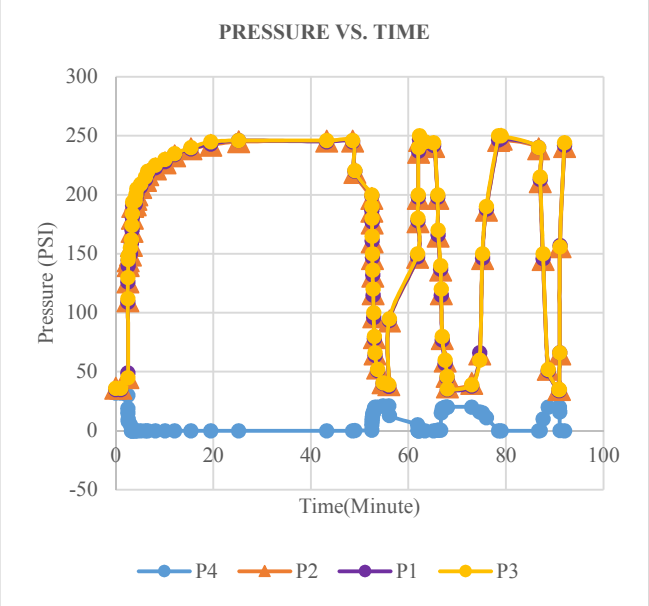

Figure 9: Pressure Versus Time

The figure 9 represents the *Pressure Vs Time Curve* (P_1, P_2, P_3, P_4,) all together. This figure represents the pressure P_1, P_2 , P_3 as the discharge pressure and P_4 as the suction pressure. All discharge pressure values are almost same and show the approximately same characteristics. Discharge pressure always increases when compressor turn ON. Suction pressure value always increases when the compressor turns OFF. Only the suction pressure will be zero when the compressor turns ON. Figure 9 also indicates that when discharge pressure value is at maximum position, at that time suction pressure value is at minimum position. On the other hand, when discharge pressure value is at minimum position at that time suction pressure value is at maximum position. This figure clearly indicates that discharge pressure and suction pressure is vice versa.

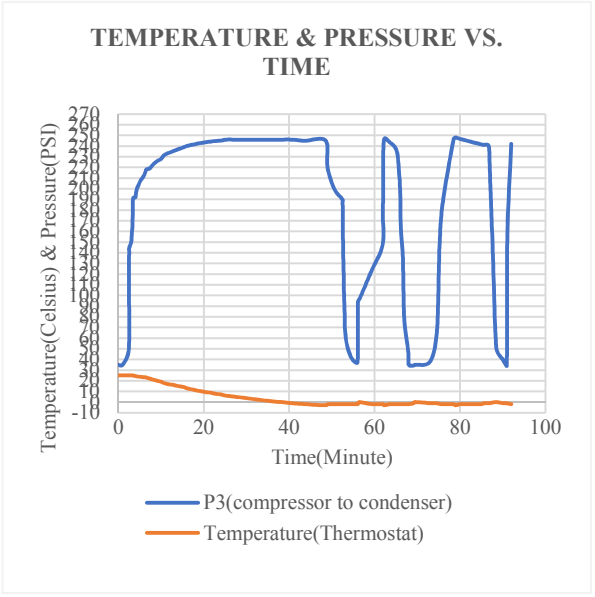

Figure 10: Temperature and Pressure (Compressor To Condenser) Versus Time

Thermostat temperature and the pressure for compressor to condenser is shown in figure 10. The figure 10 indicates that when the temperature was decreasing to the desired set temperature -2°C, at that time, discharge (compressor to condenser) pressure was increasing up to 248 psi. So, it is clear that compressor was also at working condition at that time. Additionally, it proves that when compressor is at running condition, at that time temperature is decreasing but oppositely discharge pressure is increasing.

A. Heat Loss

Outside temperature, $\boldsymbol{T_{out}}$ = 24.5 °C
Inside temperature of the SAR, $\boldsymbol{T_{in}}$ = -2°C
$\boldsymbol{T_{out}} - \boldsymbol{T_{in}}$ = 24.5°C – (-2°C) =26.5°C = 299.5 K
Area, A= 30 inch × 24 inch = 0.464 m^2
Wall thickness, x= 4 inch =0.1016 m
Thermal conductivity of Aluminum sheet, $\boldsymbol{K_1}$= 205 W / m K
Thermal conductivity of 97% Aluminum Foil, $\boldsymbol{K_2}$= 0.34 W / m K [8]
Thermal conductivity of Polyurethane Foam, $\boldsymbol{K_3}$=0.03 W / m K
Thermal conductivity of Air, h=0.025 W / m K

$$Q = \frac{A(T_{out} - T_{in})}{\frac{1}{h_{out}} + \frac{1}{h_{in}} + \frac{x}{K_1+K_2+K_3}}$$

$$Q = \frac{0.464(299.5)}{\frac{1}{0.025} + \frac{1}{0.025} + \frac{0.1016}{205+0.34+0.03}}$$

Q = 1.73 watt
So, heat loss is 1.73 watt.

B. Energy Consumption

Current Consumption, I = 0.7 Ampere [Measured with the help of clamp meter]
Voltage, V = 220 Volt
Power factor = 0.8
Compressor works total 6 hours per day
So, total Energy consumption per day = $\frac{220\times0.7\times0.8\times6}{1000}$ = 0.7392 kilowatt-hour
Total energy consumption per month = (0.7392 × 30) = 22.176 kilowatt-hour
It is expected that the SAR will consume 22.176 kilowatt-hour energy per month.

C. COP Calculation (Practical)

Efficiency, η = 30%
Total Q = 9.68 kJ/minute
P = 110 watt
W = P η = 110 Watt × 0.3 = 33 J/ Minute
C.O.P = Q/W
$= \frac{9.68\times1000}{33\times60}$
= 4.89
COP = 4.89

D. Verification of Using the Correct Rating of Solar Panel, Battery and Inverter Size

Measured energy consumption = 220×0.7×0.8 = 123.2 watts.

At the time of implementing the SAR, a 200-watt peak (Wp) PV panel was used that can produce 127.5 watts.

As the measured energy consumption is slightly less than the produced energy per second by the PV panel, the SAR can run properly. Since the measured energy consumption is perfectly matched with the produced energy by the PV panel, so the solar charge controller, battery and inverter rating selection was also correct for the SAR for running it properly.

V. Cost Analysis

In the following table, the cost of the project is described. Solar PV panel, battery and inverter are the most expensive items of the project. If these components could have procured at a lower price, then the cost of this project would have reduced significantly.

The total cost of the project is 22,410 Bangladeshi Taka (Approximately). The cost is very affordable. Locally available material and technology were used for keeping the construction cost low. If the SAR unit is mass produced, the cost of each unit will reduce drastically. Then the price of per unit of this SAR system will be in the grasp of the poor rural hard-working people of Bangladesh who are deprived of grid connectivity.

TABLE III

Serial	Name of The Equipment	Price (BDT)
1	Compressor	1,900/-
2	Digital Thermostat	1,100/-
3	Polyurethane Foam	900/-
4	Metal Sheet	1,200/-
5	Wheels	350/-
6	Compact Condenser	400/-
7	Insulation Material	350/-
8	Evaporator Tube	960/-
9	Refrigerant (R-600a)	500/-
10	Solar Panel (PV Array)	4,000/-
11	Charge Controller	750/-
12	Inverter	4,800/-
13	Battery	5,000/-
14	Others	200/-
	TOTAL:	22,410/-

VI. Conclusion

By using traditional technologies and locally available materials, the fabrication of the Solar Assisted Refrigerator was implemented successfully. The temperature profile for different points at inside and outside of the SAR was analyzed. In addition, the pressure profile for discharge pressure and suction pressure was also analyzed. The C.O.P of the system is 4.89 that is the highest C.O.P for the refrigerant "Iso-Butane (R600a)". The heat loss and the power consumption were also calculated for the SAR. Calculations show that the heat loss and the power consumption are very low as the four-inch thickness wall combined with several layers of polyurethane foam and 97% reflective aluminum foil were used. It can be said without a doubt that the proposed SAR model is one of the best choices for saving energy consumption as the heat loss is very low and the coefficient of performance is very high. The price of the SAR very affordable. If this SAR can be made available to the people of rural areas where there is no grid connectivity, then the SAR can contribute in saving a lot of lives by preserving live saving medicines at accurate temperature and thus contributing into the prosperity of the country.

***Abstract*—The performance of an automatic voltage regulator (AVR) system controlled by an optimal linear-quadratic-Gaussian (LQG) controller augmented with an integral action is investigated in this article for maintaining constant output voltage. The aim of this controller is to keep stable terminal voltage of a single area power system during sudden load change. To verify its efficacy, a comparison is conducted with some existing controllers for instance the rate feedback stabilizer, proportional-integral-derivative (PID) controller, and linear quadratic regulator (LQR). The comparison is done on the basis of some important transient response characteristics and the proposed control scheme shows strong robustness against voltage variation due to load change.**

Keywords—Automatic voltage regulator (AVR), linear-quadratic-Gaussian (LQG) controller, rate feedback stabilizer, linear quadratic regulator (LQR), single-area power system model, settling time.

I. INTRODUCTION

With the increasing demand of electricity it is becoming more and more difficult to keep the power system stable [1]. The electricity supplier has to provide quality power to the consumer. Every piece of electrical equipment has its own operating voltage range which should be maintained for effective operation. When the voltage level falls outside the operational range, a device may be unable to start its operation or it may malfunction. Furthermore, the device may be damaged. So, it is very essential to minimize the variations in voltage in order to protect the equipment using electricity. Load of a power generating unit is continuously varying and a change in reactive power affects the system voltage. The basic way of controlling the voltage of a generating unit is by using the automatic voltage regulator (AVR) loop [2], [3]. It is designed to automatically control, adjust and maintain a constant voltage level to avoid the costs associated with equipment damage and downtime caused by poor voltage levels. AVR controls the system voltage by controlling the generator's excitation system through a buck or a boost action. Any change in reactive power influences terminal voltage to be changed. Hence, any mismatch between generation and demand deviate the system voltage from scheduled values. As, this deviation is not desired an effective control is necessary to restore the terminal voltage. Traditionally, voltage regulation in power system is achieved by balancing generation and demand.

In the past literature, various investigations have been carried out on AVR with their mathematical model [4], [5]. The transient response characteristics of the basic AVR loop was not satisfactory. It shows approximately 83 % overshoot along with steady state error of 9 %. Moreover, the settling time, a crucial parameter for power system stability, is approximately 19 s which is quite high. For better response during load variation, an improved dynamics of AVR is demanded. In order to improve the system dynamics a rate feedback stabilizer was implemented in [5] which reduces the overshoot to around 4 %, steady-state voltage variation was 0.09 and minimizes settling time to 8 s. but it is not wise to use as the settling time is again large.

Proportional-integral-derivative (PID) controller based AVR control technique was introduced in [6]. The step response of PID controlled AVR loop gives smaller overshoot as compared to open-loop AVR, steady-state error was reduced to 0.001 with a lower settling time of about 4.5 s. From all the above literature it is clear that, the control system for AVR have to be more efficient hence optimal control techniques can be a better solution of the problem which can track the reference trajectory more effectively.

Optimal control is a branch of modern control theory that deals with the problem of finding a control law for a given system. The control problem includes a cost function which is a function of state and control variables of the concerned system. An optimal control is actually a set of differential equations that describes the paths of the control variables to minimize the cost function. Linear quadratic regulator (LQR), an optimal control technique, has been introduced in [7] and [8] to mitigate the voltage deviation due to load variation in power generating system. LQR helps to enhance the transient stability under different operating conditions. When a step response is obtained for the LQR controlled AVR loop it gives around 0.6 % of overshoot with approximately 0.9 s settling time.

All the above mentioned literatures provide a large time to be settled down for a power generating unit which motivated for further research to improve the transient response characteristics. A robust controller is needed to effectually improve the system dynamics. The main goal of

the controller should be to give better transient response to a sudden change of load. If a significant mismatch between load and generation is not properly coordinated it is possible for the system to become unstable. Furthermore, high voltage deviation may lead to system collapse. Encouraged by the importance of controlling AVR loop a robust control scheme based on linear-quadratic-Gaussian (LQG) controller augmented with an integral control action is proposed here which will help to improve the performance of the control loop. It will be proved as an accurate and fast acting optimal controller to maintain constant nominal terminal voltage accompanied with a short settling time.

The remainder of the paper is organized as follows: In Section II, the model and step response of AVR is developed for a single-area power system. The controller design is presented in Section III and implementation of these controllers on AVR system is provided in Section IV. Section V includes a comparison of the proposed controller with the existing control techniques and finally, section VI draws conclusion.

II. Modeling of AVR

An increase in the reactive power load of the generator goes along with a drop in the terminal voltage. The function of AVR is to regulate the voltage. It takes the fluctuate voltage and changes them into a constant one. It works on the principle of detection of errors. The output voltage of an AC generator obtained through a potential transformer and then it is rectified, filtered and compared with DC reference. The difference between the actual voltage and the reference voltage is known as the error voltage. The error signal is then amplified which increases the terminal voltage of the exciter. So the generator field current is increased.

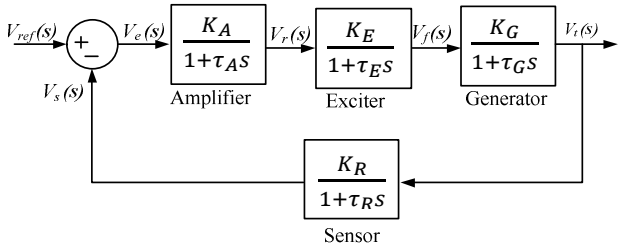

Fig. 1: AVR block diagram of an isolated power system.

TABLE I. PARAMETERS OF AN ISOLATED SYSTEM [5]

Elements	Gain	Time constant
Amplifier	K_A=10	τ_A = 0.1
Exciter	K_E = 1	τ_E = 0.4
Generator	K_G = 1	τ_G = 1.0
sensor	K_R = 1	τ_R = 0.05

As a result, the reactive power generation is increased accordingly and hence the terminal voltage is raised to the desired value. The block diagram of an AVR system is shown in Figure 1 [5]. The AVR model parameters used for an isolated system are presented in (Table I) [5].

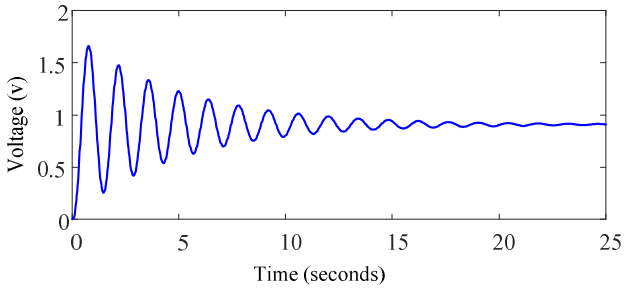

Fig. 2: Terminal voltage step response of AVR.

With the primary AVR loop, a change in the system load will result in a steady-state voltage deviation. Moreover, the response is highly oscillatory and it takes approximately 19 s to be settled down. Figure 2 shows the step response of AVR loop. So using alone the AVR loop to control the voltage is not wise as the response of the system is not satisfactory.

III. Controller Design

A. Design of Rate Feedback Stabilizer

In order to improve system dynamics a rate feedback stabilizer was introduced in [5]. It adds a zero to the AVR open loop transfer function which helps to remove the oscillation from the step response. Figure 3 shows the block diagram of the AVR system with rate feedback stabilizer.

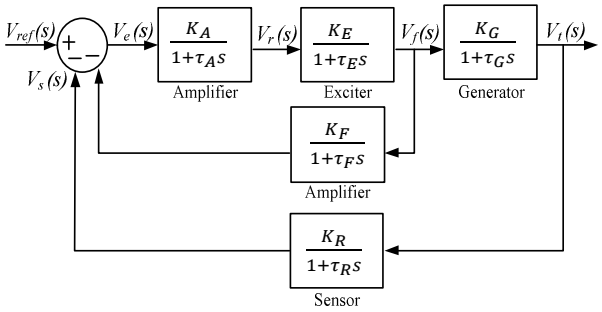

Fig. 3: Block diagram of an AVR system with rate feedback stabilizer.

B. Design of PID controller

PID controller is widely used in industrial control systems. It continuously calculates an error value as the difference between a desired set-point and a measured process variable then applies a correction to the plant based on proportional, integral and derivative action. The transfer function of the PID controller is

$$G_C(s) = K_P + \frac{K_I}{s} + K_D s \qquad (1)$$

A simple block diagram of a PID controlled system is showed in Figure 4.

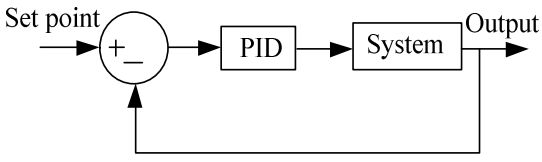

Fig. 4: Block diagram of PID controller.

C. Design of LQR

LQR controller is a form of optimal control that provides optimally controlled feedback gains to enable the closed-loop stable and high performance design of systems. It is a well-known design technique that provides practical feedback gains. In LQR, the plant dynamics are described by a set of linear differential equations and the cost is described by a quadratic function, so the name is linear quadratic regulator. If the plant described by

$$\begin{cases} \dot{x}(t) = Ax(t) + Bu(t) \\ y(t) = Cx(t) + Du(t); \end{cases} \quad (2)$$

where, x is called the state vector, $x(t) \in \mathbb{R}^n$, y is called the output vector, $y(t) \in \mathbb{R}^q$, u is called the input (or control) vector, $u(t) \in \mathbb{R}^p$, A is the state (or system) matrix of $n \times n$, B is the input matrix of $n \times p$. C is the output matrix of $q \times n$, D is the feedthrough (or feedforward) matrix (in case where the system model does not have a direct feedthrough, D is the zero matrix), of $q \times p$. $\dot{x}(t)$ is the first derivative of x(t). The problem is to find the vector $K(t)$ of the control law

$$u(t) = -K(t)x(t) \quad (3)$$

which minimizes the value of a quadratic performance index

$$J = \int_0^\infty (x^T Qx + u^T Ru)dt. \quad (4)$$

Here Q is an $n \times n$ positive semidefinite matrix, also called the state weighting matrix. R is an $p \times p$ positive definite matrix known as control weighting matrix [7].

$$K = R^{-1}B^T P \quad (5)$$

here P is the unique positive definite solution of the algebraic Riccati equation (ARE) [7].

$$A^T P + PA + PBR^{-1}B^T P + Q = 0. \quad (6)$$

From the state space representation of the plant the value of A, B, C and D matrices can be found. The control scheme is

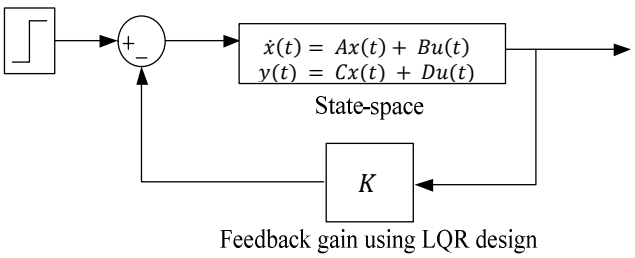

Fig. 5: Block diagram of an LQR controlled system.

based on placing the closed-loop poles in a suitable region in the complex plane to ensure desired transient response. By proper selection of the Q and R matrix the value of P and therefore the value of K can be obtained which will place the closed-loop poles of the system in the most perfect place using the LQR method with respect to the cost function. Figure 5 shows a simple block diagram of an LQR controlled system.

D. Design of LQG

LQG is one of the most fundamental optimal controllers that concerns linear systems driven by additive white noise. The name LQG arises from the use of a linear model, an integral quadratic cost function, and Gaussian white processes to model disturbance signals and noise. The problem is to determine an output feedback law that is optimal in the sense of minimizing the expected value of a quadratic cost criterion.

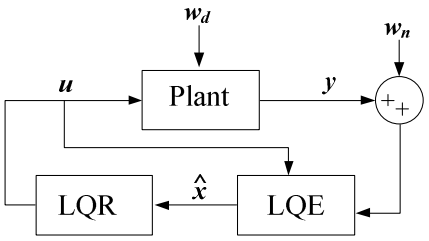

Fig. 6: Block diagram of an LQG controlled system.

Output measurements are assumed to be corrupted by Gaussian noise and the initial state is assumed to be Gaussian random vector. The LQG controller is simply a combination of a linear-quadratic estimator (LQE), together with a LQR. The separation principle states that the state estimator and the state feedback can be designed independently. Figure 6 shows a block diagram of LQG controlled system. For LQG the stste-space plant model is described as

$$\begin{cases} \dot{x}(t) = Ax(t) + Bu(t) + w_d \\ y(t) = Cx(t) + Du(t) + w_n; \end{cases} \quad (7)$$

where the variables x, y, A, B, C and D represents the same as for LQR. w_d and w_n are additive white Gaussian system noise and Gaussian measurement noise respectively. Now the problem is to find the optimal control u(t) which minimizes the cost function as given in [9], [10].

$$J = \lim_{T \to \infty} E \int_0^T (x^T Qx + u^T Ru)dt. \quad (8)$$

Where E denotes the expected value, Q is the state weighting matrix, and R is the control weighting matrix.

IV. IMPLEMENTATION OF CONTROLLERS ON AVR

The step response of the basic AVR loop for an isolated power generating unit, whose parameters are given in TABLE I, is not satisfactory which is indicated by Figure 2.

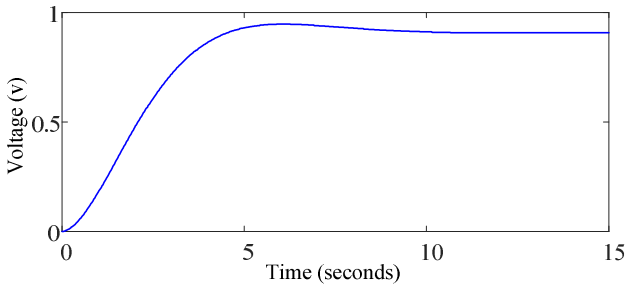

Fig. 7: Terminal voltage step response with rate feedback stabilizer.

Use of a rate feedback stabilizers can be a key to the problem. With proper adjustments of derivative gain, K_F and stabilizer time constant, τ_F better response as compared to conventional AVR loop can be obtained. When $\tau_F = 0.04$ s and $K_F = 2$, then the step response of the control loop is shown in Figure 7.

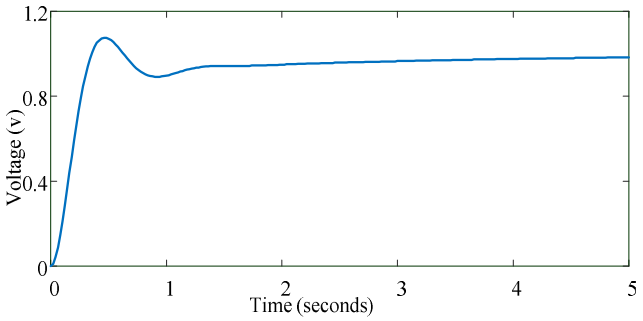

Fig. 8: Terminal voltage step response for PID controller.

The system gives about 4 % overshoot along with reduced steady-state error and a settling time of almost 8 s. When PID controller is added in the forward path of the AVR system then the step response of the combined system is given in Figure 8 which yields better transient response characteristics.

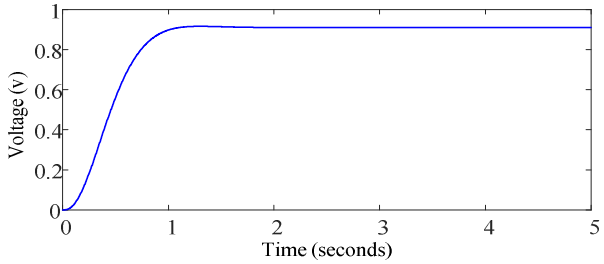

Fig. 9: Terminal voltage step response with LQR controller.

It shows about 4.5 s settling time with much improvement in the steady-state error but suffers from overshoot issue. Figure 9 shows the step response for the AVR system when LQR control technique is implemented. For the robust control of system dynamics and to improve transient response characteristics proposed control scheme based on an LQG controller augmented with an integral action

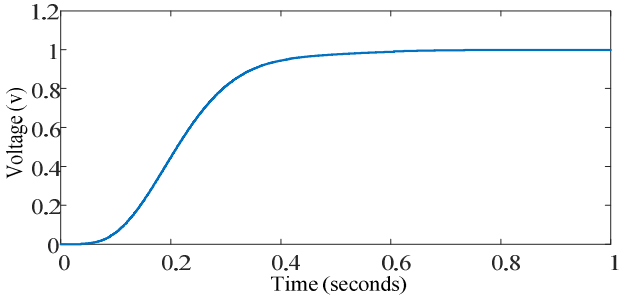

Fig. 10: Terminal voltage step response with proposed LQG controller.

is implemented on the same AVR model. Figure 10 shows the improved step response with around 0.5 s settling time accompanied with no overshoot issue and much reduced steady-state error.

V. COMPARISON AND RESULT

To investigate the robustness of the suggested LQG control technique for restoring the terminal voltage on load variation a comparison is demonstrated with existing controllers which is shown in Fig. 11. From figure 11 it can

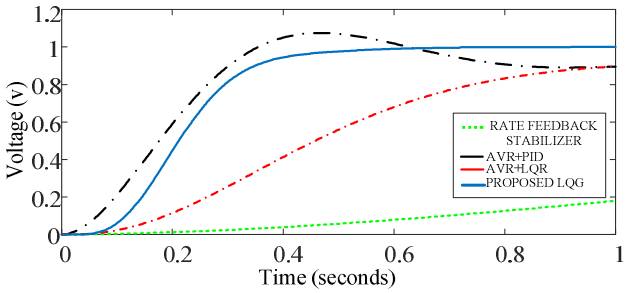

Fig. 11: Terminal voltage step response for different controllers.

be observed that after implementing proposed controller the closed loop system performance satisfies the requirement criteria more effectively. TABLE II illustrates the results for different control techniques implemented on AVR containing some important transient responses. With the proposed method, the steady-state error is relatively small with a zero overshoot and the settling time is approximately 0.5 s, which is a significant improvement.

TABLE II. Performance parameters of different control techniques

Controller	Settling Time (seconds)	Overshoot (%)	Steady-State Error (%)
Rate feedback stabilizer	8.1274	4.1812	0.0913
PID	4.5010	7.5763	0.0010
LQR	0.9697	0.6359	0.0910
Proposed LQG	0.5161	0	5.82e-04

VI. CONCLUSION

A broad analytical analysis of AVR control loop for regulating the terminal voltage is presented in this article. Different control techniques to control the basic AVR loop are inspected by taking their corresponding step responses of terminal voltage. The design and implementation of an optimal LQG controller augmented with an integral action for the robust control of AVR system dynamics is described in this article. Then some transient response characteristics of terminal voltage are investigated and compared with the existing controllers which justify the effectiveness of proposed control scheme. The control methodology is applicable for an isolated power generating unit but with some modifications it can be applied to the interconnected power grid as well, which may be considered as the future work to perform.

***Abstract*—In this work, we implement automatic power factor correction technique using a microcontroller to minimize penalty charges, cut the losses and save power. The chief objective is to improve the power quality by continuously monitoring the load power factor, when the load power factor falls below a specific value it results in the increase of line current, resulting in more line loss and greater voltage drop. Thus, the aim is to inject capacitances of required value when the power factor falls below the specified level. In this work, we use static capacitor method which will be controlled by PIC Microcontroller with very low cost although many existing systems are present which are expensive and difficult to manufacture. In this study, many small rating capacitors are connected in parallel. The suitable number of static capacitors is automatically connected according to the instruction of the Microcontroller to improve the power factor close to unity**

Keywords— microcontroller, detector, power factor, loads, correction.

I. INTRODUCTION

Electrical vitality portion is of fundamental significance to mechanical and business organizations working in the presently focused markets [1]. Ideal utilization of plant and hardware is one of the important thing that companies are attempting to harmonize with the vitality proportion for both financial and natural reasons. As society turns out to be continuously aware of its side effects on nature, limited vitality utilization turns out to be more ideal, which is a feasible objective for everybody. Using estimates, for example, readdressing of control factor, power utilization improvement, which at last direct to diminish of vitality utilization and diminished CO_2 greenhouse gas radiation [2]. Programmed control factor controller is needed to raise the control factor consequently at whatever point the power factor falls underneath an unequivocal level [3].

As the interest for electrical vitality is amplifying day by day, an ever increasing number of inductive burdens are being utilized in mechanical and local applications. Inductive loads are the primary purpose behind low power factor in the power system [4]. This way we have to build up a strategy to enhance control factor naturally. Programmed control controller can answer this issue. By rising force factor of intensity framework typically, control framework effectiveness can be improved [5]. In this work, microcontroller, relays, potential transformer, current transformer, and zero intersection circuit are utilized for creating power factor amendment model. The essential morals behind this programmed power factor enhancement are the power ideality in a power framework which has turned into a vital issue these days with a beautiful advancement of intensity gadgets innovation application and nonlinear load as of late prompts symphonious impedance in the power framework. Another inspiration is, in a request to guarantee most great condition for a supply framework from the building.

Furthermore, from financial point of view, it is imperative to have control factor as near solidarity as could be expected under the circumstances, that is the reason we require programmed control factor enhancement. In our nation, the more significant part of the heaps in the majority of the enterprises are inductive, which have slacking power factor. So on the off chance that we can enhance the power factor level closest to the 1, it will be savvy and productive. For instance, consider an asset with 1 KVA rating which is required to control apparatuses of 80 watts each [6]. A control factor of 0.61, the asset, best case scenario can oversee 8 machines every one of 80 watts.

If a similar power factor can by one way or another be enhanced to 0.91, the asset ought to be agreeable to control up to no less than 11 gadgets according to the dealings [6]. The inner voice behind this work which began from one of the fundamental issues looked by the nearby private area. So by enhancing power factor can prompt abatement in KVA request and thus the client can perform moderate charging. Along these lines, in light of the above contentions, it tends to be expressed that enhancement in power factor enhances framework productivity [6]. Chaitanya N. Jibhakate, Madhuri A. Chaudhari, Mohan M. Renge proposed a work where Power factor enhancement is accomplished by controlling DC interface capacitor voltage and PID controller is utilized to control capacitor voltage, however the work isn't ideal for various strategies aside from controlling capacitor-voltage [7].

II. SYSTEM DIAGRAM

A. Block DIagram

Here Fig. 1 stands for the block diagram representation of the total operating system which depicts its working process and how the proposed work manages to venture down the voltage [8]. The equation of electromagnetic enlistment is being used by the transformer to drive electrical vitality starting with one circuit then onto the next loop or inside a similar circle. Time shifting attractive fields in a transmitter

deliver compel for electromagnetic acceptance and Transformers can be utilized to venture up a voltage or venture down energy relying on its arrangement for the utilization in various electrical circuits[9]. The microcontroller at that point uses its competency and program to deduct the stage edge and stage fluctuation between two waveforms. The pins of the microcontroller are associated with the hand-off IC and afterward to transfers.

At the point when a low voltage circuit is utilized to drive a heap which is associated with high voltage an IC is used which is known as Relay driver IC. A hand-off loop requires more current as break down to different gadgets. Incorporated circuits, for example, Op-amp circuits can't supply such expansive flows to driver delays. Transfers are individual under lock and key and have replaced sturdy state switches and are more grounded than sturdy state gadgets. Transfers have high current limits. To drive circuit disconnection and to spare from ESD, transmissions can be utilized

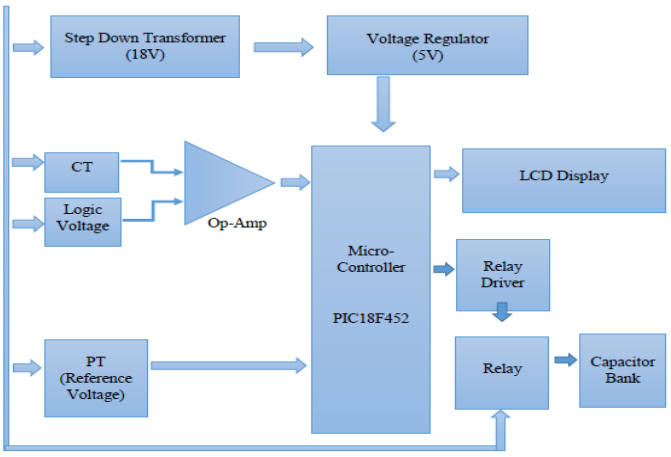

Fig. 1. Block diagram of the entire system.

III. Circuit Diagram

A. *Circuit Diagram for Auto PFC*

Fig. 2 demonstrates the circuit outline for Auto PFC(Power Factor Correction). In circuit graph of programmed control factor controller, the present transformer is used to get present waveform of load current, and current transformer likewise ventures down air conditioning current. The operational intensifier is utilized as a comparator in this circuit. Also, voltage transformer is utilized to get the present waveform and sustained this wave to Op-amp comparator. LM358 has been used as zero intersection indicators in this work after that both current and voltage waveforms are nourished to PIC18F452 microcontroller [10].

PIC18F452 microcontroller calipers zero intersection location and power factor by estimating time contrast among current and voltage wave frame. Microcontroller incorporates control factor and takes required activities dependent on power factor. Transfer driver is associated with a microcontroller which is issued to drive transfers. Microcontroller occupies large flag to hand-off driver IC at whatever point control factors fall under 0.9. Hand-off driver turns on transfers which consequently interfaces capacitor and keeps money with the heap. As a matter of first importance, the stage distinction among voltage and current wave shape are estimated, and after that, the power factor is figured. If there should be an occurrence of low power factor, capacitors are added to enhance it.

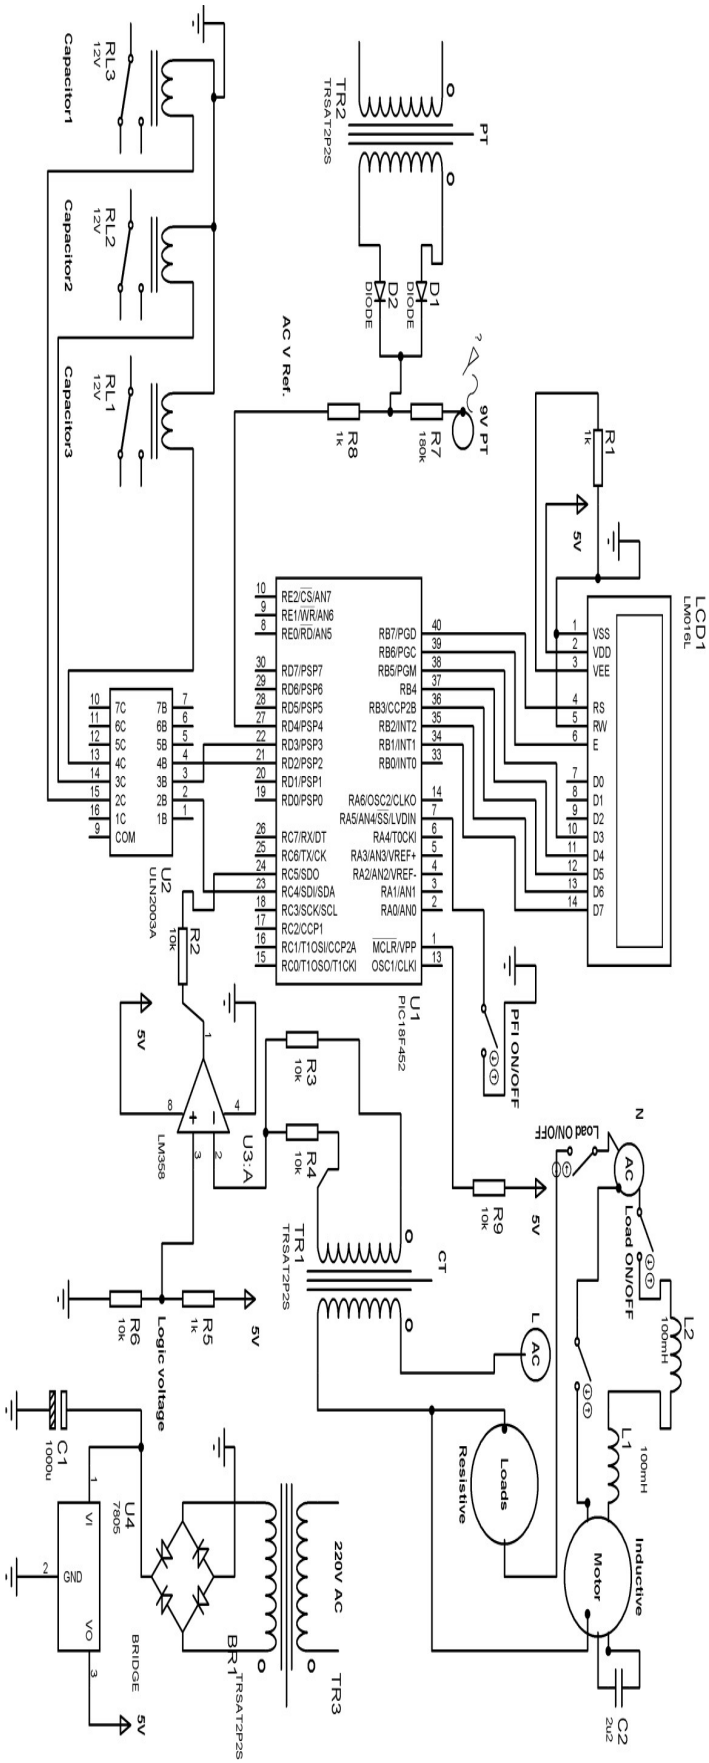

Fig. 2. Circuit diagram for auto PFC.

B. Hardware Implementation

The PCB was fabricated according to the diagram for the complete circuit and all the components are soldered on it. The connection for the potential transformer [11] and current transformer [11], capacitor bank was done at the respective places [12]. Continuity check using the multimeter was carried out to avoid any accidental short-circuits.

1) Prototype of Realized PF Correction Equipment:

In Fig.3 shows the prototype of realized power factor correction equipment where different types of components are set up on the PCB Board.

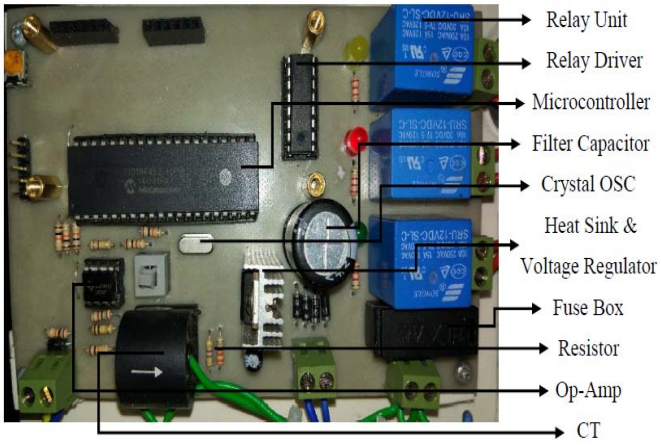

Fig. 3. The realized PF correction equipment.

2) The Complete Circuit Implementation: Fig. 4 shows the complete hardware model of APFC (Automatic Power Factor Correction).

C. Algorithm of PFC

- Step -1: Take input for voltage and current in the circuit.
- Step -2: Measure the phase lag and calculate the power factor.
- Step -3: Differentiate power factor from the targeted power factor.
- Step -4: Switch ON or OFF appropriate number of capacitors from capacitor bank.
- Step -5: Again compare the power factor with targeted PF and continue from step-1.

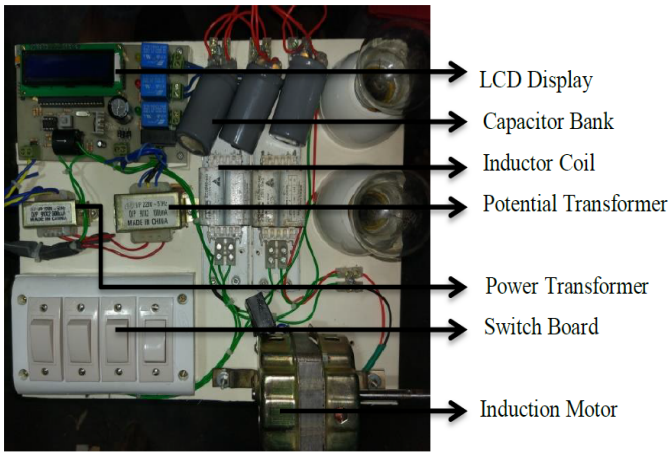

Fig. 4. The complete hardware model of APFC.

3) Flow Chart of PFC:

Fig. 5 represents the entire flow chart for power factor correction. In the flowchart, first, we start our whole system with power supply. The system will get initialized and read out the input voltage and current. After that, the operational amplifier will convert the sine wave to square wave for PFC angle translation. The microcontroller measures the power factor and displays it. If the power factor is one than Power Factor 1 is displayed on the LCD otherwise it will add capacitor bank by relay connection to remove the magnetizing current, and increasing power factor thus it will display power factor one on LCD, then the system will be stopped.

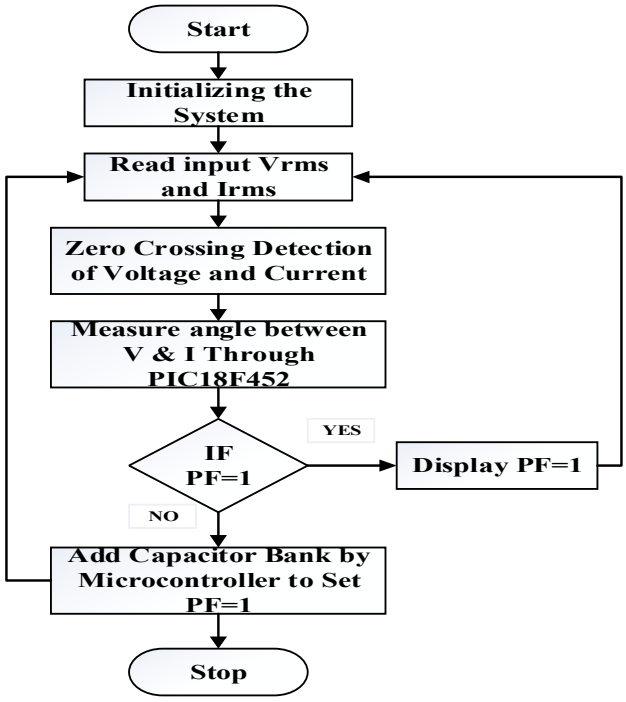

Fig. 5. Flow chart of PFC.

IV. Results and Calculations

A. Measurement of Power Factor

All the measurements need to be done for the three different types of load designed, separately with and without the correction equipment. The setup is shown below Fig. 6.

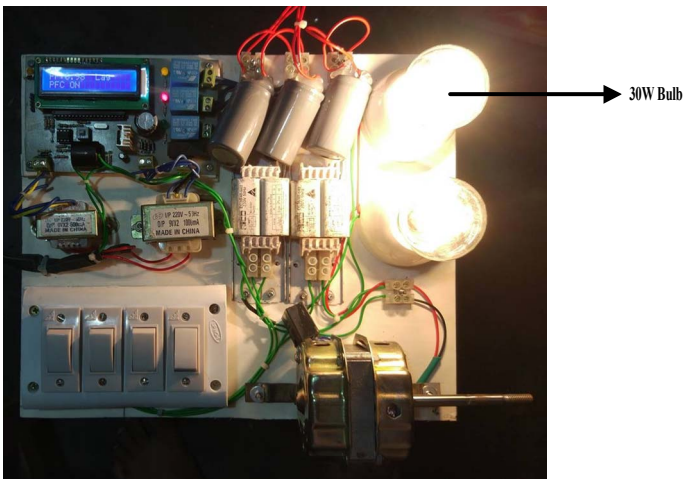

Fig. 6. Setup for measuring power factor.

B. Wave shape for Different Loads

1) Wave shape for Resistive Loads: When the resistive load is ON, there is no phase detain between current, and voltage signals and they are in phase. In this case, the power factor would be 0.9 as documented value, so there is no portion of capacitors as shown in Fig.7. In the fact of resistive load, the V and I are in phase, so there is no part of capacitors to improve power factor as shown in Fig.8.

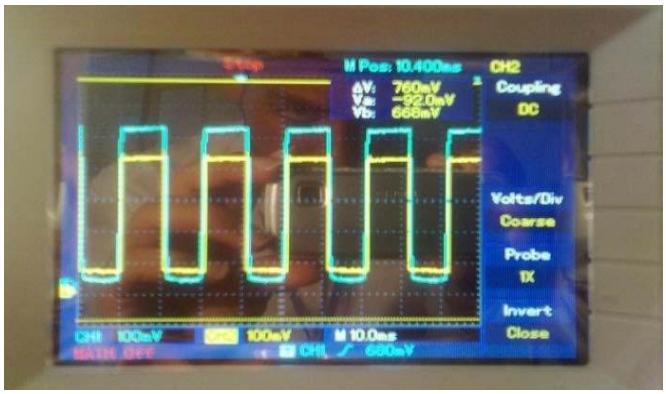

Fig. 7. Zero crossing detection for resistive load.

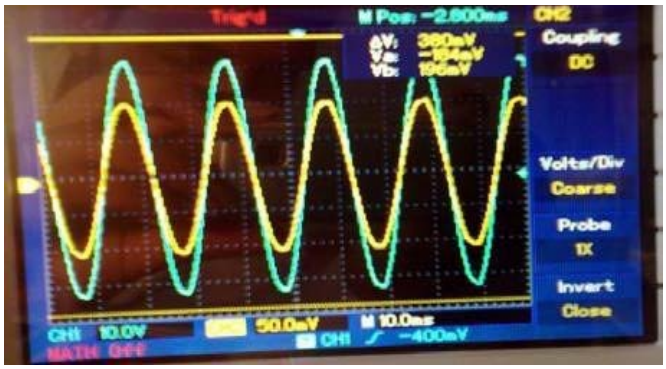

Fig. 8. V and I behavior for resistive load.

2) Wave Shape for Inductive Loads before Correction:

At the point when an inductive heap of an enlistment engine is ON, there is a stage confine among voltage and current signs. Microcontroller detects the confine delivered by the load, and as indicated by the keep, it enters the coveted estimation of the capacitor to enhance the power factor of the framework as appeared in Fig. 9. The zero-intersection identification of V and I motions for an acceptance engine has appeared in Fig. 10.

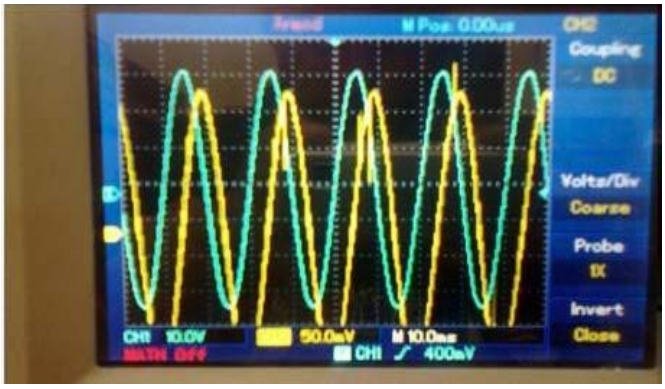

Fig. 9. V and I behavior before correction with inductive load.

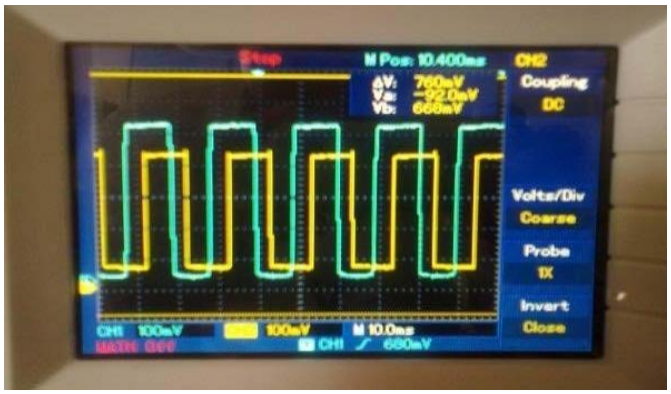

Fig. 10. Zero crossing detection before correction with inductive load.

3) Wave Shape for Inductive Loads after Correction: According to the phase delay in signals, microcontroller takes the intelligent decision and adds the desired value of the capacitor. When the desired amount of the capacitors added the required reactive power to the system, the current and voltage waveforms are in phase, as shown in Fig 11. After that, the insertion of the required value of the capacitor, the V and I zero cross detector signals are also in phase by the set referenced value of power factor (0.9) as shown in Fig. 12

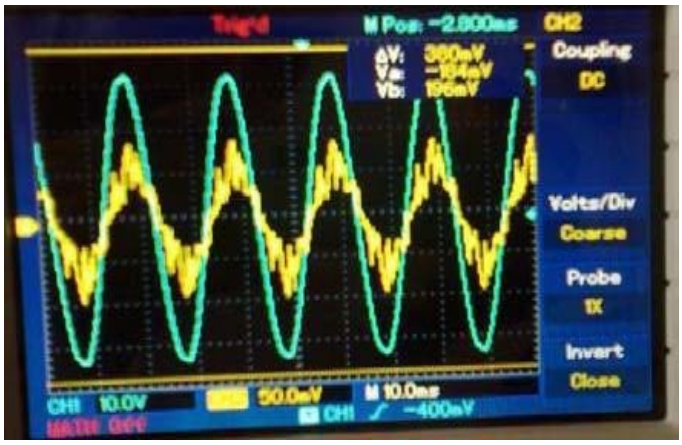

Fig. 11. V and I behavior after correction with inductive load.

Fig. 12. Zero crossing detection after correction with inductive load.

C. Output Voltage across Current Transformer

1) For No Load: When there is no load, the output voltage across the current transformer is 0.018V as shown below Fig. 13.

Fig. 13. Output voltage across current transformer (no load).

2) For Different Load: When there is Inductive, Non-Inductive and Resistive Load, the output voltage across the current transformer is 0.021V, 0.015V and 0.015V respectively as shown below Table 1. Data in Table 1 are shown in Fig.14, Fig.15, and Fig.16.

TABLE I

MEASUREMENTS OF CURRENT TRANSFORMER FOR DIFFERENT LOADS

No.	Load Type	Output Voltage (V)
1.	Resistive	0.021
2.	Inductive	0.015
3.	Capacitive	0.015

Fig. 14. Measurement of current transformer for resistive load.

Fig. 15. Measurement of current transformer for inductive load.

Fig. 16. Measurement of current transformer for capacitive load.

D. Analysis of Load before Correction: The analysis of the pure restive load (R Load), Inductive load (L) and Non Inductive load (C) was done without using the correction equipment. The designed loads were connected and the readings for different electrical parameters were recorded.

TABLE II

ANALYSIS OF LOAD BEFORE CORRECTION

No.	Load Type	Supply Voltage (V)	Load Current (A)	Power Drawn (W)	Power Factor
1.	Resistive	212	1.22	200	0.94
2.	Inductive	217	0.54	40	0.34
3.	Capacitive	219	0.36	30	0.38

E. Analysis of Load after Correction: As there is a demand for power factor improvement for load, they were connected to the supply along with the correction equipment designed. All the three loads designed were applied and the observed values were recorded.

TABLE III

ANALYSIS OF LOAD AFTER CORRECTION

No.	Load Type	Supply Voltage (V)	Load Current (A)	Power Drawn (W)	Power Factor
1.	Resistive	215	0.672	200	0.98
2.	Inductive	217	0.177	40	0.95
3.	Capacitive	219	0.142	30	0.68

TABLE IV

IMPROVEMENT OF POWER FACTOR

No.	Load Type	Percentage of improvement
1.	Resistive	4%
2.	Inductive	61%
3.	Capacitive	30%

F. Graphical Representation of Auto Power Factor Correction of Different Loads:

1) Resistive Load: Fig. 17 shows the graphical representation of auto power factor correction of the resistive load.

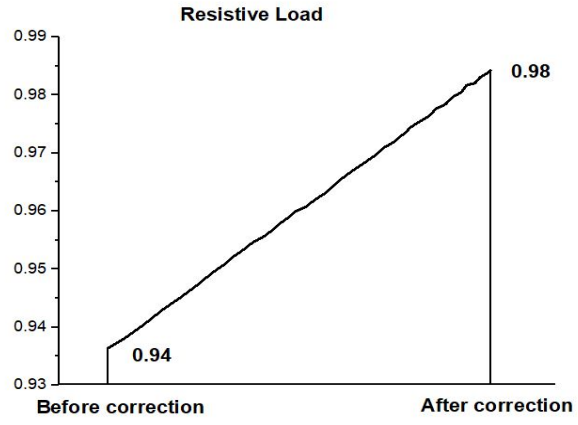

Fig. 17. Graphical representation of auto power factor correction for resistive load.

2) Inductive Load: Fig. 18 shows the graphical representation of auto power factor correction of the inductive load.

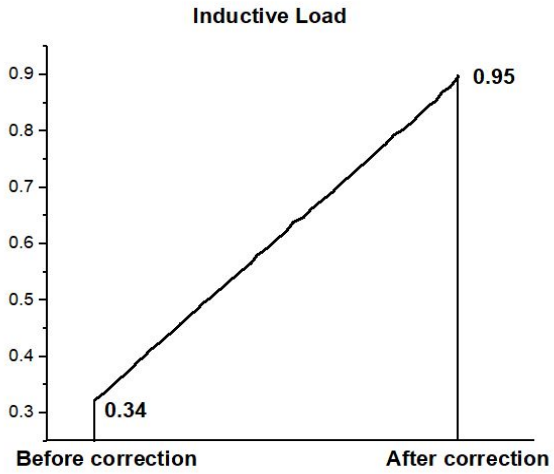

Fig. 18. Graphical representation of auto power factor correction for inductive load.

3) Capacitive Load: Fig. 19 shows the graphical representation of auto power factor correction of the capacitive load.

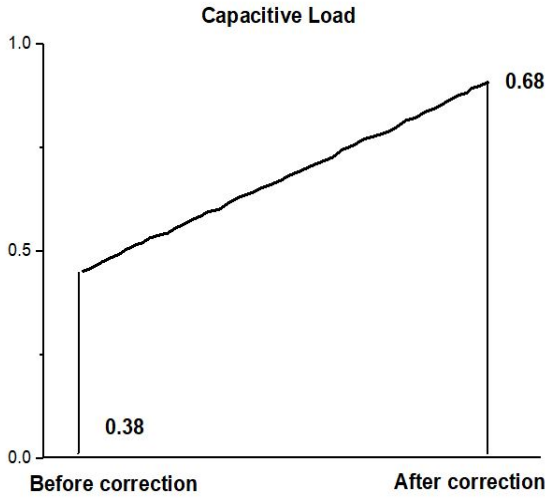

Fig. 19. Graphical representation of auto power factor correction for capacitive load.

It should be noted that when the value of power factor improves, the losses made because of low power factor also gets reduced.

V. Conclusion

It can be concluded that the power factor correction approach can be applied to the industries, power systems and also households. Thus an improved power factor reduces reactive power, copper loss, transmission loss and avoids poor voltage regulation, overloading also improve voltage control and efficiency of the supply system. However, this method comes with some limitations such as the compensation lower ratings, they have a short service life range, easily damaged if the voltages exceed the rated value. In future, PWM techniques can be employed in this scheme along with power factor correction .As it operates automatically, human resources are not required and the use of automated power factor rectification capacitor banks can help attain more efficient way of running industries in the future.

Abstract-The power lines are connected in an interconnected power system through tie lines and Load Frequency Control (LFC) places the frequency and tie line power errors zero to keep the system in steady state condition. This paper represents an effective decentralized Load Frequency Control (LFC) by means of the concept of Active Disturbance Rejection Control (ADRC). The performance of ADRC based LFC is compared with PID based LFC in two area power system. Simulation is done by MATLAB Simulink and the results demonstrated the better robustness and dynamic performances with ADRC based LFC over PID based LFC.

Keywords—ADRC, LFC, ESO and two-area power system

I. INTRODUCTION

The main problems of modern interconnected power system are sustaining a normal working position and optimum scheduling of generation [1]. To keep the system steady, active- and reactive-power are the two operating parameters [2]. Moreover, these two equilibrium point are controlled as economically and reliably as possible to meet the predetermined value of frequency and voltage in an interconnected system [3]. Changing the frequency of the power system is primarily influenced by the uncertainty of the system and dynamic external disturbances. System frequency and voltage are directly correlated with change in real- and reactive-power respectively.

The LFC loops manage the system active and frequency which is termed as Automatic Generation Control (AGC) [4]. The AGC divides the loads among the generating units and correctly control the tie line power. In order to abate Area Control Error (ACE) to zero in the presence of system uncertainty and disturbances, it is need to introduce LFC in the interconnected power system [5]. For improving the performance and stability of the power system there are some conventional controllers proposed earlier[6].The traditional PI, PID and others controllers are robust and prolific in disturbance but deteriorate performance by the nonlinearities and untrustworthy load conditions [7].

Now, the promising and a new solution is Active Disturbance Rejection Control (ADRC), which is easily enumerated and mollifies uncertainties of the system and internal-external disturbances [8]. Estimation and cancellation of disturbances can be done by using an External State Observer (ESO) [9]. In this controller hardware-software are easily comprised and easily tuned by the factory personnel in the industry.

In comparison with traditional controllers, ADRC illustrated better dynamic performances i.e. lower settling time, overshoot and oscillations [10]. LFC of multi-area power system is recommended using ADRC based on second-order sliding mode control. Here, the load variations and tie-line power exchange deviations are considered as a lumped disturbance [11]. The ADRC controller is broadly used in chemical industry, electricity, aerospace, aviation and others field with many advantages [12]. In this progression, ADRC is applied LFC of two area power system and the performance of this controller is compared with PID based LFC. To the best of my knowledge, improved LFC of two-area power system using ADRC based LFC is not reported yet.

II. ACTIVE DISTURBANCE REJECTION CONTROL (ADRC)

The new control technology, ADRC, estimate the total internal uncertainties and external disturbances using an observer called Extended Estate Observer (ESO) and actively cancel the disturbance with the nonlinear feedback controller. The plant reformatting and ADRC structure are given in the following section. The designed parameters of this controller are considered form [13].

A. Plant Remodeling

The ADRC is designed using a common transfer function model of a physical system with primary loop. Both time-domain and frequency–domain representations is considered. The foremost endeavor

is to develop ADRC for a higher order system. Hence, an n^{th} order system is introduced for the design of ADRC. By utilizing a minimum phase transfer function, a plant with finite zeros can be developed which is as follows:

$$\frac{Y(s)}{R(s)} = G_p(s) = \frac{b_m s^m + b_{m-1}\ s^{m-1} + \cdots + b_1\ s + b_0}{a_n\ s^n + a_{n-1}\ s^{n-1} + \cdots + a_1\ s + a_0} \quad (1)$$

Where, $Y(s)$ and $R(s)$ are input and output of the plant respectively. a_i and b_j *(i=1,..., n, j=1,..., m)* are the coefficient of the transfer function.

After performing the longhand division, the plant model may be shown as

$$s^{n-m}Y(s) = b_o U(s) + D(s) \quad (2)$$

with $b_o = \frac{b_{m+1}}{a_{n+1}}$

Where, *D(s)* includes both the internal and external disturbances.

A. Estimation of Generalized Disturbance

It is very important to cancel the generalized disturbance *d (t)* when the plant is remodeled. An extra state of the system is considered for handling the discrepancies called Extended State Observer (ESO).The state space model of plant represented as follows:

$$sX(s) = AX(s) + BU(s) + E(s)D(s) \quad (3)$$

$$Y(s) = CX(s) \quad (4)$$

Where

$$X(s) = \begin{bmatrix} X_1(s) \\ X_2(s) \\ \vdots \\ X_{n-m}(s) \end{bmatrix}$$

$$A = \begin{bmatrix} 0 & 1 & 0 & \dots & 0 \\ 0 & \ddots & 1 & \ddots & \vdots \\ \vdots & \ddots & 0 & \ddots & 0 \\ \vdots & \ddots & \ddots & \ddots & 1 \\ 0 & 0 & \cdots & \dots & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ b \\ 0 \end{bmatrix}, E = \begin{bmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{bmatrix},$$

$$C = [1 \quad 0 \quad \dots \quad 0]$$

in order to eliminate the error a state space model of the disturbed process can be represented as follows.

$$sZ(s) = AZ(s) + BU(s) + L\,(Y(s) - \hat{Y}(s) \quad (5)$$

$$\hat{Y}(s) = CZ(s) \quad (6)$$

$$Z(s) = [z_1(s) \quad z_2(s) \dots \quad z_{n-m}(s)] \quad (7)$$

where, $L = [\beta_1 \quad \beta_2 \dots \quad \beta_{n-m}]$

In order to trace all eigenvalues of the ESO to $-\omega_0$ observer bandwidth), the observer gains are chosen as

$$\beta_i = \binom{n-m}{i}.\ \omega_0^i, \quad i = 1,\dots,n\text{-}m \quad (8)$$

By proper designing of ESO, $Z_i(s)$ will be able to estimate the values of $X_i(s)$ closely where i= (1, 2, 3……n-m). Then,

$$Z_{n-m}(s) = \hat{D}(s) \approx D(s) \quad (9)$$

The generalized disturbance *d (t)* can be removed by the time domain estimated value x_{n+1}

$$U(s) = \frac{U_o(s) - Z_{n-m}(s)}{b_0} \quad (10)$$

Now the system is reduced to a pure integral plant by substituting

$$S^{n-m}Y(s) = b_0 \frac{U_o(s) - Z_{n-m}(s)}{b_0} + D(s) \quad (11)$$

The control law for the pure integral plants

$$U_0(s)\big(R(s) - Z_1(s)\big)K_1 Z_2(s) \dots \dots K_{n-m-1} Z_{n-m-1}(s) \quad (12)$$

To simplify the tuning process, all the closed loop poles of the PD controller are set to $-\omega_c$.Then the controller gain in have to be selected as

$$K_i = \binom{n-m}{n-m-i+1}.\ \omega_c^{\,n-m-i+1}, \quad i = 1,2,\dots,$$

$$n - m - 1 \quad (13)$$

Placing all the observer poles at one location is known as bandwidth parameterization ω_c represents the bandwidth of the controller. Increasing ω_c the tracking speed of the output of ADRC controlled system will increase. In other words the tracking error, overshoot and settling time of the output will decrease. Generally, ω_c varies from 3~10 rad/s.

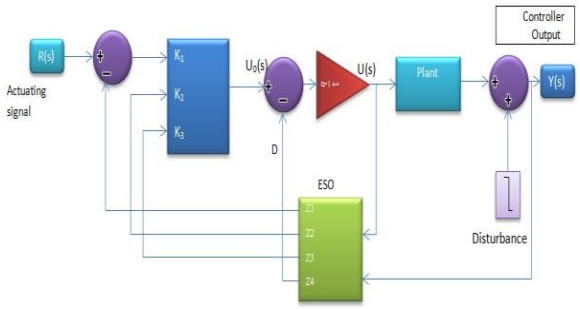

Fig. 1 ADRC structure with state feedback

The proposed ADRC control for decentralized system is shown in Fig.1. In this figure an ADRC is placed in each area acting as a local LFC under decentralized control strategy. These two decentralized areas are connected through tie line. For this LFC problem, ACE-1 and ACE-2 are the reference inputs and load changes ΔP_{L1} and ΔP_{L2} are the external disturbances in areas-1 and area-2 respectively. The parameters for both areas of the system are shown in Table 1.

TABLE-I PHYSICAL PARAMETERS OF GENERATING SYSTEM

Parameters	***Symbols(Units)***	***Value***
Inertia constant	H(p.u.sec)	10.00
Frequency sensitive load coefficient	D(p.u/Hz)	1.00
Turbine time constant	$T_i\,(second)$	0.30
Governor time constant	$T_g\,(second)$	0.10
Governor speed regulation	R(Hz/p.u)	0.05
Synchronizing coefficient	T(p.u/rad)	22.00
ADRC Bandwidth	$\omega_c\,(rad/sec)$	10.00
Observer Bandwidth	$\omega_o\,(rad/sec)$	20.00
Load change in area-1	$DP_{L1}\,(p.u)$	0.10
Load change in area-2	$DP_{L2}\,(p.u)$	0.08

The ESO is derived for observer bandwidth ωo = 20 rad/s. Next controller gains are computed for controller bandwidth ωc = 10 rad/s, as K1 = 1000, K2 = 300, K3 = 30.

III. PROPORTIONAL INTEGRAL DERIVATIVE (PID) CONTROL

In a closed loop system, the exact permutation is done among proportional, integral and derivative actions. This controller has universal applicability regardless of their low order. The conventional PID controller is represented by block diagram in Fig. 2. The tuning constraints of the controller are given in Annexure. A simplified implementation of the basic principle in error-based feedback control can be found in a classical PID controller. The control law is driven by the dissimilarities between the set point *v* and plant output *y,i.e.* $e = v - y$, as well as its differentiation de/dt and integration $\int e\,dt$ in Equ. 14.

$$u = k_0 \int_0^t e\ dt + k_1 e + k_2 \frac{d\,e}{d\,t} \qquad (14)$$

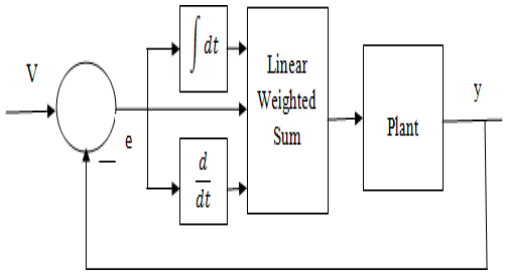

Fig. 2 Architecture of PID controller

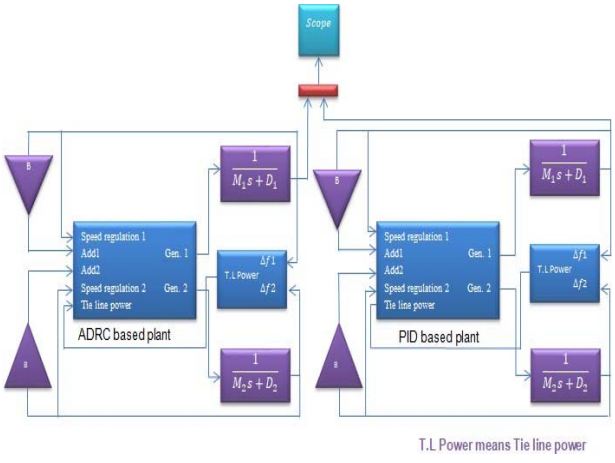
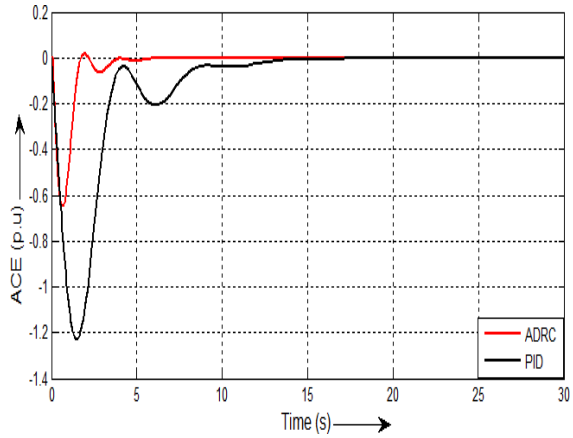
Symbol	Name of the Parameter	Value of the Parameter
P	Proportional Gain	0
I	Integral Gain	-0.0298920
D	Derivative Gain	0

IV. PERFOMANCE COMPARISON OF ADRC AND PID BASED LFC FOR TWO AREA POWER SYSTEM

The two area power system consists of two different decentralized areas, which are connected to each other through tie-lines. Each area has three major components, which are turbine, governor and generator. The ADRC controlled interconnected power system is shown in Fig.3.The parameters of the system are obtained from [5, 6], and listed in TABLE 1.

For each decentralized area in Fig. 3, an ADRC is designed based on the transfer function $G_p\,(S)$.





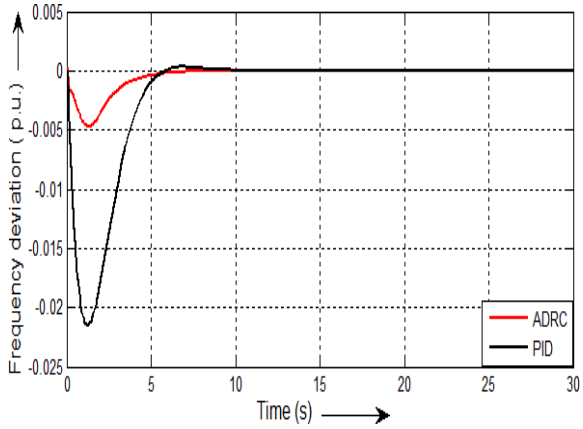


Fig. 3 ADRC and PID based LFC model of two-area interconnected power system

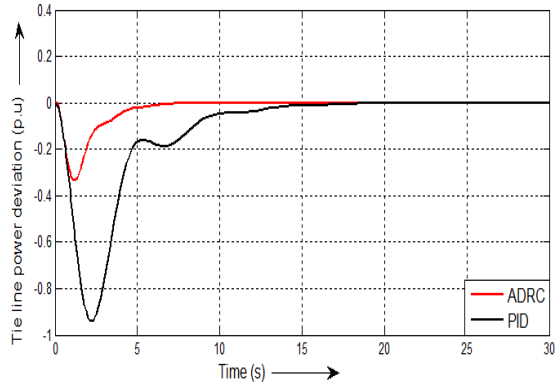
V. SIMULATION RESULTS



The effectiveness of ADRC is tested in this case by simulating the closed-loop control system in Fig.4.

(a)

(b)

(c)

Fig.4: Comparison of performance of PID and ADRC based LFC (a) ACE, (b) frequency error, (c) tie-line error

In order to verify the effectiveness of ADRC, a series of simulations are conducted comparing with PID controller in two-area interconnected power system. The system responses for two different areas are shown in Fig. 4. In case of LFC, area control error, frequency error and tie-line error are considered as output.

Comparison of ACE responses between ADRC and PID controller in both areas (Fig. 4) shows that, For ACE: ADRC has an over shoot, %OS = 0.63 and settling time, T_S = 5.10 sec. whereas the PID controller has an over shoot of %OS = 1.22 and settling time, T_S = 13.00 s. ADRC has lower settling time and less over shoot, hence the ADRC shows better performance than PID controller for ACEs in two area interconnected power system.

Similarly, the comparison of frequency deviation and tie line power deviation responses between ADRC and PID based LFC in both areas (Fig. 4). Better performance is illustrated in ADRC based LFC than PID based LFC.

All the responses of ADRC based LFC and PID based LFC are tabulated for better comparison in Table. III.

TABLE-III PERFORMANCE COMPARISON OF ADRC AND PID CONTROLLER BASED DOUBLE AREA POWER SYSTEM

SL. No.	***Controllers***	***Performances***	***PID Controller***	***ADRC Controller***
1.	Area control error (ACE)	Overshoot (p.u.)	1.22	0.63
		Settling time (Sec.)	13.00	5.10
2.	Frequency deviation error (Δf)	Overshoot (p.u.)	0.023	0.005
		Settling time (Sec.)	8.00	7.50
3.	Tieline power deviation (ΔPtie)	Overshoot (p.u.)	0.94	0.35
		Settling time (Sec.)	13	6.00

a. Dynamic Performance Analysis

To test the dynamic performance, a 0.01 p.u. step load change is applied in area-1. Observer bandwidth and controller bandwidth are considered 20 and10 respectively for ADRC. On the other hand, for PID controller, K_P = 0.5, K_i = 0.83 and K_d = 0.5. The simulation results are shown in Fig.4. From the simulation results, it can be demonstrated that the ACEs, the frequency errors and the tie-line power deviations have been driven to zero by ADRC in the presence of load power changes. Similarly, it is observed that due to the disturbance compensation by ADRC controller, the overshoot of frequency deviation in both areas and tie-line power deviations

are greatly reduced comparing with PID controller. Therefore, it can be vindicated that the ADRC controller provides a better dynamic performance.

b. Robustness Analysis

In order to test the robustness of ADRC, the variations of all of the parameters (*M, D, T,* T_i *,* T_g *, R*, and *B*) of the single unit can be changed. However, the controller constraints of ADRC are not changed with the variations of the system parameters. From the simulation results, it is observed that even though such large parameter variations, the system responses do not show remarkable differences from the results. Therefore, the simulation results demonstrated the toughness of ADRC against system parameter variations. If the system parameters are changed for reheat unit or non-reheat unit, the termination will be same since the model for each area is similar to the other.

The simulation results established the effectiveness of ADRC on the LFC problem in various aspects. First of all, ADRC is capable to cancel the ACE to satisfy the LFC requirements of maintaining the standard frequency and keeping the tie line power exchange according to the schedule. Secondly, ADRC is efficient to terminate both random and large load disturbances. Thirdly, ADRC can be used to resist the interferences to the controller intend of parameter uncertainties. Thus, ADRC is considered to be a suitable control technique for LFC solution.

VI. CONCLUSION

In this works, an improved LFC is proposed using ADRC for two-area interconnected power systems. Two area power systems is modeled and developed to examine the steadiness, steadfastness and toughness of ADRC controlled system in the presences of external disturbance, system constraints dissimilarities. The simulation results proved the usefulness of ADRC through successfully regulating the ACEs, frequency errors and tie-line power errors in the presences of external disturbance, parameter uncertainties. Eventually, it can be said that this scheme is much capable of handling anomalous stipulation in a power system produced by load variations. The ADRC presents the following satisfactory performance indices:

1. Overshoot: overshoot can be reduced by using ADRC

2. Rise Time: Which minimum as compare to the other control techniques

3. Steady state error: almost zero

***Abstract*--Phasors are significant to power system analysis in both steady-state and dynamic conditions. IEEE Standard C37.118.1 2011 along with its recent amendment C37.118.1a2014 define synchrophasor measurements with the focus on the behavior of phasor measurement units (PMUs) under steady-state and dynamic operating conditions. The synchrophasors can find many applications in modern power systems including real-time status monitoring, precise state estimation, validating simulation models, protection, taking centralized control actions using wide-area measurements and integrating renewable and intermittent resources. In this paper, various PMU algorithms are compared to find out the best algorithm which gives best result in specific conditions. As different research papers suggested and focused on different criterions, it is very difficult and cumbersome task to accumulate all data in a common platform and compare them. After vigorous research a unique way is developed to present overall comparison result in a well-defined and more understandable manner.**

Keywords--Synchrophasor, Taylor, EPLL, Kalman, Clarke, DFT, FIR Filters.

I. INTRODUCTION

Phasor Measurement Unit (PMU) has become an important tool for power system monitoring and control. Being a new a concept, the main advantage of this synchrophasor measurement over the existing SCADA system [1] is that their measurements are time-stamped using a reference synchronization signal, generally provided by a Global Positioning System receiver, and are taken much faster. In this way, PMUs can yield phase information with much greater accuracy.

IEEE Standard C37.118.1-2011 [2] along with its amendment C37.118.1a-2014 [3] mention requirements for synchrophasor, frequency, and rate of change of frequency (ROCOF) particularly in the presence of amplitude and phase modulated signals, linear ramp of frequency, and step changes. The standard defines two performance classes of PMUs, namely P and M. The P-class is intended for applications requiring fast measurement response time, while the M-class is there for measurement accuracy. A standard compliant PMU should meet all the requirements at least for one class. The main differences between the two performance classes are the test conditions for steady state performance and the requirements for dynamic condition. On the other hand, the standard leaves to PMU manufacturers free choice on hardware, software architecture, and algorithm for phasor, frequency, and ROCOF computation.

Various algorithms have proposed so far and which can be broadly divided into two categories 1) DFT- based approach 2) Non-DFT- based approach. Due to its less computational burden, more tolerance in harmonics and easy implementation, DFT based approach is used in the standard [2] and many authors have tried to implement it after slight modifications. The classic DFT based method works well when the system frequency is close to nominal frequency but due to spectral leakage issue in DFT, a significant error will arise when deviated from the nominal value. A lot of efforts have been made to improve the accuracy of DFT-based estimation algorithms under off-nominal frequency conditions. The common DFT based approaches includes Interpolated DFT based approach [4]-[5], Adaptive phasor and Frequency algorithm [6], Taylor Fourier Multifrequency Model [7], Clarke Transformation based DFT algorithms [8].

The non-DFT based algorithms includes Kalman filter based approach [9], Enhanced phase-locked loop [11], recursive approach [12], Taylor Fourier transform [13], Taylor-Kalman filters [14], Adaptive Cascaded filters [16], fast and accurate PMU algorithms [17], Polynomial Phase-Locked-Loop Taylor–Fourier Filters [18], Space Vector-Based PMU Algorithms [19], Positive-Sequence Synchrophasor Estimation Algorithm [20] etc.

From this vast range of algorithms, it is really tough to select appropriate algorithms for particular purposes. This paper gives a general overview of various existing algorithms and a comparison of these algorithms in a common platform which certainly be helpful for the users to select required algorithms.

The organization of this paper is as follows: Section II describes various algorithms, Section III summarizes results, Section IV describes discussion and lastly Section V gives conclusion by discussing future scope.

II. VARIOUS METHODS DISCUSSION

In PMU standard [2], a sinusoidal signal can be represented as,

$$X(t) = A(t)\,cos(\psi(t)) \quad (1)$$

Where, $\psi(t) = 2\pi f t + \phi(t)$

Where, Amplitude (A), frequency (f), Phase (ψ) & Phase shift (ϕ). Frequency is defined as

$$f(t) = \frac{d\psi(t)}{2\tau dt} \quad (2)$$

The ROCOF is defined as,

$$ROCOF(t) = \frac{df(t)}{dt} \quad (3)$$

Various PMU algorithms are described below:

A. Enhanced Phase-Locked Loop (EPLL)

Conventional PLL method uses Phase Detection Scheme (PD), Low Pass Filter (LPF) and a Voltage Controlled Oscillator (VCO) which generates a signal whose frequency is proportional to the input signal.

Though PLL system works properly for three phase balanced system, it faces obstacles when operating with three phase unbalanced system as it generates double frequency ripple in the loop. To mitigate this problem EPLL [11] is proposed which continuously updates the parameters to reduce error. If (2) is the output of the system, then an error index is defined (3). Hat sign is used to indicate estimated values.

$$y(t,P) = \sqrt{2}\hat{A}\cos(\hat{\psi}(t)) = \sqrt{2}\hat{A}\cos(2\pi\hat{f}t + \hat{\phi}) \quad (4)$$

$$J(t,P) = e(t,P)^2 = [X(t) - Y(t,P)]^2 \quad (5)$$

Vector parameter P contains $\hat{A}, \hat{\omega}, \hat{\phi}$. Gradient Descend Method (GDM) is use for continuous adjustment of P vector for minimizing the error index. The following sets of differential equation are obtained from $\dot{P} = -K(\partial J / \partial P)$, here *K* is positive definite matrix.

$\dot{\hat{A}} = 2k_1 e\,\widehat{cos\,\psi}$, $\dot{\hat{\omega}} = -2k_2 e\,\widehat{sin\,\psi}$, $\dot{\hat{\psi}} = -2k_3 e\,\widehat{sin\,\psi} + \hat{\omega}$

Here,

$e(t) = X(t) - \sqrt{2}\hat{A}\,\widehat{cos\,\psi}$

B. Taylor^K-Kalman Filter

In this method [13], a bandpass signal model of a power oscillation is defined by the state transition matrix of the K-th order Taylor approximation to the dynamic phasor and its first derivatives.

The signal is simplified for complex exponential function as,

$$X(t) = Re\{p(t)e^{j2\pi f_1 t}\}; -T/2 \le t \le T/2 \quad (6)$$

Here, $p(t) = A(t)e^{j\phi(t)}$ is referred to as dynamic phasor. The complex dynamic phasor function *p(t)* can be approximated by Kth Taylor polynomial centered at t_o. If *p(t)* is a smooth function the approximation would be more exact as $t \rightarrow t_o$ and then the truncated signal (7) can be applied at any time instance as the time interval is very short.

$$X_k(t) = Re\{h^T P_k(t) e^{j2\pi f_1 t}\} = Re\{h^T r_k(t)\} \quad (7)$$

Here, h^T extracts the first component with K zeros and *r(t)* is the rotated vector. Finally, the truncated signal model is given by (8) that shows the instantaneous dependence of the signal model on the dynamic phasor.

$$X_k(n) = \frac{1}{2}(h^T h^T)\begin{pmatrix} r_k(n) \\ \bar{r}(n) \end{pmatrix} \quad (8)$$

Kalman recursive method will be used to minimize the error for *nth* cycle according to Kalman gain (9)

$$K(n) = P^-(n)H^T(HP^-(n)H^T + \sigma_\omega^2)^{-1} \quad (9)$$

in which, $H = (h^T h^T)$ and σ_ω^2 is the variance of the measurement unit. State of the signal model is updated according to the Kalman gain.

To avoid the tradeoff between P (protection) and M (measurement) classes, the center of the window is considered fixed at Δt_a equal to one nominal cycle before the reference time and the synchrophasor is obtained by [fast@accu REF]

$$A_c = A + A'\Delta t_a$$
$$\varphi_c = \varphi + f\Delta t_a$$

C. Interpolated DFT Algorithm

Interpolated Discrete Fourier Transform (IpDFT) [4] can estimate synchro phasor parameters both in steady state and dynamic condition when two or three cycle length observation intervals are used.

The relationship between $f_{in,}$ *and* f_s is (11) where, *l* and δ are the integer and fractional parts of number of acquired signal cycle λ_o.

$$\frac{f_{in}}{f_s} = \frac{\lambda_o}{M} = \frac{l+\delta}{M} \quad (11)$$

In IpDFT method the signal (10) is multiplied by a window sequence,

$$w(m) = \sum_{h=0}^{H-1} a_h \cos\left(\frac{2\pi h}{M}(m + \frac{1}{2})\right) \quad (12)$$

Here, $m = -\frac{M}{2}, \ldots, \frac{M}{2} - 1$ and *H* is the number of window terms and *h = 0, ..., H-1* indicates the window coefficient. DFT of the windowed signal, $x_w(m) = x(m).w(m)$ is calculated as,

$$X_w(k) = \frac{A}{\sqrt{2}}[W(k-\lambda_o)e^{j\phi_o} + W(k+\lambda_o)e^{-j\phi_o} \quad (13)$$

If, $|\lambda| << M$ then, the DTFT of the window signal (12) is expressed as,

$$W(\lambda) = \frac{M\sin(\pi\lambda)}{\pi}\sum_{h=0}^{H-1}(-1)^h a_h \frac{\lambda^2}{\lambda^2 - h^2} \quad (14)$$

After, calculating δ, phasor amplitude and phase are measured according to,

$$\hat{A} = \frac{\sqrt{2}|X_w(l)|}{|W(-\hat{\delta})|}$$
$$\hat{\phi} = phase\{X_w(l)\} \quad (15)$$

When, K cycles of signal (10) are observed then window of order H≤ K must be used for accurate phasor estimation.

D. Finite Impulse Response (FIR)

A complex analytical signal $X_p(t)$ of the input signal *x(t)* is obtained by passing the signal through K-tabs FIR bandpass filter [6] whose, complex exponential with respect to the center frequency is,

$$h_{BP}(k, f_c) = h_{\cos}(k, f_c) + jh_{\sin}(k, f) \; ; k = 0,1,\ldots,K-1$$

The center frequency f_c can be re-tuned as it's an adaptive filter. FIR prototype derived form a 4 cycle Taylor window is used for M class accuracy,

$h_M(n) = \frac{1}{2K}\sum_{h=0}^{8}(-1)^h A_h \cos(2\pi h \frac{n}{2K})$; *n = 0,1,..., 2K-1*

1.2 cycle of the Taylor window is used for P class accuracy,

$$h_p(n) = K + (1-K)W_h(n) \text{ ; } n = 0,1,..., K-1$$

Here, K = 0.5189 and W_h is Henning window.

E. DFT based Demodulation Approach

Demodulation system [6] is efficient for tracking phasor. Demodulation system (16) first brings the signal back to the bass band with N_1 point low pass FIR filter,

$$X[\mathrm{k}] = \sum_{n=k}^{k+N_1} h_1[n-k].\mathrm{e}^{-2\pi f_o(n-k)T}.x[n] \tag{16}$$

Here, k is the discrete time index and T is the sampling time period. The raw phasor is filtered again with N_2 point low pass FIR filter (17) and replaced on (16) to get modified demodulated signal (18).

$$h_1(n) = \frac{1}{N_1}, n = 0,1,...,\mathrm{N}-1 \tag{17}$$

$$X(k) = \frac{1}{N_1}\sum_{n=0}^{N_1} x[n-k].e^{-2\pi j f_o nT} \tag{18}$$

It is seen that the FIR filtering method can be implemented recursively as,

$$X[k] = \frac{1}{N_1}[x[k] - x[k-N_1]] + W_{fo}X[k-1]$$

Where, $W_{fo} = e^{-2\pi j f_o T}$.

This is a very fast process and cannot provide good attenuation at high frequency, but it is very efficient in rejecting the harmonics in the absence of frequency offset.

F. A Novel Modular Positive Sequence Synchrophasor Estimation Algorithm

In this method there are four steps are included for estimating positive sequence synchrophasor for both P and M classes. In the first step, the signal is demodulated to separate the positive, negative and zero sequence signal (19) in frequency domain to eliminate the zero-sequence signal.

$$x_{dq}[n] = a_1[n]\begin{bmatrix}\cos(\phi_1[n])\\ \sin(\phi_1[n])\end{bmatrix} + a_2[n]\begin{bmatrix}\cos(2\omega_o nT + \phi_2[n])\\ -\sin(2\omega_o nT + \phi_2[n])\end{bmatrix} \tag{19}$$

Then, prefiltering is used to mitigate the noise and interference according to,

$$y_{dq}[n] = \begin{bmatrix}y_d[n]\\ y_q[n]\end{bmatrix} = \begin{bmatrix}(h_{PF} * x_d)[n]\\ (h_{PF} * x_q)[n]\end{bmatrix} = a[n]\begin{bmatrix}\cos(\phi[n])\\ \sin(\phi[n])\end{bmatrix}$$

After that the synchrophasor parameters are extracted according to PLL algorithm. A phase predictor is used inside the loop for accuracy.

Forth step is to use a Narrow-band Compensation Algorithm (NCA) to compensate the effects of the filters on the main signal.

G. Clarke Transformation Based DFT Transformation

In this method [8], Clarke Transformation generates a second signal that is exactly 90-degree phase angle difference from the input single-phase signal that help to reduce the estimation error for a wide frequency range and then Weighted Least Square Taylor Fourier (WLS-TF) is used to make their amplitude identical.

At first the signal is passed through a Moving Average Filter (MAF) to get rid of the noise. Then the three phase signals (20) are passed through Clarke transformation unit.

$$\begin{aligned} X_A(k) &= \sqrt{2}A * \cos\left\{\frac{2(f_0+\Delta f)k\pi}{f_0 N} + \varphi\right\} \\ X_B(k) &= \sqrt{2}A * \cos\left\{\frac{2(f_0+\Delta f)(k-\frac{N}{3})\pi}{f_0 N} + \varphi\right\} \\ X_C(k) &= \sqrt{2}A * \cos\left\{\frac{2(f_0+\Delta f)(k+\frac{N}{3})\pi}{f_0 N} + \varphi\right\} \end{aligned} \tag{20}$$

Equation (20) can be expressed as,

$$X_{ABC}(k) = \begin{bmatrix}X_A(k)\\ X_B(k)\\ X_C(k)\end{bmatrix} \tag{21}$$

T is the Clarke transformation matrix (22).

$$T = \begin{bmatrix}\frac{2}{3} & \frac{-1}{3} & \frac{-1}{3}\\ 0 & \frac{1}{\sqrt{3}} & \frac{-1}{\sqrt{3}}\\ \frac{1}{3} & \frac{1}{3} & \frac{1}{3}\end{bmatrix} \tag{22}$$

According to (23) V(k) is obtained, and from that Amplitude, Phase, Frequency and ROCOF are estimated.

$$V_{\alpha\beta\gamma}(k) = TX_{ABC}(k) \tag{23}$$

H. Other Algorithms:

Other algorithms like adaptive cascaded filter [16], fast and accurate method [17] which is basically Taylor Fourier Transform (TFT), Taylor Fourier multi-frequency method [7], Polynomial PLL Taylor Fourier Filter [18], Space Vector based algorithms [19] are the slight modification of above-mentioned algorithms. Due to space limitation and lack of uniqueness, description of these algorithms is not included in this paper. But the result of these algorithms is tabulated below, and users can easily go through these algorithms from reference if they need.

III. RESULTS

The parameter that is needed to be calculated is the Total Vector Error (TVE), Frequency Error (FE), and Rate OF change of Frequency Error (RFE). The standard formula for calculating this are,

$$TVE = \sqrt{\frac{(\hat{X}_r(n) - X_r(n))^2 + (\hat{X}_i(n) - X_i(n))^2}{(X_r(n))^2 + (X_i(n))^2}}$$

$$FE = |f_{true} - f_{measured}||\Delta f_{true} - \Delta f_{measured}|$$

$$RFE = |(df/dt)_{true} - (df/dt)_{measured}|$$

Now to be compliant with this standard, a PMU shall provide synchrophasor, frequency, and ROCOF measurements that meet the requirements of the standard. These requirements shall always be met and under all configurations whether the PMU function is a stand-alone physical unit or included as part of a multifunction unit. There are two types of compliances for testing one for steady state compliances and another for dynamic compliances under modulated test signal, ramp of system Frequency and input step change. The result based on the standard and from different algorithms are tabulated below to show which algorithms maintain the standard and to see which class perform how under different conditions.

IV. DISCUSSION

There have been several comparison-based works in other domains [10][15]. In PMU domain, most of the algorithms tried to maintain the IEEE standards in most of the cases but few results outperform others. Some of the algorithms are concerned with few cases only, this is might be due to time shortage or the limitation of the algorithms. But we didn't find any single algorithm which is okay with the standard and maintained all the requirements. Some algorithms have calculation burdens, and some are easy but less accurate. So, it is tough to say which algorithms are the best and which one is the worst. From the result we found for off nominal frequency condition space vector method out performs other in the case of TVE (%), FE and RFE. Again, in presence of harmonic distortion, space vector method is better even though dynamic phasor-based algorithms do well. For out of band interference condition CT-DFT based algorithm performs better than other. For modulated signal and frequency ramp test space vector-based method and fast and accurate P+M method perform better than other algorithms. For input step change fast and accurate P+M, space vector-based method, wide frequency range method and IpDFT based algorithm perform better.

V. CONCLUSION

There are numerous methods proposed in the literature for the estimation of the phasor, frequency and rate of change of frequency. All of the algorithms try to maintain all the requirements as mentioned in the standard. But from the literature we found some limitations as most of the algorithms don't test all the cases and take different conditions during the test. In general, it is not so straightforward to identify which approach possesses the superior performance. For steady state compliances the Space Vector based algorithm performs well whereas for Dynamic State compliances no single algorithms do remarkably well. So, there are lot of work to do to increase the performance and accuracy of phasor measurement unit. Our aim was not to find novel algorithms rather we worked on existing algorithms to find out the limitations of the various proposed algorithms and give a proper guideline for the users as well as for the scholars. To provide the proper guidelines for the given applications, several commonly used methods have been reviewed and compared in this paper, according to the viewpoint of the IEEE Standard.

***Abstract*—The existing linear generator are mostly made of conventional iron core and permanent magnet (PM). During the operation of this generator, it becomes heated because of the magnetic and mechanical losses. When the temperature rises in the linear generator, then the output power becomes low because of degradation of the remanence magnetism of the PMs. In this paper, a cooling system is proposed for the linear generator for preventing temperature rise. Simulation is executed by ANSYS Maxwell software to perform finite element analysis. To observe the temperature effect, a permanent magnet linear generator along with a heating, ventilation, and air conditioning (HVAC) are designed. The generator is placed inside a water cooled wind chiller based HVAC system. Simulation results show that, the linear generator using the proposed HVAC system produces 23.9 % more output power than that of the same without using HVAC.**

Keywords—cooling, energy conversion, generators, HVAC, magnetic materials, permanent magnet machines, renewable energy sources, temperature control, wave power.

I. INTRODUCTION

The generation of electricity is very important in order to minimize the global energy crisis [1]. Most of the power generation system uses fossil fuels which are harmful for not only environment but also closely involves to the greenhouse effect. To avoid this situation, the importance of renewable energy is increased day by day. At present, wind, solar, and oceanic wave are popularly used to extract the electrical energy. Out of these energies, the sea wave energy contains some effective advantages such as high energy density, much predictability, and availability [2], [3].

The basic concept of the generation of electricity from the oceanic wave is considered in 1799 [4]. But this energy conversion system becomes much popular in 1970s after occurring the oil crisis [5]. According to the installed location, two types of converters are found which are onshore and offshore. In general, offshore is suitable place for the large scale generation than onshore installed converter [6]. At present, there are two types of converter applied for the conversion of oceanic wave energy viz. rotational generator and direct drive linear generator (DDLG). It is found that, the topology of DDLG is much attractive than rotational type generator because of having no complexity for mechanical gear box design [1].

A DDLG based wave energy converter is presented in Fig. 1. It is consisted of a linear generator, inverter, and rectifier. The main elements of a linear generator (LG) are stator and translator. This translator is connected to a floating buoy by a connecting rod. When the translator moves with that buoy with respect to stator, the electricity is generated according to the Faraday's law of electromagnetic induction.

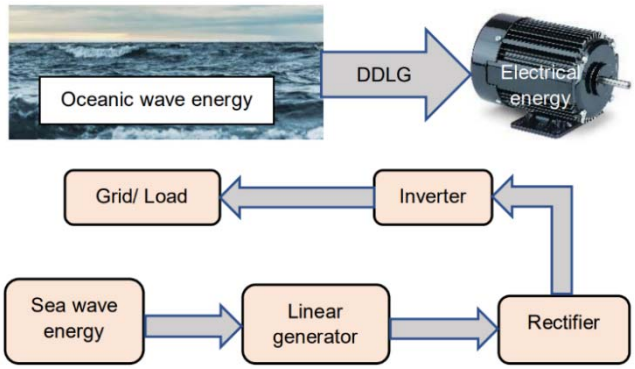

Fig. 1. Block diagram of the working principle of WEC.

The stator is made of magnetic core and coil winding and the translator is made of magnetic core and permanent magnet (PM). Recently, a 21.21W DDLG is developed where the magnetic attraction between the iron core and PM is applied in order to overcome the alternating magnetic field. It utilizes only 0.36 square meter area [7]. An LG is numerically simulated by using MATLAB which supplies 300W output power [8]. Another 1kW LG is validated both in experimentally as well as numerically where detent force is reduced [9]. An electromechanical design of a MW scale high temperature superconductor based LG is presented in [10] in which, the mechanical structure and cryogenic cooling system are highlighted.

Recently, some linear generators are designed by using high grade NdFeB PMs and magnetic cores in order to achieve better performance, higher output power, lower core loss, and higher efficiency. Such as, two types of high grade magnetic cores are applied in an LG in which Supermendur core based generator exhibits better performance [11]. During the operation of linear generator, it becomes heated. For this reason, the LG designed with an ordinary neodymium iron boron (NdFeB) PM is demagnetized. In order to avoid this problem, a high grade NdFeB is proposed in [12] which has higher operating temperature than that of the conventional NdFeB. The application of superconductors in a DDLG are presented in [13] and [14]. The effect of temperature in linear generator is presented in [15], in which NdFeB PM is used to achieve high performance at high temperature. This permanent magnet's maximum operating temperature is 200°C.

The conventional NdFeB PM cannot generate much output power because of decreasing the remanence magnetism at high temperature. This problem is solved by applying high grade NdFeB PM N28EH in an LG [12]. But, high grade PMs add an extra cost to the DDLG and has lower magnetic saturation point. As the generator becomes heated during

operation, for this reason, the PM becomes demagnetized for its property. As a result, the generator cannot produce much output power.

From the review of some research works on DDLG, it is found that, cooling system is not familiar with this machine [1], [5]–[15]. In this paper, a cooling system is included with an LG to avoid the problem of demagnetization due to heat generation and is compared with the same without cooling. The load currents, instantaneous, and rms powers are compared for both cases. As per simulation results, it is found that, the proposed LG with HVAC system generates much output power than that of the LG with no HVAC.

II. Mathematical Model

The temperature effect on conventional NdFeB permanent magnet is presented in Fig. 2. It is found that, the remanence magnetism and coercive force of the magnet at 100°C are lower than that of at 60°C. The highest coercive force, remanence, and energy product of this PM at 20°C are greater than other temperatures.

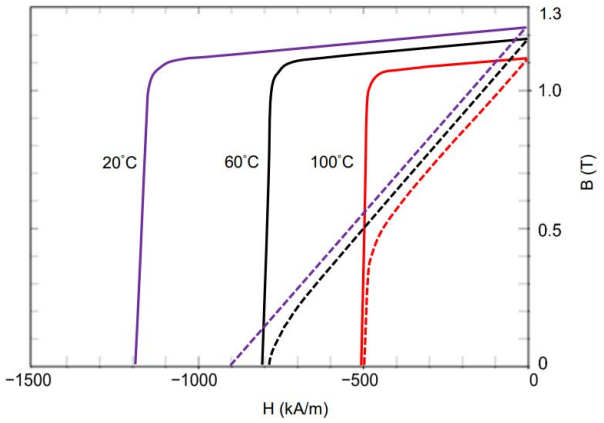

Fig. 2. Temperature effect of conventional NdFeB PM.

Since, the energy product of permanent magnet is high at low temperature and vice-versa, the low temperature is required to achieve high output power from DDLG placed near the shore of the ocean. The model of oceanic wave energy considers shallow water wave. In general, sine wave is considered for description of the energy of sea wave for the simulation of LG [16] where the nominal vertical speed is 0–2 m/s and time period is 4–6s. The model of shallow water is described in Fig. 3.

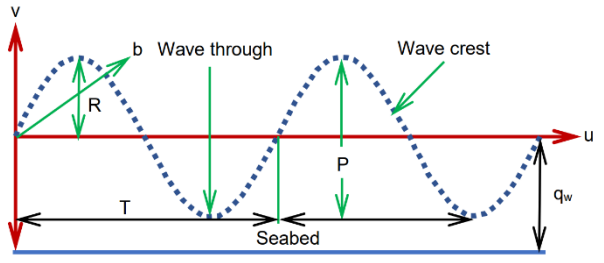

Fig. 3. Sinusoid form of the oceanic wave.

The amplitude, vertical distance, water depth, time period, and angular velocity are denoted by R, P, q_w, T, and ω, respectively. We know that, b is considered as zero as the sea wave propagates along u direction where the component u is horizontal and v is vertical and can be explained as

$$U = R\omega \frac{\cosh\{k(v+q_w)\}}{\sinh(kq_w)}\cos(ku-\omega t) \quad (1)$$

$$V = M\omega \frac{\sinh\{k(v+q_w)\}}{\sinh(kq_w)}\sin(ku-\omega t) \quad (2)$$

where k is the number of wave. In this case, T is much greater than wave height and q_w. That is why, $T >> q_w$ and $T >> R$. Hence, (1) and (2) can be described as

$$U_s = M\omega \frac{e^{k(v+q_w)}+e^{-k(v+q_w)}}{e^{kq_w}-e^{-kq_w}}\cos(ku-\omega t) \quad (3)$$

$$V_s = M\omega \frac{e^{k(v+q_w)}+e^{-k(v+q_w)}}{e^{kq_w}-e^{-kq_w}}\sin(ku-\omega t)\,. \quad (4)$$

Now, (3) and (4) becomes

$$U_s \cong \frac{M\omega}{kq_w}\cos(ku-\omega t) \quad (5)$$

$$V_s = M\omega\left(1+\frac{v}{q_w}\right)\sin(ku-\omega t)\,. \quad (6)$$

When $kq_w << 1$, then $\omega = k\sqrt{gq_w}$. If, $v = \frac{\omega}{k}$ and g is the gravitational acceleration, the speed of phase of the oceanic wave can be found as $s = \sqrt{gq_w}$.

III. Construction of the Linear Generator

The basic construction of a DDLG is presented in Fig. 4. It has mainly two parts viz. translator and stator. The generator contains three stators which are shown at left hand side.

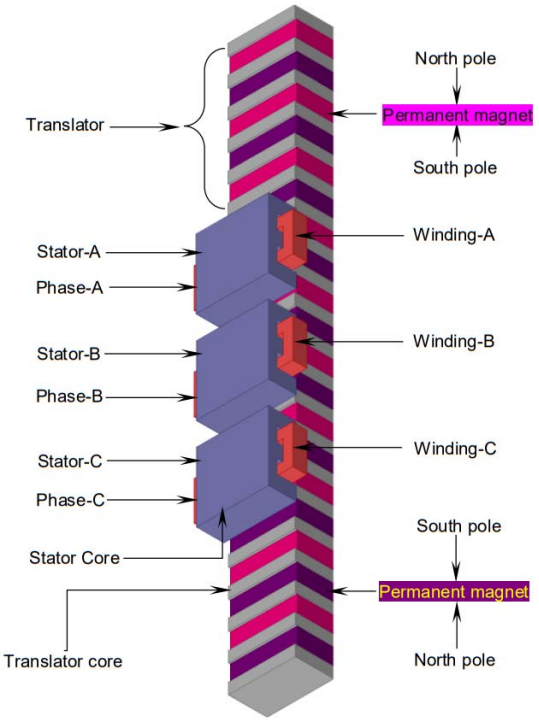

Fig. 4. Basic structure of proposed DDLG.

Each stator is made of "E" shaped magnetic core and copper windings. Winding-A, winding-B, and winding-C are placed inside the stator slots which are also shown in Fig. 4. The translator is shown beside the stator which is made of magnetic core and permanent magnets. The orientations of the permanent magnets are presented in the right-hand side of the translator. Air gap between the translator and stator is considered 3 mm. Table I shows the physical dimensions of the proposed DDLG. This translator is connected with a buoy that floats on oceanic wave. It moves upward and downward with the wave. Due to having connection with buoy, the translator also moves upward and downward with respect to stators. At this stage, emf is induced in each winding by following the Faraday's law of electromagnetic induction.

TABLE I. DIMENSIONS OF THE PROPOSED DDLG

Name of The Parameters	Value
Width of DDLG (m)	0.36
Width of translator (m)	0.25
Width of winding (m)	0.14
With of stator's core (m)	0.1
Height of translator (m)	2.04
Height of winding (m)	0.05
Height of magnetic core (m)	0.25

IV. THE PROPOSED DDLG WITH COOLING SYSTEM

A. Cooling system

The proposed generator with cooling system is shown in Fig. 5. Cooling system is consisted of a chiller, air handling unit (AHU), dehumidifier, supply chilled water pipe (SCWP), return chilled water pipe (RCWP), and control panel.

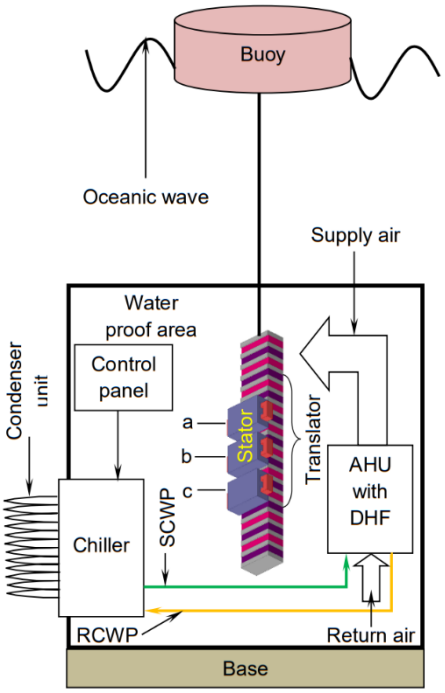

Fig. 5. Proposed cooling system with DDLG.

There are three different sensors used in this system. One is required to collect existing temperature of chilled water which is fitted on the RCWP and the other is required to measure the actual temperature and humidity in the linear generator. According to the signal of sensors, the chiller, AHU, and dehumidifier are operated automatically with the aid of control panel to maintain the desired temperature and humidity. In Fig. 5, a, b, and c indicates phase a, phase b, and phase c, respectively.

The basic block diagram of the proposed chiller is depicted in Fig. 6. Chiller is an electromechanical arrangement that reduces the temperature of water around 8°C. The main parts of this system are compressor, condenser, evaporator, filter core, solenoid valve, and expansion valve. The complete operation is maintained by a control panel according to the signal of chilled water sensor.

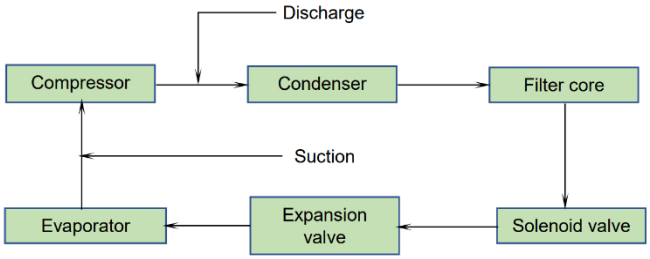

Fig. 6. Basic architecture of chiller.

The refrigerant R22 is filled in the whole chiller unit. In general, the suction pressure of refrigerant is kept 80 PSI at rest mode and 50– 65 PSI during the operation mode. On the other hand, the discharge pressure is considered around 250 PSI at operation mode and same as suction pressure at rest mode. When the compressor is started, the pressure of refrigerant gas increases from 80 PSI to 250 PSI and fed it to condenser unit. At this time, the discharge pipe becomes much heated approximately up to 70–80°C. This condenser unit is made of some copper coil and aluminum fins.

When the gaseous refrigerant enters into the chiller unit, its heat and pressure decreases for which phase transition occurs and its state changes into liquid. This liquid refrigerant goes to expansion valve through the filter core and solenoid valve. The filtered refrigerant's flow is controlled by a solenoid valve which is operated by control panel so that it reach a desired value. The expansion valve is a key element of the chiller which converts the liquid refrigerant into vapor according to the signal of a gas operated valve sensor. Further, the chilled refrigerant flows through the coils in evaporator which is also called cooling tower. When the water flows through the cooling coil, it also becomes chill. Finally, this refrigerant returns in the compressor through the suction pipe. Thus, it completes a cycle and the whole process runs continuously.

B. The Basic Operation of AHU Along With Dehumidifier

The network between evaporator of chiller and cooling coil of AHU is made by using stainless steel pipe. A chilled water pump is connected between these. The main components of AHU are cooling coil or fins coil, mixing box, temperature sensor in both supply and return duct, humidity sensor on return duct, motorized valve on chilled water return (CW-R) or chilled water supply (CW-S) pipe, and supply fan motor. Another return duct is fed to the dehumidifier which supplies the moisture free air to the mixing box of AHU. The chilled water is continuously flowed through the cooling coil by the pump. A controller is applied for receiving the signal of temperature and humidity sensor which are fitted on the

return duct as well as controls the motorized valve, dehumidifier, and speed of supply fan motor in order to maintain the desired temperature and humidity. The network of this system is depicted in Fig. 7.

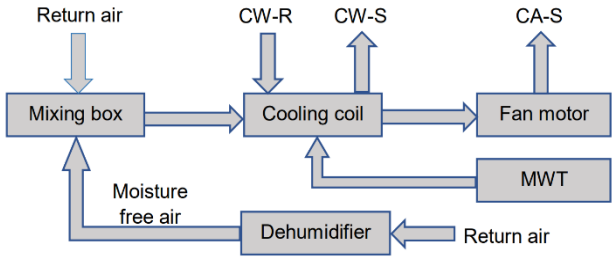

Fig. 7. Connection between AHU and dehumidifier.

When the fan motor is started, the return air flows through the fins coil and enter into the DDLG through supply air duct. The supplied air becomes cool because of passing through the cooling coil. The working principle of dehumidifier (DHF) is illustrated in Fig. 8. It is mainly made of a silica gel disc, electric heater, a blower fan, and a disc driving induction motor.

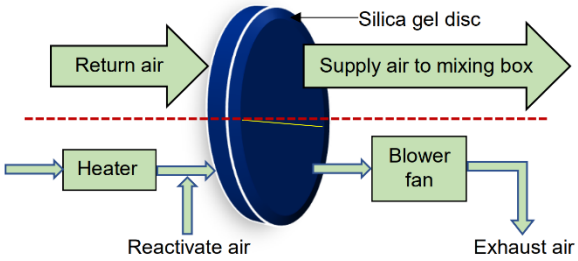

Fig. 8. Basic structure of dehumidifier.

The signal of dehumidifier sensor plays a vital role for controlling the whole system. The motor makes the disc rotating slowly. When the return wet air passes through the disc, the moisture is isoloted from the air and this air is supplied to the mixing box of AHU. At this time, the air passes a portion of the disc reaches to near saturation state. In order to avoid saturation, reactivation arrangement of silica gel bed are ensured. The whole system is seperated into two sections namely, active and reactive. At first, reactivation air is made by passing the fresh air through the heater. When this heated air passes through the wet disc by blower fan, the disc gets reactivation which is also a continous process.

V. Simulation Results

Simulation is performed for the DDLG considering both conditions, with and without using HVAC system. The velocity of translator is set to 1 m/s. Resistive load is connected to the output terminals of the proposed DDLG. The magnetic field intensity and flux density are shown in Fig. 9 and Fig. 10, respectively to observe magnetic properties. The output voltage of propsed linear generator is plotted in Fig. 11. The peak value of votages found for Phase-A, Phase-B, and Phase-C are 263V, 264V, and 256V, respectively.

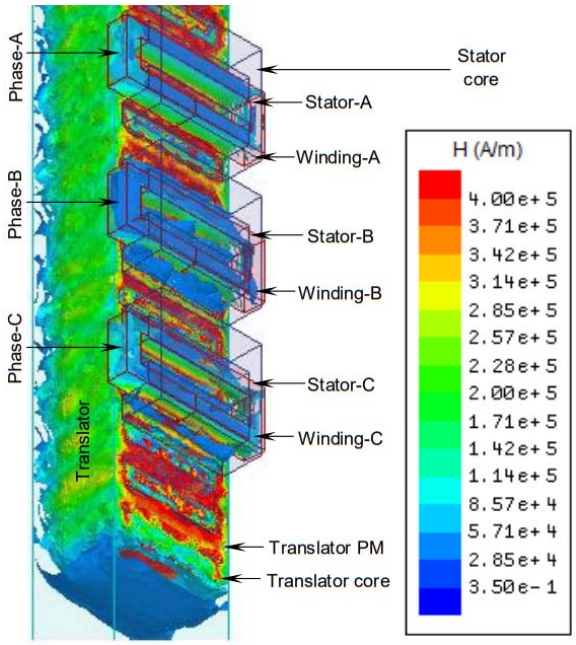

Fig. 9. Field intensity of the proposed linear generator.

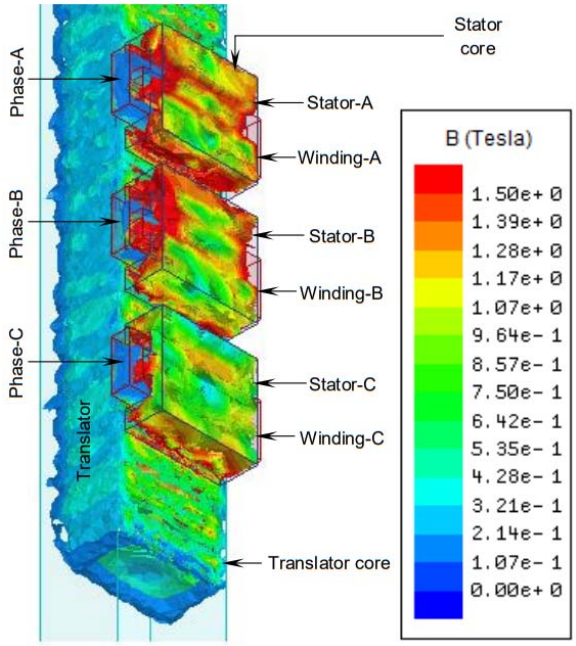

Fig. 10. Flux density of proposed linear generator.

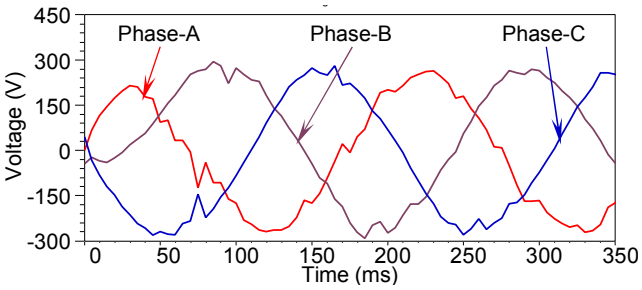

Fig. 11. Output voltages of the proposed DDLG.

The load current of the proposed linear generator is plotted in Fig. 12. The rms value of current found for Phase-A, Phase-B, and Phase-C are 15.56A, 16.3A, and 16.3A, respectively.

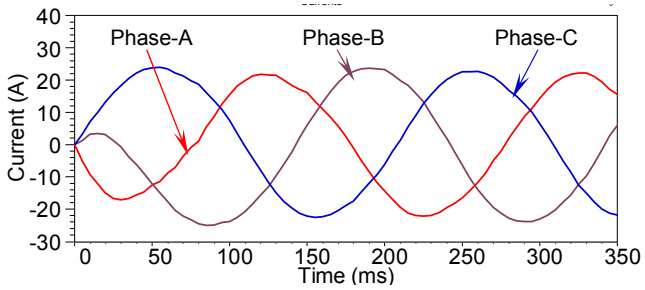

Fig. 12. Load currents of the proposed DDLG.

The flux linkage of proposed linear generator for three phase windings are shown in Fig. 13 and the vertically moving force applied to the translator by the oceanic wave is also plotted in Fig. 14.

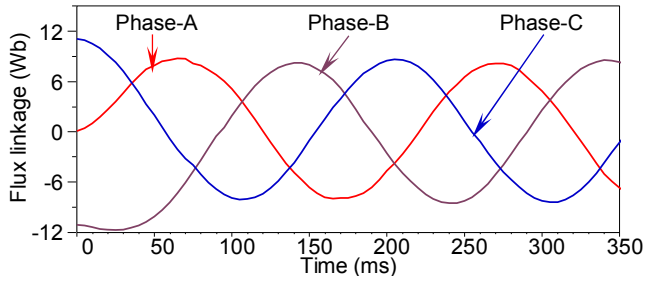

Fig. 13. Flux linkages of the proposed DDLG.

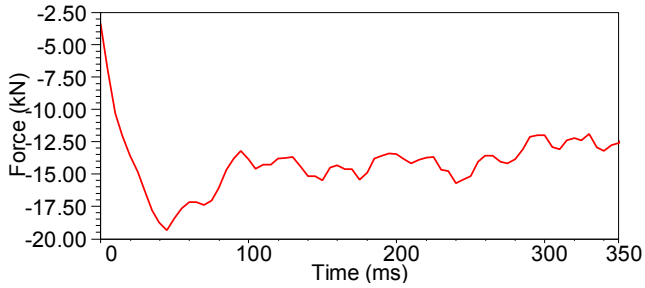

Fig. 14. Applied force to the translator of the proposed DDLG.

The comparison of load currents is found for the two cases as shown in Fig. 15. Out of these, one is conventional and another is proposed cooling system based DDLG. It is seen that, the cooling based generator produces higher current than that of the conventional one.

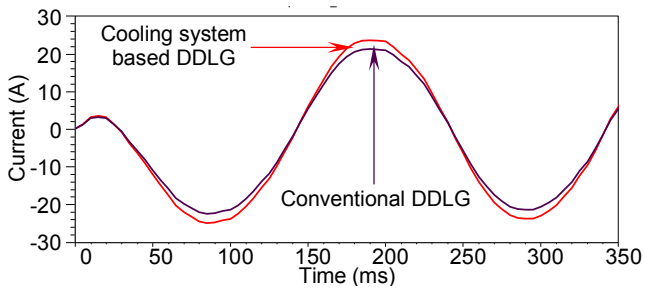

Fig. 15. Comparison of load currents between coventional and cooling system based DDLG.

The comparison of rms powers between the DDLG with and wihout cooling system are plotted in Fig. 16. The generator which uses cooling system produces more electrical power than that of the conventional counterpart.

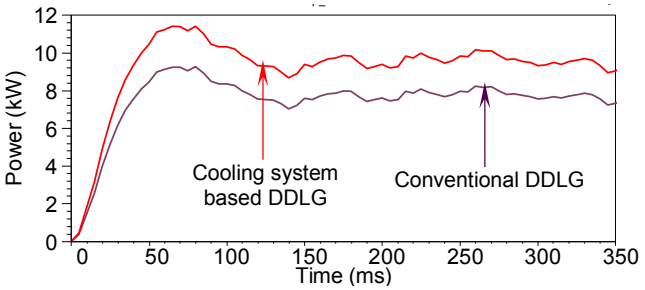

Fig. 16. Comparison of rms powers between the coventional and cooling system based DDLG.

Another comparison of output powers for the two cases is presented in Fig. 17 where the coventional DDLG produces 4755W and the proposed one produces 5870.4W which is more than the conventional one.

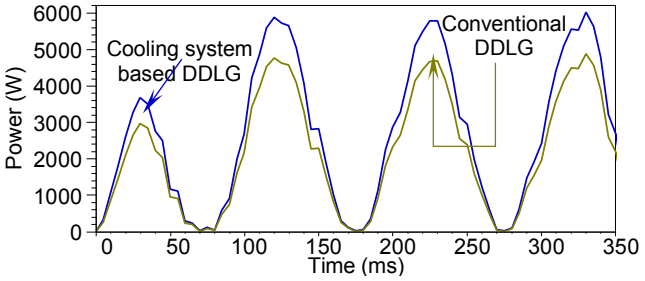

Fig. 17. Comparison of instantaneous output powers between the coventional and cooling system based DDLG.

The comparison of different parameters of the DDLG for two different cases are shown in Table II.

TABLE II. COMPARISONS OF DIFFERENT PARAMETERS

Name of the parameters	Conventional DDLG		Cooling system based DDLG	
	Peak	*RMS*	*Peak*	*RMS*
Current (A)	21.2	15	23.5	16.62
Power (W)	9200	6500	11400	8061

VI. CONCLUSION

The paper introduces an effective cooling system for the DDLG placed in the ocean for electrical power generation. The proposed HVAC system based DDLG is compared with the conventional DDLG. The simulation results show that the cooling system based linear generator produces 2.2kW more electrical power in the output than that of the conventional one. Since heat and humidity inside the linear generator is controlled, it is expected that, the life span and performance would be better for the proposed system.

***Abstract*—The conventional permanent magnet linear generator (PMLG) used for oceanic wave energy extraction are made of ordinary graded neodymium iron boron (NdFeB) permanent magnets (PMs). As a result, while the temperature of the generator gradually increases because of continuous operation, the generation of electrical power would be low because of demagnetization. In this paper, it is analyzed that, the conventional PMLG can not produce much electricity at high temperature because of using the ordinary graded NdFeB PMs. On the other hand, NdFeB that can maintain its remanence magnetism at high temperature saturates at low magnetic field. Therefore, high graded N48H NdFeB is proposed to be used in the PMLG to overcome this dilemma. Simulation results show that, because of using N48H PMs in the PMLG, the generated voltage, current, flux linkage and output power reaches to higher value than that of using the conventional N35 NdFeB PMs. The proposed PMLG with N48H is able to produce 28% more electrical power output than that of using the conventional N35. Finite element method is used for the simulation platform. During the simulation, same operating temperature and parameters of the PMLG is considered for both the high graded and ordinary one for fare comparisons.**

Keywords— linear generator; magnetic materials; permanent magnet machines; renewable energy sources; temperature; wave power conversion.

I. INTRODUCTION

With the enhanced market of electricity in the world, environment is polluted by carbon dioxide that is produced in fossil fuel-based power generating stations. On the other hand, renewable energy sources such as solar, thermal, wind, and wave energy minimizes the production of carbon dioxide. Wave energy is one of the most promising resources among the others. It conceives with great potentiality of producing clean energy and provides major contribution in alleviating carbon dioxide [1]. The suitable system for the extraction of wave energy is direct-drive wave energy conversion (WEC).

The renewable energy includes conventional solar, wind, or hydro, but, ocean is one of the most promising [2] sources. It is estimated that, 70% oceans in the world are capable of providing 1 TW of electrical power [3]. In another estimation, the wave energy resource is calculated to be 2 TW which is presented in [4]. Wave energy resources are substantial and the total world's resources can provide 10 TW power in the open sea as reported in [5].

The design and testing procedures of wave energy converters using nine concepts are presented in [6] that also calculated energy production of each system. This is on the basis of measured model performances, scaled up to the wave conditions at a specific site in the North Sea. The direct drive linear generator is developed experimentally based on the electromagnetic and electric circuit models for getting higher efficiency of the transverse flux machine in a WEC system as presented in [7]. A direct drive linear generator with superconducting coils are used in [8] for WEC so that, better performance and production of more electrical energy can be achieved. The difference between the conventional and improved transverse flux permanent magnet linear generator (PMLG) for WEC is presented in [9]. The oceanic wave converts mechanical to electrical energy by several steps that is shown in Fig. 1. It depends on different factors such as wave energy, linear generator, converter, inverter, and load etc.

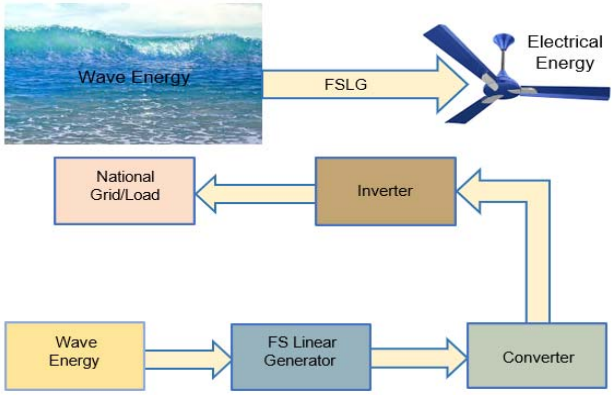

Fig. 1. Steps of the wave energy conversion.

The oceanic wave force is used as the input of a permanent magnet flux switching linear generator (FSLG). The FSLG generates ac output power from the oceanic wave. The generator output is connected to the converter which converts ac power to dc power. The dc power is connected to the inverter which is producing sinusoidal ac power to be transferred to the load or grid. This procedure is called wave energy conversion system.

Two high graded magnetic cores are used in a linear generator with comparisons for oceanic WEC in which Supermendur core exhibits better performance [10]. High graded core used in the PMLG produces less heat energy due to its low core loss profile. The internal resistance of the armature winding is also minimized by using superconductor. A piston driven PMLG is optimized using an automated method of optimization considering the constant or sinusoidal speed of the piston [11]. Due to the simplicity of linear generators, these are ideally suited for the power take off systems for completely submerged WEC system.

The Archimedes wave swing model is used to convert wave energy into electrical energy using a PMLG in addition to a current source inverter so that, about 18% output can be

improved yearly [9]. During electrical power generation by conventional PMLG from the oceanic wave, a temperature rise occurs in the translator and stator cores [12]. The Sm_2TM_{17} type permanent magnet (PM) is improved to meet the infliction at a high temperature which is discussed in [13]. Another linear generator designed by neodymium iron boron (NdFeB) N28EH PM that is proposed in [14] for mitigating the temperature effects on the PMs. A non-oriented DI-MAX HF-10X electrical steel is proposed in [15] as the magnetic of a linear generator.

The direct drive PMLGs are generally connected to a substation and the temperature metering is performed in the offshore location of the WEC array. The generated voltage of the linear generator is rectified and then connected to a common DC-link. With the aid of power inverter, 50 Hz ac voltage is generated and transmitted to shore to facilitate the grid-connection. During the operation, the temperature of the machine and cable increase to 70°C [16]. It is analyzed in [14] that, the performance of permanent magnets depend on temperature and N28EH PM is proposed to be used in PMLGs. The high temperature N28EH NdFeB permanent magnet has a major limitation which is its low remanence even at room temperature [14].

Fig. 2 shows the remnant magnetic flux density (B_{rem}) of N48H which is 1.33 T while operated at 60°C, coercive field strength is −930 kA/m, and knee point is 1.2 T. Again, B_{rem} of N35 is 1.14 T for 60°C, coercive field strength is −690 kA/m, and knee point is 1.06 T. Therefore, at the same temperature of the FSLG, B_{rem} and coercive field strength for N48H is more than that of the conventional N35 NdFeB PM.

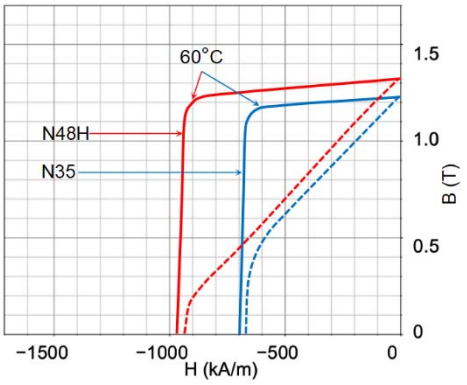

Fig. 2. Demagnetization curve of N48H and N35 PM.

A permanent magnet FSLG is designed and simulated individually for testing the performance of two different PMs N35 and N48H. From the simulation result, it is observed that, using N48H in the FSLG exhibits better result than that of using N35 for the same temperature. Therefore, N48H NdFeB PM is proposed to be used in the FSLG in order to obtain more output power at high temperature as well as prevention of demagnetization.

II. Mathematical Model

Fig. 3 illustrates the operating point for magnetization with the armature for the proposed FSLG where the magnetic permeance is denoted by G_t. The F-coordinate represents the reverse magnetic field intensity. The point K of the secondary hysteresis known as recoil line is realized by the resultant G_t drawn from the point $F'_{ad\max}$. The magnetomotive force (MMF), $F'_{ad\max}$ resembles to the highest demagnetizing d-axis field working directly on the permanent magnet that can arrive during the operation of FSLG. The magnetic permeance can be expressed in the following.

$$G_t = \frac{\phi_K}{F_K - F'_{ad\max}} \tag{1}$$

where, ϕ_k is magnetic flux at k point, $F'_{ad\max}$ is the highest demagnetizing MMF.

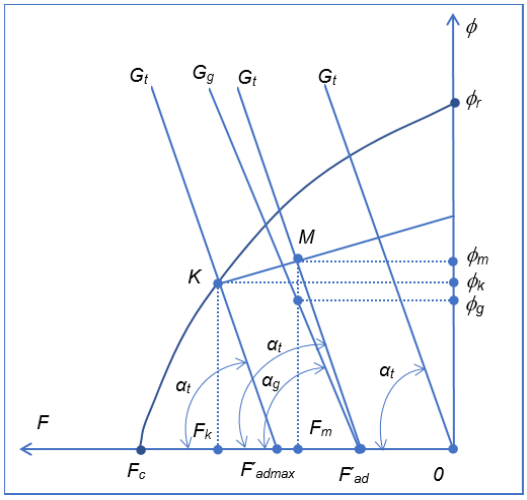

Fig. 3. Operating point for magnetization with the armature for FSLG.

The starting of the recoil line is determined by G_t of the permanent magnet which is mounted in the armature.

If $a_0 > 0$, the MMF corresponding to the point K is

$$F_k = b_0 \pm \sqrt{b_0^2 - c_0} \tag{2}$$

where, F_k is MMF, b_0 and c_0 are constant coefficients

$$\begin{aligned} b_0 &= 0.5\left(\frac{F_c}{a_0} + F'_{ad\max} + \frac{\phi_r}{a_0 G_t}\right) \\ c_0 &= \frac{(G_t F'_{ad\max} + \phi_r)F_c}{a_0 G_t} \end{aligned} \tag{3}$$

If $a_0 = 0$ for rare-earth PMs, the MMF F_k can be expressed as

$$F_k = \frac{\phi_r + G_t F'_{ad\max}}{G_t + \phi_r / F_c} \tag{4}$$

The magnetic flux ϕ_k can be found from (1).

III. Equivalent Magnetic Circuit

Fig. 4 depicts the equivalent magnetic circuit of the proposed permanent magnet FSLG where the open circuit MMF is working along the internal G_t denoted as G_M which can also be expressed by inversed internal reluctance $R_{\mu M}$. In Fig. 4, F_{ad} is the d-axis armature reaction MMF, ϕ_g is the useful magnetic flux in the air gap length, ϕ_{la} is the leakage flux of the external armature winding, ϕ_{ad} is the magnetic flux

produced by the armature winding, G_{lM} is the permeance for leakage flux because of the permanent magnet, $G_{\mu M}$ is the internal permeance, $G_{\mu g}$ is the air gap permeance, G_{la} is the external armature leakage permeance.

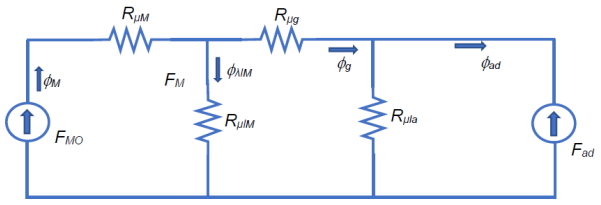

Fig. 4. Equivalent magnetic circuit of proposed FSLG.

According to the equivalent magnetic circuit shown in Fig. 4, the following equations can be written.

$$\begin{aligned} \phi_M &= \phi_{lM} + \phi_g \\ \phi_{la} &= \frac{\pm F_{ad}}{R_{\mu la}} \end{aligned} \tag{5}$$

where, ϕ_M is the total flux, ϕ_{lM} is the leakage flux, ϕ_{la} is the leakage flux of external armature, and $R_{\mu la}$ is armature leakage reluctance. The magnetic flux in the air gap length ϕ_g of the permanent magnet can be expressed in the following.

$$\phi_g = \left[F_{mo} \pm F_{ad} \frac{G_g (G_g + G_{lM})(G_M + G_{lM})}{(G_g + G_{lM})(G_g G_M)} \right] \left[\frac{G_g G_M}{G_g + G_{lM} + G_M} \right] \tag{6}$$

where, G_g is useful permeance and G_{lM} is leakage permeance. The full equivalent circuit of the proposed FSLG is shown in Fig. 5 where the field resistance R_F is in series with the adjustable resistor R_{adj} for controlling the field current. As the proposed FSLG is a permanent magnet machine, the equivalent circuit for field winding is replaced with a permanent magnet for production of the magnetic flux. The equivalent circuit at the right hand margin represents the model for three phase.

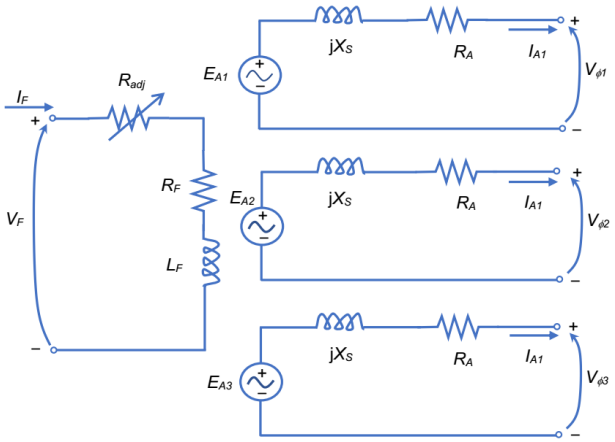

Fig. 5. Equivalent circuit of the proposed FSLG.

IV. Construction and Magnetic Properties

The construction of the proposed FSLG is shown in Fig. 6 including its different elements. The main parts of the machine are translator which is made of magnetic core and a stator with copper coil. Another essential component is NdFeB permanent magnet. The magnetic property of NdFeB used in the FSLG for different temperatures are shown in Fig. 2. As the buoy moves up and down with the oceanic wave, the translator also moves vertically with respect to stators. There is a relative motion between the translator and stators. The permanent magnet is installed inside the copper winding and stator pair. Because of relative motion by Farady's law, electromotive force is induced in the copper winding due to occur electromagnetic induction.

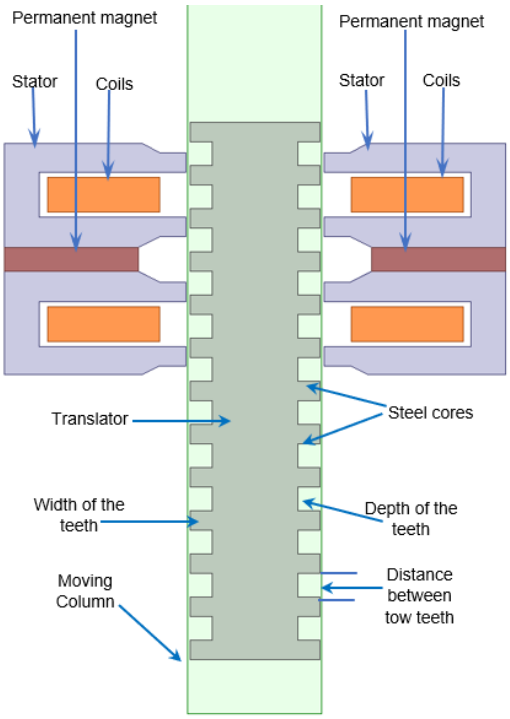

Fig. 6. Construction of the proposed FSLG.

Fig. 7 illustrates the magnetic field distribution of the FSLG for using the proposed N48H. The blue color represents zero magnetic field intensity, H(A/m), green represents the average, and red represents the maximum magnetic field intensity. Also, the scale of H appears in Fig. 7 as rainbow spectra.

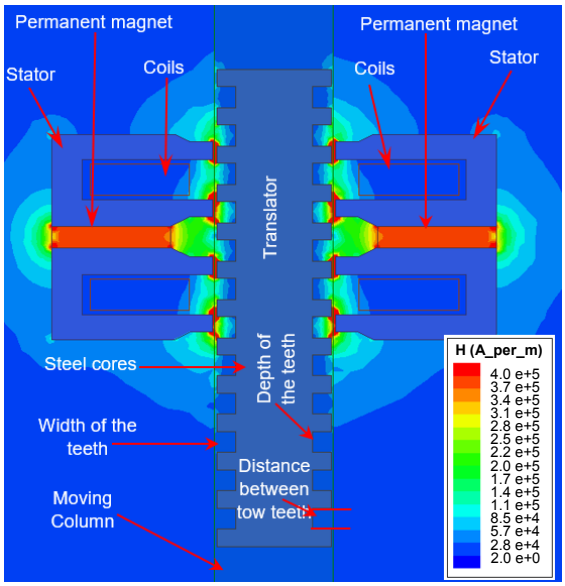

Fig. 7. Magnetic field intensity of FSLG using N48H.

The permanent magnet is placed on both sides between the stator pares in the FSLG. The translator is encompassed with the stators maintaining air gap. The moving column is situated along the transalator which represents the way of translator motion. Mesh plot of the FSLG is shown in Fig. 8 whereas Fig. 9 illustrates magnetic flux lines of the proposed FSLG. The rainbow spectra present the scale of magnetic flux lines in the surrounding area. The red and blue colors represent the maximum and minimum values of the magnetic flux.

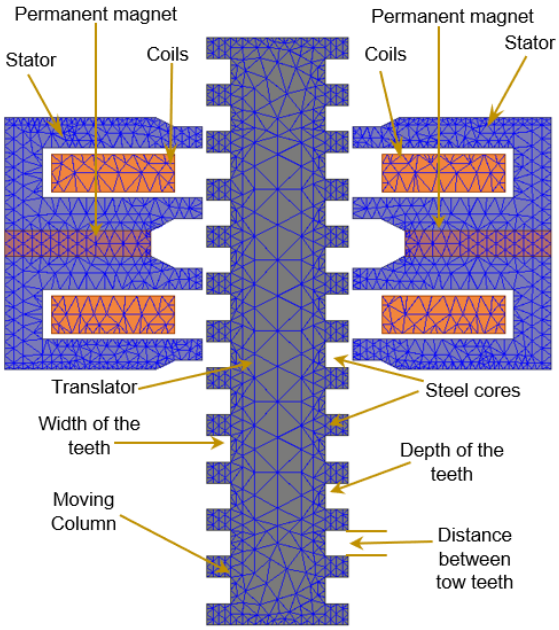

Fig. 8. Mesh plot of the of the FSLG using N48H.

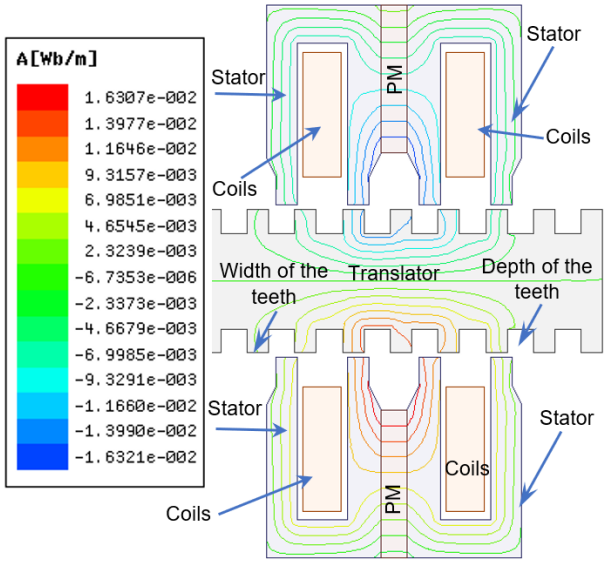

Fig. 9. Magnetic flux lines of the proposed FSLG.

Fig. 10 shows magnetic flux density, $B(T)$ of the FSLG using N48H where the zero magnetic flux density is represented by blue color. Green color represents average magnetic flux density. The scale of B is shown by rainbow spectra in Fig. 10.

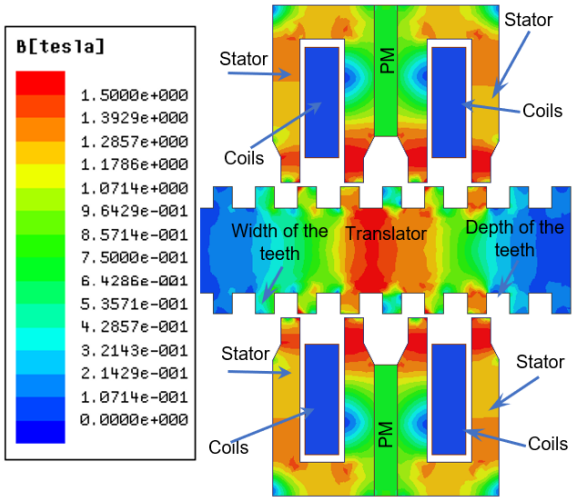

Fig. 10. Magnetic flux density of the FSLG using N48H.

V. Simulation Results

The translator speed is selected 1m/s with an air gap length of 1 mm. The thickness of the permanent magnet is 5.6 mm turns of the coils is 210. The load (resistive) of this proposed FSLG 10 Ω. Fig. 11 shows the voltage comparison for using the proposed N48H and conventional N35 permanent magnets.

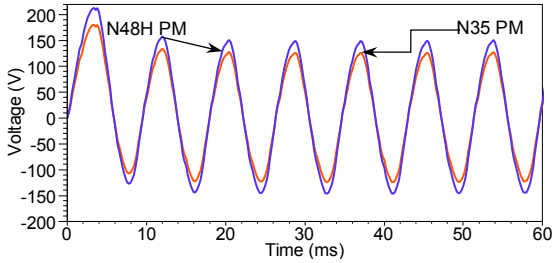

Fig. 11. Voltage waveform of the proposed FSLG.

In Fig. 12, current comparison of the FSLG with the proposed and conventional permanent magnet is shown. The load currents are plotted with respect to time. The red color presents load current for using N48H permanent magnet and green color represents the same for using N35. The peak value of current is near about 1 A for using N48H which is more than that of using N35. Fig. 13 shows the force (N) working on the moving translator. The purple and pink colors represent the horizontal and vertical force components of the translator, respectively.

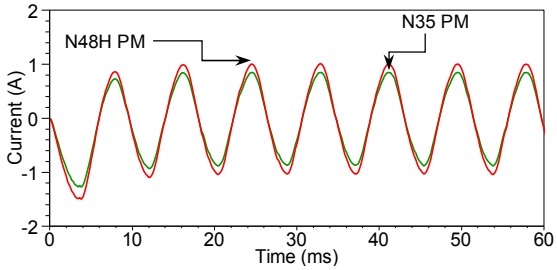

Fig. 12. Current waveform of the FSLG.

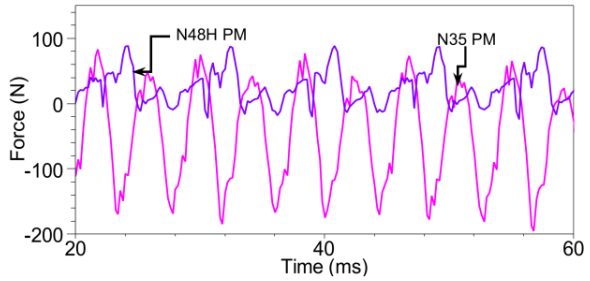

Fig. 13. Moving force of the proposed FSLG.

In Fig. 14, the core loss profile of the proposed FSLG is shown with respect to time. Fig. 15 plots the flux linkage of the proposed FSLG. Fig. 16 shows the comparisons between the instantaneous output power of the FSLG for using the proposed N48H and the conventional N35 permanent magnets. The output electrical power of FSLG for using N48H is represented by red color and blue color indicates the same for using N35. During operation of the FSLG, the temperature gradually increases and the output powers are plotted for the same temperature. Comparison shows that, the FSLG with N48H permanent magnet generates more electrical power than that of using the conventional one. In Fig. 16, the peak value of the power output is 112 W for using the conventional permanent magnets as indicated by blue color. On the other hand, the peak value of the power output is 156 W for using the proposed one as sketched by red color.

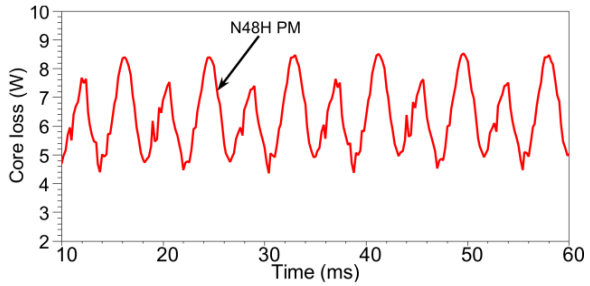

Fig. 14. Core loss of the proposed FSLG using N48H PM.

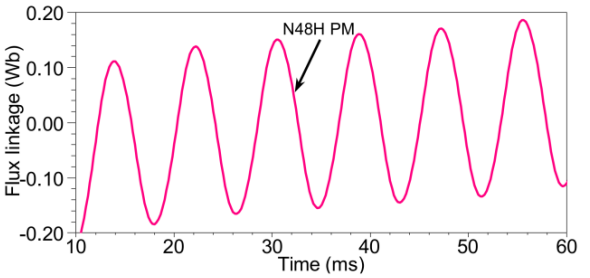

Fig. 15. Flux linkage of the proposed FSLG.

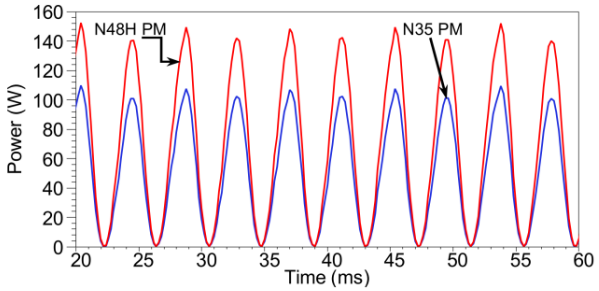

Fig. 16. Comparisons of power outputs of the proposed FSLG.

VI. Conclusion

From the simulation results it is shown that, the permanent magnet FSLG using the conventional grade N35 NdFeB permanent magnet produces less amount of electrical power compared to that of using the high graded N48H. Because, N48H can maintain the high magnetic remanence and large coercive force even at high temperature. The same FSLG can generate 44W more electrical power because of using N48H instead of N35. The operating temperature of the FSLG is considered 60° C for using both the conventional and the proposed NdFeB PMs. Simulation work is executed by using the software ANSYS/Maxwell.

bikash.shuvendu@gmail.com

***Abstract*—Language modeling is a fundamental task for building any natural language processing application or language understandable intelligent system. Language modeling becomes difficult with the increase of input sequence length. It is even more difficult for Bangla as it is more complex than many other languages and contains more character in its alphabet. Few previous works that were done on Bangla language modeling used statistical language modeling or simple neural network very recently. With the neural network, the RNN is the fundamental choice to deal with sequential data but we follow the recent development in convolutional neural network in sequential modeling. In this work, we used dilated convolution to solve the issues of long sequence and improved the performance of Bangla language modeling.**

***Index Terms*—Language-Modeling, CNN, Dilated-Convolution**

I. Introduction

Language modeling is central and fundamental to many other natural language application. So, it is important to improve the language modeling first to get better performance in many other applications. Language modeling is the task of predicting next word or character or any token in a sequence. Bangla being a complex language compared to other pauses some challenges to model. Recently, neural-network-based language models have shown better performance compared to statistical language modeling. The input to the language model being sequential, the main choice for language modeling is Recurrent Neural Network. But the RNN and its variances have limitations dealing with very long sequences. In this work, we have proposed the use of Convolution to improve the Bangla language modeling and the experiments compare the performance with other previous approaches.

Recurrent neural network(RNN) is a kind of neural network that is used with sequential data. For language modeling task the input data is sequential and variable length. That is way RNN and some other variations of RNN were used for language modeling task. One problem with vanilla RNN is vanishing gradient. When the sequence of the input becomes larger it becomes hard for the model to propagate the gradient from the last time step to the initial time step. As a result, the model does not learn well for the earlier time step. To reduce the vanishing gradient problem few variations of RNN was proposed. Among them LSTM [1] and GRU [2] are the most popular. Even with these models input with very long sequences suffers from the same problem.

One other model called Convolutional Neural Network(CNN) [3] is mainly used for fixed size input like an image. This model does not have issued with vanishing gradient but it is not proper for sequential data. However recent research has found that certain varieties of CNN can reach state-of-the-art-result with sequential data. For our application of language modeling, we are not allowed to see the input after time step $(t + 1)$ while outputting for time step t. For this, we have used casual convolutions [4] which does not see the input after time step t. To see the input from very far and still avoiding the vanishing gradient problem van den Oord et. al. [5] proposed Dilated Convolution architecture. In this word, we used the dilated convolution architecture for improving the Bangla Language Modeling task.

II. Related work

Language modeling with the neural network was first proposed by Bengio et. al. [6] which was very successful compared to classical language modeling. later with the improvement of neural network and deep learning, the performance of language modeling with neural network kept improving. Not many works are available on Bangla language modeling in particular. Recently a word level stochastic language modeling for Bangla was proposed by Haque et. al. [7].

The concept of using regular CNN for sequential application is not new but it is showing good result only recently because of some variations of CNN. The use of diluted convolution in wavenet [5] gave convolution the way to look much more time step back than the result convolution. They used it for wave synthesis purpose. The convolution was used for language modeling by Dauphin et. al. [8]. Later Bai et. al. [4] introduced causal convolution with diluted convolution.

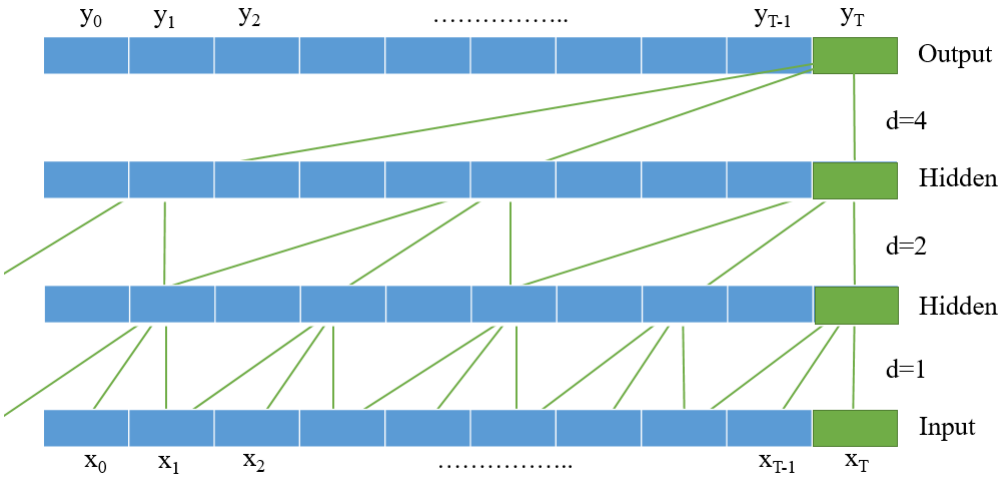

Fig. 1. A dilated causal convolution that has dilation factors of d = 1, 2, 4 with kernel size k=3. The entire receptive field of the dilated convolution covers all the input values in the sequence.

III. Methods

We used dilated convolution with causal convolution for modeling the sequence. The two main feature of the model is- 1) there is no information leakage from future to present or past time step. This is important for language modeling. In the case of regular RNN, we process one input from the sequence at a time so there is no scope for getting the input of future time step. 2) The architecture can take input sequence of any length just like the regular RNN with the help of dilated convolution operation.

A. Sequence modeling

Before defining the model architecture of formulating the language modeling task. Suppose the input sequence is $x_0, x_1, ..., x_T$, and we want to predict the corresponding output $y_1, y_2, ..., y_T$. For one time step, we are given all previous input and we want to predict y_T. The restriction here is that we are not allowed to see the input after the current step, which is this case is $x_0, x_1, ..., x_T$. Formally, we can define the task as $f : X^{T+1} \rightarrow Y^{T+1}$ which can be represented as

$$y_1, y_2, ..., y_T = f(x_0, x_1, ..., x_T) \tag{1}$$

For a language model by setisfying the constrain the current output y_T depends on only $x_0, x_1, ..., x_T$ and not $x_{T+1}, x_{T+2}, ...$ Then the task of laguage modeling is to find the function f to minimize the loss between the predicted and the actual output with a given loss L. The loss can be represented as $L(y_1, y_2, ..., y_T, f(x_0, x_1, ..., x_T))$.

B. Network Architecture

Our network has 3 main components. 1)causal Convolutions, 2) Dilated Convolution, and 3) Residual Connection. Following sections describe these components in details.

1) causal Convolutions: As mentioned above, our model is based on causal convolution. The is the model is not allowed to see the future input while processing the current output. And the other properties of the model is that the input and output size of the model is the same. For this, we used a 1D fully-convolutional neural network with zero padding of size $K - 1$, where K is the kernel size. Here the length of the hidden layer and the input layer is also the same. This part of the network is enough to generate the desired output. But the major disadvantage of this model is that for modeling such big input it will require a massive neural network which again will be hard to train. To solve this issue we used dilated Convolution instead of regular convolution.

2) Dilated Convolutions: A regular causal convolution can look back in history only with a size linear to the depth of the network. This makes it harder for such network to process the input data long back into the sequence. To solve this issue we follow the architecture of van den Oord et. al. [5] on diluted convolution. The idea to employ exponentially large receptive field. Mathematically, let x be a 1-D sequence of $x \in \mathbb{R}^n$ and a filter $f : \{0, 1, ...(k-1)\} \rightarrow \mathbb{R}$, s be a sequence on which the dilated convolution F is defined as

$$F(s) = (x *_d f)(S) = \sum_{n=1}^{k-1} f(i).X_{s-d.i} \tag{2}$$

where k is filter size, d is the dilation factor which is equivalent same as adding a fixed step between two adjacent taps. When d=1, the modified dilated conv. is the same as regular convolution. Here, $s - d.i$ directs to the past. The output in the top layer can include information from a wider range of input just by increasing the receptive field.

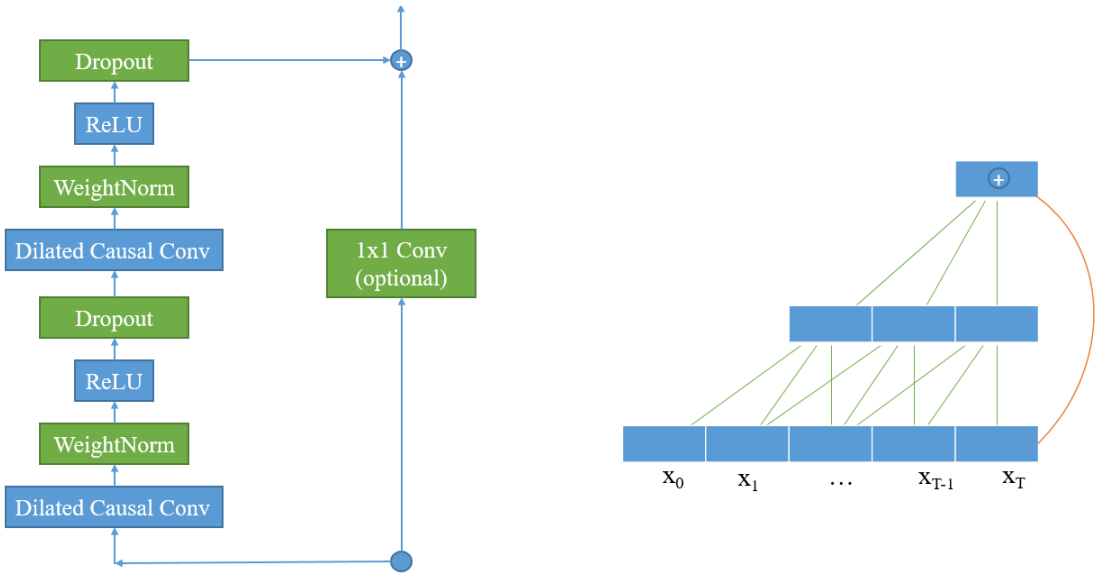

Fig. 2. A residual block.

We can increase the receptive field in 2 ways in this model. 1) by increasing the filter size *k*, 2) by subsequently increasing the dilation factor *d*. The effective history the output can see in one layer is *(k-1)d*. An efficient strategy to increase the dilation factor is to increase the value of d exponentially(i.e. d = O(2^i), i is the level of the network). Fig. 1 shows an illustration of dilated convolution operation.

3) Residual Connection: The concept of the residual block was introduced by He et. al. [9]. This is an important concept in deep learning and triggered a new era of training even deeper models possible. The residual block made many very deep CNN model for various computer vision applications possible. As our model is derived from the concepts of CNN it is used as an important concept for training our model.

The idea is to pass the input to a layer of the model and add with the output of that layer or some sequence of layers. If x is the input to a sequence of layers F, a residual operation will be

$$output = Activation(x + F(x)) \tag{3}$$

Fig. 2 shows one block of residual network.

Such residual connection helps the layer to learn the change in the transformation. Also, it helps to prevent over fittings and train bigger network.

IV. Experiments

We have implemented the model with pytorch [10] int python. All experiments were done in NVIDIA 1060 GPU.

A. Dataset

To compare the effectiveness of the model we trained the model on both English and Bangla dataset. Language modeling is a popular application and many research has used some common dataset for this task. We used text8 dataset [11] for character level language modeling. It contains about 100M characters from Wikipedia (90M in the train, 5M in the test, and 5M in validation set). It is a cleaned 27 unique character dataset.

As there is not much research done on Bangla language modeling and no common dataset was used we collected our own dataset following the source of text8. Training the language modeling requires a lot of plain data. So, we collected wiki-dump, which is XML format data of many wiki page combined. We used the total of 350MB raw data. To process the data we first removed the XML tags to collect the raw text then find out all the unique characters. The corpus had more than 11k unique characters and symbol. We removed all characters except Bangla alphabet. The resulting cleaned dataset is more than 100MB and contains 130M characters.

B. Experimental Setup

To train this model we used SGD optimizer with an initial learning rate of 4.0 and decayed it overtime with a decay rate of 0.95 and trained the model for 100 epochs. We used a kernel size of 3 in convolution. Used total 3 levels of convolution.

For the input data, we used the maximum sequence length of length 400 and the input character was embedded into the embedding dimension of 100. The number of hidden dimensions was 450.

All the training parameters of the model are summarized in table I.

TABLE I
VALUES OF TRAINING PARAMETERS

Parameters	Values
Kernel size	3
Levels	3
Input sequence length	400
Embedding dimension	100
Optimizer	SGD
Learning rate	4.0
LR Decay rate	0.95
Epochs	100
Batch size	32

C. Result Analysis

We trained our model with English and Bangla dataset and reported the performance in Bits per characters(BPC), which is a common measurement for language modeling and reported by many papers on this topic. First, we conducted the experiment of Vanilla RNN with English dataset. This is the most common and bottom lime method to compare the result. We got the bpc score of 1.69 with this. We got some improvement with the popular variations of RNN called LSTM and GRU with 1.50 and 1.43 bpc. But our dilated convolution method outperforms all this RNN method with a good margin of 1.45 bpc.

The table below summarizes the experimental result on English(text8) dataset-

TABLE II
COMPARISON OF THE PROPOSED METHOD WITH PREVIOUS APPROACHES ON ENGLISH

Experiment	bpc
Vanilla RNN	1.69
GRU [2]	1.53
LSTM [1]	1.50
Proposed method	1.45

Previously known best performing Bangla language modeling used LSTM. We trained our model on LSTM and dilated convolutional neural network.

TABLE III
COMPARISON OF THE PROPOSED METHOD WITH PREVIOUS APPROACHES ON BANGLA

Experiment	bpc
LSTM	1.80
Proposed method	1.56

As we can see from the table above our proposed method outperformed the LSTM model in a very big margin for Bangla dataset.

V. CONCLUSION

Language modeling is a fundamental part of any further development of a model for any language. This is also a benchmark for any sequence modeling architecture. In this work, we have used the dilated convolution to improve the Bangla language modeling task. The experiment has shown a big improvement from the previous benchmark for Bangla language modeling. This work will help further development of Bangla language in other applications.

Denoising Sequence-to-Sequence Modeling for Removing Spelling Mistakes

Shuvendu Roy
dept. of Computer Science and Engineering
Khulna University of Engineering & Technology
Khulna, Bangladesh
bikash.shuvendu@gmail.com

***Abstract*—Rule-based spelling correction system focused on finding the most matched word with the misspelled word. But this approach does not work well inside a sentence with multiple errors that has a combination of possible correct words to replace but only one current sentence. Replacing each word individually will result in errors. So, the spelling corrector system must understand the context of the sentence including the tense and gender of the subject and so on. The most popular example of typing mistake correction is the one Google provides in their search engine. It was introduced quite a while ago but no such good performing system is developed by anyone else. In this work, we have proposed a spelling correction system using deep learning. The basic intuition of our approach is taken from denoising autoencoder. Here we have trained the model with noisy input generated by changing, removing or adding extra character at random position inside the sequence. The job of the model is to model this noisy input to output the original errorless sequence. We have experimented with large English dataset and reported the performance in terms of character level accuracy. The proposed model has shown impressive results in correcting the spelling mistakes.**

***Index Terms*—Sequence modeling, Attention, Spelling correction**

I. Introduction

Typing mistake is very common for most people. Google introduced their famous algorithm for suggesting the right sentence in spelling mistake is there in the search query. Their spelling correction feature was unique and many search engine still does not have such facilities. The ”Did you mean?” algorithm was never fully disclosed. Not many research paper has solved this issue or produced any such result. The time it was introduced the deep learning was not that powerful and the algorithm used classical machine learning and natural language processing for this.

The recent success of deep learning has achieved the state-of-the-art result in many natural language processing application. Most of the application of NLP works with sequential data. In deep learning, the model of choice for working with sequential data is the recurrent neural network(RNN). The RNN module takes one token of the sequence of inputs at a time. Each of this is called one time-step. The model unfolds overtime to take the whole input sequence as input. At each time step, the RNN generates an output and a hidden state. The hidden state is passed to the next time step. This hidden state is responsible for encoding all the information it has received in all previous step. This operation is found to be inefficient and prone to losing information after few time-step. This problem is known as the vanishing gradient. To reduce this problem few variations of RNN were proposed. The most common are LSTM [1] and GRU [2].

In this work, we have proposed a neural network based method making a spelling corrector system. The model is trained on plain English text. The input to the model is noisy text, e.i. deliberately introduced errors into the sentence. The output is the original errorless sentence. Both input and the output of the model are sequences. The type of model that deals with this kind of input is commonly known as sequence-to-sequence model in the literature. These models are encoder-decoder based. The encoder takes all the input in the sequence and generates a bottleneck vector. The decoder takes this vector as input and generates one token of output at each time step. The main disadvantage of this kind of model is the bottleneck vector. One single vector often does not contain enough information to generate the entire output. Recently a new concept introduced in computer vision called ”Attention” has changed the approach. The attention operation is responsible for looking over the entire input sequence and give importance to the important section for the current output. This is deployed with the previous LSTM based encoder-decoder system. Later Vaswani et. al. [3] showed that attention alone with a simple feed-forward connection is enough to model complex long sequence.

We have taken the intuition of denoising sequence-to-sequence modeling from denoising auto encode in computer vision. Here the autoencoder is trained with a noisy image to reconstruct the original image. The model is consist of encoder-decoder architecture. The image is transformed into a low dimensional matrix which is upsampled by the decoder to reconstruct the original image. This method can reconstruct good quality images. Following this intuition, we have trained a sequence-to-sequence model with noisy input to reconstruct the original sentence. The noisy input is generated randomly to resemble all types of mistakes someone can make during spelling.

The central objective of the model is to use a sequence to sequence model for learning the sentence representation in character level. Until recently, for any sequence modeling task, the popular choice model involves recurrent neural network(RNN). But a recently proposed method called Annotated Transfer [3] has introduced attention based linear modules for sequence-to-sequence modeling and demonstrated on machine translation getting a significant improvement over the previous state-of-the-art result on machine translation. In this work, we have taken the idea from Annotated Transformer model and modified the objective to create the spelling corrector.

II. Methods

Sequence-to-sequence models are consist of encoder-decoder structure [4]. The task of the encoder is to encode the input sequence $(x_0, x_1, ..., x_n)$ into a intermediate sequence $(z_0, z_1, ..., z_n)$ or in some case a single vector z'. Given z as input to the decoder, the decoder then generates the output sequence $(y_0, y_1, ..., y_n)$, one symbol at each time step. Our model is also consist of encoder and decoder but none of those use any RNN block. The main building blocks of our model are stacked self-attention and point-wise fully connected layer. Fig. 1 shows the entire architecture of the model.

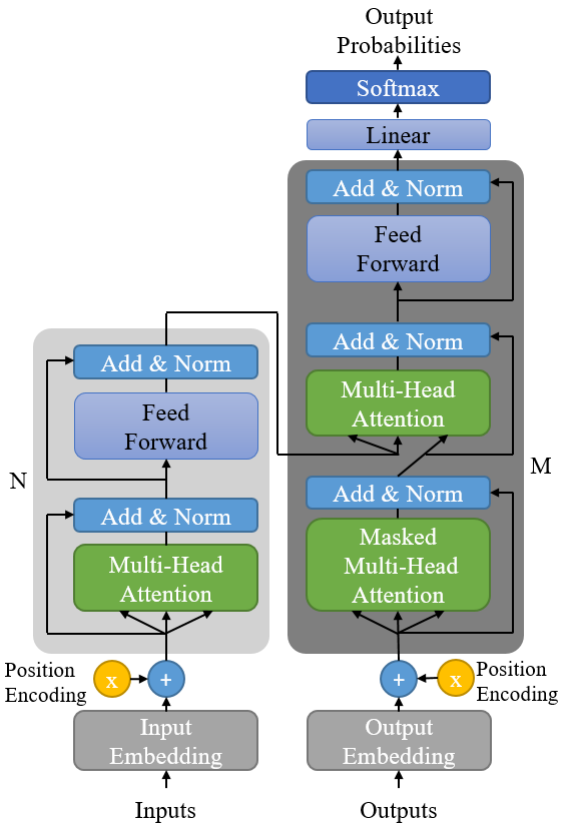

Fig. 1. Full Model architecture.

The entire encoder-decoder structure is auto-regressive at each step, i.e. it uses the previously generated output as additional input while generating current output.

$$y_i = x_i + y_{i-1} \tag{1}$$

As shown in Fig. 1 *N* and *M* is the number of identical layers of encoder and decoder. For encoder *N=6*, which means the encoder has 6 similar blocks each of which has two components- a multi-head attention and a position-wise feed-forward network. Each of this sub-layer contains a residual connction [5] followed by a layer normalization [6]. The concept of residual block is to add the output of a layer with the input of that layer. On top of that, it has a normalization layer. If x is the input to the sublayer that the output will be as followed.

$$y = LayerNormalization(x + sublayer(x)) \tag{2}$$

The decoder has also 6 identical blocks. Along with Multi-head attention and feedforward layer, it has a masked multi-head attention layer. The purpose of the musk is to prevent the model from seeing the subsequent positions in the output sequence. This makes sure the prediction of position i can depend only on the known outputs of position less than *i*. It also has the residual connection and the layer normalization.

Now we will go over the components of the encoder-decoder sublayers.

Attention. Attention is a concept of focusing on a particular portion of data while generating the current output. It is an important part of the current state of the art neural machine translation model. When translating the current word it worth giving more attention to current word and last few words and less attention in the very past sequences. But it is not a hardcoded rule. It might be important to give attention to where the last gender was introduced which might be important for the current word, e.g. his/her. So, attention is also a learnable parameter of the network. In our case, to correct the current word it is most important to see the last few words. The attention concept was popularized in computer vision application of image caption generation [7].

Both the encoder and the decoder use multihead attention. The input to the attention function is a set of key-values and a queue. The attention maps the query and key-values into the output. Here, all the inputs are vectors.

Fig. 2 shows two types of attention function. The left one is simple scaled dot-product attention, the right one is the modification to create the multi-head attention.

Scaled Dot-Product Attention. Two commonly used attention functions are dot-product attention and additive attention. The additive attention a single layer neural network to compute the output. Whereas the dot-product attention are simple matrix multiplication and faster than the additive

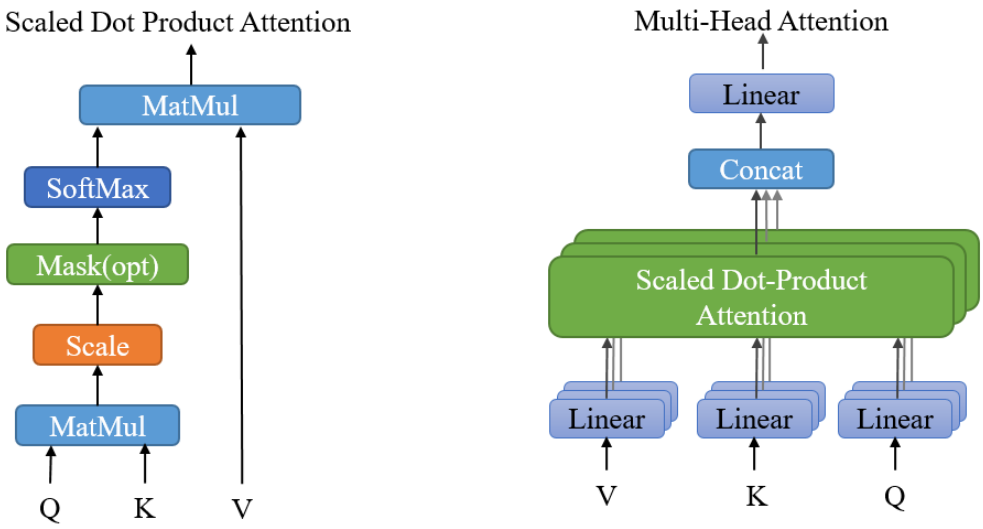

Fig. 2. (left) Sacled Dot-product attention. (right) Multi-Head Attention of several layers of attention.

attention.

Let, K is the keys and V is the values and Q is the queries as the input to the attention function. Where, queries and keys of dimension d_k and values have dimension d_v. The output is the softmax over the dot product of keys with queries and the output multiplied by values. The transformer [3] model introduces scaled dot-product attention by scaling the dot product with the square root of the dimension of keys. The output of the attention is represented as:

$$Attention(K, Q, V) = Softmax(\frac{QK^T}{\sqrt{d_k}})V \quad (3)$$

Multi-Head Attention. Instead of using simple one attention function it is beneficial to linearly project parallel sets of keys, values, and queries. We can calculate the parallel sets of attention outputs and concatenate them input single output. This multi-head approach gives the model an opportunity of attending more than one place at a time. The formulation can be represented as:

$$MultiHead(K, Q, V) = Concat(h_1, h_2, ..., h_n)W^O \quad (4)$$

$$h_i = Attention(KW_i^K, QW_i^Q, VW_i^V) \quad (5)$$

Here, n is the number of parallel queries. We have used n=8. W^Q, W^V, W^K, W^O are weight or projection parameters for queries, values, keys, and outputs.

In the attention function of the encoder-decoder layer, the encoder provides keys and values to the function and the decoder provides queries. As a result, the decoder has information overall input and output sequences got so far. This gives the model similar capabilities that a sequential attention-based model has.

The encoder attention is self-attention. If the queries, keys, and values all comes from the same place, the attention is called self-attention. In this case, the encoder can attend all position in its past sequence. Similarly, the decoder also contains a self-attention block before the attention over encoder. The decoder self-attention is masked. The purpose of the masked attention is to restrict the decoder attending or seeing the future position output in the current position. On top of that, the outputs are shifted one position as the current position must see up to one last position output at generating current output.

Position Encoding. As the model does not have any recurrent or convolution unit, the model has no way to know the position information. To let the model understand the position information we feed the input with a position data. There are different ways of assigning fixed-length position data. We followed the sine-cosine function introduced in the annotated transformer model.

$$PositionEncode(p, 2i) = sin(p/10000^{2i/d}) \quad (6a)$$

$$PositionEncode(p, 2i+1) = cos(p/10000^{2i/d}) \quad (6b)$$

where p is the position and i is the dimension. d is the dimension of the intermediate output of the model.

III. Experiments

We have implemented the model with pytorch [8] int python. All experiments were done in NVIDIA 1060 GPU. Here we first describe the dataset and the training procedures. We have provides the experimental setup and the analysis on the result.

A. Data

To learn the pattern of English language and correct the spelling errors we need a large dataset with lots of plain text. There are a few datasets of plain English text which are used for language modeling purposed mainly. We chose to use the Wikitext-103 [9] dataset for our application. This is a dataset collected from wiki dumps.

The dataset contains a vocabulary size of around 268k collected over 28k Wikipedia articles. It contains a total of over 100 million words. The dataset is divided into train, test and validation set. The test and validation dataset contains 60 articles each having around 246k and 218k respectively. This is a more realistic and representative dataset compared to other.

B. Experimental Setup

To train the spelling corrector we have taken the denoising approach. For that, we have built a sequence to sequence model. The input to the model is noise added English test and the output is the corrected sentence. The noise comes in form of changing, removing or adding a few characters. The model is trained with the original sequence for learning to remove the spelling errors.

Instead of regular stochastic gradient descent optimizer, we have used Adam [10] optimizer. It has two momentum parameters for controlling the learning rate. These are called beta1 and beta2.

We have applied dropout [11] to the output of all the sub-layers before it is added to the sublayer input residual connection and normalizes. Dropout is an efficient method for handling overfittings. We have used the $P_{drop} = 0.1$. We trained the model for 50 epochs with an initial learning rate of 0.001 and a batch size of 64.

All the training parameters are summarized in table I.

TABLE I
VALUES OF TRAINING PARAMETERS

Parameters	Values
Optimizer	Adam
Adam: beta1	0.5
Adam: beta2	0.999
d_{model}	512
d_k	64
d_v	64
n_{head}	8
Epochs	50
Batch size	64
Learning rate	0.001
LR Decay rate	0.99

C. Result Analysis

We have done the experiment with different types and variations of errors. First, we have done the experiment with a different number of errors in a sequence. The errors are introduced in character level. For this experiment we have takes the total length of the input sequence as 50. We reported the result in accuracy metric. We accuracy is calculated at the character level, where the accuracy is the percentage of character correct compared to the original sequence.

Table II summmarizes the result.

TABLE II
NUMBER OF ERRORS VS ACCURACY COMPARISON

Number of errors	Accuracies(in percentage)
2	99.36
3	99.06
4	98.18
5	97.88

We have introduces 2 to 5 characters errors in the sentences. Having more than 5 error in a 50 character sequences changes the meaning in a very unrecoverable way in most cases. From the table, we can see the increase in accuracy with less number of errors. The model produces enough good result with even 5 errors in the sentence.

Then we conducted experiments with the total length of the sentence. Regular RNN based sequence to sequence model has a tendency of generating a bad result with increased in the length of the sequence. Our attention-based model is more rigid with the length of the sequence. For this experiment, we introduced 1-4 character errors randomly.

Table III summarizes the result.

TABLE III
SEQUENCE LENGTH VS ACCURACY COMPARISON

Number of errors	Accuracies(in percentage)
30	98.12
50	98.18
75	98.02
100	97.93

From the table above we can see that the accuracy of the model fluctuates very little with the length increment. Even that is an increase in accuracy from an increase of 30 to 50 in length. The reason here is the fact of the number of errors. Too many errors in a short length of sentence introduce too much information loss to reconstruct the original sequence.

IV. CONCLUSION

The spelling mistake is a natural phenomenon in typing and it is important to have a system capable of correcting those. The simple dictionary-based spelling corrector system focuses on correcting each error separately without understanding the meaning or the context of the sentence which result in an error in sentence-level meaning or grammar. In this work, we have used deep learning to build a context-aware spelling corrector system that uses an attention mechanism to focus on the entire sequence to generate the output. The experiment shows impressive results on a wide range of errors. Our model is robust to change in the length and number of errors in the sentence and achieved close to perfect accuracy. This work

will help to lead a new way of solving the spelling correction problem.

***Abstract*—This manuscript manifests the results of our work on extracting RDF triples from raw text data. We took a corpus of news articles and applied several methods for extracting "subject - verb - object" relationships from texts. The first method that we used is syntactic parsing and constructing triples from *nsubj* and *obj* syntactic relations. The second approach incorporates extracting semantic roles with the help of frame parser and constructing triples from *agent*, *patient* and *predicate* relationships. After applying the aforementioned methods, a manual evaluation was done over a small number of hand labeled samples. Our system achieved a Precision score of *0.34*, Recall of *0.46* and a combined score of *0.39* for F-measure as the final result.**

***Keywords*—Knowledge and Data Engineering, Semantic Information Processing, RDF, Text Analysis and Mining, Natural Language Processing.**

I. Introduction

Dealing with unstructured data is a common problem in the field of Semantic Web and Linked Data. Probably the most prominent project in the field – DBpedia – has mostly processed data in Wikipedia tables, thus discarding the huge amount of information available in the article texts. The system we developed is thus dedicated to extracting *'Resource Description Framework'* (RDF) triples from raw texts. We aim at extracting specifically RDF data and not just some named entities because the extracted RDF triples then can be used for constructing knowledge graph and creating intelligent *Question Answering* (QA) systems and chatbots.

The goal of our project is to test simple methods that can be used to extract RDF data from natural language texts. The existing research has shown that carefully extracting triples from the text is a very complex task, but we can explore what we can achieve using shallow parsing and simple rules. Even a small amount of extracted data can be useful in various applications.

The full paper has the following structure: in Section II, we will describe the background and existing research, in Section III we will be describing our methodology and in Section IV, the results of our system will be depicted. Section V will present the evaluation of our results. In Section VI we will report what other methods apart from syntactic and semantic parsing we also tried to use. Finally, in Section VII we will conclude our work.

II. Background And Motivation

Several previous works have dealt with the topic of extracting RDF triples from unstructured text. In particular, we are inspired by the work by [1]. They have used a pipeline of semantic processing tools to extract DBpedia RDF triples from Wikipedia articles. Among others, they extracted existing Wikipedia links from the articles, perform semantic parsing based on PropBank [2] and coreference resolution on the article texts and used the Wikifier [3] tool to recognize further entities for which DBpedia entries exist. After the above steps, they obtained triples of the form *subject - predicate - object*, which they subsequently mapped onto the DBpedia namespace. Thus, the central contribution of their work is the extension of the DBpedia knowledge base with the facts which they extracted from Wikipedia articles in the form of RDF triples.

Other applications in the same vein include LODiffier by Augenstein et al. [4] and KnowledgeStore by Cattoni et al. [5]. The former also incorporated Wikifier and used deep semantic analysis and discourse representation structures to obtain relations between the entities recognized. The latter creates a knowledge base from multimedia resources with the aid of an existing background knowledge base; among others, they resolved coreference and used clustering to detect entities about which attributes can be extracted using so-called *triggers*. Gerber and Ngomo [6], on the other hand, used a pattern-based approach; instead of performing semantic parsing, they obtained triples by extracting recurrent patterns which represent natural language predicate-argument constellations.

In our project, we largely proceed along the lines of [1]. From the raw text, we intend to extract facts in the form of *subject-predicate-object* RDF triples with the help of semantic processing which will be compatible to be mapped into the DBpedia namespace where possible. In contrast to [1], we will not be using Wikipedia articles but rather plain running texts. This has the advantage that we will not need to clean our data of annotations in Wikipedia's markup language. On the other hand, Wikipedia articles will already contain useful links for entities which are covered by DBpedia, while our plain text data will not.

III. Methodology And Experimental Setup

A. Dataset

For the purpose of our experiment, we decided to use a corpus consisting of *News Articles*[1] provided by Signal Media [7]. It consists of texts from several news agencies, websites and blogs. The overall size of the dataset is over 100 million tokens, but we decided to use a portion of it that consists of 500000 tokens.

B. Pipeline

We intended for our system to be a pipeline of the following component:

[1] http://research.signalmedia.co/newsir16/signal-dataset.html

a. The Plain raw text has been obtained from the corpus data.
b. Tokenization and POS-tagging is performed on the data.
c. Both the dependency parsing and semantic role-labeling techniques have been explored.
d. From the processing output of step c, triples are extracted in the form: *subject argument - verb - object argument*
e. Finally, triples of the aforementioned structure are converted into RDF-triple (JSON-LD format).

Both the extraction of triples based on dependency parsing (hence syntactic processing) and on semantic role-labeling (hence semantic processing) were explored. At a later stage, we chose the latter.

C. Triple Extraction Based on Dependency Parsing

We performed syntactic parsing using UDPipe [8], which tokenizes the input sentences and returns for each sentence, among others, the word lemmas and the universal dependency relations which hold between the individual words in the sentence. We then extracted the following three lemmas to form a triple:

- The lemma with the dependency relation *root* (i.e. the root word of the sentence).
- The lemma with the dependency relation *nsubj* to the sentence root word.
- The lemma with the dependency relation *obj*, to the sentence root word.

The above three lemmas would respectively correspond to the *verb*, the *subject argument* and the *object argument* of a triple. To illustrate, Fig. 1 shows the relevant parts of the UDPipe output for the sentence '*The Texas State football team scored 63 points in its home opener*', from which we extracted the triple *(team - score - point)* (in red).

1	The	the	DET	DT	Definite=Def|PronTy	5	det
2	Texas	Texas	PROPN	NNP	Number=Sing	3	compound
3	State	State	PROPN	NNP	Number=Sing	4	compound
4	football	football	NOUN	NN	Number=Sing	5	compound
5	team	team	NOUN	NN	Number=Sing	6	nsubj
6	scored	score	VERB	VBD	Mood=Ind|Tense=Pa	0	root
7	63	63	NUM	CD	NumType=Card	8	nummod
8	points	point	NOUN	NNS	Number=Plur	6	obj
9	in	in	ADP	IN	_	12	case
10	its	its	PRON	PRP$	Gender=Neut|Numb	12	nmod:poss
11	home	home	NOUN	NN	Number=Sing	12	compound
12	opener	opener	NOUN	NN	Number=Sing	8	nmod
13	.	.	PUNCT	.	_	6	punct

Fig.1. Example UDPipe output with tokens forming the triple marked in red

This approach, based on dependency parsing, was characterized by the fact that each triple element would consist of exactly one single token. But this easily gave rise to errors of the following kind: The alleged triple *(Williams - get - America)* was falsely extracted from the sentence *Vanessa Williams Finally Got Her Miss America Apology*, which is at least in part due to the fact that the object argument, *(Her) Miss America Apology* consists of multiple tokens, while the dependency parser will only assign to one of the dependency relation *obj*. For this reason, we chose not to base further processing steps on this approach but turn instead to triple extraction on the basis of semantic processing described in the next section.

D. Triple Extraction Based on Semantic Role-labeling

Semantic role-labeling was conducted using the Senna system [9], which performs, among others, tokenization, chunking and semantic role-labeling on plain texts. A sample output of Senna for the sentence '*VETERANs saluted Worcester's first ever breakfast club for ex-soldiers which won over hearts, minds and bellies*' is given in Fig. 2 (with the columns with information on POS-tags and semantic roles marked in red).

VETERANS saluted Worcester's first ever breakfast club for ex-soldiers which won over hearts, minds and bellies.

VETERANS	NNP	S-NP	0	-	S-A0	0	(S1(S(NP*)
saluted	VBD	S-VP	0	saluted	S-V	0	(VP*
Worcester	NNP	S-NP	S-ORG	-	B-A1	0	(NP(NP*
's	POS	B-NP	0	-	I-A1	0	*)
first	JJ	I-NP	0	-	I-A1	0	*
ever	RB	I-NP	0	-	I-A1	0	*
breakfast	NN	I-NP	0	-	I-A1	0	*
club	NN	E-NP	0	-	E-A1	0	*)
for	IN	S-PP	0	-	B-A2	0	(PP*
ex-soldiers	NNS	S-NP	0	-	I-A2	S-A0	(NP(NP*)
which	WDT	S-NP	0	-	I-A2	S-R-A0	(SBAR(WHNP*)
won	VBD	S-VP	0	won	I-A2	B-V	(S(VP*
over	IN	S-PP	0	-	I-A2	E-V	(PP*
hearts	NNS	S-NP	0	-	I-A2	B-A1	(NP*
,	,	0	0	-	I-A2	I-A1	*
minds	NNS	B-NP	0	-	I-A2	I-A1	*
and	CC	I-NP	0	-	I-A2	I-A1	*
bellies	NNS	E-NP	0	-	E-A2	E-A1	*))))))))
.	.	0	0	-	0	0	*))

Fig.2. Example Senna output with POS-tags and semantic roles marked in red

In accordance with the PropBank framework [2], adopted by [9] for Senna - *V*, *A(rgument)0* and *A(rgument)1* respectively denote the predicate, the agent and the agent arguments. For each sentence, we therefore, extracted from the Senna output those words tagged as *A0* as the subject argument, those tagged as *V* as the verb, and those tagged as *A1* as the object argument. In the example shown in Fig. 2, we would output the triples *(VETERANS - saluted - Worcester's first ever breakfast club)* and *(ex-soldiers which - won over - hearts, minds and bellies)*.

However, without further cleaning, our approach would include alleged triples in which the subject is a personal pronoun, or in which some elements (e.g. the verb) length is longer than usual length for example the chunk '*obtain amid an expected record turnout, in what would be a big boost to a secession campaign which has been losing support over the last two years*' as Senna would tag the entire phrase as *V*. Therefore, we included the following constraints into the extraction process, which relate to the length of each element of a triple as well as the POS categories of the words:

- Words forming the verb in the triple must have as their POS-category one of the following tags: VB, VBD, VBG, VBN, VBP, VBZ or IN. These are the verbal POS-categories with the addition of IN for

prepositions, which is intended to include phrasal verbs such as *win over*.

- Words forming the subject and object arguments must *not* be of the POS-categories PRP, PRP$, WDT or WP, which represent personal and possessive pronouns as well as WH-determiners and pronouns.
- Alleged triple is discarded if the *verb* consists of more than three words.
- Alleged triple is discarded if the *subject* or *object* argument consists of more than eight words.

The above constraints ensured that, for instance, we would in fact extract *(ex-soldiers - won over - hearts, minds and bellies)* from the example in Fig. 2, excluding the word *which* from the subject argument.

E. Conversion of Triples to RDF

After extracting the triples from the Senna output we needed to convert it to a suitable format so that these can be read as RDF. We used JSON-LD format as an intermediate form because it is easy to convert text into JSON programmatically. Since JSON-LD is a *Linked Data* type, it is easily readable by any program such a Protégé. We thus used Protégé to convert the JSON-LD file to RDF/XML.

The entire pipeline of our implementations is given in Fig.3., with the UDPipe module greyed out as we did not continue onwards with its output.

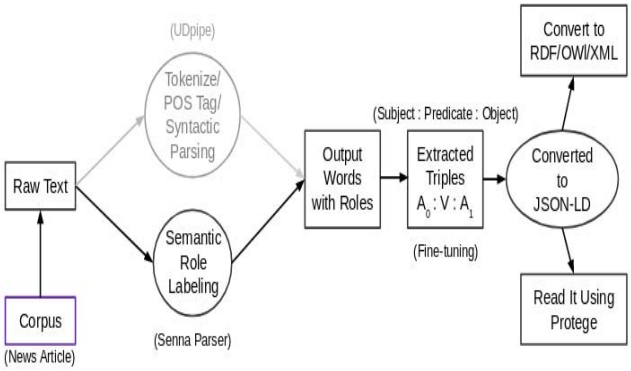

Fig.3. The Pipeline of our system with UDPipe module greyed out

IV. Result

As the result of our project, we extracted 2361 triple from our data[2]. The triples look in the following way:

Subject	Predicate	Object
A migrant	holds	A banner

The extracted triples were organized in an ontology with different subjects and objects serving as instances of individual classes, and predicates serving as object properties. The overall organization of the ontology can be seen in Fig. 4.

[2] Results of our system can be downloaded from the following link under the folder *Final RDF* - https://goo.gl/z4Yuiz

The ideal organization of the ontology would be to create different general classes like *Person*, *Organization* etc, but as we do not have a gold standard which we could use as a training data for classifying our instances, this step remains to be added in the future.

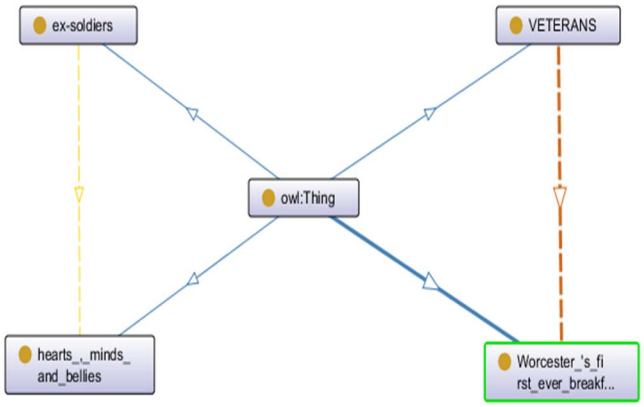

Fig.4. Organization of triples in the ontology.

V. Evaluation

Evaluation poses a challenge to our proposed project since we cannot compare the triples extracted by our system to an existing gold-standard. One possibility is simply to select a small sample of data and to manually extract triples from these sentences. The results of this manual extraction can function as gold-standard against which the system's performance could be evaluated in terms of precision, recall and F-measure.

To perform this kind of evaluation, we manually annotated a sample of 100 sentences. The main difficulty is to define what exactly we want to count as a part of a triple. It is obvious that triples should not include only named entities. At the same time, many cases are not interesting or useful for constructing a knowledge graph. For example, in a sentence '*mother talks with her daughter*' we wouldn't want to extract anything, though the triple can be extracted with the means of semantic parsing. In the end, we decided to analyze as triples those entities which are not generic, for which a Wikipedia page exists or might exist, or which can be considered named entities.

In the selected sample our system has found 81 triples. Based on the annotated sample, we calculated recall and precision measures. They can be found in Table I. The most common problem that can be noticed while annotating the triples is that borders of an extracted and annotated triple do not coincide. The system tends to take larger chunks, whereas only two or three words are enough for manual annotation. Also, our system has clear rules by which it selects certain phrases as parts of a triple: the chunks should have such semantic roles as agent, patient or predicate. Meanwhile, the data that can be used in RDF triples is much more varied, and many other semantic roles might be included in the triple. For example, time and place such as in the phrase '*The Worcester Breakfast Club ... met at the Postal Order in Foregate Street at 10 am on Saturday*'. are not detected by our system, whereas they should be included in a proper knowledge graph.

TABLE I. RESULTS FOR THE EXTRACTION OF RDF TRIPLES

Precision	*Recall*	*F-measure*
0.34	0.46	0.39

VI. DISCUSSIONS AND FUTURE WORK

At present, our triples have been mapped to our own example URL and are therefore not linked to any existing knowledge base. Ideally, we would like to enrich an existing knowledge graph with the facts we express in our extracted triples to the effect that these facts can be queried in a question answering system. This would resemble the final step in Exner and Nugues's work [1], in which they map their extracted triples to the DBpedia namespace.

Hence, we also attempted to link our triples to DBpedia entities using DBpedia Spotlight [10] or Wikifier [3], the latter of which have been used both by Exner and Nugues [1] and by Augenstein et al. [4]. The idea was to apply either of the tools to our raw text data. Ideally, some of the entities recognized (i.e. entities covered by DBPedia) would correspond to the subject or object arguments in our triples, and the fact expressed by our triples would be added to those entities as novel knowledge.

However, we ran into a similar problem as mentioned in the previous section with regard to evaluation: Senna outputs large chunks of text as subject and object arguments. They often have a complex internal structure and, for our purpose, ought to be further broken down into more "atomic" units. For instance, the object argument '*Worcester's first ever breakfast club*' of our aforementioned triple (see section III.D) is in fact internally complex, from which we would ideally extract, at a minimum, the triples *(unique_id – isA - breakfast_club)* and *(unique_id - hasLocation - Worcester)*. Both DBpedia Spotlight and Wikifier were able to recognise and link *Worcester* and at times also *breakfast_club* (depending on the pre-selected confidence value); however, '*Worcester's first ever breakfast club*' as a whole, which functions as the object argument in our triple, could, plausibly, not be recognized by either tool. Therefore, in order to connect our triples to the DBpedia knowledge base in the future, more fine-grained processing of the elements of each triple is needed, possibly using further semantic tools.

VII. CONCLUSION

In our system, we attempted to apply simple methods for extracting RDF triples from raw text data. It turned out that this task can be solved to some extent using semantic parsing and converting the extracted semantic roles to RDF triples. The resulting F-measure was 0.39, which can be improved in many ways, but still is decent for the beginning.

The process of extracting RDF triples can be improved both on the side of semantic parsing and on the side of conversion. In terms of semantic parsing, we can try to extract more complex semantic relations like date and time and also do anaphora resolution. Apart from that, our data needs more linguistic preprocessing like filtering out non-English words and special symbols, lemmatizing all the triple instances and removing possible duplicates. While in the case of conversion, we need to better work through the structure of our ontology and develop macro-classes for our individual instances so that the ontology becomes less sparse and more concise. For doing that, we need to collect gold standard data which can be used for applying machine learning to classify individual instances.

***Abstract* - Automatic spelling correction for Bangla language is a very important thing as the modern world is almost completely dependent on digital devices where electronic keyboards are used. Bangla is a largely used language (3.05% of world population), worldwide securing the 7th most spoken language. But concerning the natural language processing it is still in its initial stage. Automatic spelling correction of Bangla language is just crossing its primitive stage. A few works have been done on automated Bangla spelling correction but those numbers are not still adequate. This research work is based on correct word prediction of typed Bangla sentences by using edit distance method and fractional accuracy. The results are promising. So, there is a high chance that the proposed model will help and have a great impact on automated Bangla spelling correction.**

Keywords - Bangla Spelling, Spelling Correction, Non-word error, Fractional Accuracy.

I. INTRODUCTION

Written form of a language is a very important factor in communication; whether it is handwritten or typed. When speaking it is not important to know proper spelling of a word and even without proper maintenance of grammar communications can be conducted, but when writing it is very important to have correct spelling. Spelling mistake is a common issue especially if it is a complex language such as Bangla. Bangla is one of the most used languages (3.05% of world population) [1] and it has complex word construction, so it is common to have spelling error while writing. It is not necessary that the reasons for spelling mistakes are only because of its complexity, it might also occur due to fast typing or lack of knowledge. As it is a common phenomenon to make spelling mistakes, automatic spelling correction processes are a must. There are lots of work on this issue but when considering Bangla there aren't many notable works. The main focus of this research work is checking the spelling of Bangla word following by the correction of it using fractional accuracy. Direct dictionary lookup and edit distance method will be used to check correctness and gain possible corrections of the word then the accuracy will be calculated. There are some works that used the edit distance method but, in this research, a much larger dictionary and new method to calculate accuracy are used which will give better results.

The rest of the paper is organized as follows: in section II a literature review is done where previously published works that are similar to our work has been discussed. Section III is about the methodology of our work where the process of our work described. Next, in the implementation section, results of our work is shown. Section V shows the comparison results with previous works. Finally section VI concludes the paper describing how this work is promising.

II. LITERATURE REVIEW

There are quite a number of works done on spelling mistake detection and correction. Spanish, English, Mandarin, Bangla etc. are some of the most spoken languages on earth, so it is normal to work on these languages but automated spell checker and correction is of such an importance that a number of works were also done on less spoken compared to the languages mentioned before or local languages such as Myanmar, Persian and Hindi [2], [3] and [4]. All over the world people are working on this topic not necessarily focusing on any specific language but also on language independent spell checker and corrections [5].

Languages such as English, Chinese and Arabic are largely spoken languages thus having more works focusing on them. Some notable works on English are done in [6], [7], [8], [9] and [10] using different methods such as edit distance, tree traversal etc. [11] and [12] are two works done on Chinese and Arabic.

As the main focus of this work is on Bangla, so if works done on automated spell checking in Bangla is considered then number of papers are small [13], [14], [15], [16], [17], [18], [19], [20] and [21] that focus on this common concern with this paper. All these papers have different techniques deployed but there are two common facts about all these papers and those are small corpus size and lack of balance. As a solution to the problem of Bangla spell checking using clustering and edit distance is performed by P. Mondal and B.M.M. Hossain claiming to have an accuracy of 99.8%, which was applied on 2450 words [13]. N.U. Zaman and M. Khan claimed accuracy of 91.67% with the data set of 1607 words using mapping based on double metaphor and edit distance as a solution [16]. To identify phonetic error, string matching is used by Bidyut Baran Chaudhuri [17]. He used 2 dictionaries to check and correct errors but his process mainly considered phonetic errors and it also needs double memory for the dictionary and the reverse dictionary he used for correction of misspelled words. In another one of M. Z. Islam, M. N. Uddin and M. Khan's paper they used stemming algorithm in which if the stem is not found, then it produces a list of possible suggestions using suggestion generation process [18]. They used to edit distance algorithm to find best match. Another work focusing on phonetic error is done by N. U. Zaman and M. Khan in which they modified phonetic encoding based on soundex algorithm for matching Bangla phonetic [15]. Using finite state automaton M. K. Munshi et. al. proposed an approach to suggest the probable list of correct words against the error word [19]. NH Khan, GC Saha, B Sarker, MH Rahman for checking error used character-based N-gram but it didn't

suggest any correction to the misspelled word [21]. To detect error words a direct dictionary, look up and binary search method and to suggest correct word against the incorrect word recursive simulation method is used by ABA Abdullah, A Rahman in their paper [20].

There are many English spell checking and correction works having the accuracy of 86.95%, 96.1% and 96.4% for both real word and non-word errors [8], [7]. Even though English spell checking and correction have been studied in [6], [7] corpus size or test data size were not mentioned. In [11] a work on Chinese language spell checking and correction, edit distance algorithm, soundex algorithm, and combining them with pinyin is used. In [12], a system for checking Arabic language spelling using context words and N-gram language models is used with a corpus size of 41,170,678 words and twenty-eight confusion sets for their experiment. Their average accuracy rate is 95.9% that handle both real-word errors and non-word errors.

A. Types of Error

Kukich [22] classified all spelling errors into two types. One is real-word error and the other one is non-word error. Contextually inappropriate though the word is valid is called real-word error. For example, in the sentence "I eat milk.", "eat" is not contextually appropriate but it is a valid word. Similarly, in Bangla, in the sentence "আমার আব্বু বাটি যাবে", বাটি is not contextually appropriate but it is a valid word. So, a real-world error is found here. Lexically invalid words are called Non-word error. For example, in the sentence "we aer going to play", 'aer' is not a valid word. In the same way in Bangla, 'নাটি' is a lexically invalid word in "আমার আব্বু নাটি যাবে". There is some more classification of non-word spelling errors offered by Kukich [22]. One is cognitive error and the other one is typographical error. Cognitive error occurs when user does not know the spelling of the erroneous word. Typographical error occurs due to typing mistake. For example, different errors of the Bangla word "চলমান", 'চলম্মান', 'চমান', 'চমমান' and 'চলমনা' are caused by insertion, deletion, substitution and transposition respectively.

III. METHODOLOGY

In this work we are handling non-word, especially typographical errors. We used direct dictionary lookup method to detect an error word. We have a dictionary from which we are searching if the typed word is available. If the typed word is not available then we can consider it as an error and then use edit distance algorithm to correct the erroneous word. To correct the error, we estimate similarity of structure between misspelled word and candidate correct words using minimum edit distance. It measures the minimum number of total operations required to transform one string into another. There can be various operations like insertion, deletion and/or substitution. To calculate edit distance, Levenshtein algorithm [23] is used as written in Algorithm 1. The working principle of Algorithm 1 is that, if we consider two strings X and Y (X= misspelled word, Y= candidate correct word) with the lengths m, n and create a matrix of order m×n edit distance between different sub-strings of X and Y. The corresponding values will express the minimum distance between X and Y. It is assumed that insertion and deletion each has a cost of 1 and substitution has a cost of 2.

Algorithm 1. Algorithm for calculating minimum edit distance

```
min_distance(misspelled_word,candidate_correction)
   m ← length(misspelled_word)
   n ← length(candidate_correction)
   create distance matrix dis [n+1, m+1]
   for each column i ← 0 to n
   for each row j ← 0 to m
                    dis[i,j]←min(dis[i-1,j]+ins-
                cost(candidate_correctionj),
                   distance[i-1,j-1]+subst-
                cost(misspelled_word,
                   candidate_correctioni),
                   distance[i,j-1]+ins-
                cost(misspelled_wordj))
   return min-distance
```

System chooses the word with the minimum edit distance for the misspelled word. We calculate the accuracy using fractional accuracy method [24]. For fractional accuracy the accuracy is measured by taking both the matching of suggested word with intended word as well as the order of matching into account. Therefore, accuracy rate is used in order to address this issue. Suppose w_m matches with v_{mi}, where w_m is intended word and v_{mi} is suggested word (i.e. w_m equals v_{mi}, where $1 \le i \le n + 1$), then the accuracy is

$$Acc = \frac{n+1-i}{n} \times 100\,\% \qquad (1)$$

Here n is length of suggestion list and i is the position of matching word. Failure occurs when i equals $n + 1$. $(n + 1)$-th match means no match has taken place, i.e. accuracy equals 0. The whole methodology is shown in Figure 1

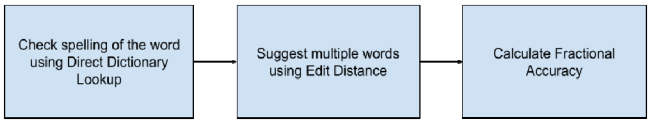

Fig. 1. Block Diagram of Proposed Method

IV. IMPLEMENTATION

As described earlier we are using a dictionary to check if the input word is correct or not. We have a large dictionary consisting of 4,039,603 unique entries. If a word of the input text is not available in the dictionary then it is marked as erroneous word. When an error word is detected, edit distance method is used to generate list of the correct words. Then we find which word from the generated list is similar to the intended word and we calculate fractional accuracy based on the method described above. For example, we have a list of 4 generated words, we found our intended word at position two then our fractional accuracy will be

$$\frac{4+1-2}{4} * 100\% = 75\%$$

The text used in our research are collected from social sites as well as auto generated. One third (50000 words) of the data is collected from social media and two third (100000 words) is auto generated. Percentage of accuracy based on edit distance range is shown in Table 1.

TABLE I. ACCURACY BASED ON EDIT DISTANCE RANGE

Edit distance range	Total number of error word	Total number of success word	Accuracy
1	135,000	132,000	97.78%
2-3	15000	13245	88.3%

We can see that if edit distance range is between 2 and 3 then we get higher accuracy. Another table (Table 2) shows the accuracy based on source of input text.

TABLE II. ACCURACY BASED ON SOURCE

Source	Total number of error word	Total number of success word	Accuracy
Social Media	50,000	47,145	94.29%
Auto generated	100,000	98,100	98.1%

V. COMPARATIVE RESULTS

After discussing different types of results of our work it is better to conclude with total accuracy result which shows that this research work is promising enough. As we see from Table 3 and Figure 2 that the higher the suggestion word list length is the higher accuracy rate we get. If the suggestion list length is only 1 then the accuracy is 65.17% whereas the accuracy is 96.83% if the length is 9.

TABLE III. ACCURACY TABLE BASED ON SUGGESTION LIST LENGTH

Suggestion list Length	Accuracy
1	65.17%
2	74.14%
3	82.62%
4	86.69%
5	88.76%
6	92.10%
7	93.79%
8	94.48%
9	96.83%

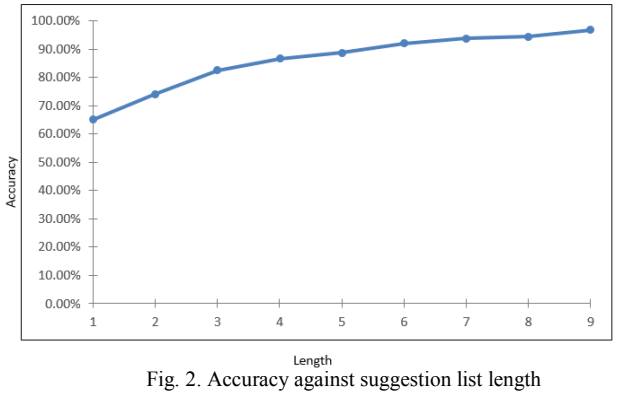

Fig. 2. Accuracy against suggestion list length

Also if we make a comparative table of all works done in Bangla spell checking, we see that our work is promising than others. Table 4 shows the comparative study.

TABLE IV. THE COMPARATIVE ANALYSIS OF ALL WORKS REPORTED

Work/Article	Type of Errors Handled	Algorithm	Test Data Size	Accuracy
This work	Non-word error	Edit distance	150,000 words	96.83%
[13]	Phonetic, typographical	Clustering	2450	99.8%
[14]	Phonetic, typographical, OCR generated	2-edit distance and phonetic encoding	1607	91.67%
[15]	Phonetic, Typographical	Phonetic encoding	*NM*	More than 80%
[16]	Orthographic rules in Bangla	1.Double metaphone 2. Mapping rule.	1607	Edit Distance 0: Correct:1473 Error:134 Accuracy:91.67% Error: 8.33% Error: 107 for edit distance1 Error: 27 for edit distance 2
[17]	Phonetic error	String matching algorithm	25,000 words	high accuracy with 5% false positive detection
[18]	Complex orthographic rules	Stemming algorithm and Edit distance	13,000 words	90.8% for correcting single error misspellings and 67% for correcting multiple error misspellings
[19]	Substitution errors, insertion errors	Finite state automaton	291 words	92% for correcting single character misspellings and 70% for correcting multiple character misspellings
[20]	Typographical errors and cognitive phonetic errors	Direct dictionary look up method and Recursive Simulation algorithm	*NM*	*NM*
[21]	Non-word error	*N*-gram Model (character based)	50,000 correct words and 50,000 incorrect words	96.17%

VI. CONCLUSION

So, the goal of this research was finding a better way which can handle non-word Bangla spelling mistakes. The authors proposed a model based on edit distance method but with different accuracy calculation method than the previous papers on Bangla spelling correction. It is clear that the model proposed here is promising as a large dictionary is used and the accuracy of the model is 96.83%. This research work dealt with non word errors. The authors are working on another research which will deal with real word errors.

Abstract — **Web is being updated rapidly day by day. As a result of the modern media development, news also published very quickly. Generally, it takes less time to appear in the newspapers than an incident happens. But searching the relevant news through internet about one's choice is the foremost task. News classification is the promising area that fulfills what they want .As Bengali is the common language for a huge number of people; they feel comfortable to use it for publishing news in different news portal and social media. Different post and comments are also written in Bangla. So Bangla new in web are promptly increased, classification of Bangla news according to the subject is definitely needed. This paper focused on some machine learning methods such as Naïve Bayes Classifier that is based on probability theory, Support Vector Machine and Neural Networks to classify news as well as post or comments written in Bangla. 1000 long written post are collected from different news portal as well as social media. A Self- created News Corpus is used for experimental analysis. For training and testing a Feature Vector is constructed which is based on TF-IDF. The result shows that the Naive Bayes performs better than other three algorithms. In order to get better accuracy stop word are removed from documents. Bengali stemming has done to reduce the size of the dictionary. Moreover a comparison has been made to show the accuracy of different algorithm.**

Keywords— Naïve Bayes, Stemming, Dictionary, Support Vector Machine, Neural Network.

I. INTRODUCTION

Because of the availability of the Internet and its speed, electronic communication is now much more convenient. Satellite, submarine network everything have made possible to be connected with the global network. So people of every country are fully dependent on the electronic media, social network to collect the news within a short time. Especially youth generation is fully dependent on online publishing newspaper. The score of any games, schedule, commentary etc. are updated time to time in online news portal. Besides, now a day it is very common to advertise anything in social media due to the people's regular activity in social media. In political section, election campaign is very popular in social media for collecting public attention. So social media is also contributing a vital role for publishing important news with the news portal [2]. It's a good initiative to publish news for mass people with their native and mother language. That is why Bengali news portal is taking all kinds of privileges. So Bengali written news classification according to public sentiment is on demand. Previously, the task of news classification has done manually. At present due to success of machine learning process, this manual task running automatically uses some classification methods.When the information or data is much higher, the classification method is more effective. In addition classification of Bangla news is quite penitent because of high frequency of Bangla words and there is no available dictionary for Bangla words.

Recently Various measurable and machine learning procedures has been produced for news classification[1] in vaious dialect.In [5] , KNN is utilized to predict the sample text category in order to find the probability. Naive Bayes probabilistiic classifier is regularly used in content arrangement applications and tests due to its straight forwardness and adequacy which fundamental thought is to utilize the joint probabilities of classes given a record [7]. Naïve Bayes is highly used method for e-mail filtering such as anti-spam [13], [14], [15]. By using Naïve Bayes implement is easier than most other conventional methods [3].Support vector machine (SVM) classifier transforms the original data in a higher dimention using hyperplane. But it also acts much higher when there is poor recall [9].With the accrual of micro-blogging, researchers tried to acquire the sentiment of people and analyzed the opinion of people as negative or positive [10],[11],[12].During the election of Bangladesh Facebook and twitter[8] was used too much to criticize the political situation by the politician in 2014.Many researchers tried to classify post and comment of social media by using naïve Bayes method but without stemming of word. Because of same meaning of various words, the data dictionary can be huge [6].In the field of computational phonetics and probability, n-gram[16] is a contiguous subsequence of n-items in some random succession. An n-gram is a sub-sequence of n-items in any given sequence, where the sequence items or "grams "can be anything, from characters to words. In computational linguistics n-gram models are used most commonly in predicting words (in word level n-gram) or predicting characters (in character level n-gram) for the purpose of various applications [4]. In[17][18] they proposed four dimensionality reduction techniques and show that Principal Component Analysis (PCA) was found to be the most effective in reducing the dimensionality of the feature space. Therefore, the goal of this research is to filtering Bengali written political and sports news from social media using Naive Bayes classification Uni-gram technique in used to compute

probability occourences of each word .Moreover, Bangla stemming is being added to shrink the dictionary size. Thus the present section introduces the problem addressed in this research, while methodology is elaborated in the Section II. The results are presented in Section III and Section IV concludes the paper.

II. METHODOLOGY

The main purpose of news classification is to divide the documents into their respective categories. So we have followed the instructions given below:

1. To collect our data, we have selected some different online news portal based on popularity related to our content and some random post and comments from social media sites.

2. We use individual word file news document for the convenient of use.

3. After creating distinct document file we prepare the documents text by several techniques such as tokenization, punctuation removal, digit removal and so on.

4. In our training phase we fabricated a light Bengali lexicon such as Bengali data dictionary with proper keyword related to sports and political words and those are frequently uses in such articles.

5. We carry out some advanced text processing task like single letter words removal as well as stop word removal.

6. We induced a light Bengali stemmer to identify the stem of each word. It helps us mostly to reduce the size of our established dictionary.

7. In this way we derive each text document as a word-vector. Thus we found the trained document; the result are feed to new documents and we categorize the documents based on Naive-Bayes classifier.

The overview of our approach is depicted in Fig. 1.

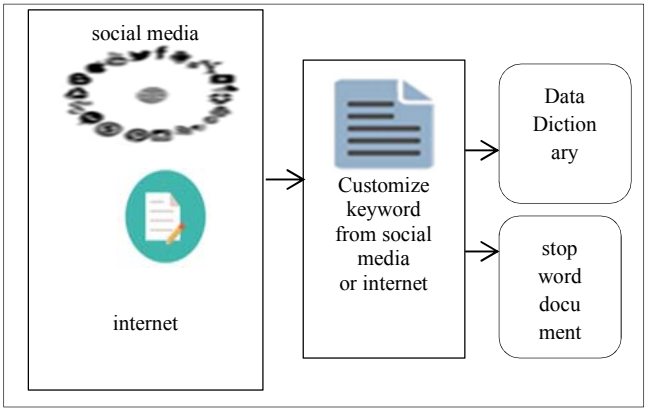

Fig.1.Overview of the Training Phase

A. Data collection

The source of our data is from different online news portal. Mainly we have collected long post and comments so that the sentiment of that post can be verified correctly.Sample collection of our data is given in Table I.

TABLE I. Different Types of Post

"ক্রিকেটারদের টাকা-পয়সা নিয়েও বেশ কিছু নিয়ম বেঁধে দিচ্ছে বিসিবি। যেসব ক্রিকেটারকে ক্লাব রেখে দিতে চায়, ড্রাফটের আগেই তাদের পাওনা টাকার ৫০ শতাংশ দিতে হবে, নাহলে তারা ড্রাফটের জন্য উন্মুক্ত হয়ে যাবেন। ড্রাফট থেকে নেওয়া ক্রিকেটারদের মোট টাকার ৫০ শতাংশ দিতে হবে ড্রাফটের পর বেঁধে দেওয়া সময়সীমার মাঝে, ২৫ শতাংশ দিতে হবে টুর্নামেন্ট চলার সময়ে, বাকি ২৫ শতাংশ টুর্নামেন্ট শেষ হওয়ার পর[19]. "
"হাথুরুসিংহে যোগ দেওয়ার পর পরেই তিন বছর আগে ফিল্ডিং কোচ হিসেবে যোগ দিয়েছিলেন হ্যালসলও। গত বছর হয়েছেন সহকারী কোচ। হাথুরুসিংহে চলে গেছেন, তবে হ্যালসল মনে করছেন এটা খেলোয়াড়দের জন্য শাপেবর হতে পারে[22][23]".
"৮ চার ও ১ ছক্কায় সাইফ তুলে নেন ফিফটি। ভিসাভাদিয়ার বলে ফিরলে বিপদে পড়ে দল। আফিফ কিছুটা সামাল দেওয়ার চেষ্টা করেছিলেন আমিনুল ইসলামকে নিয়ে, তবে সেটা বেশিক্ষণ স্থায়ী হয়নি। ১০ ওভার বাকি থাকতেই সব উইকেট খুইয়ে ফেলে বাংলাদেশ। ভিলজোয়েন একাই ৫ উইকেট নিয়ে ধসিয়ে দিয়েছেন বাংলাদেশের মিডল অর্ডার[24][25]। "

We used 1000 post and comments related to the sports, political and other topics. Table I is the sample of our collected sports news. In Table II, we have given some sample post and their source including their category. The sample dictionary keywords are given in Table III. The entire process is given in fig 2.

B. New Filter for Text Classification

The dictionary keywords related to the political and sports and the stopword set that we created in the training phase as we shown in figure 1.In order to predict the class level of a post as well as sentiment,first of all we have to choose a classification method.We used Naive bayes classification to find the probability of the class level. For testing we extract each of the word from a test text.After removing the stopwords we have done stemming process.It should be mentioned that the stoprwords are such kind of words that are not carrying any importance of meaning i.e conjunction. After the total stemming process words back to their own root word.then we count them and done their frequency checked.With the bayes theorem we found the probability of individual sports and political matching and nonmatching words with the dictonary keywords. Comparing two probabilities , we can predict the class level.

C. Tokenization

Tokenization is a process by which a text can be fractured and eliminnate white space , newlines , puncuations , digits and so on . It separates each word for the convenience of counting frequency as they have no importance but they only carry the weight of text. We also remove single words from our collected Bengali news document. Bengali verb, adjective and

noun are infected. So after tokenization we reform them to their root word through streaming.

TABLE II. SAMPLE COLLECTION OF DATA

	Data	Source	Data types
1	৫ ফেব্রুয়ারি থেকে শুরু হবে ঢাকা প্রিমিয়ার ডিভিশন ক্রিকেট লিগ। এ লিগের জন্য ‘প্লেয়ার বাই চয়েস’হবে ২০ জানুয়ারি। প্রত্যেক ক্লাব ৫ জন করে পুরোনো ক্রিকেটার ধরে রাখতে পারবে, তবে সেটা ‘এ প্লাস’ বা ‘এ’ ক্যাটাগরির ক্রিকেটারদের নয়। এরকম ১২ জন ক্রিকেটারের তালিকা প্রকাশ করবে বিসিবি, যারা ড্রাফটের জন্য উন্মুক্ত থাকবেন। সিসিডিএম চেয়ারম্যান কাজী ইনাম ক্লাব ও বিভাগভিত্তিক দলগুলোর প্রতিনিধিদের সঙ্গে সভার পর আজ জানিয়েছেন এসব তথ্য[20][21].	খেলার খবর	news
2	জনঅধিকার, সংবিধান ও গণতন্ত্র আজ প্রহসনে পরিণত হয়েছে। আইনের শাসন ও গণতন্ত্রের অভাবে জনগণই আজ সবচেয়ে বেশি শক্তিহীন হয়ে পড়েছে। অথচ এর বদলে সব ধরনের ক্ষমতায়ন হয়েছে দুর্বৃত্তদের। আর এর প্রায় পুরোটাই আজ রাজনৈতিক দুর্বৃত্তদের কব্জায়। যে দল ক্ষমতায় যায় রাষ্ট্রের সব শক্তিকে ব্যবহার করে তারাই হয়ে যায় একেকটা মহাদুর্বৃত্ত। সেখানে কদিন আগের ক্ষমতায় থাকা আরেক মহাদুর্বৃত্তও হয়ে পড়ে সবচেয়ে অসহায়। এ যেন আজব এক যুদ্ধ বিজয়ের মতো অবস্থা।	Facebook	Comments
3	প্রধানমন্ত্রী বলেন, সরকারে ধারাবহিকতা আছে বলেই উন্নয়নের ছোয়া লেগেছে। উন্নয়নের জন্যই আওয়ামী লীগে ভোট চাই। আপনাদের কাছে ওয়াদা চাই।	বাংলাদেশ আওয়ামী লীগ	news
4	বাসা থেকে প্রাইভেট পড়তে বেরিয়ে নিখোঁজ হওয়া শ্রীকান্ত দেব নাথকে পাঁচ দিন পর উদ্ধার করেছে নগর গোয়েন্দা পুলিশ। শুক্রবার দিনগত রাত দেড়টায় নগরীর কর্ণফুলী থানাধীন মইজ্জ্যারটেক এলাকায় ঢাকাগামী একটি বাস থেকে তাকে উদ্ধার করা হয়।	BD news 24	news

	রাউন্ড	ফিল্ডিং
Political	সরকার	ক্ষমতা
	জনগণ	রাজনৈতিক
	গণতন্ত্র	উন্নয়ন
	বিরোধী	নেতা

D. Stemming

To reduce the data size of the dictionary,stemming is the best procces. In this process a word is shorten as well is transform its root word without changing its morphological meaning.In our entire system, stemming is playing the most important part. Before stemming words were like this structure that is Shown in table IV. After stemming the result is shown in table V.

TABLE IV. BEFORE STEMMING

আনুষ্ঠানিক" "দল" "ক্যাম্প" "মূলত" "দল" "বোলার" "বল" "ব্যাটিং" "অনুশীলন" "অনুশীলন" "মুখোমুখি" "সংবাদ" "মাধ্যম"

E. Naive Bayes classifier

From Naïve Bayes theorem we measure the probability that helps us to do the classification. With the probability theory we measure matching words with the dictionary and count the frequency of words [1].Naive Bayes theorem is a probabilisticclassifier and mostly used classifier for text categorigation.[2]From Bayes theorem, we can compute the maximum a-posteriori probability (MAP) for the data. If Bayes rule is applied to a document *d* and a class *c*, then we can get

$$P_{MAP} = a\text{rgmax}_{c \in C} P(c|d) \qquad (1)$$

P (d |c): Probability of d given c.

P (c_j) can be estimated from the frequency of classes in the training examples and P(x_1, x_2.... x_n|c_j) can only be estimated if a very large number of training example is available. Here, we have applied Multinomial Naïve Bayes Classifiers (c_{NB}) to classify a text.

$$P_{NB} = a\text{rgmax}_{c \in C} P(c_j) \prod_i P(x_i|c_j) \qquad (2)$$

$$P_{NB} = \text{argmax}_{c \in C} P(c_j) P(x_1 = \text{“our”} | c_j) \ldots . P(x_n = \text{“text”} | c_j) \quad (3)$$

We can extract vocabulary from the training corpus and calculate the required P (cj) and P (xk| ck) for each cj in C as

$$P(x_k | c_j) = \frac{n_k + 1}{(n + |\text{vocabulary}|)} \quad (4)$$

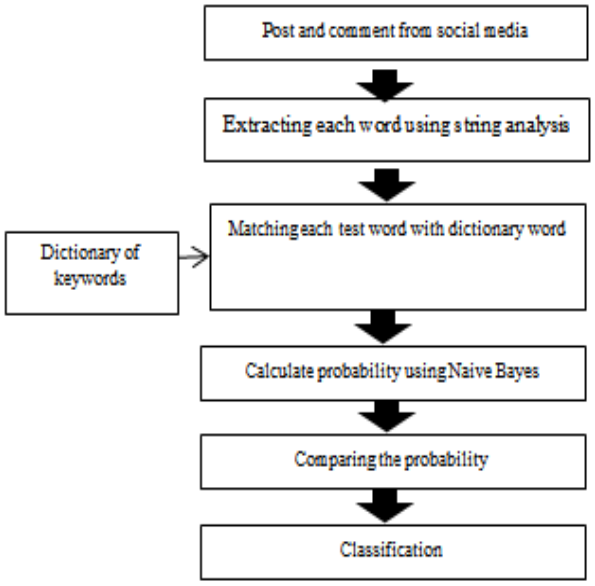

Fig.2. Entire process of our testing phase for Naïve Bayes

F. Support Vector Machine

Support Vector Machine [18] classifies data into a two class by using hyperplane. So it is a binary classifier. Data points which are closer to the hyperplane is called Support vector and it influence the location and direction of the hyperplane. Classifiers margin are maximize by using the support vector. The location of the hyperplane will change by removing the support vectors. These points benefited us to build our SVM. We extract the features and divide it into training data and testing data. 90% of the data is used for training and the rest10% is used for testing.

G. Neural Network classifier

To solve a specific problem neural network is used .It is classifier that is consist of a huge number of highly interconnected elements. In this research, Back propagation Multilayer Perceptron is used. The news classification learning methodology is given in Figure 3. It contains Preprocessing, Feature Extraction, Classification and Evaluation Phases. The experimental parameters learning rate alpha (ε) for the Neural network are used to determine the optimal results/outputs.

Framework for various machine earning technique is given in fig 3.

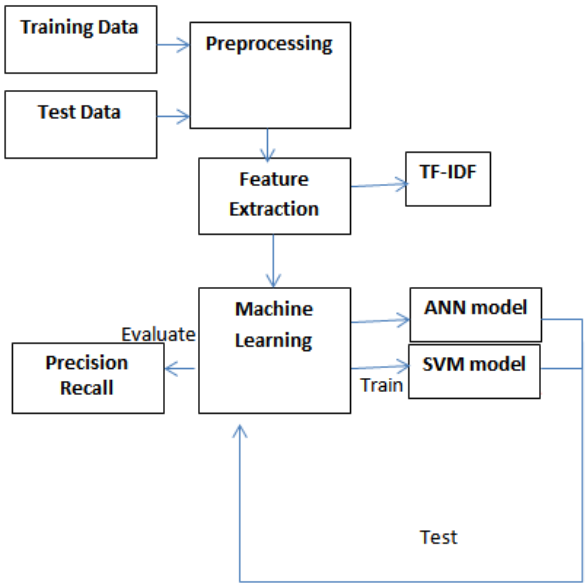

Fig.3. Framework for various machines learning technique

III. RESULT AND DISCUSSION

A. Evaluation Metrics:

To evaluate the accuracy of the system, we used recall and precision as a common Information Retrieval (IR) measure. Theoretically we can define them as follows:

Precision, P: Precision is the ratio of the number of items which define exactly by classifiers to the number of items which classifiers defined to this category, so the precision of is defined as following:

Precision;

$$P = \frac{items\ correctly\ identified}{items\ correctly\ identified + items\ incorrectly\ labeled\ as\ not\ items} \quad (5)$$

Recall, R: Recall rate is the ratio of the number of items which define exactly by classifiers to the number of items which are this category in fact, so the recall rate is defined as following:

Recall;

$$R = \frac{items\ correctly\ identified}{items\ correctly\ identified + individuals\ incorrectly\ labeled\ as\ items} \quad (6)$$

$$F1\text{-}Measure := 2 * \frac{R * P}{R + P} \quad (7)$$

B. Quantitative Analysis

We have tested 500 posts which were collected randomly from news portal and social media sites. Among those 200 posts are sports, 200 are political and 100 are random posts. The overall accuracy is 90%. Table VI shows the sample of class level prediction and table VII shows the testing dataset.

TABLE VI .SAMPLE OF CLASS LEVEL PREDICTION

TABLE VII. Testing Dataset

Sl.No	Domain	No. of Post	No of words in post
1	Sports	200	1500
2	political	200	2500
3	others	100	1000

As define above this research focused on classification of news for two domains namely sports and political news so we trained out the test set of document against each of them. Precision and recall were determined by looking at the number of documents that were correctly labeled for a particular section. We have tested 500 posts. The accuracy of the systems are given in table VIII, table IX and X in terms of Precision and recall. The experimental setup is done in two observations with variation in train and test splits. The experimental results are shown below.

B.1. Experiment results with Naive Bayes

Since From Naïve Bayes theorem we measure the probability that helps us to do the classification. With the probability theorem we measure matching words with the dictionary. The result obtained from experiment for Naïve Bayes is shown in Table VIII.

TABLE VIII. Experimental Result for Naïve Bayes

	Accuracy	Precision	Recall	F-Score
Sports	88	89	88	87
Political	89	80	89	88

B.2 Experiment results with SVM

The result obtained for SVM is given in TABLE IX

TABLE IX. Experimental Result for SVM

Exp.	Accuracy	Precision	Recall	F-Score
Sports	76	73	72	72
Political	72	74	73	72

B.3. Experiment results with Neural Network

The result obtained from experiments for Neural Network is shown in TABLE X.

TABLE X .Experimental Result for ANN

Exp.	Accuracy	Precision	Recall	F-Score
Sports	82	83	83	82
Political	83	84	84	83

To investigate the efficiency of results; a comparison has been made between Naïve bays, SVM and ANN. Fig.4 and fig 5.shows the results of all the three systems, including, Naïve Bayes, SVM and ANN. From the overall point of view, Naïve

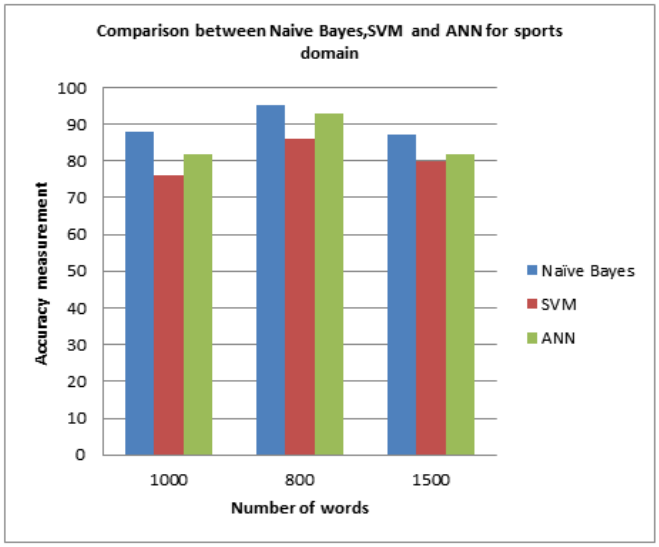

Fig.4. Comparison between Naive Bayes, SVM and ANN method for sports

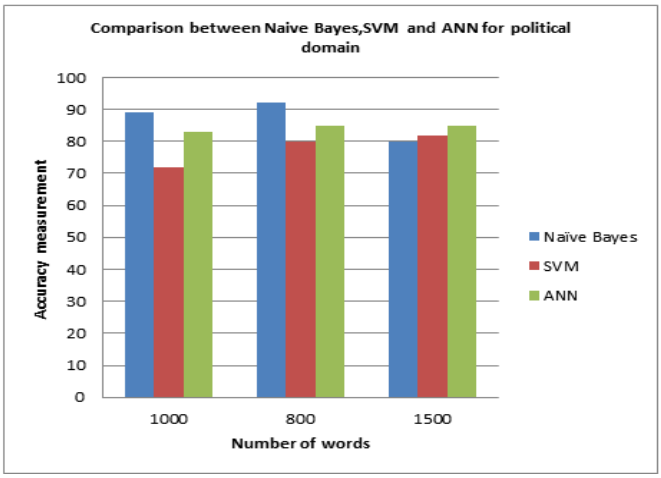

Fig.5. Comparison between Naive Bayes, SVM and ANN method for political news

IV. CONCLUSION AND FUTURE WORK

Due to rapid growth of social media and online news portal, it's an ultimate necessary of filtering to find the relevant news in a shortest way. For this a proper classification need to be used to solve the heterogeneity of categorization. In our paper we used Naïve Bayes classification that based on probabilistic theory to find a satisfactory result. The appropriateness of our classification system mainly reclines on the data set of dictionary and stemming process as well as training phase. Because of stemming we reduced our dictionary size. The accuracy can be different if we use different classification method further. This classification only can be possible if the post or comments are written in Bengali. So correct spelling should be needed for post as well as comments. As we only show the text based classification; adding image that contains information can mislead to find proper result and correct result can be varies to identify exact probability. So text conversion of images also an ultimate necessary to find an exact classification. Therefore, for better filtering as well as rapid classification, other n-gram techniques are also being a useful feature. The future recommendations on the development of this work are extract textual data from image and apply CNN based approach to solve the Bangla new classification problem.

***Abstract*—** Micro-blogging is one of the most popular social network services that enable users to share their thoughts, ideas and discuss current issues every day. Some popular micro-blogging sites are Tumblr, Twitter, Pinterest, Flattr, Meetme. This research will work to represent the study of sentiment analysis to extract emotions from textual contents by using several methods of tracking mode. Several classifiers are trained to extract basic moods such as Joy, Trust, Fear, Surprise, Sadness, Disgust, Anger, and Anticipate from text. The aspect of this research is to give a nearly concept about sentiment analysis techniques and the related areas.

Keyword—micro-blog; sentiment analysis; emotion extraction; emotion.

I. INTRODUCTION

Among all users, micro-blogging has become one of the most well-liked social networking applications. It plays a pertinent role in providing information. Lots of messages appear daily in popular sites where users can share their feelings, views etc. Various systems have developed to detect user's opinions or sentiments by processing natural languages on some micro-blogging platform. Based on the 20 latest articles where different approach is used , the contribution of this survey is- it provides futuristic categorization, which will help researchers of Sentiment Analysis (SA) to use appropriate techniques in certain field. As various SA approaches are categorized here, new comers can have an extensive view on entire SA field.

This section focuses on sentiment analysis and it's classification as well as detection method. Sentiment or opinion Analysis is a computational study that refers to process natural languages and analyzes texts to extract and determine people's attitudes and emotions. Sentimental analysis can be classified into two types- Machine learning approach and Lexicon based approach. Figure 1 shows the Sentiment Classification methods.

A. Machine learning approach

Machine learning approach uses linguistic features and appliesvarious famous algorithms on these for analyzing their sentiments. J. Bollen *et. al.* and Wenbo Wang *et. al.* have used this approach for their research. Machine learning approach can be divided into 2 classes.

A.1. Supervised learning

A supervised learning problem can classify sentiment can with two labels (i.e. positive and negative). Input dataset is considered to be a labeled one when machine learning approaches are used to classify sentiment. Dmitry Davidov *et. al.* has used this approach. Various types of supervised learning classifiers are used for classifying sentiment like Naive Bayes, Maximum Entropy, Stochastic Gradient Descent, Support Vector Machine, Decision Tree, K-nearest neighbour, Artificial Neural Network and n-gram method etc. *Ze-Jing Chuang et. al.* and Agarwal *et. al.* have used SVM classifier. Alexander Pak *et. al.* has used Naive Bayes classifier. John *et. al.* has used Maximum Entropy classifier.

A.2.Unsupervised learning

An unsupervised learning approach classifies sentiment based on some fixed words and phrases. Datasets are consisting of input data without labeled resources.

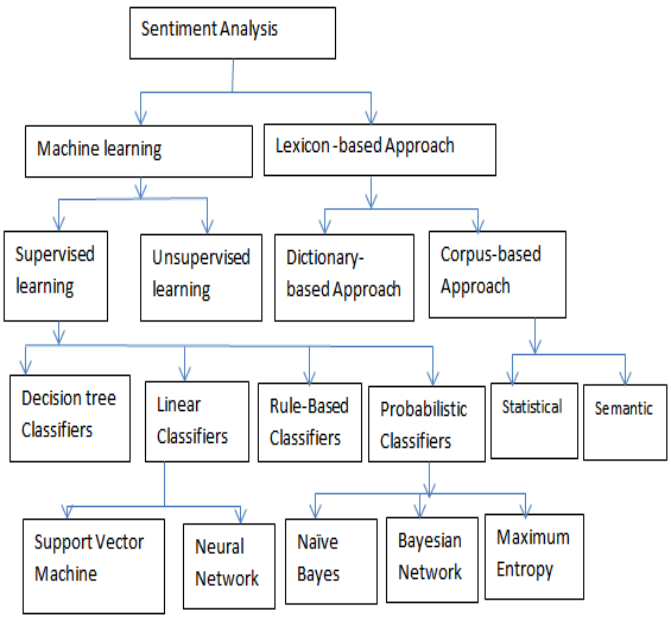

Fig.1. *Sentiment classification methods [1]*

B. Lexicon based approach

Lexicon based approach depends on reliable and organized sentiment labels. Opinion words like positive words or negative words are used to classify sentiment. Lexicon based approach can be divide into 2 classes.

B.1. Dictionary based approach

This simple approach is based on bootstrapping and uses small set of simple words or online dictionary such as WordNet, thesaurus to classify sentiment.

B.2 .Corpus based approach

This approach uses a list of words and words pattern to find other words in corpus with the help of context specification orientation [1]. Carlo Strapparava *et. al.* has used this approach for her research.

There are another method known as Hybrid approach which is the combination of both machine learning approach and lexicon based approach [2].Again SA can be carried out in three basic levels. These are sentence level, document level and aspect level SA. Document level SA is used to categorize an opinion or sentiment as positive or negative. Sentence level SA is used to discover whether the sentence is biased or aimed and then find out whether the verdict expresses positive or negative sentiment. Aspect level SA is used to recognize the entities and then determine their aspects [3].In the last few years, the field of Sentiment Analysis has enhanced with various algorithms that were proposed and developed. These fields comprise Emotion Detection (ED), Building Resources (BR) and Transfer Learning (TL). Emotion detection is used to detect and analyze explicit or implicit emotions of users in the sentences to identify user's emotional state such as anger, confusion or joy across both voice and non-voice channels. Building resources focuses to create data set, corpora in which emotions of users are annotated based on their divergence. Transfer learning classification is used to analyze data from one particular field and then use the consequences in marked field.

C. Emotion Detection Techniques

There are basically four techniques for emotion detection including Keyword spotting technique, Lexical affinity method, Learning based method and Hybrid method.

C.1 Keyword spotting

This technique can be defined on the basis of some definite predefined keywords which have been classified into some categories such as surprised, angry, sad, joy and disgusted. This technique analyzes the intensity of words to identify emotion. The process is shown in the fig. 2

C.2 Lexical Affinity

Lexical Affinity approach works with probabilistic 'affinity' for a specific opinion to random words spaced out from picking up sentimental keywords.

C.3 Learning and Hybrid method

Learning based method is used to categorize the input string into different emotions. Learning based methodology and keyword based spotting methodology is combined to create Hybrid methods .

Thus the present section introduces the problem in this work while methodology review is elaborated in the Section II. And Section III concludes the paper.

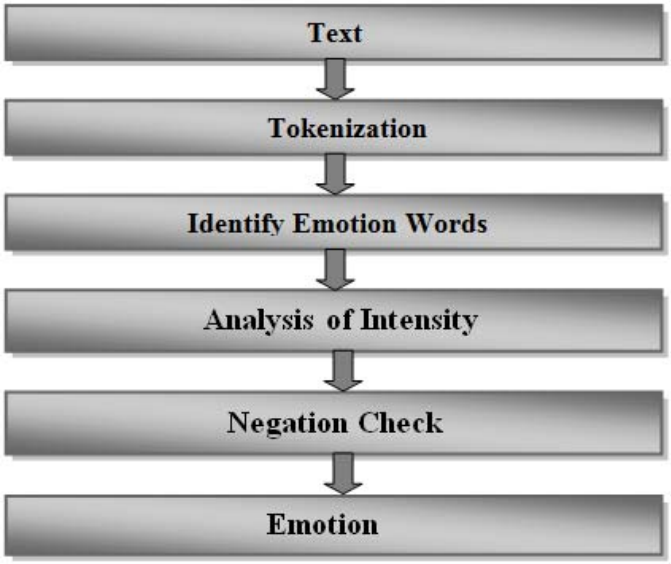

Fig 2. *Keyword Spotting Techniques [2]*

II. METHODOLOGY REVIEW

In 2002, X. Zhe *et. al.* [4] worked on online textual information and build a machine that can extract emotion. The engine is able to analyze a given string from online conversation and extract the emotion. The output is delivered to the communicating user display. There are three functions of the engine: Input analysis function, tagging system and the parser. The operation of the engine is showed in Fig. 3.

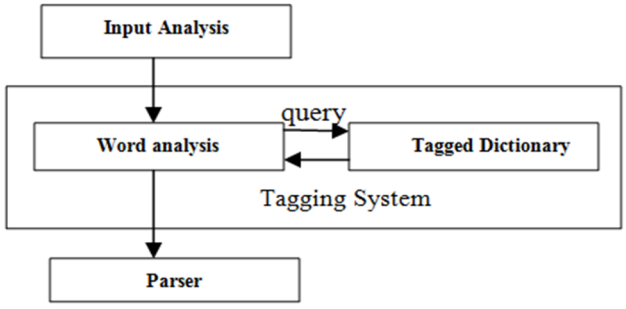

Fig. 3. *The working flow of engine [4]*

Semantic analysis is used to recognize the emotions of text. Two types of tests are used to test the engine performance. They are static and dynamic. Static test construct emotional sentences artificially. Dynamic test enables users to input any sentences freely. Here, the emotion extraction engine requires extremely low bandwidth for real time communications.

Therefore, image transmission is avoided here because of large bandwidth.

In 2003, Tetsuya Nasukawa *et. al.* [5] have demonstrated a sentiment analysis on some organizations and their products to extract positive or negative sentiment for particular subjects from a textual context rather than categorizing the entire content into positive or negative towards the subject. The key issue of this task is to recognize the semantic relationships between subjects and sentiment-related terms because the polarization of the emotion may be wholly different depending on the relationships. They define the framework of the sentiment lexicon. They had 3,513 records in the sentiment analysis lexicon, as shown in Table 1.

TABLE I. DISTRIBUTION OF SENTIMENT TERMS

POS	Total	Positive	Negative	Neutral
Adjective	2465	969	1495	1
Adverb	6	1	4	1
Noun	576	179	388	9
Sentiment verb	357	103	252	2
Transfer verb	109			

POS tagging is used to disambiguate some polysemous expressions and syntactic parsing is used to find out the relationships between sentiment expressions and the subject term. The framework is not suitable to deal with the long and complex sentences because of negating the local sentiment for the whole.

In 2004, *Ze-Jing Chuang et. al.* [6] have recognized emotion from voice signals and textual content. They extract thirty-three visual features in the analysis of voice signals from the voice signal input. . Principle component analysis (PCA) is used to select most significant and Support Vector Machines (SVM) are applied to classify the sentimental state of speech input and fed into the textual emotion recognition module. They define all sentiment modification words and emotional keywords physically. The final result is regulated from the sentiment outputs from the visual and textual approaches. The final result shows that the multi-modal approach gives an optimistic result for emotion extraction than uni-modal strategy.

In 2005, Xiao *et. al.* [7] have extracted and analyzed a feature set by "Fisher's Discrimination Ratio" and selected few best features that are computed from F0-fundamental frequency with range between 60-450 Hz. Including the feature list and selection result, they have introduced a new definition of emotions as 3-states emotion with active, passive and neutral state. They have also built a database to verify states of emotional speech with speech samples. In this paper fifty feature are used to analyze and they also examined voice samples separately for male and female and finally sadness, anger and disgust these tree emotion are categorized. Those confused emotions should be found out in our future work such as neutral and fear, boredom .Their future work will include the description about sub-states and difference between sub-states. For verifying the states definition of emotional speech a new database is being built.

In 2008, Alastair J. Gill *et. al.* [8] study the capability of naive raters of sentiment to identify eight emotional categories (joy, anger, fear, sadness, surprise, disgust acceptance, anticipation) from a real data set and use 200 samples. Principles of CMC and potential applications in HCI is used to range from recognizing emotion from blog posts to allow dynamically adaptive interfaces.. Contributors used the activation-evaluation wheel exposed in Fig. 4. There do not apply any machine learning classification, which sets a challenges in future work for possible judging naive human including emotion monitoring of blog posts, or dynamic interfaces.

They unravel the text-based communication of emotion which is built upon Hancock *et al.* [9] basically in three ways: (1) they develop their classification of emotion into the eight main emotion categories from positive and negative sensation. (2) they emphasis on exactly classification of emotion based on asynchronous short blog post excerpts of 50 and 200 words, resulting from (3) real sentimental blogs.

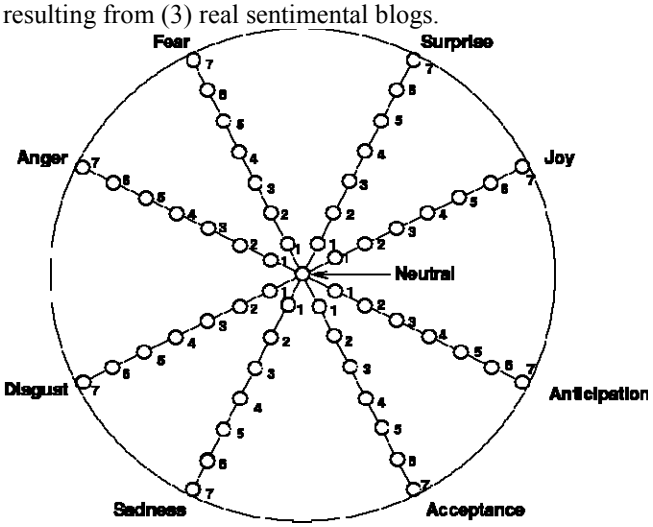

Fig. 4. *Emotion wheel used for text rating [8].*

In 2008, Carlo Strapparava *et. al.* [10] have extracted emotion of news headlines from newscast sites. Headlines are normally made of a few words and are often written by inventive persons to seek the reader attention. That's why a short sentence may represent the emotional features which help to create this type of text predominantly appropriate for use in an automatic sentiment identification system. The lexicon contains news headlines taken from popular newspapers. Two types of lexicon were available one is progress lexicon containing 250 annotated headlines and another is a test lexicon containing 1,000 annotated headlines. A Web-based annotation interface was established to display one headline to perform the annotations at a time, together with six slide bars for sentiments and one slide bar for valence. Inter-tagger agreement studies are conducted for each of the six emotions. Using the Pearson correlation measure, the agreement calculations were carried out which is shown in Table 2.

TABLE II. PEARSON CORRELATION FOR INTER-ANNOTATOR AGREEMENT

Emotion	Detection in %
Anger	49.55
Disgust	44.51
Fear	63.81
Joy	59.91
Sadness	68.19
Surprise	36.07

They carried out on a big lexicon of 1,000 deadlines through relational estimations of a number of knowledge-based and corpus-based techniques. Future work is to implement deeper semantic processing of the text and analyze the emotions lexical structure in the knowledge-based and corpus based classification.

In 2009, John *et. al.* [11] have built a system that will classify the emotions of "the word of interest" of a tweet with "Maximum Entropy Classifier" and if the emotions related to "the word of interest" are different from the emotions of tweets, this system will try to predict the emotion of "the word of interest". Though their classifier was able to classify emotions versus neutral texts of twitter over 70% of time but they did not get enough data to distinguish between negative and positive emotions. In Twitter their classification model is capable to identify emotion vs neutral text by selecting 3 categories of emotion such as positive, negative and neutral. They also believed that for a big corpus of data they will get an excellent performance and also include 50% data on 500 tweets that are labeled is perfect for optimism.

TABLE III. DATA SETS USED IN CLASSIFICATION

Data	Description
3-way	Compares neutral, positive and negative in a three way classifier.
+,#	Compares emotion present versus no emotion (2-way).
+,-	Compares positive emotion to negative emotion (2-way).

In 2009, Go *et. al.* [12] have shown that using emoticons as noisy labels with tweets, is an effective way for performing distant supervised learning. They have developed a novel approach using "Distant Supervision" to classify the sentiment of twitter messages automatically as either negative or positive with respect to query and achieved high accuracy when using this method. Their method could use tweets with emoticons to identify opinions of individuals for distant supervised learning. As features, they have explored the uses of parts of speech, unigrams, bigrams, unigrams and bigrams. The accuracy of their classifier is shown below:

TABLE IV. CLASSIFIER ACCURACY

Features	Keyword	Naïve Bayes	MaxEnt	SVM
Unigram	65.2	81.3	80.5	82.2
Bigram	N/A	81.6	79.1	78.8
Unigram +Bigram	N/A	82.7	83.0	81.6
Unigram + POS	N/A	79.9	79.9	81.9

There works with English sentences, in future use this approach to classify sentiment in other languages and attention will be paid to neutral sentiment.

In 2010, Dmitry Davidov *et. al.* [13] proposed a supervised sentiment classification framework is in this paper which is based on twitter data.50 Twitter tags and 15 smiley's are used here. They consider dependencies and overlap between different smileys and Twitter hash tags sentiment. They assessed diverse feature types for sentiment exaction including punctuation, words, patterns and n-grams and assuring that each feature type come up with the sentiment classification framework. They recommended two different methods for automatic reorganization of sentiment type overlap. The first is tag co-occurrence and the second type is feature overlap. In future these methods will be applied for automated sentiment clustering and sentiment dependency rules and multi-class sentiment identification and classification in other domains of Twitter data .They construct an engine which can identify and classify different types of sentiment automatically for the text which are not so long. They used supervised classification with hash tags and smileys as training labels. They considered different types of feature for sentiment extraction such as words, n-grams, punctuation and patterns to confirm that each type of feature is used for the classification of sentiment. By using hashtag and different algorithm the accuracy are given below

TABLE V. ACCURACY OF ALGORITHM

Algorithm	Data Set	Accuracy	gc	%above guessing
MaxEnt I	3-way	47.60%	5.1%-	14%
MaxEnt II	3-way	41.09%	5.9%	7.76%
MaxEnt II	=.#	72.79%	5.1%	22.79%
MaxEnt II	+.-	51.08%	4.5%	1.08%
MaxL N	+.-	55.91%	7.2%	4.91%

In 2010, Alexander Pak *et. al.* [14] carried out semantic analysis of the composed corpus and describe discovered phenomena in their research. Multinomial Naive Bayes classifier is used to build a sentiment classifier that uses POS-tags and also N-gram features, using the corpus which is capable to define positive, negative and neutral opinions of corpus. To gather an input with positive and negative opinion they present a method in which no human exertion is desired for categorizing the documents. They also perform statistical semantic analysis of the collected input and bearing experimental evaluations on real micro blogging posts. The size of the collected corpora is not restricted. POS-tagging is used to build tree Tagger and discovered the variance in flows among negative, positive and neutral sets. Syntactic structures are used to describe emotions or state facts. Their work is to gather a multilingual corpus of Twitter information and compare the attributes of the corpus crosswise over various languages and also implement a multilingual negative and neutral sets their classifier is capable to fix three sentiments like positive .negative and neutral of documents.

In 2011, Agarwal *et. al.* [15] have worked to analyze the sentiment of twitter data and for this purpose they have introduced a feature based model i.e POS-specific prior polarity features and tree kernel and demonstrate their performance on unigram baseline by SVM-Support Vector Machine. They also have reported a gain for two classification tasks- i) positive vs. negative vs. neutral i.e a 3-way task and ii) positive vs. negative i.e a 2-way task. For their experiment they have took those features that merge the preceding schism of words and parts of speech tags in twitter data.

In 2011, J. Bollen *et. al.* [16] have used psychometric instrument to extract six different types of emotions from a sentiment analysis of tweets between august 1 to December 20,2008. For each day in the timeline they evaluate a six dimensional mood vector. Then they compare their results with some media events. Profile of Mood state (POMS) is used to measure the sentiment of each tweets. Their method used an analytic tool rooted in decades of empirical psychometric research which showed a valid replacement of machine learning to determine sentiment and associate its oscillations with a timeline of media events. In this article ,an extended version of the Profile of Mood States (POMS) is used for sentiment analysis of messages published on. We know that political and social event are significantly correlated and economic and cultural also correlated, it fluctuate depend on the level of public mood in a range of different mood of dimensions. Moreover they proposed a substitute to machine learning for the detection of public sentiment.

In 2012, Shiv Naresh Shivhare *et. al.* [17] have proposed a framework which is separated into two main mechanisms: Emotion Ontology and Emotion Detector.

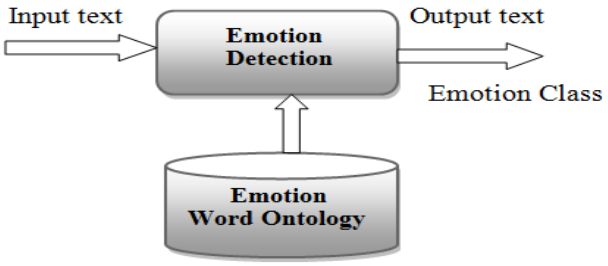

Fig. 5. *Working flow of framework [17]*

Ontologies allow an understanding of particular domain to be connected between publics, application systems and institutions. Sentiment word hierarchy is transformed into ontology. The ontology, which was proposed, contains the relationship layout of sentiment class's and subclasses. High weight age is appointed to the upper level sentiment classes and low weight age is appointed to the lower level sentiment classes. Emotion detection algorithm is used to recognize the emotion of the textual data. The weight for certain emotion is computed by the algorithm by storing weights assigned at each level of hierarchy and same calculation is done for its counter emotion, then both scores are compared and larger one is occupied as the identified emotion. Different parameters are considered to determine weight age to be allocated for several sentiment words so that they can be fixed based on it.

In 2012, Wenbo Wang *et. al.* [18] automatically formed a large emotion-labeled lexicon by hitching sentiment-related hash tags existing in the tweets. Two different types of machine learning algorithms are applied for opinion extraction to learn the efficiency of several features and the effectiveness of the scope of the collected data. They show the grouping of unigrams, bigrams and sentiment bearing words. Using data of 2 million tweets for 7 sentiment categories the uppermost accuracy was attained. They collected 5 million tweets and to verify their quality they arbitrarily selected a set of tweets as sample. They developed a set of filtering heuristics based on the set of collected tweets. They explore various features which are enabling to provide better perceptions for emotion identification. In this paper emotion are identified automatically. They collect more than 2.5 million tweets to cover these seven categories of emotion. This is one of the biggest datasets. The results illustrate that the combination of feature bigrams, unigrams, current sentiment and also emotion lexicons, and POS achieves the higher accuracy which is 65.57%.To identify the fine-grained emotion lexicon based and POS are less effective .And also there was no dataset for not so popular emotions such as surprise and fear etc.

In 2012, Zhang *et. al.* [19] have constructed an emotional vector with hierarchical composition based on taxonomy to act upon opinion analysis. Through this emotional vector algorithm, their system could soak up new emotional words and could perform multi-level analysis for emotional perspectives. Their experimental assessments have showed a well-built connection between bursty actions and public emotions. Their proposed "Emotional Vector Algorithm" analyze sentiment effectively rather than traditional orientation

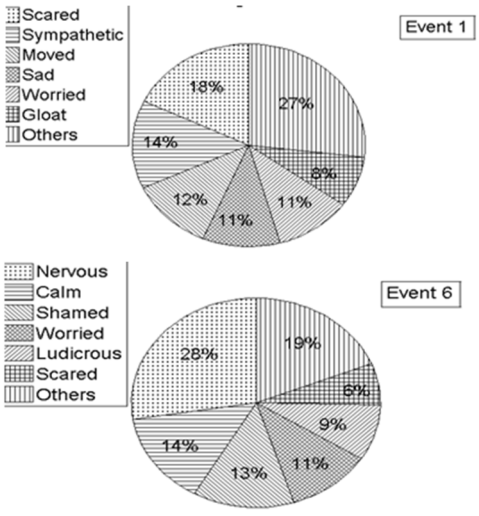

Fig. 6. *Distribution of emotional vector of events [19].*

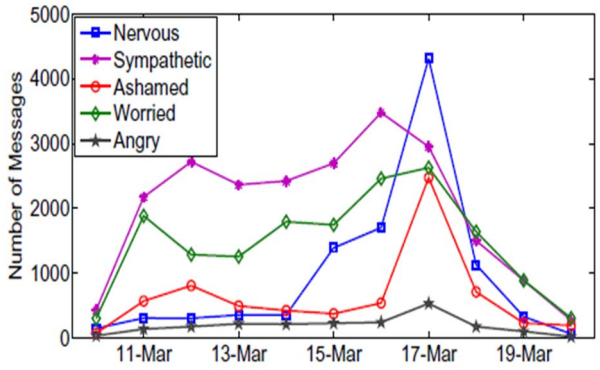

Fig. 7. *Five typical dimensions of emotional vector overtime [19]*

In this paper, they build an emotional vector based on hierarchical structure to achieve sentiment analysis and multi-level analysis is done to show how emotional changes time to time. Their experiment exhibited that their methods could effectively evaluate public moods.

In 2012, Mohammad *et. al.* [20] have created emotion word hashtag type input from twitter texts. He has shown consistent self-labeled hashtag annotations. He also proposed a technique to progress the correctness in the classification of emotion by using tweeter corpus in different domain of micro-blogs. Using TEC classifier, he has extracted emotion based on lexicon from twitter and exhibited that their system performs better than conventional crafted WordNet Affect lexicon in the task of emotion classification and combines labeled data to improve classification accuracy.

In 2012, Robert *et. al.* [21] have introduced a corpus annotated with seven emotions: Love, Sadness, Fear, Joy, Surprise, Anger and Disgust. They have analyzed how emotions are distributed in text, applied a simple supervised method for detecting emotions, compared it with other emotion-annotated corpora and developed a baseline approach for this comparison. For expressing emotions of corpus, they have also characterized the linguistic style as below:

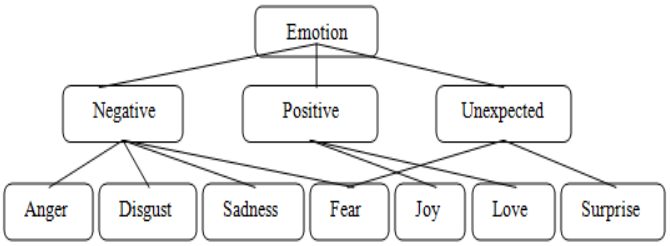

Fig.8. *Emotion ontology for the six Ekman emotions (plus LOVE). Solid lines indicate inheritance [21]*

System used for automatically identifying emotions in the corpus is given below:

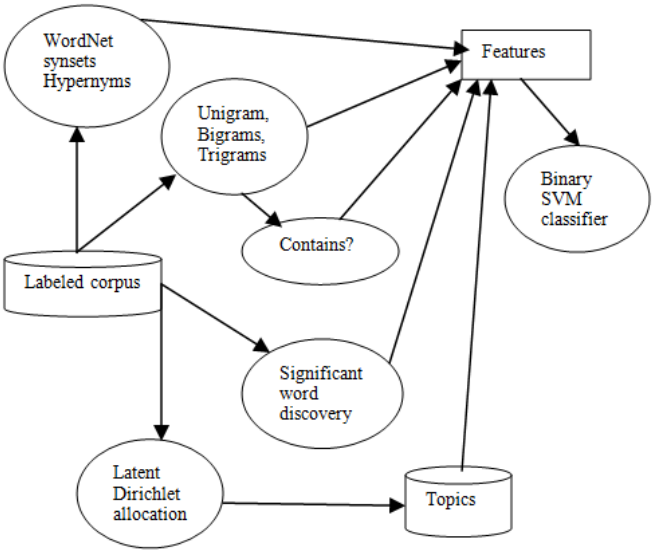

Fig. 9. *System used for automatically identifying emotions in the corpus [21]*

In their paper they made an emotion corpus created from the micro-blogging service Twitter. It categories seven different emotions. They also established a standard approach to use for Bench marking and used then compare their corpus with several present emotion corpora. We have also supervised method is also used for detecting emotions can be trained on this corpus. Moreover this analysis should lead to the design of novel supervised and unsupervised emotion detection technique

In 2013, Neviarouskaya *et. al.* [22] have focuses on phrases that are related to causes of emotion automatically. For this purpose, they have developed a set of phrases with 22 specific emotions from the OCC model. They have introduced a method for detecting linguistic correlations between an emotion and its cause and extracting those, which are related to emotion causes. Their method has employed the enslavement and syntactic information, provided by parser and a system for analyzing 8 types of emotion-cause linguistic relations to extract emotion causes automatically.

In their result section error analysis on the sentence is performed and also illustrates how other method failed to extract correct phrases. Rules are added and modified in the emotion extraction method; they got the following evaluation results: precision in 0.821, recall in 0.852, and F-score in 0.810. In that way, their method performed with about 15% gain in accuracy.
The main objective of their research are the creation of a corpus of emotion causes specific for 22 emotions from the OCC model and the advance of a novel method for extraction of emotion causes from sentences based on the analysis of syntactic and dependency information provided by the parser. causes as positive, negative, or neutral.

In 2014, Li *et. al.* [23] have developed a rule-based system to detect and extract event of emotional post automatically. They have built an emotion corpus which has been labeling by human annotators with Chinese micro-blog-"Weibo" texts.

They have selected features by using Emotion Cause Extraction and trained their classifier to classify emotions using SVR. To detect and extract emotions from original texts, they have designed a rule-based sub-system which generates a set of features for training the classifier. Their experiment has improved traditional emotion classification models with emotion cause extraction technique. Due to multi-class problem, their experiments has ‘‘one-vs-rest’’ manner. it is important for them to compare their system with a baseline system which based on convention feature selection method. They use 75% posts in their corpus as the training dataset, and 25%as the test dataset

In 2014, Hasan *et. al.* [24] have established a novel approach called “EMOTEX” to categorize twitter messages of individuals to assume their emotions. They have used Circumflex model that characterizes experiences with valence and arousal to mock-up emotional states. Their classifier could identify multiple classes of emotion on large data set with no manual endeavor. In their experimental assessments, they have investigated the utility of some features like-unigrams, punctuations, negations and emoticons. Again they have used Lexicon of emotions to solve the sparse problem and high dimensional feature space problem in twitter data set. Their technique has achieved an accuracy of 90% over other machine learning algorithms like- KNN, SVM, Naïve Bayes and Decision Tree for classify twitter messages.
They use a lot of number of hash-tags corresponding for each class of emotion depending to each class of emotions. Four classes of emotions are used here namely, Happy-Inactive, Happy-Active, Unhappy-Active, and Unhappy-Inactive The initial list of keywords that are used listed below: • Class Happy-Active: Happy, Excited, Delighted, Astonished, Aroused • Class Happy-Inactive: Serene, Contented, Satisfied, Relaxed, Calm • Class Unhappy-Active: Tense, Angry, Afraid, Annoyed, Distressed • Class Unhappy-Inactive: miserable, Depressed, Sad, Gloomy. They also compared the accuracy of several machine learning algorithms such as SVM, Naive Bayes, KNN, and Decision Tree for classifying the moods of Twitter messages. This method are not used for other pieces of information such as, sleep data, exercise and physical activities, and food information because of limitation of keyword used

.

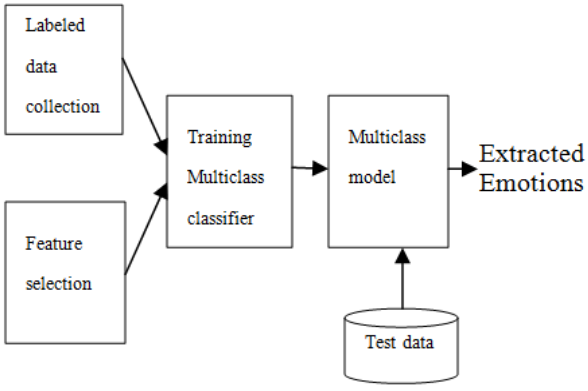

Fig.10. *Model of Emotex [24]*

TABLE VI. CLASS IDENTIFICATION

Class	Number of tweets before pre-processing	Number of tweets after pre-processing
Happy-active	39600	34000
Happy-Inactive	41000	29200
Unhappy-Active	44000	37000
Unhappy-inactive	40700	33900
Total	165300	134100

III. CONCLUSION

This research presents a synopsis on opinion analysis and emotion extraction related fields that use a variety of sentiment analysis techniques such as Machine learning approach and Lexicon based approach for various real-world applications. Twenty of the recently introduced related workings are summarized here. Comparing different Machine learning approach, it is clear that Support Vector Machines Classifiers (SVM) is the most frequently used technique for solving Supervised Learning problem. On the other hand, Semantic approach is the best technique to solve problems of Corpus based in Lexicon based approach. WordNet is the most common lexicon source used in analysis.Natural language process (NLP) is one of the most facilitated tools used in the SA process. It helps to produce more accurate results in SA related problems by processing natural language. In future we will build an emotion extraction method that can automatically detect emotion from tweets from an experience of emotion specified by emotion token and the classification of causes as positive, negative, or neutral. Also collect a multilingual corpus of Twitter data and compare the characteristics of the corpus across different languages.

***Abstract*—One of the central motivations behind Natural Language Processing is detecting patterns. Given a text document, the task of identifying the context is known to be as topic classification. This paper explores the performance of three different classifiers namely Decision Tree, K-Nearest Neighbors and Multinomial Naive Bayes on a topic classification task (with six topic class). The evaluation is done on the basis of accuracy, precision, recall, and f1-score based results. Among those three aforementioned classifiers, we have selected the Multinomial Naïve Bayes as our best model using which we achieved 91.8% accuracy.**

***Keywords*—Text Classification, Natural Language Processing, Machine Learning**

I. INTRODUCTION

Topic classification (TC) is one of the classic subdomains of natural language processing which deals with allocating predefined classes to text documents. Due to the abundance of textual information in digitalized format, the need for categorization of documents has become a thriving interest for the past few decades. The first idea probably originated back in 1961 from the seminal work of Maron on probabilistic text classification [1]. One dominant approach to tackle this problem is based on machine learning techniques, which recently took the research communities by storm.

The prime inquisitiveness in most of the text classification task spans from finding out the best possible combinations of features with best Machine Learning (ML) classifiers. Our motivation in this article also extends towards the investigation of how different supervised machine learning classifier performs on a multi-label text classification task. We tried to experiment with the parameters of three different classifiers (Decision Tree, K-NN and Multinomial Naive Bayes) implemented using the scikit-learn library. We managed to elevate the performance of each of these baseline classifiers by employing some form of pre-processing (stemming, stop-word removing, lemmatization etc.). Apart from that, both *tf-idf* and *count* features were explored in order to compare the results for the aforementioned classifiers under different settings.

II. RELATED WORKS

Perhaps one of the earlier prominent work in this domain is the usage of Support Vector Machine (SVM) for learning to classify text [2]. The paper delineates a comparison between SVM and four traditional machine learning approaches. Two corpora were used for evaluation and an SVM with an RBF-kernel gained 86.4% and 66.0% accuracy respectively.

This paper [3] describes the correction scheme of the Reuters Corpus Volume I (RCV1-v2) from the original RCV1-v1. Apart from this, they have used the above amended corpus to evaluate three popular ML algorithms (SVM, k-NN, Rocchio). A micro F1 score of 0.816 and macro F1 of 0.619 was obtained using an SVM.

A paper [4] by Sebastiani et al. provided an in-depth exploration of nearly every type of classification techniques including the neural network and could be recalled as a starting point in our research. The paper also compared state-of-art systems at that time among which the best-reported method [5] using SVM obtained an accuracy of 92% and Decision Tree (DT) gave 88.4% accurate results using the Reuters corpus.

Another article [6] provides a heuristic on character-level Convolutional Neural Networks (CNN) for the task of textual document classification. They have compared several traditional as well as deep learning models and claimed that character-level CNN is a better choice in terms of data scalability.

III. DATASET

For our experiment, we have considered a fraction of Amazon's product review corpus consisting of 6000 text documents from which 75% (4500) documents are used for *training* purpose. The rest 25% (1500) data are used for *testing* the performance of the system. Each review is annotated as one of *six* topic type categories (*books, camera, dvd, health, music, software*) which corresponds to multi-class variants. The distribution of classes in both training and testing data is shown in TABLE I.

TABLE I. DISTRIBUTION OF VARIOUS LABELS IN THE DATASET.

Labels	Training Set	Testing Set
Books	760	233
Camera	730	258
DVD	770	242
Health	743	243
Music	767	260
Software	730	264
Total	4500	1500

IV. Methodology Of The System

In this section, a brief idea about the settings and approach taken for all the three classifiers is given. But before going to the details about the classifiers we will have a look at the *pre-processors* used in our system:

A. Preprocessing

We have experimented with three types of preprocessing techniques that are popular in text analysis domain. First of all, we have removed the *stop words* (such as *a*, *of*, *the* etc.) which occurs regularly in English text and do not generally contribute that much in classification. The second pre-processing techniques that we followed is the *stemming* of multiple forms of a single word into the same root. We have used *Porter's Stemmer* from NLTK for stemming. Both of these improved the results substantially for example in the case of K-NN classifier. The accuracy improves from 75.7% to 82.6% (7% for tf-idf feature) and from 41.87% to 59.1% (17.23% for count feature). The other classifiers performance also improves between 1-2%.

Another tool that we experimented with our system is the WordNet *lemmatizer* from NLTK which didn't improve the performance, this may be due to the reason that, for topic classification task it is important to preserve the word as it is instead of converting it to lemma.

B. Decision Tree

Decision Tree (DT) constructs classification models by breaking down a dataset into smaller subsets while incrementally building an associated tree. The final tree contains *decision nodes* and *leaf nodes* (Fig.1). A decision node consists of two or more branches (e.g., color, size and shape) while a leaf node (e.g., edible) represents a decision or classification. The best predictor, also referred to as the **root node**, is marked by the topmost decision node. DT can operate on either numerical or categorical data. Perhaps the intuition for the decision tree can be best described by an example (Table II):

TABLE II. An Example Dataset.

Color	Size	Shape	Edible
Yellow	Small	Round	Yes
Yellow	Small	Round	No
Green	Small	Irregular	Yes
Green	Large	Irregular	No
Yellow	Large	Round	Yes
Yellow	Small	Round	Yes
Yellow	Small	Round	Yes
Yellow	Small	Round	Yes
Green	Small	Round	No
Yellow	Large	Round	No
Yellow	Large	Round	Yes
Yellow	Large	Round	No
Yellow	Large	Round	No
Yellow	Large	Round	No
Yellow	Small	Irregular	Yes
Yellow	Large	Irregular	Yes

A decision tree utilizes *entropy* to compute the homogeneity from a sample. *Information gain is* another terminology which indicates the mitigation of entropy when a dataset is partitioned based on an attribute. Constructing a node in the DT thus involves finding attribute that produces the maximum *information gain*. Thus, the first Branch of the tree in Fig.1 consist of the attribute *size* because it has the maximum Information Gain (0*.*106) among all the three features [$G(color) = 0.036$; $G(shape) = 0.036$].

In the scikit-learn implementation of the Decision Tree classifier, we have experimented with several parameters such as *maximum depth* of the tree, *minimum samples* to split an internal node, *minimum samples* per leaf node, *maximum number of features* and etc. We have tried different

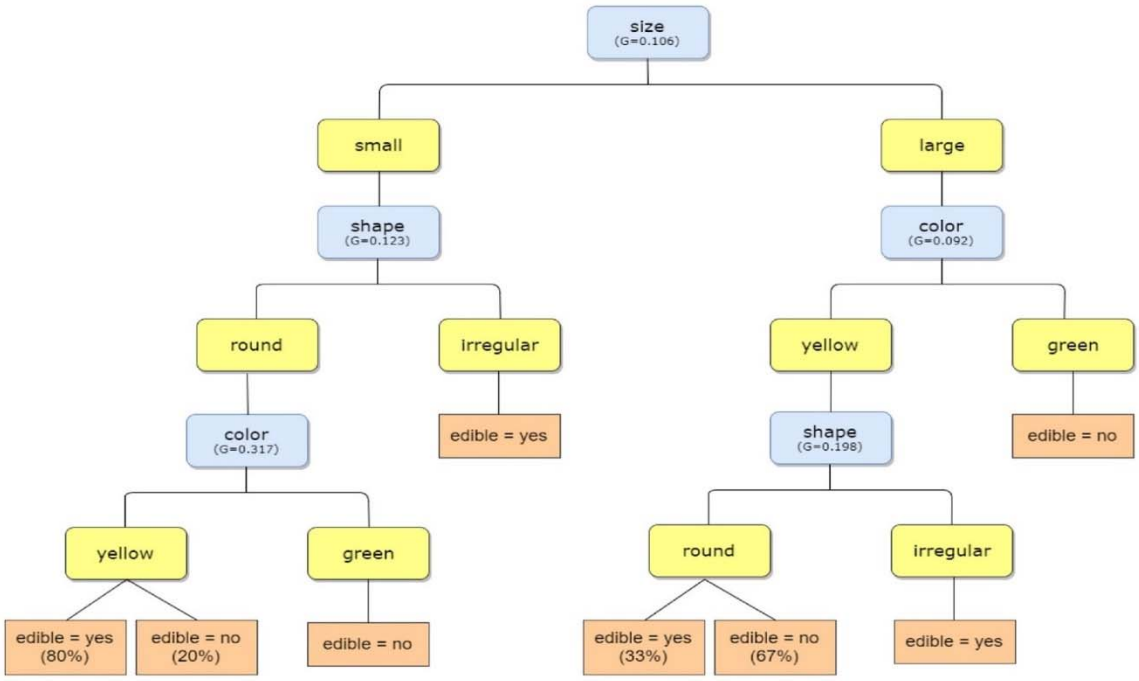

Fig.1. Decision Tree for the dataset of TABLE II.

combinations by changing these parameters. One such setting for example, is given below:

```
DecisionTreeClassifier
(min_samples_split=3,
min_samples_leaf=2, max_depth=10,
max_features=1000)
```

Changing the value of parameter reduces the performance of the classifier from an accuracy of 79.4% (tf-idf feature) and 79.93% (count feature) to 48.47% and 47.4%.

C. K-Nearest Neighbors

The second classifier that we compared for performing a six-way classification was the K-NN classifier. By experimenting with different values of *K*, we have observed the following phenomenon after plotting the *accuracy* and *f1-score* (Fig.2.). The observations are as follows:

a) Accuracy gets better with a higher K in the observed experiment.

b) The overall performance (both accuracy and f1-score) increases drastically from *K=1* to *K=10*. After that, the curves seem to have more like a plateaued progression having upward trends with some fluctuations.

c) The *bias* for K-NN classifier increases monotonously with the value of *K*, while the variance drops off as *K* is increased. In fact, under reasonable assumptions, the bias of the 1-nearest neighbor (*K=1*) classifier disappears completely with the size of the training data approaching infinity.

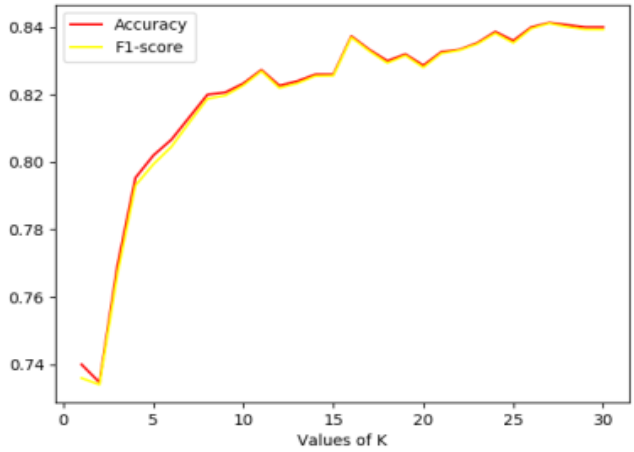

Fig.2. Performance of K-NN classifier for different values of K.

A comparison based on *time* (in seconds) taken for training and testing the other two classifiers with K-NN is given below in Table III.

TABLE III. COMPARISON OF TRAINING AND TESTING TIME.

	NB	**DT**	**KNN**
TRAINING(S)	0.906	3.914	0.789
TESTING(S)	0.215	0.208	1.015

From Table III, we can see that the different classifier has different training and testing time. The lowest training time is achieved by K-NN classifier (0.789) while the highest training time is for Decision Tree (3.914). The testing time, on the other hand, is highest for K-NN (1.015). These training and testing time heavily depend on the architecture of the classifier itself. As building tree takes linear time $O(n)$ with a searching cost of $O(\log n)$, the overall complexity gets high for DT. For Naïve Bayes it's fairly simple, it takes only the time to construct the frequency table and the multiplication time to calculate the conditional probability of the individual words. On the contrary, K-NN has properties that are quite different from most other classification algorithms. Training a K-NN classifier simply involves the task of determining *K* and preprocessing documents. In fact, if we pre-select a value for *K* and do not pre-process, then K-NN requires no training at all. For *n* samples in *D* dimensions, the test time for k-NN is $O(\text{D n log } n)$. It is linear in the size of the training set as we need to compute the distance of each training document from the test document. Test time is independent of the number of classes. K-NN therefore, has a potential advantage for problems with large class size.

D. Multinomial Naïve Bayes

The third classifier that we have used is the "Multinomial Naive Bayes" classifier which is a slightly modified version of the Naive Bayes classifier. The only difference is that while the Naive Bayes works with conditionally independent features the modified Multinomial version could be used to estimate the likelihood of conditionally dependent features by considering them as independent features. As it uses a bag of word feature in the text, it assumes that there is no relation between each word through the text, which is okay as long as we don't consider the semantic relationships of words in a sentence or among the sentence.

V. RESULTS AND EVALUATION

In this section, we will compare the results of three different classifiers mentioned in the previous section (Section III). For our evaluation purpose, we considered *accuracy*, *precision*, *recall* and *f1-score* based measures. We have also used a *10-fold cross validation* over the entire dataset for further evaluation regarding each type of classifiers performance.

For the purpose of simplification, we have only illustrated the comparison of the overall score (micro average) for the three classifiers (Table IV and V). Based on the comparison, we have chosen *Multinomial Naive Bayes* classifier with *Tf-Idf feature* as our *Best Model*. A detailed result for each of the class label for the best model is depicted in Table VI.

TABLE IV. COMPARISONS OF RESULTS FOR DIFFERENT CLASSIFIER (TF-IDF FEATURE).

Model	**Accuracy**	**Precision**	**Recall**	**F1-Score**
DT	0.788	0.794	0.788	0.790
KNN	**0.826**	0.831	0.826	0.826
NB	**0.918**	0.920	0.918	0.918

TABLE V. COMPARISONS OF RESULTS FOR DIFFERENT CLASSIFIER (COUNT FEATURE).

Model	**Accuracy**	**Precision**	**Recall**	**F1-Score**
DT	**0.796**	0.802	0.796	0.798
KNN	0.591	0.613	0.591	0.590
NB	**0.905**	0.908	0.905	0.905

TABLE VI. DETAILED RESULTS OF MULTINOMIAL NAÏVE BAYES CLASSIFIER.

	precision	**recall**	**F1-score**	**support**
Books	0.935	0.923	0.929	233
Camera	0.862	0.942	0.900	258
DVD	0.920	0.901	0.910	242
Health	0.971	0.840	0.901	243
Music	0.947	0.962	0.954	260
Software	0.892	0.936	0.913	264
Avg/Total	0.920	0.918	0.918	1500

To have a clearer look at the accuracy results, we have also evaluated our classifiers with the 10-fold cross-validation scheme. These are depicted in Table VII.

TABLE VII. 10-FOLD CROSS VALIDATION ACCURACY RESULTS FOR THREE DIFFERENT CLASSIFIERS(BASED ON BEST RESULTS).

Folds	**NB**	**DT**	**KNN**
Fold-1	0.926	0.797	0.856
Fold-2	0.863	0.778	0.810
Fold-3	0.882	0.750	0.796
Fold-4	0.893	0.800	0.793
Fold-5	0.886	0.731	0.825
Fold-6	0.812	0.731	0.731
Fold-7	0.792	0.772	0.778
Fold-8	0.926	0.832	0.852
Fold-9	0.872	0.757	0.750
Fold-10	0.858	0.723	0.777

VI. CONCLUSION

From the result section, we can see that the overall accuracy for Multinomial Naive Bayes classifier for the task of topic classification in our experiment was 91.8% which is better than Decision Tree (79.6%) and K-NN (82.6%) classifier at their best settings. This is the prime motivation behind selecting *Multinomial Naive Bayes* as our best model. Again, the time consumed by MNB (Table III) is a good trade-off in terms of both training and testing perspective. The approach that MNB takes is also straight forward to understand as it directly considers the prior and posterior probabilities for classification purpose and there is no further complexity under-the-hood. We have used three different pre-processing techniques in our experiment. Although, it would have been nice to incorporate other normalization and feature selection techniques to see if the result improves or not, nevertheless what we have achieved is pretty much similar to the state-of-the-art systems in this domain.

***Abstract*—Digital contents in Bengali text are increasing with the advancements of World Wide Web (WWW) to express the sentiment of content originators from mixed perspectives. These high voluminous unstructured web contents can be utilized to build smarter tools to assist people through Natural Language Processing (NLP). Though Bengali NLP tools are still inadequate due to its inherent complexities, research on Sentiment Analysis in Bengali is flourishing as a challenging area and is getting researcher's attention at a rapid pace. To do research in this area, researchers spend a lot of their time to investigate previously published works to understand the advancements for further enhancement; one of the most stressful and challenging parts of research. In this regard, we are going to demonstrate domain specific available pre-processing steps along with existing research methodologies, respective datasets and evaluation metrics of notable works related to sentiment analysis of Bengali language as our research finding. Moreover, we also incorporate a series of directions for future researchers to augment their research in this exciting domain.**

Keywords: *Sentiment Analysis*, *Opinion Mining*, *Machine Learning*, *Information Extraction*

I. Introduction

Textual documents in Bengali are continuously increasing together with web contents of other languages on the World Wide Web (WWW) consisting of our regular activities like enhancing Banglapedia[1], producing social media posts, publishing documents of financial and economic markets, spreading political views, sharing reviews of online products along with published online news and so on. These available web information express originators sentiments and emotions toward various topics in daily life and they are important to make human decisions as well as for making automatic decisions through machines. Though, human being can extract sentiment in a limited extent by utilizing their intuitive learning, machines are incapable of doing so. In this regard, researchers performed their research in the last few decades all over the world to develop smarter methods by experimenting with classical machine learning and statistical tools to detect major properties of the text including subjectivity detection and emotion or polarity detection. The subjectivity detection determines the text is either subjective or objective, while the polarity detection asserts that the text is either positive, negative or neutral[1].

Furthermore, textual documents of a language are analyzed from document level, sentence level, phrase level or lexical level perspectives. The analysis in these perspectives are performed using supervised, unsupervised, semi-supervised or case based reasoning techniques[2]. In the supervised approach, researchers applied classical machine learning models, such as Naïve Bayes (NB), Maximum Entropy (ME), Artificial Neural Network (ANN), Support Vector Machines (SVM), whereas Latent Dirichlet Allocation (LDA) and theme based clustering are used as unsupervised techniques[3][4]. Moreover, graph based [5] and deep learning[6] approaches are also applied as modern trend for Sentiment Analysis (SA) research now-a-days.

Additionally, domain-specific data plays an important role in SA research; however, the lack of annotated and standard benchmarking datasets make the research much harder in this area[7]. Research in these multi-domain areas is considered as a part of Natural Language Processing (NLP) tasks which attract research community to perform their research[8]. As a result, researchers have developed a series of language-specific NLP tools to extract text properties of many languages like *Arabic, Hindi, Chinese, Czech, French, German, Italian, Japanese, Russian, Thai* to enrich their linguistic area for knowledge extraction[9]. In spite of having some research works in SA on the Bengali language, this area is still underdeveloped and therefore, research in this area would provide extensive opportunities to develop linguistic NLP tools for analyzing Bengali texts in the next few decades. In this connection, it is important for researchers to understand the chronological improvement in this area because imminent research constantly relies on the advancement of outcomes of previous works.

The rest of the paper is organized as follows. **Section II** introduces general terminologies together with related processing activities. Overview of a system related to SA is articulated in **section III**, while **section IV** focuses on the review of SA research along with our judgment in Bengali language text. Concluded remarks in addition to some directions for future research are described in **Section V**

[1]http://bn.banglapedia.org/

II. General Terminologies and Related Processing Activities

In this section, we introduce some definitions of general terminologies along with various processing activities of SA research those are found in our investigation. This will help researchers to understand the essence of our review on textual documents of Bengali language.

A. Sentiment Analysis and Emoticons

Sentiment Analysis (SA), also known as Opinion Mining (OM) refers to extract the subjective impressions or attitudes of content originators from published texts in terms of topics or contextual polarity through the use of NLP, statistics or classical machine learning techniques. On the other hand, emoticons are graphical facial expressions that represent the meaning of verbal communications without observing the change of body language. These pictorial presentations express a range of tone or feeling which plays an important role in social media as well as messaging in cyber-world[10][11]. The Fig.1 represents a snippet of Bengali text document that includes emoticon, hash tags, punctuation, and URLs.

'আয়নাবাজি' দেখে এলাম; যেমন ভেবেছিলাম, তার চেয়েও হাজার গুন ভালো লেগেছে :) ছবির এই দৃশ্য অসাধারণ ছিল http://images.myreviewsite.com/aynabaji.jpg। সময় করে দেখে নিন। #আয়নাবাজি #Aynabaji

Fig. 1. A snippet of document written in Bengali language

B. Stop Words, Punctuation, Hash Tags and URL Removal

Single letter words or less influential extremely high frequent words known as stop-words should be filtered out before processing the text. Since stop words and punctuation characters have no association with sentiment polarity, they are also removed by using their Unicode representations. Uniform Resource Locators (URL) are used to identify resources in the WWW but have no significance in SA. Moreover, hashtags in social networks are also marked with a number sign (#) in front of a word or unspaced phrase in a document[12][13]. The Fig. 2 shows the output of Fig. 1 after removing stop-words, punctuations, hash tags and URLs to understand the significance of this process in SA.

আয়নাবাজি দেখে এলাম ভেবেছিলাম হাজার গুন ভালো লেগেছে ছবির দৃশ্য অসাধারণ সময় দেখে নিন

Fig. 2. Stop-Words, Punctuation, Hash Tags and URL remove from Fig. 1

C. Tokenization and Normalization

Tokenization or text segmentation is a process of dividing the written text into meaningful units or tokens, such as words, sentences, or topics delimited by whitespace, tab, new line and so on. In bag-of-words approach, each input sentence is tokenized into words which act as the primary features of SA. Normalization is the process of converting each token into unified scale for further processing. The Fig. 3 demonstrates the process of tokenization of texts after removing stop-words, punctuations, hashtags, URLs of Fig. 1 to close look the process of recognized individual words in a system.

'আয়নাবাজি', 'দেখে', 'এলাম', 'ভেবেছিলাম', 'হাজার', 'গুন', 'ভালো', 'লেগেছে', 'ছবির', 'দৃশ্য', 'অসাধারণ', 'সময়', 'দেখে', 'নিন'

Fig. 3. Tokenization of words from Fig. 2.

D. Vectorization

Vectorization is a process to reconstruct a collection of texts in a document into numerical feature vectors. A document is considered as a collection of words with or without considering the information of their relative position. High frequent words having very little meaning must be excluded to prioritize rarer yet more interesting terms in the corpus. In order to reweight these count features into floating point values, Term-Frequency and Inverse Document-Frequency ($TF-IDF$) transformation or word embeddings are used. Fig. 4 illustrates the vectors of words of Fig. 1 after removing less important words and performing tokenization operation.

(আয়নাবাজি, 9), (দেখে, 34), (এলাম, 69), (ভেবেছিলাম , 54), (হাজার, 21), (গুন, 60), (ভালো, 45), (লেগেছে, 11), (ছবির, 76), (দৃশ্য, 51), (অসাধারণ, 75), (সময়, 23), (দেখে, 34), (নিন, 97)

Fig. 4. Vectorization of text from Fig. 3

E. Stemming and Lemmatization

Stemming is used to reduce inflectional forms of a language by splitting a word into its constituent root part and affix without doing the complete morphological analysis. As Bengali is a highly inflected language with pragmatically free word order i.e., Bengali (verb, noun, adjective) words are inflected forms of roots stemming is performed on the tokenized words[14] to reduce the dictionary size. In Fig. 5, we portrayed stemmed words of sentences that are given in Fig. 1 to comprehend the essence of a stemmer in SA. On

'আয়না', 'দেখ', 'এল', 'ভাব', 'হাজার', 'গুন', 'ভালো', 'লাগ', 'ছবি', 'দৃশ্য', 'অসাধারণ', 'সময়', 'দেখ', 'নে'

Fig. 5. Stemmed words from sentences of Fig. 1

the other hand, $lemmatization$ is the process of grouping different inflected words so that these words analyzed as a single item. Though the stemmer operates on a single word without contextual knowledge, lemmatization process understands the context of a word in a sentence. To familiar with the lemmatized words as output Fig. 6 is given to demonstrates the importance of lemmatization process.

'আয়নাবাজি', 'দেখে', 'এলাম', 'ভেবেছিলাম', 'হাজার', 'গুন', 'ভালো', 'লেগেছে', 'ছবির', 'দৃশ্য', 'অসাধারণ', 'সময়', 'দেখে', 'নিন'

⇓

'আয়না', 'দেখ', 'এল', 'ভাব', 'হাজার', 'গুন', 'ভালো', 'লাগ', 'ছবি', 'দৃশ্য', 'অসাধারণ', 'সময়', 'দেখ', 'নে'

Fig. 6. Lemmatization after tokenization of contents of Fig. 1

F. Parts-of-Speech (POS) Tagger

Automated POS tagger is used as a NLP tool to detect each word with a corresponding POS in a sentence. It helps

to verify and validate textual data, annotate named entities in the large corpus, translate one language to another language, correct the grammatical errors, and so on. As a result, Bengali POS tagger is an essential tool to enrich Bengali language, especially in the area of NLP. To comprehend the influential effect of a POS tagger, the Fig. 7 recognize respective POS of texts those are given in the Fig. 1.

'আয়না_NN', 'দেখ_VRB', 'এল_VRB', 'ভাব_VRB', 'হাজার_NN', 'গুন_NN', 'ভালো_ADJ', 'লাগ_VRB', 'ছবি_NN', 'দৃশ্য_NN', 'অসাধারণ_ADJ', 'সময়_NN', 'দেখ_VRB', 'নে_VRB'

Fig. 7. Parts-of-Speech Tag of words of contents in Fig. 1

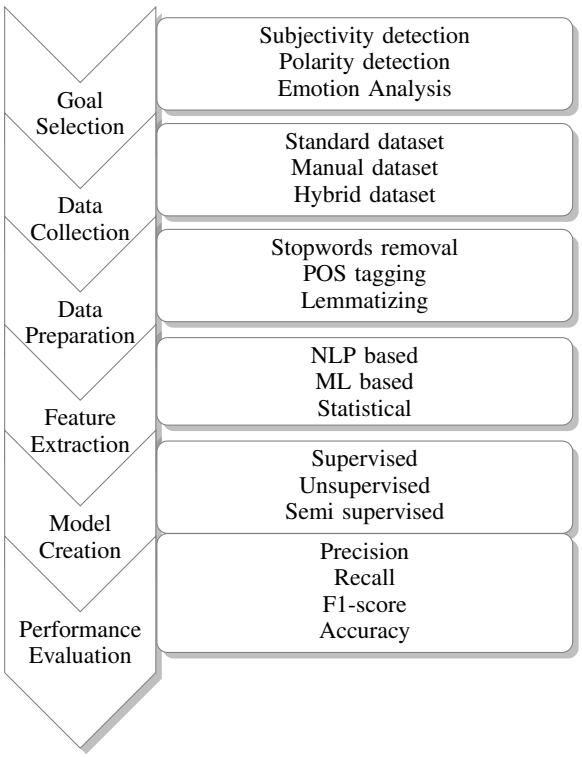

Fig. 8. Steps in a Sentiment Analysis System

G. WordNet and SentiWordNet

$WordNet$ is a lexical database of English language having nouns, adjectives, verbs and adverbs grouped into sets of cognitive synonyms called $synsets$. This database is used for word-sense disambiguation, information retrieval, automatic text classification, text summarization, machine translation and so on. On the other hand, $SentiWordNet$ is a lexical resource for SA which assigns three numerical sentiment scores (positivity, negativity or objectivity) to each synset of WordNet for the quantitative analysis of associated synsets and the use of vectorial term representations for semi-supervised synset classification[15].

III. Overview of a Sentiment Analysis System

*S*entiment *A*nalysis (SA) is a complex system that follows step-by-step logical phases to execute specific operations to achieve particular goals of the research. These phases of SA system are demonstrated in Fig. 8 to figure out the significance of SA research.

a) Goal Selection: Considering the application areas and associated text properties, the system goal is defined in the first phase which determines whether the given text is subjective or not. If the text is identified as subjective then the polarity is extracted and emotional level is investigated by quantifying sentiment scores.

b) Data Collection: Domain-specific datasets play an important role to achieve the desired goal where they can be either standardized or manually developed for benchmarking. Though standard benchmark datasets are available for some rich languages, most of the low resource languages use manual dataset either created by the expert system or crawling diverse online sources by custom crawlers.

c) Data Preparation: Raw data consisting extraneous noise like emoticons, stop words, punctuations, hashtags, $URLs$ must be removed. In this phase, stemming or lemmatization is used for highly inflected languages to convert words to its base form while POS tagger is used to detect each word with a corresponding POS in a sentence.

d) Feature Extraction: Influential features having a positive impact on the performance of the system can be examined from various perspectives such as NLP, Machine Learning (ML) or Statistical. For NLP based feature extraction, the system implements linguistic knowledge where ML approaches use training on corpus data and the statistical techniques consider the weighted importance of features in the system.

e) Model Creation: Selected features from the feature extraction phase are fed to a model that can be either lexicon based, supervised, unsupervised or semi-supervised. As a supervised model, NB, ME, SVM, ANN can be considered where clustering approaches and bootstrapping are considered as unsupervised and semi-supervised models respectively.

f) Performance Evaluation: The performance of SA system is evaluated by several metrics including expert analysis, precision, recall, F-score, accuracy to justify the acceptance of the system under considerations. Therefore, remarks on limitations and future directions are given by discussing the performance of a system.

IV. Sentiment Analysis in Bengali Language

Numerous amount of textual electronic documents in the Bengali language from diverse domains such as online news portals, social media text, online product reviews and so on are published on the WWW and it is continuously increasing where subjective information plays a great role from both the user and organizational perspectives. Due to this twofold importance and the exponential growth of Bengali text on the web, researchers are attracted to perform their research in this area. Although Bengali is an highly inflected language suffering from major challenges such as lack of labeled dataset or absence of rich NLP tools[16], researchers performed their individual research in the document level, sentence level, phrase level or lexicon level.

Document level SA represented in [17] use Mutual Information (MI) as a feature extractor for NB classifier. The researchers used Amazon Watch Reviews and their word by word translation in Bengali as datasets. After performing standard preprocessing, the experiment results show that the system works well for Bengali considering negation. But the drawback is word by word translation of the English dataset. Another similar works in [18] utilizes translated Bengali dataset from Amazon watches for polarity detection. But these texts are cross-checked using dictionary word mapping to avoid meaningless sentences. The system recognize positive and negative polarity where each polarity is subdivided into weak, steady and strong. Though the work presents 85% accuracy for Bengali, it requires double translation for negation handling. In [19], the authors use NB classifier to extract sentiment from Facebook user comments (3000 statuses from 70 users) where negations are handled by antonym substitution. Standard preprocessing steps are performed before stemming operation extract bigram as features. The system demonstrates 77% precision but the small size to dataset is a limiting factor in this work. Relating to that, researchers in [20] claims NB model is incapable to detect complex multi-line sentences of a document for SA. The system results 83.20% accuracy for NB with bigram, stemmer, and normalizer. It also shows that WE performs better when the the dataset size is increased. Moreover in [21], the authors claim that NB classifier is ineffective for social media texts as these texts are not well written by maintaining a standard format. Using Facebook user comments on food reviews as dataset, the work represents lexicon-based approach for SA. Though they claim that dictionary-based approach exhibits better accuracy; however, they do not perform any sort of experiments to evaluate performance metrics regarding their statement.

Sentence level polarity detection on twitter posts is presented in [22] where the authors us SVM and ME text classifiers. This work demonstrates semi-supervised bootstrapping method where a small labeled dataset is used to label other unlabeled texts and generate sentiment lexicon. Investigators consider several features in this scholary work and show that SVM (accuracy 93%) outperformed ME (accuracy 85%). Relating to that, polarity detector for Bengali online news texts is presented in [23] where the authors utilize several features in SVM classifier. Separating subjective texts from the acquired dataset, authors use sentiment lexicons from SentiWordNet(Bengali)[24] in order to score the sentences. The system considers many features like POS tags, chunk level information, functional words, stemming cluster, negative words, and dependency tree features. The experimental result by considering all of these features demonstrate precision of 70.04% where the baselines are 63.02%. Moreover in [25], the authors investigate linear and non-linear SVM using N-gram based modeling on diverse social media documents. The system preprocess manually collected data and shows that N-gram vectorization approach results in highest accuracy 91.581% and 89.271% for linear and non-linear SVM respectively. Another traditional SVM based SA system having accuracy of 64% on Bengali cricket review is done in [26].

Furthermore, word level experiment is performed in [38] by demonstrating data standardization techniques where the automatic translation process is accomplished to organize positive and negative words of SentiWordNet. But this elementary research without dataset is less efficient for complex systems and it does not consider Bengali inflected word terms, spelling errors, colloquial terms for sophisticated analysis. Therefore, different researchers perform experiment in [39] to exhibit shared SA task of Bengali tweets along with Hindi and Tamil. Since the datset is very small, this work in not compatible with modern deep learning techniques. On the other hand, one more research in [27] presents a theme cluster-based approach in a corpus developed from news and blog domains to recognize the subjectivity of texts. As a subjectivity classifier researchers deal with various features in their experiment and they examine the results by using Samsad English-Bangla Dictionary, Multi-Perspective Question Answering ($MPQA$) corpus and International Movie Database ($IMDB$). In addition, document-level SA in [28] propose Contextual Valence Analysis (CVA) for polarity detection in Bengali language texts using WordNet and SentiWordNet. To evaluate the proposed system, authors use expert analysis to justify the approach to a satisfactory level. The deficiency of this work is the earlier translation process from Bengali to English to perform their analysis. One more research on horoscope data is observed in [30] where the data are annotated by two native speakers and when disagreement appears between them, a third annotator finally annotate these sentences. After the dataset preparation, five classifiers are trained (NB, SVM, $K-Nearest\ Neighbours$ (KNN), Decision Tree (DT) and Random Forest (RF)) with their different parameters. Among these five classifiers, SVM with unigram features produce an accuracy rate of 98.7% as the best sentiment classification model. Relating to that in [34], the authors demonstrate SVM outperforms NB when applied to a manually developed Bengali movie review dataset. The system also provides a comparative analysis on different features having precision of 0.86 while considering stemmed unigram in SVM classifier. In the same fashion, sentence level research introduces deep learning methods for both plain Bengali and Romanized Bengali texts to extract the sentiment in the context of either positive or negative polarity [29]. In this research, they use binary cross entropy and categorical cross-entropy as loss functions with Recurrent Neural Network (RNN) specially Long Short Term Memory ($LSTM$) model. The major challenge of this research is lack of standard and large dataset since deep learning models require a huge dataset compared to other machine learning models. The successive research in [32] shows the Word Embedding (WE) with Hellinger PCA can be useful for detecting sentiment from Bengali text. In this stage, WE extracts the syntactic context of the words rather than the sentiment words. The authors implement Sentiment Specific Word Embeddings ($SSWE$) to recognize their respective sentiment in this research. The results depict that the performance can be increased with large corpus. In

TABLE I
SUMMARY OF INVESTIGATION OF SENTIMENT ANALYSIS ON BENGALI LANGUAGE

Paper	Analysis	Context	Dataset	Preprocessing	Methods	Result
[27]	Subjectivity Detection	Reviews, news, blog sites	Manual, Standard	POS tagging, clustering	CRF	Precision - 72.16% and 74.6%
[28]	Document Level		Manual	Word translation, sense values from SentiWordNet	CVA	
[17]	Document Level	Product reviews	Manual	Review rating selection, stopwords removal, negation handling	NB	Accuracy - 85%
[29]	Sentence Level	Social media, news, product reviews	Manual	Emoticons, proper noun removal	RNN (LSTM)	Accuracy - 70%
[30]	Sentence Level	Horoscope	Manual	Punctuations, stopwords removal, IG index	NB, SVM, KNN, DT, RF	Accuracy - 98.7% (SVM)
[18]	Sentence Level	Product reviews	Standard	Translation, negation handling	NB	Accuracy - 85%
[19]	Sentence Level	Social media	Manual	Hashtag, url removal, stemming	NB	Precision - 77%, Recall - 68%, F-score - 72%
[22]	Sentence Level	Social media	Manual	Tokenization, normalization, POS tagging	SVM,ME	Accuracy - 93%
[31]	Sentence Level	Social media	Manual	Removal of punctuation marks, extra spaces, unrecognized characters	word2vec, WE	Accuracy - 75.5%
[32]	Sentence Level	Microblogging sites	Manual	Removal of punctuation marks, extra spaces, unrecognized characters	WE	Accuracy - 70.0%
[23]	Phrase Level	News	Manual	POS tagging, clustering	SVM	Precision - 70.04%, Recall - 63.02%
[33]	Sentence Level	Social media	Standard	Special characters removal, irrelevant features removal, word level sentiment polarity tagging	CNN	Accuracy - 46.80%
[25]	Sentence Level	Social media	Manual	POS tagging, emoticons and punctuation removal, stemming, negativity separation	SVM	Accuracy - 91.684% and 89.271%
[34]	Sentence Level	Social media	Manual	URL, emoticon, punctuation, stop words removal	NB, SVM	Precision - 0.86%
[26]	Sentence Level	Reviews, Social Media	Manual, Standard	Tokenization, stop words removal, punctuation and number removal	SVM	Accuracy - 64%
[35]	Sentence Level	Social Media	Manual, Standard	Emojis, symbols, numbers, stickers, English letters removal	RNN	Accuracy - 85.67%
[36]	Sentence Level	Reviews, Social Media	Manual	Non Bengali character and symbol removal	Word2Vec	Accuracy - 83.79%
[37]	Sentence Level	Social Media	Manual	Tokenization, URL, punctuation, user tags, mentions and stop words removal	LSTM, CNN, NB, SVM	Accuracy - 65.97% and 54.24%

addition, the research in [31] depicts words2vec model for Bengali SA in the sentence level; where researchers claim that WE of sentences determine the characteristics of words and their respective context. In this research, investigators remove all noise from the data source through some general preprocessing steps. Then positive and negative scores are calculated using both syntactic score and mutual score among these data. Although the performance is low, the authors use WE to capture the sentiment properties of words in a sentence. Researchers also neutralize the effects of valence shifting words by using threshold value for highly positive and highly negative in their corpus. With the recent improvements in deep learning techniques, authors in [33] develop a SA system based on deep Convolutional Neural Network (CNN) for twitter dataset[39]. The proposed method includes preprocessing for removing special characters, irrelevant features and lexical level sentiment polarity from Sentiwordnet[24]. In order to compare the performance, the authors have implemented a traditional Deep Belief Network (DBN). More related deep learning based systems in [35] and [36] shows that the scarcity of benchmark dataset in Bengali poses a challenge for deep learning techniques in SA task. Table I provides a summary of discussed notable research works in Bengali SA task.

V. CONCLUSION

This review article demonstrates existing procedures, achievements, and limitations of available works of Sentiment Analysis (SA) on Bengali texts. In our findings, we represent

preprocessing steps regarding the domains, context of research, comparisons of different experimental methods as well as performance evaluation of a system which will help the new researchers to do their research in this field. In our judgment, a small number of evaluation metrics are satisfactory regarding problem domains on Bengali texts; however, there are a large number of domains available that are not explored till now and hence it can be an exciting field to contribute. Moreover, Bangla Natural Language Processing ($BNLP$) tools, standardized datasets for benchmarking are not up to date for Bengali language to develop SA system effectively which must be kept in mind during the future experiments.

***Abstract*— This Scientific Research paper is a synopsis of an automated system "Doly: Bengali Chatbot" which gives a reply to a user query on behalf of a human for the education system in the Bengali language. This is an AI-based Chatbot system, mainly based on machine learning algorithms and Bengali Natural Language Processing (BNLP). The machine gets embedded with this knowledge to identify the desired sentences and making a decision within itself, as a response to answer questions. There are many English Chatbot's which used in education, web query, banking sector & various sectors. In this case, we've propounded a complete data-driven retrieval based closed domain Chatbot which is easily colloquy in the Bengali language with the users. We've created the train function adapter to train the Doly by encoding (encoding="utf8") our corpus from bot data. An input adapter has been created to take input and for output, an output adapter has been created to generate automated responses to a user's input. We've also used a machine learning algorithm like search algorithm for finding an appropriate list of matching results from the corpus and use Naïve Bayesian algorithm to select right answer form list of matching result. The main aim of this Chatbot based system is to bridge the gap between the knowledge sources by providing instant replies to the questions and queries that have to ask in the Bengali language.**

***Index terms*--- Chatbot, Dialogue & Corpus, Naïve Bayesian algorithm, AI, Bengali Natural Language Processing (BNLP).**

I. INTRODUCTION

By Technology-based education, learners can easily get access to unlimited online resources. It creates huge facilities for technical learning, distance learning, and self-learning. Nowadays chatbot is using as an only one learning platform for the education system. Personal education chatbot will help students to interest by self-learning & also it can also remove the dependency from tutor & other technology. The chatbot is a conversational intelligent agent that can easily communicate with human users by using Natural Language Processing. It is likewise known as a chatterbot, Bot, IM bot, talkbot, Interactive agent, or Artificial Conversational Entity. The user can interact with the bot in written, oral, or mixed format of conversation. The applications of chatbots can be applied in various fields such as Health, Tourism Business,Customer Confirmation and so on. The architecture of Chabot integrates language models with computational algorithms. Normally, a chatbot works by a user asking a question or developing a comment and replying the question or initiating a new topic. We can deliver instance examples of Cleverbot [1] ALICE [1] etc.The Bengali language is the main language of Bangladesh and the fourth most popular language in the world. Bangla is spoken by about 245 million people of Bangladesh and two states of India [3]. The literacy rate of Bangladesh is 75.4% and the numbers of total students are 23,907,151. The rate of literacy is increasing day by day in Bangladesh. Nowadays the educations system is being dependent on Intelligent Instructing Systems of computer circumstance for education.This is why the paper proposes the Bengali language chatbot named 'Doly' based on the Bengali language with the help of Natural Language Processing (NLP) as well as Machine Learning (ML) techniques for developing an education tool of Bangladesh. The trial spectacle is that our chatbot is capable to impart responses to the users in the real time. To constructing Bengali chatbot 'Doly', we installed Python 3.7.0 & Anaconda in our Machine. For Natural Language Processing (NLP) we installed Natural Language Toolkit (NLTK). We also need to install Chatterbot that comes with built-in adapter classes that allow it to connect to various types of databases. We can't run directly the Bengali chatbot in chatterbot as it did not support Unicode.As a Unicode Decode Error for the implementation of Bengali chatbot 'Doly', we have to encode Bangla NLP with a chatterbot. We created the train function adapter to train the Doly by encoding our corpus from bot data. It this case we use encoding="utf8" in our .yml corpus to read Bengali data. To take input we created an input adapter and for output, we created an output adapter to generate automated responses to a user's input. This makes it easy to create chatbots and automate conversations with users. The task separated by four parts, training data, input data, process input, and return response or output. We also use machine learning algorithm like search algorithm for finding the appropriate list of matching results from the corpus and also use a Bayesian algorithm to select right answer form list of matching result.This paper described a created chatbot that returns a relevant answer to questions asked by the user in Bangla language.

The contributions are summarized as follows:

- We have proposed a Bengali chatbot as 'Doly' by imparting Bengali Natural Language Processing.
- For the pre-processing Bengali language, we have created our own BLTK tool in python.
- As algorithms, we have used Naive Bayes classifier and popular algorithm Edit distance of dynamic programming
- Various adapters were developed for our proposal task.

The paper is composed as follows, Section 2 gives the details of the related works on the chatbot technology. Section 3 contains the Bengali Natural Language Processing (BNLP). Section 4 described the design and methods used for Creating Doly: Bengali Chatbot. In section 5 offers the results and analysis. Section 6 included Comparison between others Chatbot. Section 7 concludes research work with future directions. Finally, Section 8 highlights the conclusion.

II. Related Work

Weizenbaum, J. et al.[1] discussed the first idea of chatbots originated in the Massachusetts Institute of Technology [2] where the Eliza chatbot (also known as "Doctor"). The users of this chatbot imagined Computer programs really could hear their problems and understand, and help them in a constructive way. There are other chatbots called ALICE that used heuristic pattern matching to follow the rules from the input [3].Breazeal, C. et al.[4] research has a robotic chat-bot which understand and relate to users in human or social terms, adapt and learn throughout their lifetime. It also communicates with users. Vinyals, O. et al.[5] discuss the converse model in natural language interaction that predicting the very next command given the previous command in conversations. Bickmore et al.[6] researched agent based chatbot. This chatbot is relational computer agents that they mapping social-emotional relationships for users. An artificial intelligence chatbot like Jabberwacky [7], that studies language and context-based human interactions. To find appropriate response to some stored data such as conversations and comments.Bickmore et al.[8] also research a relational agent which applied different relational behaviors to establish social bonds with museum visitors and evaluate the ability of an experimental relational agent to comfort users in stressful situations [9]. Cassell, J. et al.[10] The most popular agent called Rea that shows non-verbal behaviors such as hand gestures, facial displays, an eye gaze, body posture etc. This behaviors improve the effectiveness of communication and can create a more immersive experience for users. Augello et al.[11] proposed a social chatbot model for a communicative skill learning game based on "Social practice" that can choose the most appropriate dialogue. Hill J. et al.[12] shows a different chatbot such as human-chatbot conversations lack in content, quality and vocabulary and human-human conversations over IM.Pan, X. et al.[13] discussed a virtual agents chatbot. They suggested a projection based system virtual party like an environment. In this system, a conversational male user approached by a female character called Christine. Christine also can formulate personal questions and statements. This female character is interested in a male user that involves smiles, headnotes, eye contact, leaning towards. Crutzen, R. et al.[14]studies an information chatbot that helps users to know about sex, drugs, and alcohol use among adolescents. This chatbot also called question related chatbot or search engines. Shawar et al.[15] described existing work on chatbot knowledge acquisition is mainly based on human annotated datasets. Their approaches are helpful to develop sense knowledge for Bangla chatbots, but there are not available of extracting knowledge for the specific task and technical challenges and design issues in Bangla language processing[16]. Shrestha et al. [17] proposed a way is to detect pairs in an email conversation for the work of email summarization. Zhou and Hovy [18] developed a summarization system for technical chats and emails about the Linux kernel.

Unlike these works, we have created a search based chatbot for Bengali language using BNLP. For Bengali Natural Language processing, we have created BLTK and BRE tools.

III. Bengali Natural Language Processing (BNLP)

The Bengali language is the fourth most spoken language in the world. It is the mother tongue of the people of Bangladesh; there are also few parts of India like as Calcutta who talk with Bangla. But it is really a matter of great mournful that the Bengali language deliberated as the low-density language because of the insufficient digitized text element is available in the Bengali language. But nowadays Bengali Natural Language Processing (BNLP) is the most interesting research field and AI (NLP) filed in Bangladesh. Developing an ideal Chatbot is mandatory because it needs a huge database of Bangla Language and must give reasonable answers to all interactions. Due to lack of availability of large Bengali conversation corpus, for the prototype, the system enhanced with a sample hand-crafted dataset for basic interactions. So the main goal of our task is to develop an ideal chatbot in Bengali which will able to interact in Bangla Language as well as building a corpus in Bangla. We name it "Doly".

Fig. 2. Bengali Alphabat.

IV. Proposed Work

We propound a simple encoder and decoder based conversational method of an intelligent agent that will provide for chatbot users an existence with Bengali knowledge base by interactively asking for its characteristic. In the section of BNLP helps to encode or decode Bengali corpus for training, input, and output return. BNLP is also imparted for the pre-processing questions and answer.

In the beginning, 'Doly' is nothing but an unskillful chatbot which introduction herself with no sense of how to connect with conversations. In a certain moment a user inputs affirmation, the store protects the affirmation that they are

given and the affirmation that was in reply. As 'Doly' accepts more input the number of affirmation protected in the library and that it can reply and the accuracy of each answer increase the relation with the input affirmation.

The system chooses the best closest matching reply by investigation the closest matching acquainted statement that matches the input; it then chooses an answer from the chosen of acquainted reply to that affirmation.

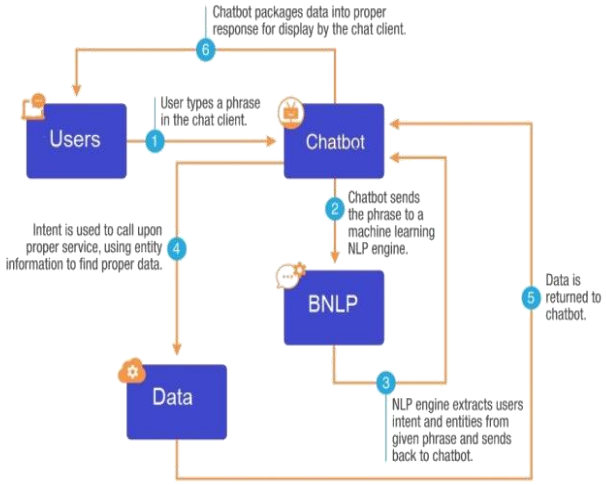

Fig. 1. Propose Model

A. Bengali Corpus

For dialog corpus of Bengali chatbot Doly we made some simple Bengali Language corpus which is saved by .yml or yaml file. YAML is an acronym that keeps for "YAML Ain't Markup Language" which is very immensely common, intelligent, human-friendly and ideal for data serialization for all programming languages. To complete our novel task, we collected 2393 questions and its related answer as our inserted data of Bengali eductions. We separated the whole data as their related group.

```
categories:
- scinece
conversations:
- - ভর কাকে বলে?
  - কোন বস্তুতে পদার্থের পরিমাণকে ভর বলে
- - পদার্থ কি?
  - যার ভর আছে ,স্থান দখল করে,বল প্রয়োগ করলে বাধাঁ সৃষ্টি করে এবং যা পাঁচটি ইন্দ্রিয় দ্বারা অনুভব করা যায় , তাকে পদার্থ বলে।
- - পদার্থ কই প্রকার?
  - তিন প্রকার। যথাঃ (১) তরল পদার্থ (২) কঠিন পদার্থ ও (৩) বায়বীয় বা গ্যাসীয় পদার্থ।
- - মোল কাকে বলে ?
  - দার্থের পারমানবিক ভর বা আণবিক ভরকে গ্রামে প্রকাশ করলে যে পরিমান পাওয়া যায় তাকে সংশ্লিষ্ট পদার্থের এক মোল বলে
- - হাইড্রোজেনের এক মোল সমান কত গ্রাম?
  - ১.০০৮ গ্রাম
- - রেখা কাকে বলে? যার দৈর্ঘ্য আছে কিন্তু ,প্রস্থ ও বেধ বা উচ্চতা নেই তাকে রেখা (line)বলে।
  - যার দৈর্ঘ্য আছে কিন্তু ,প্রস্থ ও বেধ বা উচ্চতা নেই তাকে রেখা বলে।
- - বক্ররেখা কাকে বলে?
  - যে রেখা এক বিন্দু থেকে অন্য বিন্দুতে যেতে দিক পরিবর্তন করে অর্থাৎ সোজাসুজি চলে না তাকে | বলে।
```

Fig. 3. Bengali Corpus use in Doly Chatbot.

B. Environmental setup

Natural Language Processing method and Natural Language Toolkit for Python are provided developing an apparatus in order to explore speech, intelligent explanation and human-like responses. While constructing of Bengali chatbot 'Doly', we introduced Python 3.7.0 to our Machine. Python is a high-level object-oriented language (OOP) which is suitable for scientific examination and tools development. We took the Anaconda as the apportionment of Python. Anaconda creates the best stage for open source data science which is powered by Python. For Natural Language Processing (NLP) we installed Natural Language Toolkit (NLTK). We also need to install ChatterBot that comes with built-in adapter classes that allow it to connect to various types of databases.

Python 3.7.0 is used for the implementation of Bengali chatbot 'Doly' because of providing "Unicode Decode Error". Unicode Decode Error is a runtime error which is caused by non-English language like Bengali with a large number of letters in the alphabet. The Unicode range of Bengali is 0980–09FF which has 11 vowels and 40 consonants. We use encoding="utf8" to encode the Bengali Language Unlike English Language, it has consonant conjuncts, modifier, and other graphemes. So Bengali cannot be set up with ASCII decoding system. In many pre-processing steps, NLTK has no value for the Bengali Language such as to remove a stop word, lemmatization etc. In this case, we've created BLTK for the preprocessing all inserted questions and answer.

Fig. 4. Official Unicode Consortium Code Chart of Bengali.

C. Procedure

We've created the train function adapter to train the Doly by encoding our corpus from bot data. It this case, we've applied the encoding ="utf8" in our .yml corpus to read Bengali data. To take input we've created an input adapter and for output, we've also created an output adapter to generate automated responses to a user's input. This makes it easy to create chatbots and automate conversations with users. The task divided into four parts, training data, input data, process input and return response or output.

1) Pre-Processing: To enable data for the training need to be pre-processed widely. We've applied various types of pre-processing techniques for the best deal with an answer such as anaphora, removing stop words and lemmatization. 'Anaphoric' which describe to a word that is led in a sentence and replacing pronoun from a noun. It needs a successful identification and resolution of Natural language processing (NLP). In the proposed chatbot, we have limned a review of the task done in the field of anaphora resolution in the Bengali language which is the influence of cases on pronouns, mainly personal pronoun. Using the Hobbs' algorithm of Anaphora resolution. Another preprocessing technique is to remove stop words. A stop word removing

is an action which commonly applied to delete a word that does not impress on documents or sentences for an instance of Bengali stop words. The other preprocessing process is lemmatization. Lemmatization is an efficient process to turn a word to its root word. It's one kind of Natural Language Processing and active for imparting in several purposes such as text mining, questions replying or Chatbot and others that boost to deal with root words of any language. In our proposed Chatbot, we've used two novel techniques for lemmatization based on data structure and the hash table of computer programming. The novel techniques are 'BDSEA' and 'Trie'. 'DBSRA' refers to 'Dictionary Based Search by Removing Affix' which is a really easy concept and more suitable for the lemmatization of Bengali words with the lowest time and space complexity.

2) Training Via Corpus Data: This training action authorizes to 'Doly' to be trained through a catalog of strings where the catalog illustrates a conversation. In this case, the order of each response is based on its allocation from a conversation or the list of strings. To instruct the data or corpus we've imparted the train function. In Doly, a lot of corpus data and effectiveness module that trained our chatbot in quickly for communication. We have to simply individualize the corpus data modules that we want to use. This training function approves the 'Doly' to be instructed using data from the dialog corpus that we made. While working with string type data in Python, it is practical to encounter errors. In this case, we use 'utf8' for encoding our corpus. When a chatbot trainer has provided with a data set, it builds the essential way in the chat bot's knowledge graph so that the questions or statement inputs and responses are correctly enacted. It sorted all the states from the corpus like graph sorted database in Fig 5.

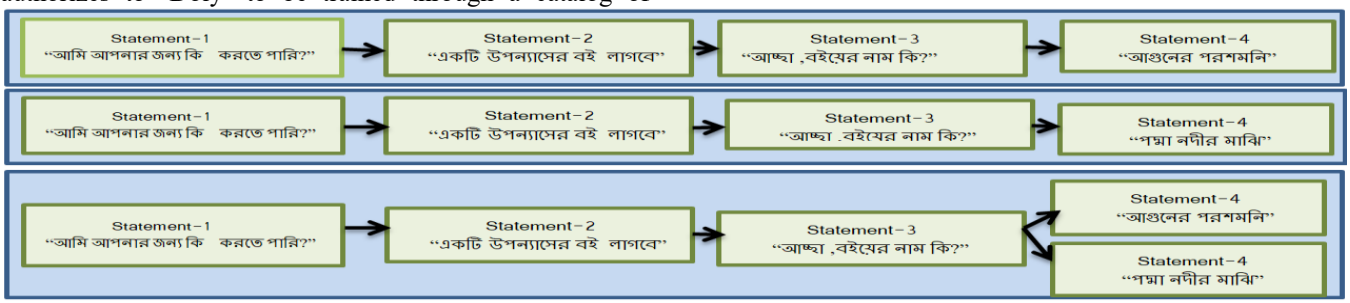

Fig. 5. Training data.

3) Input Adapters: Doly's input adapters are developed to authorize the chatbot to have a versatile method of adoption or restoring input from a given source. Input adapter is applied for getting input from some source, and then to convert it into a format that 'Doly' can access. So we created a format for the affirmation of our inputted data.

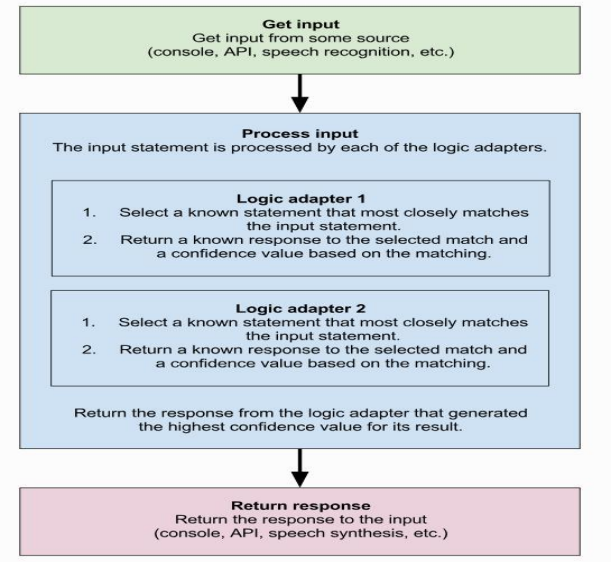

Fig. 6. Process flow diagram of Doly.

4) Process Unit: We've created the procedure of the adopted input. The input affirmations have been applied by an algorithm which would find the best likelihood valued reply for the query. The algorithm has been selected all the acquainted affirmations that most closely resemble with the input affirmation. It will return the acquainted repercussion to the selected match and a confidence estimate value based on matching after computation of each of the response. Here the confidence score is the likelihood value of the response. The algorithm will return the explanation that generated the highest likelihood value for itself.

5) Algorithams: To create 'Doly' we apply different types of machine learning methods to yield its responses. We also use machine learning algorithm like search algorithm for finding the appropriate list of matching results from the corpus and also use a Bayesian algorithm to choose the best possible answer form list of matching result. In probability theory, Bayes' theorem is also known as Bayes' law or Bayes' rule which recounts the probability of a happening, based on previous knowledge of conditions that may be related to the happening. The Bayesian hypothesis is the most common application of Bayes' theorem that is a statistical hypothesis. Testing of the drug, productions, materials as well as computing the entire output of a company based on machines are the one kinds of example.

This theorem states mathematically in the following equation:

$$M(A \mid B) = (M(B \mid A)\ M(A))/(M(B))$$

where A and B are events and $M(B) \neq 0$ and $M(A \mid B)$ is a conditional probability of event A happening given that B is true. Similarly, $M(B \mid A)$ is also a conditional probability happening given that A is true. Yet M(A) and

M(B) are the probabilities of watching A and B independently of each other which is called the marginal probability. In a general way some of the various machine learning and artificial intelligence way that are implemented throughout Doly's methodology.

Search Algorithm: A searching system is a basic principle to find out data form given corpus or database in artificial intelligence. Search is the most momentous part of how Doly quickly and efficiently recuperate the possible statements that it can respond to the user. A few ways of characteristics that help the Doly select a response include

I.The similarity of an input statement to known statements

II.The frequency in which similar known responses occur.

III.The likeliness of an input statement to fit into a category that known statements.

Classification Algorithm: In various types of logical adapters 'Doly' make sense to conduct Naive Bayesian classification algorithms to calculate if an input question is gathered to a particular set of criteria that take a response to be generated from that logic adapter. So simply we can mention that Doly is a Search-based artificial intelligence technique. For the sake of Search-based artificial intelligence, there are also some following optional algorithms implemented in Doly that can be used as the 'statement_comparison_function' for a logical adapter.

Levenshtein distance: Levenshtein distance or editing distance is dynamic programming algorithms where we can measure the minimum number of single characters are dissimilar between two words or strings. In Edit distance there are different sets of string operations such as removal, insertion, or substitution. The Edit distance follow some properties such as (a)A non-negative cost has been edited by every operation (b)For each operation, there is a reverse operation with equal costs.

There are several applications in Levenshtein Distance such as Natural Language Processing and Computational biology.

$$\mathrm{lev}_{a,b}(i,j) = \begin{cases} \max(i,j) & \text{if } \min(i,j) = 0 \\ \min \begin{cases} \mathrm{lev}_{a,b}(i-1,j)+1 \\ \mathrm{lev}_{a,b}(i,j-1)+1 \\ \mathrm{lev}_{a,b}(i-1,j-1)+1_{(a_i \neq b_j)} \end{cases} & \text{or} \end{cases}$$

Equation 1: Levenshtein Distance between two string

Here $a_i and\ b_j$ is an exponent. If $(a_i = b_j)$means the contained character of ai and bj are not unequal there are unchanged and edit=0. Otherwise if $(a_{i!} = b_j)$ then edit=1. If we want to strings lemmatization than we have to check the entire corpus of root words with the inserted sentences through the help of minimal edit distance algorithm. The minimal edit can be greater than zero. If a corpus's word and an inserted string are equal then the edit will be zero or it is changeable.

Synset Distance: For calculating the synonymous similarity between statements, NLTK provides Synset distance. In Bengali words, we developed a corpus of synonymous similarity which covers to implement for data.

Jaccard Similarity: The Jaccard index also called the Jaccard similarity coefficient is a statistic for comparing the similarity and diversity of sample sets which are distant. The Jaccard similarity measured the similarity between finite sample sets and is defined as the ratio between the size of the intersection and union of sample sets. If P and Q be two sets the Jaccard index formula is given

$$\mathrm{J_{index}}(P,Q) = \frac{|P \cap Q|}{|P \cup Q|} * 100 = \frac{|P \cap Q|}{|P|+|Q|-|P \cap Q|} * 100$$

$$\text{here, } 0 \leq \mathrm{J_{index}}(P,Q) \leq 1$$

The Jaccard distance measures dissimilarity between sample sets that are complementary to the Jaccard coefficient.

$$\mathrm{J_{distance}}(P,Q) = 1 - \mathrm{J_{index}}(P,Q) * 100$$

Now, let an example using set notation and Venn-diagram

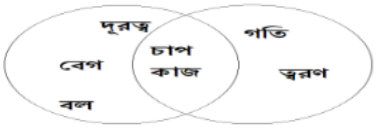

Fig-2: Jaccard similarity.

P= { দূরত্ব, বেগ, বল, চাপ, কাজ },Q= { কাজ, চাপ,গতি,ত্বরণ}

$$\mathrm{J_{index}}(P,Q) = \frac{|P \cap Q|}{|P \cup Q|} * 100$$

$$= \frac{|\{\text{কাজ, চাপ}\}|}{|\{\text{দূরত্ব, বেগ, বল, চাপ, কাজ, গতি, ত্বরণ}\}|} * 100$$

$$= \frac{2}{7} * 100 = 28\%$$

$$\text{And } \mathrm{J_{distance}} = 1 - \mathrm{J_{index}}\% = 1 - 28\% = 72\%$$

So,we conclude four postulates such as (a) If $J_{index} = 50$ similar which means the sets share all members.(b)If $J_{index} \ll 50$ similar which means the sets share few members. (c) If $J_{index} \cong 50$ similar which means the sets share half of the members. (d) If $J_{index} = 0$ similar which means the sets share no members.

D. Logic Adapters

The Logical adapters are identified as the logic for making responses of a conferred input statement or question by a Chatbot. The logical adapter which Doly used can be determined by applying the logic adapters parameter to the recruitment path of the logic adapter that needs to use. It is pretty possible to input any number of logic adapters for our chatbot in order to make jurisprudence. If multiple adapters are exercised, then the chatbot will retire the response with the best-enumerated confidence value.

E. Response Selection Method

Response selection methods determine which response should be used in the event that multiple responses are generated within a logic adapter. Doly uses Statement objects to hold information about things that can be said. An important part of how a chat bot selects a response is based on its ability to compare two statements to each other. This module contains various text comparison algorithms designed to compare one statement to another.

We use the get first response method for the selection of a response. This method takes the input statement and selects the statement in the knowledge base which closely matches the input to the chatbot from a list of statement options to choose a response from.

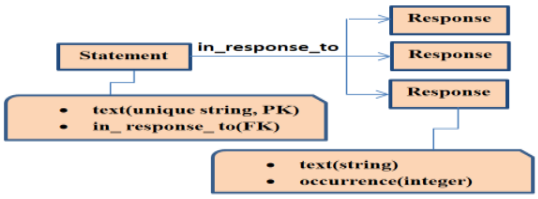

Fig. 7. Response System.

V. Results & Analysis

The difficulty of appraisal is intrinsic as each conversation having an effect on each other and the equivalent conversation will not happen to exceed once; one slightly different answer will lead to a completely different conversation [12]. So, for the excellent improvement of the chatbot, we compared our chatbot system with previous existing chatbots. When we checked the 2776 questions releted to inserted corpus on our chatbot system ,it returned 2448 correct reply.That means 88 % accurate.

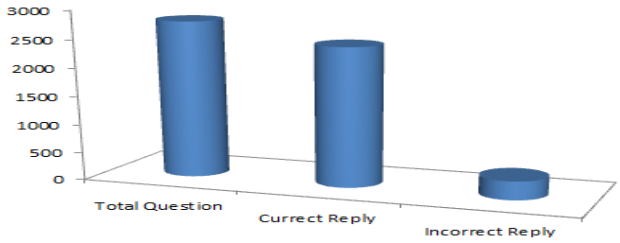

Fig. 8. Results Analysis.

VI. Comparison Between Others Chatbook

Our purpose is creating Bengali chatbot in the sake of the educations system of Bangladesh. So, we compared 'Doly' with two chatbots which are Neural Conversational Machine (NCM) and Cleverbot. Neural Conversation Machine is a chatbot which can be developed with the end-to-end and this model chats by predicting the next sentence given the previous sentences or sentence with a few handcrafted rules [12]. So NCM is a generative based conversational agent whereas our task is a retrieval-based system. We give some random questions to the NCM and our system for the comparative study between the two. It responds to the input by finding how a human responded to that input when it was asked, in part or in full, by Cleverbot. In this case, 'Doly' acted pretty good and responded with the best way.

VII. Future Work

In future works, we will try to enable 'Doly' among all Bengali native speaker students as in the sake of effective educations tool with the Bengali language. We will create a chatbot with the help of neural network technique as well as a sequence to sequence chatbot via Bengali Language Corpus. Also, we will try to generate own large Bengali Language corpus and try to develop a great system for Bangla Natural Language Processing (BNLP).

VIII. Conclusion

This research is a pioneering work in the field of dialogue system in Bengali. The main challenge of this work is to create a chatbot based on the accurate knowledge base. Due to the lack of large dataset, we implemented a retrieval based closed domain chatbot which will converse with the user based on the pattern matching algorithm and will improve its performance measure by learning from the interaction. Our work will provide a Bengali conversation corpus which will assist in the construction of a system for Bengali Language Processing research.

Chittagong-4331, Bangladesh
puja.csecu@gmail.com, hanif@cu.ac.bd

***Abstract*—Threat and abusive languages spread quickly through social media which can be controlled if we can detect and remove them. Since there exist many social media like Facebook, Twitter, Instagram etc and a huge number of social media users, we need a robust and effective automatic system to identify threat and abusive languages. In our proposed system Machine Learning and Natural Language Processing techniques have been implemented to build an automatic system. Previous research on Bengali abusive language detection used Multinomial Naïve Bayes (MNB), Support Vector Machine(SVM) algorithms and considered Bengali Unicode characters to build their system. We considered both Unicode emoticons and Unicode Bengali characters as valid input in our proposed system. Besides MNB and SVM algorithm, we implemented Convolutional Neural Network (CNN) with Long Short Term Memory(LSTM). Among three algorithms, SVM with linear kernel performed best with 78% accuracy.**

***Index Terms*—Natural Language Processing (NLP), Multinomial Naïve Bayes (MNB), Support Vector Machine(SVM), Convolutional Neural Network (CNN), Long Short Term Memory (LSTM), Bengali Text Classification, Bengali Hate speech Identification**

I. INTRODUCTION

Social media is an interactive platform to share important information, opportunities, news and good thoughts. But one of the major problems of social media is threat and abusive language which can also be referred as cyberbullying. A text can be considered as threat or abusive if it contains sexist or racist slurs, attacks or criticizes any community or religious view, provokes criminal activities etc. Offensive language has a fatal detrimental effect on teenage people which even can lead them to suicide. Bully victims are more likely to (between 2 and 9 times) commit suicide than non-victims [1].

Removing offensive and abusive data can reduce the negative effects from society. It was reported that 4.021 billion people accessed internet and 3.196 billion people used social media in 2018 and the rate of internet and Facebook users increases by 7 percent and 13 percent each year respectively[2]. According to Bangladesh Telecommunication Regulatory Commission (BTRC), the total number of internet subscribers in Bangladesh has reached 91.348 million at the end of December, 2018 [3]. Since so many people use social media, checking each and every post and/or comment manually is not possible. So, we need a strong and effective automatic system which can detect whether a post and/or comment is abusive or not.

Many machine learning and Natural Language Processing(NLP) techniques have been used to detect hate speech or abusive languages. Support Vector Machine (SVM) classifier with unigram, bi-gram, tri-gram features weighted by its TF-IDF is used to classify hate speech and offensive language by Thomas Davidson, Dana Warmsley, Michael Macy, Ingmar Weber [4]. Zeerak Waseem and Dirk Hovy proposed a model to detect hate speech from Twitter in which they detected 10 most repeated words for each class and used as classification feature. Besides, gender and location of the users were also collected which were also used in their proposed system [5]. Maral Dadvar and Franciska de Jong also used gender specific language features and implemented the classification approach using SVM algorithm in their research [6]. Template based strategy to generate features was used by William Warner and Julia Hirschberg in which they implemented 10-fold cross validation SVM and obtained 94% accuracy [7]. In another approach, prposed by Z. Rui Zhao and K. Mao, Latent Semantic Analysis (LSA) was used to extend pre-defined insulting words which was further used for classification [8]. In a different research, Multinomial Naïve Bayes (MNB) and SVM were used to detect abusive Bengali text with count vector and TF-IDF by Shahnoor Chowdhury Eshan and Mohammad Shahidul Hasan [9].

For our proposed system, we have collected data from different Facebook pages. Prothom Alo [10] and BBC News Bangla [11] are most popular Facebook pages of Bangladesh [12]. A great number of data have been collected from these two pages. We considered both Unicode Bengali words and emoticons as valid input in our proposed system. Besides, consecutive exclamation and question marks are taken in special consideration. After preprocessing, we used three different techniques, MNB, SVM and CNN-LSTM, to classify the data as threat and abusive or not.

This paper is divided into different sections. A brief description of related work in this field is mentioned in section II, Dataset preparation is explained in section III, classification approach of our proposed system is illustrated in section IV. Experiment and evaluation of the proposed systems is described in section V and finally the paper concludes in section VI.

II. Related Work

For the last couple of years, many researches have been conducted to detect hate speech automatically and most of the related works are based on English text.

Thomas Davidson, Dana Warmsley, Michael Macy, Ingmar Weber (2017) conducted a supervised learning on Twitter dataset [4]. They classified their training data into three classes, namely *Hate*, *Offensive* and *Neither*. After converting each tweet into lowercase character, they used stemmer, logistic regression with L1 regularization, linear SVM etc classification tools which resulted in 90% F1 score. This model was trained on 24802 labeled data and the data were biased. Only 5% of the tweets belonged to *Hate* class and as a result 40% of *Hate* data were misclassified. To train any type of model, the data should be balanced. Our proposed system is a binary classification problem where we used balanced dataset.

Jin Wang, Liang-Chih Yu, K. Robert Lai and Xuejie Zhang (2016) used regional CNN-LSTM model for sentiment analysis where they used Stanford Sentiment Treebank (SST) (Socher et al., 2013) and Chinese ValenceArousal Texts (CVAT) (Yu et al., 2016) as their dataset [13]. In their research they concluded that among lexicon-based method, regression based method, CNN, RNN, LSTM and regional CNN-LSTM model, for both English and Chinese dataset, regional CNN-LSTM model resulted in minimum error because CNN tracked down local information and LSTM found long distance dependency.

Another system, proposed by Shahnoor Chowdhury Eshan and Mohammad Shahidul Hasan(2017) is based on Bengali Unicode text implemented both count vector and TF-IDF for unigram, bi-gram and tri-gram. Then MNB and SVM (linear and RBF) classifiers were used[9]. This system only dealt with Unicode Bengali words while we considered both words and emoticons. Besides, consecutive exclamation marks and questions marks are considered as single word in our system.

III. Dataset

Total 5644 (*Table I*) posts and comments have been collected from different pages of Facebook which include Facebook page of newspapers, celebrities, entertainment pages etc. Among the collected data approximately 50% are threat and abusive type (which are labeled as "YES" in the dataset) and the rest of the data are not abusive (which are labeled as "NO" in the dataset).

TABLE I
Dataset

NO	YES	Total
2905	2739	5644

IV. Classification Approach

Overview of our classification approach is exposed in **Fig 1**. Dataset is preprocessed and after that the training data are used to train the model. Finally, the trained model predicts the class of test data and based on the predictions the performance of the models are calculated.

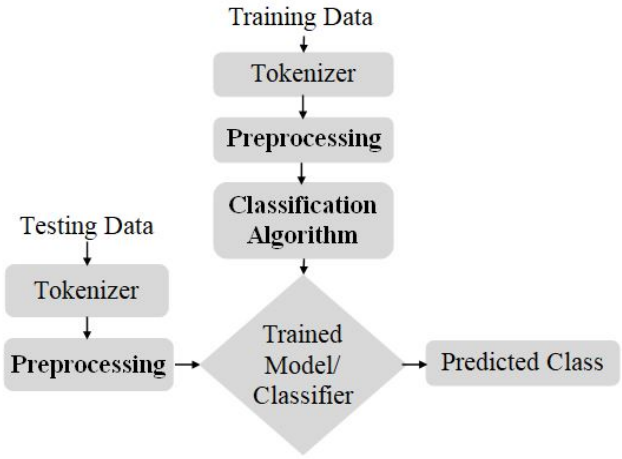

Fig. 1. Classification Framework

A. Preprocessing

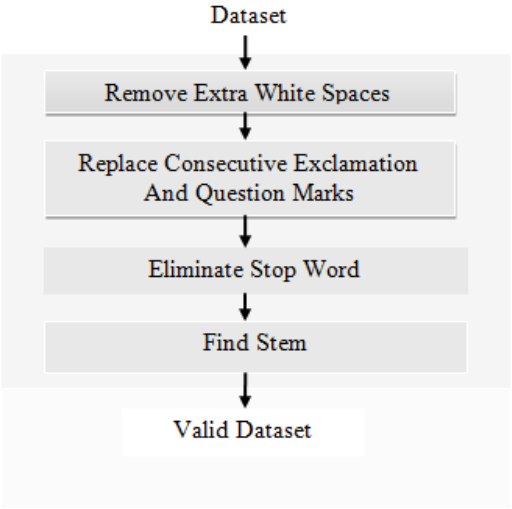

Fig. 2. Data Preprocessing

Input data are processed before they are used to train and test the models. Basically, preprocessing(**Fig 2**) step is a combination of few individual steps.

In the first step of preprocessing extra spaces from each document are removed. Consecutive exclamation marks (e.g '!!!', '!!!!!') and question marks (e.g.'??','????') are considered as a single word because consecutive exclamation and question marks do not represent exclamatory or interrogative emotions always, rather they are used to express anger, disgust or negative emotions. In the code, sequential exclamation marks are replaced with 'exn' and question marks are replaced with 'qsn' so that consecutive marks can be identified uniquely. Unicode

emoticons, Bengali Unicode, exclamation(!) and question() marks are considered as valid input. All special characters i.e. '$', '#', '@' etc and punctuation marks are removed. Stop words are removed as well. Finally a Bengali stemmer[14] is used to find the stem of the Bengali words.

B. Classifiers

Multinomial Naïve Bayes (MNB), Support Vector Machine (SVM) and CNN-LSTM are used as classification algorithm in our proposed system.

1) Multinomial Naïve Bayes (MNB): For **Fig 3**, n-grams ranged up to three(unigram, bigram, trigram) are considered to calculate TF-IDF. Thereafter prior probability of each class is determined based on the training documents. Then the conditional probability of each n-gram (which are referred as token in Fig 3) is computed. The probability that a test document should be of "YES" type and "NO" type both are calculated based on the prior probability of each class and the conditional probability of the tokens contained in the test document. Between them, the class with maximum probability is selected as the label of the test document.

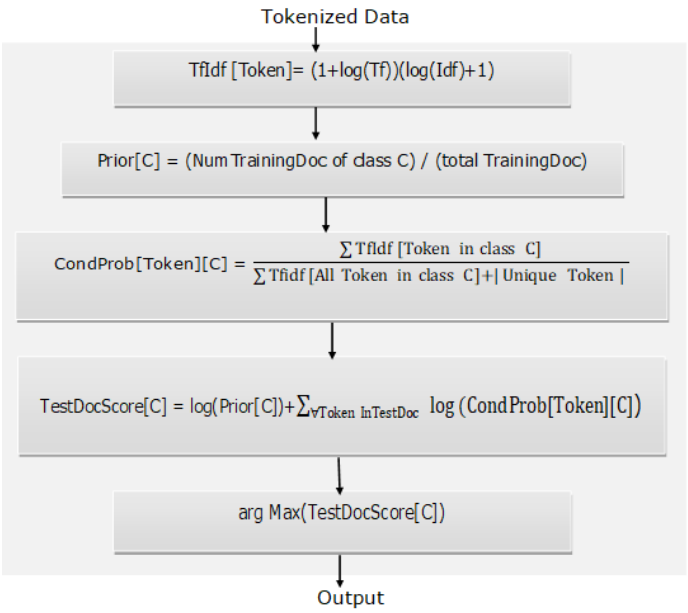

Fig. 3. MNB Classifier

2) Support Vector Machine (SVM) : According to **Fig 4**, same feature extraction techniques (TF-IDF of n-gram ranged up to three) as MNB classifier is used. The notations used in Fig 4 are stated below:

$W : Word\ Vector$
$X : Input\ Vector$
$b : Bias\ Value$
$y : Document\ Labels$
$e : Vector\ of\ all\ ones$
$\alpha : Langliers\ Multiplier$

At first each document is mapped into a higher dimensional space. Then we need to find out a hyperplane which will divide the documents on the high dimensional space in two region such that each region contains only one type of document. In our system, dual form of primal optimization problem is solved. W is determined after α is calculated. Finally after finding the support vectors, $b, y_i\alpha_i \forall i$ these values are stored which are used in the prediction of test document.

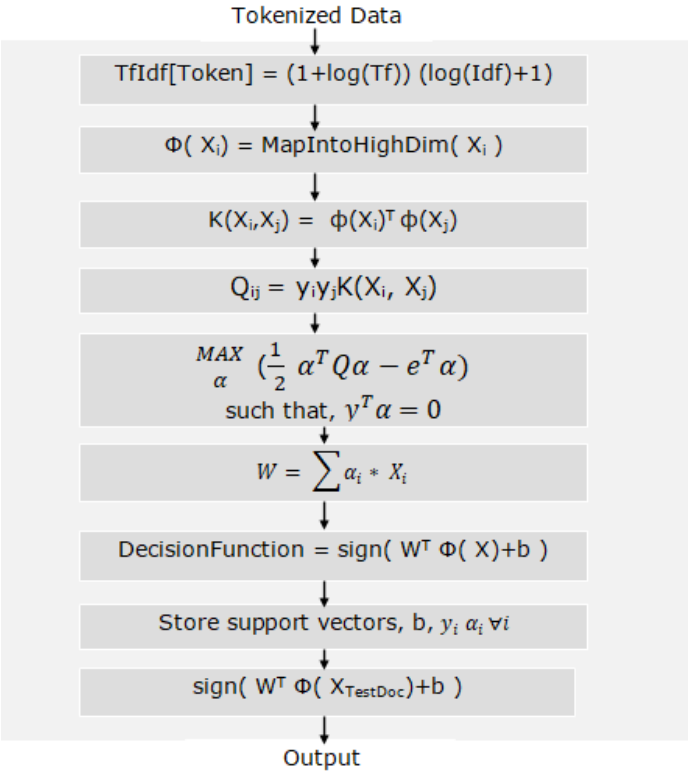

Fig. 4. SVM Classifier

3) CNN-LSTM: Each word, emoticons or consecutive exclamation or question marks are considered as token for CNN-LSTM network. For **Fig 5**, each unique token of data-set is converted to an integer value before feeding to the network. After that the model is designed with four layers namely embedding layer, convolution layer, LSTM layer and a fully connected layer. Each consecutive layer is denoted by different shades in **Fig 5**.

The document which has maximum length is set as the input length for embedding layer. Each token is converted to a word vector of length 32 and therefore each document is represented as a list of vectors.

In convolution layer, 32 different filters each with length 3 is added. Every filter overlays over the word vectors and performs an element-wise multiplication for all its 3x32 elements, and then aggregate up the multiplication result and obtain one numeric value which is stored as the element of the output sequence.

In LSTM layer 100 hidden nodes are used where each node consists of a forget gate, an input gate, an output gate and a

combined gate to calculate current cell memory. Output from each node of LSTM layer are used as the input in the next layer where sigmoid function is used as the activation function to give final output.

In total we used 50 epochs and the batch size was 128. The dataset is divided into training dataset, validation dataset and testing dataset.

From training dataset, at a time 128 data are used to train the model which are fed to the network. After that the whole process described in **Fig-5** is conducted on those data and based on the loss obtained from this output the parameters in different layers are updated. Then, the next 128 data are fed to the network and the same process repeats until each and every documents in the training dataset are passed through the network. All these steps form a single iteration.

The symbols used in the LSTM layer of the process in Fig-5 are stated below:

$X : Input\ Vector$
$H_{t-1} : Previous\ Cell\ Output$
$C_{t-1} : Previous\ Cell\ Memory$
$H_t : Current\ Cell\ Output$
$C_t : Current\ Cell\ Memory$
$W : Weight\ Vector$
$B : Bias\ Value$

The target of neural network is to minimize the loss of the system. After training the network, documents of the test dataset are passed through the network and it predicts the labels of the documents. Based on the prediction, the accuracy of the system is determined which is stated in **Table VII**.

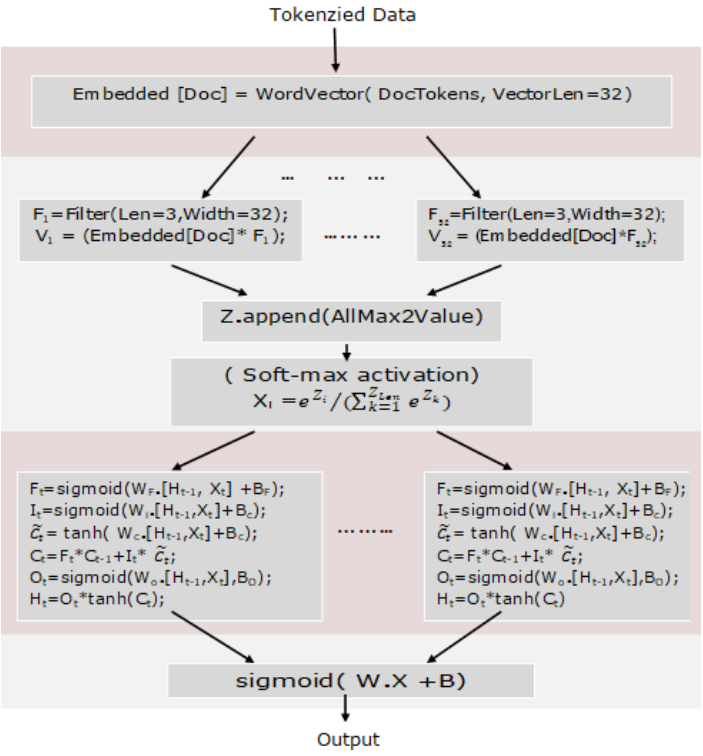

Fig. 5. LSTM Classifier

V. EXPERIMENT AND EVALUATION

A. MNB and SVM Performance

According to **Table II**, with 1426 documents MNB classifier is able to detect 99% of *NO* type documents accurately where it detects only 6% of *YES* type documents correctly. If we observe the precision rate, we see that only 40% of the test documents which are predicted as *NO* by MNB classifier are actually *NO* type documents and among the predicted *YES* type documents, 97% are correctly predicted. Linear SVC classifier correctly predicts 87% and 42% documents of *NO* class and *YES* class respectively. According to the precision rate of Linear SVC classifier, among the predicted documents 45% of *NO* type documents and 85% of *YES* type documents are predicted right. RBF SVC classifier correctly detects 63% of *NO* type data and 70% *YES* type data. It should be mentioned here that among the test data, 35% are *NO* type documents and the rest 65% are *YES* type documents. Besides training data are biased toward *NO* type class.

From **Table III**, we can see that with the increased data, the performance of Linear SVC has improved. Where the performance of other two classifiers have decreased. Linear SVC identified 46% *NO* type and 47% *YES* type documents accurately. Both Linear SVC and RBF SVC have same F1 score and accuracy in this case. Though MNB classifier predicts almost 99% *NO* type documents correctly, it predicts only 17% of total *YES* type documents right. Among the documents which are predicted as *NO* by MNB classifier, 60% of them are actually belong to *YES* type class.

According to **Table IV**, accuracy of MNB classifier was highest than other two classifier. Here MNB classifier detects 97% of *NO* class documents accurately. Though the documents that are labelled as *NO*, among them 61% documents are actually of *NO* type. Linear SVC and RBF SVC identify 77% and 70% *NO* class data properly. On the contrary, MNB classifier could recognize only 38% *YES* type data but linear SVC and RBF SVC could identify 55% and 62% *YES* type documents perfectly. One thing that should be mentioned, any stemmer was not used up to these three runs. Besides the data were biased. Among 3604 data, 3404 data were used as training data where 63% of the data were labeled as *NO* and 27% data were of *YES* class.

Using a Bengali stemmer and running the module on the same 3604 data we noticed that Linear SVC performed better than MNB and RBF SVC classifier. From **Table V**, we observe that linear SVC performed better to identify both of the classes where MNB and RBF SVC could identify data of one type of class much better than other type of class. If we compare with Table IV, we notice that for linear SVC the percentage of correctly identifying *NO* and *YES* type documents has increased from 77% to 79% and from 55% to 67% respectively.

After replacing consecutive exclamation and question marks with a specific word(which is less prone to appear in dataset)

we trained the models again and the obtained result is displayed in **Table VI**. We can see that MNB classifier is able to detect 95% of *NO* type documents and only 5% of *YES* type documents accurately. Here, SVM could identify both type data in a balanced way.

TABLE II
MNB, SVC, RBF COMPARISON WITH 1426 DATA

(a) Confusion Matrix

	MNB Classifier		Linear SVC		RBF SVC	
	NO	**YES**	**NO**	**YES**	**NO**	**YES**

Accuracy(%)	46.15		59.87		59.87	

B. CNN-LSTM Performance

From **Table VII**, we noticed that accuracy of LSTM network has increased with the increase of volume of dataset and we achieved 77.5% accuracy for 5644 data. For 3604 data we obtained 65.5% accuracy and with 4933 data we got 73% accuracy.

C. Accuracy Comparison:

Fig 6 illustrates the accuracy of each models (MNB, Linear SVC, RBF SVC and CNN-LSTM) where the X-axis indicates the dataset size and the Y-axis represents accuracy in percentage. The first two cells for CNN-LSTM are intentionally left blank because the CNN-LSTM model was not build when we had only 3324 data.

TABLE IV

F1 Score	0.76	0.59	0.80	0.76	0.76	0.32
Accuracy(%)	70.00		78.00		74.50	

From **Fig 6** it is evident that the accuracy of each classifier, except than RBF SVC, has increased with the increased amount of data. If we notice the rate of change in accuracy, we see that when total data increased from 4933 to 5644 the

TABLE VII
CNN-LSTM ACCURACY

Data	Accuracy %
3604	65.5
4933	73.0
5644	77.5

accuracy for both MNB and linear SVC classifier has increased about 2% but CNN-LSTM model has highest rate of change in accuracy from 73% to 77.5%. Though linear SVC has highest accuracy for 5644 data, CNN-LSTM model has almost reached to the accuracy of linear SVC for the same amount of data.

	1426	3324	3604	4933	5644
MNB	47.16	46.15	67.5	68	70
Linear SVC	58.19	59.87	73	76.5	78
RBF SVC	67.89	59.87	58	69	74.5
CNN-LSTM			65.5	73	77.5

Fig. 6. Accuracy of models

VI. CONCLUSION AND FUTURE WORK

From the result of our proposed system we observed that SVM with Linear kernel performed better than other algorithms when the data is balanced. With biased data MNB classifier was able to classify only one type data more accurately. We noticed that for most of the cases, MNB failed to identify threat and abusive type data. Rather, it predicted most of the data as non-abusive. We noticed that the result of SVM classifier with RBF kernel fluctuated to a large degree. The result of SVM classifier with linear kernel was more consistent as its performance improved as we balanced our dataset and its accuracy peaked at 78%.

In future, We are going to research about other features to improve our system. Besides, we will expand our dataset. We noticed that the accuracy of CNN-LSTM increased at a large rate with larger dataset. Since CNN-LSTM model is able to focus on both local information and long dependencies, we will try to find whether CNN-LSTM can perform better or not than other algorithms with huge amount of data. We will implement other feature extraction techniques (for example word2Vec etc.) with CNN-LSTM and will compare the result so that we can improve our system.

***Abstract*— A Virtual Assistant is an application program that can understand natural language (audio and text) commands and perform tasks for the user. The importance and usage of the virtual assistant are growing exponentially worldwide. In this paper, we have demonstrated a comprehensive design and development methodology of a Bangla virtual AI assistant 'Adheetee (Erudite)' for smart devices such as smartphones and personal computers. Bangla is the native language of Bangladesh and some states of India with millions of native speakers worldwide. There are some popular virtual assistants available in English and other languages but not in Bangla. Therefore, using a virtual assistant become very difficult for Bangla speaking people around the world. Moreover, a large portion of Bengali speaking people is illiterate. This makes using a virtual assistant more difficult. This gives us the motivation to build a comprehensive virtual assistant for Bangla language. We have covered vast varieties of most frequent commands in our system with the accuracy of 94.065%.**

Keywords—Adheetee, Virtual Assistant, Bangla, Commands, API

I. INTRODUCTION

A Virtual assistant makes tasks of a person in a smartphone or a personal computer easier by just giving a voice command or a written command. The usage of a virtual assistant is presumed to hit 1.8 billion worldwide in 2021 [1][2]. People can get benefits of 21st century's technology by using a virtual assistant as for using it no extra knowledge is required. A user can use it just like they communicate with a human being. Intelligent natural language processing makes the system understand the natural language commands of a human being [3]. A virtual assistant can be used to set a reminder, sending email, know weather information, search information in Google, update to-do list etc. Bangla is the 6th most widely spoken language with approximately 250 million total speakers worldwide [6]. However, there is no virtual assistant yet developed for Bangla language. Euromonitor International reports only 18% of the total population in Bangladesh can understand and speak English [7]. In addition to that 27.2% of the total population is illiterate who cannot even read or write Bangla language [8]. Due to the low literacy rate and ineptness of English knowledge among the Bangla speaking people we are not being benefited properly by the English virtual assistants. Therefore, the authors decided to propose a comprehensive Bangla virtual assistant which takes both verbal and text Bangla input as a command. According to Newzoo's Global Mobile Market Report 2018 [11], there are around 27 million Smartphone users in Bangladesh. Our proposed system can help these enormous users to be able to utilize features of their smartphones more easier and faster way in their mother tongue.

Previously, a considerable amount of work had been done in virtual assistant in English and other western languages such as Google's Google Assistant, Apple's Siri, Microsoft's Cortana, and Samsung's Bixby etc. Although most of them have the same functionalities, each of them has some new features and abilities [5]. However, no virtual assistant has been designed or developed in Bangla language yet. Note that there are some chatbots available in Bangla. T.D. Orin proposed Bangla chatbot named Golpo in 2017, which can have basic text conversations [10]. In 2018, Anirudha Paul et al. proposed a closed domain contextual chatbot framework for resource-poor languages including Bangla [9]. However, these are only text chatbots for general conversations and thus have very limited functionalities.

In this paper, we have proposed a comprehensive Bangla virtual assistant for smart devices. We have named our system 'Adheetee' which is a Bangla word, meaning 'Erudite (having or showing great knowledge or learning.)'. It contains a large set of most frequent commands and variations of those commands. Our system is consists of a large database containing several types of information about different commands and their potential responses. We have distributed our commands as basic commands and core commands. Basic commands handle a basic conversation like a chatbot. However, our basic conversations are not just introductory communications; we have stored a user's important information through the conversation for future references, make the system more customized and to provide responses based on context. In the core commands, the system handles more complex device oriented activity. Handling varieties of the same command is a difficult task, however, we have used Named Entity Recognition (NER), Keyword Extraction (KE) and Cosine Similarity (CSM) algorithms to identify and respond accordingly for command variations. We have built our system to be able to respond by itself using its intelligence and the information stored in its database. However, to handle unknown commands and fetch the latest information the system sometimes depends on external API calls.

The paper is organized as follows: In section II, we describe the proposed system and step by step demonstration of the system diagram with proper examples and algorithm. The paper demonstrates experimental results in section III with examples. Section IV interprets performance from the experiments, while section V concludes the paper with limitations of our system and future work.

II. PROPOSED METHOD

Our system takes both voice command and text command as input. A person can wake up our system just by calling "হে অধীতী (Hey Adheetee)" or "ওহে অধীতী (Hello Adheetee)" or simply "অধীতী (Adheetee)". On the other hand, a user can put written text as a command. For voice command, we translate the speech into text by using a Speech to Text (STT) system. We have used Google's STT

API to do this work [12]. Then, we extract keywords from the text command. We need to extract the keywords from command due to the fact that the commands are given in natural language. Therefore, a different user can speak or write the same command in different ways. Moreover, even the same user can speak or write differently in different time periods. For example, if we observe the following commands:

a. *আমাকে আবহাওয়ার খবর বলুন?* (Give me weather update.)

b. *আজকের আবহাওয়া কেমন?* (How is the weather today?)

c. *বাহিরের তাপমাত্রা কত?* (What is the temperature outside?)

d. *অধীতী, আজ বাহিরের তাপমাত্রা কত?* (What is the temperature outside today?)

e. *কাল আমাদের এলাকার তাপমাত্রা কেমন থাকবে?* (What will be the temperature tomorrow in our area?)

We can see that all of these different commands actually mean the same thing and it is requesting for the weather update. Thus, here, our keyword is আবহাওয়া (weather) for the examples a and b, and তাপমাত্রা (temperature) for the examples c, d and e. Based on these keywords, we determine the type of commands such as whether it is a basic command or a core command. We have divided commands into two different phases. These are,

1. Basic Commands
2. Core Commands

In basic commands, we handle commands with basic conversations. Such as asking for a name and storing the name. Having basic knowledge question answering conversation goes to basic commands. In this case, we generate a cosine similarity measure [14][15] between the keywords and commands stored in our knowledge base to determine the command category. This helps us to determine commands category of the same command in different variations. On the other hand, more complex commands such as a command that need actions goes to core commands such as opening an app, setting up an alarm, searching specific information on the Internet etc. Figure 1 demonstrates the system diagram of our proposed system.

On receiving a command, the system determines whether it can respond by itself or we need to call an external API to fetch the information from other sources. In some commands, we do not depend on external APIs such as, all basic commands and commands that the system can handle itself. In this case, our system collects data from our knowledge base and/or store data from the user for future references. On the other hand, in some commands, we need to call an external API to do our work. We also determine based on keywords whether we need to translate the keyword into English since some external APIs do not support Bangla words as input parameters. In such cases, we apply machine translation API to translate the Bangla text to equivalent English text and pass the English text as a parameter of the external API. For machine translation, we have used the Google Translate API [13]. In some cases, Google Translate API provides some garbage data such as '#?' with the result. Thus, we have developed a program based on several regular expressions to filter out these unwanted garbage data.

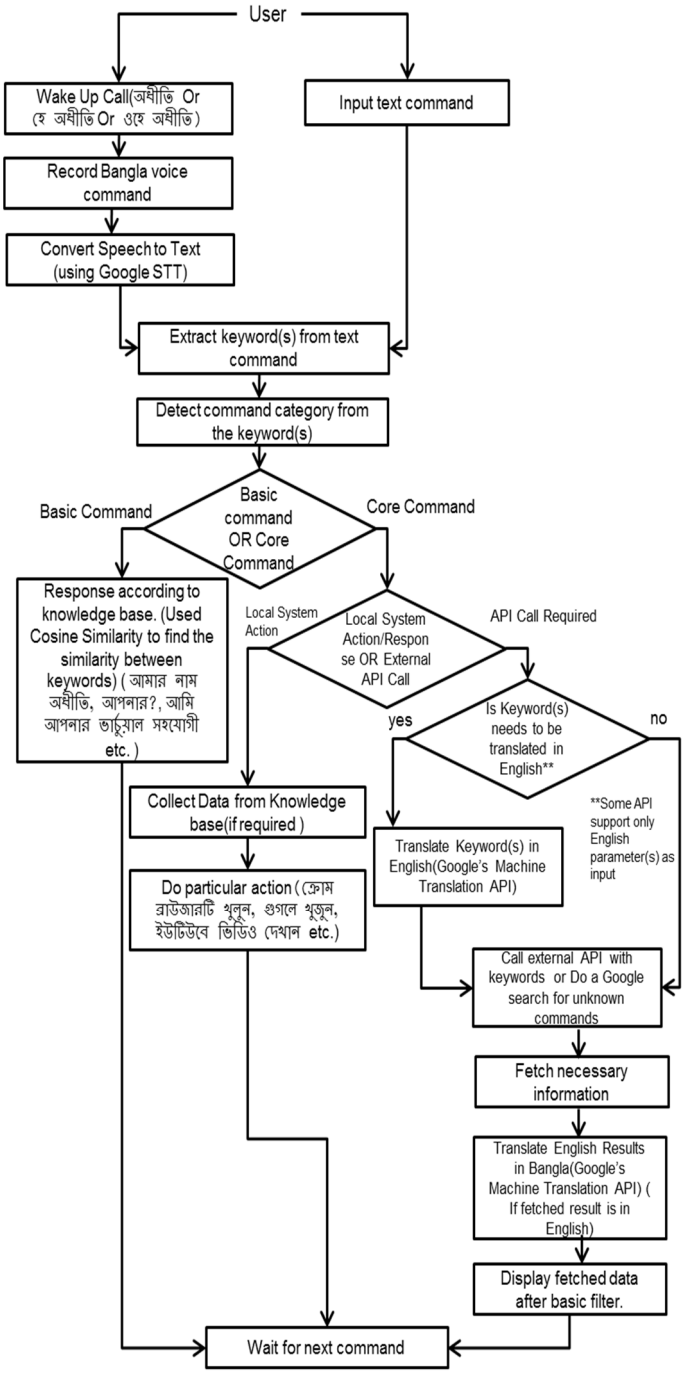

Fig.1 System Diagram of Proposed System

The algorithm of our proposed system is given below.

Algorithm 1: Algorithm of proposed system

```
IF wakeup call OR press the voice button THEN
    RV ← record voice command
    IN_TXT ← convert speech command to text(using Google's STT)
ELSE
    IN_TXT ← read text command
END IF
KEY ← extract keyword(s) by analyzing IN_TXT
CAT ← detect command category using KEY
IF CAT is a basic command THEN
    CS ← measure cosine similarity between CAT and keywords from knowledge base.
    based on CS determine closest command and give response accordingly.
```

```
KB ← Store basic user information in knowledge base for future reference (such as user's name, birthdate, favorite color)
ELSE
    LORAPI← detect whether the command can be handle by our system or we need external API call
    IF LORAPI indicate our system call handle THEN
        collect data from knowledge if required
        do particular action based on command
    ELSE
        ENG← detect whether translation of keyword(s) to English required or not
        IF ENG indicate translation required THEN
            translate keyword(s) to English (using Google's Machine Translation)
        END IF
        call external API with the keyword(s) as parameter
        JSON←fetch necessary information and display accordingly
        IF JSON returns English texts THEN
            convert JSON to Bangla (using Google's Machine Translation)
        END IF
        Extract necessary information from JSON
        Display JSON
    END IF
END IF
```

We have created a dataset of keywords and their corresponding actions. However, if someone put command with a keyword outside of our dataset of keywords, we search the whole command in Google and show the result accordingly. This dataset also let us know whether we need to call an external API to fetch information or our knowledge base is sufficient to respond to the command. In our knowledge base, we have developed an SQLite database and we have several JSON and text files which contain different types of data from different domains and functionalities. The reason behind this distributed knowledge base is to ease of access and to make modification easier. We have an index JSON file that contains commands, keywords of commands, flag that indicates whether it is a basic command or core command, flag that indicates whether we candle this by our system or we need an external API call, flag that indicates whether we need to translate the command keyword(s) in English or not and some other necessary information. This file makes our work easier to decide what to do next. On each external API call, we get JSON formatted data as a result and we keep a local log of the command and fetched data to enrich our system. However, we also store the latest data whenever we find new data for the same command to keep the system up to date.

III. Experimental Results and Analysis

In this section, we have demonstrated the output of different commands in our proposed system and analysis of the results. We have distributed the commands into Basic and Core commands. In total, we have processed 221 commands.

a. Basic Commands

In basic commands, we have processed commands that people use for an initial conversation, to know basic information about our system and some basic mathematics. We have designed the responses as natural as human conversation and our system stores important details for contextual responses. At the very beginning of a conversation with our system, if a user says introductory words such as 'Hi', 'Hello' or 'Hello Adheetee', our system responds mentioning the user's name. Knowing the name of a user is very important for natural friendly conversation. Thus, we address the user as '(বন্ধু) friend' until we know the name of the user. After storing the user's name, we always call the user with his/her name. We have processed 101 basic commands and variations of these commands so that it responds in a natural way just like a human does. Examples of basic commands are:

a. আপনার নাম কি? (What is your name?)

b. আপনাকে কে সৃষ্টি করেছে? (Who created you?)

c. আপনি ছেলে না মেয়ে? (Are you a boy or a girl?)

d. আমার নাম করিম, আপনার নাম কি? (My name is Karim, What is your name?)

e. অধীতী, আমার প্রিয় রঙ লাল এটা মনে রাখুন? (Adheetee, Remember my favourite colour is Blue.)

f. অধীতী, আমার নাম কি বলুনতো? (Adheetee, Tell me my name?)

g. আপনার প্রিয় রঙ কি? (What is your favourite colour?)

h. ২৫ কে ৩ দিয়ে ভাগ করলে কত হয়? (What is 25 divides by 3?)

Figure 2 shows a very initial conversation with a user.

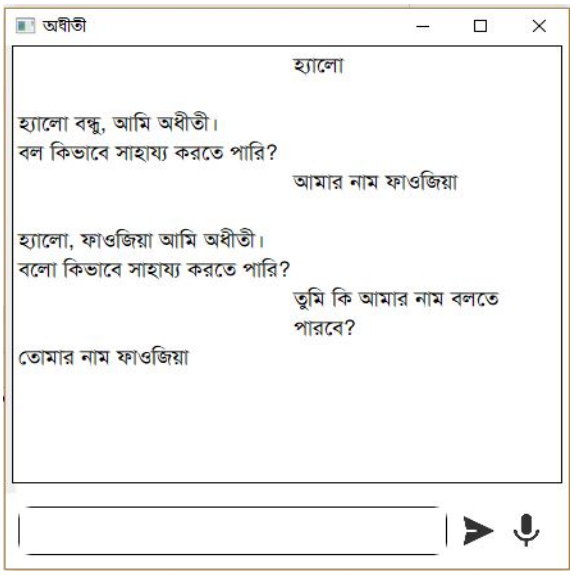

Fig.2 Initial conversation using basic commands

b. Core Commands

In core commands, we have processed commands that need particular actions such as opening a browser, setting an alarm, opening a file, playing a song etc. Core commands are mostly action based with very little conversation. We have processed 120 core commands in our system. Examples of core commands are,

a. অধীতী, দুপুর দুইটার জন্য অ্যালার্ম সেট করুন। (Adheetee, Set an alarm for 2 PM.)

b. অধীতী, ক্রোম ব্রাউজারটি খুলুন। (Adheetee, Open the Chrome browser.)

c. আমার প্রিয় গানটি বাজান। (Play my favourite song.)

d. ইউটিউবে ইংরেজি শেখার ভিডিও চালান। (Play video tutorial of English in Youtube.)
e. মোহাম্মদপুর থেকে মতিঝিল যাব কিভাবে? (How to visit Motijheel from Mohammadpur?)
f. অধীতী, রাশিয়ার রাজধানীর নাম কি? (Adheetee, what is the capital of Russia?)
g. আজ আমার এলাকার তাপমাত্রা কত? (What is the temperature today in my area?)
h. করিম কে ইমেল কর যে আমি আজ অফিসে যাব না। (Send an email to Karim saying I will not go office today.)

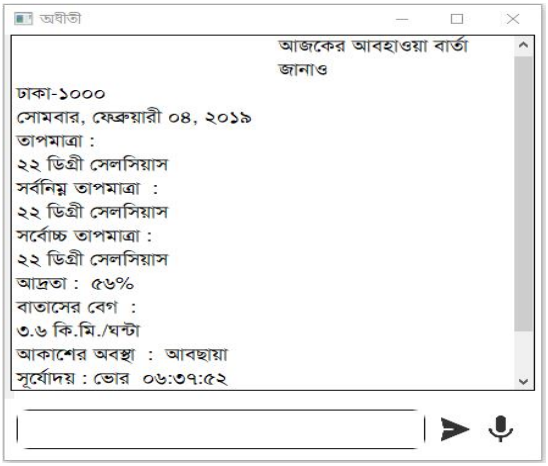

Fig.3 Example of weather command

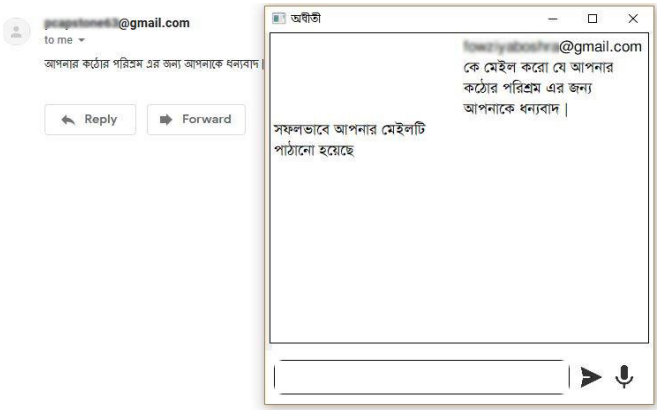
Figure 3 shows how our system responds for a weather command. We fetch information from internet based on GPS (Global Positioning System) location. As weather information, we fetch different information including temperature, sunset, sunrise, and humidity. Our system shows all this information for a generic weather command. However, if a user asks for specific information the system shows only that specific information.

Sending an email is one of the most important tasks in our daily life. Thus, our system makes it easier to send an email using simple Bangla command. A user needs to say the intended email address or just the name of a recipient with the text.



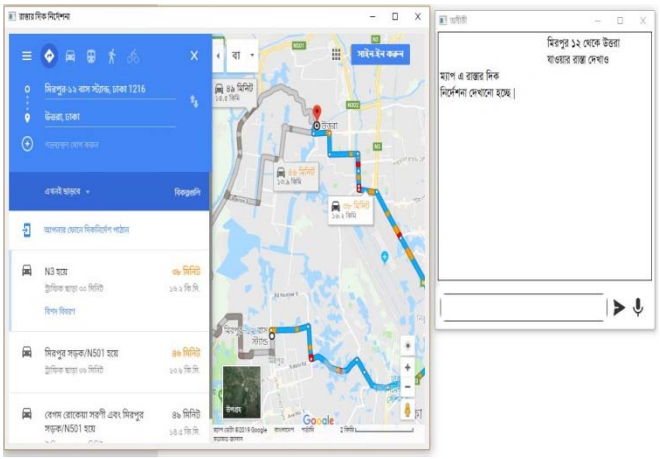


Fig.4 Example of sending email command

In order to send an email by just a name of a recipient, a user must have to give a command anytime earlier so that our system store the email address corresponds to that name. However, if our system does not have an email address for a name it automatically asks for the email address later. Figure 4 shows the response to an email command.

Travelling in a large city such as Dhaka is difficult. In order to go to a new place we often depend on the map. Our system makes it easier to get a map direction from one place to another in the Bangla language. We have used Google Map to display the direction from a source to a destination. For a simple Bangla command such as 'আমাকে মিরপুর ১২ থেকে উত্তরা যাওয়ার রাস্তা দেখাও। (Show me the direction from Mirpur 12 to Uttara.)'. In this case, we have used an NER (Named Entity Recognition) algorithm [4] and gets the name of source and destination. After that, we call the Google Map API using these names in appropriate parameters and finally display the route from the source to the destination. If the user says a command with no source but only destination such as 'আমি বাড্ডা যাব কিভাবে? (How to go Badda?)', we find the source location using the GPS. Figure 5 shows a direction command.

Fig.5 Example of seeking direction in map command

To open a browser, a user needs to mention the name of the browser. Our system opens the browser immediately if the browser is available in the device. Figure 6 shows a command 'অপেরা ব্রাউজারটি ওপেন কর। (Open the Opera browser.)' that open the Opera browser.

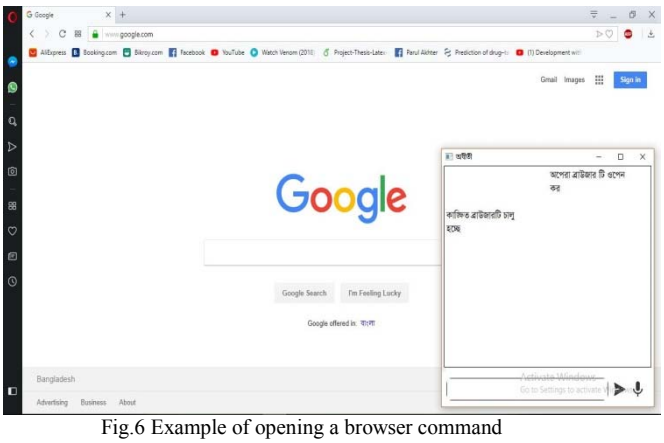

Fig.6 Example of opening a browser command

If a user searches for a video or wants to play a song he can command with appropriate name and source such as Youtube, Amazon Prime, Vimeo etc. If a user asks for a video without mentioning the source of the video, then by default we search the video on Youtube. In Figure 7, we

have shown an example of command seeking for a video on Rubik's cube without mentioning the source.

Fig.7 Example of video command

Our system can fetch any general information from different sources. It can give answers to almost any general knowledge questions. We have an enormous database that contains all the basic general information of all the countries in the word. This contains basic information such as counties name, capital, the biggest city, size, celebrities, poets, the name of the presidents, national sports etc. If a user asks for such basic commands, our system first tries to give answers from its database. However, if there is no data available for specific countries our system fetches the information from the internet. Figure 8 shows some basic general knowledge commands.

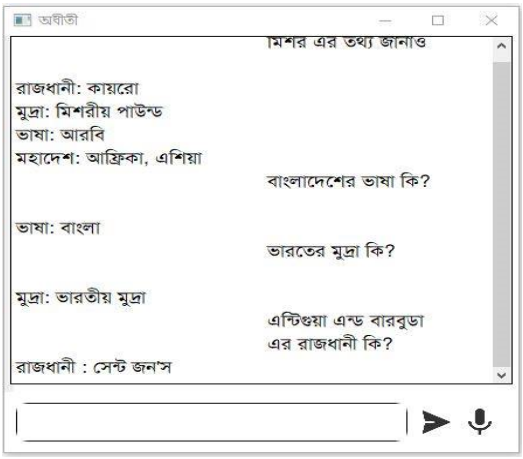

Fig.8 Example of responses to general knowledge commands

A user can search a term in Google using our system with Bangla command. Moreover, if a user asks something that cannot be answered by our system itself, then our system search the command or term in Google directly and show the search result of Google. Figure 9 shows a search result of Google by our system.

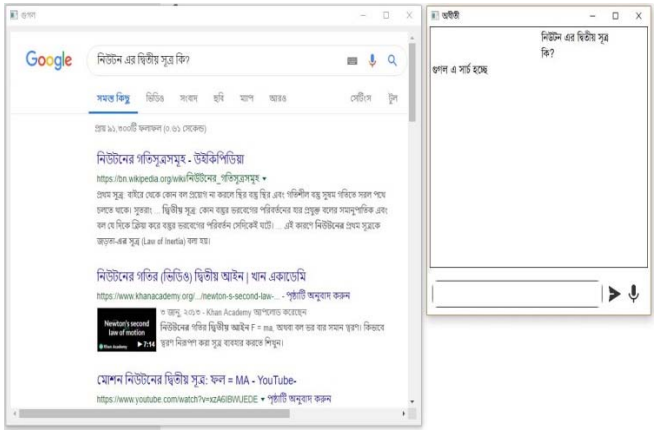

Fig.9 Example of Google search for unknown term by our system

IV. PERFORMANCE ANALYSIS

In order to calculate the performance of our system, we have tested our system in two phases. In the first phase, we have tested our system with some basic commands known and unknown to the system such as, "আপনার নাম কি? (What is your name?)" "আপনি কি কি করতে পারেন? (What can you do?)" etc. In this phase, we have determined our system's ability to have a basic conversation with a user. In the later phase, we have applied our core commands such as "অধীতী, ক্রোম ব্রাউজারটি খুলুন (Adheetee, open the Chrome browser.)", "অধীতী, ধানমন্ডি থেকে বাড্ডা যাওয়ার ম্যাপ দেখান (Adheetee, show the direction in map from Dhanmondi to Badda)" etc. to test our system's ability to do complex things with a device. In this case, we have provided all possible variations of a command a user can ask to our system. We have considered a test success if our system correctly identified our command and correctly provided the expected output. On the other hand, if our system failed to detect our command correctly or it provided incorrect or irrelevant output then we considered the test as a failure. Table I demonstrated the test summary of our system.

TABLE I. PERFORMANCE SUMMARY OF OUR SYSTEM

Phase	**1**	**2**
Name of Phase	Basic Commands	Core Commands
Total Commands Tested (including all variations)	102	112
No. of Correctly Identified and Responded Commands	99	102
No. of Incorrectly Identified or Responded Commands	3	10
Error Rate	2.94%	8.93%
Accuracy Rate	97.06%	91.07%

TABLE II. AVERAGE ERROR AND ACCURACY RATE

Average Error Rate	$\frac{2.94\% + 8.93\%}{2}$	= 5.935%
Average Error Rate	$\frac{97.06\% + 91.07\%}{2}$	= 94.065%

In Table I, we have demonstrated the test results of both phases and Table II demonstrates the average error rate and accuracy rate of the system. The average accuracy rate of the system is 94.065% with the error rate of 5.935%. Since our proposed virtual assistant is the first Bangla virtual assistant

and there is no Bangla virtual assistant available to compare with, we have compared our system with existing English virtual assistant. Figure 10 shows a comparison of the accuracy rate between English virtual assistants and our system 'Adheetee'. The accuracy rate of these English virtual assistants was reported in an article of Business Insider [16].

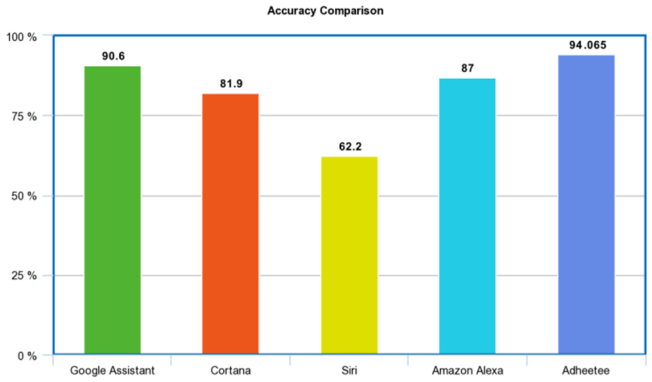

Fig.10 Accuracy comparison between English virtual assistants and Adheetee.

V. Conclusion and Future Work

This paper demonstrates a comprehensive Bangla virtual assistant. We have demonstrated each and every step of building the system. Moreover, we have shown different experimental results and analysis of the results and finally, we have demonstrated the test results. We find our system very impressive according to our test results.

Although we have reached our goal, the system has some limitations. Such as, our system mostly depends on external APIs to fetch information which makes the system dependent on other systems. Since the system depends on the internet to fetch most of the information internet speed may affect the performance of the system. Finally, we have covered a limited number of commands at this stage which makes the system less versatile.

In future, we are planning to do a user experience survey according to HCI discipline based on a robust online and offline questionnaire. We are developing some APIs to reduce the dependency on external APIs. Moreover, we are developing a mobile app for both Android and IOS platforms. Handling more frequent commands is our most important future task. We are planning to test the system with more complex commands and hence increase the accuracy rate of the system.

A Bangla Spell Checking Technique to Facilitate Error Correction in Text Entry Environment

Tanni Mittra[1], Sadia Nowrin [2], Linta Islam[3] and Deepak Chandra Roy[4]
Dept. of CSE, East West University, Dhaka, Bangladesh
([1]tanni@ewubd.edu)

***Abstract*—Spell checker is a common tool used in different text entry techniques for error free writing. Recent advances in spell checking techniques in different languages significantly decreases word and sentence level typos from writing text. But developing an optimized spell checker in Bangla language is still a great research challenge due to the complex rules of Bangla spelling. To overcome the challenge we propose a new technique of spell checking considering both word and sentence level errors to facilitate the text correction techniques of Bangla language. We use a hybrid approach by combining edit distance algorithm and probability based N-gram language model for the error detection and correction tasks. A large corpus is built containing almost 0.5 million words and 50,000 n-gram sentences to detect and correct the errors. We evaluate the performance of our proposed method with different test data collected from online sources. Again, the efficiency of proposed technique is estimated by conducting a pilot study involving users of different ages. The accuracy rate of our proposed spell checker is approximately 97%. The validity of our claims have been proved through comparison with other Bangla spell checkers.**

Keywords*—Bangla spell checker, Real-word error, Natural Language Processing, N-gram

I. Introduction

Spell checker is an optimized application which determines misspelled words and provides most probable suggestions based on the wrong words. Usually spell checker is integrated with the text entry techniques of different word processing software like Microsoft Word, Writer, Ispell, Aspell4, LibreOffice, etc. [1]. It helps users to write error-free textual documents by detecting spelling errors.

Spelling errors are classified into two broad categories [2]. One is non-word error, which occurs when an invalid word is present in the text and not found in the word dictionary. Another is the real-word error, which occurs if the word is valid but not syntactically and semantically correct [1], [3]. Any spell checking technique is evaluated by its capability of handling both non-word and real-word errors. As a result, detecting both types of error and automatically correcting them is still a major research challenge. Plenty of research works have been done on automating the process of spell checking in English and non-English language like Bangla, Hindi, French, Spanish etc.

The evaluation in recent years indicates that, spell checking system of Bangla language has made a measurable improvement [3]. Considerable works have been done on Bangla spell checker. For example, phonetically similar word grouping based spell-checker [4], phonetic encoding for better spelling suggestions [5], double metaphone encoding technique [6], a light weight stemmer for bengali spell checker [7] are some of the automated processes for correcting misspelled words in Bangla. However, there exists some more challenges to improve the performance of Bangla spell checker [3]. Among them, handling both types of error together with great efficiency is a big challenge. Because for any spell checker, increasing the efficiency of error detection as well as improving its quality has great importance.

According to our best knowledge, some of the spell checkers concentrate on structural similarity of words while other focus on syntactic similarity of words in a sentence. A very few of them focus on both structural and syntactic similarity. On the other hand, current spell checkers are not optimized for efficiency handling and memory consumption. So in overall, the main challenge is to emerge an optimized solution that can detect errors by handling all complexities and provide justifiable suggestions based on the wrong words. To overcome these challenges, we present a new smart Bangla spell checking technique with two features. Firstly, it can handle both types of error by considering the complex rules of Bangla spelling and provides justifiable suggestions. Secondly, it improves the performance of spell checking by reducing search time and space. The method described in this paper constructs a group based dictionary, where each of the words having equal length is grouped together. Thus the issue of time and space complexity is minimized. A simple edit distance algorithm is used to check the structural similarity of words. The syntactic similarity is calculated using probability based N-gram model. In the result analysis section, we compare our method with a well established spell checker to analyze the performance of our method.

The rest of the paper is organized as follows. Section II covers background study and section III discusses about some related research works. Section IV contains brief descriptions of the proposed method, section V describes the evaluation procedure and results attained by different experiments. Finally, Section VI discusses the future plan with conclusions.

II. Background Study

Bengali also known as Bangla is an Indo-Aryan language spoken in South Asia. It is the official language of Bangladesh and second most widely spoken language of India. Bangla is the seventh most used native language in the world and fifth most widely used writing system in the world[1]. It has 49 letters in it's alphabet and 10 digits in decimal number system [8]. Among the set of letters, it has some complex set

[1]https:/en.wikipedia.org/wiki/Bengali_language

of characters which have made it's writing very difficult rather than the verbal communication [3]. They are: 1) Phonetically similar characters example:ন,ণ,শ and স 2) Consonant cluster example:ক্ষ ,ল্ম and ন্ম 3) Phalas such as YA-phala, RA-phala and LA-phala example: ব্য,ক্ষ 4) Matra example: পর্ব ,কর্ম 5) vowel characters example: ◌া, ◌ো, ◌ী .

The complex rules of using above-mentioned characters in writing script have emerged different types of the spelling error. According to the classification of spelling error Kukich [2] classified non-word error as word level error and real-word error as sentence level error. In context of Bengali writing, most of the non-word error occurs because of less knowledge of the spelling rules [9] and due to inaccurate insertion, deletion of characters while typing. Example: চুল, তালী, উপককরণ,মানুস all are the example of non-word errors because they are not the valid words. Contrarily most of the sentence level error occurs due to the inappropriate use of phonetic characters, Phalas and Matras. Example: if someone write a sentence আমার মণ খারাপ where all of the three words are valid dictionary word but the word মণ is inappropriate in the context of the sentence. The correct sentence would be আমার মন খারাপ . Another example এখানে অন্ন কেউ , where the word অন্ন is invalid in this sentence.

III. Related Works

There exists some well established algorithms for spell checking such as double metaphone encoding [10], metaphone encoding [11],soundex algorithm [12] and phonix algorithm [13]etc. They used phonetic codes for detecting misspelled words and generating suggestions. But, all of them are used for developing spell checker in the English language. To our best knowledge, a small number of researchers worked on these concepts to implement spell checker in the Bangla language [3]. For example, UzZaman et al. provided Bangla phonetic encoding based on soundex algorithm [5]. They modified existing soundex algorithm for Bangla and proposed a new encoding technique. It considered only phonetic problems and used the phonetic encoding to provide suggestions. A double metaphone technique for Bangla [6] is used to detect spelling errors and improve suggestions. They considered the phonetic problem and used traditional edit distance based method to produce suggestions.

A light weight stemmer algorithm [7] is used to detect misspelled word. By using this stemming algorithm they reduced dictionary size and improved efficiency of spell checking. They used simple minimum edit distance method to find suggestions. UzZaman et al. used a direct dictionary look up method for determining errors [14]. They handled both phonetic and real-word error by considering edit distance and double metaphone encoding.

A reversed dictionary [4] was built by reversing the characters of each word and also an original dictionary where phonetic characters were grouped together. A simple string matching algorithm is used to detect the phonetic error. Both dictionaries were used to provide suggestions. It considered the phonetic problem and can correct a single error.

Finite state automation [15] is used to determine the spelling error and probability is used to generate suggestions. Khan et al. [16] used n-gram model for determining the error in Bangla text. To check the error, the probability was calculated using the N-gram model. Statistical n-gram model is used to recognize real-word error in the Bangla sentence in [17]. On the other hand, clustering approach [18] is used to oraganize the dictionary. This organization reduces the search time and space of the algorithm. But this algorithm worked only for non-word error.

Although there exists some well-established methods for Bangla spell checker, most of them focused on the non-word error. A very little amount of work focused on the real-word error. These error detection and suggestion generation operations require more efficiency. As a result, we focus on the design of an optimized spell checking solution that can handle quality with proper efficiency of the error detecting task.

IV. Optimized Bangla Spell Chekcing Technique for Error Correction

The spell checking technique of our proposed method detects all types of erroneous words and provides most probable corrections based on the wrong input. The main goal of our work is to detect misspelled words efficiently by minimizing the search time and space. A relatively straight-forward algorithm is used to determine the correctness of the word and generate most likely candidate words as suggestions. In the following subsections, we discuss the implementation details of our proposed method.

A. Determining Erroneous Word

Determining erroneous word is the first step of any spell checker. The error detection process of our proposed method is subdivided into two basic steps. They are: 1) non-word and 2) real-word error detection.

1) Non-word Error Detection: When a user enters a word which does not exist in the dictionary is known as non-word error [2]. To check non-word error, we build a Bangla word dictionary with approximately 6,00,000 words. All words are collected from different online repository of Bangla words[2], newspapers, social networking sites and Bangla blogs. All words of the dictionary are organized according to the length of the words i.e. all words having equal length are grouped together. Then each of the words is subdivided into a set of trigrams which are also stored in the dictionary. For example: trigram set of the word মানুষ is <ম ◌া ন >, <◌া ন ◌ু> , <ন ◌ু ষ>. The main reason behind this organization is to minimize the searching time. So to determine the non-word error at first we determine the length of the inputted word and divide the word into trigrams. Then the word is searched on the group having the same length in the dictionary. Comparison starts with the trigrams of the trigram set. If the trigrams are not matched with any other words of the dictionary, then the word is treated as non-word error. For example: if a user types সে মানুস হিসেবে ভালো in his typing episode, our system takes each word sequentially and verifies with the dictionary. From the above example our system determines মানুস as incorrect word.

[2]http://www.english-Bangla.com/bntobn

(a) 1a (b) 1b

Fig. 1: Non-word and real-word error detection

In some cases, words may contain suffixes. For example, the word করেছিলাম contains the suffix িলাম.For this type of word, our system finds no exact matching in the dictionary. In order to reduce this type of problems, we use the concept of the stemming algorithm [7] that only strips the root word and the suffix. We consider some frequent suffixes for stemming: ই,ব, িলাম,ি, ী, টি ,সব etc. and order the suffixes in descending order according to the length of the suffix. We match the inputted word from the right with the suffix list. If any matches found, then we remove the suffix from the actual word. Then we use the same procedure as discussed above to determine the non-word error.

If any word is detected as an incorrect word, then our system generates suggestions based on the wrong word. For this, we match the first trigram of the entered word with the first trigrams of other words from the dictionary. If any matches found, we select them as candidate words. Then we calculate the length difference between the inputted and the candidate words. If the length difference is between zero to five, then the words are selected as suggestions. Continuing the previous example, suggestions generated for the word মানুস are মানুষ , মানুষকে , মানুষের which is illustrated in Figure 1a.

2) real-word Error Detection: The next step is to check whether the word is syntactically correct or not. For example, in text "`his presence ink my room`", the word "`ink`" is a real-word error. In Bangla, as discussed above this type of error generally occurs due to substitution of a phonetically equivalent letter. Based on Hoque and Kaykobads Soundex type encoding [19] and Zaman and Khans Soundex type encoding [5] we have created some phonetic groups containing similar phonetic characters, which are shown in Table I

TABLE I: Phonetically Similar Characters Grouping

Group Number	Members
1	ন, ণ
2	স, শ, ষ
3	র, ড়, ঢ়, ঋ
4	খ, ক্ষ
5	ে , ে,ঊ , উ
6	ী , ি,ই ,ঈ
7	জ, য
8	ব, ভ

If a word contains any of the above mentioned letters, then our method searches for the candidate words containing other phonetic words of the same group having Levenshtein distance [20]equal to 1 from the word dictionary. Then it calculates the probability of the candidate set along with the inputted word. Based on that, it detects real-word error and suggests some relevant words from the candidate set simultaneously.

a) Candidate Set Construction: The candidate set of a word W_k is a set of words which needs to perform single edit operation to generate W_k. An edit operation is either insertion, deletion or substitution. The candidate set C_{W_k} is represented as:

$$C_{W_k} : \{W_1, W_2, W_3,...,W_i\}$$

Here k is the position number of the word in the typed sentence and i is the word number of the candidate set. For example: if a user types আমার মণ খারাপ then our system finds that মণ contains phonetic letter from above mentioned group and generates মন, বন,সন,শন as its candidate set. For better understanding, we have used the above mentioned example in the following subsections.

b) N-Gram Model Generation of Candidate Set: After generating the candidate set the next step is to form bigram (N=2) and trigram(N=3) for each member of the candidate set C_{W_k}. For bigram, we generate both left and right bigram by considering left word and right word and for trigram we use both of them. Following model (taken from [1])is used to generate bigram and trigram model for each member of the candidate set.

$$\begin{aligned}\text{Left Bigram} &: \{W_{k-1},W_k\}\\ \text{Right Bigram} &: \{W_k,W_{k+1}\}\\ \text{Trigram} &: \{W_{k-1},W_k,W_{k+1}\}\end{aligned}$$

Table II shows bigram and trigram models of each candidate word along with the original word of the above mentioned example.

TABLE II: N-gram Models of Candidate Set

Candidate words	right bigram	left bigram	trigram
মণ	আমার মণ	মণ খারাপ	আমার মণ খারাপ
মন	আমার মন	মন খারাপ	আমার মন খারাপ
বন	আমার বন	বন খারাপ	আমার বন খারাপ
সন	আমার সন	সন খারাপ	আমার সন খারাপ

The occurrence of these bigram and trigram models is calculated from an experimental Bangla corpus containing 50000 sample text collected from different newspapers, blogs and from an informal survey.

c) Probability Calculation of N-Gram Model: The bigram and trigram probabilities of each candidate word is calculated using the following maximum likelihood (ML) estimation equation.

$$\text{P1}(W_k|W_{k-1}) = \frac{\text{Count}(W_{k-1}W_k)}{\sum_0^i \text{Count}(W_{k-1}W_i)} \quad (1)$$

$$\text{P2}(W_k|W_{k+1}) = \frac{\text{Count}(W_kW_{k+1})}{\sum_0^i \text{Count}(W_iW_{k+1})} \quad (2)$$

$$P3(W_k|W_{k-1},W_{k+1}) = \frac{\text{Count}(W_{k-1}W_kW_{k+1})}{\sum_0^i \text{Count}(W_{k-1}W_iW_{k+1})} \quad (3)$$

Here, equation 1 estimates left bigram probability by counting total number of left bigram W_{k-1},W_k. The denominator is the summation of the total count of all bigrams, containing previous word W_{k-1} of the typed sentence and one word W_i from the candidate set. In the same way, both P2 and P3 estimates right bigram and trigram probability of the candidate set. These three probabilities are combined to count a weight of each candidate word using the principle of Linear Interpolation.

$$\begin{aligned} W(W_k) = \lambda_1 P1(W_k|W_{k-1}) + \lambda_2 P2(W_k|W_{k+1}) \\ +\lambda_3 P3(W_k|W_{k-1},W_{k+1}) \end{aligned} \quad (4)$$

Here, λ_1+λ_2+λ_3= 1. To estimate the value of λ a small training set is built containing 20% of the experimental corpus. We noticed that, the results are best if we estimate λ_1 = λ_2 = 0. 3 and λ_3= 0.4. As trigram models are low biased and have a robust count on given sufficient training data [1], so we maximize λ_3.

d) Error Detection and Suggestion Generation : The above equation is used to calculate the weight of each candidate set. After generating the weight we sort the weight in descending order. If the weight of the actual word that was typed is zero then it is considered as real-word error. In some cases,the weight of each candidate set is nonzero, in this regard we check if the weight of the actual word is greater than other words of the candidate set then it is also considered as real-word error. Continuing the previous example, we have the candidate set মন, বন,সন,শন. For each of the candidate set we calculate the weight as shown in Table III. There is no count for bigram আমার মণ and মণ খারাপ as well as trigramআমার মণ খারাপ of actual word . So the total weight for the actual inputted word মণ is zero. So it can be considered as real-word error. Figure 1b illustrates the process.

TABLE III: Candidate Set With Weight

Candidate Word	Weight
মন	3.75
সন	0
মণ	0
বন	0

Let us consider another example আমার আসা নেই. Here ,the word আসা is a phonetic word and generates আসা , আশা ,বাসা as candidate set. In this case, the weight of each candidate word is nonzero, so our system rearranges the weight in descending order as shown in Table IV. However, the total weight for the actual inputted word আসা is less than the weight count of word আশা. So it can be considered as real-word error.

Again weight zero may not always mean real-word error. If a particular bigram or trigram is absent in the corpus then the weight may be zero. This type of problem arises if the inputted phonetic word contains suffixes. For example, if the given text is তোমার ফোনের আশাই করেছিলাম, our system finds no bigram and trigram count generated by the word আশাই. In order to reduce this type of problem we use the same concept of stemming described in section IV-A1. After removing the suffix from the actual word we use the same procedure as discussed above to determine the real-word error.

TABLE IV: Candidate Set with weight

Candidate Word	Weight
আশা	0.875
আসা	0.5
বাসা	0.25

If an inputted phonetic word is considered as real-word error then we select the ordered candidate set and provide them as suggestions. Because we rearrange the candidate set according to the weight in descending order. If the weight of a candidate word is greater than a threshold value 0.5 then the word is treated as a suggestion. We choose this value as threshold value because we perform different experiments on the weight of different candidate words and notify that most of the candidate words having a weight greater than 0.5 are considered as a good candidate for suggestions.

V. Experiments and Evaluation

We developed an android application to implement our proposed method. To develop the application we used android studio(Version 3.3.2), an official IDE for android application development[3] which uses Java language to write codes. We tested our application with 50,000 words and 3000 sentences collected from different sources such as Bangla newspapers, social networking sites and Bangla blogs. Again, we tested our application by ten users who used our application for their text writing purpose. For a better evaluation, we compared our spell checking technique with another familiar spell checking method [16] which used N-gram model to check spelling errors. The following subsections contain the discussion of results attained from different experiments in terms of error detection accuracy and suggestions generation efficiency.

A. Evaluation Dataset

As there is no specific dataset available for Bangla language, so in this experiment we created our own dataset. As discussed above we collected 50,000 structurally correct words from different sources to determine non-word error detection accuracy of our application. Among them, 27000 words were collected from two prominent newspapers i.e. Prothomalo[4] and Kalerkontho [5], 10200 words from social networking sites(i.e. facebook) and 5400 words from Bangla blogs[6]. Rest of the 7400 words were tested by the application users. Again, among the 3000 correct sentences as stated above almost 1000 texts were collected from online sources and other 1600 were from application users.

[3]https://developer.android.com/studio/
[4]https://www.prothomalo.com
[5]https://www.kalerkantho.com/
[6]http://www.sachalayatan.com/

B. Experimental Methodology and Result

We conducted two types of experiments in order to figure out, (i) the correctness of error detection and (ii) correctness of suggestions . The first experiment was done to determine error detection quality considering both non-word and real-word error. Because error detection quality reflects the effectiveness of the detection algorithm and a good detection algorithm increases the possibility of correct detection. At first, we tested our application with 50000 correct words to determine non-word error detection quality. Then we manually modified these words by performing single edit operation i.e. insertion or deletion operation to generate 50000 incorrect word. The result generated for both correct and incorrect words are shown in Table V, which shows that the average error correction rate of our proposed method is 96.32% for non-word error.

TABLE V: Result Generated for Non-word Error

Type	Total Words	Correct Detection	Efficiency
Correct	50000	47640	95.28%
Incorrect	50000	48681	97.36%
Average			96.32%

Again to determine the real-word error, at first we tested 1000 correct sentences containing approximately 1990 words and 50 phonetic words as stated above. Among them, 600 sentences were from newspapers, 300 from blogs and 100 were from social networks. The result generated by the experiment with correct sentences is shown in Table VI.

TABLE VI: Result Generated from Correct Sentences

Source	Total Sentences	Correct Detection	Efficiency
Newspaper	600	578	96.83%
Blogs	300	285	95%
Social Networks	100	97	97%
Average			96.27%

As all the sentences contain correct words, so for another experiment we prepared an erroneous test file containing corrupted words to test our system. To make such an erroneous file, we replaced the correct phonetic word with erroneous word by performing single edit operation including insertion, deletion and substitution at phonetic letter position. In this way, we generated 3000 erroneous test cases of real-word error. Then we computed the actual detection of real-word error R and the erroneous detection rate E of the proposed method. Let consider e_1 represents the total number of error, e_2 represents the total number of error detection and e_3 represents total number of correct real-word error detection. Where,

$$R = \frac{e_3}{e_1}$$

$$E = \frac{e_2 - e_3}{e_1} * 100\%$$

Table VII represents the percentages of incorrect identification of real-word error and erroneous detection rate of our proposed system.

TABLE VII: Efficiency Calculation of Erroneous Sentence Detection

Correct Detection	Erroneous Detection Rate
94.37%	3%

As described above, for a better evaluation we also evaluated our application by conducting a pilot study involving 10 participants aged from 18 to 40. Participants used sentences containing different length of words. According to the length, we classified these sentences as simple, complex and compound sentences. For this experiments, participants used almost 1600 number of sentences of different length. Table VIII indicates that the accuracy of our proposed method is on an average of 96.68%. Therefore, the average real-word correction rate of our developed application is 96.48%.

TABLE VIII: Performance Evaluation from User Study

Type	Word Length	No. of Sentences	Correct Detection	Accuracy
Simple	1-4	680	678	99.70%
Complex	5-7	532	512	96.24%
Compound	8-10	356	335	94.10%
Average				96.68%

Our second experiment was for determining correct suggestion generation rate. If any word selected as non-word error, then our system can generate suggestions for approximately 95% misspelled word. As discussed in IV-A1, suggestions are generated if the entered and the candidate word from the dictionary having a minimal length difference. Depending on the procedure, we divided the generated suggestions into two categories. Category 1 contains words having length difference between 0 to 3 and Category 2 contains words having a difference from 4 to 5. Table IX represents the result, which shows that 90% suggestions are of a length distance between 0 to 4.

TABLE IX: Results Based on Suggestions for Non-word Error

Length Distance	Selected as Suggestions(%)
0-3	90%
4-5	5%

Again for real-word error, our system can generate approximately 90% correct suggestions treated as top-ranked suggestion. If a word is treated as real-word error, then the candidate suggestions are generated based on the sorted score of each candidate set. Based on the sorted score we divided suggestions into relative ranks. The relative ranks of the suggestions are shown in figure 2. It is observed that almost in 85% cases Rank1 suggestions were correct and 8% correct suggestions were from Rank2. This results show that our proposed method generates correct suggestions for almost 93% of the cases with a failure rate of 3%.

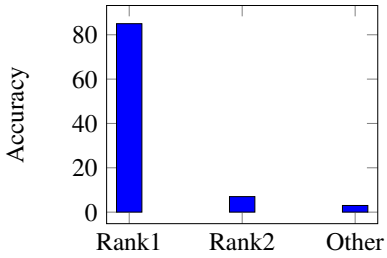

Fig. 2: Evaluation of ranked suggestions

Again we compared our proposed method with another well-known spell checking algorithm [16]. We selected this paper for comparison because it used the N-gram model to detect error correction. Table X represents the result obtained from above-mentioned comparison. The result showed that the error detection correctness is 96.65% while for another method the correctness is 94%.

TABLE X: Result Obtained from Comparison with Other Method

	Proposed Method	**Compared Method**
No. of words	2540	2540
Correct Detection	2455	2389
Accuracy	96.65%	94.05%

VI. Conclusions and Future Work

In this paper, we presented a new spell checker to facilitate the error correction technique of Bangla text. The proposed method can effectively detect word and sentence level errors and provide suggestions based on the errors. We used the concept of edit distance algorithm in our own way to detect the word-level error. For the sentence level error, the probability of the N-gram models are calculated using the principle of linear interpolation model. We evaluate our proposed spell checking technique with test words and sentences collected from different online sources and by conducting a pilot study. The evaluation results showed that this technique significantly detects both errors and provides relevant corrections based on the error. Results also revealed that our proposed method works better than other spell checking technique of Bangla language.

The future work may involve creating a spell checker that can handle multiple non-word and real-word errors in sentences. In the future, we will develop a complete spell checking application for Microsoft word. Moreover, our future target is to apply the spell checker for patient complaint system in the medical sector of Bangladesh.

***Abstract*—Problem Based e-learning(PBeL) in bangla language is one of the most progressing areas of the use of ICT in education. Question Bank(QB) is the main component of any PBeL system. Searching similarity in the complex structure of QB is a challenging task in the development of PBeL system. We have been developed an efficient Question Bank Similarity Searching System(QB3S) to find similar questions, handle duplicate question and rank search result of a query input based on NLP and Information Retrieval techniques. QB3S has four modules: bangla documents processing, question structure analysis and clustered indexing by B+ tree , word-net construction and Information retrieval module. Lexical analysis, stemming by finite automata rules and stopwords removing have been used for bangla document processing. The most challenging procedures of QB3S were Analyzing the structure of data for clustered indexing in the sorted sequential file of the QB database with a B+ tree data structure and improved TF-IDF algorithm with weighted functionality. A Word-net has been used for handling synonyms. Vector Space Model(VSM) has been designed from the value of TF-IDF weighted matrix. By using cosine similarity product rule, we have been Calculated the similarity value between the query input and all mcq of DB from VSM. QB3S has been evaluated in some experimental dataset to find results by imposing different test cases. The accuracy of searching performance which has found to be satisfactory.**

***Index Terms*—Tokenization, Stopwords Removing, Stemming, Clustered Indexing, B+ tree, Word-Net, TF-IDF, VSM, Cosine Similarity**

I. Introduction

Problem-Based eLearning(PBeL) systems have been proved to be effective in blended learning in classroom and also in asynchronous learning. The PBeL system [1] developed for ICT course in Higher Secondary School(HSC) level contains a rich question bank of different types and complexities. It is utmost requirement of the QB to contain only distinct questions in terms of title, contents and answers. This requires a rigorous similarity search to remove the possible duplicate questions. In this research, we have developed a similarity searching system on complex structures of QB using NLP and IR technique. Beside duplicate handling, it also can be ranked searching results of a query input based on similarity values.

Information Retrieval (IR) [2] system can be construed as a set of techniques and tools dealing with access to information from a set of structured, semi-structured or unstructured documents database in order to allow the user to retrieve the correct and relevant information. IR algorithms for fetching relevant information from large amount of structured data of QB database where data is represented in tabular form, need to strategically better searching techniques.

We have used NLP tools [3] like, Tokenization or lexical analysis of bangla text corpus [4], StopWord removing, Rule-based sementic analysis or stemming to modify inflected word and analyzed the structured data to build a dynamic B+ tree clustered indexing to speed up the retrieval of records. To build the generative laexicon [5] for bangla language, many paper had been already published in the field of computational linguistics morphology. The stem need not be identical to the morphological root of the word; it is usually sufficient that related words map to the same stem, even if this stem is not in itself a valid root. Algorithms for stemming have been studied in computer science since the 1960s. In [6], A rule-based approach of stemming bangla word had been found an excellence solution. Sometimes Bangla words get more complex morphological structure in addition of inflectional suffix, derivational suffix and agglutination . There are existing efforts at building a complete morphological parser for Bangla [7], where experiments have been carried out with two types of algorithms: simple suffix stripping algorithm and score based stemming cluster identification algorithm. Another rule-based intelligent Bangla parser is to ease the task of handling semantic issues in the subsequent stages in machine translation [8].

B+ tree data structure for indexing Object Oriented Database has been found time efficient searching, inserting and deleting algorithms in [9]. Clustered Metric Tree(CM-Tree) had been constructed for a dynamic clustered index in unstructured metric database for searching similarities [10]. Variations of the TF-IDF(Term Frequency - Inverse Document Frequency)

weighting scheme are often used by IR techniques as a central tool in scoring and ranking a documents relevance given a user query [11]. Many TF-IDF weights function has been developed for verious IR applications like, an improved TF-IDF weights function is proposed which uses the distribution information among classes and inside a class [12]. Improved version of a well functional weighting scheme of TF-IDF algorithm based on question title or option or answer terms, Vector Space Model [13] for representing documents as a vector in t-dimension (If the document contain t no. of terms) and find the similarity with query vector using cosine similarity product rules are the main area of IR techniques used in QB3S. A hash-mapping WordNet is used to handle same meaning words or synonyms. Main objective of our research showing below:

- To improve in a certain level of Bangla documents processing tools like tokenization, stopwords removing, stemming to accomplish the processing of QB data-set.
- To analyze the structure of data and indexing in sorted sequential records(Clustered Indexing) of QB database for faster access by using B+ tree data structure.
- To construct a hash mapping word-net to handle synonyms.
- To improve a weighted functional TF-IDF algorithm.

The rest of the paper has been organized as follows. Section II describes the structure of QB[14-17]. The system architecture for QB3S has been given in section III. Section IV shows the results obtained after the application of QB3S in the existing eLearning system [1]. A detailed discussions on the results has also been given in this section. Finally the conclusion is given in section V.

II. Question bank Structure and e-learning of ICT course

A sequence of papers [14-17] were published in journals or conference towards improving PBeL in ICT course of secondary and higher secondary level of Bangladesh. Problem based e-learning system (http://epbl.org) for interactive learning of ICT course, practicing and model examination from question bank and C programming, HTML, SQL, ERD learning based on higher secondary book have already been implemented successfully. Question bank data are important resource for Problem Based e-Learning(PBeL) which requires a search engine to retrieve query information from the large scale of data and this can be used by the admin of PBeL system to find the duplicate question, user can find out searching result of the relevant query input.
Let us take a closer look at the information and utilities available in a bangla question bank database. It can be Categorized the Multiple choice questions in three classes:

1) Cognitive class:
   The simplest structure where there are a question title and 4 options.Like,
   আধুনিক কম্পিউটারের জনক কে?
   ক) অ্যাডা লাভলেস
   খ) চার্লস ব্যাবেজ
   গ) বিল গেটস
   ঘ) জেমস ক্লার্ক ম্যাক্সওয়েল
2) Analytical class:
   It contains three option and the scope of answer is the four combinations of these options.As example,
   কম্পিউটারের সময় অপচয়কারী ব্যবহার –
   i) প্রোগ্রামিং শিক্ষা
   ii) ভিডিও গেম
   iii) সামাজিক যোগাযোগ
   নিচের কোনটি সঠিক ?
   ক) ii ও iii খ) i ও iii
   গ) i ও ii ঘ) i. ii ও iii
3) Higher Ability class: One of the most complex structure and scenario based questions.There are may be two or three Cognitive or Analytical mcq question based on a scenario. As example,
   নিচের অনুচ্ছেদটি পড় এবং 1-2 নং প্রশ্নগুলোর উত্তর দাও:
   বর্তমান আমাদের দেশে বেকার সমস্যা মানাতœক সামাজিক ব্যাধি। প্রায় প্রতিটি সমাজেই এ ব্যাধিতে আক্রান্ত। বেকার সমস্যা দূর করতে বর্তমানে HTML, CSS, JAVA Script সহ বিভিন্ন ধরনের CMS সফটওয়্যার এর মাধ্যমে ওয়েব ডিজাইন করে বেশ অর্থ উপার্জন করছে।
   1. CSS- এর পূর্ণরূপ কী?
   ক. Caseding Style Sheet
   খ. Compund Style Sheet
   গ. Compund Shorting System
   ঘ. Cacacing Simple Sheet
   2. কত সালে তাদের প্রতিযোগিতামূলক ব্রাউজার রিলিজ করে?
   ক. ১৯৯৫ সালে
   খ. ১৯৯৬ সালে
   গ. ১৯৯৭ সালে
   ঘ. ১৯৯৮ সালে

Orgatization of stroed question in database schema is showing in Fig. 1. We need to analysis the structure of question and cluster it with three decision boundaries of three different classes will be described in sec. III.

III. QB3S system architecture

Theoretical analysis of the body of methods and principles associated with branches of procedure. QB3S has taken an input mcq or part of a mcq, processing data and performing search for finding the maximum similar mcq from entire QB DB. See Fig. 2, showing the architecture of system in terms of process flow. The whole process can be split into four modules:

1) Question structure analysis and clustering module
2) Document processing module
3) WordNet module
4) IR module

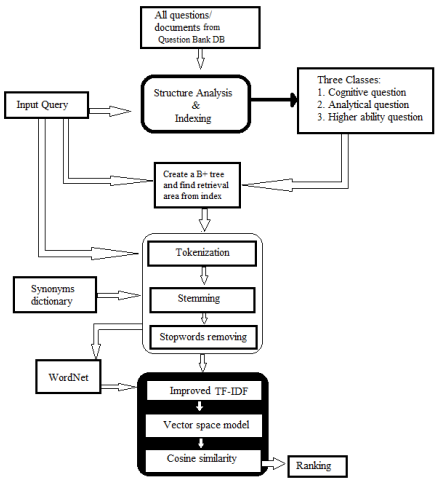

Fig. 2. System Architecture of QB3S

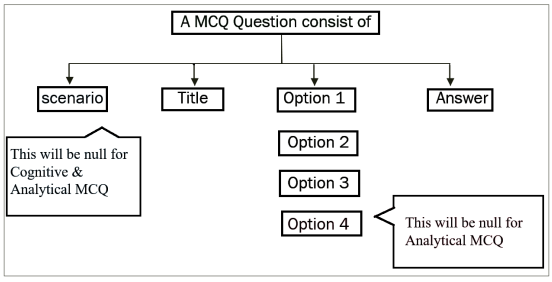
A. Question Structure analysis and clustering

In sec. II, we have been already discussed about the structure of question bank data and categorized them in three classes. Criteria of classification based on structure of question is showing in Fig. 3.



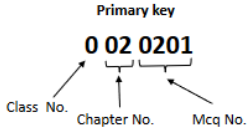


Fig. 3. Question structure analysis

PBeL system of ICT course database schema has been designed such a way that a table allocated for each class. Each table for a specific class contains identical questions of all chapters.

Clustered indexing by B+ tree:

B+ tree data structure has been used to track the clustered index(primary key on sorted order) of database table. B+ tree efficiently reduce the access time of search space in database of QB. In case of ICT course QB, it has 6 chapters and 3 classes of question. Primary key of table has been maintained as,

We had been compelled to track 18 indexes in the leaves node, each one pointed to the starting key of sorted data and degree of the B+ tree 6 in this case(see Fig. 4). So the height of tree ceil(log(18)/log(6/2)) = 2.

During the search operation, h nodes are read from the disk to the main memory where h is the height of the B+ tree and $h = log_t(n)$, where n is the number of the keys stored in the tree and t is size of a block or node . In addition of the disk reads, B+ tree searching algorithm performs a linear search in every node read from the disk. The time complexity of each linear search is O(t) . Thus, the total time complexity of the B + tree search operation is $O(tlog_t n)$ and same time complexity for inserting and deleting [18].

In case of higher number of chapter, it needs higher order and for adding other courses in QB, extra level will be added dynamically by imposing precondition [19].

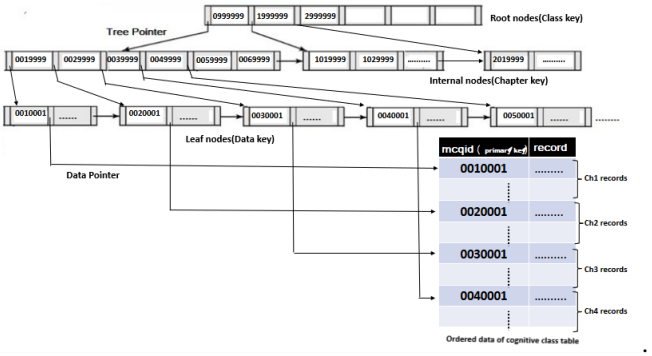

Fig. 4. B+ tree structure for clustered indexing

B. Bangla Document Processing

In the field of Bangla language processing, we have been already discussed the existing work of tokenization, Stemming and stop words removing in Sec. I. Now we are going to explained the tools of language processing which have been used in QB3S.

1) Tokenizer: Tokenization is the process of breaking up the given text into units called tokens.Tokenization refers lexical analysis in natural language processing.

We use a standard tokenizer, which splits text into terms on word boundaries using white space, as defined by the Unicode Text Segmentation algorithm [20]. It removes most punctuation symbols. Array-list data structure has been used to store the terms after tokenization.

2) Stemmer: A very simple-to-use rule based stemmer [6] for Bangla word parsing is used for semantic analysis. Which take a inflected word as input and output the corresponding root stem. Some common rules which is used for semantic analysis showing below and See examples of common rules text file contains in Fig. III-B2.

X #When X appears at the end of a word, remove it

$Y \rightarrow Z$ #When Y appears at the end of a word, replace it with Z

$Y.Z \rightarrow A.B$ #When Y, followed by some character a, followed by Z appears at the end of a word,replace it with AaB

(

ই	৯ এটাই, সেটাই
ও	৯ এটাও, সেটাও
তো	৯ হবতো, করলতো

)

(

কে	৯ এটাকে, আমাকে
তে	৯ যসতে, গাইতে
রা	৯ বহিমরা, করিমরা

)

Fig. 5. Examples of some common rules for stemming

3) Stop words Remover: 'Stop Words' usually refers to the most common words in a language.There is no single universal list of bangla stop words. We build stop words list in followed way:

1) From some pre defined words
2) From the most frequently occurring word in Question Bank database

All stop words are removed from the array-list by using UTF-8 string matching library in java [21].

C. Word-Net module

As you know, synonyms are words that have similar meanings. A synonym set, or synset, is a group of synonyms. A synset, therefore, corresponds to an abstract concept.We have been constructed a runtime hash mapping from text file which contains bangla synonym dictionary(see Fig. 6).

প্রতিস্থাপন করা;বিনিময়,স্থলাভিষিক্ত করা,আদান প্রদান করা,বিকল্প
নেটওয়ার্কিং;জালাধান
রক্ষণাবেক্ষণ;যত্ন
জড়ো হওয়া;জমান,সমবেত হওয়া,সঙ্কলন করা,সংগ্রহ করা
সুবিচার;যথার্থতা,বিচারক,
ভংগুর;তুচ্ছ,শিষ্ট,ভঙ্গুর,ক্ষীণ হওয়া
ভান্ডার;জমা হওয়া,ন্যাসরক্ষক,স্মৃতিসৌধ,সচিব
হেলিক্স;পেচানো
ডিকোডিং;ডিক্রিপ্ট করা
বিধিলঙ্ঘন;অমান্য,বিধিলঙ্ঘন,অপকর্ম

Fig. 6. Bangla synonym dictionary txt file

Step of hash-mapping word-net construction:

1) Take input from bangla dictionary text file
2) Tokeniztion
3) Stop-word removing
4) Stemming
5) Use hash function, $f(n) = charAt(0) \mod 128$ for finding hash value (total 128 bangla character,unicode value 0980H-09FFH).

Hash-map of the first line of Fig. 6 showing in Fig. 7.

Searching time complexity : O(1)

Fig. 7. Representation of dictionary hash-map

D. Information Retrieval module

1) Improved version of Weighted TF-IDF: Term Frequency(TF) measures how frequently a term occurs in a document.Suppose we have a query or input mcq consisting terms, $t_1, t_2, t_3, t_4 ..... t_n$ and there are many documents $mcq_1, mcq_2, mcq_3 ..... mcq_m$ where the tf-idf will be performed.Then,

$$TF(t, mcq_j) = \frac{f(t, mcq_j)}{\sum_{T \xi mcq_j} f(T, mcq_j)} \quad (1)$$

$Where, f(t, mcq_j) =$ Numbers of time Term t appear in mcq_j

Inverse Document Frequency(IDF) Measures how important a term is. Log base e of ratio between total number of documents and Number of documents with that term t in it.

$$IDF(t) = ln\frac{N}{n} \quad (2)$$

Where, N = Total number of documents And n = Number of documents with term t

We have been developed an improved version of this algorithm where we used some pre-defined weighting factor based on the classification of question structure.
Weighting Factor,

$$W(t) = \begin{cases} w1 & if\ t\ is\ a\ Answer \\ w2 & if\ t\ is\ an\ option \\ w3 & otherwise \end{cases}$$

Where, w1> w2>w3
So tf-idf equation with pre-define weighting factor as like,
$TF - IDF_{improved}(t, mcq_j) = \frac{f(t, mcq_j) * W(t)}{\sum_{T \xi mcq_j} f(T, mcq_j) * W(T)} * ln\frac{N}{n}$

2) Vector space Model Representation from TF-IDF: Vector space model or term vector model [22] is an algebraic model for representing text documents as vectors of identifiers like index terms. Formally, a vector space is defined by a set of linearly independent basis vectors.The basis vectors correspond to the dimensions or directions of the vector space. The basis vectors are linearly independent because knowing a vectors value on one dimension does not say anything about its value along another dimension. Documents and Query are represented as vectors.

$$D_j = (w_{1,j}, w_{2,j}, \ldots, w_{t,j})$$

$$Q = (w_{1,q}, w_{2,q}, \ldots, w_{n,q})$$

Each dimension corresponds to a separate term. On the off chance that a term happens in the document, its incentive in the vector is non-zero. Graphical representation of a vector space in Fig. 8.

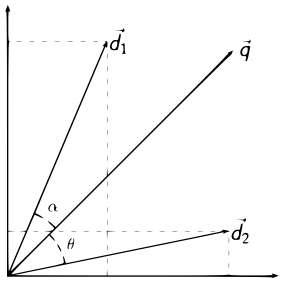

Fig. 8. Vector space model

Vector Space Model (VSM) is a common technique to depict the text feature in text classification. It adopts TF-IDF weights to compute the term weighting in each element of the text feature. Be that as it may, it just considers the connection between the term and the entire content however disregards the relationship between various terms. VSM has been used for representing tf-idf weight of a mcq as a vector in the space. Let's assume we have a query mcq '**Q**' like,

নিচের কোনটি উচ্চস্তরের ভাষা?
A. পাইথন
B. ভিজুয়াল বেসিক
C. জাভা
D. সব ক'টি
Answer: সব ক'টি

After processing it using the method described in Subsec. III-B '**Q**' will be transformed into:

নিচ উচ্চস্তর ভাষা পাইথন ভিজুয়াল বেসিক জাভা সব

Query '**Q**' can be represented in the 7-dimensional vector space. Calculated the value of TF-IDF in a wighting matrix where each row represents a vector of a document in the space of query document.After performing improvedTF-IDF algorithm the weighting matrix is showing in Table I.

TABLE I
VECTOR REPRESENTATION FROM TF-IDF VALUE IN VSM

Doc	$term_1$	$term_2$	$term_3$	$term_4$	$term_5$	$term_6$	$term_7$
mcq_1	0.0	0.05	0.05	0.05	0.05	0.05	0.05
mcq_2	0.05	0.08	0.0	0.01	0.0	0.03	0.0
mcq_3	0.0	0.12	0.22	0.33	0.44	0.55	0.83
mcq_4	0.0	0.0	0.0	0.0	0.0	0.0	0.0
mcq_5	0.0	0.0	0.03	0.03	0.03	0.03	0.03
mcq_6	0.09	0.0	0.11	0.1	0.1	0.1	0.1

3) Similarities measurement using Cosine Similarity: Cosine similarity is a measure of similarity between two non-zero vectors of an inner product space that measures the cosine of the angle between them. This metric is a measurement of orientation and not magnitude, it can be seen as a comparison between documents on a normalized space because were not taking into the consideration only the magnitude of each word count (TF-IDF) of each document, but the angle between the documents. To assign a numeric score to a document for a query, the model measures the similarity between the query vector and the document vector. The similarity between two vectors is once again not inherent in the model. Typically, the angle between two vectors is used as a measure of divergence between the vectors, and cosine of the angle is used as the numeric similarity [23]. Cosine has the nice property that it is 1.0 for identical vectors and 0.0 for orthogonal vector. If $\vec{D}$ is the document vector and $\vec{Q}$ is the query vector, then the similarity of document D to query Q (or score of D for Q) can be represented as:

$$sim(\vec{D}, \vec{Q}) = \cos\theta = \frac{\vec{D} \cdot \vec{Q}}{\|\vec{D}\|\|\vec{Q}\|} = \frac{\sum_{i=1}^{n} D_i Q_i}{\sqrt{\sum_{i=1}^{n} D_i^2}\sqrt{\sum_{i=1}^{n} Q_i^2}} \quad (3)$$

Cosine Similarity will generate a metric that says how related are two documents by looking at the angle instead of magnitude, like: Using the eq. 3, we can find out the similarity

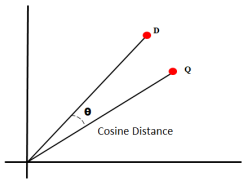

Fig. 9. Cosine distance between $\vec{D}$ and $\vec{Q}$, where $0 \leq cos\theta \leq 1$

between Query vector and other mcqs in VSM showed in table. I .The **Cos**θ values for different mcqs or docs in range of 1 (Most Similar) and 0 (less similar) and ranking(see table. II) from calculated cosine value.

TABLE II
RANKING FROM COSINE VALUE

Doc	$CosineValue$
mcq_1	0.93
mcq_3	0.81
mcq_2	0.64
mcq_5	0.32
mcq_6	0.24
mcq_4	0.00

IV. RESULT AND DISCUSSION

QB3S has been evaluated its first experiment in a multiple choice question bank(ICT) database. It contains total 1289 mcq. Information of experimental data-set is showing in table. III.

We implied two test case with present or absent of condition and analysis the result graphically. Accuracy of searching performance, Sensitivity and specificity have been calculated

TABLE III
EXPERIMENTAL DATA-SET

Chapter ID	Chapter Name	Total Question
c11001001	Information and Communication Technology	304
c11001002	Communication Systems and Networking	245
c11001003	Number system and digital device	273
c11001004	Web Design Contacts and HTML	166
c11001005	Programming language	152
c11001006	Database management system	149

from the value of True Positive(detects the condition when the condition is present), False Negative (does not detect the condition when the condition is present), True Negative(does not detect the condition when the condition is absent) and False Positive(detects the condition when the condition is absent) [24].

Test 1: Select 50 existing full or part of a mcq as query inputs from 'Communication Systems and Networking' chapter and found the maximum cosine valued mcq. Graphical result showing in Fig. 10.

Test result can be True Positive(TP) or False Negative(FN) depends on the value of cosine similarity.In case of TP, cosine value greater than 0.5, it detects the condition where query mcq belongs to this chapter is satisfied. otherwise FN.

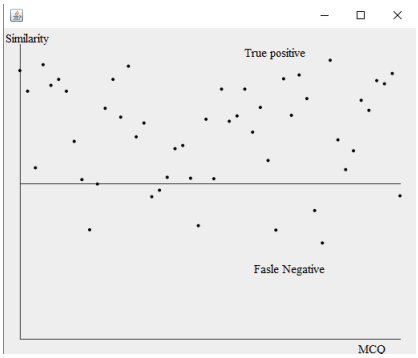

Fig. 10. Result of test 1 where 42 True Positive(TP) and 8 False Negative(FN) value was detected

Test 2: Select 50 full or part of a mcq as query inputs from other chapter except "Communication Systems and Networking" chapter(Not exist in this chapter) and find the mahapterximum cosine value holder mcq.Graphical result showing in Fig. 11.

Test result can be True Negative(TN) or False Positive(FP) depends on Cosine value. In case of TP, cosine value less than 0.5, it detects the condition where query mcq doesn't belongs to this chapter, otherwise FP.

In this experiment of QB3S, we found TP=42, FN=8, TN=43, FP=7

$$Accuracy = \frac{TP+TN}{TP+FN+TN+FP} = \frac{42+43}{42+8+43+7} = 85\%$$
$$Sensitivity = \frac{TP}{TP+FN} = \frac{42}{42+8} = 84\%$$
$$Specificity = \frac{TN}{TN+FP} = \frac{43}{43+7} = 86\%$$

Fig. 11. Result of test 2 where 7 False Positive(FP) and 43 True Negative(TN) value was detected.

V. CONCLUSION

Information retrieval techniques are effective in finding similar documents from a text database. These techniques are not efficient in finding the similarity of questions in a Question Bank developed for PBeL systems for many reasons: i) the document structure is different in nature that the conventional text documents, and ii) the contents of the different parts of the documents have different weights.

In this paper, we have analyzed the structure and weight of the different types of questions in the QB and developed an improved TF-IDF algorithm based on the weight. At the initial stage we applied NLP tools and techniques like tokenization, stemming, stopword removal in the bangla text. Handling synonym is critical in any similarity searching system. We have developed a WordNet based on hash technique technique count of of synonym in TF-IDF. We have created a the Vector Space Model using the improved TF-IDF weighted matrix. For faster and efficient access to the QB DB, we have used a B+ tree index structure.

Using the above techniques, we have developed a Question Bank Similarity Searching System(QB3S). We have applied QB3S in a real life dataset emerging from the PBeL systems for ICT course of HSC level in Bangla. We have achieved an accuracy level of 85% for similarity search in the QB.

***Abstract*—Question answering (QA) problem is one of the most frequent tasks in natural language processing (NLP) over language input. To understand the natural language, semantic parsing is an extensively used process. For deriving syntactic and semantic structures of texts, synchronous frameworks are being used frequently. With the aim of answering questions efficiently, in this paper, an approach by semantic parsing of texts with a view to leveraging semantic information is introduced. The proposed approach uses the method based on lambda calculus for semantic parsing to derive logical forms of sentences. The questions are analyzed by collecting significant features to find out correct answers from the facts. Unlike traditional approaches, this paper extends lambda calculus based dependency parser methodology for question analysis. This proposed approach for answering questions is based on generalized searching techniques. Proposed system achieves 95% accuracy for Yes/No questions with an overall 83% mean accuracy for the five tasks of bAbI-10k question answering dataset surpassing the existing approach by about 11%.**

***Index Terms*—Natural Language Processing, Semantic Parsing, Lambda Calculus, Question Answering, Logical Forms, Text Parsing.**

I. Introduction

A complicated task in natural language processing [1]–[4] is question answering which requires the understanding of the meaning of a text and the ability to reason over relevant facts. To represent the meaning of sentences of the human language, semantic parsing is the best-defined tasks that support automated inference for knowledge representation [5], [6]. Relevant works includes Transforming Dependency Structures where they use lambda calculus for parsing method to find dependency of sentences [7]. The dependency of words in a sentence can be found by open text semantic parsing [6].

For building a question answering system, it is important to analyze the question and input text; then the answer has been found from the relevant facts. One of the popular question answering task is factoid question answering to find the correct answer in documents [7]. Dynamic memory network, a neural network architecture has been introduced by Kumar et al. that processes input sequences and questions, forming episodic memories, and generates relevant answer [8]. Query-Regression Network (QRN) approach, a variant of recurrent neural network (RNN), is able to effectively handle long-term dependencies and is highly parallelizable [9]. This model is also suitable for end-to-end machine comprehension. Todai robot project on Japanese examination system has been learned the exam answers and test that from the student answers [10]. Question answering by using syntactic information is also enhanced in several attempts using heuristics analysis for ranking potential answers [11]. Some interesting works on question answering system are found in [14]–[16], [20]. QA module has been also designed for business module [15].

In the question answering system, syntactic information gives good accuracy than information retrieval. In proposed approach both sentences and selected questions in the top documents are parsed and stored in their corresponding database. We propose a novel technique to find out the answer to questions by a generalized searching algorithm. Our method first analyzes the input text and questions and find the relevant facts. It finds the answer by searching technique from the relevant facts. Fig.1 provides an example for question answering technique:

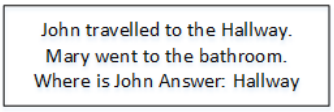

Fig. 1. Example of inputs and questions, together with answers.

This paper consists of following sections: Proposed structure and methods are discussed in section II. Section III contains

the results and discussions. Finally, the paper is concluded in section IV.

II. Proposed Structure and Methods

Proposed system introduces a searching based novel approach to find the answers from corresponding text. However, it consists of four modules: Input module, Facts finding module, Question Module and Answer module (figure 2). Proposed system is designed to map the sentences to its logical forms. Features from questions are found and the actual answers are extracted by searching from facts.

It first computes a representation for all inputs and the questions. The question representation has been triggered an iterative attention process that searches the inputs and retrieves relevant facts.

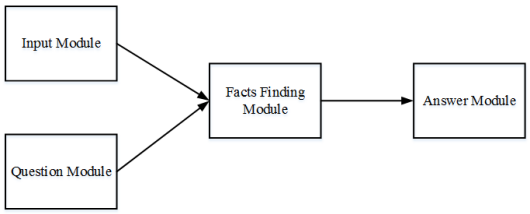

Fig. 2. Proposed Question Answering System

A. Input module

In the input module, a set of text is given. The text represents a long sequence of sentences of a story or movie. All the sentences are in simple sentence structure which have sequential meaning. Firstly, each of the sentence is being parsed from the text by nltk POS tagger [13]. Logical forms of each sentence are derived from lambda calculus based dependency parsing method [12]. Lambda calculus based dependency parsing method has been chosen for parsing because it puts the main $verb$ as root word of a sentence. The semantic form of each sentence depends upon the $verb$. The $subject$ and $object$ of a sentence have been affiliated by verb.

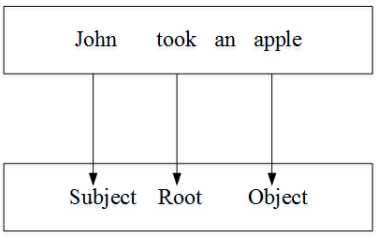

Fig. 3. Lambda calculus parsing method.

The facts are found from the text by parsing method based on lambda calculus dependency parsing [12]. Lambda calculus method has been used for making a relationship with $subject$ and $object$ of a sentence by taking the verb as a root of the sentence. An example of lambda calculus method is depicted in fig. 3.

B. Facts finding module

The given input text has been analyzed in this module. The $subject$ and $object$ of the sentence are also derived by checking tagged parts of speech of each words of that sentence. The $verb$, $subject$ and $object$ from each sentence have been taken and stored in corresponding database for easily finding the answer.

Logical forms derived from lambda calculus dependency parsing [12] will help further to find the features those eventually lead us to analyze question to find answers.

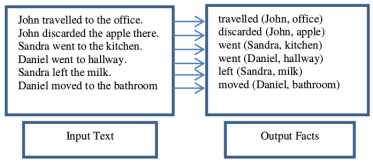

Fig. 4. Lambda calculus parsing method is used to find facts from input text.

In fig. 4, a sequence of input sentences have been parsed by lambda calculus dependency parsing method. Three types of feature are found from each sentence. The extracted features are stored in their corresponding databases, like verb database (VB_i), subject database (SB_i) and object database (OB_i). It assumes that if there are n number of sentences in a text, then the number of $verb$, $subject$ and $object$ are also n numbers. Here *i* represents the position of sentences in each text. Answer of the question has been extracted from these databases. The database of $verb$, $subject$ and $object$ extracted from fig. 4 has been shown in fig. 5, 6, 7.

Travelled, discarded, went, went, left, moved

Fig. 5. Verb database (VB_i) for corresponding input text.

John, John, Sandra, Daniel, Sandra, Daniel

Fig. 6. Subject database (SB_i) for corresponding input text.

Office, apple, kitchen, hallway, milk, bathroom

Fig. 7. Object database (OB_i) for corresponding input text.

C. Question Module

The corresponding question is also expressed in natural languages which is related to the input text. We mainly work on analyzing two types of question. They are 'W/H' question and 'Yes/No' question. 'W/H' questions are started with 'WH' tagged word by using the natural language toolkit (NLTK) [13]. Example:

$$Where\ is\ Daniel?$$

The answer of the question which starts with $Where$, indicates that the answer should be a place. Similarly, 'W/H' question extracts the factual answers from the text. On the other hand, 'Yes/No' question starts with a auxiliary verb (like, am, is, are etc). This type of question only requires 'Yes' or 'No' as answers.

After parsing and tagging each word of a question, we find two features from that sentence.

- Question Word (QW)
- Object Word (OW)

Question represents a sentence according to the input text. For example $Where\ is\ Milk?$ is an input question. Question should be corresponding to the input sequence. The important features from the question have been derived by extracting the features which is depicted in fig. 8. The two important features (w/h question word and object word) have been derived from each question.

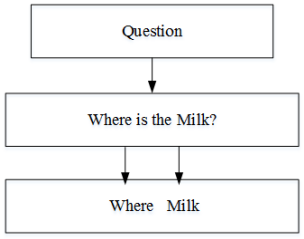

Fig. 8. Feature finding from W/H question.

Let we take two main features in QW(question word) and OW(object word). Fig. 8 shows that
QW = 'where'
OW = 'milk'
QW is also known as W/H feature. W/H feature is 'where' which indicates to find the location of the milk.

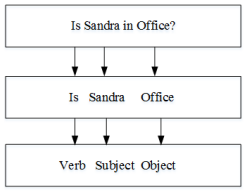

Fig. 9. Feature finding from Yes/No question.

Similarly, Figure 9 shows the feature finding from 'Yes/No' question word. Two features ($Subject$ and $Object$) are collected from this 'Yes/No' type question.

D. Answer module

This module generates the answer analyzing by the facts those are found from input module and question module. We have found two types of question in our test from the dataset. Firstly, we made a database of verb which indicates the position of that subject. For example, $Daniel\ Moved\ to\ office$. In this case, $moved$ indicates the location of the subject of this sentence. The positional verb database T_i is shown in figure 10.

Fig. 10. Positional verb database T_i.

Storage of positional verb helps us to find the answer of a question which starts with 'where'. For finding the last position of the given Object Word (OW) in the question, it is important to search from the last position of the database and find the matches. The question which is started with 'where', our proposed system finds the answer by the given algorithm:

Algorithm 1: Finding answers of Questions starting with "Where"

Input: OW
Output: Position of SBi (where i is the position of sentence)

```
Take OW from the question
Check OW with SBi and VBi with Ti,
  answer = OBi
if OW matches with OBi then
    position of SBi of corresponding OBi is found by
      previous step.;
end
```

To test our algorithm, we give two examples here. For instance, the question is $Where\ is\ Sandra?$. Here, the OW = 'Sandra' and by using our algorithm the answer is 'kitchen'. It generates 'kitchen' as answer because the last position of Sandra is in 'kitchen'.

We also design an algorithm for 'Yes/No' question answering. It is known to us that two features ($Subject$ and $Object$) are collected from the corresponding question for 'Yes/No' answers. The algorithm is as following:

Algorithm 2: Finding answers of Yes/No Questions

Input: Subject, Object
Output: Answer

```
Take Subject and Object from the question
if Subject = SBi and Object = OBi (where i is the
  position of sentence) then
    answer = 'Yes';
else
    answer = 'No'
end
```

For example, the question is $Is\ Sandra\ in\ Office$, where $Subject$ = 'Sandra' and $Object$ = 'Office'. By using our proposed algorithm, it finds no matches where 'Sandra' and 'Office' occurs in the same sentence. So, the system gives 'No'

as it's answer. Moreover, we also make the similar matching algorithm for finding the answer of question which starts with $what$.

III. Results And Discussion

A. Dataset Collection

To analyze proposed model, bAbI-10k English question answering dataset [9] has been used. It's a synthetic dataset featuring 20 different tasks. The dataset comes in two sizes: bAbI-1k and bAbI-10k, referring to the number of training examples of each task. Proposed system is tested by 5 different tasks of bAbI-10k. Five tasks are listed with their corresponding class name in table I.

TABLE I
THE TASK IN BABI/TASKS CORRESPOND TO THOSE FROM THE ORIGINAL DATASET AS FOLLOWS:

	Task	Class Name
1	QA with single supporting fact	WhereIsActor
2	QA with two supporting fact	WhereIsObject
3	QA with three supporting fact	WhereWasObject
4	Yes/No questions	IsActorThere
5	List/Sets	Listing

In case of single supporting facts, only the questions about the position of the $Subject$ are asked. Tasks with two supporting facts have class name $Where\ Is\ Object$ which indicates to find out the location of the object. But, three supporting facts uses the sequential sentences and the question is about the position of object using the word either $before$ or $after$. On the other hand, Yes/No questions just justify the truth value of the question. Another task is about Lists/Sets, where more than one answer would be generated from the question.

B. Experimental Analysis

Analyzing each questions using proposed algorithm 1 and algorithm 2, answers are found for each question. For Parts of Speech Tagging, proposed system uses the NLT POS tagger [13]. As there is no need to update memory like dynamic memory network [8] or QRN [9] , it is easy to find the relevant facts without any complexity. It can retrieve answers easily by searching from the databases of facts.

C. Performance Evaluation

Accuracy of proposed Question Answering system for different tasks are shown in TABLE II. Better accuracy have been gained for each tasks excepts Lists/Sets. TABLE II also shows the number of input sentences and questions for testing the system. The proposed system gives the highest accuracy (95%) for Yes/No questions. Without the Lists/Sets task, the system gives more than 80% correct answer for given questions. The performance degrades when new type of tasks are included as input in the system. Though it gives high performance for sequence of simple sentences but for compound and complex sentences, it will be tough to find the features by lambda calculus based dependency parsing method.

TABLE II
ACCURACY OF QA FOR DIFFERENT TASKS

	Task	No of Sentences	No Questions	System Accuracy
1	Single Supporting Facts	13	10	90%
2	Two Supporting Facts	25	10	90%
3	Three Supporting Facts	37	10	80%
4	Yes/No questions	40	20	95%
5	List/Sets	60	10	60%

Table III and Figure 11 show the comparison of Structured Support Vector Machine(SSVM) [14] and proposed system. Our proposed QA system gives a better accuracy than SSVM for Two and Three supporting facts. To be precise, our system gives 80% accuracy for Three Supporting facts whereas SSVM gives only 17%. The overall mean accuracy of our system is 83% for these five types of tasks which surpasses the SSVM. The mean accuracy of SSVM is 71.8% for this five types of tasks.

TABLE III
COMPARISON OF STRUCTURED SVM AND PROPOSED SYSTEM

	Task	Structured SVM	Proposed System
1	Single Supporting Facts	99%	90%
2	Two Supporting Facts	74%	**90%**
3	Three Supporting Facts	17%	**80%**
4	Yes/No questions	99%	95%
5	List/Sets	70%	60%
	Mean Accuracy	71.8%	**83%**

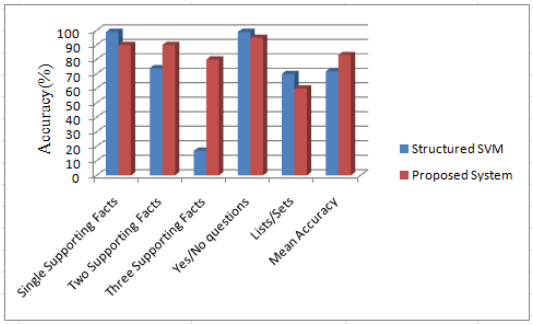

Fig. 11. Accuracy of Structured SVM vs Proposed System

We have considered 5 specific tasks for our work. For these tasks, our system shows better accuracy than some other existing methods. Most of the existing methods used machine learning approach which requires a large data sets. On the other hand, proposed method performs well for small dataset which resembles real life problems. Performance comparison with existing methods [14] is shown in Table IV.

IV. CONCLUSION AND FUTURE WORK

In this paper, a new methodology of question answering system has been introduced. POS tagging and semantic parsing techniques have been used for finding the answers from a given text. Proposed system is easy and less complex than existing systems in case of simple sentences. Moreover, it gains a better accuracy for five types of tasks in question answering

TABLE IV
PERFORMANCE COMPARISION WITH EXISTING METHODS

Methods	Accuracy
N-gram	26.8%
LSTM	36.6%
MemNN	68.8%
Proposed Method	**83%**

systems than the existing system. However, proposed question answering system is implemented only for simple sentences. In future, we will work with compound and complex sentences and long sequence of text. Machine learning technique with position vector will be used to learn the input text and retrieve the answer.

ACKNOWLEDGEMENT

We are very grateful to Biprodip Pal, Assistant Professor, Dept of CSE, Rajshahi University of Engineering Technology (RUET), Md Al Shayokh, Assistant Professor, Dept of IT, University of Information Technology and Sciences (UITS) and Syntax and Semantic Research Group (SySeReG) for their kind cooperation and contribution.

***Abstract*—Nowadays, like the English and other languages, Bangla also plays a significant role to strengthen the web repository. The storing rate of Bangla information is augmented day-by-day. Because of the numerous documents in the World Wide Web, it is very difficult for a user to retrieve the desired information. Furthermore, finding the useful documents tends to be more time spending as well as an annoying job. These demands emerge to develop an Information Retrieval (IR) system to document ranking for Bangla language. In this paper, we have built such a retrieval system where users can find their needed documents which correspond to their own query strings throughout the ranking index. Although a lot of works have been done for English and other languages to rank the documents, unfortunately, we have found a very negligible amount of contributions in Bangla Language. Many methods such as – Boolean model, Maximal Marginal Relevance (MMR), Portfolio Theory (PR), Quantum Probability Ranking Principle (QPRP), Query Directed Clustering (QDC), Vector-based TFIDF and so on, have been proposed to implement the document ranking system. Here, we have applied a new approach, called Latent Semantic Indexing (LSI) to do the same task for Bangla documents. LSI uses the mathematical method called Singular Value Decomposition (SVD). After that, we have applied the cosine similarity to rank all the documents. We believe that the performance result of our proposed system has reached the trustworthy level.**

Keywords*—IR, Bangla document ranking, LSI, SVD, Cosine similarity.

I. Introduction

At the present time, Bangla is considered the sixth popular language in the world and almost 230 million people use Bangla as their first and second language [1]. Furthermore, the use of Bangla language now increasing at a dramatic rate in the web repository. Within this vast information which is located in different documents, it is very tough to find the expected information from the desired documents. Again the online Bangla documents are highly categorized and there are a huge number of documents that carry the similar type of information. Readers are really confused which documents are more related that fulfill their demand. For these reasons, it is needed to develop a document ranking system for Bangla language based on the user query to get the expected information from the document based on the priority. There have been very few works in Bangla document ranking system. In this paper, for ranking the documents based on the more relativeness with the query, we have used a new approach, called Latent Semantic Indexing (LSI) [1] [2] [3]. LSI is an indexing and retrieval method that uses a mathematical technique called Singular Value Decomposition (SVD) to identify patterns in the relationships between the terms and the documents from an unstructured collection of text. A key feature of this technique is that it has the ability to produce the conceptual contents from a body of the document and each one is converted into a vector. Before applying the LSI, we need to generate a term-document matrix and a query matrix. Then we vectorize all the documents and the query string, using the formula of SVD which comes from the field of linear algebra. After that, we find the relativeness between the query vector and the document vectors through the method of cosine similarity. In that way we score all the documents and rank them based on the scores.

The rest of the paper has organized as follows: in **Section II**, we describe the related works. **Section III** conveys our proposed system and implementations details for ranking the document. Pre-processing for LSI technique has also been described here. **Section IV** involves the establishment of a baseline level of performance, and statistically investigates the importance of factors. The conclusion and the future direction of the paper are present in **Section V**.

II. Related works

In English and some other European languages, there are many document ranking techniques available.

Carbonell and Goldstein [4] proposed query rele-

vance based document ranking method named Maximal Marginal Relevance (MMR). However, there is a scope to increase the performance of the ranking system.

Shen and Zhai [5] combined the query history to enhance the retrieval performance in the document ranking process. However, this strategy always does not give desired outcomes. It performs inconsistent improvement in the retrieval performance.

Zuccon and Azzopardi [6] applied Quantum Probability Ranking Principle (QPRP) to improve the perfection of the document ranking for subtopic retrieval. They showed that the performance of QPRP takes advantages against the other document ranking techniques such as – Probability Ranking Principle (PRP) [7], Maximum Marginal Relevance (MMR) [4] and Portfolis Theory (PT) [8].

Zuccon et al. [9] proposed Interactive Probability Ranking Principle (iPRP) for document ranking which showed empirical effectiveness against to others ranking techniques. Here, they only worked on one possible interpretation. Interaction of other possible instantiations is not explored here.

Mitra et al. [10] proposed a method called Dual Embedding Space Model (DESM) which ranked the document according to the semantic relatedness between the query terms and all the document terms. They showed that this method performs better than the traditional term frequency based technique.

In contrast to the other languages, we get a bit of contribution in Bangla language to build up a document ranking system. Islam and Masum [11] first developed a system to rank the Bangla documents. They used term frequency with the help of a Unicode document corpus, named Bhasa. In this paper, they do not clearly specify the accuracy level of this system. Thakkar and Shrawankar [12] developed text categorization and summarization process. Here, manual selection is used for selecting a document from a set of categorized documents.

In this paper, to rank the Bangla documents, our proposed approach does these things in an effective way with more reliable compared to the existing systems.

III. Implementation Details

The main purpose of document ranking is to order the similar documents which correspond to the user query. To implement the whole process, we have divided this into two segments - pre-processing and final processing.

A. Pre-processing

In the pre-processing part, there are four tasks - removing the stop words, stemming the words, calculating terms-weight of each document and finally generating both term-document matrix and query matrix. Fig. 1 shows how pre-processing part works step by step in the document ranking system.

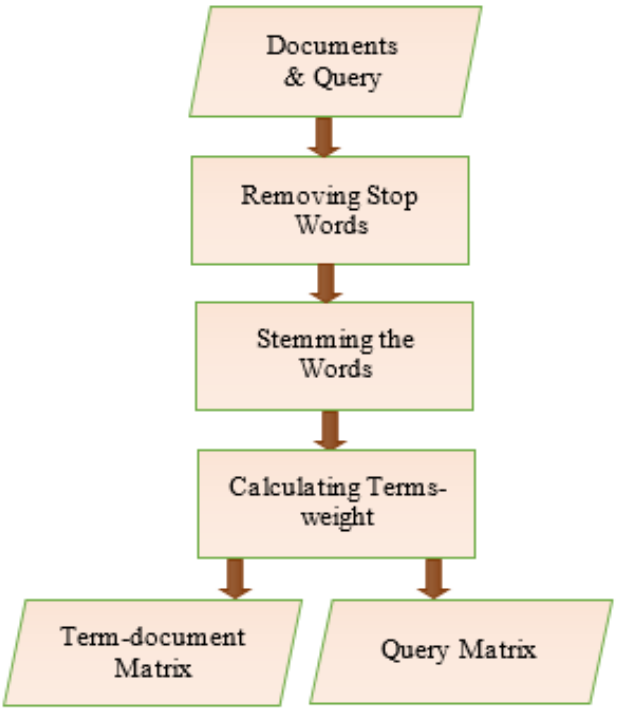

Fig. 1. Preprocessing part for generating term-document matrix and query matrix.

1) Removing stop words: Throughout the statistical analysis of the documents we have seen that some words have very low frequencies, while the others show just the opposite scenario. The most common thing of these words is that they do not carry any significant information about the document. Actually, they are used to maintain only the grammatical structure of the sentences. These words are known as the stop words [13]. From [14], we generate the stop words list. Here, we get 300 possible words. After inspecting on those words, we remove all the nouns and adjectives and add some non-information bearing words. Finally, we get 174 words of various types of articles, pronouns, prepositions and conjunctions, as the Bangla stop words.

Since the stop words of the documents do not play any role to carry out the actual meaning of the documents, at the first stage in the pre-processing, we filter all the stop words. It reduces the complexity of the overall ranking process.

2) Stemming: After removing the stop words, we apply the stemming on each word all over the documents. Stemming is the process which tries to convert the word into its root word by eliminating suffices. A suffix is considered as an affix which is embedded at the end of the root word according to the tense, numbers, persons, inflections, etc. Consider a word "বাংলাদেশ". It has various forms such as "বাংলাদেশের", "বাংলাদেশকে", "বাংলাদেশি", etc. In this paper, we have used a stemmer [15] which is applied all over the documents to get the root word from the suffix-word.

3) Calculating terms-weight: In this step, we calculate the terms-weight of each document. It is measured by counting how many times a word occurs in a particular document. Here, terms-weight will be used as the element of the term-document matrix and query matrix.

4) Generating a term-document matrix and a query matrix: Using the values of the terms-weight we build term-document matrix A, where terms represent the rows and each document corresponds to a column. By following the same procedure, a query matrix Q has been constructed.

B. Final Processing

Two matrices - terms-document matrix and query matrix, generated in the pre-processing part which are used in this segment. At first, we construct the document vector for each document and generate a new query vector by using the method of LSI [1] [2] [3]. After that, we apply the cosine similarity for each document vector with the query vector to rank the documents. All the steps in the final processing part are shown in Fig. 2.

1) Apply LSI: LSI is a good model which uses multidimensional vector space to establish a relationship between terms and documents. From each dimension in that space we get a concept which is called the topic layer or latent layer. Thus we get more topics of a document and these are encoded to vectors. Now, we generate the document vectors and the query vector.

a) Generate documents vectors:
LSI uses the mathematical technique, called Singular Value Decomposition (SVD) to get the document vectors from the term-document matrix A [Fig. 2]. SVD uses the formula comes from the linear algebra to decompose the matrix A into three matrices – two of them are orthogonal matrices V and U, where U will be transposed and the third one is diagonal matrix S, which entries are the singular values of A. The decomposition formula of matrix A can be written as, $A = USV^T$, where, U^TU and V^TV both will be the identical matrices.

To calculate the SVD we first find the eigenvalues and eigenvectors of AA^T and A^TA respectfully. The column of V is made up by the orthonormal eigenvectors of AA^T and the column of U is made up by the orthonormal eigenvectors of A^TA. The singular values in S are calculated by the square roots of eigenvalues of AA^T or A^TA in descending order. We can calculate the eigenvectors and eigenvalues using the following formula:

$$W\vec{x} = \lambda\vec{x} \tag{1}$$

Where, W is a square matrix comes from the matrix A, $\vec{x}$ is a nonzero eigenvector of W and λ represents a scalar value. Here, λ is said to be an eigenvalue of A and $\vec{x}$ is an eigenvector of A associated to λ. Using the value of λ we can determine the values of three matrices - U, S and V. Now we deduct the irrelevant or less important topic which has a rare contribution in the document scoring. Since in the S matrix, elements are organized in descending order, the lower values indicate that corresponding topics are less important or sometimes they are irrelevant. For these reasons, by neglecting the lower values, we reduce

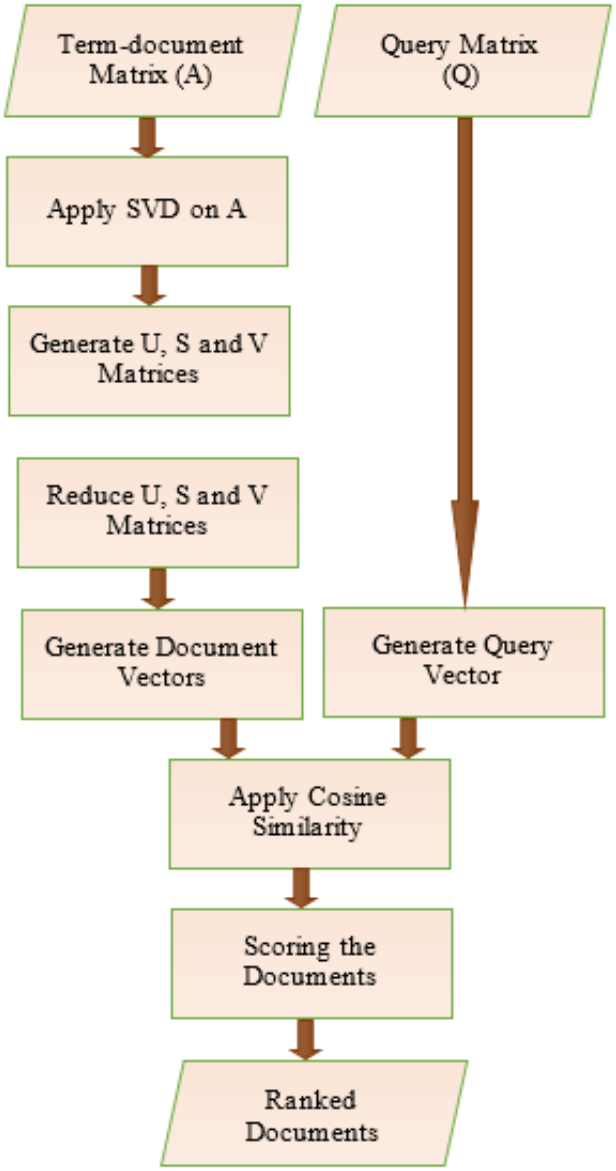

Fig. 2. Final processing part to rank the Bangla documents.

the dimension about 5% from the total dimension (n x n), then we get a new dimension i.e. k x k for the matrix S. The new column value k is used to all other matrices as $U \approx U_k$, $S \approx S_k$, $V = V_k$, and $V^T \approx V_k^T$. Here, rows of V_k holds the eigenvalues. These are the coordinates of the individual document vectors. In this way, we get $\vec{d_1}$, $\vec{d_2}$, ..., $\vec{d_n}$ as document vectors for n documents.

b) Generate query vector:
Now we generate the query vector $\vec{q}$ using the Q, U and S matrices by applying the following matrix operations:

$$\vec{q} = Q^TU_kS_k^{-1} \tag{2}$$

2) Apply cosine similarity: Cosine similarity is applied to two non-zero vectors which measure the closeness between them by measuring the angle. In our system, we consider this technique to evaluate the likeness of the query

vector with each document vector. To do this we use the following formula:

$$Sim(\vec{q}, \vec{d}) = \frac{\vec{q}.\vec{d}}{|\vec{q}||\vec{d}|} \quad (3)$$

Thus, we get the similarity score of each document. Here, the angle between the two vectors lies from 0° to 90° i.e. the similarity value is bounded between -1 and +1. The higher value means that the corresponding document is too related to the query than the other documents which carry the lower values. In that way, we rank all the documents according to the higher score to the lower score which helps the readers to choose their expected documents from the rank list.

IV. Experiment and Evaluation

To measure the performance of our system we experiment on 50 documents which are collected from different popular Bangla newspaper – the daily Prothom-alo, the daily Ittefaq, the daily Samakal, etc. We divide them into five groups. Each group contains ten news. To calculate the accuracy we use the precision and recall of this system.

A. Precision

Precision is considered a positive predictive value. It is the fraction value of relevant documents among the retrieved documents. On the other hand, we said that the percentage of selected documents that are corrected. Precision is measured by the following formula:

$$P = \frac{a}{a+b} \quad (4)$$

Where,
P = Precision.
a = Number of selected documents that are correct documents.
b = Number of selected documents that are not correct documents.

B. Recall

Recall represents the sensitivity of the documents. It is the fraction value of relevant documents that have been retrieved over total relevant documents. On the other hand, recall is the percentage of corrected documents that are selected. We can calculate the recall value from the following formula:

$$R = \frac{a}{a+c} \quad (5)$$

Where,
R = Recall.
a = Number of correct documents that are selected.
c = Number of correct documents that are not selected.

C. Accuracy

To measure the performance we now calculate the accuracy of this system. To do this we use the precision and recall value from equation (5) and (6). Now we calculate the accuracy throughout the following formula:

$$Accuracy, A = \frac{2 * P * R}{P + R} \quad (6)$$

As a sample, we show the similarity representation for a group Group-I, depicted in Fig. 3. Here, we observe that there are some negative document scores. The main reason is that when we apply the SVD technique we get some negative values for both the document and the query vectors.

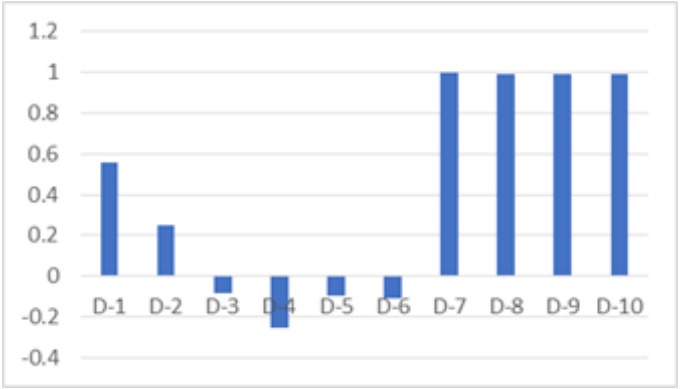

Fig. 3. Similarity representation.

To measure the accuracy, we simulate our data more times and decide the threshold value as 0.4 which mean that if the similarity value is above 0.4 then the document is selected otherwise the document is not selected. Table I gives the precision, recall and accuracy value of all five groups and shows the average value of them which are 86.22%, 92.286%, and 88.557% respectively. These values show that our system is considered as a more reliable system to rank the Bangla documents.

TABLE I. Performance evaluation of the proposed system.

	Precision	**Recall**	**Accuracy**
Group-I	83.333	71.43	76.924
Group-II	77.778	100	87.5
Group-III	100	90	94.737
Group-IV	80	100	88.889
Group-V	90	100	94.737
Average	86.22	92.286	88.557

Our system does not reach into 100% accurate level. This system will fall when the query does not fully or partially match with the searched documents. It has many reasons. If the query string carries an abstract meaning, it will produce incorrect relevancy. Again, a word has a different meaning in different contexts which causes a problem to retrieve the actual documents.

V. Conclusion and Future Direction

In our document ranking system for Bangla language, we have presented a loyal approach which shows the 88.557% accurate result. The main key point of this system is the intermediary topics layer, which is formed, based on the relative importance of the topics in the documents and we discard the less important topics which reduce the time complexity at a high rate without affecting the outcome of the system. This system gets struck when the search keywords are not matched with the documents i.e. if the keywords are contextually used or they have a different meaning in the documents. Therefore, in future, we want to try to resolve these issues with increasing the accuracy rate by linking the web data through the concept of Semantic web.

bikash.shuvendu@gmail.com

***Abstract*—With growing interest in animation movie, the demand for building an automated system to convert the real video into animation is higher than ever. The frame-by-frame editing of animation generation process is very costly and time-consuming. To help to generate animation quickly and easily in an automated process we proposed a generative model that converts real-world images into corresponding-animation image without losing important details of the source image. We used a variation of the generative adversarial network as underlying architecture with custom loss function to preserve the content of source image which converting to animation image.**

***Index Terms*—Generative model, GAN, CNN, Image-to-animation**

I. Introduction

Animation movies are currently one of the most popular forms of entertainment. Nowadays, the animation has become more realistic and it is not drawn frame by frame by artist rather it is acted by actors then given animation look to the real video to generate the animation. This process lots of expert graphics a lot of time to complete one animation. This is because the animator has to go through the video frame by frame and change the character and scenarios into the animation form. To help this process we have proposed a neural network based conditional image generation model that takes a real-world image and generate a corresponding animation image. Fig. 1 shows an example of a generated animation image.

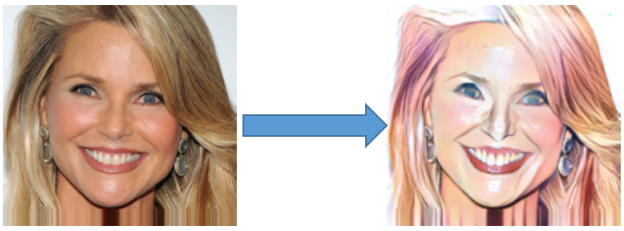

Fig. 1. Generated animated version of source image with the proposed model.

Generating animation from the real image is a conditional image generation task, where the generator model is conditioned on the source image. From another perspective, it is an unsupervised problem. We do not have the corresponding images of real and animation dataset to train a supervised model. To train this model we need a lot of real and animation images. For animation, we used the anime dataset. Anime of a form of Japanese animation which is very popular and many images of this is available. For this, we have used the word animation and anime interchangeably.

The recently proposed model called generative adversarial network(GAN) [1] has shown impressive results in generating images. Our model is built upon the conditional generative adversarial network. It takes the source image as input and generates the target image. To preserve the content of the source image which applying the style of target distribution we have combined generative loss with the content loss. In the experiment, we have shown the effect of each part of the loss and compared the result with other versions of generative models. In this work, we have focused on the dataset of the facial image only but it can be extended to build a general-purpose animation generator by changing the dataset only.

II. Related work

Generative adversarial network(GAN) has shown impressive results in generating data in different domains, especially image. Initially, GAN was used to generate random images of the target domain. Later conditional adversarial network [2] introduced control over the generated image. In conditional settings, GAN is used to generate the next frame of video, produce a photo, image from information or annotation, image inpainting, super-resolution image generation. The generator of GAN is consist of two parts-encoder and decoder. The encoder compresses the data into a low dimension matrix the decoder than generated the image of target domain from it. Generating image from given image is commonly known as image-to-image translation. The first successful image-to-image translation that generates high-resolution images was proposed by Isola et. al. [3] which is known as Pix2pix model. The pix2pix model was a supervised model. Later CycleGAN [4] proposed a method for generating images from one domain to another domain in unsupervised training.

The job of the discriminator in the GAN model is to identify the real image and generated image and help generator generate better images to fool the discriminator. The original GAN proposed a discriminator to output a single real number indicating real or fake signal but later models with high-resolution input were not able to generate good images with

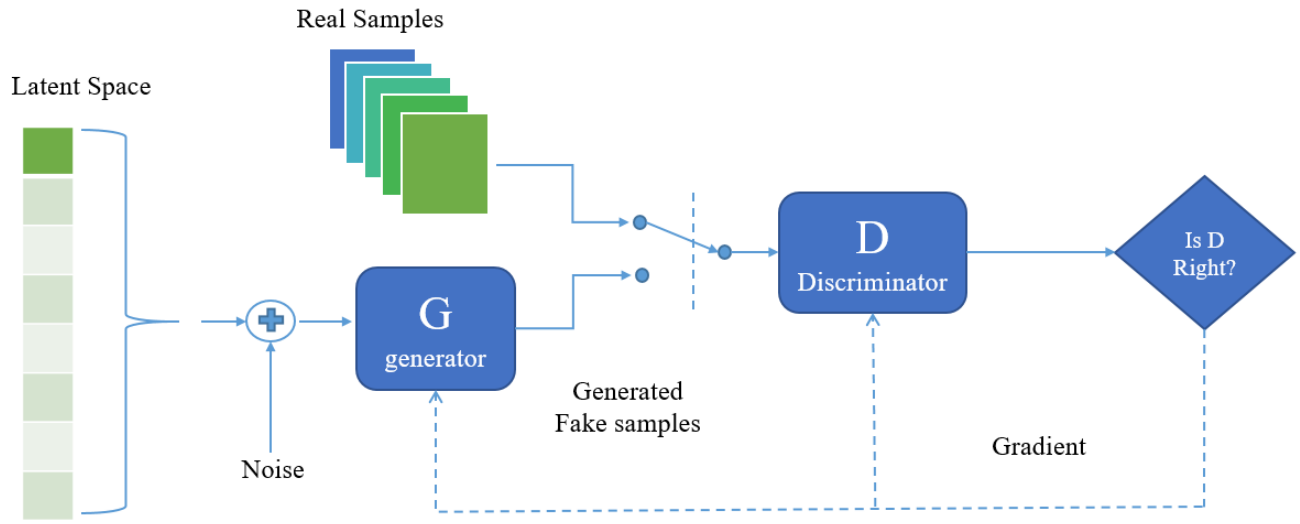

Fig. 2. Training steps of a Generative Adversarial Network.

this. Later PatchGAN [5] proposed outputting a matrix of output by the discriminator rather than single value. The patch size of 4×4 to 16×16 are common. The objective is to get all values one for real image and zero for a fake image.

Our work focuses on generating the animation from real images. Not many works had focused on this topic. Recently Chen et. al. [6] proposed CartoonGAN which focuses on generating cartoon with fewer details or share corners in images. To remove the shape edges which is not present in cartoon images, this model takes special cares by training of edge smoothed cartoon images. Our model focused on generating detail animation images and do not requires such steps.

III. Methods

We have used custom loss function of the recently proposed generative method called Generative Adversarial Network(GAN). GAN is consist of two parts-Generator and Discriminator. The job of the generator is to generate an image and the discriminator tries to separate the real image from the generated image. The model is trained as a two-player min-max game. The GAN loss helps the generator to generate a realistic looking image. In our application, the job of the generator is to generate an image that looks like real Anime. Along with the GAN loss, we have added a content loss to preserve the identity or feature of the source image.

A. Generative Adversarial Network

GAN was proposed by Goodfellow el. al.(2014) [1]. Here the generator and discriminator is trained as a two-player min-max game. Where the generator tries to fool the discriminator by generating a good looking image and the discriminator tries to distinguish the real the synthetic images.

GAN in unconditional settings just tries to generate a good looking real image. In this case, the input to the generator is a random variable draws from a normal distribution. Let x be a source image drawn from the source distribution P_X and r is a random variable from the normal distribution $\mathbb{R}^d$. We define the generator and the discriminator as G and D. The generator takes z as input and generates an image $G(z)$ of the dimension of real image x. The discriminator takes an input of the dimension of the real image and output a real number. It takes real or generated image and tried to say if it is a real image or generated image. In perfect cases, $D(x) = 1$ if $x \sim P_x$ and $D(x) = 0$ if $x \sim P_G$. The generator in the meantime tries to make the output of the discriminator 1. The generator and discriminator are trained at the same time one epoch each with opposite objective. The generator tries to minimize the following cost function while discriminator tries to maximize this.

$$\min_G \max_D V(G, D) = \mathbb{E}_{x \sim P_x}[log\, D(x)] + \mathbb{E}_{z \sim P_z}[log\,(1 - D(G(r)))] \quad (1)$$

Fig. 2 visually describe the GAN training process.

B. Image-to-Anime Generation

The GAN can be used in conditional settings to generate the target image from the source image. This is commonly known as image-to-image translation. Here the generator is given a source image as input. The generator is consist of two parts- Encoder and decoder. The encoder converts the image into some low dimensional space. The decoder than upsample it to the image dimension to generate the target image. The second input to the generator is the random variable, which is combined with the output of the encoder and passed the combined vector to the decoder. This random variable introduces some randomness in generated image and prevents generator to generate exactly the same image every time. The Objective function for cGAN is-

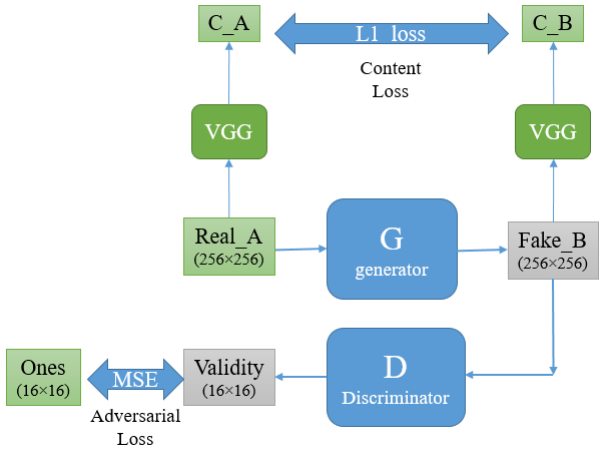

Fig. 3. Training the generator with Adversarial Loss and Content Loss.

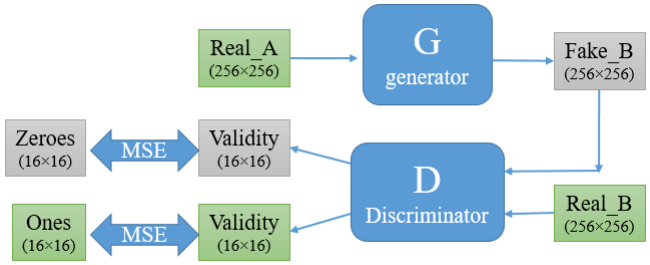

Fig. 4. Training the discriminator.

$$\mathcal{L}_{cGAN} = \mathbb{E}_y[log\, D(y)] + \mathbb{E}_{x,z}[log(1 - D(G(x, r))] \quad (2)$$

It is shown by Isole et. al. [3] that conditioning discriminator with the image helps the training. So, the objective becomes-

$$\mathcal{L}_{cGAN} = \mathbb{E}_{x,y}[log\, D(x, y)] + \mathbb{E}_{x,z}[log(1 - D(x, G(x, r))] \quad (3)$$

Redford et. al. [7] proposed a deep CNN based encoder-decoder architecture for the generator. It generates 256×256 resolution images. We followed the architecture of encoder and decoder from it and added BatchNormalization [8] both is generator and discriminator.

As the network is highly nonlinear, with random initialization, the optimizer sometimes falls into local minimum position. To solve this problem we have adopted a technique from Chen et. al. [6]. It has proposed an initialization phase to help improve the performance of the training. Here, the object of the overall model is to generate an image with the style of the target domain preserving the content of the source image. We start the adversarial training with a generator with the objective of only reconstructing the content of input images. To achieve this we pre-train the model only on the content loss for 20 epochs.

C. Loss Function

The loss function of the model consists of two parts: (1) Adversarial Loss, which drives the generator to match the generated data distribution to the real data distribution, and (2) Content Loss, which makes sure the content of the generated image match that of the source image. It has shown to be useful and helps to preserve the content in previous works [6], [9].

$$\mathcal{L}(G, D) = \mathcal{L}_{adv}(G, D) + \lambda \mathcal{L}_{con}(G, D) \quad (4)$$

Here λ is a hyperparameter that controls the importance to the content of the source and target image. The larger the value of λ is, more the target image preserves the content of the source image. The smaller value of λ results in a more cartoon-like image with less content preserved from the source image. We have conducted experiments with different values of λ.

Adversarial Loss: It is responsible for making the generated image distribution matches the target image distribution. In this application, we did not use any random variable in the generation process. During the generator training, the generator is trained to make the output of discriminator 1. For discriminator training, the discriminator is trained to output 1 for real image and 0 for generated images.

$$\mathcal{L}_{adv} = \mathbb{E}_y[log\, D(y)] + \mathbb{E}_x[log(1 - D(G(x))] \quad (5)$$

Here, x is sampled from the source data distribution, which is real human images. y is sampled from target data distribution, which is anime images. From this final GAN loss function, we have removed the source image as input to the discriminator. Also, rather than outputting as simple real number as validity we have followed the patchGAN [5] technique. It output a matrix of values as the validity. For images of real distribution, all the values of this matrix will be ones and zero otherwise.

Content Loss: It is the difference between the content of the source and the generated image. In this model, we have adopted the high-level feature represented by a VGG network [10] trained with ImageNet [11]. It is proved to have good object preservability. So, two images with the same content should have similar representation by a VGG network. For this experiment, we have used VGG19 for extracting the content of an image. The content loss is the difference between the representation of two images in the VGG network. We define the content loss as-

$$\mathcal{L}_{con}(G, D) = \mathbb{E}_x[||VGG_l(G(x)) - VGG_l(x)||_1] \quad (6)$$

Here, l represent the output of a specific layer of the VGG19 network. In this case, we have used the output of layer $conv4_4$. We measured the difference in term of l_1 sparse regularization instead of l_2 because the l_2 loss is proved to be generating blurry images.

Fig. 3 and 4 visually shows the training steps of the generator and discriminator.

IV. Experiments

We have implemented the model with pytorch [12] int python. All experiments were done in NVIDIA 1060 GPU.

A. Dataset

As the approach of generating Anime of corresponding human image is an unsupervised learning problem, we need unpaired images of both domains. For the human image, we have used the Large-scale CelebFaces Attributes (CelebA) Dataset [13]. This is a large-scale facial dataset with attributes. It contains 202,599 images of 10,177 different peoples. It also contains 40 attributes of each image that can be used for facial attribute detection, face detection etc. For our application, we only need some plain images.

For images of Anime domain, we have used "Danbooru2017: A Large-Scale Crowdsourced and Tagged Anime Illustration Dataset" [14]. This is a large dataset with over 2.94m images. We have used a subset of this dataset with equal images that of CelebA dataset. All the images are resized to 256×256.

Fig. 5. Few sample image from both training dataset. Top rows contains image from CelebA dataset. Bottom row contains samples from anime dataset.

B. Experimental Setup

The input to the generator and discriminator of the model is 256×256. We have used Adam optimizer [15] for training both networks. It has two momentum parameter to control the learning rate decay-beta1, beta2. We applied image augmentation for images of both domains. Table I summarizes the augmentation settings.

TABLE I
Values of Augmentation Parameters

Type of Augmentation	Values
Rotation	-20 to 20
Horizontal Flip	Yes
Scaling factor	1.1

Other parameters of training the model are summarized in table II.

TABLE II
Values of Training Parameters

Parameters	Values
Image input size	256×256
lambda (λ)	10
Epochs	50
Batch size	8
Adam: beta1	0.5
Adam: beta2	0.999
Learning rate	0.0002
LR Decay rate	0.99

C. Effects of Losses

Our proposed method is trained with the loss function in Eq. 4. It is consist of two losses which is described in Section III-C. Two demonstrate the importance of both component of the loss, we have conducted experiments with only the Content Loss and with only the Adversarial Loss.

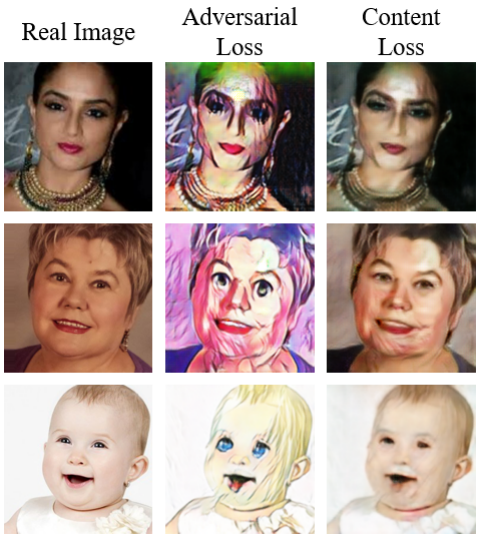

Fig. 6. Effect of only adversarial loss and only content loss.

As we can see from Fig. 6, with the adversarial loss only the generated image does look like target distribution but it losses the content of source image and some image are hard to identify as the source subject. On the other hand, content loss force the target image preserve the content of source image but it does not help to generate images with the target effect of Anime.

D. Evaluation Matrix

Evaluating generated image is an open problem and still has no general purpose solution to evaluate this rather than visual inspection. As we are using the facial image in the generation process, we have followed the evaluation matrix used by Antipov et. al. [16]. They used face recognition score for evaluating the generated image. Here a trained face recognition algorithm is used to verify two images if the FR model thinks people in this two images are the same person.

We used OpenFace [17] face recognition library for this. The reported FR score is the average of the correctly detected face similarities.

E. Result Analysis

We have conducted experiments on a few different variations of models to generate the Anime images. We trained the model with only adversarial loss. It does not keep the content of source images in the generated image, as a result, the FR score for this is very low as though the generated image looks like an anime image. Another model good for generating images with unsupervised training is CycleGAN [4]. This model is computationally expensive as it is a bidirectional model with double the number parameters to train and did not do good enough to preserve the content of source image. Table III below summarizes the results of our experiments.

TABLE III
COMPARISON OF FACIAL RECOGNITION SCORE ON COMPARISON WITH PREVIOUS METHODS

Experiment	***FR Score***
Adversarial Loss [1]	35.33%
Cycle GAN [4]	68.87%
Proposed method	76.24%

Fig. 7 shows some of the generated images of our model.

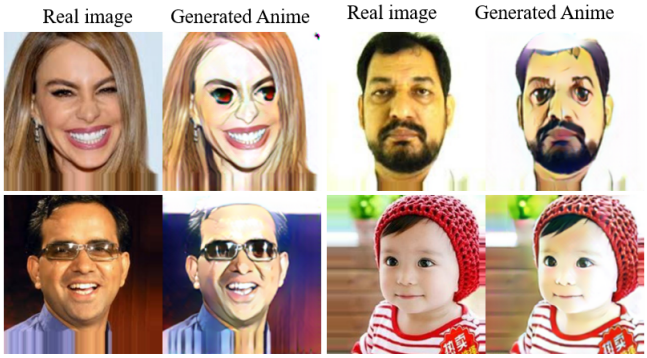

Fig. 7. Few sample image from both training dataset. Top rows contains image from CelebA dataset. Bottom row contains samples from anime dataset.

V. CONCLUSION

Generating animation from the real image with cartoon look is very important in the movie and animation industry. This is a very hard and complex job for the animator to create this animation frame by frame. In this process, the human images look too much like the real world and don't provide the cartoon-like look in this animation. To bring such look or deal with a non-existing character the animator has to go through each frame and edit. In this work, we have proposed a neural network based animation generation model that can create a nice looking animated image with preserving the content of the source image. This work will help the industry to generate animation faster and efficiently and help further research in this direction.

***Abstract*—Like other developing country, traffic jam is one of the common problems for Bangladesh. Every day almost a hundred thousand vehicles roaming and creating a serious traffic jam in the metropolitans. In this manner, it becomes impossible for an inhabitant to reach his/her destination on time. In this paper, we have introduced a scheme, named FTCP (Future Traffic Condition Predictor). This system has carried out to examine traffic conditions by vehicles measurement and the main theme of the study is to find out that factors which describe traffic problems by exploiting big data concept. We have categorized each key factor in different classes and each class has different traffic causes along with time durations of self-solving. When a traffic seeker is requesting for the information for a specific junction by any electronic devices, the system has acquired data information in favor of two ways. The first acquisition will be completing by collects previously recorded data and on the other, current data information of target junction via images and date-times. Here, previously recorded data were analyzed according to system define format and image samples were estimates by through FCN (Fully Convolutional Network). At last, experiments all of the major factor by vector analytical method. The experimental simulation was achieved promising accuracy in terms of using sophisticated datasets.**

Keywords—vehicles, traffic jam, traffic rules, image processing;

I. INTRODUCTION

Real-time road traffic update is highly desirable both in developed and developing countries. Nowadays, providing accurate information on road traffic conditions and situations is the most challenging part of such area of research. A various study has been done by ITS (Intelligent Transport Systems) that performed quite fast and impressive [1, 2]. However, there are still many problems that need to solve and also make traffic management as comfortable and effective as possible. In every year developing countries like Bangladesh losing message amount of money, property and intellectual life due to traffic congestion and accident. Recently, a study had conducted by ARI (Accident Research Institute) of BUET (Bangladesh University of Engineering and Technology), where researchers mentioned around 1.2 million peoples of Bangladesh have died and nearly 50 million Bangladeshi were extremely injured or permanently disabled with significant losses of resources and properties by road traffic accidents that's creates enormous burden on not only society but also economy.

Citizens of Bangladesh especially locals of Dhaka and Chattogram cities constantly being angry and frustrated about the unbearable problems of traffic jam and air pollution. This thing not only occurring heavy damage of our time, health and livelihood but also affects earnings. People from subaltern economic area bear their heavy loss due to the excessive jam. Therefore, if it could possible for a citizen to get exact time-table of traffic congestion and duration of resolve then he/she would able to make their daily working plan more effectively and efficiently by taking advantage of alternative route or strategy.

In the study [3], they had introduced a forecasting algorithm based on pheromone communication model. Congestion-forecasting technology is one of the main elements of ITS. The two main methods of congestion classified mostly in many studies, long-term forecasting is a method of statistically analyzing past traffic data, and discovering a pattern where congestion has occurred. And, short-term forecasting of congestion which is a few minutes ahead by using real-time information. It could effectively make forecasts under regular-congestion conditions though that had originated from car and road situations, a large amount of past data is necessary for analysis. Besides, it has weaknesses in forecasting under irregular-congestion conditions, for example, traffic congestion that experienced from the Christmas-holiday season in the U.S.A or during the Golden-week holidays in Japan or Bengali New Year (Pôhela Boishakh) holidays in Bangladesh. Some studies used machine learning classification algorithm such as random forest to build a congestion prediction model [4]. As input variables, they had considered weather conditions, time period, special conditions of the road, road quality and holiday. Although the random forest algorithm has the characteristics of high robustness, high performance, and high practicability, the study generalized some errors explaining less applicability to the prediction of the congested condition. And, in this study [5], they had shown a report where constant civilization growth will bring an additional load of around 3 billion vehicles to road networks by 2050 that will certainly lead to increased air pollution concerns, highly congested roads.

In this study, we present a novel method for traffic condition forecasting in Bangladesh based on a machine learning approach. The proposed approach employs current data and previously recorded information for the forecast as the data source simultaneously. Firstly, the system going to acquire real-time data information from a target and nearest junctions through high definition images from finest different angles (standard decision: 0^0, 180^0, 270^0, 360^0) and current date-time statistics. Then, segmenting images to carry out assessment data of traffic transports (number of and type of transports) by applying FCN [6]. Secondly, on the other way, it will gather past several years (for this study, it was 10 years) traffic count data sets for these particular junctions and after analyzing previous traffic patterns with current traffic situation, a logistic relationship will be formed. Based on this relationship, the system makes an educated guess (prediction) on the traffic condition of the future. Both FCN and MAD are widely cited machine learning algorithms and successfully applied in many areas of science, engineering and vehicular technology.

Our contributions are explaining in follows:

- We propose a distinguish examination of road traffic, ensuring the efficiency of recognizing traffic situation for future based on enormous data analysis.
- Although, there is an abundant number of datasets of road traffic, there are lacking in terms of accuracy, efficiency and some sensitivity issues. Many researchers had been working with real-life data of traffic images, but, most of them were previously recorded [4, 7]. However, our system gathers data information based on the immediate request of the user. Besides, another deficiency was to deal with imbalance data cause of million sources. In this manner, we have collected all of the data items by following some specific data variables, which is also can be defined as the system data format.
- In the end, the system is able to generate a complete evaluation report, which had covered every scenario of our examines.

This paper has been organized as follow. Section II provides a brief review of the previous works. Section III describes the proposed approach for traffic congestion prediction and Section IV presents the experimental setup. Section V describes the evaluation methods and presents the results. Finally, Section VI concludes the paper.

II. Related Work

There is various great investigation of traffic condition improvement. That's why it's become an active area of research and innovation. In this section, some previous works been reviews in the relevant literature.

Nguyen et al. [7] proposed a traffic system for congestion monitoring, which includes data collection, the establishment of segmented structure, traffic-flow modeling, local segment traffic congestion prediction, and origin-destination traffic congestion service for drivers. They used Fuzzy rules as local segment traffic congestion prediction in their proposed approach to determining the traffic congestion state and concluded that neural network (NN) have a statistically significant impact on the field of traffic congestion.

Yan [8] employed the support vector machine (SVM) to build a method of a short-term traffic condition prediction. As they mentioned, their method can effectively deal with the negative effects of outliers that inevitably exist in collected traffic data, thus enhance the robustness of the model and improve the generalization ability. Based on simulation results, it was shown that the classification method improved better accuracy than other machine learning methods.

Jayaratne al. [9] studied the relationship of urban speed-flow in Sri Lanka. Their study was targeted at filling the gaps of urban four-lane roads with the speed-flow model. In that way, they had described the PCU (Passenger Car Unit) tool and the simulation result shown a theoretical capacity report. They found that the nature of the traffic flow is unendingly changing by the data of 2481 PCU/h/lane for 5-minute interval data.

Anggraini et al. [10] developed a new approach to resolve the lack of getting the right information problems. They design visualization of traffic conditions in the form of a map, where the information obtained from Twitter, CCTV, user and operator PRFM (the radio information about traffic conditions in Bandung). Then, another predictive system was designed to get traffic conditions based on information from Twitter, so people can predict traffic conditions for one week ahead. However, when this study was compared with NNs, the calculations showed the performance much faster.

Wan et al. [11] developed a new perspective on traffic video analysis. They have had presented a total of three contributions to their work. First, they had shown the definition of congestion by proposing a unique state of traffic. Secondly, a precise labeling method was introduced to get the ground truth of the congestion level accurately. Finally, Inverse Perspective Mapping (IPM) based algorithm was proposed to analyze the traffic situation. However, their system was becoming slow for IPM mapping and system results acknowledge the lack of greater data sets.

In studies [12-14], the authors illustrate the advantage of uses of NNs (Neural Networks) in various sectors. For example, rice yields prediction has been done by perceptron NN along with weather predicting [12]. Meanwhile, a recommendation system has made to predict movie for user satisfaction via NN [13]. Moreover, A fraud detection engine has been conducted for recognizing credit card fraud activity, which builds by the help of backpropagation feed-forward NN [14]. In this study, also, we have used sorts of NN that specialized to segment particular image objects.

The above review confirms that historical data has a significant impact on the traffic forecasting and employing this sort of data in huge amount may result from a significant improvement in prediction accuracy [e.g. 7]. In this study, we further spread our approach for traffic forecasting in a different way. Contrast to the previous studies that used current data to predict traffic condition, we use both current and previous data sets as big data concept.

III. Future Traffic Condition Predictor (FTCP)

In this prototype, FTCP (Future Traffic Condition Predictor), we have been forecasting the traffic conditions on the basis of different variables of traffic measurement (see Fig.1). A mobile application has been made to provide user to request for traffic condition report for the specific junction. Therefore, based on data requester's GPS (Global Positioning System) location, the system is able to track user junction point, which helps the system to compare two aspects: (a) distance different between seeker junction to target junction and (b) determining all of road junctions as nearest junction of target one. There are also two criteria, one is measuring from Target junction and another computing from Requester junction. From the target intersection, we have measured nearest junctions by applying Bellman Ford's algorithm where the shortest path contains at most edges. On the other hand, all intersections also are selected among Requester and Target. In this way, figure 2 demonstrates this point of view as a general model of the selection process of nearest junctions where two possibilities are analysis via "P-1 Junction B" and "P-2 Junction-B" route (could be more for another junction). Then, on depending of the shortest distance, the direct route will be selected and considering all of the intersection as the nearest junction between target and source junction

In order to do so, the first and foremost thing is acquiring each parameter values of real-time traffic statistics via images from the target and adjacent junctions which's collected or, captured from standard angles along with data-time information. Image data variables: $img_{total}^{k} = [img_0^{360}, img_1^{270}, img_2^{180}, img_3^{0}]$, where k is the number of capture objects of a junction and date variables: $dt_{img_0}^{n} = [dt_{img_0}, dt_{img_1}, dt_{img_2}, dt_{img_3}]$, where n is the define a number of image items. Now, categories information

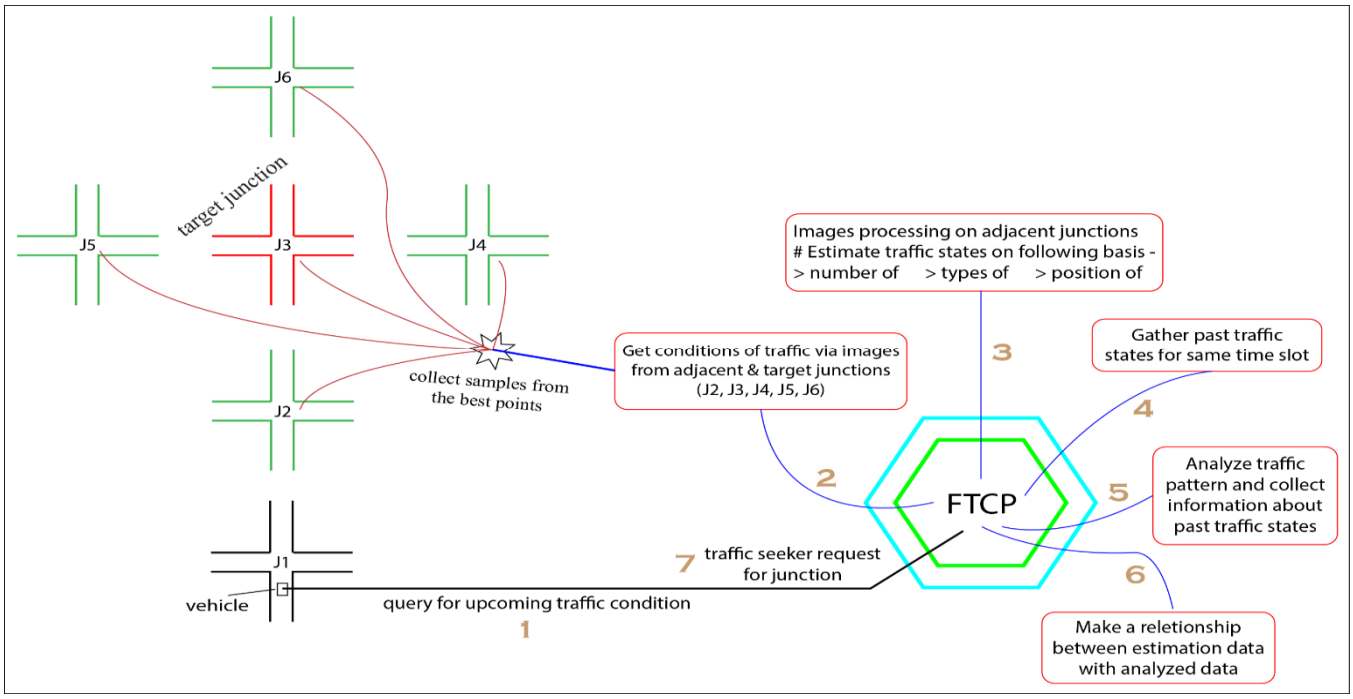

Fig. 1. FTCP System Prototype and Operational Overview.

according to the number of vehicles, types of vehicles and the position of vehicles. By mean of position is to ensure that transports are following road lane or not. It will help our system to figure out the calculation time according to measuring Signal Cycle Length (SCL) when the traffic signal is green. Then, the estimation process of image segmentation had done by using FCN NNs also known as ConvNet [15]. After that, the system will start folding data sets that gathered from the previously recorded database (see Table I) according to our system specified format. For this study, we accumulate data on about 10 years from several associations of the government of the People's Republic of Bangladesh.

Before examining the outcomes, SVM (Support Vector Machine) analytical tool have used to figure a relationship between experimental data and assessment data. As we define, we had used two sorts of datasets: (a) previous historical data and (b) currently collected data.

Finally, the system will calculate a robust measure of the variability of a univariate sample of road traffic quantitative data that explained a systematic empirical investigation of traffic condition observable via statistical statement. This process has been done by exploiting MAD (Median Absolute Deviation) method and softmax/sigmoid function.

A. Fully Convolutional Network for Image Segmentation

As 3-dimensional array layer ($x \times y \times z$) segmentation of FNN or Convnet, the first layer has considered by image samples with pixel size, x, y and d panels. From this section to the next phase known as receptive fields of path connection. Convnets are literally arranged with two common procedure: sampling and pooling by the aid of an activation function like other ANNs. The real-life implementations of these have done by CNNs (Convolutional Neural Networks). There is a subsection of machine learning technology that is inspired by biological neurons, deep neural network. It's also a subfield of ANNs (Artificial Neural Networks). CNNs is special sorts of deep NNs along with feed-forward ANNs combinedly, which means feed-forward referred to as multi-layer NNs. That defines, it's working right through the model and there is no feedback mechanism which output feedback

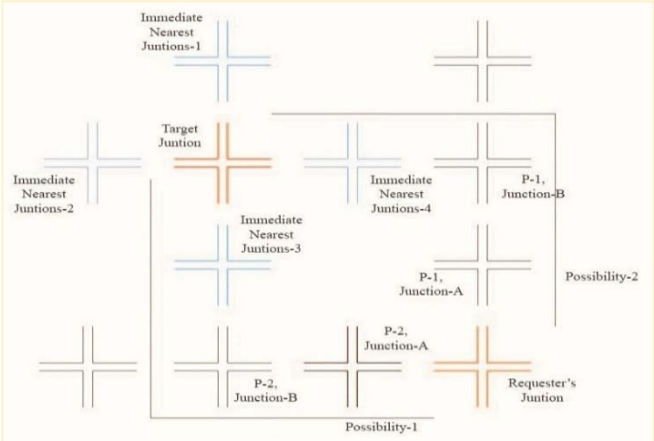

Fig. 2. Selection Procedure of Adjacent Junctions.

model comes backward by itself. The biological visual cortex has some sensitive specific visual areas that contain cells.

Figure 3 depicted the construction process of FNNs by exploiting one of our experimental data substances. This sample is collected via a mobile camera which has the standard rage of resolution. After the image leveling procedure complete, one of the segmented items picks up for the convolution process, where multiple possibilities calculated by mean of Matrix. During this process, calculated specific neurons that are connected with receptive regions of input. In the input volume, weights and a receptive field considered as a dot and then the best extraction small dot matrix go for the sampling process.

The main idea of the subsampling process is to get representation data by removing its dimensions that are actually helpful to rid of the overfitting problem. This technique is also known as pooling (max), which is able to select the maximum pixel value based on its size. The convolution and sampling process are occurring several times to detect the best-fitted data spot respectively.

Another objective of FNNs to acquiring high-range features that have learned by combining its all features.

Finally, bypassing those features to the layer of output. Then, we have used softmax or normalized exponential function to make the educational guess of input class.

In the learning process, after setup, the network by assigning input nodes, weighted (w) and bias (θ) parameter values define randomly. Then, the network function calculated as equation (1) for each neuron along with activation function (2).

$$\sum_i^n w_i \times \theta_i \tag{1}$$

$$f = (\sum_i^n w_i \times \theta_i) \tag{2}$$

B. Analytical Vector Regression

SVM (Support Vector Machine) is a supervised regression model involved with machine learning methods. Regression analysis is considered a kind of statistical process used for the accounted relationship between variables. As a notation, the following parameters are considered in SVM:

- Obscure variables are denoted as the β symbol.
- Independent variables as Y sign.
- Dependent variables as X.

By equation (3), a regression model is represented, where X and β is a function of Y. Furthermore, SVM regression means values calculated by (4) and (5) equations.

$$Y \equiv f(X, \beta) \tag{3}$$

$$Subside: {}^{1}/_{2}\,(|w^2|) \tag{4}$$

$$Related\ to: \begin{matrix} y_i - (w, \Delta_i) - \theta \leq \varphi \\ (w, \Delta_i) + \theta - y_i \leq \varphi \end{matrix} \tag{5}$$

Here, the threshold value defines by y_i and φ with the training symbol, Δ_i. In our study, input parameters considering by through scalability ration of time series, where ultimately equation is formed like (6).

$$Y = \beta_0 + \Big[\big(S_{curr_{img1}}, S_{curr_{img2}}, \dots S_{curr_{imgN}}\big) \times \big(S_{curr_{dt1}}, S_{curr_{dt2}}, \dots S_{curr_{dtN}}\big) + \big(S_{his_{img1}}, S_{his_{img2}}, \dots S_{his_{imgN}}\big) \times \big(S_{his}, S_{his_{dt2}}, \dots S_{his_{dtN}}\big)\Big] \tag{6}$$

The hyperplane formula (7) that differentiate the negative class to the positive class. And, bias update with the value of offset by (8).

$$\tilde{w} = \sum_i \beta_i S_i \tag{7}$$

$$Y = wX + \theta \tag{8}$$

IV. Design of Experiments

A. Simulation Design and Datasets

Table I illustrates all of the sources of our datasets, that publicly available records of the Government of Bangladesh. Here, some datasets are collected from Bangladesh Bureau of Statistics (BBS), which is a centralized official bureau in Bangladesh for collecting statistics on demographics. This agency is established with two other statistical organization by the Bangladesh government in 1974. In this way, it provides various statistical analysis report such as agriculture statistics, health, labor-employment, road accident, income, expenditure & poverty survey, ICI, climates GDP, trade and many more. And, another source was Transparency International Bangladesh (TIB). It's a Berlin-based International Transparency branch in Bangladesh, that's a dedicated civil society against corruption. Then, the final sources come by the annual traffic report generated various times by Dhaka Metro Police. These datasets have their own formats, for our study, we have collected and merged our required data sets on the following basis:

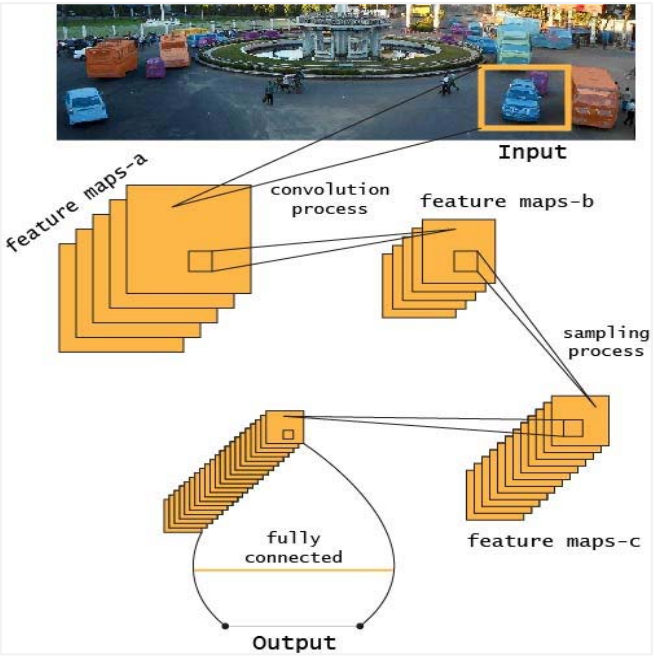

Fig. 3. The Architecture of Fully Convolutional Neural Networks.

- ***No. of transports:*** We have measured vehicles numbers of the particular junction. It helps us to calculate the estimation of time probability for the next junction.
- ***Type of transports:*** We used information of categories vehicles on the basis of the report of "Manual Classified Traffic Counts" of Bangladesh Ministry of Communications of Roads and Highways Department. The Vehicle Identification Sheet shows 15 different lists of vehicles type described based on 3 categories.
    a) Trucks and Buses.
    b) Light Motorized Vehicles.
    c) Non-Motorized Vehicles.
- ***Transports position:*** Traffic signal cycle lengths have a significant impact on the quality of the urban area. Hence, we have calculated position lengths by the following equations. In context, probabilistic cycle length calculates by (9) and TRRL model (10), which for the optimal minimum delay cycle length.

$$c_0 = \frac{1.5 \times L + 5}{1 - Y} \tag{9}$$

Where c_0 represents the optimal cycle length (sec); L represents the total lost time (sec), and Y represents the sum of the critical flow ratio of all phases.

$$C = \frac{L}{1 - [\min(CS, RS)/RS]} \tag{10}$$

Where C represents the cycle length (sec); L represents the total lost time (sec/cycle); CS

represents the sum of the critical phase traffic volumes (veh/h); RS represents the reference sum flow rate $(1710 \times PHF \times fa)$, (veh/h); PHF represents the peak-hour factor; and fa represents the area type adjustment factor [0.9 if the central business district and 1.0 otherwise].

B. Methods of Evaluation

The evaluation process has been done by using two kinds of estimation methods: (a) first one is a statistical method, which we used for measuring average absolute deviation between actual and predicted values. The univariate variable (in this case, transports parameters data) have considered as quantitative data that refer to the similar parameter of MAD calculation. In this way, a univariate data set subject to real date-time define as: $T_{dt_k} = [T_{dt_1}, T_{dt_2}, \dots, T_{dt_n}]$ and average mean calculate by following equation (11).

$$MAD = (||T_{dt_k} - \overline{T_{dt_k}}||) \tag{11}$$

We have to exploit MAD as median similar in order to the consistent estimator, which the main objective is to use it as standard deviation, σ. Since we have acquired data values from images, we did measure scale factor in order to find out relational distributed data by through standard deviation formulation (12).

$$\sigma = q \times MAD \tag{12}$$

Where scalar factor, q is $\frac{1}{(\vartheta^{-1} \times 3/4)} \approx 1.4826$, ϑ denoted as quantile function.

(b) Another method, we had exploited to measure our outcome is a normalized exponential function also refereed as Sigmoid or SoftMax function. We used this method as a neural network-based classifier of the final layer of NNs. It's a probability distributor between two set of events that estimate a mean number of bits (also called cross-entropy). Over a given event sets, the cross-entropy could be defined as follows (13).

$$E_{(x,y)} = E_x(\log y) = E_x + D_{KL}(x||y) \tag{13}$$

Where E_x is entropy of x and $D_{KL}(x||y)$ is the *kullback–leibler divergence* of x and y. In this case, cross-entropy is calculated using (14) equation.

$$E_{(T,y)} = -\sum_{k=1}^{N} \times \frac{1}{N} \times log_{2 \times} y(e_k) \tag{14}$$

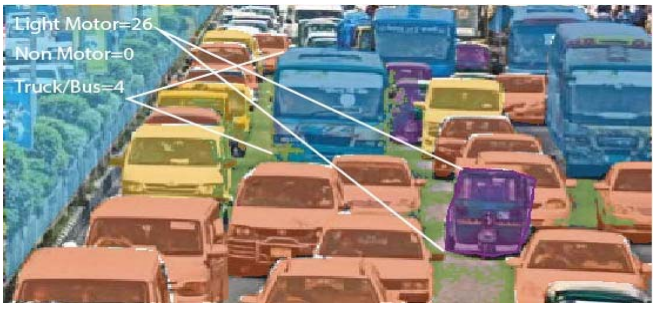

Fig. 4. One Sample Segmented Images of Chattogram Traffic.

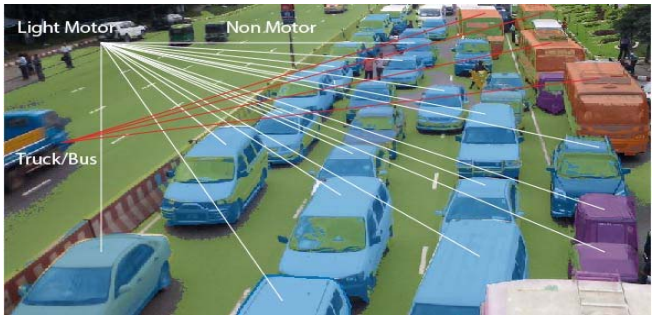

Fig. 5. One Sample Segmented Images of Dhaka Traffic.

Here, N is the test set size and the probability of the event, e calculated from a training set, T, which denoted as $y(e_k)$.

V. Results Examine

FCN is a normally consider as CNN, where the last fully connected layer is substituted by another convolution layer with a large receptive field. Figure 4 and 5 show some sample results of the segmented image, where color leveled on the vehicle based on our vehicle classification notations. There are two sorts of segmentation way applied, Edge-based and Point-based. For example, in fig. 4, some heavy and light motor-based vehicle have been selected by two portions: the upper and bottom edge. As opposed to, selecting the labeled color motors. In this study, we have found the edge-based technique much efficient than the other. It also shows a minimum error margin in term of separation of same types of motor vehicle.

By fig. 6, we showed the state of training result, which explained the fitness of our data sets by thought gradient number. It's showing, the average gradient we achieved, was almost 3.5 after 17 loops of training. The algorithm had used, "Scaled Conjugate Gradient (SCG)". It's a supervised learning algorithm for feedforward neural networks and is a member of the class of conjugate gradient methods.

Tables II and III illustrate two case studies of evaluation outcomes respectively. Here, accuracy values referred to the efficiency acknowledgment of results. Moreover, we have shown (see Fig. 7) a comparison depiction regarding other opponents. A compared method is actually a mapping data of space topology that classification leads to best accuracy with the variance networks [20].

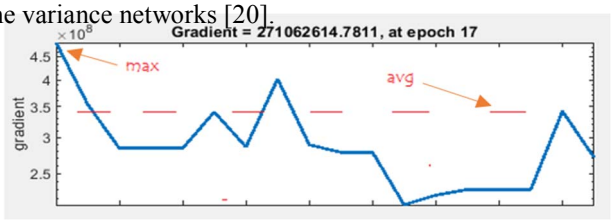

Fig. 6. Training States Outcome of Applied Datasets.

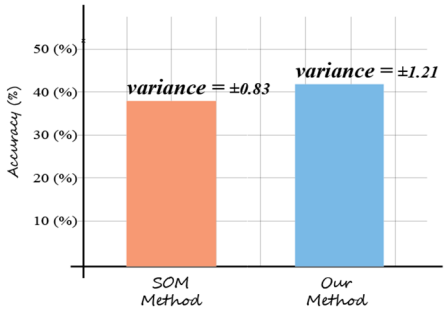

Fig. 7. Proposed Method Comparison Graph

Meanwhile, we have also calculated our proposed system by running multiple times where around 30 subject to the accuracy level. If we notice fig. 8 of our accuracy model, in which we have shown the performance criteria of our work. Here, we have presented the epoch values in five sequences after 5 loops. In this way, our accuracy level gradually increased to 86% after a slight downward on around 75%.

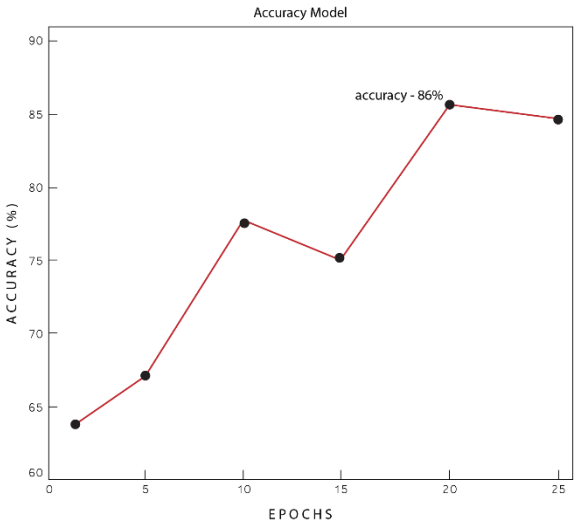

Fig. 8. Accuracy Model Generated By Matlab Statistics

VI. CONCLUSION

We have presented a new approach that predicts traffic conditions for the future by through relationship between two sorts of datasets. Our approach analysis both data sets according to time sequence that determined groups of traffic states with similar patterns. We found that working with a maximum amount of data sets was beneficial. Also, we found that the proposed ConvNet neural network was real affection for images classification or segmentation.

***Abstract*—In this paper, we have introduced a beetle detection system of cultivation field of Bangladesh, which will recognize both harmful and useful insects on the basis of the real-time image. Based on this estimating analysis, the system is going to predict upcoming status and production quantities of target crops land. Our system has established on two scenarios, learning & classification and recall process. In the learning process, we have categorized two types of insect data items: Useful and Harmful and subclassified various types of harmful beetle in order to acquaint them by the help of ANN (Artificial Neural Network) terminology. Then, we have stored those classified datasets into a database repository. In next phase, the detection system will segment/cluster all of the insects from real life images and synchronize them with our pre-categorized data storage apropos to figure some educational guesses of the situation of agriculture ground and the ratio of the number of crop yields. Here, Fully Convolutional Network (FCN) had applied as a detection tool to estimates image samples. Finally, a regression technique, SVR (Support Vector Regression) has exploits to predict the desirable outcomes. An effective outcome has been presenting by through experimental study.**

Keywords—artificial neural network; support vector machine; image segmentation; insect detection; means absolute error; mean relative error;

I. INTRODUCTION

Agriculture production means not just produce crops, it is a technique for producing food, feed, fiber and many more. There are many more things and each has its own way of production methods. It's one of the major practices that have a serious impact on the services of the ecosystem. These eco-services are surrounded by a wide area of soil retention, pollination, water quality, carbon sequestration, biodiversity conservation, and nutrient cycling. By practicing ecosystem, agricultural productivity could far beneficial to consider it as the main point of good environmental change. This is a complex methodology relationship between agricultural practices and ecosystem impact. An ecosystem is a precise area of interaction among climate, landscape, animals, and plants. It's basically included physical and chemical components (e.g., soils, water and plants) to bacteria. In this way, people become part of ecosystems, mostly health and wellbeing of populations of the human. Also, moths are a small part of both agriculture and ecosystem, where it's very crucial aspects of the agricultural study.

In the study [1, 2], the authors had described beetles by categorizing them in gender, where they had expressed the behavioral pattern of both male and female moths. Generally, male insects are searching partners by observing females plume of its source. There are several pests, they had introduced such as pink bollworm, the tomato pinworm and, fruit moth. Moreover, they have explained the sex pheromones impacts using species-specific behavior-modifying chemicals in agriculture. Also, this study had monitored the existence and absence of insects by pheromones (hundreds of amount) and other semi-chemicals, that has been discovered to projects ecosystem against farmland beetles. There have been enormous studies done on insect classification. However, there are a few past works of literature shows by using image acquisition and features extract algorithms. Meanwhile, some of the previous methods were based on insect specimens [3-7].

In this study, we have demonstrated a differentiating process for insect detecting of farmland in Bangladesh based on the machine learning approach. Our proposed approach employs real-time data information that has collected from high-dimensional images of the different region of farmland. In this way, we have acquired around 2351 samples that contains various sizes of image. Here, we have used different types of cameras (DSLR, mobile camera) to collect our required images. That's why images contain different resolution along with dissimilar sizes. Therefore, by using MATLAB, we have resampled them into exact same resolution where pixel set on 1024×768 depth. In this way, less than half a percent of images had transformed into fixed sizes. This system has been categories into two according to our objectives. Firstly, the system going to acquire real-time data image and extract information about various sorts of moths. Secondly, the system will be learning these features through the help of Perceptron neural network. Important note, two types of beetle's data has considered – Harmful and Useful moths. As machine learning algorithms, ANN is widely used neural network technique and effectively applied to learn anything. Meanwhile, FCN also extensively applied image processing method in many areas of science, engineering, and technology.

Our contributions are explaining in follows:

- We propose a novel examination in insect detection, ensuring the efficiency of recognizing farmland's beetles and the future situation of production ratio based on cognitive data analysis.
- We have used datasets that had collected by ourselves (with the aid of high-resolution digital camera). Because of the issues of elusive and sensitivity, these types of authentic data sets has serious lacking to gather tangibly. Therefore, we had gathered our required data items (images) from different district of farmland around Bangladesh. Also, data diversity was another challenge with our datasets. We have resolved this sort of crux by using several times of collaborative filtering, where system collaborate data associated with the study [8]. In this study, the authors have explained the various features and characteristics of many harmful and useful beetles. Moreover, we did several academic surveys on some particular places that related to farmland beetle cultivation.

- Furthermore, based on our experimental results, we have also estimated the future situation of target cropland and possibilities ratio of production quantities.

The section has organized as following, where Section II builds on some literary works. And, Section III will have explained our proposed method. Section IV and V will be describing estimation methods and outcomes respectively. At last, the study concluded in Section VI.

II. Related Work

In this section, some prior experiments had been reviews in the relevant literature such as pest control and ANN.

In Study [9], where Zhong et al. proposed a flying insects recognition system with vision-based counting. Also, it's a classification system that had made on the basis of various aspects. First, we had designed a vessel for the surveillance camera to collect real-time images. After that, YOLO (You Only Look Once) object detection, which is also a course counting method and SVM classification techniques had exploited to bring out global features. At last, both insect counting and recognition system applied on Raspberry PI. Six species to major the system efficiency. For insect count, they had used a portable predefine counting system, where our proposed system is able to figure the counting by itself (with the system own counting class).

Hossain et. al. [10], authors had predicted future crops production associated with weather-based datasets, which were predicted before and uses them as inputs. By this experiment, they have shown a good work of ANN perceptron method. The presented approach (WPSRY) built a weather-based model and have got an educational guess of upcoming weather condition. Then, by using these data as parameter input values with the agricultural data and simulated for target production quantities of rice yields.

Meanwhile, in this study [11], they have built a neural engine for movie recommendation system by exploiting user's behavioral patterns. Here, two types of data were used to make a class database, which has constructed based on user interest. Authors had presented a brilliant work with Hopfield Neural Network (HNN) that were sequentially transformed the combination of primitive and user interaction data into a class dataset.

In Izumi et. al. [12], A behavior model had been built to specify the fire and gas leakage position at disaster time by using the beetle pheromone activity. Two outcomes have characterized to find out the equation of the relation of the gas and the results of a semiconductor gas sensor. By using a portable robot equipped with a gas sensor (semiconductor), they had performed discovering gas sources and simulation outcomes shows the effectiveness of the applied system. This study illustrates how important to extract behavior pattern for any simulation.

In a study [13], they had introduced a pest detection system based on insect shape, where the image processing method was exploited to extracts shapes features in the sugarcane crops field. Furthermore, a Sobel edge detection technique had used for image segmentation in opposite to background. With 9 geometric shape's features learning, the system has the ability to detect by several angles: circle, oval, rectangle and triangle angles. Authors have explained that image classification or segmentation is quite important for a study that related to farmland simulation.

Kiskin et. al. [14] had proposed a mosquito detection system using neural networks. Like our study, they also had used Convolution Neural Network (CNN), which was exploits to operate audio wavelet transformation by investigation of the network's power (predicted) and visual statistics. This statistic visualization helps the system to observe a deep insight of components missing data detection problem. In this context, they have applied CNN on another purpose however we have used another method of CNN, which is FCN for image classification and segmentation to clustered insects based on our objectives.

ANN is an effective method to study any kind of real activity or any behavioral pattern. A recent study has been published that had shown the importance of ANN to learning user's interests. In this study [15], a banking credit card fraud detection system (FDE) has been presenting along with the user's interests selection tool (FST). During transaction procedure, FDE has deployed to find out any sorts of intruders with investigating credit card holder's behavioral activity. FST is the tool that has the ability to observing user's operational movements and try to find out any unexpected activity.

Nguyen et. al. [16], introduced 3D insect detection and diagnostics system in high-throughput color ratio using a robotic-based arm to beetle control process. They had used light field cameras to gather images in depth one shot along with the aid of 3D web tools on purposes of annotation, visualization and distribution. In our study, we have also used high-resolution based digital images as our datasets. However, we didn't use any filtering tools to improve visualizations.

In the study [17], they have presented that a mobile phone can be low-cost equipment for mosquito surveillance. After studying mosquito species in medically, they had defined quantitatively acoustic supports by spatiotemporal metadata, non-invasive species and enable rapid proofs. Finally, a novel paradigm had been demonstrated for mosquito surveillance.

Grieve et. al. [18], they have shown how several multispectral sensors of the image could be effective to detect real-time whitefly insects. Simulation experiments had conducted with four types of viral vectors on both cassava and aubergine plant leaves, where outcomes indicate an efficient classification by case result among 85% to 95%. This study has described the effectiveness of using sensors images on insect detection experiments. However, it's compulsory to use image filtering tools with this method for disturbance of pixels.

By Study [19], authors have introduced a monitoring system that will constantly be observing farmland by video image processing and cloud computing combinedly with the help of robotics concepts. Here, the proposed detection system works on one of the popular fruits (tomato) farmland. Although, video processing is more effective than image segmentation but many more things are challenging to acquire efficient datasets. For instance, in video surveillance, many image frames become a disturbance for speed and resolution qualities. In this manner, highly efficient filtering tools required, which is sometimes could be a time-consuming process.

Also, Santiago et. al. [20] have proposed both detection and monitoring system for farmland insects using ANN and Mel-frequency cepstral coefficients (MFCCs). Here, the ANN method had used for classification and MFCCs as feature extraction tool. The main focus of this study was

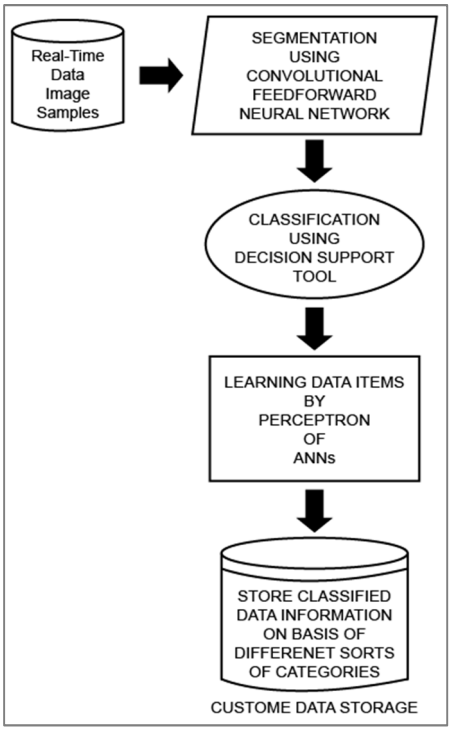

Fig. 1. System Learning Procedure

further experiments on acoustic methods of pest management. Moreover, this study had used Sitophilus oryzae (L.) sounds, which commonly known as rice weevil along with five different sensors, which will provide effective support to ANN for recognizing insects sounds.

The above review confirms that the neural network is a commonly used method for the study like insect detection or crops yields prediction [e.g., 10, 14, 16]. In this study, we further expand our approach by using useful insect. After some academic survey, we have noticed some beetles are helping the crops land to increase production quantity.

III. Proposed System (Pest-Inspector)

In this prototype, the first and foremost was designing a learning process. In order to do so, we had collected information (extract features) about several insects related to croplands by analyzing real-time segmented images (using the FCN image classification method). Here, we had extracted shapes and color feature of beetle on the basis of different angles and deepness. Both are the most challenging operation causes of similar reasons for multiple different insects. For example, according to study [8], ground beetle such Carabidae and rove beetle like Staphylinidae has various shapes similarity and both have the same color as well. On the contrary, Ladybirds and Pupa have exact shapes similarity, so, in here, color features help the system to figure out the variances. To solve these sorts of problems, we have exploited a Decision Support System (DSS) that combine with both decision tree and neural networks [21]. By using decision tree integration and backpropagation multilayer feed-forward algorithms, this method had developed to figure out a clinical decision for Eye Disease Diagnosis, which was quite related to our objectives. They had applied it on multiple sorts of syndromes of eye disease. Moreover, the uses of Object-Oriented methodology along with Object-Oriented Programming (OOP) that makes this system far effective with more than 88% success rates. Next, by perceptron multilayer feed-forward neural network, we have learned all the features to the system as per two types of insects' categories: USEFUL and HARMFUL beetles (See Fig. 1). Finally, we have stored all learning data information into data storage (p_db) similar to system requirements.

Also, for recall operation of our system, we have exploited FCN image classification and segmentation method. As per figure 2, the system has the ability to detect farmland insects keep in similarity according to our custom database (p_db). If the operational aspects of beetle symptoms have matched with our predefine prominences of insects than the next phase will start. In the following stage, system will acquire given information according to series of data information ($f = f_1, f_2, f_3, \ldots\ldots, f_n$).

At last, the system will calculate a vigorous measure based on succeeding requirement characteristics, (a) Insects genre, (b) Insects amount – (b1) Number of useful and (b2) Number of harmful. And then, SVM regression has used to predict actual insects and the require data features by making a relationship of both primitive and real-time data. Furthermore, on basis of these outcomes, we have also measured an educated guess on two future aspects of targeted farmland, where we will measure the status of cropland during a specific time of cultivation and possibilities of the number of production quantities.

Ultimately, the evaluation procedures have done by exploiting three popular estimation methods: Root Mean Square Error (RMSE), Mean Absolute Error (MAE), and Mean Relative Error (MRE).

A. Used of Custom Decision Technique

In a study [21] where Kabari el. at. had presented a Decision Tree-Neuro based model for clinical DSS of eye disease diagnosis. This model has made on basis of DSS tree and ANN feed-forward techniques combinedly with the help of OOP programming framework. We picked this method as a support for our model because of the following reasons:

- As we know, working with the DSS system environment is very competitive and stressful as well. Meanwhile, other problems like overburden information and its disturbance throughout the scope affect the potentiality of a system. Therefore, we

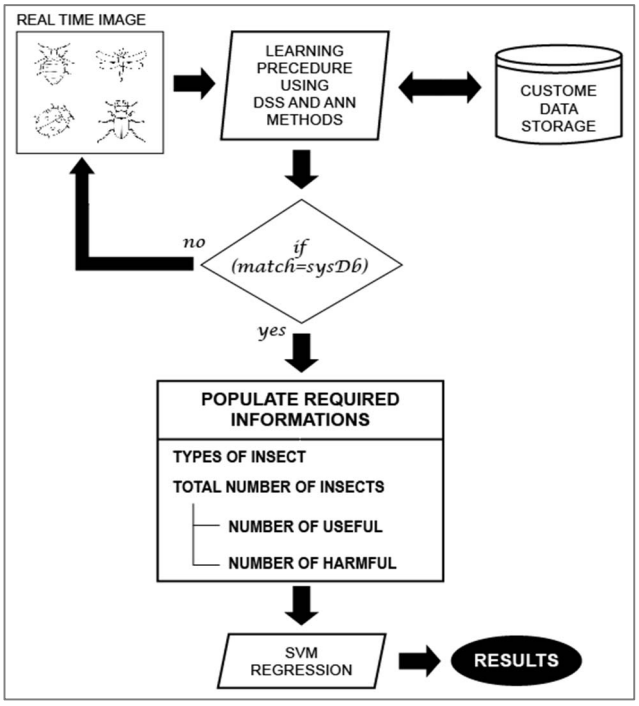

Fig. 2. System Recall Procedure

found this model more effective than other traditional DSS systems especially the uses of the ANN method associated with it

- The next reason is that this model already showed the effectiveness by through applying in diverse fields such as medical diagnosis. So, as we have explained in Sec. 1 that our datasets are diversity based (see some sample data in fig. 3). Therefore, after our analysis we have found, this hybrid approach is quite similar according to our objectives.
- The final reason was, the advantage of using the system that integrates with multiple techniques may get far better-predated results to compare to exploiting primitive method or any separate techniques.

B. *Artificial Neural Network - Perceptron*

Figure 4 illustrates the learning model that we have built for our system. This model has constructed with n input neurons for both color and shape features, U hidden neurons and V output neurons. In here, U hidden ensembles have chosen best parameter value and each and every parameter initialize by some randomly define weights value.

Perceptron ANN is one of the supervised learning algorithms which is presented by vector mathematics. Just like other feed-forward neural networks, its work on moving forward way from inputs section without maintaining any loops/cycles. There are two sorts of Perceptron ANN: Single and Multi-layer. We have exploited multi-layer feed-forward Perceptron, which is design to interconnect with the extra hidden layer.

According to the problem and its solution technique, we have set up the ANN network and its connections along with randomly initialized weights (W_{ij}) values and threshold (β) range. And, a calculative learning rate (δ). Based on our desire objectives, we did prepare the expected target model (T_j) to run the verification. Here, following formula (1) helps to calculate network function by binary outcome series as per (2) notation.

$$\sum_{i=1}^{n}\sum_{j=1}^{n} W_{ij} \times \beta \tag{1}$$

$$Y_j = \begin{bmatrix} 1 & net > 0 \\ & if \\ 0 & net \leq 0 \end{bmatrix} \tag{2}$$

Then, if this notation $(T_j - Y_j) \neq 0$ is satisfied, we are going to update connection weights and bias by following the equations (3) and (4) respectively.

$$\Delta W_{ij} = \propto (T_j - Y_i) X_i \tag{3}$$

$$\Delta \beta_j = -\propto (T_j - Y_i) \tag{4}$$

Fig. 3. Sample Images Collected From Different Farmland Region.

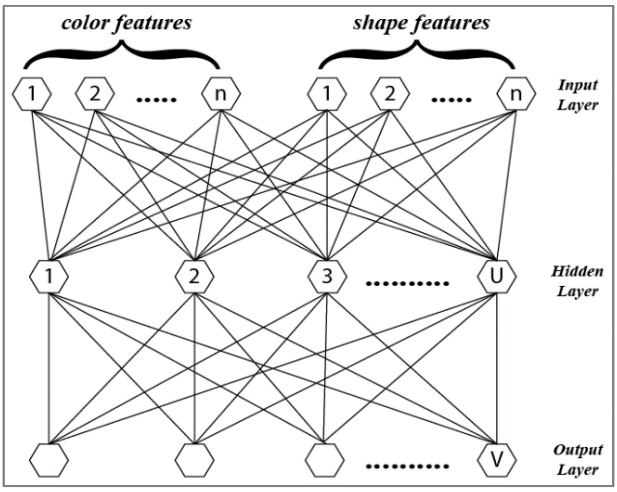

Fig. 4. Constructed ANN Model for Our System.

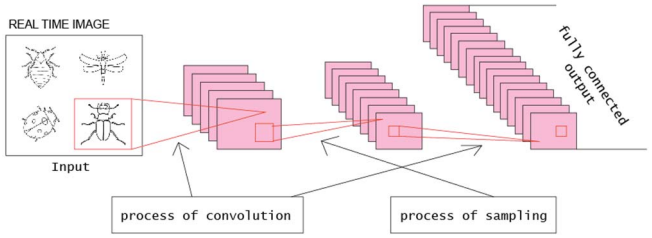

Fig. 5. Operational Procedure of FNN Convolutional Method.

Where Δ indicate the new value and is $\propto$ denoted for learning rate value. Next, after replacing old values with new, run the above operation again until following equation (5) fulfilled.

$$T_j - Y_i == 0 \tag{5}$$

C. *Convolutional Neural Network – Fully CNN Method*

As 3-dimensional array layer ($x \times y \times z$) segmentation of FNN or Convnet (see fig. 5), the first layer has considered by image samples with pixel size, x, y and d panels. From this section to the next phase known as receptive fields of path connection. Convnets are literally arranging with two common procedure: sampling and pooling by the aid of an activation function. After the multiple numbers of sampling and pooling, (until satisfied the condition) processes, input data vector (X) of a particular location (i, j) have calculated for desire output (Y_{ij}) by (6) as per study [23].

$$Y_{ij} = f_{ks}(\{X_{si+\delta i, sj+\delta j}\} 0 \leq \delta i, \delta j < k) \tag{6}$$

Where k is denoted for the kernel size, s for subsampling factor and f_{ks} determine the type of layer. And, the transformation rules (7) used when a computation has occurred with a non-linear function, which is also defined as deep filter or FNN.

$$f_{ks}\sigma g_{k`s^1} = (f\sigma g)_{k`+(k-1)s`,ss`} \tag{7}$$

IV. Evaluation Methods

A. *Applied Datasets*

By fig. 3 we have shown some sample data images of our work. As we explained before, as our dataset considered as diversity based, so, before applying CovNet operation, our system has analyzed each of them through scaling procedure where we have data of measurement that applied on CNN

```
%% Acquire reference image
ref_vid_img = snapshot(hCamera);

%% Quantize images and outputing to the screen

frames = 2000;
for i = 1:frames

% Acquire an image from the webcam
    vid_img = snapshot(hCamera);
```

Fig. 6. Operation Screenshot of Collection of Image Datasets.

technique. Meanwhile, as for color dimension, blue-gray ($b^{\emptyset}g^{\emptyset}$) color combination helps the system (CNN CovNet) discriminate the differs among them. All of these operations had conducted on MATLAB by using its own Image Processing Toolbox. It is a high-level language based interactive environment for visualization programming. It also includes predefine mathematical functions (for instance, Matrix.) to operating visualizing image data such as scaling. By through fig. 6, we have shown an operational snapshot while our system was performing the collected image data where reference data acquired into an array variable.

B. *Results Analysis*

Test efforts are not some pre-defined timeline setting but it is an approximation, which is a value used for certain objectives even though input data could be unstable. Estimation is based on several things such as historical data, both past and present knowledge, and assumptions. And, accuracy is a determination of the ratio of reality. However, some important factors always effect on every estimation: (a) input data, (b) the calculative steps, (c) in which way or how closely the previously collected data calibrate.

For estimating the accuracy of continuous parameters, both MAE and RMSE are two most popular evaluation metrics uses by many various studies. MAE estimator is counting the average magnitude errors of a series of predictions. MAE is the upgrade equation of both Mean absolute Scaled Error (MASE) and the Mean Squared Error (MSE) by the mean of using selected performance issues. It will become a slight change if we don't consider absolute value. Then, it will be estimating the average bias model as Mean Bias Error (MBE). The given equation (8) states the MAE error estimation, where Mean Magnitude of Relative Error (MRE) have using to find out the difference of MAE outcomes in percentage (9).

$$MAE = \frac{1}{n}\sum_{i=0}^{n}\left|Y_i - \hat{Y}_i\right| \quad (8)$$

$$MRE = \frac{1}{n}\sum_{i=0}^{n}\left|Y_i - \hat{Y}_i\right| \times 100\% \quad (9)$$

Where Y_i and $\hat{Y}_i$ denoted as actual and predicted data outcomes of the number of n selected objectives. RMSE is a quadratic rule for measuring the mean magnitude error (define by formula (10)).

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=0}^{n}\left(Y_i - \hat{Y}_i\right)^2} \quad (10)$$

There are several differences between MAE and RMSE. Here, in RMSE, all errors are being square before figure out the average values. That's why we have to provide a high amount of weight values on larger errors. In this way, for undesired maximum errors, it could be more efficient.

V. RESULTS

The estimation results show by Table I, where the accuracy and training time describe our approach achieved satisfied accuracy. Here, 13 best exertions have clarified, where the average accuracy of sensitivity standard 91.73%, it has shown the maximum edge of the efficiency of our method. Also, the training time took less than 5 minutes for every best effort along with the exact performance of the operation. If we notice our precession chart (see Table I), our approach has gained more than 90% of actual and overall 8.5% MRE performance ratio which indicates the effectiveness and efficiency of the applied system.

According to our precision outcome, the marginal productivity has plotted (see fig. 7) by MVP (Marginal Value Product) associated with the probability ratio of upcoming production quantity. MVP measure is increasing when the number of useful insects exits on land. In the left-side, MVP margin scale indicates and right-side vertical axis presents the level of quantity. MVP margin specifies the state of cropland.

Moreover, we have analyzed our approach by comparing it with another method. Figure 8 illustrates a clear compares chart along with MRE consequences. The technique [23], we have exploited for comparing, was built by National Academy of Agricultural Science (NAAS) which is a research platform in the fields of crop & animal husbandry, fisheries & agro-forestry founded of Government of India. So, if we notice the comparative analysis between our and

TABLE I. OVERALL PRECISION RESULTS

Endeavor	RMSE	MAE	MRE (%)	Exactness (%)	Training time (min)
1	0.0423	0.465	5.20%	89.24%	3.0
2	0.8756	0.876	6.23%	91.25%	3.5
3	0.6378	0.832	6.80%	91.11%	2.5
4	0.5378	0.543	4.98%	88.79%	3.0
5	0.8634	0.358	5.96%	90.21%	2.5
6	0.7565	0.754	5.88%	89.25%	2.9
7	0.6962	0.700	6.68%	85.16%	3.1
8	0.7562	0.711	7.01%	90.97%	4.0

10	0.9200	0.829	8.91%	91.12%	3.9
11	0.5663	0.555	5.98%	84.21%	3.4
12	0.8923	0.858	8.29%	87.15%	2.4
13	0.7236	0.711	7.15%	79.15%	3.0

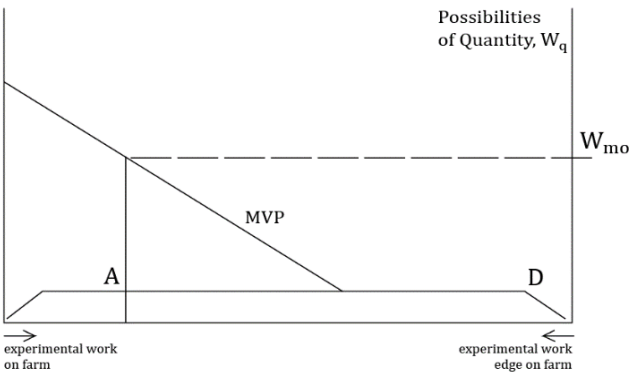

Fig. 7. MVP Response of Experimental Farmland.

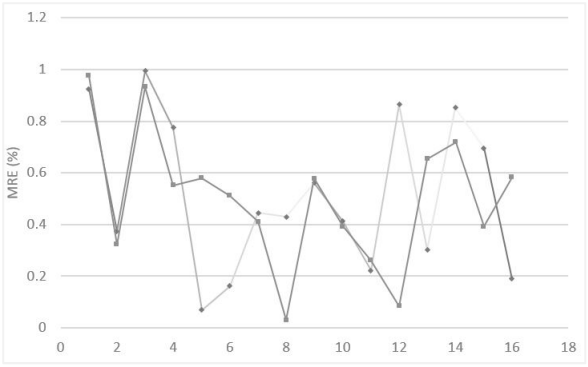

Fig. 8. Comparison Of Analysis Outcomes

another method, we can see the amount first 4 epoch, performance was average with it. Afterward, the accuracy level suddenly drops for the compared approach in minimum ratio. On the other hand, although our technique dropped on 8 epoch but it was going upward quickly in next 2 epoch at 0.6. However, the compared method staying on average MRE accuracy compare to our performance criteria.

Furthermore, we have constructed another comparison overview with previous studies [13, 14] that have already explained in section II. Here, the study [13] had exploited image processing approach to detect beetle shapes where images were segmented via Sobel based edge technique. In our study, also we have exploited image shape segmentation by using MatLab scaling tool. And, in [14], the authors explained mosquito detection operation via Artificial Neural Network. So, as we explained, CNN also an ANN concept which specifically focuses on image processing and segmentation. In this way, these two different methods have achieved fewer performance values compare to our approach. As we notice, method [13] had reached on 7.6% and [14] on 8.09% MRE where our technique had maximum MRE 9.15%.

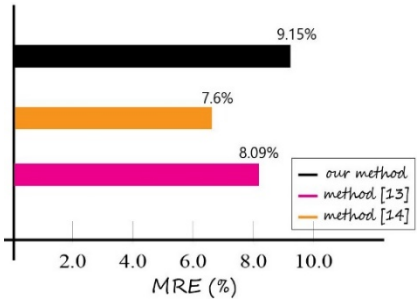

Fig. 9. Compare Results With Another Two Approaches.

VI. Conclusion

We have introduced a novel approach to insect detection for any farmland. However, our method also has capabilities to working on any study like beetle detection. Our main objective is, estimating the future condition of cropland based on the oppression of both harmful and useful insects.

***Abstract*—The fundamental objective of this paper is to describe the applications of Microsoft Kinect sensor with robust algorithm and solution to present 3-D surface reconstruction mapping with different measurements. In the line of Sensor operations, there could be two possible categories into 3-D reconstructions such as exorbitant laser scanner and other is by taking photos from various angles. In this paper, we have used indoor environmental scenes by depth sensor camera Microsoft Kinect. Data Pre-operations, sensor posture evaluations, computational fusion of the depth sensor data and 3-D surface extractions are the four major part of this experiment. The algorithm of this paper has been built uniquely with C# programming.**

***Index Terms*—Microsoft Kinect sensor, 3-D reconstruction, Depth- sensor camera, image processing, Algorithms.**

1. INTRODUCTION

Microsoft Kinect sensor for X-box 360 has infrared projector and RGB camera inside the Kinect. Red, Green and Blue color defines the object distance measurement and a visual imagination. Kinect depth sensor has a wide range from 1.6 ft. to around 17 ft. and can generate up to 30 (FPS) frames/ Sec. Depth Camera generally collects the videos from RGB camera and measure the depth distance from the object to it [1-2]. The four major steps of this paper are Data pre-processing or surface measurement, sensor posture evaluation, rationalize the model and surface extraction for 3-D surface reconstructions. The graph plotting and other algorithms has been visualized through MATLAB. Our Robust Algorithm has been built with C# programming.

2. LITERATURE REVIEW

Using image processing techniques has been introduced that how Microsoft Kinect Sensor can be cost-effective to extract 3D surface with a volumetric method that fuses entire depth data using the ICP algorithm [1]. An inexpensive 3D camera like Kinect has the ability to quantify topographical surfaces with an accuracy using a digital elevation [2]. Depth data can attain surface reconstruction by enhancing ray casting of the color texture of reconstruction objects [3]. 3D reconstruction can assist a robotic vehicle to navigate visually without GPS support [4]. The history and scrutinized contemporary efforts in the research community to accentuate the fact that 3D reconstruction has significance on higher-level and mid-level of 3D understandings [5]. In [6] Nguyen, Izadi, Lovell have proposed a system that quantify lateral as well as axial noise patterns of angle and distance of a perceived surface using Kinect sensors. In paper [7], the authors introduced an approach to fetch 3D structured surface area of cultivated land with sensors of Kinect Camera. The main aim of their technique is to obtain three-dimensional land surface data that estimates wheat emergence capacity. The researchers have utilized Kinect depth-data that stacks set of 3D datasets from forest gravel roads to quantify surface roughness. The sole purpose of the research was to identify the roughness of distinct gravel roads they correlated vibration analysis with three-axis accelerometers which were placed into experimental vehicles [8]. Bokaris, Muselet, Trmeau have explained an approach to reconstruct three-dimensional indoor scenes consisting planar plots also uses RGB-D data for a single image [9].In paper [10], the authors have shown which will explore the technique of making an improvement of the Kinect fusion algorithm that enhances the precision of 3D scanning objects and lessens the noise factors. The authors in [11] have also presented a remarkable procedure by applying an upgraded version of (LEHF) Line-based Eight-directional Histogram that constructs better 3D model than original Kinect fusion. Ling, Shlizerman, Shapiro present a unique algorithm that yields high-resolution 3D meshes of face images captured by a single depth view of Kinect, this method also includes Kinect Fusion that allows the algorithm to take high depth images [12]. Calibration of depth camera and accuracy setting has been implemented on the other two papers [13-14].

In this paper, we have developed our Kinect sensor reconstruction unique algorithms in C# programming with real time fusion model of indoor environmental scenarios for 3-D reconstructions.

3. DATA ANALYSIS

Kinect has mainly 3 sensors for its operation. An RGB camera, IR light projector and CMOS sensor. Light coding technique is actually the depth measurement into the Kinect sensor. CMOS sensor operates with the light coding techniques rather than other sensors which make Kinect sensor a low cost device. The IR emitter beams a packet of light which can track the shape of the object in the basis of distance. In some past

studies, standard deviation of depth data with calibration error has been shown [13-14].

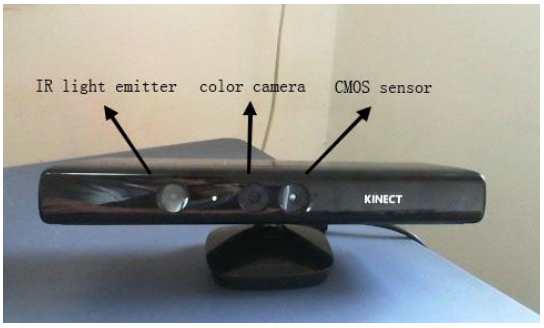

Fig. 1. The Microsoft Kinect sensor, X-box 360.

4.1 Data pre-operations

This stage implies the raw data of depth sensor camera measurement. After the data measurement, we will generate the point cloud as well as figure out the map. But the point is, there are error into the depth data measurement [3]. For example: when the edge of the surface are scanned, a low cost sensor device may have some wrong information about the depth image calculation. Furthermore, little Gaussian noises exist in the depth map that will make the surface unsmooth. In fig.2, we can see that the plots are distracted from the region lines of the actual values. This happens when Kinect is in a long distance from its corresponding object. In the line of 450 cm or approximately 15 meters, the actual depth distance calculation will be wrong and far from the actual value. Some gross error may occurred3 when scanning the edge and IR may

not reflect a sharp object which will create an undependable data. For example: during scanning objects like metal glass or hardware tools, Kinect cant detect the object as these tools dont reflect the infrared light. For overcoming these problems, we need to pre-process the raw data to get rid of gross error as well as noises every time. We applied bilateral filter to reduce Gaussian noises and gross error.

4.1.1 Bilateral Filter:

Bilateral filter is nonlinear filter for image that reduce the noise and preserves the edge by restoring the intensity of each pixel with the weighted average of intensity value from nearby pixel [9-10]. The bilateral filter is defined as:

$$I^{filtered}(x) = \frac{1}{W_p}\sum_{xi\in\Omega} I(x_i) f_r(||I(x_i)-I(x)||) g_s(||x_i-x||)..(1)$$

here,the normalization term will be defined as :

$$W_p = \sum_{xi\in\Omega} f_r(||I(x_i)-I(x)||) g_s(||x_i-x||)..(2)$$

here, $I^{filtered}$ is the filtered image, I is the original input image, x is the required coordinates that is to be filtered, Ω is the window which is located in x, f_r is the range kernel for the smoothness in intensities and g_s is the spatial kernel for the smoothness in coordinates. Now the weight formula is:

$$\omega(i,j,k,l) = \exp(-\frac{(i-k)^2+(j+k)^2}{2\sigma^2} - \frac{||f(i,j)-f(k,l)||^2}{2\sigma_r^2})..(3)$$

where σ and σ_r are smoothing parameters, and I(i,j), I(k,l) are the intensity of pixels (i,j) and (k,l) accordingly. Here, let the size window σ to be 10, 30 and 50 respectively and σ_r to be 0.1, 0.3 and 0.5. The figure has shown in below fig.4.

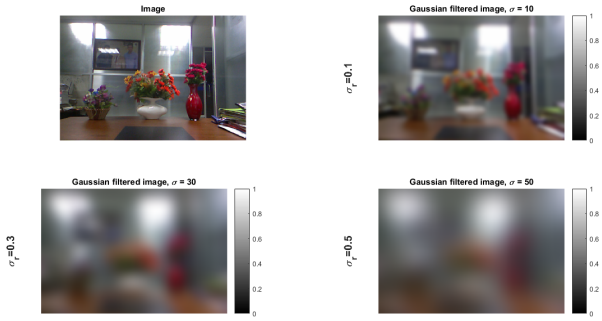

Fig. 4. Bilateral filter application for pixel intensity.

4.1.2 Point to point cloud with normal:

Let a matrix K that defines matrix of camera calibration by depth sensor camera. In time k_0, original raw depth map R_k shows the depth calculation R_k(u) at each image pixel u. showing the camera posture/ pose by transformation matrix $T_{g,k}$ and this is a 3DOF (3 degree freedom) rotation matrix. As Kinect can rotate 27 degree up to 27 degree down with total 54 degree 3-D movement at straight. 3DOF makes Kinect more reliable [4].

$$K = \begin{bmatrix} f_{dx} & 0 & u_{d0} \\ 0 & f_{dy} & v_{d0} \\ 0 & 0 & 1 \end{bmatrix} ..(4)$$

$$T_{g,k} = \begin{bmatrix} R_{g,k} & t_{g,k} \\ 0 & 1 \end{bmatrix} ..(5)$$

$$u = (u,v)^T, \dot{u} = (u^T|1)^T ..(6)$$

$\dot{u}$ is the corresponding homogeneous vector of u. now the normalize vector will be defined as: $N_k(u) = \frac{N_k(u)}{||N_k(u)||^2} ..(7)$

Now the corresponding image $\dot{u}$ is: $V_k(u) = R_k(u)K^{-1}\dot{u}$. Here, V_k is the point cloud and it is obtained by back projecting the filtered depth value into sensors scanning space.

4.2 Sensor Pose/posture Estimation:

As soon as we get the point cloud then we proceed for the 3-D surface model. For that we need to get the rigid transformation matrix of the sensor posture and reform point cloud to global model. In this stage, we need ICP algorithm to find the important point with higher accuracy and efficiency. It also decreases the number of correspondence. RGB frames optical flow calculation is important to find out point features between two closest frames. Here base alignment can be done by the previous transformation matrix equation (5). ICP algorithm then will be used forgetting the accurate sensor pose estimation [11].

4.2.1 ICP Algorithm:

Iterated closest point. The basic characteristics is to find the rotation and translation values between two points. It is really an essential algorithm to calculate the displacement between scans and determine the correct data association. The rotation valued vectors are represented as: $\vec{q}_{rot} = [q_0, q_1, q_2, q_3]..(8)$; here $q_0 \geq 0$ and $q_0^2 + q_1^2 + q_2^2 + q_3^2 = 1$. The three by three rotational matrix by unit quaternion is defined as:

$$R = \begin{bmatrix} q_0^2+q_1^2-q_2^2-q_3^2 & 2(q_1q_2-q_0q_3) & 2(q_1q_3+q_0q_2) \\ 2(q_1q_2+q_0q_3) & q_0^2+q_2^2-q_1^2-q_2^2 & 2(q_2q_3-q_0q_1) \\ 2(q_1q_3-q_0q_2) & 2(q_2q_3+q_0q_1) & q_0^2+q_3^2-q_1^2-q_2^2 \end{bmatrix} ..(9)$$

The translation unit vector is $\vec{q_t} = [q_4, q_5, q_6]..(10)$. By this the result of $\vec{q}$ is $\vec{q} = [\vec{q}_{rot}|\vec{q_t}]^T..(11)$. At the time of scanning by RGB-D camera, let us assume $P = \vec{p_l}$ is the calculated data set which is needed to align with point $X = \vec{X_i}$, and N_x and N_p (where N_x = N_p) be the model point amount and measured point amount respectively. The mean square object equation: $f(\vec{q}) = \frac{1}{N_p}\sum_{i=1}^{N_p} ||\vec{x_l} - R(\vec{q}_{rot})\vec{p_l} - \vec{q}_T||^2..(12)$ The translation vector will be defined as:

$\vec{q_t} = \vec{\mu}_x - R(\vec{q}_{rot})\vec{\mu}_p$ ..(13)

Here, $\vec{\mu}_x$ is the central mass of the measured point set P.

4.3 Fusion of Depth Sensor Data:

with the implementation of sensor posture estimation, every single frames of depth images get fused with each other and become one single model of frame through volumetric representation method. This also known as truncated signed distance function (TSDF) [12].

4.3.1 Volumetric representation:

it is really obvious that visuals are captured into 3-D forms into human eyes. Every surface and objects are in 3 dimensional form. So Kinect depth data frames volumetric understanding is the next step for object recognition and reconstruction. Every figure is made up by the alignment of pixels. Volumetric pixel is called voxel. Voxels represent color

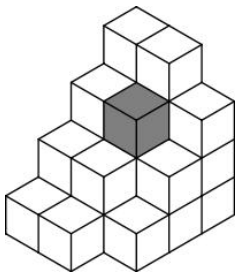

Fig. 5. 3-D format volumetric representation of Kinect sensor.

picture by aligning its position [1].

Voxel shows data point center in 3-D module. This could be opacity, various segment of data etc. This solely depend upon the user how he/she wants to use the data point. Now in truncated signed distance function, weighted signed distance function D(x) will be: $D(x) = \frac{\sum w_i(x)d(x)}{\sum w_i(x)}..(14)$ and the cumulative weight W(x) will be: $W(x) = \sum w_i(x)..(15)$ Here $d_i(x)$ is named signed distance function from i-th distance of image. Now describing the un-weighted signed distance function, the very fundamental phenomenon is adjusting some critical situation when sensor scan the object with distance, sometimes the space surface has negative distance while the behind have some positive distance. When the weight is 1, surface will be created by the averaging of two range surfaces. Now we fuse the depth frames incrementally like:

$$D_{i+1}(x) = \frac{w_i(x)D_i + w_{i+1}(x)d_{i+1}(x)}{w_i(x) + w_{i+1}(x)}..(16)$$

$$W_{i+1}(x) = w_i(x) + w_{i+1}(x)..(17)$$

4.4 Surface Extraction:

Each time we upgrade the TDSF, every voxel is targeted into image plane of the depth sensor to have the corresponding image pixel. After this the signed distance will be calculated. When the normal map is extracted into previous process stage, normal x is used to show the normal of the projected voxel using the similar formula as (16). Now about the voxel, the surface extraction will be: S(p) = p + N(p). F(p); (18) here, p is the voxel point. But we cant accept the result if surface is extracted from outside voxel.

5. EXPERIMENTAL RESULTS

Our total Kinect algorithm project is built with C# programming with MATLAB application. Starting with the Data pre-processing to Surface extraction for 3D reconstruction, every steps has been implemented accordingly and successfully. First step was surface measurement for reducing the Gaussian noise and gross error in depth data. If we project the camera calibration matrix into real time parameter co-efficient from data table, the following result could be found for 3D model Data,

$$K = \begin{bmatrix} f_{dx} & 0 & u_{d0} \\ 0 & f_{dy} & v_{d0} \\ 0 & 0 & 1 \end{bmatrix} = \begin{bmatrix} 593.36 & 0 & 322.69 \\ 0 & 582.74 & 231.48 \\ 0 & 0 & 1 \end{bmatrix}$$

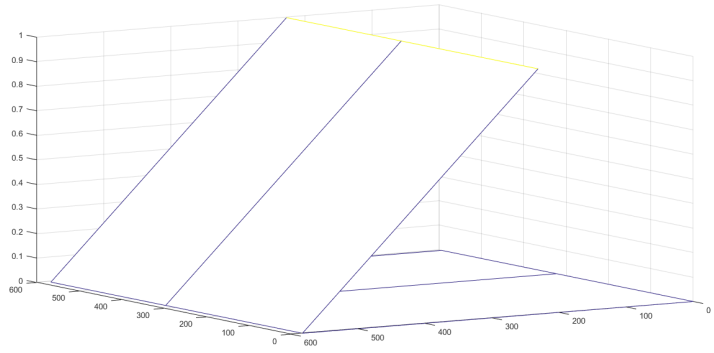

Fig. 6. 3-D model of calibration matrix of depth camera.

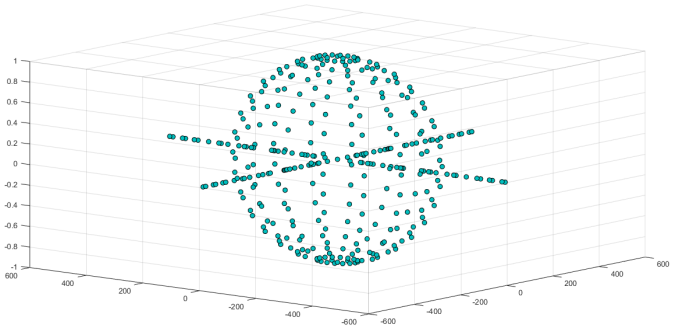

Fig. 7. Scattering 3-D model of calibration matrix of depth camera.

Bilateral filter can certainly improve the quality of pixels and recover every pixel that need to be fixed. The value is already given.

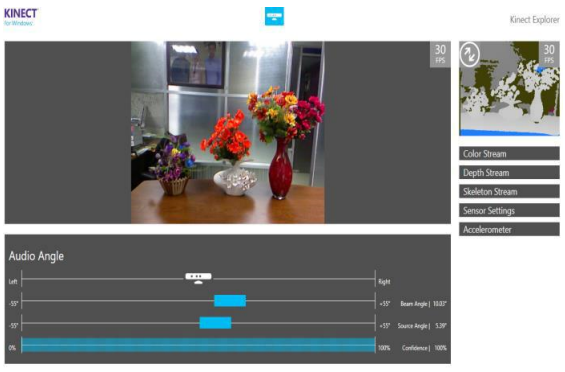

Fig. 8. Raw data image in Kinect sensor.

The basic principle of the ICP algorithm is fusion with the point clouds. Alignment of the point and give the correct data. There could be some error crossing in alignment of the data point. But ICP algorithm helps to gain a satisfactory level of accuracy.

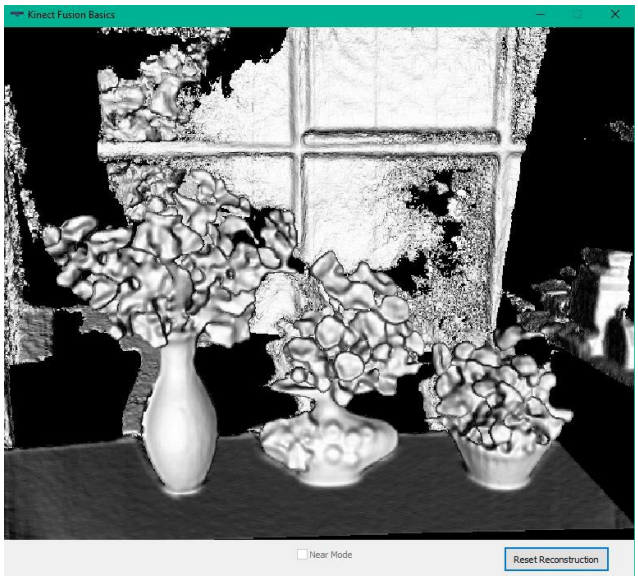

Fig. 9. Fusion point cloud with ICP algorithm.

Kinect even works in darkness with very good efficiency. There will be a big error in data point if we don't implement the ICP algorithm properly.

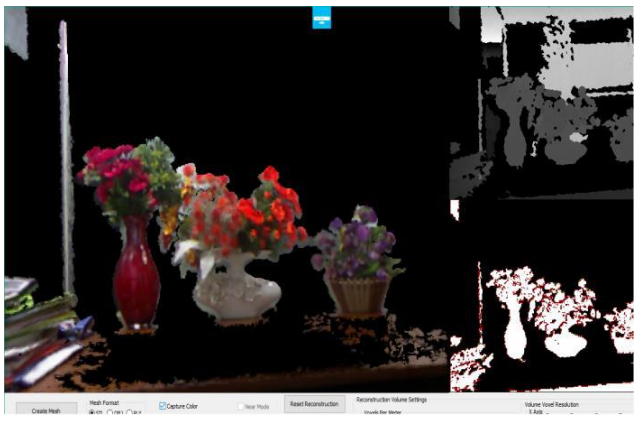

Fig. 10. Kinect real time fusion mapping.

A little bit of disadvantage that Kinect fusion has that sometimes Kinect sensor consume a little more time than usual for fusion mapping reconstruction. This happens because sometimes the aim object is not placed properly or sometime IR takes more time to scan. It is clearly visible that in fig.12 the second image is more accurate and visible. The comparative error rate of the fusion reconstruction image in fig.12 became very low in error rating comparing with the first image in fig. 12 and became more accurate.

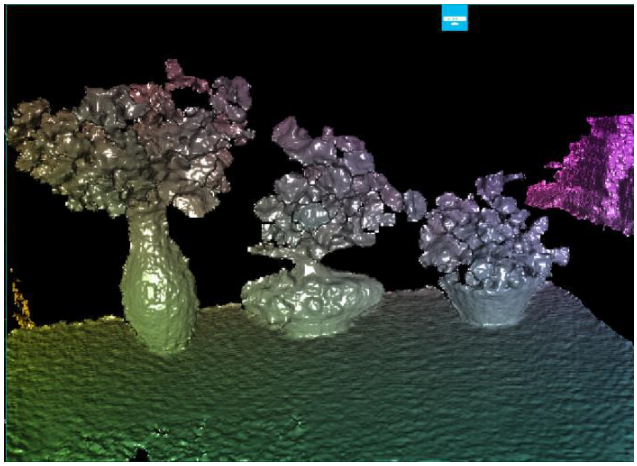

Fig. 11. Kinect fusion real time surface reconstruction.

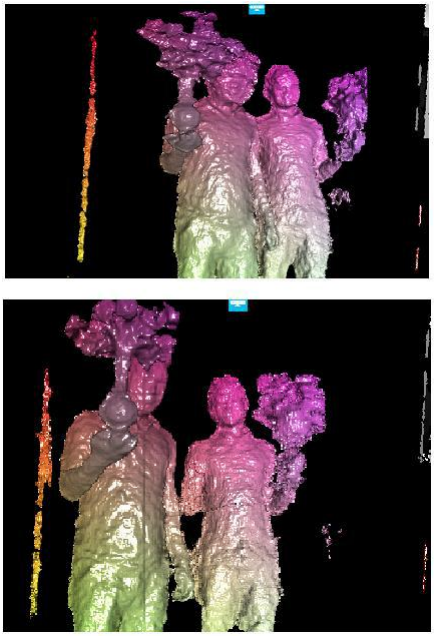

Fig. 12. Comparison of some limits of Microsoft Kinect.

6. DISCUSSIONS AND FUTURE WORK

The overall observation of the paper is clear cut. The main focus of this paper is C# algorithm structure with indoor environment Kinect fusion mapping.The execution of the research is very much cheap and adjustable in any environment. In the field of image processing, 3D reconstruction by RGB-D sensor may very much common, but apart from that similarity, Our pseudo-code is robust and very efficient to use. Some constructive error has been modified due to adjusting problem of kinect. But that could be executed by any machine and that is completely normal. In future, we will try to execute industrial security measurement by the depth sensor camera like Kinect. It will be an unique approach for the industrial security issue.

7. CONCLUSION

In this paper, we have shown the 3-D Microsoft Kinect fusion indoor environmental reconstruction mapping with accuracy and authenticity. The paper reflects the state-of-the art of different algorithms that helps Kinect to construct the work perfectly. Our robust algorithm is built with C# programming and some of the 3-D graph and calculations has been measured by MATLAB. Latex software has been used to build our robust algorithm of this paper.

***Abstract*— Lung cancer is one of the most threatening diseases and prediction of it, is challenging problem nowadays. Most of the cancer cells are overlapped with each other. It is hard to detect the cells but also essential to recognize the presence of cancer cells in the early stage. Early detection of lung cancer may reduce the death rate. In this study, we use the grey level co-occurrence technique (GLCM) to extract the feature of the cancer affected lung image and then support vector machine (SVM) to detect abnormal lung nodules. Our experimental evaluation using MATLAB demonstrates the efficient performance of the proposed system.**

***Index Terms*— Lung Cancer Detection, Gabor Filter, Computed Tomography, Marker-Controlled Watershed, GLCM, SVM.**

I. INTRODUCTION

Lung cancer is the maximum mainstream cancer that cannot be neglected. It is the second most regularly analyzed cancer in men and women. An anticipated 234,030 new instances of lung cancer are normal in 2018, representing around 14% of all cancer analyze [1]. The rate has been declining since the mid-1980s in men, however just since the mid-2000s in women [1]. Gender orientation contrasts reflect authentic examples of smoking take-up and end in the course of recent decades. During 2005 to 2014, lung cancer frequency rates decreased by 2.5% per year in men and 1.2% per year in women [1]. Lung cancer represents a larger number of deaths than some other cancer in men and women [1]. An expected 154,050 deaths are relied upon to happen in 2018, representing around 1 of every 4 cancer death. The lung cancer death rate has decayed by 45% since 1990 in men and by 19% since 2002 in women due to reductions in smoking, with the pace of decline quickening over the past decade; from 2011 to 2015, the rate decremented by 3.8% per year in men and by 2.3% per year in women [1]. Identifying of lung cancer are often done through its symptoms embrace a cough, coughing of blood, fatigue, unexplained weight loss, shortness of breath etc. Computerized tomography (CT) is that the most efficacious technique of lung nodule detection for its competency to make three-dimensional (3D) pictures of the chest, leading to more immensely colossal resolution of nodules and tumor pathology. A CT image by a computer process to avail lung nodule medicine has been widely utilized in the clinic. the method of computer availed diagnosis (CAD) of lung cancer are often divided into a detection system (often abbreviated as CADe) and diagnostic system (often abbreviated as CADx). The forsaken system divides the candidate nodules kenned within the precedent step into nodules or non-nodules (i.e., traditional anatomic structures). The goal of the CADx system is to relegate detected nodules into benign and malignant nodules [2]. Since the likelihood of malignancy is approximately associated with the geometric size, shape, and look, CADx will distinguish the benign and malignant pulmonary nodules by the efficacious options like texture, shape, and rate of magnification. Thus, the prosperity of a culled CADx system is often quantified in terms of precision of identification, haste, and automation level [3].

In this study, image enhancement, segmentation, and feature extraction and lung nodules detection procedures have been implemented using MATLAB. The paper is aiming to get the more accurate results by introducing a new feature extraction process which is much effective and less time-consuming to detect cancerous lung. In the first section of this paper, methodology has been explained and rest of the paper following contents are classification with SVM as well as result and discussions. And at the end, summary of the works and future work scope has been explained in conclusion.

II. RELATED WORKS

S. Avinash et al [4] showed that early detection of lung cancer is applicable for efficient analysis and it will help the opticians to provide initial treatment. Prior to this, researchers employed methods such as fast fourier transform (FFT) for image enhancement, thresholding method for segmentation and extrusion methods for feature extraction etc. The research has computerized these selections, enhancing databases, selecting features of lung cancer images, lung cancer detection, quality and accuracy improvement. Image processing approaches brought huge benefit for identifying Lung Cancer at an early stage. Magnetic resonance imaging (MRI), which produces computerized images of the body that are used to diagnose several different cancers, was developed by Paul Lautenberg and Peter Mansfield [5]. The imaging is based on the different signals obtained from different tissue

types that are subjected to a high magnetic field. In 2003 the developers won the Nobel Prize in medicine for their work.

Radiologists have interior relied on examining images from chest radiography and PET scans to detect lung cancer [6]. Fatema el al. [7] proposed a technique based on CT technology, the proposed system consists of a few steps like photo acquisition, preprocessing, feature extraction and categorization. At the preprocessing stage, RGB images are converted to grayscale images, used for reducing the Gabor filter, the adaptive thresholding method transforms CT scan images into binary images, and the REGIONPROPS function is used for the right body, from the binary image to the region. Feature extraction platforms, such as contrast, correlation, energy, home genetics, are characterized by a static method called Gray Level Co-occurrence Matrix (GLCM). To ameliorate the hand annotation of nodules, medical experts expand beyond an axial scan mode and rely on other techniques such as maximum intensity projections and 3D volume renderings [8]. Maximum intensity projection (MIP) is a volume rendering technique for 3D images that projects voxels with a maximum intensity of the parallel rays from a given viewpoint onto the plane [9]. This technique makes it more facile to detect denser objects like nodules since maximum projections will be concentrated in a particular area, whereas other structures like thin blood vessels will have maximum intensities more distributed throughout the lung/image. In Rashmita al. [10] are based upon gabor filter within Gaussian rules, thereafter the segmentation principles are applied over the enhanced region of the image and the input for feature extraction is obtained. In this research they have done classification based upon artificial neural networks which is used their own software.

In [11] the authors largely fixate on adequately great amelioration in contrast of masses along with the suppression of background tissues is acquired by processing the parameters of the proposed transformation function in the definite range. The manual analysis of the sputum samples is time-consuming, erroneous and needs concentrated trained person to evade diagnostic mistakes. The segmentation results will be utilized as a base for a Computer Availed Diagnosis system for early detection of cancer, which increases the chances of the patient survival. As well as Gabor filter is proposed by authors for enhancement of medical images. It is a good enhancement to implement for medical images.

Thus, Researchers are becoming more and more concerned with the elaboration of automated CAD systems for lung cancer. Many publications proposed different automated nodule recognition systems utilizing image processing, and including, different techniques for segmentation, feature extraction, and relegation. Moreover, the detection processes work in the middle stage of the lung cancer, which is very hazardous for the affected patient [12].

III. METHODOLOGY

The methodology focuses to obtain a more accurate result. In the proposed method, it is enhancing the contrast of the input image through the pre-processing method. It is done by first converting the input image to a grayscale image and then it is modified with the Gabor filter to enhance [13].

In image processing, segmentation is moreover very important part, in this section ideally enhanced images is segmented into two or more sub-segments that will be the more easier representation of the images for further extracting the elements. Segmentation could be utilized for object recognition, occlusion boundary estimation within motion or binaural systems. The goal of image segmentation is to cluster pixels into relevant image regions, corresponding to individual surfaces, objects, or natural components of objects. We mainly follow an approach like a Marker-Controlled Watershed. In feature extraction, a pixel comparing process is proposed in this paper.

We can see the various steps of lung cancer detection in the following fig 1.

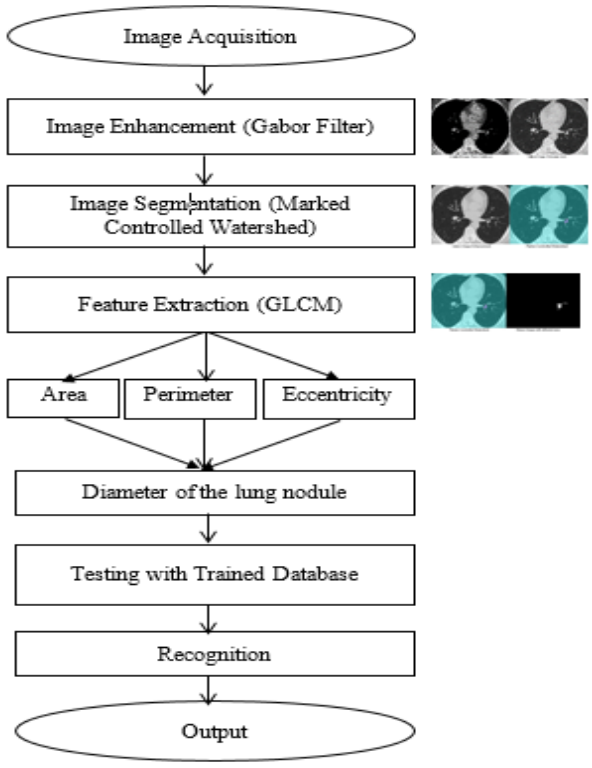

Fig. 1. Block diagram of the proposed system to detect lung cancer.

A. Image Acquisition

The first stage of methodology starts with taking a collection of CT images (normal and abnormal) from the available Database from IMBA Home (VIA-ELCAP Public Access) [12]. Lung images are very high when X-ray and MRI compared to the CT scan image. Therefore, they are considered for developing strategies. The main advantage of using calculated tomographic images gives more transparency and less distortion. In the appearance of these facts, the images collected from ELCAP public lung image database which is released December 20, 2003. The whole-lung dataset consists of 50 CT scans obtained in a single breath hold

with a 1.25 mm slice thickness. DICOM (Digital Imaging and Communication in Medicine) has become a standard for medical imaging.

The acquired image is in raw form. A lot of noise in the acquired image is observed. To improve contrast, transparency, background sound separation, it needs to be pre-processed. Therefore, different techniques like enhancement, the required form is developed from images.

B. Image Enhancement

The image pre-processing stage commences with image enhancement. The aim of image enhancement is to modernize the interpret-ability or perception of information included in the image for human viewers or to provide better input for other computerized image processing techniques. Image enhancement techniques can be divided into two categories: Spatial domain methods and frequency domain methods [14].

1) Spatial domain techniques- which operate directly on pixels.
2) Frequency domain techniques- which operate on the Fourier transform of an image.

The various image enhancement techniques can be characterized as spatial domain methods and frequency domain methods. This includes smoothing of image and removal of noises, blurring etc. There are many ways to enhance the image but Gabor filter was found to be suitable for both the CT and MRI images. In the image enhancement stage, we utilized the following Gabor filter techniques.

Gabor Filter: A Gabor filter is a linear filter whose impulse replication is defined by a harmonic function multiplied by a Gaussian function. Because of the multiplication-convolution property, the Fourier transform of a Gabor filters impulse replication is the convolution of the Fourier transform of the harmonic function and the Fourier transform of the Gaussian function [15]. It fundamentally analyses whether there is any concrete frequency content in the image in concrete directions in a localized region around the point or region of analysis. A set of Gabor filters with different frequencies and alignment may be helpful for extracting useful features from an image. In the discrete domain, 2D Gabor filters are given by,

$$G_c[i,j] = Be^{\frac{i^2+j^2}{2\alpha^2}} \cos(2\Pi f(i\cos\theta + j\sin\theta)) \quad \text{.....(1)}$$

$$G_s[i,j] = Ce^{\frac{i^2+j^2}{2\alpha^2}} \sin(2\Pi f(i\cos\theta + j\sin\theta)) \quad \text{.....(2)}$$

Where B and C are normalizing factors to be determined. 2-D Gabor filters have rich applications in image processing, especially in feature extraction for texture analysis and segmentation. f defines the frequency being looked for in the texture. By varying θ , we can look for texture oriented in a particular direction. By varying α , we change the support of the basis or the size of the image region being analyzed shown in fig 2.

C. Image Segmentation

Image segmentation is to facilitate the representation of an image into something that is more meaningful and easier

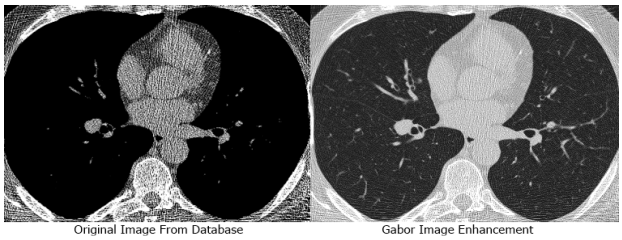

Fig. 2. Enhanced image by using Gabor filter

to analyze. Image segmentation is used to allocate objects and boundaries. It is the process of assigning a label to every pixel in an image such that pixels with the same label share certain visual characteristics [16]. The result of image segmentation is a set of segments that collectively cover up the entire image or a set of contours extracted from the image. Each pixel of the image in a region is similar with respect to some characteristic or computed property, such as color, intensity, or texture; adjacent regions are crucially different with respect to the same characteristics [17]. In this research, we used watermarked image segmentation approaches:

1) Marker-Controlled Watershed Approach: The Watershed transformation considers the gradient enormity of an image as a topographic surface. Pixels having the highest gradient enormity intensities (GMIs) match up to watershed lines, which represent the region boundaries. Water placed on any pixel roofed by a flow downwards to a common local intensity minimum (LMI). Pixels are draining to a common minimum form like a catchment basin, which signify the regions. Image segmentation result is a set of segments that cover a set of contours that are fully outlined in the whole image [18]. The marker-controlled pond section follows these basic methods and shows such fig 3.

In segmentation, image are been segmented in various sections which made easy for extraction features with GLCM process. With watershed segmentation, we detected the unwanted nodules with abnormal pixels. The outlined of abnormal pixels positions with light violet color are very similar with given position (affected cell with nodules) which is obtained from the database.

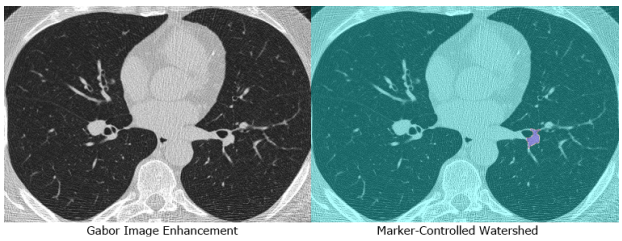

Fig. 3. Enhanced image to watershed

Algorithm 1 Marker-Controlled Watershed

1: **procedure** MARKER-CONTROLLED WATERSHED
2: Calculate a segmentation function. This is an image in which we are trying to segment them with dark areas.
3: Counting foreground markers. This is attached to the blobs of pixels in each object.
4: Counting background markers. This pixel is not part of an object.
5: Modify the segmentation function so that it only has minima at the front and background marker position.
6: Calculate the watershed transform of the revised segmentation function.

D. Feature Extraction

In image processing, the Image features extraction stage is very vital image processing techniques which utilizing algorithms and techniques to detect and isolate portions or shapes (features) of an image [19,20]. Once the segmentation is accomplished on the lung region, the features can be obtained from it and the diagnosis rule can be designed to precisely detect the cancer nodules in the lungs. This diagnosis rules can eliminate detection of cancer nodules resulted in segmentation and provides a better diagnosis [21-23]. In this stage to obtain the general features of the enhanced segmented image, GLCM is used as shown in fig 4.

Grey Level Co-Occurrence (GLCM): For extracting feature using the Gray-level co-occurrence Matrix (GLCM) to represent a set of features to reduces the misclassification of the glaucoma image. GLCM describes how many coordinates of pixel brightness values in an image illustration. GLCM represents the combined frequency of all pairs of gray levels i and j divided by a distance in the direction of nodules. GLCM Characteristics of basic character areas, perimeter, and Eccentricity this scale is measured in. These features are defined as:

A) Area: This is a scalar value that gives the actual number of actual pixels in extracted ROI (Region of interest). The Transformation function creates an array of ROI, which contains pixels with 255 values.

$$\text{Area} = A = (A_{i,j} \text{ , X ROI[Area]} = i \text{ , Y ROI [Area]} = j) \quad ..(3)$$

Where, i,j are pixels in size within the shape. ROI is Interest Area. X ROI [] is vector contain ROI X position, Y ROI [] vector retains ROI Y position [24].

B) Perimeter: This is a scalar value that actually gives nodule pixels. It extracted ROI borders length. Transform function creates an array on the edge of which the pixels contain 255 values, at least one pixel that contains 0 values [22].

$$\text{Perimeter} = P = (P_{i,j} \text{ , X edge[P]} = i, \text{ Y edge[P]} = j) \quad ..(4)$$

Where X is the edge [] and Y is the edge [] The vector represents the combination of i^{th} and j^{th} pixels by creating curves respectively.

C) Eccentricity: This metric value is called as roundness or circularity or irregular complex (I) equal to 1 for only round and it is less than 1 for any other shape.

$$\textbf{Eccentricity} = \frac{Lengthof Major Axis}{Lengthof Minor Axis} \quad ..(5)$$

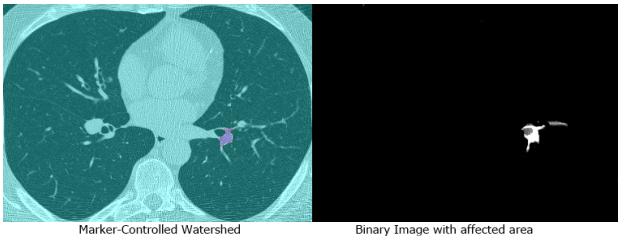

Fig. 4. Feature extraction from segmentation

After segmentation when we used GLCM on segmented images, it made a gray scale image which helped us to abstract the abnormal nodule sections with white color. Then we measured the sections with following steps. Approximate features for separate nodule of given sample images mentioned in Fig. 5 were found as follows:

1) Area: It is the most simple property and its given size. Therefore, it is the total number of white pixels in the extracted area.

2) Perimeter: Another simple property defined by the scope of this region. It's external ROI borders length.

3) Eccentricity: It is used to decide the shape or circularity of the object.

Area: 2291 Perimeter: 221 Eccentricity: 0.8289 Stage 3 Detected

IV. CLASSIFICATION

Support vectors are a learning model that is supervised by the relevant learning algorithms that can identify data analyzes and patterns for machine analysis. The basic SVM input takes a set of data and for each given input, predicts that the two classes form the input, it creates a non-possible binary linear classifier. SVM uses a kernel function that maps the given information to an individual location. Separation can be made with very complex boundaries. The various types of kernel functions, including polynomial, RBF, quadratic, Multi-Layer Perceptron (MLP). Each kernel is formulated by its own parameter γ, σ, and so on. Fig 5 shows the maximum margin hyper plane. The main hyper-plane algorithm is a way of creating non-linear classifications using the most margin hyper-plan kernel trick. In feature extraction we extracted and measured the existing nodules in the cells. Using SVM we created a hyper-plan.

V. RESULT AND DISCUSSION

A. Stage of Lung Cancer

The lung nodules are increased in small-scale in the lungs, which measure from 5 mm to 25 mm. The unusual nodule size in images are more than 25mm.

Assessing the size of cancer in staging and entering the

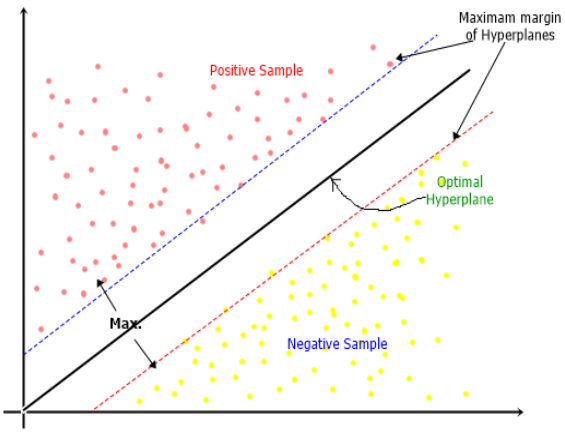

Fig. 5. SVM classifier hyperplanes

tissue surrounding it, as well as the presence or absence of metastasis in lymph nodes or other organs [25]. The stage from I to IV according to the intensity:

1) Stage I: cancer is confined to the lung
2) Stage II and III: cancer is confined to the chest
3) Stage IV: cancer has spread from the chest to other parts of the body.

This experimental information consists of 50 patients with more then 10,800 lung images. These 10,800 lung images are passed through the proposed method. Then the rules of diagnosis are generated from those images and these rules are sent to SVM classifier for the learning process. After learning, a lung image which is collected from hospital is passed through the proposed method. Then the proposed method has processed through its processing steps and finally it able to detect whether the following lung image is affected or not.

The proposed CAD system is capable of detecting nodules

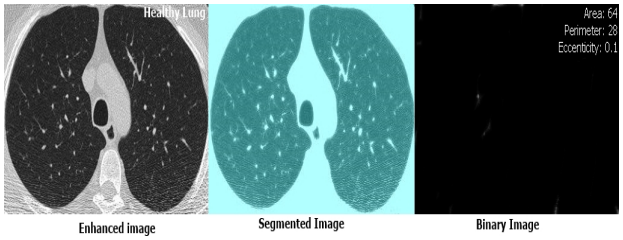

Fig. 6. A healthy lung

of lungs, larger than 25 mm of diameter, which means they are able to detect nodules in the lungs at the initial stage. In this way, diagnosing the primary disease will improve the patient's survival rate. Discrimination between cancerous and non-cancer candidates nodules which are shown in fig 6, 7 & 8. For making decision

B. Gaussian Radial Basis Function

Radial basis functions kernel have received significant attention, most commonly with a Gaussian of the form,

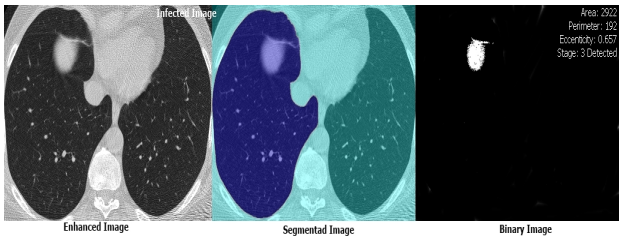

Fig. 7. A stage 3 affected lung

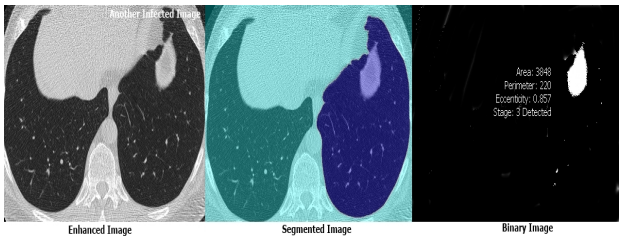

Fig. 8. Another stage 3 affected lung

$$K(a,a') = \exp(-\frac{||a+a'||^2}{2\sigma^2}) \quad .....(6)$$

Generally, a method of clustering is first employed to select a subset of the centre. An interesting feature of SVM is that this selection is perfect, each support vector centred on that data point, contributing to the local Gaussian function. The basic equation for support vector machines is:

$$C_o = H^T * F_o + b \quad .....(7)$$

Where, C_o= Output Class; H= Hyper-plane; F_o= Input Feature; b= Bias.

Now the dataset success rate is being compared with Rashmita al. [10] and Mokhled al. [13] which has same dataset with threshold binarization process. Patient one is the result with same patients' MRI analysis report is done by this paper and subject two is the result with same patient done by the following paper. Table 1 is highlighting comparison with our method to others. Confusion matrix is one of the most intuitive and easy metrics used to find the accuracy and accuracy of the any model. It is used for classification problems where the output can be two or more types of classes. Here, FP: False positive, FN: False Negative, TN: True Negative and TP: True Positive. TAR and FAR is calculated respectively as fraction of positive and negative scores exceeding my method.

TAR = TP/(TP+FN) and FAR = FP/(FP+TN)

VI. CONCLUSIONS

Lung cancer is one of the most dangerous diseases in the world. Proper diagnosis and early detection of lung cancer can increase the survival rate. CT scan images are collected from different hospitals and databases. A method is being proposed and developed for the detection of the stage of the cancer. Gabor Filters for image enhancement and Marker-Controlled Watershed segmentation gives the best results in the pre-processing phase. From the arising regions of interest (ROI), three properties are extracted from GLCM, such

TABLE I

Total Success Rate		92.64%	89.97	95.32

as area, perimeter and eccentricity. These three properties measure the nodules to detect lung cancer levels. The size of nodule indicates the different levels of the tumor. Also for the purpose of classification, support vector machine modeling is an attractive approach. It combines generalization controls with a strategy to address dimension of nodules. In the classification problems, the generalization control is achieved by maximizing the margin, which is consistent with the weights of the weight vector in a canonical structure.

***Abstract*—Hazy image enhancement is one of the challenging fields in the area of image processing because the presence of haze reduces the visibility of outdoor images. In order to remove haze, various algorithms have been proposed in recent years. Most of the algorithms remove haze but hardly enhance the image with better contrast. In this paper, we have proposed an effective method for removing haze from the image. The main benefit of our method is that it dehazes image as well as preserves ramp edges providing better contrast of the image. The qualitative and quantitative comparison among few states of the art methods have been performed which show that our method gives better output images compared to those methods.**

***Keywords*—Haze, Ramp Edge, Nonlinear Complex Diffusion Process, Contrast, Noise.**

I. Introduction

The appearance of the outdoor images is important in case of surveillance, intelligent vehicles and remote sensing system which may be affected by bad weather conditions such as rainy, foggy, haze and smoke etc. The image which is taken in bad weather condition offers low contrast and poor visibility of the scene. This condition is caused by small-sized water droplets which are present in the air [1]. Attenuation and airlight are two primary environmental extents cause scattering [2]. Attenuation is a light beam. It travels from a viewpoint via the atmosphere and gets attenuated because of the scattering by the atmospheric particle [1]. It reduces the contrast of the scene. Airlight guides to the change in color and this condition increases with the distance from the object [3].

For the better performance of the computer vision applications, haze removal is highly desired. For removing haze from an image we need to estimate the depth map or airlight map. Depth map holds information about the distance of the surfaces of scene objects from an angle of vision [4]. For estimating depth map various methods have been proposed based on two or multiple images. Two images are used for stereoscopic estimation of depth. Another approach uses multiple images of different times [2] or with different polarizing filters [5]. For existing images we can not use this kind of methods because they are constraining for the acquisition [3].

There are a good number of existing methods for removing haze from image. Robby T. Tan [6] proposed a method by observing two basic things. They first noticed that images with enhanced visibility have more contrast than images plugged by bad weather. The second thing is the airlight tends to be smooth. Based on these two observations, they developed a cost function in the framework of Markov random fields which can be efficiently optimized by various techniques. However, this method over enhances the image and the output image looks unnatural. Another method introduced by Raanan Fattal to remove the indeterminacy problem which is based on the independent component analysis (ICA). In this method optical transmission in hazy scenes is estimated and based on this estimation scattered light is removed to increase the visibility of the scene and recover haze from scene contrasts. Unfortunately, this method works only for color images not for gray images. As dense fog is colorless, this method also fails when there is dense fog. Another method proposed by Kopf et al. [7] which discards the need of various assumptions about the color of the scene. It is based on the use of a 3D model of the scene. But this method fails as it is an application dependant method and requires expert interaction. The methods mentioned above have one drawback which is computation time. So, to remove this problem Tarel et al. [8] proposed a method assuming airlight as a percentage between local standard deviation and local mean of the whiteness. Although this method is based on the linear assumption, it requires many parameters. He et al. [9] proposed another

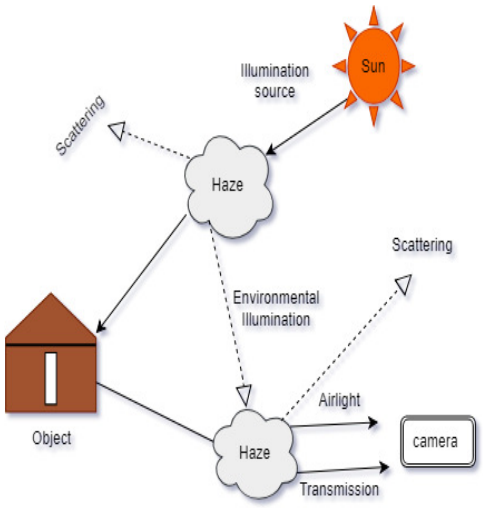

Fig. 1: Capturing image in hazy weather

effective method for outdoor RGB images based on the dark channel prior which also reduces computation time. Unfortunately, this method fails when the brightness of the scene objects are similar to atmospheric light. As most of the dehazing algorithm rely on user input, Sulami et al. [3] proposed a new method which does not rely on user input. Their proposed method based on recovering the atmospheric light vector in hazy scenes of a single input image. First, it estimates the color of the atmospheric light using few windows. Second, it tries to predict the magnitude of the atmospheric light by learning the magnitude of normalized color vector. However, this method is time consuming. Recently, another method proposed by Salazar et al. [10] uses a multilayer perceptron to compute the transmission map directly from the minimum channel and a contrast stretching technique to improve the dynamic range of the restored image.

From the aforementioned discussion it can be seen that though existing haze removal methods can remove haze, it hardly preserves ramp edges enhancing contrast of the images. Therefore, in this paper we proposed an effective haze removal method based on filtering approach. For filtering we used ramp edge preserving noise removal nonlinear complex diffusion process. Our proposed method is able to achieve equally and sometimes even better result to hazy images compared to existing methods. The novelties of this proposed method are as follows.

- A modified transmission map.
- We have refined transmission map using nonlinear complex diffusion process to preserve ramp edge.
- Post-processing using Multiscale Retinex Algorithm (MSR) to increase the contrast and brightness of the image.

II. Haze Model

The haze model which is widely used in computer vision and computer graphics to describe the formation of haze [2], [6], [11] is as follows:

$$I(x) = J(x)t(x) + A(1 - t(x)) \tag{1}$$

The goal of haze removal is to recover A, J and t from I where, I is the input image, J is the light reflected from its surface. x defines the pixel coordinates. A is the airlight vector representing single color in the image areas where t = 0. The scene transmission t(x) is distance dependant and is defined by Eq. (2).

$$t(x) = e^{-\gamma d(x)} \tag{2}$$

γ is the attenuation coefficient of the atmosphere and d(x) is the distance of the scene at pixel x from the sensor or camera. Here, the transmission acts as the matting between the scene and airlight. So, now from (1) and (2) haze model can be represented as,

$$I(x) = J(x)e^{-\gamma d(x)} + A(1 - e^{-\gamma d(x)}) \tag{3}$$

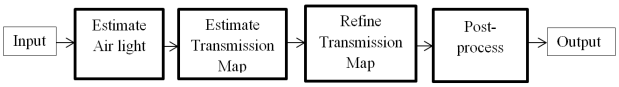

Fig. 2: Block diagram of proposed method

Here, in the right hand side first term is called direct attenuation [6] and second term is called airlight [6], [12]. For restoring haze free images information of airlight map A is needed. Airlight map depends upon the depth of the scene.

III. Proposed Method

In this paper, we have proposed a new haze removal method which first estimates the transmission map. After that, it refines the transmission map by nonlinear complex diffusion process. Nonlinear complex diffusion process removes haze from the image by preserving ramp edges. Hence, the haze-free image provides a clear concept about the objects. Afterward, we post-process the image using Multiscale Retinex Algorithm (MSR) because removal of haze from image gives a dark or low contrast view of the haze-free scene. So, post-process is needed because it will increase the contrast and brightness of the image. Our proposed method uses a modified transmission map which is different from other existing methods. Fig. 2 shows the block diagram of our proposed method which is described in details in the following subsections.

A. Estimate Airlight

In most of the existing methods, the airlight is estimated by the most haze-opaque pixels of the image. In Robby T. Tan's method, the pixel with the highest intensity is used as airlight and further refined [6]. However, this method does not always work because the brightest pixels could be any white object. Therefore, we have used dark channel for automatically estimating airlight. Dark channel is proposed by He et al. in [9] to find the minimum pixel in each color channel in hazy images. According to He et al. in [9] we took 0.1 percent brightest pixels in the dark channel. The pixel which has the highest intensity in the input image is chosen as airlight.

B. Estimate Transmission Map

In this section, We are going to estimate the transmission map. According to the dark channel prior method, the minimum intensity value can be described as,

$$J^{dark}(x) = \min_{y \epsilon \phi(x)} (\min_{c \epsilon (r,g,b)} (J^c, y)) \tag{4}$$

Here, J^c defines the color channel of RGB image J. $\phi(x)$ defines local patch around x. $\min_{c \epsilon (r,g,b)}(J^c, y)$ defines the minimum pixel of the RGB channel and $\min_{y \epsilon \phi(x)}$ is the minimum filter [13]. The dark channel value of the outdoor haze free images is close to zero when the image lacks haze [9]. It can be represented by $J^{dark} \rightarrow 0$. The region in which dark channel

(a) (b) (c)

Fig. 3: Transmission map of the hazy image (a) original (b) normalized (c) refined

value is large is likely to exhibit haze. According to He et al. in [9] the formula of estimating transmission map is

$$P = \min_{y \epsilon \phi(x)} (min_{c \epsilon (r,g,b)} (I^c, (y)/A^c)) \tag{5}$$

$$t(x) = 1 - \omega p \tag{6}$$

Where, ω is between 0 and 1. The transmission map which is used in our paper is different from the existing transmission map used by the method of He et al. Here, we have normalized the transmission map by the maximum value in p. This normalization technique reduces the value for further smoothing. This reduction of pixel value removes unnecessary information from the transmission map. The result of the normalized transmission map is shown in Fig. 3(b) where we can see that after normalization the values reduced to a certain level and the refining filter works well on this normalized transmission map.

C. Refine Transmission Map

For refining transmission map we have used nonlinear complex diffusion process [14]. After removing haze, the output image may not provide enough information about edges of the image. Specially ramp edge of image may not be preserved by many haze removal algorithms. So, we need to refine the transmission map in such a way that can smooths the image as well as preserves ramp edges. Nonlinear complex diffusion process does this very well.

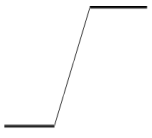

Fig. 4: Ramp Edge

The nonlinear complex diffusion process is performed using Eqs. 7 and 8:

$$I_t = \bigtriangledown (c(I_m(I)) \bigtriangledown I) \tag{7}$$

$$c(I_m(I)) = \frac{e^{i\theta}}{1 + \{\frac{I_m(I)}{k\theta}\}^2} \tag{8}$$

Here, I is the input image in case of denoising, noisy image. Where k is threshold parameter. $e^{i\theta}$ is called unit complex diffusion coefficient. The phase angle θ should be small ($\theta << 1$). In Eqs. 7 and 8, I_m is the imaginary part of the input image. Here, I_t consist of both real part and imaginary part of the image where imaginary part is the second derivative of the real part. The imaginary part is related to localized phase and zero crossing of the image where zero crossing forms thin line. This formula reduces noise preserving ramp features of the images.

As, here the imaginary part is normalized by θ. This process is not affected much by changing the value of θ as long as θ stays small [14]. The transmission map after implying nonlinear complex diffusion process shown in the Fig. 3 (c).

D. Restoration

When the value of transmission map $t(x)$ is close to zero, the direct attenuation $J(x)t(x)$ term can be close to zero. Here, transmission map $t(x)$ is restricted to a lower bound t_0, which means that a small amount of haze is present in every dense haze regions [9]. The output scene is recovered by [9]:

$$J(x) = \frac{I(x) - A}{max(t(x), t_0)} + A \tag{9}$$

E. Post-processing

The restored image may have low contrast after haze removal. So, for increasing contrast of this image, we applied Multiscale Retinex Algorithm (MSR) [15]. MSR is calculated by Eq. 10,

$$MSR_i = \sum_{n=1}^{N} W_n R_{ni} \tag{10}$$

Where, N is the number of scale, W_n is the weight of each scale and R_{ni} can be written as,

$$R_{ni} = [log(J_i(x,y)) - log(F_n(x,y) * J_i(x,y))] \tag{11}$$

Here, J_i is the input image which is the recovered scene from haze model. Here, i defines the color channel and R_{ni} is the retinex output image on the i-th channel. F is the

normalized surround function. This operation is performed on each channel. So, we can write from Eqs. 10 and 11

$$MSR_i = \sum_{n=1}^{N} W_n[log(J_i(x,y)) - log(F_n(x,y) * J_i(x,y))] \tag{12}$$

Here, $F_n(x,y) = C_n e^{-(x^2+y^2)/2(\sigma_n)^2}$ and $e^{-(x^2+y^2)/2(\sigma_n)^2}$ is the gaussian function where σ controls the amount of spatial detail which is retained.

According to Jobson et al. three scales are enough and the value of these three scales are experimentally fixed 15, 80, 250 by them. Here, weights can be identical. MSR ensures the overall contrast and details of local information of the images keeping the good effect.

IV. Experimental Analysis

In this section, we have made qualitative and quantitative comparison among our method and some existing methods. In our experiment, the transmission map is estimated using Eq. 6 described in Subsection III-B with a scaling parameter $\beta = 0.7$. For these images, the airlight is automatically estimated in Subsection III-A. The patch size is set to 3 here. We can notice from the following Figs. 5, 6, 7, 8, 9 and 10 that our method brings out hidden information of a hazy image robustly. The refined transmission map of our method is smoothed with preservation of ramp edges.

It is difficult to compare the performance of haze removal algorithms for general outdoor images. For this purpose, we have taken 6 challenging images for both qualitative and quantitative comparison. These images are also used by Salazar et al. in their proposed method [10].

For getting the experimental result of the images we have used MATLAB R2014a. Our system configuration is : Processor: Intel Core i5, RAM: 4 GB.

A. Qualitative Measurement

In this section, we have analyzed the visual quality of the six hazy images named "hazy wall","forest","hazed2", "mountain", ny17_input and y1_input. Haze covers important parts of these natural images. So, for clear view of all objects there needs to remove haze perfectly.

For "hazy_wall" in Fig. 5, He et al.'s method undercorrects the result and gives over saturated scene. Result produced by Sulami et al.'s method excessively corrects the red wall but fails to improve the scene of the grass. Salazar et al.'s method does not improve output image quality and there remains a little bit haze hidden under the leaf. In this case, our proposed method removes haze robustly and gives pleasing result than other methods.

For "forest" in Fig. 6, Sulami et al.'s method over corrects the haziest region leaving that region dark and undercorrects other regions. Salazar et al.'s method undercorrects the image while He et al.'s method removes haze robustly but gives a saturated scene. From Fig. 6, we see that our proposed method gives a well balanced result with better contrast enhancement than the existing methods.

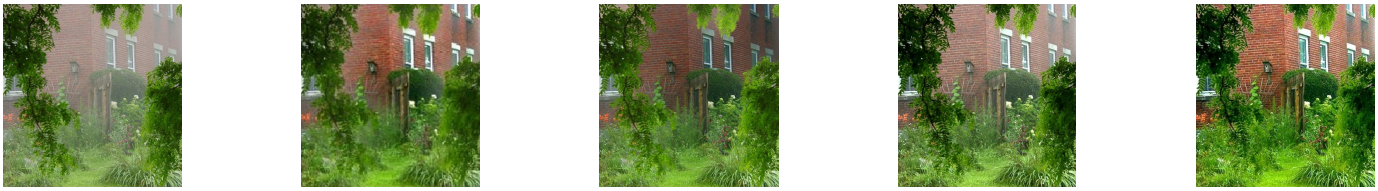
For "hazed2" image in Fig. 7, He et al.'s method removes haze perfectly but gives over saturated view on the other side the result produced by Sulami et al.'s method contains artifacts. Salazar et al.'s method overcorrects the result as well as the grass are not visible here after haze removal. Fortunately, our proposed method removes haze very well and the edges of the grass can be clearly identified here.

For "mountain" image in Fig. 8, the method of He et al. and Sulami et al. give over corrected result. In the case of Salazar et al.'s method, the output is the result of limited ability to dehaze. Compared to these methods our proposed method gives a well balanced result.

For "ny17_input" image in Fig. 9, Sulami et al.'s method overly saturates the sky region which affects the whole image. Salazar et al.'s method gives an over corrected result. On the other side, He et al.'s method and our proposed method remove haze robustly and give the same quality result but the sky region in our method seems more satisfiable.

For "y1_input" image in Fig. 10, Sulami et al.'s method overcorrects the result while He et al., Salazar et al. and our proposed method remove haze efficiently and give well balanced result.

B. Quantitative Measurement



Only observing the visual quality of the image we can not define which method really works well on this type of image. So, we need a quantitative measurement. For this measurement, we consider here two quality metrics such as Contrast to Noise Ratio (CNR) and Root Mean Square (RMS). The detail description is provided in the followings.

1) **Contrast to Noise Ratio (CNR):**

Contrast to Noise Ratio (CNR) is used as a quantitative noise measurement to define image quality. CNR is important when there is indicative influence in an image, such as from haze [16]. We took CNR formula from mathwarks[1]. Here, the larger the CNR the better the visibility of the object in an image. From TABLE I, we see that in the case of "forest", "hazy_wall", "mountain" and "y1_input" images our proposed method gives higher value than other methods. So, we can say that our method gives better quality image than others. In case of "forest" image the CNR value is 89.52 which is greater than other methods. This means that in our method the quantity of noise is less. If we take a look in Fig. 6, we can see that our method provides sharp edges with better reduction of noise that is haze. This is true for other images too.

2) **Root-Mean-Square (RMS):** RMS contrast is the way to define the contrast of the images [17], [18], [19], [20]. It destines standard deviation of pixel luminance in an image which is divided by the average luminance of the whole image.

Fig. 10: ”y1_input” image enhancement (a) Original (b) He et al. (c) Sulami et al. (d) Salazar et al. (e) Proposed

TABLE I: Contrast to Noise Ratio (CNR) of all methods

Image Name	He et al.	Sulami et al.	Salazars et al.	Proposed
forest	56.07	89.25	82.35	89.52
hazy_wall	61.83	65.48	78.38	93.07
mountain	72.63	62.26	65.64	72.65
ny17_input	93.73	97.71	112.19	106.99
y1_input	72.34	57.08	49.72	72.87
hazed2	107.39	90.40	80.53	100.72

TABLE II: Root Mean Square (RMS) of all methods

Image Name	He et al.	Sulami et al.	Salazars et al.	Proposed
forest	0.18	0.15	0.20	0.22
hazy_wall	0.20	0.17	0.23	0.26
mountain	0.24	0.19	0.26	0.25
ny17_input	0.23	0.19	0.26	0.27
y1_input	0.29	0.26	0.29	0.30
hazed2	0.23	0.15	0.29	0.24

If L_i is the luminance of pixel number i, and there are N pixels then we can write, $L_m = \sum L_i/N$.

$$RMS = \sqrt{\frac{\sum (L_i - L_m)^2}{N}} \tag{13}$$

The value of RMS can vary from zero to one. Here, the largest RMS value defines the highest contrast of the image. From the Figs. 5, 6, 9, 10, 7 and 8, we see that our proposed method shows better contrast than other methods. For example, the RMS value of "forest", "hazy_ wall", "ny17_input" and "y1_input" are 0.22, 0.26, 0.27 and 0.30 which is larger than existing Fattal et al., Salazar et al. and He et al.'s methods. TABLE II shows that our method gives the highest contrast image than other methods in most of the cases.

V. Conclusion

This paper presents a new approach to remove haze based on filtering. The proposed method uses an improved transmission map and then refines it by nonlinear complex diffusion process. Computer vision applications such as remote sensing system, surveillance, automated car, etc. can be benefited from our proposed method as it gives enhanced image with clear view of all objects of an image. From the quantitative and qualitative measurement subsections it is clear that in most of the cases our method gives better or similar result compared to existing methods. In future, we will work on this approach for further improvement so that it can work for multiple images instead of single image.

Abstract— **Underwater image is affected by absorption and scattering when light propagates through water; resulting in poor visibility, reduced contrast, color attenuation. So before going into any restoration processing activity of an image, it is mandatory to enhance the image first. In this paper, a fusion based technique is introduced, where the method is to use wavelet decomposition. The proposed method has two inputs enhanced from the original underwater image. One is color corrected image and other is illumination adjusted image. Illumination adjustment is done by adaptive histogram equalization, gamma correction and filtering in the proposed system. Histogram equalization and adaptive histogram equalization techniques are used for color correction on the adjusted image. These modified images are then fused based on their maximum coefficient values and the resulted output shows promising result improving the haze of the underwater image. This is a very simple method and the resulted image is clearer than the hazy image.**

Keywords— Underwater image, Color illumination, Color enhancement, Wavelet decomposing, Fusion.

I. INTRODUCTION

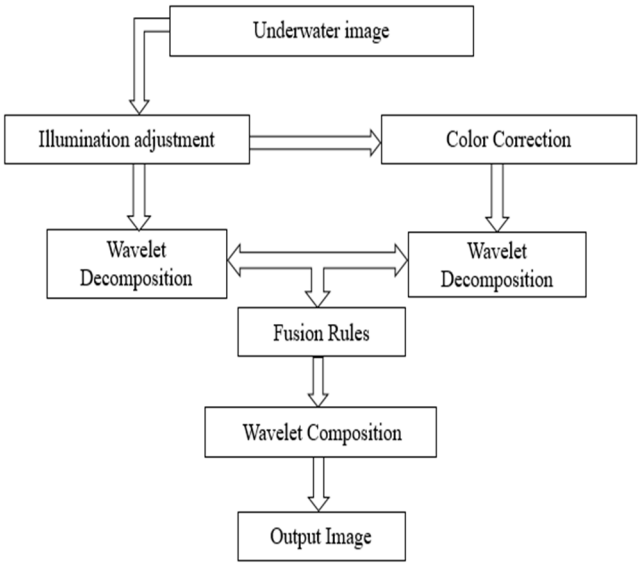
In the last few decades, underwater image processing has received considerable attention in ocean engineering. Due to absorption and scattering [1] underwater images (UW) can face different types of difficulties resulting in degradations including color cast, noise, due to floating particles, low contrast, skewing and blurring [2]. In underwater it is hard to notice color, size of an object due to attenuation and mileage [3]. The objective of image enhancement is to recover the explicability of information in underwater images for human viewers, or to give corrected image for other automated image processing techniques [2]. Image enhancement techniques applied for in-air images cannot be applied to underwater images because of different optical properties of air and water. Non-uniform illumination [4] correction problem is ignored by many researchers, degradation by forward scattering is not attempted by most of the researchers [5]. Most of the dehazing techniques by researcher are complex and computation is heavy. So to enhance the underwater images it is necessary to develop algorithm that can correct all the four types of degradation, non-uniform illumination [4] and contrast degradation (caused by back scattering), blur (caused by forward scattering) and diminished colors (caused by scattering and absorption).
Rest of the article is indexed as follows. Section II presents some related article on Underwater Image Enhancement, proposed system architecture is described in section III. Section IV hold the conclusion and future work of this paper.

II. PREVIOUS RESEARCH WORK

In the field of underwater image enhancement, a lot of works have been done in the past to modify the haziness of images taken underwater. Authors in [6] estimated fusion based algorithm with two inputs, one is color corrected image and other is contrast enhanced image. Writers in [7] implemented wavelet based fusion technique to overcome color and contrast issues in underwater images. They employed CLAHE and histogram stretching techniques for contrast enhancement and color correction to address low contrast and color attenuation of the hazy images. Writers in [8] derived different images each having a significant feature by processing the original degraded image and then fuses all the images to get final output image which is a blend of all the features of processed images in it. Authors in [9] proposed a fusion based underwater image enhancement solution built on wavelet decomposition and multiscale fusion principle. Multiscale fusion principle is applied to the low frequency and high frequency components. Quality and reliability of the image processing is affected because of the floating particles of the water and that's why color correction is needed. Writers in [10] proposed a new method to enhance the underwater image depending on Dark Channel Prior. Authors of [11] enhanced the low quality images using unsupervised color correction method. The proposed approach is based on color balancing contrast correction of RGB color model and contrast correction of HIS color model. Writers in [1] proposed image enhancement method via color correction and illumination adjustment. For color correction they used simple normalization method and for illumination adjustment component, the Retinex theory is exploited.

III. PROPOSED SYSTEM ARCHITECHURE

Proposed system architecture mainly divided into three sections. Section A portrays illumination adjustment part, section B briefly describe color correction part and section C presents the fusion processing part.



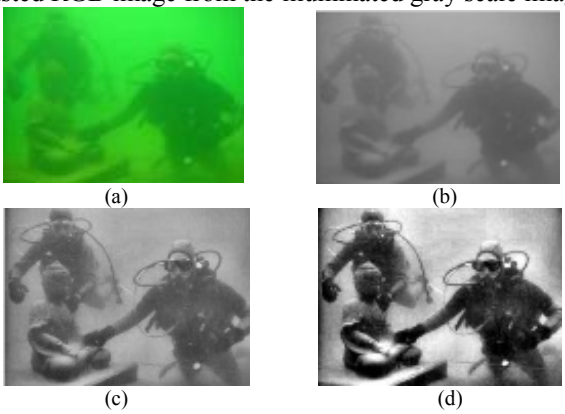


Fig. 1. Architecture of the proposed system.

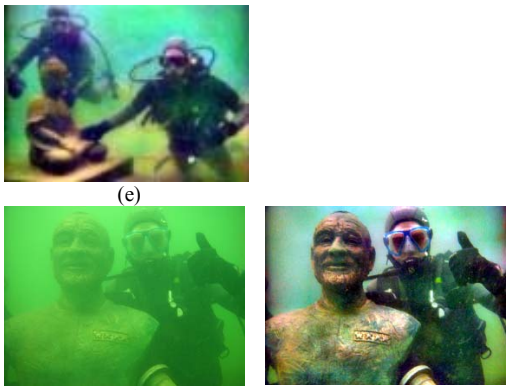
A. Illumination Adjustment



Illumination of an underwater image appears because of propagation of light in water. Illumination of an M×N dimension underwater image can be denoted by illuminant, t_c [3],

$$t_c = k_{|\sum_{j=k}^{L-1} h_c(j) > \frac{pMN}{100} AND \sum_{j=k+1}^{L-1} h_c(j) < \frac{pMN}{100}}$$

To remove illumination from underwater image in this proposed method the original image is first converted into gray scale image. Then Adaptive Histogram Equalization is applied on the gray scale image to manage the local contrast of the pixels from the neighboring areas [10]. The background from the AHE image is then subtracted and gamma correction is applied on the image to correct the images luminance. Median filter is then used on the image to remove any unwanted noise in the image. The process from background subtraction to filtering the image is done again two times (total three time) in order to convert back to the RGB color space of an image. The three resulted filtered images are then combined to produce the illumination adjusted RGB image from the illuminated gray scale image.

(e) (f) (g)

Fig. 2. (a) Original image 1, (b) Gray scale image for image 1, (c) Adaptive Histogram Equalized image for image 1, (d) Illumination adjusted gray scale image for image 1, (e) Illumination adjusted output image for image 1, (f) Original image 2, (g) Illumination adjusted output image for image 2

B. Color Correction

For color enhancement the input image is the output image of illumination adjustment. In underwater, images are affected by low contrast due to scattering. To enhance the color, illumination adjusted image is first converted to RGB space to HSV space. Hue, Saturation and Value are then processed with max luminance to highlight the higher visibility region in the output. Then histogram equalization is used on the processed image. Histogram equalization which is a useful technique for adjusting image intensities for to enhance contrast. But sometimes it spoils the unhazy parts and gives indiscriminate result. So, Adaptive histogram equalization [9] is then used on the histogram equalized image of the input image of color enhancement. AHE works by taking into account only small regions and based on their local cdf, enacts contrast enhancement of these regions. This technique executes histogram equalization on the intensity values of individual frames of the image and modifies the color of each RGB channel distinctly.

C. *Fusion Process*

Wavelet transforms are essentially extensions of the idea of high pass filtering. The process of applying the DWT can be represented as a bank of filters. At each level of decomposition, the signal is split into high frequency and low frequency components; the low frequency components can be further decomposed until the desired resolution is reached. The wavelet transform is designed to get good frequency resolution for low frequency components (average intensity values of the image) and high temporal resolution for high frequency components (edges of the image). Illumination adjusted image and contrast enhanced image are decomposed into low frequency and high frequency components. Since the wavelet transform is applied in both dimension, the low pass filter and high pass filter is applied on the rows first and then the columns. When low pass filter is applied on the rows it gives horizontal approximation value and applying high pass filter gives horizontal detail. The sub signal produced from low filter have a highest frequency equal to half of the original. Low pass filter and high pass filters is again applied on the columns of the horizontal approximation and horizontal detail resulting in four sub images [2]: approximate image, vertical detail and horizontal detail, diagonal detail respectively. This is one level decomposition of the input image as shown in figure 4 [8].

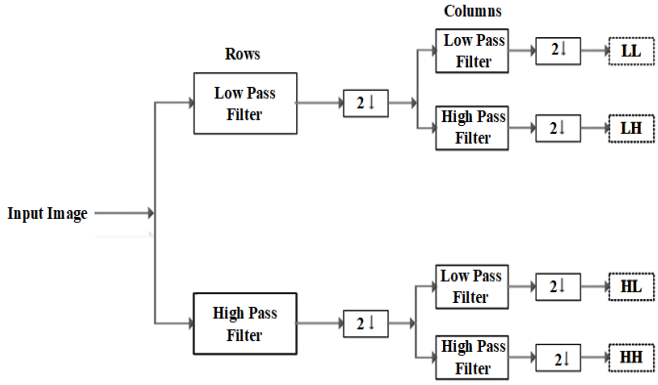

Fig. 4. One-level-2-dimension wavelet based image decomposition [8]

The approximate image which is the decomposed result of the first level becomes the input image and gets decomposed into the wavelet coefficient maintaining the same process as the first level in the second level decomposition. In the proposed method the decomposed wavelet coefficients of both illuminations adjusted image and color enhanced image is used and fused together using the maximum value of the approximation and detail coefficients.

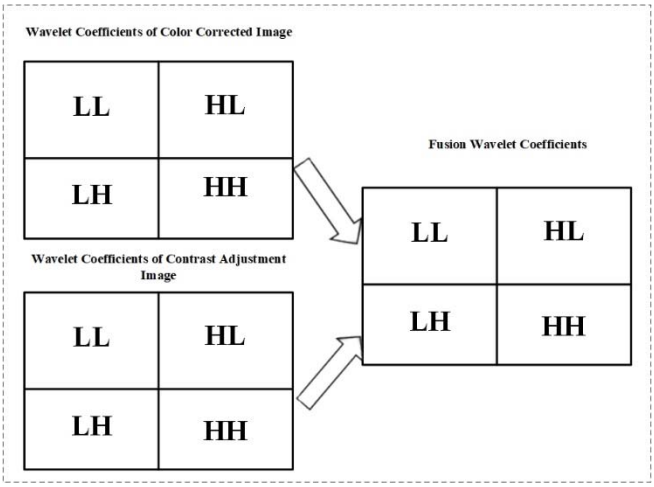

Fig. 5. Two-level-2D wavelet based image decomposition [8]

Every input image is decomposed into its coefficient and inversely composed respectively using wavelet transform to get the modified image as output. The decomposition in wavelet transform is done by down-sampling and up-sampling is used for the inverse composition.

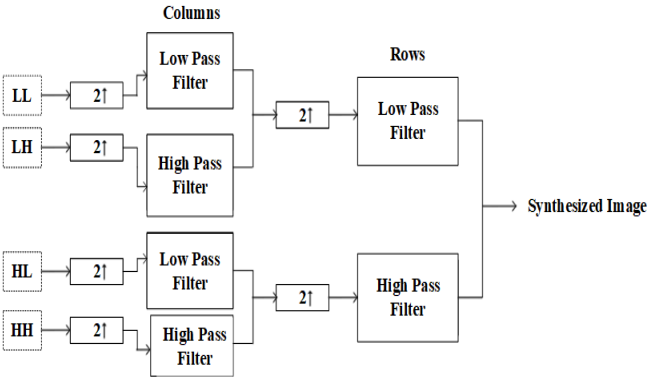

Fig. 6. One-level-2d wavelet based inverse composition [8]

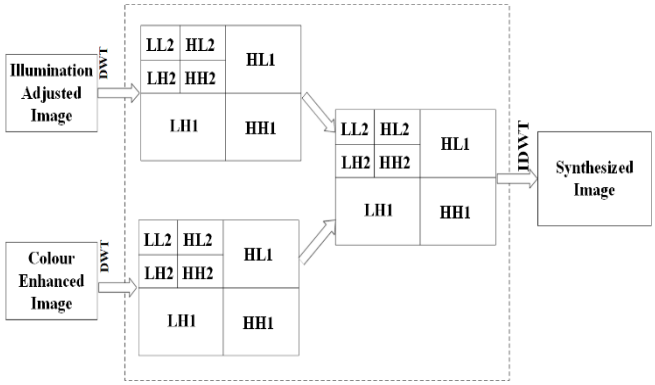

Fig. 7. Two-level-2D decomposition, fusion of coefficients and image synthesizing [8]

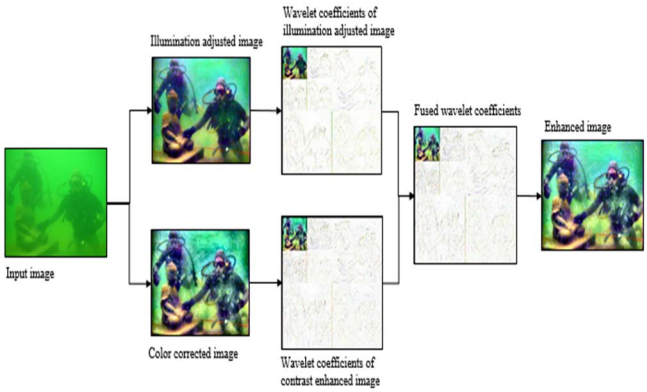
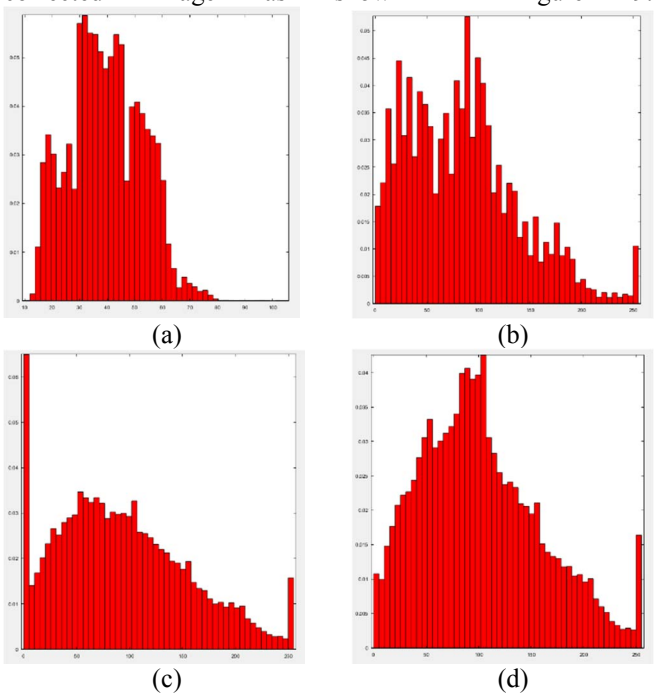
In figure 7, the output image of illumination adjusted image and color enhanced image is the input for DWT decomposition. Thereafter inverse transform is applied on the coefficients of its decomposition and fused together using the maximum values of the coefficients.





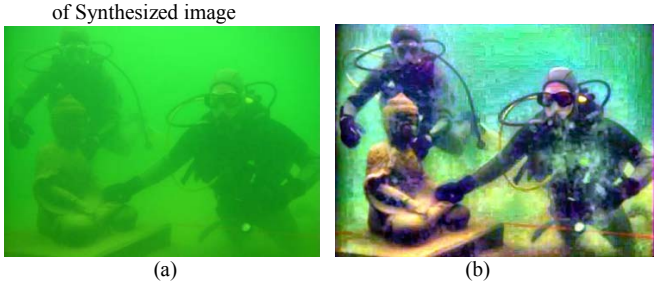


Fig. 8. Two-level-2D decomposition, fusion of coefficients and image synthesized of the proposed method

Histogram of an image illustrates a graph that can be used to appraise the quality of an image by comparing the values of an image before and after enhancement [6]. The histogram of underwater input image is darker and histogram of the enhanced output image has brighter pixel values which is the combination of illumination adjusted image and color corrected image as shown in figure 9.

TABLE I. Numerical Results of performance measurement parameters: Entropy for image (d) and comparison with Ancutti et al. [13] and Singh et al. [13] Method

Image	Entropy		
	Ancutti et al. [13]	Singh et al. [13]	Proposed
d	6.8683	7.5112	7.9053

IV. RESULT AND DISCUSSION

This paper proposed underwater image enhancement based on wavelet based fusion technique which will ensure the effective improvement of visibility of degraded underwater image. The turbid water images are victim of attenuation in water, blurring and scattering. The proposed method faces the problems head on correcting the color and illumination of the image to take two input image and fuses them together. This method generates admissible result and improves clarity for all the test images. The amount of information that stays in the output image is entropy. The amount of distortion is less in the final image if the value of entropy is less. Table 1 clearly shows that the resultant images obtained from our method has higher Entropy value as compared to Ancuti et al. and Singh et al. as desired for a good quality image. A main limitation of fusion based method is represented by the fact that the noise contribution may be amplified significantly with the depth causing undesired appearance of the distant regions. We can improve this in future. In future, the work will extend to underwater inspection and observation tasks, particularly in vision system for aquatic robot inspection and IOT.

ACKNOWLEDGMENT

We the authors are very obliged to Department of Computer Science and Engineering and Department of Electrical and Electronic Engineering, Bangladesh Army University of Engineering and Technology for the remarkable support and guideline during the process of this work.

***Abstract*—In most of the developing countries the seats of educational institutions are limited and barley 30% of the total eligible candidates get the opportunity to get admitted after facing competitive admission test. The scenario is worse in the job market. The growing graduation to unemployment ratio has become a major concern in developing and underdeveloped countries. As a result, job recruitment tests have become more competitive than ever. In order to survive in these types of competitive examinations, many candidates try to take unethical approaches. Because of large number of candidates, exam administrators cannot validate each and every candidate one by one. Moreover, modified image in registration paper makes it difficult to identify valid examinee. This is the weakest point of examinee validation system of competitive examination and significant number of candidates try to pass the examination by exploiting this weakness. The easiest way to exploit this weakness is to hire and send proxy examinee who has higher possibility of passing the exam instead of actual examinee. In this paper, we are proposing an automatic, fast, efficient and accurate yet simple to implement examinee validation system using eigenfaces. Our system will make it almost impossible for a proxy examinee to enter the exam-center.**

Keywords—examinee validation, face recognition, eigenface, segmentation, innovative registration.

I. INTRODUCTION

The rate of cheating in the competitive examination through proxy examinee is rising at an alarming rate [1]. It deprives the meritorious candidates from getting the positions they deserve. And if the cheaters do not get caught, they get employed in important positions. In the long run the productivity of the organizations they join, educational institutions they get admitted in end up in poor productivity. The purpose of competitive exams is to find out the appropriate candidates. If wrong person sits in important position through unethical means, they will not perform their responsibility as the proper candidate would have done. It is very dangerous for a nation, especially for developing countries. In developing countries excessive population creates extra pressure on both educational institutions and job market. Because of having limited seats, institutions can barely take 30% of total eligible candidates. The condition in job market is worse than this. The competition has become so tough that more candidates are being engaged in cheating in competitive examinations. At the same time, it is not possible for exam-administrators to verify every individual because of large number of candidates. This is where the weak point is and tendency of getting in exploiting this weak point is becoming acuter day by day.

Automatic examinee validation system is the most effective solution to proxy examinee problem. However, implementing such system is time consuming and challenging task. Using convolutional neural network, it is possible to validate examinee with 96.2% accuracy [2]. To gain such accuracy five images are needed of each individual. In the year 2017 against 2024 vacancies 343,532 candidates attended examination conducted by Bangladesh Public Service Commission (BPSC) [3]. In similar situation, taking five images of each candidate for training will yield 1,717,660 training images. Processing this large volume of image data and training the network using them is not a feasible solution. However, through linear segmentation of training data according to the number of exam-center, it is possible to distribute the computational task among multiple systems. In this approach the training time can be reduced significantly. Although it sounds feasible yet distributing the trained network, permanently setting up validation equipments in exam-centers, training new network before every examination make it too complex and expensive to implement.

We need a system that works in real-time and does not require training like deep neural network or convolutional neural network. The system has to be very simple, fast, accurate and instantly deployable. We are proposing an automatic examinee validation system using eigenfaces which is very simple, easy to implement and works very fast in real-time. Our system does not require any training. Theoretically, our system will work fast enough even for image database larger than 5×10^5 images. No matter how many images are there in the database, our system will always compare the test image with 10 training images and will yield over 97.88% accurate result.

The remaining part of the paper is as follows - relevant works are reviewed in section 2. The proposed method has been presented in section 3. In section 4, two ways have been shown which can be used to physically implement the validation system. The experimental result of the proposed method has been demonstrated in section 5. Finally, we concluded the paper in section 6.

II. BACKGROUND

The normalized distance between facial features and ratios among the features can be used for automatic face recognition. Bledsoe [4] and Kanade [5] have used eyes, nose, mouth and head outline as facial features. The existence of facial features, their relative positions and size are used to classify face and non-face classes. By comparing the features of images belong to face class, new faces can be recognized if they are already in existing face class. However, this approach cannot be extended to multi-view face recognition. Moreover, Diamond and Carey [6] have shown that individual facial features are inefficient for adult human face recognition. In addition, the

feature points are not prominent for all races. As a result, there are possibilities of having face images in non-face class.

Instead of classifying images based on individual facial features, face images can be considered as 2D matrix where 2D characteristics represent faces. Turk and Pentland [7] have developed eigenvector-based face detection and recognition system which can learn to recognize new faces in an unsupervised manner. Diverting from geometry or high-level visual characteristics, they have taken information theory-based approach. In this approach they have transformed images into characteristic feature images named eigenfaces. These features are the principle components of training set of face images. Then, projecting new images on the eigenfaces and comparing the position of new eigenface with existing eigenfaces, they have performed the recognition. This approach remains effective for multi-views such as profile face, view from 45° angle and straight view. Moreover, this recognition method is fast, simple and robust.

However, the size of the face space imposes challenges on eigenface construction. Sirovich and Kirby have represented their idea of reducing face space using principle component representation [8]. They have said face images can be reconstructed by storing small collection of weights of each face. However, a set of standards which will uniquely define how the weights will be distributed are required as well. Combining the weights and the standards, it is possible to reconstruct the actual face image from small image space. They have also suggested that if a face can be reconstructed from the weights and standards, a face can be recognized using the same principle as well. If a face image gives similar weights and standards as another face image, then both of the face images will be the same. In other words, weights and standards of one face image can be used to recognize the same face image. If the face image of the same person varies in dimension, the standards which are actually vectors adjust the weights proportionally. As a result, the size variation cannot affect the recognition accuracy.

Simple implementation, fast recognition and robustness of face recognition method of Turk and Pentland paved the way of using eigenface based system in application level. Wagh, Thakare, Chaudhari, and Patil have shown an application of detecting attendance fraudulent activities in class room using eigenfaces [9]. To meet the acceptance level at application level, only eigenfaces are not enough. Wagh et al. in their paper have combined luminance variant reduction technique to reduce impact of light variation among testing and training image. They have also used Viola-Jones algorithm to detect the face in order to get specific face space. After primary recognition a cross checking by students' image database have enhanced the accuracy of their system.

Eigenface-based face verification systems are enough secured for non-financial and non-confidential national defense related application. J. Galbally, J. Fierrez, J. Ortega-Garcia, C. McCool and S. Marcel have shown security vulnerabilities of Eigen-face based face verification system by hill-climbing attack [10]. The success rate of hill-climbing attack is more than 85%. It does not require a large number of training image to initiate the attack. It clearly suggests that precaution must have to be taken in eigenface-based verification system. However, hill-climb attack cannot impact effectively in real-time validation system. Which leaves a scope of implementing real-time automatic eigenface based validation system without the risk of having hill-climb or brute-force attack on the security system.

III. Proposed Method

Automatic examinee validation system using eigenface is a two-step process. The first step is related to registration system and the second step is the validation system. With the existing examination registration system, it is not possible to effectively validate examinees automatically. The training image required for validation must be acquired during registration process. In existing system, candidates register through online registration form for examinations and upload scanned copies of their photos. With a little modification of scanned images using photo editing software like Photoshop, it is very easy to alter the images in registration card to send proxy examinee instead of real examinee with very little possibility of getting caught. To leave no scope of sending proxy examinee we have to change the registration system first.

A. Proposed Registration System

With the existing online registration system, we propose an additional module which is a real-time image capturing unit. Instead of uploading the scanned copy of photo, the candidates will capture 10 photos according to given instructions. The device using which the candidates will register must have to have webcam for this registration process. Fig. 1 shows the interface of registration process. Candidates have to take 10 pictures imitating the poses recommended in the instruction. The image capturing module uses Viola-Jones face detention algorithm [12] to detect the faces and crop the face rectangle by 92×112 pixel. The images are labeled from 1 to 10. Once the candidate confirms registration, a directory is created based on choice of exam center (e.g. Dhaka) and a subdirectory is created under this newly created directory named according to the registration number of the candidate. In this way, candidates of different exam centers will have different directories. In those directories, the subdirectories will contain the images of the candidate. Each subdirectory represents individual registered candidate. As each registration number is unique, each candidate will have their images in specific subdirectory. These images are the training image of our system.

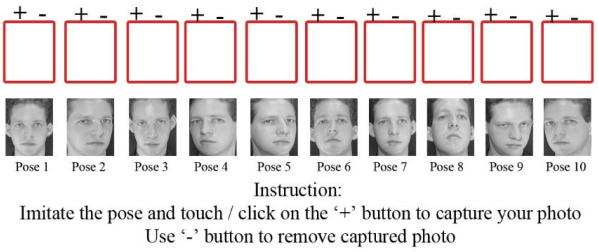

Fig. 1. Photo Capturing During Registration.

B. Examinee Validation

We have used eigenfaces for examinee validation. Even though convolutional neural network is much better at image recognition, we cannot use it in the validation system we are

proposing. Because the dataset our system has to handle is very large, which requires huge amount of time to train the network. And for every new examination, new network has to be trained. Which makes convolutional neural network unrealistic for the system we are building. Our system is based on the work of Turk and Pentland [7]. They have shown how eigenfaces can be used for face recognition. We calculated the eigenfaces in exactly the same way they did. However, we have modified the recognition phase to meet the requirement of our system. We have reduced the size of the face images by calculating and removing the mean. Instead of simply classifying as known and unknown, we have added an access method for validated candidate. The method proposed in [7] was near-real-time whereas our implementation works in real-time.

1) Prioritizing Eigenface for Recognition

Predefined measurement of facial features is not sufficient for face recognition. Instead of looking at face images from high level visual features it is much efficient in focusing from information theory perspective. Eyes, nose, lips, and hair are global feature of a face. From information theory perspective they carry very small amount of information as the probability of having these features is very high. Our purpose is to recognize faces. That is why, the variations among testing face and training faces are the major concern. The face image is a 2D matrix that carries information. From information theory perspective, our task is to extract the information from the 2D matrix and encode it efficiently. Then we will encode the training image in the same way and later we will compare among encoded pieces of information.

We have computed the variations among the face images stored in database. We are not considering those images as face images but 2D matrix those carry information. From these perspective, facial features described in [5] are simply information. There is no distinction among them from high level visual perspective (i.e. nose is not nose but some pixel variations). Once the information of the 2D matrices are collected we compare among them and identify them based on the variation of information they present. According to [8] the maximum varying regions are the principal component. They call it eigenvectors of the covariance matrix. When we represent these eigenvectors as images, it produces face images, indifferent to human eyes, but meaningful in computation in terms of variations among multiple faces.

All of the faces stored in the registration database can be represented in terms of linear combination of the eigenfaces. We have 10 images for each individual. That means there are 10 eigenfaces for each registered candidate. For our application, it is not mandatory to match all 10 of the eigenfaces with 100% accuracy with the testing image. Out of 10 eigenfaces, we compute the best eigenface based on the information variation of that face with other faces in the same directory (e.g. Dhaka). The number of training data is large even though we have classified them according to location of exam-center during registration process. As a result, reducing computational time is mandatory. Instead of taking all 10 of the eigenfaces, taking the eigenface that exhibit the highest variation when compared with other candidates' eigenface is maintained with highest priority for recognition.

Algorithm 1 Face recognition algorithm

Input: X: Exam Center; Y: Registration Number; Z = Input Image
1: **if** X = true **then** access X
  else terminate
2: **if** Y = true **then** access Y
    Image Array ← $Load\ training\ images$
  else terminate
3: **for** i = true
4: Processed Image[i] ← $Image\ Array[i] - mean(Image\ Array[i])$
5: Eigenface Array← $Eigenface\ Function\ (Processed\ Image)$
6: **end for**
7: Processed Input ← $Eigenface\ Function(Z - mean(Z))$
8: **for** i = true
9: Euclidean Distance ← $Processed\ Input - Eigenface\ Array\ [i]$
10: **if** Euclidean Distance > threshold **then** allow access to exam-center
  else deny access to exam-center

2) Algorithm for Face Recognition and Validation

The procedure or the face recognition and validation are shown in algorithm 1. As stated earlier, our system is built on [7]. We modified the approach taken in [7] and converted the method into an applicable validation system. The algorithm is initiated by user inputs which are actually the information of candidates. The candidates select the names of exam-centers, registration numbers and the system captures their frontal faces. If the inputs are correct, the algorithm executes the further instructions and return the result (line 10 of algorithm 1). It allows only valid candidates to enter the exam-center and prevent others from getting accesses.

3) Calculating Eigenfaces

Training images are 2D matrix consisted of 2-dimensional array having 92 and 112 values respectively. Each of the matrix has 10304 elements. The entire space does not represent the face. Moreover, we do not need the entire face. We are looking at the image from information theory perspective. To reduce the size of the image, we need to remove the information which will not be used in face recognition. By calculating and removing the mean from each image, we can reduce the size of the image. From matrix perspective, the value of common element will be replaced by zero. From visual perspective, the images will carry information that distinguishes them from one another.

Let the training set of face images of one candidate is be $F_1, F_2, F_3, \ldots F_{10}$,. To further reduce the size of face space, we calculate the average of the faces.

$$\text{Average face, } A = \frac{1}{10}\sum_{n=1}^{10} F_n \quad (1)$$

Now we have the average face. Using the average face, we can calculate the deviation matrix of other faces of the candidate by subtracting the A from each face.

$$\text{Deviation, } \phi_i = F_i - A \quad (2)$$

Then using principle component analysis (PCA) we find a set of vectors and values which form the eigenfaces. We followed the method of using PCA of [7] to calculate the eigenfaces. According to Turk and Pentland the eigenvalues (λ_k) and eigenvectors (μ_k) together form the covariance matrix,

$$C = \frac{1}{10}\sum_{n=1}^{10} \phi_n \phi_n^T = II^T \quad (3)$$

Here I is the array of deviation matrix. The covariance matrix is still large as it is consisted of 2 arrays containing 92 and 112 elements respectively. Computing over this large matrix is expensive and time consuming. However, [7] shows that eigenvectors can be determined my solving smaller M by M matrix and then combining them linearly. This makes the calculation much faster. At the end, the background is removed which gives us the eigenfaces only.

4) Validation using Euclidean Distance

Eigenfaces contain the pattern that distinguishes faces from one another. They are spanned in M' dimensional subspace where the original image is an 92×112 image space. The eigenvector M' which is associated with largest eigenvalues are chosen as the eigenface. Now for a new image, the face is detected using Viola-Jones algorithm [11] and cropped with a rectangle of 92×112 pixel. Then it is transformed into eigenface consisted of an eigenvector and eigenvalue. The weights of eigenfaces form vectors. These vectors represent the face images. The Euclidean distance between the weights of vectors of input image and training image describes if the new image belongs to the training image set or not. If the new face belongs to the training image located inside subdirectory named after the candidate's registration number, we consider the person as valid candidate. Otherwise the candidate is considered a proxy candidate.

IV. Implementation

The performance of the validation system depends implementation architecture. Here arises the issue of performance vs implementation cost trade-off, which leads to two different architecture – (i) Single Validation Unit (SVU) architecture and (ii) Parallel Validation Unit (PVU) architecture. The SVU architecture is preferred where implementation cost is the major concern. And the PVU architecture is preferred where performance is the major concern. One advantage of PVU architecture is here the implementation cost and performance can be adjusted by changing the number of units. On the other hand SVU architecture does not offer the flexibility of adjusting the performance vs cost parameter.

A. SVU Architecture

In SVU architecture there is one validation unit at the entrance of the exam perimeter (fig. 2). The examinees are validated one by one. Valid examinees get the access to the exam perimeter. The suspected examinees generate notifications in invigilators' office with their names and registration numbers. These examinees do not get the access to exam perimeters. Instead they are directed to invigilators' office for further investigation.

The SVU architecture is simple and easy to implement. However, it is suitable for small number of students. When the number of students increases, the total validation time increases linearly. In this case total time to validate S_t number of students V_t will be,

$$V_t = S_t \times V_i \tag{4}$$

Here V_i is average time to validate each examinee. Equation 4 shows that the total time required to validate all of the examinee is directly proportional to the number of total students. That is why for public exams where large number of candidates attend exams, SVU architecture fails to exhibits satisfactory performance. However, from network security perspective this approach is much secured. Because of having single unit, the validation server and invigilators' office can be established nearby. As a result, a wired communication is possible between server and the validation unit. It ensures security from attacks like eavesdropping or data manipulation by man-in-the-middle attack.

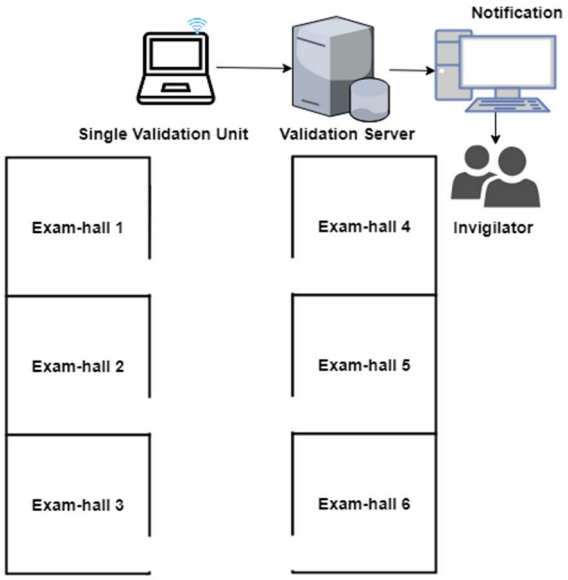

Fig. 2. SVU architecture

B. PVU Architecture

In PVU architecture (fig. 3) multiple SVU work simultaneously. In this model, the examinees can enter the exam perimeter without any validation. However, before entering the exam-hall they have to go through the validation process. Here, the valid examinees get access to respective exam-halls. And the suspected candidates are directed to the invigilators' office. In this case with username and registration number, the exam-hall number are sent in the notification.

The implementation of PVU system is not as simple as SVU system. The complexity and cost increases with the increase of validation units. However, the total time required to validate all of the examinees reduces linearly with the increases of number of validation units. Here, the total time required to validate S_t number of students V_t will be,

$$V_t = \frac{1}{U} \times (S_t \times V_i) \tag{5}$$

Here U represents the total number of validation unit. The more the validation unit the less the time required to validate in PVU method. Equation 5 shows that it is possible to reduce the total validation time by increasing the validation unit. That means the performance of the system can be enhanced. However, because of having multiple units in different spatial locations, wireless communication among units and server is the most convenient communication method. In this case, the

network security becomes a vital issue. Intruders can eavesdrop in the network to steal information. At the same time, they can alter the validating data by man-in-the-middle attack. Proper network security needs to be implemented to use PVU method.

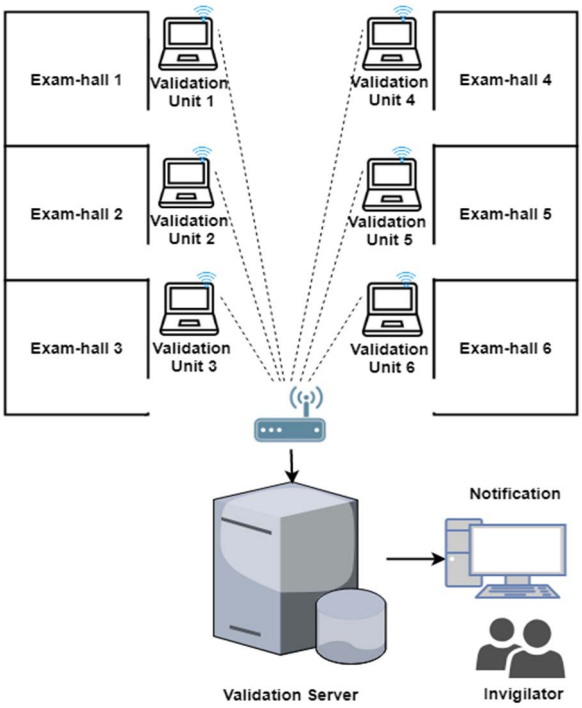

Fig. 3. PVU architecture

We prefer implementing the PVU architecture because of its performance and flexibility.

C. Validation System

The validation process starts with the user inputs. The examinee enters his username, registration number and password. The server validates the access credentials and if the credentials are valid, it serves the image capturing web application. At the same time, the server loads the image of the examinee those were taken during the registration process. In the next step, the examinee captures his image and send it to the server for validation. The server checks if recent image and previously saved images are matching using our proposed method. If the images match with acceptable rate, the candidate is declared as valid examinee. If the images do not match, then the server marks the candidate and generates an alarm at the invigilators' office. Concurrently, the candidate receives a message containing the instruction to visit the invigilators' office. The invigilators will further investigate the issue and will decide if the candidate is a valid candidate or proxy examinee.

V. Performance Analysis

We used Olivetti Research Laboratory (ORL) dataset of faces for performance analysis. Each of the images are in 8-bit grayscale. The images are in PGM format. This dataset contains 400 images of 40 person. There are 40 directories representing 40 individuals and each of those directories has 10 images of same person labeled from 1 to 10. To conduct the experiment, we used Windows 10, 64 bit operating system, with 8192 MB primary memory, powered by Intel(R) Core(TM) i3-6100 CPU, 3.70GHz (4 CPUs). All of the algorithms have been implemented using MATLAB R2017a.

We have evaluated the performance by the dataset loading time, recognition time and error rate.

A. Loading Time

The loading time maintains linear relationship with the number of images. We computed the loading time for 5, 10, 15, 20, 25, 30, 35 and 40 persons. Normally 35-40 candidates attend exam in a single room. That is why we considered it unnecessary to calculate the loading time for more than 40 candidates. To load dataset of 5 people, which is 50 images, our system took 0.098 seconds. The time was extended to 0.876 seconds for 40 candidates, which are 400 images.

B. Recongition Time

We have experimented with all 400 images. In none of the cases the recognition time exceeded 1.98 seconds. To calculate the average recognition time, we have calculated the average for every five individuals at a time. Finally, we calculated the average of these average times. And the average recognition time is 1.37 seconds. The recognition time includes the time to generate eigenfaces of training images and testing image, mean subtraction time, indexing time and Euclidean distance calculation time. Altogether, our algorithm took 1.37 seconds to successfully validate a face. However, we did not consider the time when the

Table 1 Performance summary

Serial	Person	Loading Time (seconds)	Recognition Time (seconds)
1	5	0.098	1.12
2	10	0.211	1.36
3	15	0.309	1.6
4	20	0.429	1.98
5	25	0.487	1.18
6	30	0.547	1.22
7	35	0.656	1.21
8	40	0.876	1.31

algorithm gave wrong output. The recognition time has been calculated for correct output only. In Fig. 4 the comparison

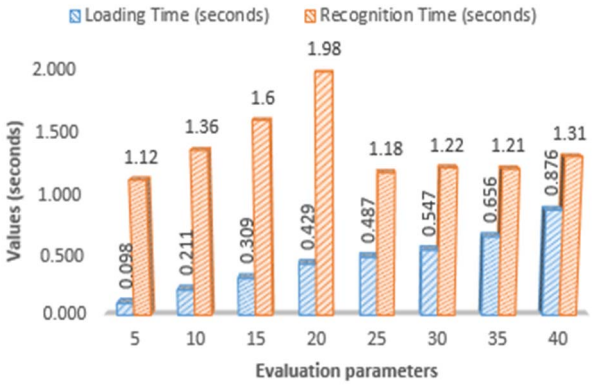

Fig. 4. Loading and recognition time.

between loading time and recognition time has been shown. In our system, the loading time is pre-validation process. It will be loaded before starting the validation process. The impact of recognition time is the major concern. Because

recognition will be conducted in real-time and it determines the speed of the validation process.

Table 2 Accuracy and Error Calculation

Trial	Correct Recognition	Incorrect Recognition	%Accuracy	%Error
1	392	8	98	2
2	388	12	97	3
3	388	12	97	3
4	396	4	99	1
5	392	8	98	2
6	392	8	98	2
7	388	12	97	3
8	396	4	99	1

C. *Accuracy and Error Calculation*

We define the error as incorrect recognition. Our system recognizes faces from information theory perspective using eigenfaces. Although the probability of having same pattern for two different eigenfaces of two different persons is close to zero, sometimes the patterns demonstrate little difference which falls below our threshold level. As a result, there is possibility of having incorrect recognition. However, it is not feasible to employ additional algorithm to detect the error rate. That is why, we have taken human inspection approach to calculate the error of our validation system.

We have 400 images of 40 person. Each of them has 10 images with different poses. In order to find out the error rate, we loaded each of the images of every individual separately and ran the program to check if it can recognize the face correctly. We repeated the process for 8 times. In the first trial, out of 400 images 392 faces were recognized correctly, whereas 8 recognitions were incorrect. In the second trial 388 faces were successfully recognized. But 12 faces gave mismatched result. The result has been enlisted in table 2.

To calculate the percentage error, we used (6), where TI means 'total image' and CR means 'correct recognition.

$$\%Error = \frac{TI-CR}{TI} \times 100 \qquad (6)$$

Equation (6) gives us the error. From the error we calculated the percentage accuracy. Fig. 5 shows the accuracy in percentage scale.

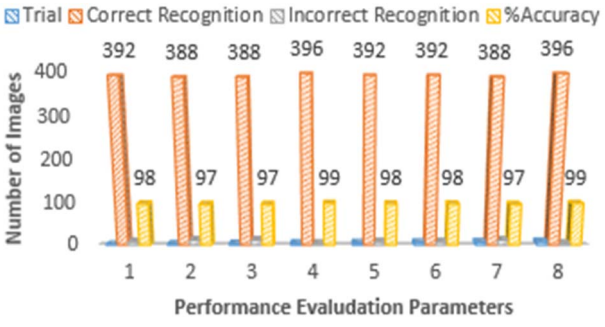

Fig. 5. Accuracy and error

The highest accuracy of our system was 99% where only 4 images were incorrectly recognized. The red bars represent the total number of correctly recognized image and the yellow bars represent the percentage accuracy.

CONCLUSION AND FUTURE WORK

An effective, efficient, simple and inexpensive method has become essential to prevent proxy examinees from taking examinations. Manual process is no longer effective because of excessive and growing number of candidates in competitive tests. The automatic examinee validation system we have proposed has all of the features required to conduct a fair environment for competition. Our proposed method is fast and can recognize faces with above 97.88% accuracy. Moreover, this system does not require any training. The registration method itself processes the images for recognition system, which validates examinees before entering the exam-center. Although it adds few more steps in registration process, considering the performance, efficiency and accuracy the system we are proposing is an excellent solution to prevent proxy examinees and ensure that only the deserving candidates will survive in competitive examinations. In our future work, we will implement the validation system physically to conduct a dummy examination. If the system performs as good as the lab experiment, we will launch the validation system as an open source examinee validation system.

***Abstract*—Potato is one of the most used crops in the world and 2nd most important crop in Bangladesh. Our economy is largely affected by the production of potato. But its production is hampered due to different diseases of potato leaves. These diseases decrease production and increase the price of potatoes. Our objective is to develop an automated system which will predict the potato disease and helps farmers to take necessary steps. In this paper, we have implemented a deep Convolutional Neural Network (CNN) which provides 98.33% accurate result in predicting different diseases of potatoes. To best of our knowledge, this is the highest accuracy gained for only potato disease prediction. The system is cost effective, less time consuming and provides an efficient way of predicting potato diseases from leaves. This will help the farmers and lead our country towards a digital agricultural system.**

Keywords— Potato Disease Prediction, CNN, Deep Learning.

I. INTRODUCTION

The potato is grown as a major crop in different countries (e.g. China, India, Russian Federation) of the world [1]. Potato (*Solanum tuberosum*) is the 2nd most important crop in Bangladesh, after rice. The total world potato production is estimated at 388,191,000 tonnes in 2017 [2]. Currently, the potato crop is grown on a significant scale in about 130 countries. Potato production is threatened by several diseases resulting in considerable production losses, and deteriorates the quality and increases the price of potatoes. The two main diseases of potato plants are *Phytophthora infestans* (Late Blight) and *Alternaria solani* (Early Blight). The farmers are facing many problems for these diseases which can be solved by early prediction of the diseases. Manual prediction of potato disease is difficult, costly, and time-consuming, while the computerized system is more efficient and cost-effective. Recently, Machine Learning (ML) system are extensively used to automate the processes. Machine learning can be an effective method for continuous monitoring of plant health status and early detection of plant diseases. Every disease has some visible symptoms on the plants, particularly on leaves. These symptoms, for example, a visible pattern of the affected leaves help to predict the disease. In this way, machine learning offers a solution to the issue of agricultural productivity and ensures food security.

Convolutional neural network (CNN) is one of the most widely used techniques for image recognition, image classification, medical imaging etc. CNN takes an input image, processes it and classify it to a certain category. CNN takes an input image as an array of pixels. Each input image will pass through a series of convolution layers with filters like pooling, fully connected layers(FC), etc. Different activation functions are applied to classify an image with probabilistic values between 0 and 1.

The main goal of this work is to develop machine learning based effective and error-free disease prediction system for the potato plants. We have used Plant Village dataset for developing our deep convolutional neural network model.

This paper is organized as follows: The related works are presented in Section II. Section III explains the dataset of the proposed work. Section IV shows the methodology and the architecture of the deep convolutional neural network. Section V represents our result and discussion. Finally, conclusion and future work are presented in Section VI.

II. RELATED WORK

Researchers explore plant disease detection using deep learning, SVM, RGB imaging, X-ray, ultrasound, and multispectral and hyperspectral technologies. In paper [3], a multiclass support vector machine model was developed for classifying potato disease detection. The model was applied to 300 different images. Different performance parameters such as accuracy, sensitivity, recall, and F1-score were calculated for measuring the performance of the model. Another work has been done for apple disease identification using Multi-class SVM Classifier which was used to train and test images [4].

In paper [5], a deep CNN model was developed for classifying 13 leaves' disease for Apple and Tomato plants. The model was able to detect leaf presence and distinguish between healthy leaves and 13 different diseases, which can also be visually diagnosed. The complete procedure was described, respectively, from collecting the images used for training and validation to image preprocessing, image augmentation and finally training the deep CNN and fine-tuning of the model. The experimental results on the developed model achieved precision between 91% and 98%, for separate class tests, and provide an average precision of 96.3%. Ferentinos and Konstantinos P. [6] used AlexNetOWTBn and VGG deep learning architecture to classify 25 different diseases. Faster R-CNN, R-FCN, and SDD has been used for classifying real-time tomato plant diseases and pest recognition.

A few works [7-11] has been done for several diseases classification problem using deep learning. In paper [12] authors used K-Means clustering. They converted an image from RGB color space to L*a*b* color space and then used color coherence vector (CCV), global color histogram (GCH), complete local binary pattern (CLBP), Gabor features, local binary pattern (LBP) and local ternary pattern (LTP). Then authors performed feature level fusion by fusing for more than two texture and color features and also applied random forest classifier on segmented image. Fruit disease was shown after classification by tagging every pixel using this method.

III. DATASET DESCRIPTION

Plant Village (www.plantvillage.psu.edu), a publicly available image database, contains 54,306 images of the different plant leaves. We have analyzed 2250 images of potato leaves. Table I shows the detailed statistics of the image dataset.

TABLE I. DETAILS STATISTICS OF IMAGE DATASET

Disease	Number of images
Early Blight	1000
Late Blight	1000
Healthy	250

IV. METHODOLOGY

We have used CNN for predicting potato disease using potato leaves. Fig. 1 shows the block diagram representing the methodology of predicting potato diseases. Our methodology is divided into two major steps. The steps are:

- Preprocessing of images.
- Deep convolutional neural network.

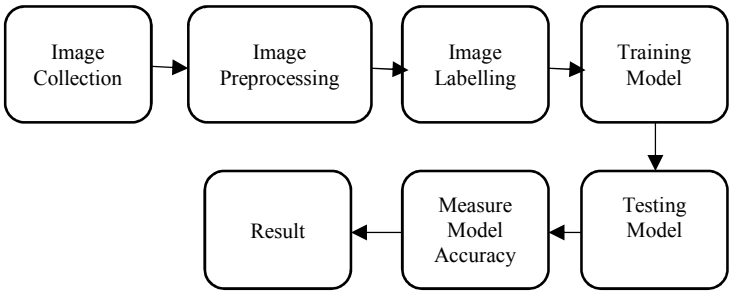

Fig. 1. The methodology of predicting potato diseases

The details of the two major steps are described below:

A. Preprocessing of images

Preprocessing refers to the transformations on the raw data before it is fed to the machine learning or deep learning algorithm. For instance, training a convolutional neural network on raw images will probably lead to bad classification performances[10], whereas preprocessing increase efficiency. The preprocessing is also important to speed up training, for instance, centering and scaling techniques.

- Gray Scaling:

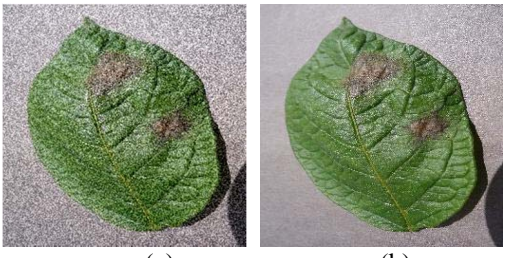
The original size of Plant Village images is 256×256 pixels. We have converted all the RGB images to grayscale images. The color channel is converted to 1 channel from 3 channel. Fig 2. shows the input image and the result of applied grayscale techniques.

(a) (b)

Fig. 2. (a) Input image (b) Grayscale image

- *Removing Blur from Images*:

We have used Gaussian blur technique for removing blur from the image. First, we have added blur and then subtracted the blurred image from the original image. Then we have added a weighted portion of the mask to get the de-blurred image.



$$g_{mask}(x,y) = f(x,y - f'(x,y)) \quad \ldots\ldots\ldots(1)$$

$$g(x,y) = f(x,y + k * g_{mask}(x,y)) \quad \ldots\ldots(2)$$

Here $f'(x,y)$ is the blurred image and k is a weight for generality

- Removing Noise from Images:

We have removed salt and pepper noise from the images. We have used the median filter to remove noise. After removing the noise, the images become more clear, sharp and noiseless. After removing noise, we have converted the image to an array of pixels for feeding into our model. Fig 3. shows the input image and noise reduced image.

(a) (b)

Fig. 3. (a) Input image (b) Noise-free image

- Labeling images:

After preprocessing all the images we have used label binarizer to label all images into corresponding class. Then we have split our dataset into train, test and validation set. Table II shows the detailed

statistics of the train, test, and validation set with the split ratio.

TABLE II. DETAILS STATISTICS OF TRAIN, TEST AND VALIDATION SET

Class	Train	Test	Validation
Late Blight	800	100	100
Early blight	800	100	100
Healthy	200	25	25
Total	1800	225	225

B. Architecture

Our proposed architecture has 5 convolution layers and 2 fully connected dense layer. The first convolution layer has 32 filters where the filters are of size 3×3, the second and third layer has 64 filters with filter size 3×3 and last two layers have 128 filters and the filter size is 3×3. Rectified Linear unit activation function (*ReLu*) is used for all layers. Total three MaxPooling layers are used and six Batch normalization are used in our model. The pool size of MaxPooling layer is 2×2. Batch normalization is used to speed up the learning. Dropout 25% was added to the first, third and fifth layer to reduce overfitting of the data. Two fully connected dense layers have been used. The first one has 1024 filters and the last one has only 3 filters for three output. We used Adam optimizer to update the weights. Table III. shows the model of our proposed deep Convolutional Neural Network.

TABLE III. SUMMARY OF THE PROPOSED DCNN MODEL

Layer	Output Shape

C. Parameters of Training model

The training model of CNN architecture is dependent on some parameters(e.g. learning rate, batch size, epoch, etc.). Learning rate is a parameter that controls how often we need to adjust the weights of the CNN model with respect to the gradient loss. Batch size defines the total number of training examples present in a single batch. We used batch size 32 so each time 32 sample images are present in a single batch. Epoch means the number of time a full dataset is passed forward and backward through the CNN. And shuffle parameter is used for shuffling the entire dataset after completing one epoch. Used parameters and the values of our training model are given in Table IV

TABLE IV. PARAMETERS OF TRAINING MODEL

Parameter Name	Value
Learning Rate	10^{-3}
Batch Size	32
Epoch	150
Shuffle	True

D. Analysis and evaluation tools

All the preprocessing and classification algorithm implementations, as well as evaluation of the classifiers, were performed using python version 3.X.

V. RESULT AND DISCUSSION

We have split our total data into train, test and validation dataset. We have applied our model to the training dataset. We have achieved an overall testing accuracy of 98.33%. We have also observed precision, recall and F1 score for better understanding and analyzing the result. Precision is the ratio of correctly predicted true observations to the total predicted true observations. Recall is the ratio of correctly predicted true observations to all observations of the actual class. F1 Score is the weighted average of Precision and Recall. Table V shows precision, recall and F1 score of the testing dataset.

TABLE V. PRECISION, RECALL AND F1 SCORE

Precision	Recall	F1 Score
0.9851	0.9809	0.9826

We have used confusion matrix to represent the visualization of the performance of our algorithm on the testing dataset. From confusion matrix, one can easily find out which class of data provides good accuracy and which provide the worst accuracy. Fig. 4 shows the graphical representation of the confusion matrix containing test data for healthy(class 0), early blight (class 1) and late blight (class 2). From the figure, we can observe that 2 data items are wrongly predicted for late blight (class 2) data. For the rest of the classes i.e. healthy (class 0) and early blight (class 1), we have successfully predicted all the diseases.

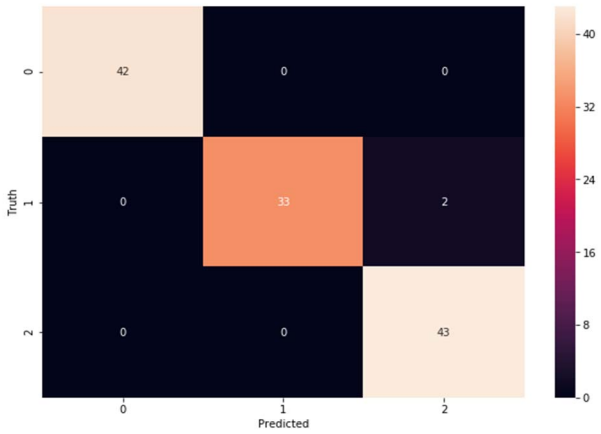

Fig. 4. Confusion Matrix represnting the visual of the performance

Finally, we have tested our trained model with test data. We took individual image of potato leaf as input to predict the disease. Fig. 5 shows the predicted result when we applied our method to some affected images. The value on the top left corner represents the accuray of the predicted result. We can see that for a sample healthy plant we got 97% accuracy, for a sample early blight plant we got 96% accuracy and for a sample late blight plant we got 99% accurate result.

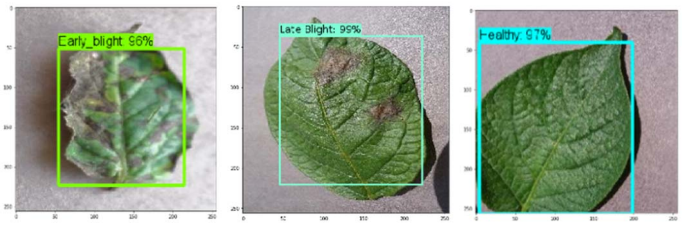

Fig. 5. Result of sample predicted disease images (a) early blight (class 1) (b) late blight (class 2) (c) healthy (class 0)

We have found two recent works on potato disease prediction. Islam et al. [3] worked with the same dataset we have used and got 95% accurate result. They used RGB imaging technique. Hu et al [13] used hyperspectral imaging technique and got 95% accuracy. Few other works have also been found regarding disease prediction of different other plants. For example Rice and Tomato. There are also several works on mixed data of different plants. But for simplicity, we have shown a comparison of only single plant disease prediction performance. Comparing with other works, we achieved the highest accuracy of 98.33%. Table VI. shows the comparison between various detection algorithm for leaves diseases prediction.

TABLE VI. COMPARISON OF VARIOUS DETECTION TECHNIQUES/ALGORITHM OF LEAVES DISEASE PREDICTION

.

Reference	Techniques	Plant	Accuracy (%)
This Work	Deep CNN	Potato	98.33
Islam et al. *2017* [3]	RGB Imaging	Potato	95
Hu et al. 2016 [13]	Hyperspectral Imaging	Potato	95
Asfarian et al. 2013 [14]	Texture Analysis and PNN	Rice	83
Xu et al. 2011 [15]	K-Nearest Neighbor	Tomato	82

VI. CONCLUSION AND FUTURE WORK

We presented a deep CNN based approach to predict the two most common diseases named late blight, early blight along with the healthy potato. We have achieved 98.33% accuracy which is the best result comparing others work on the same dataset according to our knowledge. This work can be very effective to increase the production of potato as well as decrease the price of the potatoes. Our approach will offer farmers a feasible, efficient and timesaving way of potato disease identification. This will lead to a digital agricultural system. In the future, we want to increase the accuracy by augmenting the images of the dataset. This work can also be extended for other plants to predict the diseases. As a future work, a smartphone-assisted system might be developed to automate the detection process.

***Abstract*—Human identification by using Electroencephalogram is becoming promising field and reliable to improve security systems. It is difficult to acquire EEG at a certain mental condition always such as concentration or relaxation. This paper represents a simple model to identify individuals and finding most effective primary color by using features of EEG by means of color stimuli. A comparison between primary and secondary colors for identification has also been made. Standard additive primary colors blue, green, red and one secondary color yellow were selected for experiment. Four neural networks were built by extracting various features of EEG in the domain of time and frequency. All artificial neural networks showed satisfactory performance with minimum mean square error for identification. Among the four selected colors blue color based ANN showed minimum mean square error of 6.238×10^{-08}.**

Keywords—Electroencephalogram (EEG), Human Identification, Color Stimuli, Artificial Neural Network (ANN), Biometrics.

I. INTRODUCTION

Human identification system uses identifier's features which makes it unique. Existing identification system are mostly either knowledge or possession based [1]. Password, PIN, fingerprint, voice etc. alike based database are very vulnerable in today. Facial recognition system is better but it also has been failed to complete reliability such as in the incident of Boston marathon bombing where the system fails to identify. Fingerprint can be stolen and all the data sets can be easily hacked. So human identification by using features of individual's brain wave becomes first choice for reliability [2-4].Biometrics uses special physiological or behavioral feature of individuals. As EEG consist of many features of brain, it is becoming a prominent research field [5].

Features of EEG due to different color stimuli is studied. Individual color stimuli has an effect on human emotion [6]. As EEG isn't constant and to reproduce subject need a specific environment such as concentration or relaxation, to make this system independent of hard experimental condition; the alternative method is to use color stimuli. Previous works shows that statistical and dynamic features gives best performance for human identification while using features of EEG [7]. So both domain's features is used in this proposed model.

The primary color red, green and blue are known as RGB colors. Primary colors are mixed together to generate secondary color. Researches shows significant effect of RGB on visual impact. A color theory namely opponent process describes the interpretation of color information with human visual system[8].

Practically most of the time the dataset have nonlinear relation. The dataset can be generalized by artificial neural network easily. Moreover ANN don't have input pre requisite. Besides theoretically ANN belongs to deep learning. To deal with the data complexity, volatility artificial neural network is chosen in this proposed work.

This paper presents a prominent methodology for human identification by using color stimuli. BIOPAC MP36, Acqknowledge 4.1 was used for acquiring EEG [9] and feature detection, MATLAB 2014a used for artificial neural network design.

The following sections of this article is described accordingly: section II represents the chosen methods, section III describes EEG processing and analyzing, section IV shows selection of features and comparison of colors. Section V and VI briefly discuss classification, experiment result and conclusion with future work respectively.

II. PROPOSED MODEL

A. Projected Model

The proposed model for identification of individual using color stimuli is visualized in Fig. 1 below. Having acquired EEG signal with BIOPAC with the assistance of MP36, features were taken out by Acqknowledge 4.1 and MATLAB 2014a which used to design artificial neural network. Deep learning with MATLAB leads to classification approach. By analyzing mean square error, regression, gradient, accuracy a decision is taken about whether the proposed model will work satisfactorily or not, which primary color is best and what type of color is better between primary and secondary.

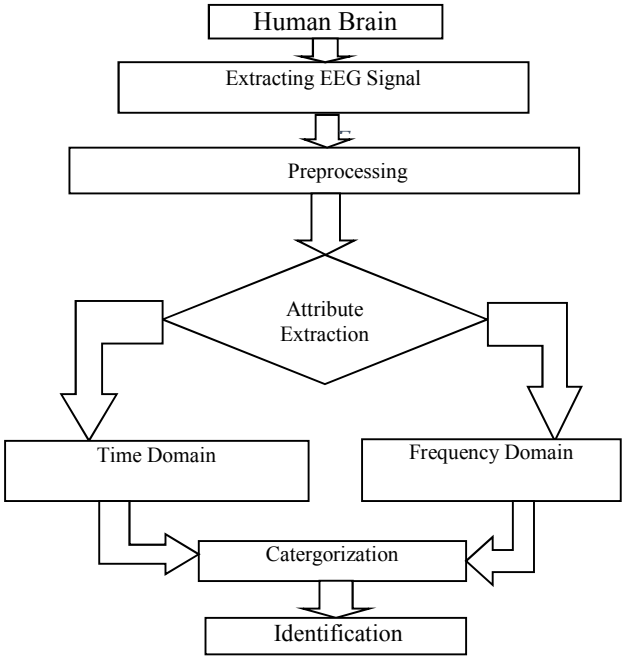

Fig 1. Flow chart of the planned approach for Biometrics using EEG

B. *Electroencephalography Acquiring and Exploratory Condition*

The test was conducted in Biomedical Engineering Lab of KUET (former BIT, Khulna), Bangladesh. Subjects were three male persons having no psychological and major visionary problem such as color blindness. Subjects were instructed to concentrate on colors. Total twenty individual trials were taken for each subject and color. Used two trials for testing purposes. Colors were shown in computer desktop screen.

C. *Experimental Setup*

1) Hardware description: BIOPAC data acquisition unit MP36 was used. Fig. 2 shows EEG signal acquisition system during the experiment.

2)Required software: Different softwares namely Acqknowledge 4.1 and EEGlab were used for signal processing approach. Relative waveforms is given by BIOPAC student Lab software after it's built in signal acquisition and processing system. Different features of signal were measured and analyzed in this platform.

Fig. 2. Pictorial view during experiment at BME, KUET.

III. Signal Processing And Analysis

A. *Filtering and Artifact Removing*

After acquiring the raw EEG signal it showed artifact and noise which due to EOG and EMG noise because of hand motion, eye blinking and line frequency (50 Hz). The raw EEG was filtered between .5 Hz to 44 Hz by band pass FIR.

B. *Smoothing*

Smoothing makes average and replace it with the real value. In words smoothing is averaging. Moderate smoothing (factor 5) was done. In (1) n, m are no. of points and samples respectively.

$$x_{output} = \sum_{r=m-\frac{n}{2}}^{r=m+\frac{n-1}{2}} \frac{x_{input}(r)}{n} \text{.....(1)}$$

C. *Domain analysis*

Standard deviation (STDDEV), Maximum value (MAX), kurtosis, skewness these statistical methods were measured in the study as time domain features. For measuring the overall power of EEG, Power Spectral Density (PSD) measures were used in frequency spectra and as a part of DFT, Fast Fourier Transform (FFT) was used as a parameter. Hamming window was used during FFT.

IV. Extracted Data

A. *Contrast of the EEG attributes of the individuals*

In time and frequency domain we used maximum, SD, skewness, kurtosis, PSD mean, PSD max, FFT mean, FFT max where the first four attributes are time domain and remaining fours are frequency domain features. The features of subject 1 in time domain while looking at blue color are illustrated below in Table I.

TABLE I. Response for blue color of subject 1

Trial	Maxm. (Micro-V)	Std. Dev. (Micro-V)	Skewness (Micro-V)	Kurtosis (Micro-V)
1	13.30831	5.79718	-0.0591	3.01581
2	8.776440	4.83765	-0.36379	2.19582
3	11.77697	3.59855	0.36564	3.68987

8	10.48134	4.81770	-0.05164	2.35189
9	17.64717	4.89702	0.80992	4.74267
10	10.48335	4.36073	-0.23235	3.21103
11	11.19927	4.68437	0.46547	2.39521
12	9.036970	4.06186	-0.21058	2.64188
13	13.93632	4.75774	0.59110	3.15644
14	8.946480	4.73119	-0.41294	2.77898

15	9.362860	3.97022	-0.08332	2.75909
16	12.61301	4.51157	0.12616	3.52430
17	8.308320	3.74044	0.01996	2.66426
18	11.40869	3.42292	0.10140	3.87897
19	8.13347	3.42092	-0.06007	2.67656
20	8.43347	3.43864	-0.06569	2.85472

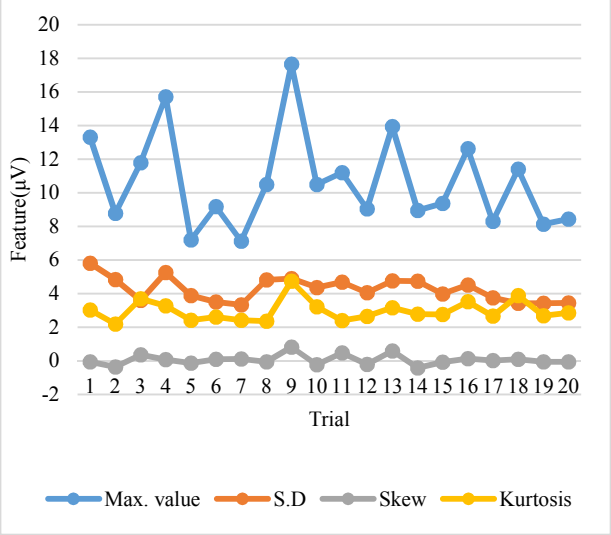

Fig. 3. Time domain features of subject 1 while looking at blue color.

Fig. 3 shows that the fluctuation of features of time series varies a little for subject 1 for blue stimuli in twenty different trials.

B. *Comparisons of features for different individuals*

After plotting definite feature of all subjects taken in twenty trials, it shows small variation of feature for same subject and comparatively more variation for different individuals. Fig. 4 shows the mean PSD for three subjects at twenty trial. Similar graphs are obtained for max PSD, mean FFT and max FFT.

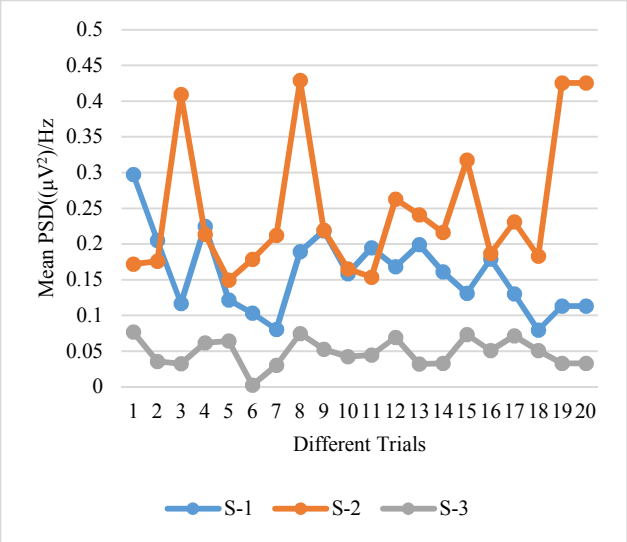

Fig. 4. Comparison of Mean PSD of different subjects.

V. Classification Results & Discussion

In this experiment we have used four color stimuli. So four neural network were built. MATLAB built in nntool GUI was used. Two layers feed forward back propagation ANN was used utilizing TANSIG transfer function and Levenberg Marquardt learning algorithm were used to design neural network.

A. *Scenario 1: Yellow color*

The ANN designed for yellow color showed mean square error of 0.22371 at epoch 1 with regression of 0.977 and successfully identified three different individuals with accuracy of 92.82%, 93.85%, 95.99% respectively. It gave the worst performance comparatively.

B. *Scenario 2: Green color*

The ANN designed for green color showed mean square of 7.7336×10^{-07} at epoch 24, overall regression 1 and successfully identified subjects with accuracy of 94.82%, 95.66%, 96% respectively. It showed good performance.

C. *Scenario 3: Red color*

The ANN designed for red color showed mean square error of 2.5798×10^{-07} at epoch 1, overall regression 1 and successfully identified all subjects with accuracy of 98.32%, 99.2%, 99.92% respectively.

D. *Scenario 4: Blue color*

The ANN designed for blue color showed mean square of 6.238×10^{-08} at epoch 5, overall regression 1 and successfully identified all subjects with accuracy of 99.98%,100%,100% respectively. Fig. 5 shows best validation performance of the neural network designed for blue color.

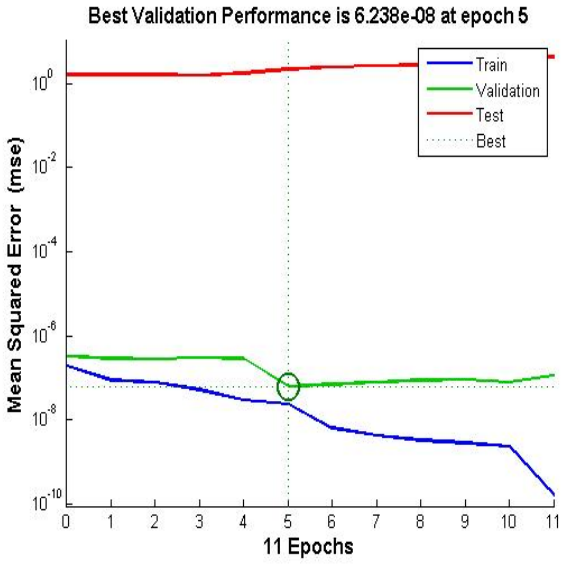

Fig. 5. Performance of neural network designed for blue color.

TABLE I I. COMPARISON DESIGNED NEURAL NETWORKS

Attributes	Yellow	Red	Green	Blue
Mean Square Error	0.223	2.579×10^{-07}	7.733×10^{-07}	6.238×10^{-08}
Overall Regression	0.977	1	1	1
Accuracy (Average)	94.22%	95.49%	99.14%	99.99%

The above table shows a comparison among ANN designed for different colors. So now the results clearly signifies that the ANN built for blue color gives best performance with 99.99% identification accuracy. Mean square error is an effective parameter for evaluating the performance of any ANN model. Lower mean square error signifies better efficiency of the designed ANN and vice versa. The value of regression varies from zero to one. Having unity or near to unity regression represents a greater efficiency and vice versa. Accuracy is measured by comparing the output and target value in terms of percentage.

VI. CONCLUSION

After the subsequent steps of EEG signal processing, it is to confirm that human identification can be done easily by means of color stimuli and EEG analysis. ANN for blue color gives lowest error of 6.238×10^{-08} whereas ANN designed for yellow color gives the highest error of 0.22371. Being primary color, blue provides best performance as it shows mean square error illustrating better performance of the network.

Development of an efficient online EEG analysis system for real application is under progress. SVM analysis of proposed model is under consideration.

Abstract— **In recent times, waste management problem has become a crucial challenge for Bangladesh, which is having a detrimental impact on the environment. This paper presents the proposition of designing a smart dustbin similar to an Automated Teller Machine (ATM) along with an intelligent embedded system, which has been dubbed as Automated Teller Dustbin (ATD). An efficient convolutional neural network (CNN) based image classifier is developed, which is able to detect and recognize any object regarded as garbage by analyzing training features. Additionally, it can also count the number of labeled objects and assign a price value to each object. The waste brought by any individual to the ATD will readily be recognized by the image classifier and the recycle value, which has been assigned for that object can be withdrawn by that individual. Therefore, a direct exchange of waste and its equivalent price is possible, which will incentivize people to use our proposed smart dustbin. After the installation cost, the operation and maintenance cost can be gained by recycling the garbage in it. A pre-trained CNN-based model ALexNet has been utilized to train and test the model with a dataset of 20 images for each of the 10 categorized objects collected from different waste management shops in Dhaka, Bangladesh. The model that has been trained for object recognition has attained an accuracy of 96%, which bears testimony to the feasibility of our proposal.**

Keywords— Waste management, Convolutional Neural Network, Automated Teller Dustbin, Object detection, Object recognition

I. INTRODUCTION

Environmental pollution in Bangladesh is rising drastically due to uncontrolled discharge of wastes in our environment [1]. Moreover, the rapid growth of population has made it even harder to handle waste management, particularly in urban areas such as Dhaka, which happens to have the highest density of population in the world (44,000 per square kilometers) [2]. According to Bangladesh Waste Database 2014, the approximate amount of waste generated in its urban areas is about 23,688 tons per day, which has been estimated to increase to 47,000 tons per day by 2025 [3]. If this growth continues, Bangladesh will soon surpass the maximum limit of waste generation that has been envisaged [3]. This disastrous outcome can only be mitigated by implicating smart waste management technologies to collect wastes properly for recycling purposes. In Bangladesh, recycling process is done manually and people involved in this process are mostly women and children. Fig. 1 represents the present conditions of recycling plastic waste collection and sorting management involving women and children. Predominantly, waste is categorized into two classes- organic waste and non-organic waste. Food waste covers most of the organic waste.

(a)

(b)

Fig. 1 Present condition of recycling plastic waste in Bangladesh.

On the contrary, non-organic wastes are comprised of metal, plastic, paper or different electric and electronic wastes, which are commonly referred to as e-waste. Due to unplanned location of dustbin as well as reluctance of people to use dustbin heavily contribute to the increasing rate of waste disposal at roadside in Bangladesh. Many researches, as well as experiments, have already been carried out about the management of wastes [4-6]. However, most of them are focused on waste management after they are readily available in dustbin [7-8]. Nevertheless, in this paper, we are more concerned about the before scenario i.e. how to collect and categorize waste in the first place; how to incentivize city residents to use the bins properly instead of littering the roadsides. For coming up with a solution, this paper concentrated on designing a smart dustbin, which will act like an Automated Teller Machine (ATM). In our proposed model, in exchange for waste in the smart dustbin, anyone can withdraw the currency equivalent of the recycle value of that waste. This kind of trading will entice people to use this smart dustbin and will have a promising impact on reducing the waste disposal on roadsides. The proposed smart dustbin has an intelligent embedded system interfaced with it, which is actually a Convolutional Neural Network-based (CNN) object recognizer. For recognizing any throw-out waste, different object images categorized in 10 classes have been collected as data from multiple waste management shops located in Dhaka. Therefore, any solid non-organic recyclable waste will readily be recognized and labeled by the CNN object recognition model. According to the labeled name, the equivalent price of the recycle value will be assigned for that object, which can be withdrawn instantly from our smart dustbin. Organic waste or other solid waste, which are not recognizable will be sorted out differently through a different channel and their equivalent price will be assigned based on their weight. Hence, in our original design, a weight sensor is also suggested for handling non-recyclable or organic wastes. The proposed design has been named **Automated Teller Dustbin** (ATD). From this point onwards, this shorthand will be used for simplicity.

The rest of the paper has been organized as follows: in section II, the proposed methodology along with the algorithm and mathematical explanation has been carried out. The performance result of the model has been evaluated in section III, whereas in section IV the key features of this research have been enlisted as a conclusion.

II. Proposed Methodology

The ATD has mainly two input pathways for waste collection-one for organic waste and the other for non-organic waste. The input for organic waste is integrated with a weight sensor. Based on the weight, automatic calculation of the price of that particular waste material is performed. On the other hand, for non-organic recyclable objects, a webcam is placed in the opening, which will take live footage of the object. A pre-trained network model named AlexNet has been utilized for detection as well as for recognition of the object. As fodder for the AlexNet, 20 images for each of the 10 categorical objects have been collected as our primary dataset. When new objects are introduced, ATD can recognize that object and put a label according to which, price is determined. If multiple objects are present in one single snapshot, it locates the objects at first, then recognition for each individual object is carried out and finally, the labeling and pricing procedures are undertaken. In Fig. 2, the key concepts have been illustrated using a block diagram.

In this research our sole focus is about handling non-organic wastes, as it required much consideration due to the variation on their recycled prices. The non-organic waste management channel of our ATD comprises of a webcam and an object recognizer. For recognizing any object, the very first step is to detect the object, then separate it and finally build a model to successfully recognize that object. The flowchart that has been followed in this paper has been shown in Fig. 3.

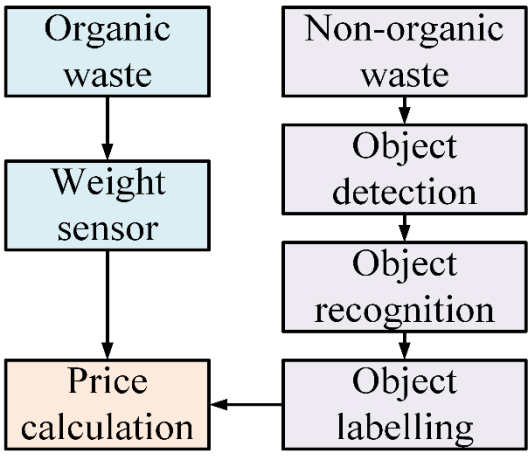

Fig. 2 Block diagram describing the work-flow of the dual input ATD.

III. System Modeling

A. R-CNN:

Region-based CNN (R-CNN) has been performed for detecting objects. This method is adopted to capture the region of an object. The detection process is basically based on hierarchical grouping algorithm. For image segmentation, the bottom-up approach has been adapted for the selective search. The total algorithm has been described in Algorithm 1 [9].

Algorithm 1: Hierarchical Grouping Algorithm
Input: I (Image)
Output: L, a set representing object location
Initial Region: K ={k_1, k_2,…, k_n}
Similarity Set: S = phi

for each neighbor region pair (k_i, k_j)
    Determine similarity s(k_i,k_j)
S=S U s(k_i,k_j)

While B ≠ phi
    Highest similarity, s(k_i,k_j)=max(S)
    Merge two regions k_t=k_i U k_j
    Cancel similarities for k_i : S=S\s(k_i, k_{new})
    Cancel similarities for k_j : S=S\s(k_{new},k_j)
    Determine similarity set between k_t and its neighbors S_t
    S= S U S_t
    K= K U K_t
Extraction of L from regions R

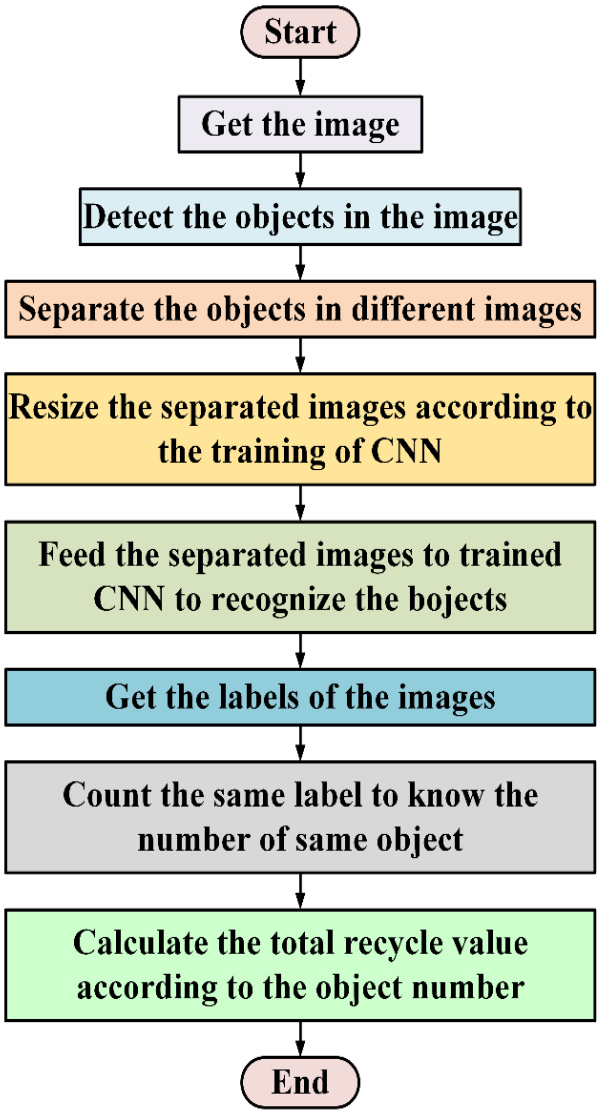

Fig. 3 Flow chart of the non-organic waste management procedure.

B. Modified AlexNet:

Object recognition can be made possible by employing machine learning methods. However, for improving the precision of the output, a large dataset is required through which, the model will be trained. AlexNet is one such model that has been trained by using over 15 million labeled images that fall roughly to 22000 categories [10]. By taking advantage of this large dataset, a well-trained AlexNet model has been developed which has 25 layers in its architecture. This pre-trained model has been modified and tuned for classifying 10 different objects. Therefore, our modified AlexNet model is basically a CNN model, which contains 5 convolutional layers and 2 fully-connected layers. The architecture of our proposed CNN model is shown in Fig. 4. The size of the input image is 224×224×3 which is fed into the first convolutional layer and is filtered with 96 kernels of size 11×11×3 with a stride of 4 pixels. The 2nd convolutional layer filters the input with 256 kernels, each of

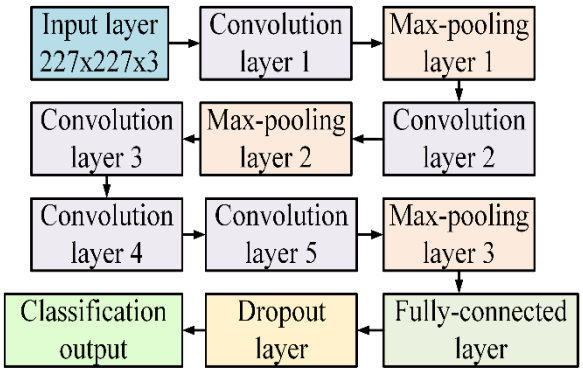

Fig. 4 Architectural block diagram of the CNN-based AlexNet model. It basically contains 5 convolutional layers and 2 fully-connected layers.

whose size is 5x5x48. After the first two convolutional layers, a max-pooling layer is entered for dimensionality reduction. The 3rd and 4th convolutional layers contain 384 and 256 kernels having size of 3x3x256 and 3x3x192, respectively. For reducing over-fitting, a drop-out layer is also added. In this layer, a neuron is made to drop out with a probability of 0.5% which obviously increases the convergence rate of the model. Nevertheless, this layer plays a vital rule to retain the model from being considerably over-fitted. For each convolutional layer, 'ReLU' activation function is associated with each neuron, as it offers much faster approach to train the whole model rather than other activation function based on saturation property e.g. 'tanh'.Only for the final fully-connected layer, 'softmax' activation function is used for determining the probabilities of each class based on which the classification is done

Let us consider the input feature map as F_i (i=1, 2,…., I), where I represents the total number of feature maps. Each of these input feature maps is connected to other feature maps in the convolutional layer based on the number of weight metrics. If the other feature map is defined by Oj (j=1, 2, …..,J), where J is the total number of other feature maps, then the total number of weight metrics will be (I×J). Let us consider the weight matrices as $w_{i,j}$=(i=1, 2, …, I; j=1, 2, …..,J).

By applying convolution operation in signal processing, the mapping can be explained. Each unit of single feature map in the convolution layer can be determined by using the following equation [11]:

$$q_{j,m} = \sigma\left(\sum_{i=1}^{I}\sum_{n=1}^{f} F_{i,n+m1} w_{i,j,n} + w_{F,j}\right) \qquad (1)$$

Where, j=1, 2,…,J. Here, $q_{j,m}$ is the mth unit of jth feature map. $w_{i,j,n}$ represents the nth element of the $w_{i,j}$ weight vector and f is the filter size.

In the maximum pooling layer, max-pooling function is employed for dimensionality reduction, which is shown in the following equation [11]:

$$p_{i,m} = \max_{n=1}^{H} q_{i,(m-1)\times x+n} \qquad (2)$$

Here, x is the shift size, H is the pooling size. Similarly, by using average function, the output can be determined as follows:

$$p_{i,m} = c \sum_{n=1}^{H} q_{i,(m-1)\times x+n} \quad (3)$$

Where, c is the scaling factor. Fully-connected layer is constructed based on the neural network algorithm. This is the most important layer of CNN. For improving performance, dropout layer has been added which helps reduce over-fitting.

IV. Result and Discussion

1) Data Collection:

In our datasets, non-organic recyclable waste has been categorized in 5 groups. These are- plastic, metal, glass, paper, and e-waste. For plastic, we have collected 20 images of each plastic bottles and boxes. In a similar fashion, for each group, we have chosen two objects and for each of them, we have collected 20 images. Hence, our total datasets have 200 images of 10 different objects along with their recycle values.

2) Object detection:

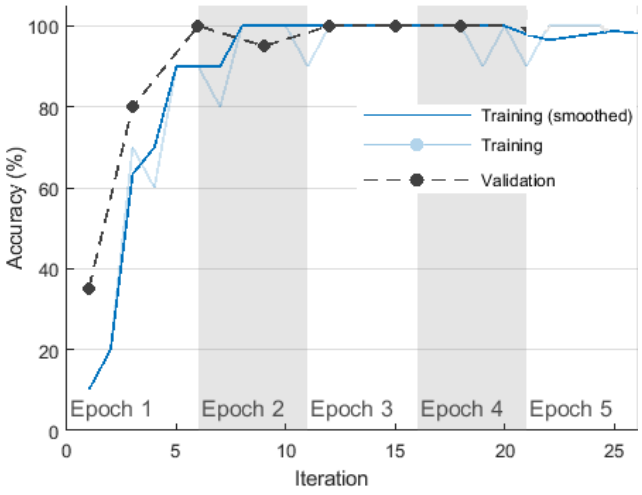
The process initiates by introducing a small region in the whole image and gradually merging them with hierarchical grouping. By analyzing the similarities between all neighboring regions, two most similar regions are selected and then grouped together. After that, the resulting group region is compared with all other neighboring regions and a new group is formed. The whole process continues until it becomes a single region. A demo of object detection and segmentation is shown in Fig. 5.

(a)

(b)

Fig. 5 (a) Detected objects in a figure (b) segmented object figures.

3) Object recognition:



After detection and segmentation, the images of the objects are fed into the trained CNN for recognition and labeling purposes. The output of the CNN-based model along with a few labeled objects are shown in Fig. 6.

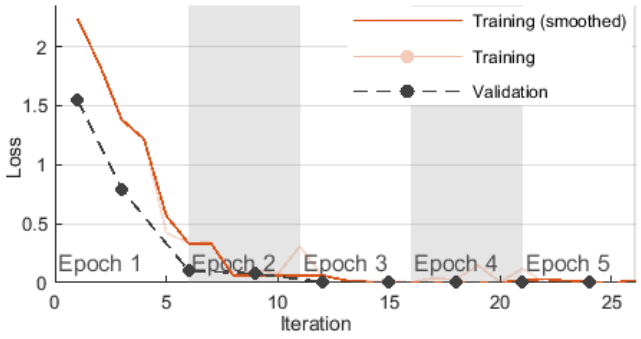


Fig. 6 Different objects that have been successfully recognized by CNN-based modified AlexNet model.

4) Performance evaluation:

In this paper, the pre-trained AlexNet model has been adapted for the purpose at hand. The training progress achieved by the modified AlexNet is shown in Fig. 7(a). From the figure, we can see that the accuracy level is progressing with each epoch and finally the validation accuracy has attained around 96 % accuracy, which is quite impressive. The loss profile of our model has also been evaluated in Fig. 7(b), which shows a gradual decrease of loss with each iteration.

(a)

(b)

Fig. 7 (a) Training progress in terms of accuracy rate. As is evident from the graph, accuracy crosses the 80% threshold after a few iterations and then saturates to 96%, (b) Loss profile with each iteration for the designed CNN model.

5) Pricing:

The price of the recycled waste according to the present market price is listed below in Table I.

TABLE I. WASTE RECYCLING PRICE LIST

Waste Category			**Price (BDT/kg)**
Non-Organic Waste	***Plastic Bottles***	Clear and Light Blue PET	10
		Colored PET	3
		HDPE natural	27
		HDPE mixed color	10
		Mixed	3
	Plastic Film	Polyethylene (PE) printed	18
		Polypropylene (PP) printed	2
		Clear natural	28
	Glass containers (jars and bottles)	Brown	1
		Clear	2
		Green	0.5
		Mixed	1
	Metal	Steel can	11
		Non-Ferrous metal	214
		Ferrous metal	10
		Aluminum can	10
	Paper	News	9
		White	25
	E-waste	Battery	50
		Display units (LCDs, CRTs)	150 per piece

V. CONCLUSION

The objective of this research was to present an idea, which can help manage roadside waste in a significant manner, especially in Bangladesh. As for the origin of road side waste, most of the time, the citizenry is responsible for not using the conventional dustbins properly. In this paper, we have presented the design of a smart dustbin with the aid of a CNN-based object recognizer. The very idea behind this design is to incentivize people to use this smart dustbin as it involves monetary compensation in exchange for a few specific waste materials. Therefore, it will not only reduce the amount of waste on the roadside but also save the long effort of waste collection. For implementing this concept, this paper has proposed the design of an ATD integrated with a CNN based object recognizer, which can readily recognize any object and then determine the recycle value of that object. With our collected datasets, the developed model has gained an accuracy of 96%, which is well-enough to move ahead for implementation in the real world.

***Abstract*— Medical image classification has gained tremendous attention in recent years, and Convolutional Neural Network (CNN) is the most widespread neural network model for image classification problem. CNN is designed to determine features adaptively through backpropagation by applying numerous building blocks, such as convolution layers, pooling layers, and fully connected layers. In this paper, we mainly focused on developing a CNN model for classifying brain tumors in T1-weighted contrast-enhanced MRI images. The proposed system consists of two significant steps. First, preprocess the images using different image processing techniques and then classify the preprocessed image using CNN. The experiment is conducted on a dataset of 3064 images which contain three types of brain tumor (glioma, meningioma, pituitary). We achieved a high testing accuracy of 94.39%, average precision of 93.33% and an average recall of 93% using our CNN model. The proposed system exhibited satisfying accuracy on the dataset and outperformed many of the prominent existing methods.**

I. INTRODUCTION

The brain tumor is one of the most feared diseases in medical science. According to the American Cancer Society's [1] estimation of the brain tumor that will be diagnosed in the United States in 2019 includes 23,820 malignant tumors of the brain or spinal cord (13,410 in males and 10,410 in females). These estimation does not include benign (non-cancer) tumors. According to their evaluation, there is a possibility that 17,760 people (9,910 males and 7,850 females) could die from brain and spinal cord tumors in 2019. Survival rates of a brain tumor vary according to the type of the tumor and age of the patient. The Central Brain Tumor Registry of the United States (CBTRUS) [2] shows that the survival rate can extensively vary according to age. These data were collected on the patients who were diagnosed for the brain tumor during the year 2000-2013. The report shows that the 5-year relative survival rates for Meningioma tumor are 87.0%, 77.4%, 70.5%, 53.7%, 47.3% for age 20-44, 45-54, 55-64, 65-74, 75+ respectively.

A brain tumor is the abnormal growth of cells in the brain. A brain tumor can be primary or secondary. A primary brain tumor originates in the brain itself or tissues adjacent to it, i.e. the brain-covering membranes (meninges), cranial nerves, pituitary gland or pineal gland, while a secondary brain tumor occurs when cancer cells from other organs like lung, kidney, breast, etc. spread to the brain [3]. Primary brain tumor initially arises because of the mutations of their DNA. These mutations allow the abnormal cell to grow and the normal cell dies. It can cause brain damage and sometimes it can be life-threatening.

In this work, we proposed a CNN model that is able to accurately classify the brain tumor. Hence, the treatment for the tumor can be started at an early stage.

The remaining part of the paper is organized as follows: Section II demonstrated the related works that have been done in this field. The proposed methodology with some theoretical explanations is investigated in Section III. The result is illustrated in details with some performance measures in Section IV. The conclusion of the paper is drawn in Section V.

II. RELATED WORK

Numerous works have been done on brain tumor classification in recent years. These works are briefly outlined as follows:

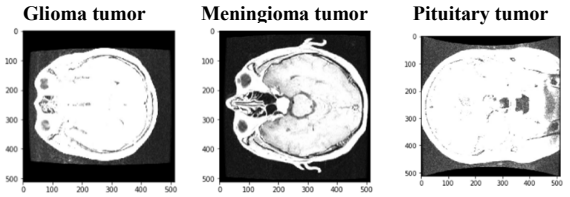
Yang et al. [4] proposed the CBIR (Content-Based Image Retrieval) method to evaluate a large image dataset. This method considers the tumor region as a query and tries to find a tumor that has the same pathological properties. The system used MID (Margin Information Descriptor) as the feature. It illustrates the image content by using the surrounding tissue of a tumor. Their proposed system was able to achieve a precision of 89.3%. But the distance metric determined by their methods is globally linear, and it disappoints to produce many local projections for separate regions. Furthermore, their system is developed using manual segmentation of the brain tumor.

Huang et al. [5] suggested a CBIR system with region-specific BoVW (Bag of Visual Words) model. It uses intensity information of the lesion region and the intensity change of the surrounding of lesion region. The proposed system also summarized that normalization and whitening gave better performance in retrieving the image. Their proposed model obtained an average precision value of 91.0%. However, the brain tumors in MRI images are outlined manually which is not proficient and advantageous. When the contour of the segmentation is far from the tumor boundary, the method strives to catch the intensity variation encompassing the tumor.

Furthermore, Huang et al. [6] described a CBIR based system. It uses BoVW model to extract information features and REML (Rank Error-based Metric Learning) algorithm to decrease the gap between low-level features and high-level connotative concepts. This system outperformed many methods with an average precision of 93.1%. However, the partition learning that was used in the system to obtain discriminative features, many of the times

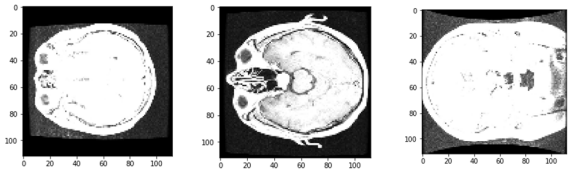
gives local optimal solutions. Moreover, the distance matric REML is globally linear and strives to determine multiple regional projections for various regions in the feature space.

III. Proposed Methodology



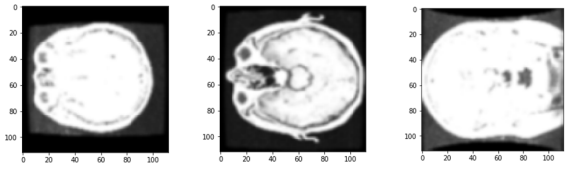
This section illustrates the detailed methodology that is used to classify brain tumors. It has the following steps: dataset collection and description of the dataset, preprocessing the images, classification of brain tumors using CNN and performance measures for the system. Each step of the proposed system is outlined as follows:

A. Dataset Collection and Description

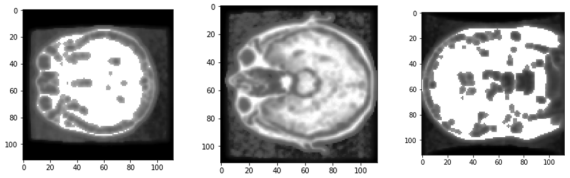


The brain tumor dataset retrieved from [7] comprises 3064 T1-weighted contrast-enhanced images. The dataset is collected from 233 patients with three kinds of brain tumor: meningioma (708 images), glioma (1426 images), and pituitary tumor (930 images). The dataset is arranged in MATLAB data format (.mat file). Each file reserves a struct comprising various fields of an image. These fields include the label (1 for meningioma, 2 for glioma, 3 for pituitary tumor), PID (patient ID), image data, tumor border, and tumor mask.

B. Preprocessing

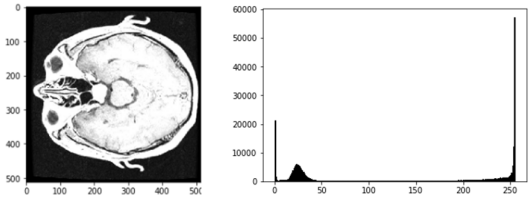


We used two fields, i.e. label and image data from each of the mat files. Fig. 1 illustrates the stepwise preprocessing of the work. The original images are 512×512 in size.

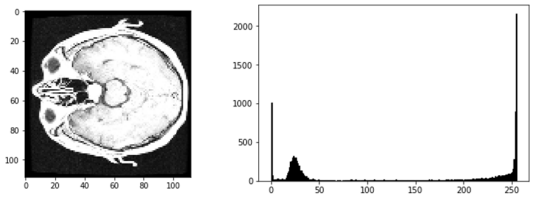


(a) Original image (512×512)

(b) Resized image (112×112)



(c) Filtered image (112×112)



(d) Equalized image (112×112)

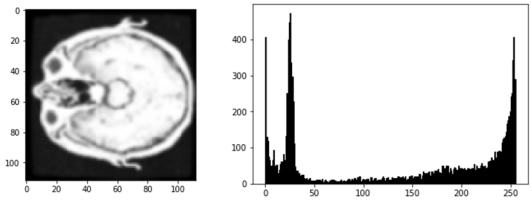


Fig. 1. Stepwise preprocessing outcome for tumor classification

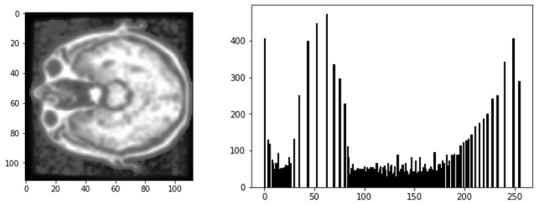

(a). Histogram of original image (512×512)

(b). Histogram of resized image (112×112)

(c). Histogram of filtered image (112×112)

(d). Histogram of equalized image (112×112)

Fig. 2. Histogram of different preprocessing step image

First, we resize the images in 112×112 and then apply Gaussian filter with kernel size 5×5. Gaussian filter smooths the image. In 2-D, Gaussian function has the following form:

$$G(x, y) = \frac{1}{2\pi\sigma^2} e^{-\frac{x^2 + y^2}{2\pi\sigma^2}} \quad (1)$$

where x denotes the distance from the origin in the horizontal axis, y denotes the distance from the origin in the vertical axis, and σ denotes the standard deviation of the Gaussian distribution.

Then, histogram equalization is used on each of the images. Histogram graphically illustrates the intensity distribution of an image. Histogram Equalization is an image processing technique, and it enhances the contrast of images. It manages to achieve this by spreading out the most frequent intensity values of the image. Fig. 2 shows the histogram of different preprocessing step image.

The total dataset is divided into three sets. These sets include train set (2051 images), validation set (513 images) and test set (500 images). Hence, the train, validation and test set contain 66.9%, 16.7%, 16.3% of the dataset respectively. The train set is used to train the CNN model.

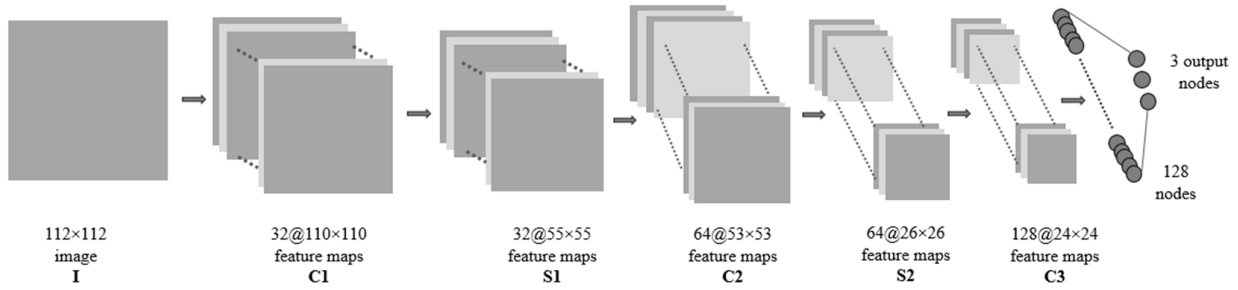

Fig. 3. CNN architecture of the model (**I, C, S** represent input image, convolution and subsampling respectively)

The validation set gives an unbiased assessment of the model while tuning the model's hyperparameters. The test set determines how well the model has been trained by evaluating the accuracy of the picked approach.

C. Tumor Classification using CNN

CNNs are unusually multi-layer neural networks. It is an effective recognition algorithm applied in pattern recognition and image processing [8]. It simulates the biological neural network through shared weight network structure. CNN is broadly practiced in the field of computer vision problem. It comprises the property of parameter sharing which decreases the number of parameters needed for the model compared to ANN (Artificial Neural Network). Moreover, the quality of the features extracted by CNN is very standard. In the CNN model we apply a series of convolution + pooling operations, followed by a fully connected layer. As we are implementing multiclass classification, the final output layer is softmax.

In our work, we used convolution on the input image using a convolution filter to generate a feature map. A 3×3 kernel is used as convolution filter. Strides = (1, 1), padding = 'valid' is used for this operation. Stride defines how much the convolution filter is moved at each step. Padding is 'valid' represents zero padding. Fig. 3 illustrates the CNN architecture that is used for this work. It includes 3 convolution layers (C1, C2, C3) with a kernel size of 5×5, 2 subsampling layers (S1, S2) with a pooling window of 2×2.

In first convolution (C1), the input image I with size 112 ×112 convolved with 32 filters with zero padding and stride = 1 which produced 110×110 sized 32 convolved features. Hence, total parameters for this operation are (3×3+1) ×32 = 320. These parameters will be learned by the algorithms in the training phase. In every convolution layer ReLU (Rectified Linear Unit) is used for activation function. It increases the non-linearity in the images. The features that are generated by the C1 layer are fed into first subsampling layer (S1). In subsampling layer max pooling is used with a window size of 2×2. Hence, 32 pooled feature maps each with size of 55×55 are produced. Pooling decreases the number of parameters which reduces the training time. Then a dropout layer is used with a dropout rate of 25%. Dropout is a regularization technique that is used to reduce overfitting [9]. Dropout is only used during training phase of the model. In dropout, some randomly selected neurons are ignored during training phase according to the dropout rate, i.e. their contribution in activating downstream neurons is shut down on the forward pass and during the backward pass, any weight updates are not applied on the neurons.

TABLE I. TRAINABLE PARAMETERS FOR CNN MODEL

Layers	Parameters
Conv2D (C1)	320
Conv2D (C2)	18,496
Conv2D (C2)	73,856
Dense (1)	9,437,312
Dense (2)	387
Total	**9,530,371**

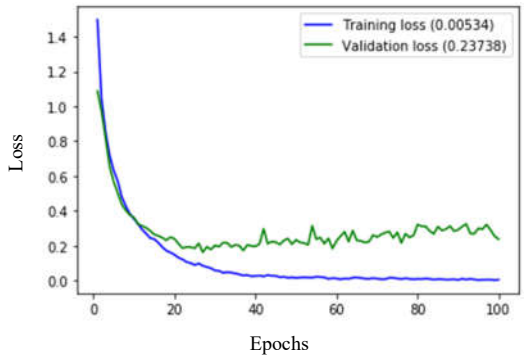
In second convolution layer (C2), 64 convolution filters are used on the previous layer's features map that result in 64 convolved features map each with a size of 53×53. Hence, total parameters for this operation are (32×3×3+1) ×64 = 18,496. These features are fed to second subsampling layer (S2) that also uses max pooling with window size of 2×2. Therefore, 64 pooled features map each with 26×26 are generated. Then, a dropout layer with 25% dropout rate is used.

In the third and final convolution layer (C3) 128 filters are used which results in 128 features map each with size 24×24. Here, total parameters are (64×3×3+1) ×128 = 73,856. Then we used another dropout layer with a dropout rate of 40% and flatten the output. Then the generated features are fed to a dense layer with 128 nodes. Here, total parameters are (24×24×128+1) ×128 = 9437312. Then, again a dropout layer with 30% dropout rate is used. Finally, we used another dense layer with softmax activation and 3 nodes for the classification. Hence, total parameters will be (128+1) ×3 = 387. The total trainable parameters for the model are shown in Table I.

D. Performance Evaluation

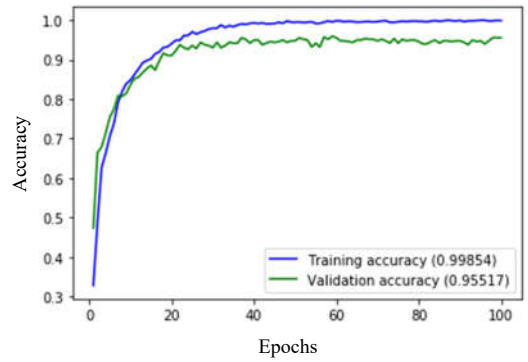
The performance of the system is analyzed using confusion matrix, precision, recall, f1-score, support and ROC (Receiver Operating Characteristic) curve. For calculating precision, recall, f1-score the following formulas are used.

$$Precision = \frac{True\ Positive}{True\ positive + False\ Positive} \quad (2)$$



$$Recall = \frac{True\ Positive}{True\ positive + False\ Negative} \quad (3)$$

$$F1\text{-}score = 2 \times \frac{Precision \times Recall}{Precision + Recall} \quad (4)$$



ROC curve represents a plot of the true positive rate (Sensitivity) versus the false positive rate (100-Specificity) for different cut-off points. In micro-average ROC scheme, the necessary individual value for different classes is summed up to compute the average while a macro-average ROC curve will calculate the required values for each class independently and then take the average. The area under the ROC curve (AUC) is a measure of how well the model is distinguishing between different classes. An area of 1 is considered to be the best in evaluating test cases.

IV. Result Analysis

After developing the CNN model, the model is compiled with Adam optimizer. It is a very powerful optimization algorithm used for training deep neural networks. It combines the advantages of two optimization methods i.e. AdaGrad (Adaptive Gradient Algorithm) and RMSProp (Root Mean Square Propagation) [10]. For fitting the training data with the model, a batch size of 256 and 100 epochs are used. Fig. 4 illustrates the loss and accuracy of the training set and validation set for 100 epochs. After evaluating the model on test data, we achieved a loss of 28.16% and an accuracy of 94.39%. Fig. 5 depicts the ROC curve. The closer the ROC curve is to the upper left corner, the higher the overall accuracy [11]. It also includes micro-average and macro-average ROC curve. Furthermore, it shows that the area under the curve ranges from 0.99 to 1 for the different classes which are desirable for the test cases.Table II represents the confusion matrix for the CNN model. For testing the model, 500

(a). Loss vs Epochs

(b). Accuracy vs Epochs

Fig. 4. Loss and Accuracy curve for 100 epochs

TABLE II. CONFUSION MATRIX FOR THE MODEL

	Class 1 (Glioma)	Class 2 (Meningioma)	Class 3 (Pituitary)
Class 1 (Glioma)	88	12	3
Class 2 (Meningioma)	13	213	0
Class 3 (Pituitary)	0	1	170

images are used. The model identifies class 3 (pituitary tumor) more accurately than other classes. From 171 pituitary tumor images, it can successfully recognize 170 as pituitary while locating 1 as meningioma and 0 as glioma. The ability of the model to predict the other tumor class is also satisfactory.

Table III illustrates some performance measure indices for the model. It shows that precision, recall, f1-score and support are used to evaluate the model. The model achieved the precision of 88%, 94%, 98% for Class 1(Glioma), Class 2 (Meningioma) and Class 3 (Pituitary) respectively which gives the average precision of 93.33%.

A comparison is exhibited in Table IV between several methods from different papers which used the same dataset. It shows that our model gives the highest average precision of 93.33% among the different methods. The CBIR method with BoVW and REML [6] also performs well with the average precision of 93.1%.

TABLE III. PERFORMANCE MEASURE INDICES

Class	Precision	Recall	F1-score	Support
Class 1 (Glioma)	0.88	0.85	0.87	103
Class 2 (Meningioma)	0.94	0.95	0.94	226
Class 3 (Pituitary)	0.98	0.99	0.99	171

TABLE IV. COMPARISON WITH EXISTING METHODS IN TESTING PHASE

Methods	**Average Precision (%)**
CBIR [4]	89.3
CBIR with BoVW [5]	91
CBIR with BoVW and REML [6]	93.1
Proposed model using CNN	**93.33**

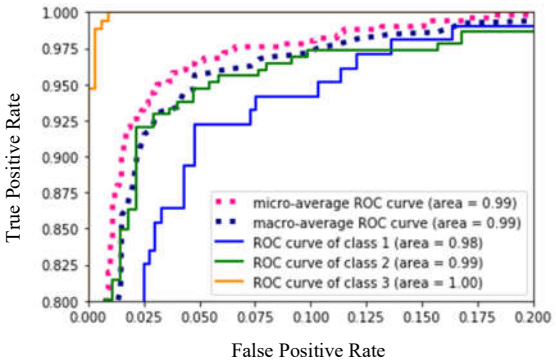


Fig. 5. ROC (Receiver Operating Characteristic) curve of the system

V. CONCLUSIONS

Brain tumor classification is very crucial in the domain of medical science. In this paper, we concentrated on developing a CNN classifier which classifies among three important tumor classes (glioma, meningioma, pituitary). Initially, the proposed system preprocesses the image data. The preprocessing includes filtering images using Gaussian filter and applying histogram equalization technique on the filtered images. Then the system classifies the images using the CNN model. The number of parameters of the model is too high, and the model is trained on a significantly small amount of data. Hence, there is a possibility of overfitting. To prevent the overfitting, a regularization technique, i.e. dropout regularization is used on the model. It helps the model to concentrate on the most prominent patterns during the training phase. Therefore, there is a better chance of generalization which keeps the model stable. The model ends up with the accuracy of 94.39% and an average precision of 93.33%. Hence, the CNN classifier will be very significant in the medical field and in saving precious lives.

***Abstract*—The Agricultural sector plays a vital role in sustainable economic growth and food security. However, crop diseases often cause a great threat in achieving this goal. As such, a successful outcome depends entirely on proper detection and classification of plant diseases. This has created many opportunities of new possibilities for researchers. Nowadays, a lot of work is being done to recognize and classify plant diseases more precisely using computer vision. The objective of this research is to create a methodology that will provide a better solution to classify plant diseases. This work mainly focuses on implementing an improved segmentation technique using a combination of thresholding and morphological operations. For classification, we have used the deep neural network. Our proposed method has achieved 99.25% accuracy in Plant Village database.**

***Index Terms*—segmentation, image processing, disease detection, plant leaf disease, deep neural network.**

I. Introduction

Bangladesh is a developing country and it is very important to increase food production in order to support its rapidly growing economy. Bangladesh is trying to become self-sufficient in producing food. However, crop loss due to various diseases poses a great threat in achieving that goal. There are several plant leaf diseases in Bangladesh. Leaf disease detection using one's bare eye is quite difficult for both general people as well as farmers. Furthermore, consulting an expert in this field is not always possible for the rural farmers of Bangladesh. As a result, farmers face several problems in controlling the diseases on crops and often have to face a massive loss in terms of production. Sometimes, it is also very difficult to identify a disease as symptoms of many different leaf diseases are quite similar. Most of the times, farmers fail to take the necessary steps even if they may have been able to identify the problem. Moreover, in some rural areas of Bangladesh, farmers cannot get rid of these problems because they do not have proper knowledge or education on how to do so. Most of the cases involve leaf diseases which are not recognized properly, and farmers end up using insecticides which may not be suitable for that particular disease. If an artificial intelligent (AI) system can detect disease from an image of any diseased leaf, it will be incredibly helpful for this industry. From this thought, we are going to provide new techniques of image pre-processing and a new combination of feature set from the processed images to make a trained model that will show how accurate our methodology is to detect diseases accurately.

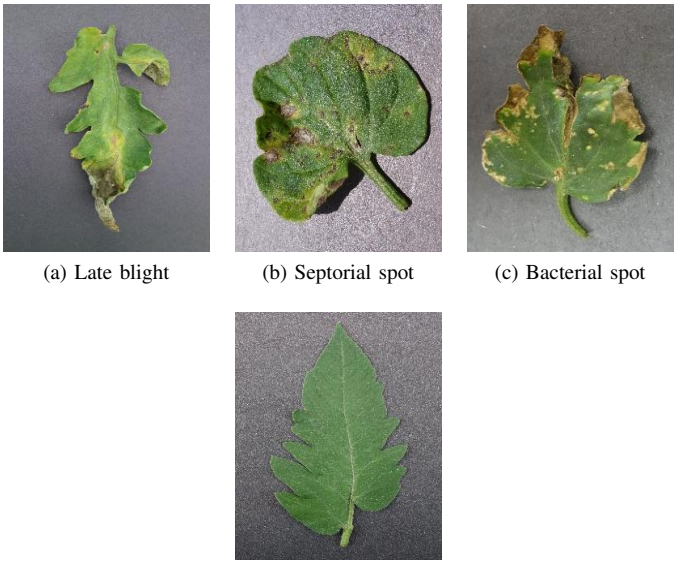
In this work, the proposed new methodology can detect leaf diseases accurately. Among various plant leaf diseases, tomato leaf disease is one of them. This work is based on three tomato leaf diseases, they are - Bacterial Spot, Late Blight and Septorial Spot. These diseases are common tomato leaf diseases in Bangladesh. The method we proposed consists of four main phases which are: image enhancement, segmentation, feature extraction and classification. This work focuses mainly on image segmentation and feature extraction techniques.

II. Related Works

Tm et al. [1], have used convolution neural network to detect tomato leaf diseases. Their proposed methodology has three stages- data acquisition, data pre-processing and classification. The plant village dataset is used as dataset. For image pre-processing, the image was normalized using the mean and the standard deviation. This is also known as Z-score method. For classification, Le-Net architecture is used for convolution neural network. Though the proposed method gave a high accuracy, it is also computationally heavy which may cause problems for larger datasets.

C. G. Dhaware et al. [2], represent techniques for detecting infected parts of plant leaves. Images are pre-processed with the help of RGB to HSV conversion technique. Cluster based method background subtraction is used for segmentation. Correlation, energy, homogeneity etc. features are also used. For image classification, support vector machine (SVM) technique

is used. In this approach, the dataset was very small and thus showed high accuracy. Additionally, there was no exact diseases classification of infected leaf.



U. Mokhtar et al. [3], describe a method of detecting tomato leaf diseases detection based on support vector machines. In image pre-processing phase they had used three techniques such as leaf image isolation and extraction, image resizing and background subtraction technique with some morphological operations. Color and texture have been considered as features. For extracting texture Gabor filter is used. For the classification phase, support vector machine technique is used.

T. N. Tete et al. [4], describe a method of detecting plant disease based on a clustering method. This process is divided into four parts- pre-processing, segmentation, feature extraction and classification. Infected parts are segmented with the help of thresholding and k-mean clustering method. For classification, artificial neural network algorithm is used.

III. Dataset Description

Images are collected from publicly available Plant Village [5] database. It contains about 54306 images of diseased as well as healthy leaves of 14 different types of crops. Fig 1 shows some sample images of tomato leaf from the dataset. Here 2000 images of tomato leaves are analyzed which have following class labels:

- Late blight affected tomato leaf.
- Septorial spot affected tomato leaf.
- Bacterial spot affected tomato leaf.
- Healthy or Non-diseased tomato leaf.

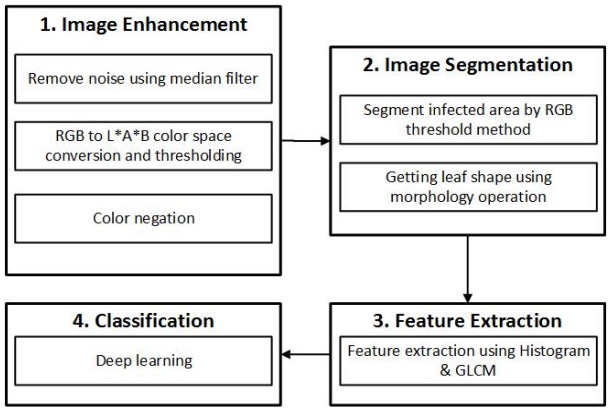
(a) Late blight (b) Septorial spot (c) Bacterial spot

(d) Healthy leaf

Fig. 1: Images of infected and healthy tomato leaves

IV. Proposed Methodology

The proposed method includes four important stages namely: enhancement, segmentation, feature extraction and classification. Steps of proposed methodology are shown in Fig. 2



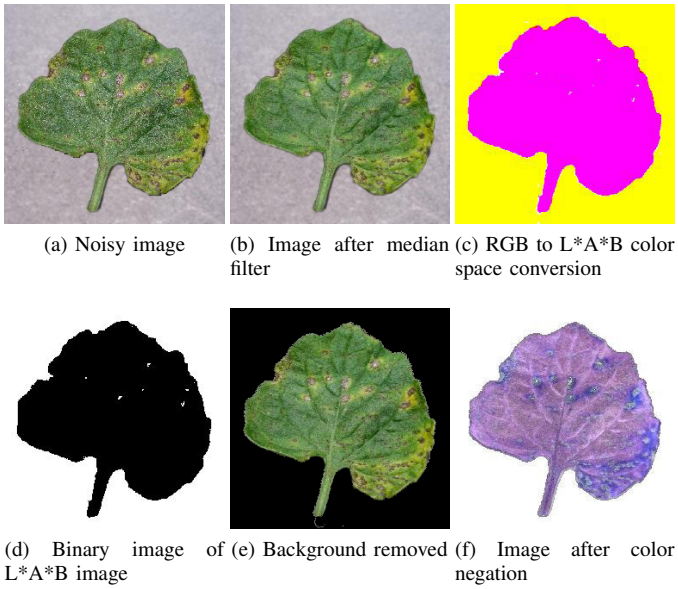


Fig. 2: Flowchart of our proposed methodology

A. Image Enhancement

Image enhancement technique is used so that input image will be more detailed and become more suitable for further experiment and analysis. Here, there are three image enhancement techniques-

- Median filter
- RGB to L*A*B color space conversion and threshold
- Color negation

First we have used median filter technique, which provides almost noise free image. On this less noisy image RGB to L*A*B color space conversion and threshold techniques are used [7], which removes background of the leaf image and provides an image having a black background. Finally, color negation technique is applied on that image which will be helpful in segmentation process. Image enhancement process are presented in Fig. 3.

(a) Noisy image (b) Image after median filter (c) RGB to L*A*B color space conversion

(d) Binary image of L*A*B image (e) Background removed (f) Image after color negation

Fig. 3: Image enhancement

B. Image Segmentation

Here two image segmentation techniques are applied. These techniques are -

- RGB threshold
- Morphological operation.

After color negation, the healthy green part of the leaf becomes magenta and the infected area become a different color. Then RGB threshold technique is used and threshold value based on blue and red level intensity as magenta color is located midway between red and blue. After RGB threshold we would be able to get infected part of the leaf. After that, morphological operation is used to achieve the leaf shape. Here we used 3*3 cube shaped structural element. If A is our color negated image and B is the structural element then mathematical formulation of output image are presented in equation 1 and output of segmentation process are shown in Fig. 4.

$$Y = (A \oplus B - A)' \tag{1}$$

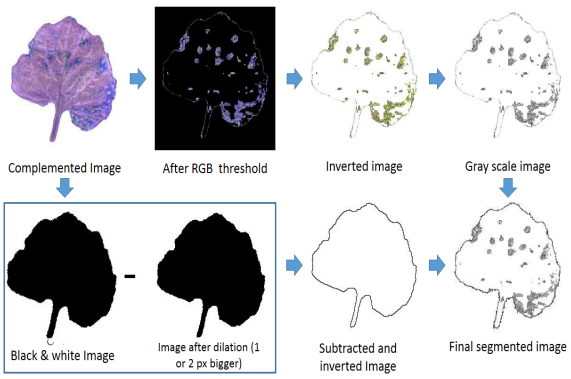

Fig. 4: Output of segmentation process

C. Feature Extraction

Some unique properties of each image from the dataset are needed to be extracted for machine learning purposes. Those unique properties are known as features of that data and the process of extracting the features is called feature extraction. In this phase, we have extracted features from GLCM and graylevel histogram and the size of feature vector is 260. Fig. 5 shows a sample image which is used for feature extraction.

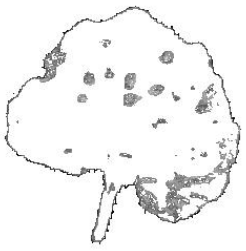

Fig. 5: Segmented grayscale image for feature extraction

1) Gray-Level Co-Occurrence Matrix (GLCM): A statistical method of examining texture that considers the spatial relationship of pixels is the gray-level co-occurrence matrix (GLCM). The GLCM characterizes the texture of an image by calculating how often pairs of pixel with specific values and in a specified spatial relationship occur in an image. By creating a GLCM and then we can extract statistical measures from this GLCM. We can retrieve following statistical information from a GLCM of an image - contrast, correlation, energy, homogeneity [8] [9] [10]. Mathematical formulation of GLCM features are given below TABLE I-

TABLE I: Mathematical Formulation of GLCM Features

Feature	Mathematical Formulation
Contrast	$\sum_{i,j} \lvert i-j \rvert^2 p(i,j)$
Correlation	$\sum_{i,j} \frac{(i-\mu i)(j-\mu j)p(i,j)}{\sigma_i \sigma_j}$
Energy	$\sum_{i,j} p(i,j)^2$
Homogeneity	$\sum_{i,j} \frac{p(i,j)}{1+\lvert i-j \rvert}$

Each of the GLCM statistical features signify some unique property of the image. Contrast is a measurement which represents local variations present in the image. Value of correlation indicates a linear relationship between gray levels of pixel pairs. Energy measures the repetition of pixel pairs of an image which is also known as textural uniformity. Homogeneity has a relationship with contrast and energy feature of GLCM. At constant energy, homogeneity is inversely proportional to contrast.

2) Gray level Histogram: An image is a set of pixels or points of different intensity values [11]. A histogram for any image is such representation where it shows the number of pixels in an image at each different intensity value found in that image. There are 256 different possible intensities for an 8-bit grayscale image. We have extracted 256 different 8-bit values from gray level histogram for each segmented image like Fig. 5.

D. Classification

Neural networks are a set of algorithms that are designed to recognize patterns. A deep learning neural network is an artificial neural network with multiple layers between the input and output layers. The deep learning neural network finds the correct mathematical manipulation to turn the input into the output, whether it be a linear relationship or a non-linear relationship. In this work, deep neural network is used for classification.

We have used Python as programming language for setting up our deep learning: neural network model. Deep learning library Keras has been used in this purpose. Keras is a high-level neural networks API, written in Python and capable of running on top of TensorFlow.

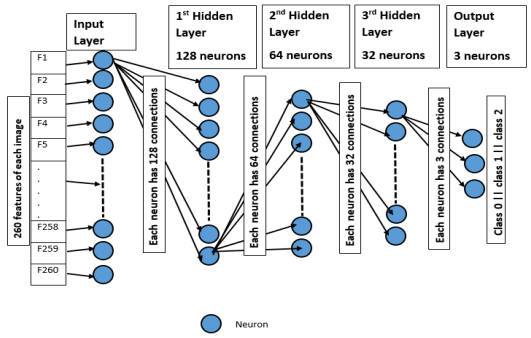

Fig. 6: Deep learning neural network model

Fig. 6 shows our deep learning neural network model. Our neural network model is a fully connected network, i.e., each layer of neuron is connected with all other neurons of the next layer. To simplify the image shown in Fig. 6, we are showing how one neuron of each layer is connected with all other neurons of next layer.

In our deep neural network model, there is one input layer, one output layer and three hidden layers. The input layer has 260 neurons as our dataset has 260 features of each data and the output layer has three neurons as we are classifying among three disease classes. In hidden layer neurons, we have used Rectified Linear Unit (ReLU) as the activation function [12] and in output layer neurons we have used Softmax as the activation function.

In this model, we have used Stochastic Gradient Descent (SGD) for weight update. SGD does sequential weight update or one update at a time. SGD slowly decrease the learning rate and SGD almost certainly converging to a local or the global minimum. We have used Minimum Squared Error (MSE) loss function. MSE is the sum of squared distances between our target variable and predicted values.

$$MSE = \frac{\sum_{i=1}^{n} (y_i - y_i^p)^2}{n} \tag{2}$$

In the equation 2, y_i and y_i^p represents actual and predicted value respectively.

V. Experiment & Result Analysis

For experiment, we have selected three diseases from Plant Village database to evaluate our proposed method. The disease name and corresponding number of images are shown in TABLE II. We have used 80% of the total image for training and the remaining 20% image data for testing. All of these images have been chosen randomly.

TABLE II: Disease Name and Corresponding Number of Images

Disease Name	Number of Images
Late Blight	500
Septorial Spot	500
Bacterial Spot	500
Healthy leaf	500
Total	2000

TABLE III: Performance Metric

	Precision	Recall	F1 Score	Support
0: Late Blight	0.97	1.00	0.99	100
1: Septorial Spot	1.00	0.97	0.98	100
2: Bacterial Spot	1.00	1.00	1.00	100
3: Healthy leaf	1.00	1.00	1.00	100
Avg/Total	**0.99**	**0.99**	**0.99**	**400**

TABLE IV: Confusion Matrix

```
[[100   0   0   0]
 [3    97   0   0]
 [0     0 100   0]]
 [0     0   0 100]]
```

The performance metric for histogram & GLCM feature combination is presented in TABLE III. The average precision, recall and f1-score hold a good score for our proposed feature combination. TABLE IV shows the confusion matrix, where 100 of 100 Late Blight disease, 97 of 100 Septorial spot disease, 100 of 100 Bacterial Leaf Spot disease and 100 of 100 healthy leaves are detected correctly. In this experiment, our proposed method achieves 99.25% accuracy.

We also compared our segmentation method with widely used k-mean clustering segmentation method [13] [14]. Both methods are tested under the same environment and the testing environment setups are shown in TABLE V.

TABLE V: Environment Setup

Segmentation Method	Features	Classifier
Our Proposed Method	Histogram & GLCM	Deep learning
K-mean Clustering	Histogram & GLCM	Deep learning

The precision and recall curve is a widely used metric to understand which model performs better. Fig. 7 and Fig. 8 shows precision and recall curve of k-mean method and our proposed method respectively. From these figures, we can see that our proposed method outperforms the K-mean clustering method.

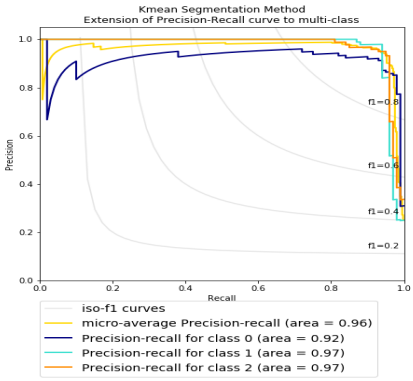

Fig. 7: Precision and recall curve of k-mean model

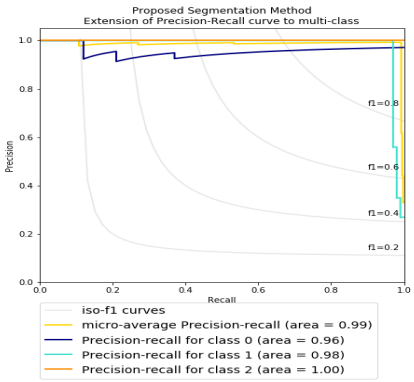

Fig. 8: Precision and recall curve of our proposed model

TABLE VI: Accuracy Comparison

	Our Proposed Method	**K-mean Clustering**
Accuracy	99.25%	93.25%

TABLE VI clearly shows that our proposed method is more effective and accurate than k-mean clustering method.

VI. Conclusion

The proposed method of this research focuses on improved segmentation approach for plant leaf disease identification. It is an effective segmentation technique and doesn't require any kind of heavy computational power. However, there is a scope to improve our work in the future by reducing feature vector size as well as keeping the classification accuracy higher. This research work can be extended by integrating a larger number of diseases of different species of plants.

Abstract— **Cancer is a kind of cell that develops out of control of the regular drives that normalizes growth. Breast cancer is one of the deadly forms of cancers for the human. Initial detection of cancerous tissues is likely to monitor the patient's strength to deal with the disease and live more. Electronic modalities are applied to diagnose breast cancers. Due to low cost and safety, ultrasound scanning is considered as one of the most frequently used electronic modalities for breast cancer detection. This research study proposed an automated approach for breast cancer detection using ultrasound gray-scale images. To this end, enhancement operation was used at the beginning to minimize the gray-scale color shifts. Median filter was used to facilitate better segmentation removing maximum unwanted noises. Threshold-based segmentation (Threshold based OTSU) was used as the test images used in this study are gray-scale images. Finally, necessary feature information that is used in the pathology laboratory by pathology experts is used in this study to identify the ROI (Region of interests) to detect breast cancer tissues. This study proposed approach achieved an average accuracy rate of 93.11%. The depicted experimental outcomes of the proposed approach outperform other contemporary existing available approaches in terms of accuracy while maintaining the medical experts' acceptable accuracy rate.**

Keywords— Breast Cancer, Ultrasound Gray-scale Images, Threshold based OTSU.

I. INTRODUCTION

CANCER is the uncontrolled growth of abnormal cells anywhere in a body [1]. There are more than two hundred kinds of cancer including breast cancer, lung cancer, ovarian cancer, leukemia, prostate cancer, cervical cancer, pancreatic cancer, brain tumor etc. [1]. The most widely recognized cancer is breast cancer that found more in ladies both within the developed and less developed countries. Breast cancer is believed to be an ailment of the developed world, right around half of the breast cancer cases and 58% of all deaths happen in less developed nations (GLOBOCAN 2008) [2]. Breast cancer creates breast cancer tissues [3]. Signs of breast cancer may incorporate an irregularity in the breast, a trade in breast shape, dimpling of the skin, and liquid originating from the nipple, a newly inverted nipple, or a purple or scaly patch of skin [4]. Lack of early detection of breast cancer is high proportion in women. It becomes severe in the late stage and the lack of adequate diagnosis and treatment facilities [2]. Early detection of breast cancer can be possible by using breast ultrasound screening.

Breast ultrasound screening (BUS) is one of the most widely used diagnostic tools to utilize and classify abnormalities of the breast. It is most appropriate for substantial scale breast cancer screening and determination in low-asset nations and areas. Automatic breast ultrasound image segmentation is vital for most cancer diagnosis and arranging treatments [5]. Ultrasound is an easy and painless system that uses sound waves to generate images of the inner of the body [5].

This research study focused on medical image processing approaches for breast cancer tissue identification and proposed an automatic breast cancer detection approach where ultrasounds images are processed. To detect the cancer region accurately this research study incorporated ultrasounds images and were processed in two different stages which include pre-processing (Enhancement, Filtering, Segmentation), and post-processing (Feature selection, Identification of ROI, Classification).

II. RELATED WORKS

Many research works have been carried out on breast cancer analysis. For breast cancer segmentation research work in [6] incorporated ultrasound images and allowed faster and more accurate radiographic contouring. The aim of the paper was to present a new method for ultrasound image segmentation of breast lesions. The Dice Index was greater than 80%. However; this existing work depends on the radiologist and not fully automated (semi-automated).

Another research work [7] proposed an automated approach to achieve error-free detection for breast cancer. The study conducted on three stages including Pre-processed Image, Pectoral Muscle Removal, and Segmented Breast Profile. Decision trees, K-nearest Neighbor (KNN), Support Vector Machine (SVM) and Random Forest classifier were used and their performances were compared. The Random Forest Classifier performed better compared to other methods in breast cancer detection.

Research work [8] reported that deep learning approach performs well in general object detection. Additionally,

convolutional neural network-based method, Single Shot Multi-Box Detector (SSD) was also used. A new dataset was collected consisting of 579 benign and 464 malignant lesion cases and the result showed that the convolutional neural network-based method achieved the best performance in terms of both precision and recall. But the resultant bounding box carries extra regions which are not cancer tissue at all. Their future work indicates that they need some automated segmentation techniques to detect tumor areas.

Proposed approach by [9] mentioned that the nodule of the breast can be automatically segmented by neutrosophic set and watershed method with some extra unwanted regions.

Research work of [10] applied watershed algorithm in breast cancer ultrasound images to extract precise contours of the tumors. During pre-processing median filter used to preserve the edges of the tumor lesion. Threshold was calculated for background and foreground areas. As a result, the method defined the contours of breast tumors in ultrasound images, and the results were close to ground truth data. However; their work failed to detect breast tumor region/regions where shadows are present inside the images.

III. Proposed Method

The working steps of the proposed method are shown in Fig. 1. The first step begins with image acquisition. Further steps are subcategorized as pre-processing and post-processing. Pre-processing includes image enhancement, filter operation and segmentation. Post-processing includes feature extraction, identification of ROI and finally classification approach to improve the accuracy rate.

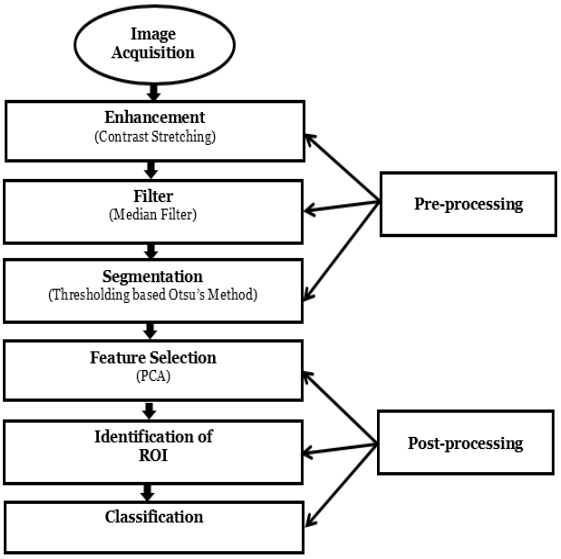

Fig. 1: Proposed method to detect breast cancer tissues

A. Image Acquisition

Image acquisition is the first step for image processing approach. Ultrasound images were collected from the pathology laboratory for this study test data set. Collected test data set was .PNG and each image size was 350 × 350.

B. Pre-processing

Pre-processing has three stages which include

a. Enhancement
b. Filter
c. Segmentation

a. Enhancement

Ultrasound RGB grayscale images were converted into HSV format as HSV color model performs better [18]. Contrast enhancement was performed on V channel. The resultant V has subtracted from initial V and the resultant images were converted back to RGB. An enhanced image of this study is shown in Fig. 2.

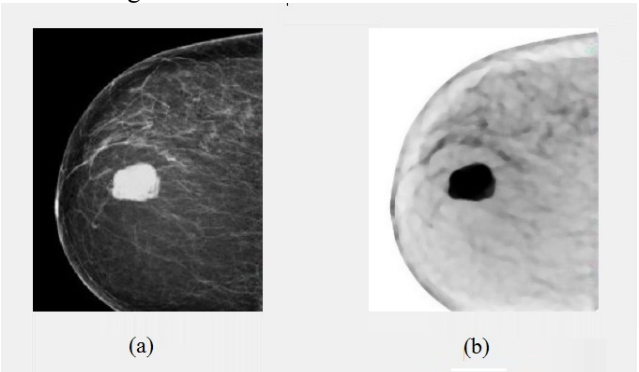

Fig 2: (a) Original test image, (b) Applied enhancement approach (contrast stretching)

b. Filter Operation

It is important to remove unwanted regions as much as possible before any segmentation approach is applied as a fact that a better segmentation leads to a better identification of regions of interests. In this study median filter was applied and compared with the results of mean and Gaussian filters. Median filter showed better results in compare to other approaches as a fact that median filter is capable to preserve image edges [15-17]. After applying a number of sampling window (starting from [3x3] to [21x21]) this study found that [7×7] sampling window performs better results. Fig. 3 indicates the filtered result of this study test image.

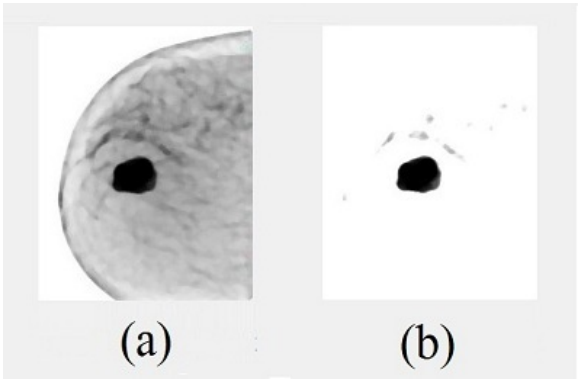

Fig 3: (a) Test image from step one (image enhancement), (b) resultant image using median filter

c. Segmentation

To extricate significant features from an image it is necessary to use segmentation approach. Threshold based gray-scale segmentation approach is considered as one of the most popular approaches. Among them Otsu's method used widely as it computes the threshold value a few times than other techniques [11].

In this study Otsu's threshold-based segmentation approach was incorporated. However; instead of considering all 3 color channels of RGB gray-scale image (R, G, B channel) this study investigated and discovered that only green and

blue channels are necessary to segment the breast cancer tissues more precisely. Therefore; for this study test images only green and blue channels were considered for segmentation using Otsu's method. Fig. 4 shows the result of the image after applying Otsu's threshold segmentation approach.

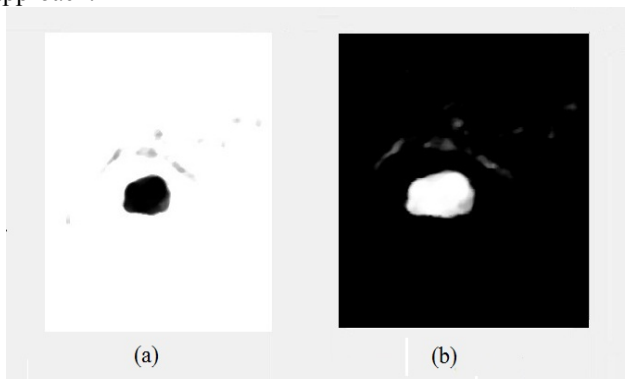

Fig 4: (a) Test image from step two (Median Filter), (b) Resultant image after segmentation

C. Post-processing

There are three parts of Post-processing. Such as:

a. Feature Extraction
b. Identification of ROI
c. Classification

a. Feature Extraction

To identify the region of interest shape, size and color features are required. As this research study used gray-scale images therefore; color features were ignored. Pathology laboratory experts' provided features were used in this research study which includes regions area, circularity, solidity, roundness, radius and diameter.

b. Identification of ROI

Using the features mentioned in the previous section identification is carried out to identify the region of interests.

c. Classification

After identification it was found that the accuracy rate was above 90% and the accuracy rate was accepted by the pathology laboratory experts. However; this research study tested with SVM classifier to check if it is possible to increase the accuracy rate. Accuracy rate did not increase and thus it is not necessary to use classifier at all as a fact that already the results have been accepted by the experts.

IV. Experimental Results

A. Result Analysis of the proposed method

In total 3 different datasets were used in this research study. Table 1 show that in batch 1 in total 130, in batch 2 in total 123 and in batch 3 in total 110 test images were analyzed.

.TABLE 1
Result Analysis of the proposed method

Dataset (No. of Images)	True Positive (TP)	True Negative (TN)	False Positive (FP)	False Negative (FN)	Accuracy
Batch1 (130)	122	1	4	3	93.85%
Batch2 (123)	112	2	4	5	91.06%
Batch3 (110)	104	1	2	3	94.55%
Total = 363	338	4	10	11	**Average = 93.11%**

Table 1 also indicates the accuracy rate for each batches used in this research study where for batch 1 the accuracy rate is 93.85%, for batch 2 the accuracy rate is 91.06% and for batch 3 the accuracy rate is 94.55%. According to pathology experts information, ultrasound image accuracy rate ±17% is acceptable. This proposed method was capable of obtaining an average accuracy rate of 93.11% which is acceptable in the pathology laboratory.

B. Experimental Outcomes

The experimental results of this proposed method is shown in Fig. 5. Three breast cancer test images with there results are shown in Fig 5.

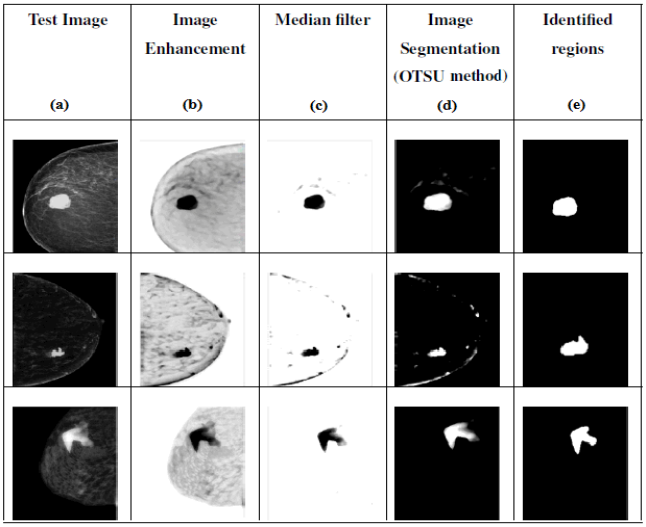

Fig. 5: (a) Test Image (b) Image Enhancement (c) Median Filter (d) Image Segmentation (OTSU Method) (e) Identified Regions

C. Comparative Results analysis

Using the images of an existing research study [14] images it was found that this study proposed approach was able to identify the breast cancer tissues accurately whereas; in [14] a number of unwanted regions were also identified which can confuse the experts' shown in Fig 6.

Fig. 6: Comparative Cancer detection using our proposed method and other existing approaches.

Although the accuracy rate is acceptable by the pathology laboratory experts' but is it still possible to increase the accuracy rate further if and only if the intra and inter-observation variability issues among pathology experts' can be minimized.

V. Conclusion

Manual detection of breast cancer tissue is more time consuming and the success rate normally depends on the person's skill. In this study, an automated approach has been proposed which is less complicated and takes less time with high precision. The aim of this research was to identify the breast cancer tissues correctly while maintaining the pathology experts' accuracy rate. Pathology laboratory experts already accepted the test results and the accuracy rate. However; in future this study will investigate further if it is possible to come up with another idea where it will be possible to increase the accuracy rate further.

Acknowledgment

This study delightedly acknowledges Dr. Sadequel Islam. Talukder (asst. Professor. Kishorgonj Medical College, Bangladesh) a pathology expert for providing the test datasets and necessary feature information for this study. This study also would like to acknowledge Green University of Bangladesh for relentless technical support.

***Abstract*—Dermatological diseases are the common and most extensive diseases worldwide. Diagnosis of dermatological diseases as well as skin cancer diseases is extremely difficult during its early to mid-stages by visual examination. Current researches propose efficient approach which can identify maximum 3- 9 types of skin diseases. It is necessary to develop an automated system which can identify more than 9 types of skin diseases. In this paper, we propose a new automated system for various kinds of dermatological diseases detection. In this automated system, a new hybrid intelligent ACO-GA algorithm including Ant Colony Optimization Algorithm (ACO), Genetic Algorithm (GA), and tabu list is used for different types of skin lesion segmentation of dermatological images and Transductive Support Vector Machine (TSVM) is used for dermatological diseases identification. Ant Colony Optimization Algorithm and Genetic Algorithm work simultaneously to search most optimal cluster centers in the problem space. After image segmentation, pixels are divided into different classes. In testing phase, the testing samples are compared with training samples using TSVM classifier and features extraction which can give the accurate disease detection result. The result of the proposed system successfully detects 24 different types of dermatological diseases with an accuracy rate of 95%.**

Keywords—digital image processing, genetic algorithm, ant colony optimization algorithm, mathlab code, transductive support vector machine.

I. INTRODUCTION

Dermatology is the branch of medical science dealing with the skin, hair, nails with their diseases and it is one of the most unpredictable and difficult terrains to diagnose due to its complexity. Nowadays, people are suffering from different types of skin diseases such as scabies, psoriasis, leprosy, acne, tinea corporis, rosea, melanoma skin cancer, benign skin cancer, kaposi sarcoma, seborrheic keratosis, squamous cell, basal cell etc. Among them, more than 125 million people are suffering from psoriasis (Chronic skin disorder). Skin cancer for example melanoma skin cancer, basal and squamous cell skin cancer, lymphoma of the skin etc. rate is increasing over the few decades. Melanoma is most diversifying skin cancer and 75% of deaths associated with melanoma skin cancer [1]. Every year, in globally between 2 and 3 million people are suffering from non-melanoma skin cancer and 132,000 people are suffering from melanoma skin cancer in accordance with World Health Organization (WHO) [2]. Researchers have been attracted to diagnosis this type of problem. Dermatophytosis is high at rural area especially in developing countries like Bangladesh. In the developing countries like Bangladesh, it is expensive for a large number of people to consult a dermatologist for their skin diseases. Every year a large number of populations in the developing countries like Bangladesh suffer due to different types of skin diseases and it is a great challenge for us to overcome this problem. For this reason, we propose an automated skin disease detection system for the patients as well as dermatologists where a new hybrid intelligent ACO-GA algorithm is used for automatic colored skin image segmentation and TSVM classifier is used for automatic skin disease detection. In the hybrid algorithm, an intelligent ant colony optimization algorithm and evolutionary genetic algorithm is used for searching the most optimal cluster centers by segmenting the image pixels into different cluster centers using updated pheromone values and tabu list. After that, we use color co-occurrence method for features extraction of the segmented image. After features extraction, transductive support vector machine is used as a classifier to detect the skin diseases automatically.

II. LITERATURE REVIEW

Nowadays, medical science and its field largely depend on computer aided diagnosis. It is more complex to detect skin disease at early stage. Different types of skin diseases detection from color image is a very challenging task in computer vision. Digital image processing can play an important role for skin disease diagnosis and it is possible without any physical contact with skin. Not only image processing but also machine learning plays an essential role in the medical field for the automation as well as to predict what type of diseases present on the skin. Researchers have been attracted by this technology. That is why researchers have been proposed various kinds of skin diseases segmentation and classification systems. Wei, Li-sheng,

Quan Gan and Tao Ji [3] have proposed skin disease recognition method based on image color and texture features where SVM is used as a classifier for finding the diseases. Sumithra, R., Mahamad Suhil and D. S. Guru [4] have proposed a segmentation and classification method of skin lesions for disease diagnosis. They used SVM and K-NN classifier for the classification using the extracted features. Yasir, Rahat, Md. Ashiqur Rahman and Nova Ahmed [5] have developed different types of image processing algorithms for feature extraction. For diseases identification, they used feed forward artificial neural network in training and testing phase. Shoieb, Doaa A., Sherin M. Youssef and Walid M. Aly [6] have implemented a computer aided model for skin diagnosis using deep learning. In their research, they use convolution neural network for feature extraction and multiclass linear support vector machine (SVM) is used as a classifier to detect the diseases. Kumar, Vinayshekhar Bannihatti, Sujay S. Kumar and Varun Saboo [7] have proposed a dermatological disease detection system using image processing and machine learning. In their experiment, they used different types of machine learning algorithms such as ANN, Decision tree and K-NN for skin disease detection. Aswin, R. B., J. Abdul Jaleel and Sibi Salim [8] have introduced a hybrid genetic algorithm- artificial neural network classifier for skin cancer detection in where, ANN classifier is used for classification and it is optimized by genetic algorithm to improve the accuracy. L. G. Kabari and F. S. Bakpo [9] have made an artificial neural networks system for predicting the skin diseases and their accuracy rate is 90%. M. Shamsul Arifin, M. Golam Kibria, Adnan Firoze, M. Ashraful Amin and Hong Yan [10] have proposed an automated skin disease diagnostic system. In their research, they used different pre-processing algorithms and feed forward back propagation artificial neural network is used for diseases identification. F. Tushabe, E. Mwebaze and F. Kiwanuka [11] have proposed a classification method to classify the image as a bacterial or viral skin infection using image processing techniques. Nidhal K. Al Abbadi, Nizar Saadi Dahir, Mushsin A. Al-Dhalimi and Hind Restom [12] have developed a psoriasis diseases detection system using feed forward artificial neural networks. M. Ganesh Kumar and J. J. B. Vasanthi [13] have implemented the melanoma disease detection technique by using preprocessing and edge detection. Md. Khaled Abu Mahmoud, Adel Al-Jumaily and Maen Takruri [14] have designed an automatic skin cancer classification system using neural network classifier based on wavelet and curvelet features.

From the literature, we can see that most of the researchers consider only 3-9 types of skin diseases in their research work. The remaining skin diseases have the equal importance in the medical field. We get another motivation from this and so, we consider 24 types of skin diseases including the previous 3-9 types of skin diseases.

III. Limitation of Existing Work

The limitation of the existing works are: 1) consider only 3-9 types of skin diseases, 2) Lack of huge amount of training samples in database, 3) Computational complexity is very high in some cases, 4) low segmentation accuracy in color image 5) low detection accuracy in accordance with the limitation of proper classification system. For this reason, we develop a new hybrid intelligent ACO-GA algorithm for colored skin image segmentation and disease detection using TSVM classifier so that we can achieve more optimization, low computational complexity and high segmentation and detection accuracy.

IV. Proposed Methodology

We know real time problem is optimization problem. In our proposed system, optimization problem is developed. A new hybrid ACO-GA algorithm is used in this system because of its much more intelligent background with easier implementation and very low computational complexity.

Our implemented hybrid intelligent algorithm for dermatological colored image segmentation and type of skin disease identification using TSVM classifier that consists of some steps are given below:

A. Image Acquisition

The first step of our automated color image analysis system is image acquisition. In this step, a good quality of skin image is captured using a digital camera and it is then transferred into image preprocessing step for color transformation.

B. Image Preprocessing

Noisy image may lead algorithm towards incorrect result and it is necessary to have quality image without any noise to get accurate result. There are a variety of image preprocessing techniques such as median filter, Gaussian filter, contrast enhancement technique, region of interest technique for removing the noise from the image. We remove the noise using median filter and contrast enhancement technique. By using median filter and contrast enhancement technique, the image will be very smooth and sharp.

C. Hybrid ACO-GA Algorithm for Clustering in Image Segmentation Phase

The intelligent ACO algorithm is used for finding the most optimal cluster centers from the problem space. In ACO phase, swarm of ants is generated randomly and all ants are walking through the image pixels. Because, image consists of pixels and all the ants move from one pixel to another by accumulating pheromone value. However, they create cluster by their intelligent behavior. Every ant on the pixels calculates its transition probability and moves to the chosen pixel by the equation (1).

$$P_{mn}(t+1) = \tau_{mn}{}^{\alpha}(t)\ \eta_{mn}{}^{\beta}(t) / \sum_{i \epsilon\, s} \tau_{mi}{}^{\alpha}(t) \eta_{mi}{}^{\beta}(t) \quad (1)$$

Where, $\Delta\tau_{mn}^{k}$ denotes the pheromone value and η_{ij} denotes the heuristic information. In each iteration, every ant chooses one pixel of its adjacent eight pixels as its next shift and records the pixels into the tabu list. However, all the ants move from one pixel to another and record the pixels into the tabu list. It will be continued until total move is finished. After finishing all ants' path construction in each iteration, we get the best solution and record the best solutions' pixels into tabu list. After that, pheromone is updated for obtaining best solution by the equation (2).

$$\tau_{mn}(t+1) = (1-\rho)\tau_{mn}(t) + \sum_{k=1}^{k=N} \Delta\tau_{mn}^{k} \quad (2)$$

The flowchart of hybrid intelligent ACO-GA algorithm is shown in Fig. 1.

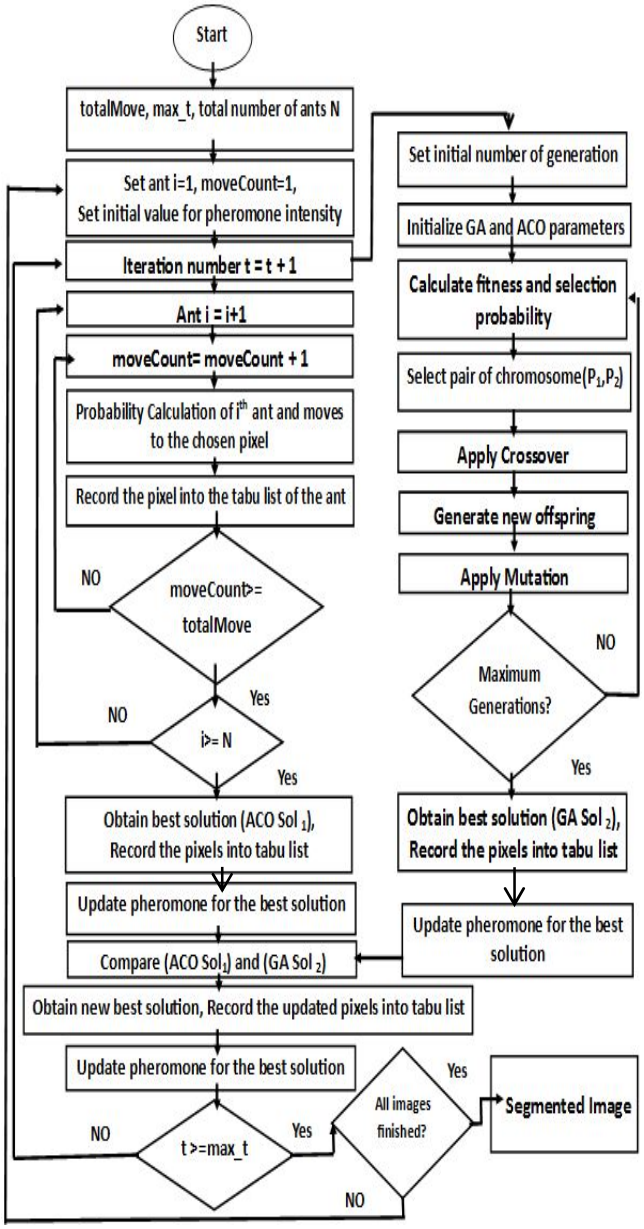

Fig. 1. Flowchart of hybrid ACO-GA algorithm for color image segmentation.

The evolutionary genetic algorithm is also used simultaneously with ACO algorithm for finding the most optimal cluster centers from the problem space. It is possible by measuring the distance using Euclidean distance. In this phase, a random initialized population is generated of any desired size at first. It is mandatory to initialize GA and ACO parameters in this phase. At each iteration, randomly produced initial population is generated with ant colony optimization in parallel manner. In each iteration of GA phase, Chromosome is generated randomly with m cluster centers where, chromosome is represented as string. Pixels are clustered by chromosome encoding scheme. The pixels are closest to the cluster center will be kept in the same cluster center. For searching most optimal cluster center, we need the equation of Euclidean distance d_i is given below:

$$d_i = \sum_{i=1}^{m} \sum_{(for\ each\ pixel\ p_j \epsilon\ cc_i)} \left|\left|p_j - cc_i\right|\right|$$

From the Euclidean distance, we get the fitness function as follows:

$$F = \frac{1}{d_i} = \frac{1}{\sum_{i=r}^{m} \sum_{(for\ each\ pixel\ p_j \epsilon\ cc_i)} |(p_j - cc_i)|}$$

After calculating fitness function, selection probability is used to select the fittest individuals from the population. The selection probability equation is as follows:

$$P_C = \frac{fitness\ of\ individual\ chromosome\ \ or\ cluster}{Total\ fitness\ of\ the\ current\ chromosomes\ or\ clusters}$$

In this GA phase, we use 2-point crossover for producing new offspring from two chromosomes and shift mutation [15] is used for creating genetic diversity.
New offspring is continuously generated until maximum generation is reached. However, we get the best solution (image pixels) from genetic algorithm and record the pixels into tabu list for storing the pixels into memory. For obtaining best solution, the pheromone value of the adjacent pixels is updated using ACO parameter in GA phase.

Both sided clustering is performed simultaneously. The obtaining best solution from GA phase is compared with the obtaining best solution from ACO phase. However, we obtain the new best solution and store the pixels into tabu list. After storing the pixels into tabu list, pheromone is updated for obtaining optimal solution. All the process of ACO and GA phase is continued until reached maximum iteration. Therefore, we get the segmented image. After image segmentation, TSVM is used for disease identification using segmented image features extraction.

D. Feature extraction

Feature extraction is a necessary step to get accurate result in biomedical image processing. The infected region of skin is determined in feature extraction phase. Instead of choosing the whole set of pixels, we can choose only which are necessary and sufficient to describe the whole of the segmented image. Using image enhancement and region of interest (ROI) technique, we can find out the necessary infected region. The frequency of occurrence of certain value in the whole of the image is obtained by histogram calculation. So, it is an important feature for frequency analysis. Afterward frequency analysis is taken by co-occurrence which is transmitted into next level. In the next level, the intensity occurrence of two pixels together is stored in the matrix. However, we get color co-occurrence matrix. The features such as Contrast, Energy, Correlation, Homogeneity and Entropy are extracted from color co-occurrence matrix data. The formulae of the features are given below:

Contrast: $\sum_{i=0}^{i=k-1} \sum_{j=0}^{j=k-1} |\mathrm{i} - \mathrm{j}|\, 2C(i,j)$

Energy: $\sum_{i=0}^{i=k-1} \sum_{j=0}^{j=k-1} C(i,j)\, 2$

Correlation: $\sum_{i,j} \frac{(i-\mu)(j-\mu)C(i,j)}{\phi_i \phi_j}$

Homogeneity: $\sum_{i=0}^{i=k-1} \sum_{j=0}^{j=k-1} C(i,j)\,/(1 + |i-j|)$

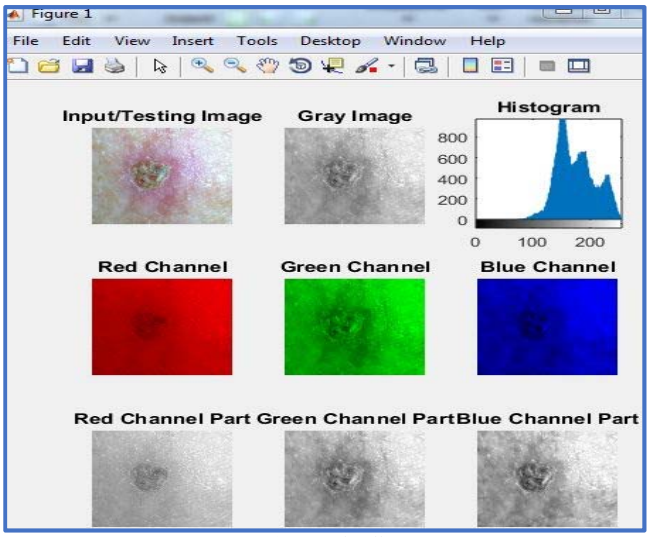
Entropy: $-\sum_{i=0}^{i=k-1} \sum_{j=0}^{j=k-1} C(i.j) \log C(i.j)$

E. Dermatological Diseases Identification

Transductive support vector machine is used not only for finding the hyper plane but also finding the labeled samples/data from unlabeled samples/data. We use TSVM classifier for detecting which type of disease present on the skin using features extraction. The TSVM objective function is as follows:

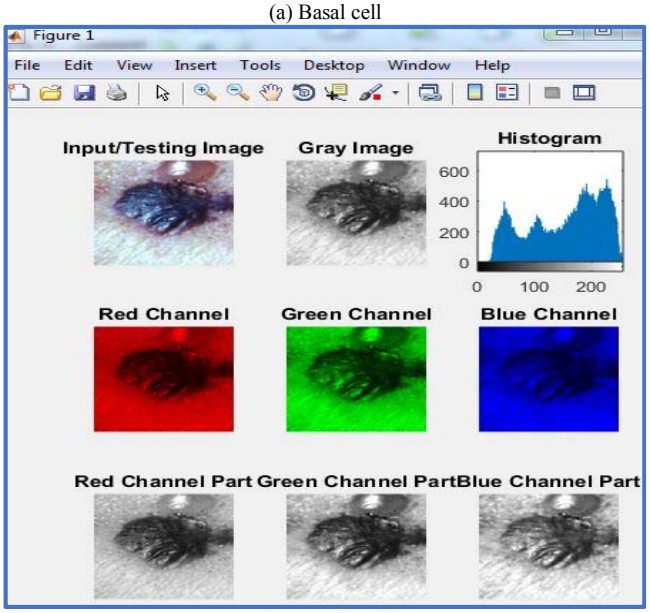
$$min_{y^*,Z,b,\upsilon,\eta^*} 0.5||Z|| + F\sum_{i=1}^{i=n} \upsilon_i + F^*\sum_{j=1}^{j=m} \eta_j{}^*$$

Algorithm 1 shows our TSVM training process.



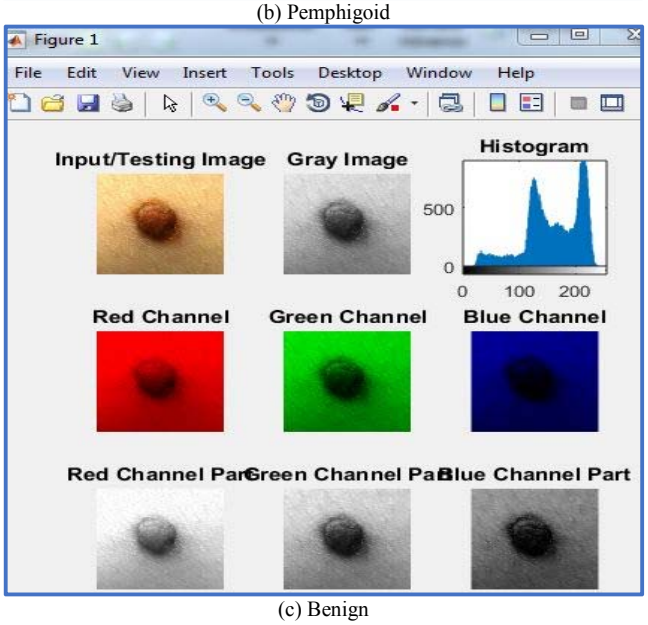
Algorithm 1: TSVM training process algorithm

1. Initialize parameter T and T^*
2. Apply inductive SVM on training data
3. Set positive label samples number
4. Find label samples for all unlabeled samples using decision boundary function value in where label samples are positive for the highest value of decision boundary function
5. Set T^*_{tmp}
6. Retrain SVM over the whole samples of labeled and unlabeled samples
7. Shift unlabeled samples to labeled samples and make the value of objective function
8. If all the data satisfy the shifting condition then $T^*_{tmp} = T^*_{tmp} + 1$, else go to step 7
9. If $T^*_{tmp} > T^*$ then obtain the output data, else go to step 6
10. Stop



In testing phase, the features of the input image are calculated and the obtained data is then compared with TSVM training data. However, skin diseases are classified and detected using TSVM classifier.

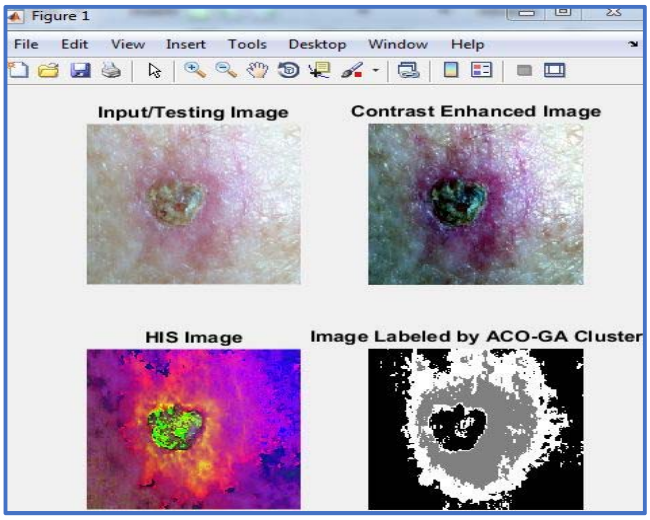
V. Results and Discussion



We implement our proposed hybrid intelligent ACO-GA algorithm using MATLAB program which can segment dermatological images accurately. We also implement transductive support vector machine algorithm using MATLAB which can detect the skin diseases accurately. In this experiment, a total of 812 colored skin images from Khulna Medical College, Department of Dermatology are collected out of 24 different types of skin diseases such as scabies, psoriasis, seborrheic dermatitis, tinea, corporis, chronic dermatitis, eczema, foot ulcer, acne, rosea, vitiligo, leprosy, lichen planus, bullae, pityriasis rosea, pityriasis rubra pilaris, shingles, melanoma skin cancer, benign skin cancer, kaposi sarcoma, seborrheic keratosis, squamous cell, basal cell and merkel cell skin cancer. Above diseased skin images are used as input dataset of the algorithm. Input query image is taken into different color channel (RGB). Gray scale image is also computed as well as its histogram information. We have also shown the segmentation and detection of two new skin diseases such as Basal cell and pemphigoid skin diseases which is not researched yet by the researchers. The output of color transformation system of input image is shown in Fig. 2.

(a) Basal cell

(b) Pemphigoid



(c) Benign

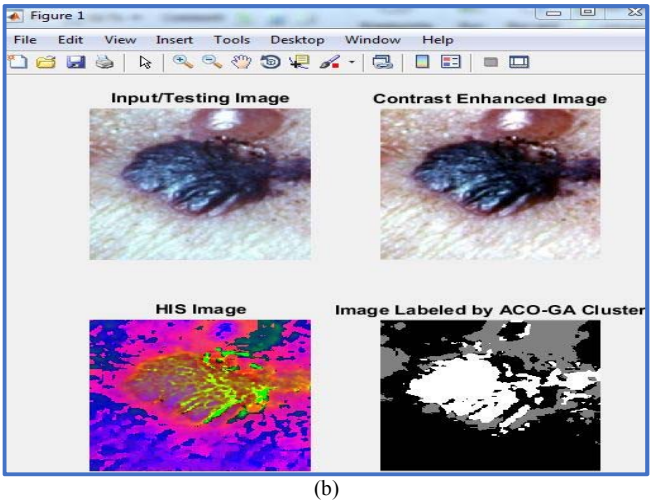


Fig. 2. Color transformation system of different infected skin images with different diseases.

Noise of the input infected skin image is removed by contrast enhanced technique and Median filter. The input

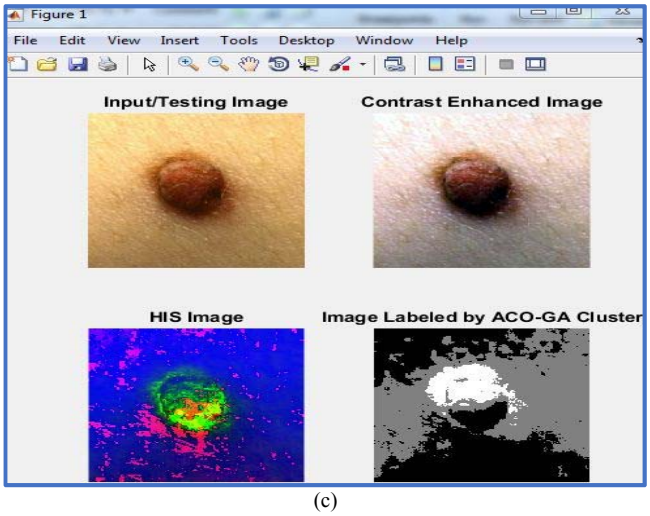

image is converted into HIS and the disease affected area is sharply appeared in Fig. 3. Afterwards, image is labeled and segmented by hybrid ACO-GA clustering.

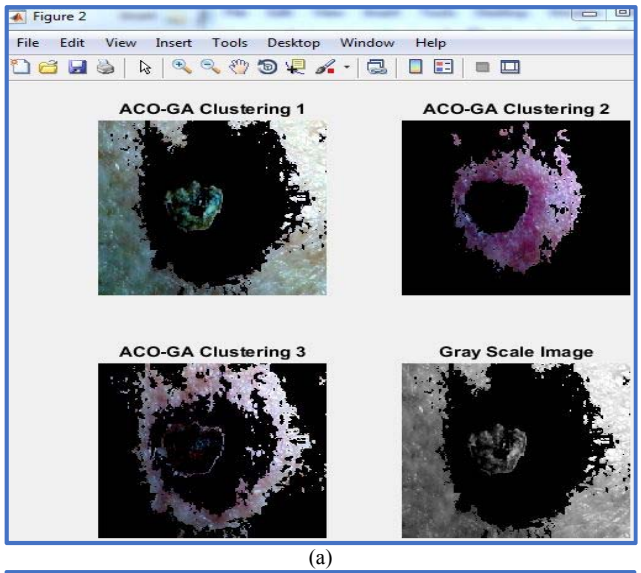
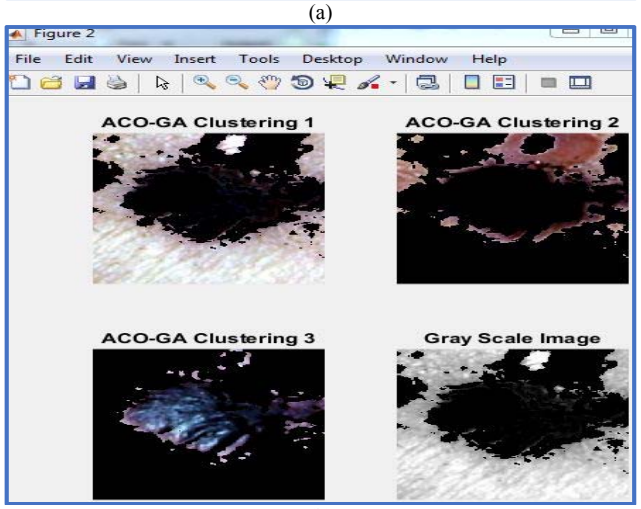
(a)

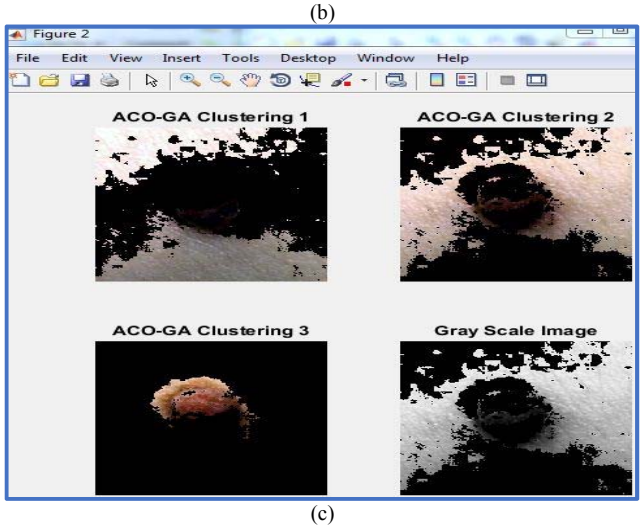


(b)



(c)

Fig. 3. Input infected skin image conversion to contrast enhanced image, HIS image and labeled image by ACO-GA clustering.



The hybrid ACO-GA clustering algorithm segments the input infected skin image by clustering process and gives us optimal solution. In this process, we use three clusters in our implemented hybrid ACO-GA algorithm. In ACO-GA clustering system, the total number of pixels from the segmented diseased area as well as skin area is detected. Fig. 4 shows the segmented output image performed by hybrid intelligent ACO-GA algorithm.

(a)

(b)

(c)

Fig. 4. Input infected skin image segmentation by hybrid ACO-GA clustering.

In training phase, The TSVM training process is performed for all the images to obtain the high detection

accuracy. The segmented image is entered into testing phase. After calculating segmented image features, the data is then compared with TSVM training data. However, the segmented diseased image is classified into different disease using TSVM classifier. Fig. 5 shows the dermatological skin diseases detection using TSVM classifier.

(a) Benign skin cancer identification

(b) Impetigo skin disease identification

Fig. 5. Dermatological skin diseases identification using TSVM classifier.

Two papers in this domain [8], [5] propose hybrid GA-ANN and Feed Forward BP-ANN respectively for identification of different types of skin diseases. The detection accuracy of their system was 88% and 90% respectively. They research with only 5-9 types of skin disease that is very inadequate. On the other hand, our proposed system of using hybrid ACO-GA algorithm with TSVM classifier has given very promising results in identification of different types of skin diseases with accuracies of up to 95%. The accuracy comparison result is shown in Fig. 6.

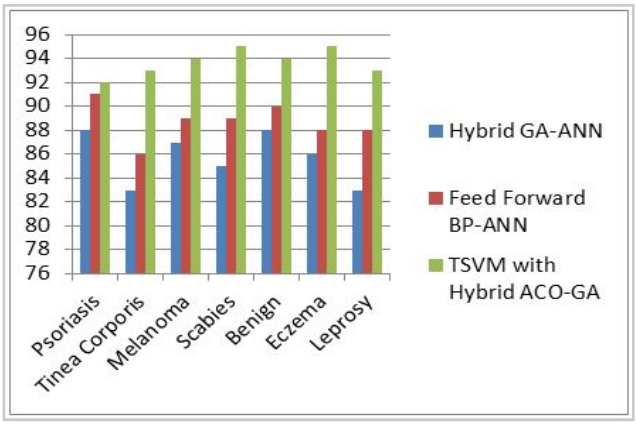


Fig. 6. Accuracy comparison of Hybrid GA-ANN, Feed Forward BP-ANN and our proposed TSVM with hybrid ACO-GA algorithm.

VI. Conclusion

The implementation of our proposed system segments the colored skin image using hybrid ACO-GA algorithm and also detects not only dermatological skin disease but also skin cancer using TSVM classifier. In this process, hybrid ACO-GA algorithm is used for finding the most optimal cluster centers from the problem space. This hybrid ACO-GA algorithm then supports TSVM to find the accurate skin diseases. In the comparison of our work with related works in this domain, there is no other research and solution to identify the skin diseases which can handle 24 different types of skin diseases. The advantage of our proposed system is to give high performance with a very low computational complexity, to achieve segmentation accuracy of about 94% and skin disease detection accuracy of about 95%. We suggest some recommendations for our future work: collect large amount of dermatological images for disease identification, give prescribed medicine information for treatment to the rural people in accordance with different types of skin diseases and also support dermatologists for skin diseases diagnosis.

***Abstract*— Method of establishing a process of interaction between human and the computer is evolving since the invention of computer technology. Though Wireless and Bluetooth mouse technology are invented still, that technology is not completely device free. A Bluetooth mouse has the requirement of battery power and connecting dongle. Presence of extra devices in a mouse increases the difficulty to use it. Our proposed virtual mouse model is beyond this limitation. This paper proposes a virtual mouse system based on HCI using computer vision and hand gestures. Gestures captured with a built-in camera or webcam and processed with colour segmentation and detection technique. The users are allowed to control some of the computer cursor functions with their hands that bear coloured caps on fingertips. Primarily, a user can perform left clicks, right clicks, and double clicks, scrolling up or down using their hand in different gestures. This system captures frames using a webcam or built-in cam and processes the frames to make them track-able and after that recognizes different gestures made by users and perform the mouse function. Therefore, the proposed mouse system eliminates device dependency in order to use a mouse. Therefore, it can be proved beneficial in order to develop HCI technology.**

Keywords—HCI (Human-Computer Interaction), HSV (Hue Saturation Value), Hand Gesture, Color Detection, Gesture Recognition.

I. INTRODUCTION

As the technologies are developing day by day the devices becoming compact in size. Some devices have gone wireless, some of them gone latent. This paper proposes a system that could make some the devices go latent in the future that is the future of HCI (Human-Computer Interaction). The proposal is to development of a Virtual Mouse using Gesture Recognition. The aim is to control mouse cursor functions using only a simple camera instead of a traditional or regular mouse device. The Virtual Mouse works as a medium of the user and the machine only using a camera. It helps the user to interact with a machine without any mechanical or physical devices and control mouse functions. In this gesture recognition system, it is very possible to capture & track the fingertip of hand with a webcam or built-in cam which is bearing a color cap or color sticky note paper and the system track the color and movement of the hand & move cursor with it.

Typically we use a mouse, keyboard or other interacting devices which is mainly compact with the computer machine. The wireless devices also need a power source and connecting technologies, but in this paper, the user's bare hand is the only input option using a webcam. Therefore, it is a very interactive way to control the mouse cursor.

This system is implemented in Python programming language using the Computer Vision based library OpenCV. This system has the potential to replace the typical mouse and the remote controller of machines. The only barrier is the lighting condition. That is why the system still cannot be enough to replace the traditional mouse as most of the computers are used in poor lighting conditions.

A. Problem Description & Overview

To track fingertips as a movable object, and to utilize it for mouse functions, the camera should be positioned in a way so that it can see the user's hands in the right positions. This can be used in space-saving situations, for those patients who don't have control over their limbs and for other similar cases. It's a virtual mouse instead of a physical mouse which will work only based on webcam captured frames & tracking colored fingertips.

B. Significance in Real World Application

Video conferencing is very popular nowadays. For this reason, most of the computer users use a webcam on their computer and most of the laptops have a built-in webcam. The proposed system which is webcam based, might be able to eliminate the need of a mouse partially. The process of interaction with a computer using hand gesture is a very interesting & effective approach to HCI (Human-Computer Interaction). There is some really good research on this interest. The hand gesture recognition technology is also popular in sign language recognition.

C. Objective

The objective is to develop and implement an alternative system to control a mouse cursor. The alternative method is hand gesture recognition using webcam and color detection method. The ultimate outcome of this paper is to develop a system which recognizes hand gesture and controls mouse cursor using color detection method of any computer.

II. RELAVENT WORK

Cursor control application using hand gesture is used in many ways, but most of the time, it requires of wearing a DataGlove. This reduces the efficiency of performance

between the user and the system. And system complexity is also an issue in this process.

There could be two possible gesture recognitions for HCI, one is hardware based & another one is computer vision based. One of the early hardware-based systems was proposed by Quam (1990) in which, the user had to wear a bulky DataGlove to use the system [1]. Though this method gives a high accuracy control, it is very difficult to use as some gesture is not meant for everyone and also very impractical for mass users in the everyday world.

Meanwhile, the vision-based hand gesture recognition is also two types: marker-based & non-marker based. Non-marker based recognition generally is not as accurate as the marker based recognition. And the maker based recognition has better accuracy compared to the other gesture recognition systems, though the user has to use a simple color cap on the fingertip. But this way is lighter and almost nothing in comparison with the DataGlove of the hardware-based system.

Gesture recognition might be a futuristic way to the computers to understand human gesture (Body Language). It will build a greater interaction between human & computer machines rather than primitive text-based interaction.

Most of the marker based gesture recognition mouse uses at least two color markers to track. Because of detecting multiple colors, the system gets slow and some laggings appear on the system during the time of performance.

In 2010, ChenChiung Hsieh and Dung-Hua Liou proposed a paper "A Real-Time Hand Gesture Recognition System Using Motion History Image" [2] based on adaptive skin color model & motion history image (MHI). In their work they used an adaptive skin color model and a motion history image-based hand moving direction detection method. The prime limitation of the paper is a problem with working for more complicated hand gestures recognition.

In 2011, Chang-Yi Kao and Chin-Shyurng Fahn published a paper "A Human-Machine Interaction Technique: Hand Gesture Recognition Based on Hidden Markov Models with Trajectory of Hand Motion" [3] that is basically learning based interaction between human & machine. Their work is very accurate but it worked only in high configuration computers.

In 2013, Angel, Neethu. P.S proposed a paper named "Real Time Static and Dynamic Hand Gesture Recognition" [4] in which design, develop and study a practical gesture recognition that can be used in a variety of human-computer interaction applications framework for real-time. But, it was unable to work at a complex background and was computable only under good light.

In 2013, Ashwini M. Patil, Sneha U. Dudhane, Monika B. Gandhi proposed a paper titled "Cursor Control System Using Hand Gesture Recognition" [5] where they developed a machine-user interface which implements hand gesture recognition using simple computer vision and multimedia techniques. But a major limitation is before working with gesture comparison algorithms, skin pixel detection and hand segmentation from stored frames needs to be done.

In 2014, Abhik Banerjee & Abhirup Ghosh proposed "Mouse Control using a Web Camera based on Color Detection" [6] titled paper where the methodology is Hand gestures were acquired using a camera based on color detection technique. The limitations of their work are the operating background has to be light and no bright colored objects are present. It works well on certain computers of high configuration.

In 2016, Yimin Zhou, Guolai Jiang & Yaorong Lin published "A novel finger and hand pose estimation technique for real-time hand gesture recognition" [7] based on directly extract fingers from salient hand edges. Considering the hand geometrical characteristics, the hand posture is segmented and described based on the finger positions, palm center location and wrist position. But this method is only compatible with high configuration computer machines.

In 2016, Pooja Kumari, Saurabh Singh & Vinay Kr. Pasi developed "Cursor Control using Hand Gestures" [8] is based on multiple color bands where different colors perform different actions. The number of colors is the key to perform mouse functions. But, multiple colors were used to control the system. It is relied on the number of colors to perform a function instead of different gestures.

In 2017, Aashni Haria, Archanasri Subramanian, Nivedhitha Asokkumar, Shristi Poddar, Jyothi S Nayak developed "Hand Gesture Recognition for Human-Computer Interaction" [9] based on background extraction and contours detection system. But it is very slow to work with.

In 2018, Abhilash SS, Lisho Thomas, Naveen Wilson, Chaithanya C published a paper on "Virtual Mouse Using Hand Gesture" [10] which designed to work with the color detection system, functions works on the number of colors detected. But it can perform only a few mouse actions, and does not work without static background.

III. METHODOLOGY

The methods used in each & every part of the system proposing in this paper are explained separately.

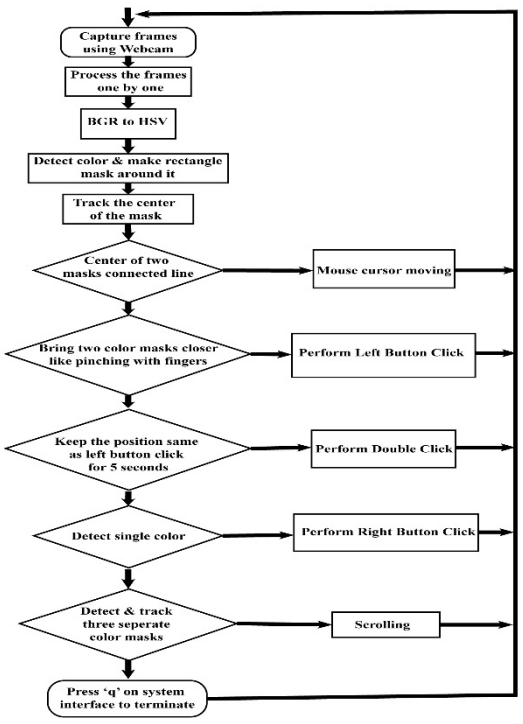

Fig. 1. Flowchart of The Methods of Gesture Based Mouse

A. Camera

The system works on the frames captured by the webcam on the computer machine or built-in camera on a laptop. By creating the video capture object, the system will capture video using webcam in real-time. In order to use a single camera with this system the device index would be "0". To add additional camera device index would be 1, 2 and so on. This camera will capture frame by frame and will pass it to the system.

B. Capturing

By using an infinite loop the webcam captures each and every frame till the program termination. The frames from the real-time video are processed from BGR to HSV color space.

C. Color Detection & Masking

In this proposed system, color detection is done by detecting color pixels of fingertips with color caps from the frames that were captured by the webcam. This is the initial and fundamental step of the proposed system. The outcome of this step will be a grayscale image, where the intensity of the pixels differs the color cap from the rest of the frame and the color cap area will be highlighted. Then rectangle bounding boxes (masks) will be created around the color cap and the color cap will be tracked. The gesture will be detected from the tracking of these color caps.

IV. Gesture Recognition

A. Mouse Movements

At first, calculation of the center of two detected color objects which is done by the coordinates of the center of the detected rectangle. To create a line between two coordinates, the built-in OpenCV function is used and to detect midpoint equation given below is used:

$$M = \left(\frac{Xa+Xb}{2}, \frac{Ya+Yb}{2}\right) \quad (1)$$

This midpoint is the tracker for the mouse pointer and the mouse pointer will track this midpoint. In this system, the coordinates from camera captured frames resolution is converted to screen resolution. A predefined location for the mouse is set, so that when the mouse pointer reaches that position, the mouse started to work and this may be called open gesture. This allows the user to control the mouse pointer.

B. Mouse Clicking

The proposed system uses close gestures for clicking events. When the rectangle bounding boxes come closer to another rectangle, bounding box is created with the edge of the tracking bounding boxes. When the newly created bounding box becomes 20% of its creation time size then the system performs left button click and it can be clicked. By holding this position more than 5 seconds, the user can perform a Double click. In addition, for the right button click again the open gesture is used. To perform the right button click, the single finger is good enough. The system will detect one fingertip color cap then it performs a right button click.

C. Mouse Scrolling

To scroll with this system, user needs to use the open gesture movement with three fingers with color caps. If the users use their three fingers together & changes its position to downwards, it will perform scrolling down. Similarly, if its position is changed to upwards, it will perform scrolling up. When three fingers move up or down the color caps gets a new position and new coordinates. By the time all three color caps get new coordinates, it performs scrolls. If their y coordinate values decrease, it will perform scrolling down and if the values increase, it will perform scrolling up.

V. Result & Evaluation

In this work, we have used HCI (Human Computer Interaction) and computer vision in order to contribute in future vision based interaction between the machine and human.

The proposed paper is on controlling the mouse functions using hand gestures. The main functions are mouse movement, left button click, right button click, double click and scrolling up or down.

In this system, the users can pick any color from multiple colors. There are a few color bands defined & the users can pick any color from the colors according to the backgrounds and the lighting conditions. This may vary in a different background. For example, when a user starts the system, it will provide the choice to pick a color from multiple colors (Green, Yellow, Red, Blue & two others). The user will have to pick one color such that, the color would not match with the background or else, he has to choose the color which will be highlighted in the current background.

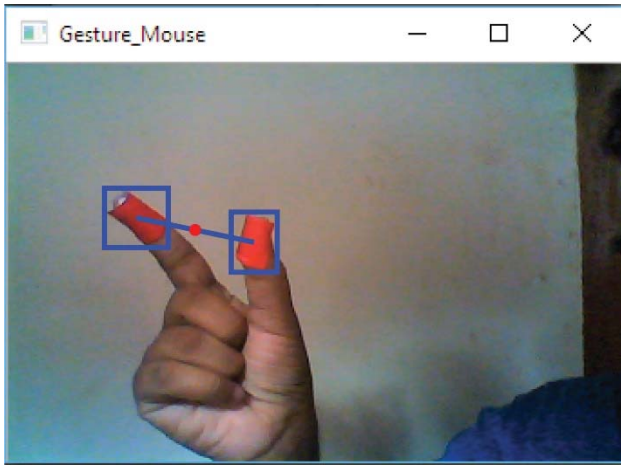

Fig. 2. Mouse Movement (Open Gesture)

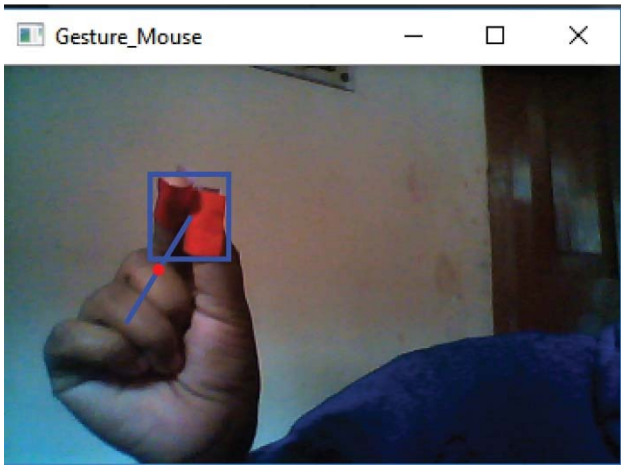

Fig. 3. Left Button Click (Close Gesture)

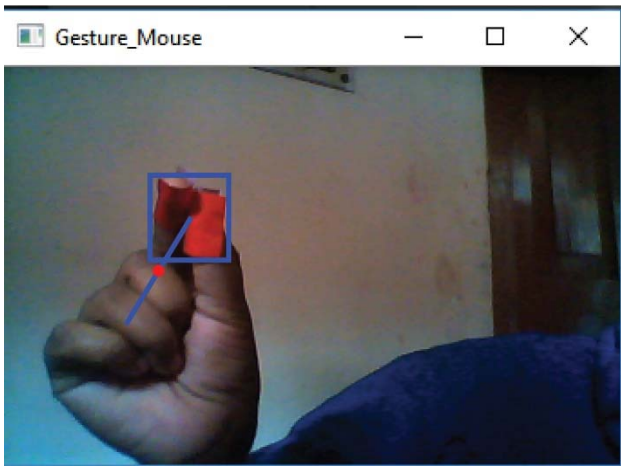

Fig. 4. 5 Seconds Perform Double Click (Close Gesture)

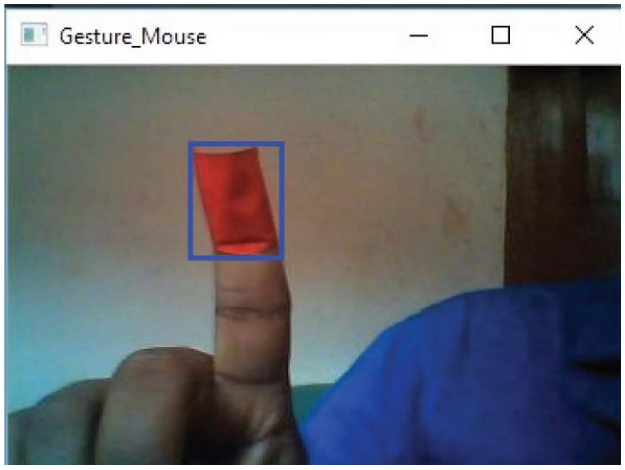

Fig. 5. Right Button Click (Open Gesture)

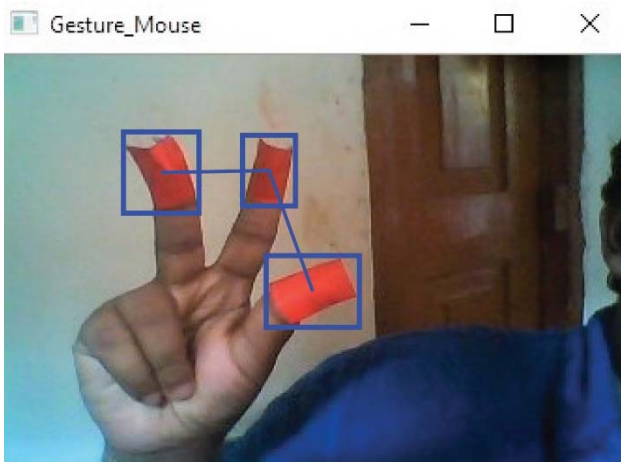

Fig. 6. Scrolling Up & Down (Open Gesture)

These testing are done with a plain background. It works very fast and the accuracy is 78-90 percent. It is also tested with some complex backgrounds, such as check printed shirt, colorful t-shirt (Though most of the people sit in front of the laptop or computer wearing regular shirts or t-shirts), complex home backgrounds, indoor daylight environments, indoor home light environments etc. These events are evaluated with the accuracy, and which is showed in a table.

TABLE I. MOUSE EVENTS & EVALUATIONS

Gesture Input	**Evaluation**		
	Mouse events	***Accuracy with plain background (in %)***	***Accuracy with complex/ non-plain background (in %)***
Two color caps (Open Gesture)	Mouse Movement	91	41
Closer two color caps (Closed Gesture)	Left Button Click	88	40
Keep closer for 5 seconds (Closed Gesture)	Double Click	87	42
Single color cap (Open Gesture)	Right Button click	95	79
Three color caps (Swipe Up/Down)	Scrolling up or down	78	40

Clearly, the system is not much efficient in the complex and rough background. However, our system is faster than the other gesture-based mouse control systems. This accuracy can be increased by using high definition camera. The readings of the table are taken from a built-in laptop VGA (Video Graphics Array) camera. Though this system is developed in Windows OS, in some events, the accuracy rate might be better in Linux base or Macintosh OS computer rather than Windows OS computer.

TABLE II. COMPARISON WITH EXISTING SYSTEMS

Existing Methods	**Comparison**		
	Recognized Gestures	***Average Accuracy (in %)***	***Control Type (Static/Dynamic)***
Color tracking and counting [8]	Five (05) : Mouse Movement, Left Click, Right Click & Double Click etc.	Not Available	Dynamic
Finger and palm tracking [9]	Seven (07) : Opening Media Player, Web Page, Launching Powerpoint etc.	78	Static
Color masking and pinchflag [10]	Three (03) : Mouse Movement, Left Button Click, File Transfer	Not Available	Dynamic
Our proposed method	Five (05) : Mouse Movement, Left Click, Right Click, Double Click, Scrolling	78	Dynamic

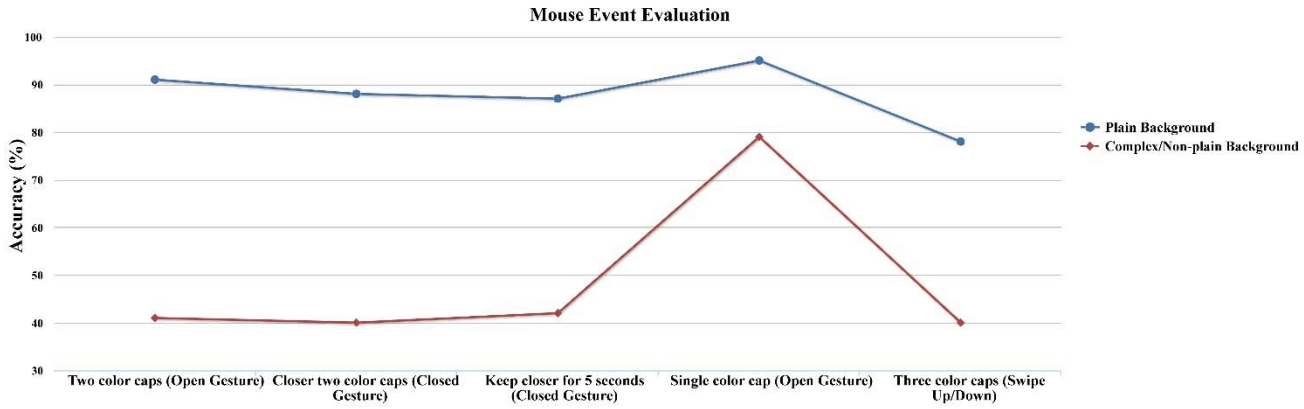

Fig. 7. Mouse Event Accuracy (%) Evaluation

VI. Application

This project can be useful for presentations and for reducing workspace and burden of extra hardware devices. In critical events such as battleground, operation theater, this project will be able to withstand itself, as it is wispier than any other contemporary system in the market for computer interaction. Since it removes the burdens of devices, it brings the user and the workspace more closer than before.

Major applications:

- Robot controlling is one of the major applications of this system. Controlling robots without machines or extra devices can be an excellent addition to this technology.
- Digital artist can draw 2D or 3D images using this gesture-based mouse on digital canvases. It will allow more freedom more dynamic more space to artists to create their art.
- Critical events like a battleground, operation theater, mining fields can be controlled by gesture mouse.
- Virtual Reality or Augmented Reality based games can be played without any extended or wireless devices with bare hands more comfortably.
- For patients with no limb control, this system can be proved very useful and effective.
- This mouse system can be applicable for sign language for the dumb & deaf people. It can help them to interact with computing machines.

VII. Conclusion

Virtual gesture control mouse is a system that profound to guide the mouse cursor and execute its task using a real-time camera. We implemented mouse navigation, selection of icons and its functions and tasks like left, right, double click and scrolling. This system is based on image comparison and motion detection technology to do mouse indicator movements and selection of the icon. Analyzing results, it can be anticipated that if we provide enough light, decent camera, the algorithms can work at any domain. Then our system will be more systematized. In future, we want to merge more features such as interaction in multiple windows, enlarging and shrinking windows, closing window, etc. by using the palm and multiple fingers.

Acknowledgement

We would like to express our special thanks of gratitude to our teacher, supervisor Samrat Kumar Dey who gave us the golden opportunity to do this wonderful project on the topic Virtual Mouse using Gesture Recognition, which also helped us in doing a research work and we came to know about so many new things for which we are really thankful. Secondly, we would also like to thank our parents and friends who helped us a lot in finalizing this project within the limited time frame.

***Abstract*—Reliable face recognition starts with the analysis of accurate and robust facial localization component and poses an unresolved challenging computer vision problem in unconstrained settings in the backdrop of clutter, and large head poses variations. The landmark localizer needs to meet robust reasonable point coordinates in correspondence with the face alignment despite to the extent the image in consideration, is under scenarios with face variability. Correspondingly, in this paper; the task is viewed as non-parametric development of local estimator that produces learned features in the leaf node of a tree with an adopted ranking in a supervised clustering way. Then, the proposed approach helps to implement a sequence of estimators based on ensembles of regression trees. The trees use simple scale invariant, asymmetirc Multi-Scale shape indexed pixel difference at each split in the internal nodes using adopted label ranking clustering methods, and this makes them able to rapid detection of the process in the region of interest. The developed system is then tested on several publicly available datasets and analyzed on the sensitivity of the experimental occlusion. The results show that the performance of our method has practical value for commercialization aspect overcoming slowness in the state-of-the-art methods and evaluates to significant accuracy compared to recent methods.**

***Index Terms*—: Facial landmark localization, clustering, detection process, intermediary face shape**

I. Introduction

The cornerstone of all applications of computer vision face analytics; Facial Landmarking with spatial and dynamic configurations of landmarks is a subset of the shape prediction problem, characterized as the detection and localization predefined descriptor points of fiducial salient **(reference gradient)** points for facial expressions or variations due to gestures [15]. In recent years, localizing the landmark points on the face images captured under unconstrained conditions have garnered avenues and witnessed a monumental growth from both scientific challenges in research and industrial practices in the backdrop of pose, illumination and occlusions of face variability [1]. Variation in studies include model fitting methods with an active appearance model and active shape model respectively in [4], [5] tend to build templates that fit the region of interest of test images. Dollar [12] et al. uses parametric model which minimizes model parameters in the training. However, smaller parametric errors do not lead to small landmark errors for alignment. The above landmark research showed a number of optimization criteria fits with the effect to have the minimized residuals between the face appearance and synthesized face template. However, due to the existence of nonlinearity between the input face and output shape, the parametric shape models suffer significant variations in the wild with limited expressive power to deal with.

On the other hand, Regression-based models measure the landmark location by local (or global) regression using image features, for example, in [7], the author uses a local image patch with SVM regressors. Belhumeur et al. [2] combines the output of SIFT-based face part detectors as local experts or regressors for constrained local models with a non-parametric global shape model for the part or entire of the face locations. The nonparametric approaches avoids the iterative alignment methods, use sequential regressors to better convergence and fast regularization. However, the downside of this approach is its low processing speed, the presence of handcrafted noisy features causes overfitting in testing. We avoid the shape constraint in the post-processing steps, instead, generate local descriptors directly for landmark localizations. Li et al. [14] proposed a special feature called SURF in a cascade of AdaBoost settings, and area under the curve (AUC) criterion to scale up the speed of face detection algorithm which in our method is adopted as multi-scale Pixel difference features with cascaded realboost settings. Cao [3] proposed a boosted regression-based method realizing nonparametric shape constraint for progressive face alignment in which features are extracted as the pixel intensity difference, thus avoids the flexibility concern in parametric model [7]. Then, local evidence with regression employed boosting method where the few prominent landmark points are initialized, and in the global stage image and shape estimation is computed from sequential regressors. We used tree-based estimators with the Decision Tree algorithm for label ranking proposed by Cheng [8]. Our work in the contribution perspective is different from the earlier researchers is that current cluster central ranking induces instances to clusters of landmarks in

a tree growing iteratively with the mechanism of supervised clustering and these new instances to clusters gives rise to reassigned cluster central rankings. Later we analyze it in the framework designed by earlier researchers [16] and found to have significant F-measure compared to the baseline algorithm. The paper is organized as follows. Section II described the adopted pixel difference features are described with the description of one stage regressor as a ranked list of greedy tree construction with the ranked leaves as output. A model of supervised decision tree in the form of clustering label is proposed. Section III describes the dataset and experimental set up and results. Finally, section IV describes the conclusion.

II. Methodology

A. Formation of a localize feature

The methodology of our systems inspired by the Viola-Jones [9] method of the learning features of pixel difference with a little variations in scaling. The adopted idea in the similar research is to learn the local tree structure with standard regression forest that estimates the increment of each $L\oplus$ facial point of the image with a cascade of binary classifiers at all reasonable positions and scales using the multi-scale shape indexed pixel difference features (MPDF). Despite split test for an internal node, we boost the shape indexed MPDF in [3] to multi-scale. Specifically, we downsample the input image to half and one fourth by scaling it upto three scales of the image. Soliciting a desirable feature starts with the selection of two random facial points as described in (1), retrieve two random offsets with those points. Then, we take the difference of these two points as the feature and thus this attribute is coined as pixel difference features is invarient to various illumination conditions as it expresses the related difference of pixel intensity values and carrying ordinal relationship in sign changes. We used the variations of Chen et al. in [13] computes a Weber Fractions of pixels in a settings of 3 3 window which is a local image descriptor, called Webers Law Descriptor for face recognition in which is scales as normalized difference.

The construction of MPDF adopted in the paper between two pixels in an image is defined as below:

$$f(\mathbb{P},\mathbb{N}) = \frac{\mathbb{P}-\mathbb{N}}{\mathbb{P}+\mathbb{N}} \tag{1}$$

where $\mathbb{P},\mathbb{N} \geq 0$ are intensity values of the two pixels and $f(0,0)$ is defined as 0 when $\mathbb{P},\mathbb{N} = 0$.

We found the MPDF is more robust to noises and necessary for detection learning for fiducial points [1]. Asymmetry in (1) brings reduced feature space.

B. Weak Classifiers as greedy regression tree

We used a label ranking clustering scenarios [8] to recursively growing decision trees grown in a supervised way. The advantage of label ranking is that it involves strict label order relations, rather than single values in the leaf node. Specifically, in the scenarios with label rankings, a set of features $\varkappa$, represent each instance. This set of features maintains a ranked order of labels $\amalg$ in a form of total (e.g. $\amalg$= 5,3,1,4,2) or partial (e.g. $\amalg$=5,3,2) order over a finite set of class labels $\aleph$ (e.g., $\aleph$=1.2.3.4.5). The label ranking problem in our paper, comprises of representing a model that maps instances $\varkappa$ to a total label order $f : \varkappa \rightarrow \amalg$.

Let us assume from the labeled faces, training data $\mathcal{D} = (\varkappa_i, \aleph_i), n = 1, , N$, is the distribution in which it is to be represented as $\Bbbk$ clusters by learning cluster representation in the feature space in the following:

$\oplus_{\Bbbk} = (\nu_{\Bbbk}\eth_{\Bbbk}) \rightarrow \eth_{\Bbbk}$ is an estimate of $\hat{\amalg}$, in which $\Bbbk$ -th cluster is a representation of the $\nu_{\Bbbk}$ clusters $\Bbbk = 1, 2, 3, ..., \Bbbk$ as following: $\nu_{\Bbbk} \rightarrow$ represents a cluster centroid, say, for example, feature abstraction that spans a certain cluster, for example, in this scenario, it outcomes as a Decision Tree. Unassigned instances can get membership of a cluster based on the feature vector $\varkappa_\nu$ by measuring a ranking of central tendency and is associated with a certain central ranking $\eth_{\Bbbk}$, $\Bbbk = 1 \cdot \cdot \cdot \cdot \cdot \cdot , \Bbbk$, both to be determined from dataset $\mathcal{D}$.

$\amalg_u \rightarrow$ In the label ranking scenario, a single instance $\varkappa$, described by dimension $\lceil$ is associated with a total order or assigned class labels. Total order is assumed by transitive and asymmetric relation $\succcurlyeq_\varkappa$ on a finite set collection of labels $\curlyvee_i \succcurlyeq_\varkappa \curlywedge_i$ given $\varkappa$

$d_e(\varkappa_\nu, \nu_{\Bbbk}) \rightarrow$ is the new unlabeled instance x_ν is assigned to the $m-th$ cluster feature space abstractions $\nu_\varkappa$, and as such is assigned a ranking $\amalg$. Kendall tau correlation [8] provides an correspondence between the two measurable quantities of label ranks and represents a rank correlations as distance measure by counting the number of mutually inclusive and conflicting label pairs.

Clustering weight: The most common clustering measures taken in this paper is the within-cluster sum of squares (WSCC) as in (2)

$$\lceil_{mean} = \frac{1}{k}\sum_{k=1}^{k}\sum_{n\in\oplus_{\Bbbk}} \|\varkappa_n - \nu_{\Bbbk}\| \tag{2}$$

in which $\nu_{\Bbbk}$ is the mean of points in cluster $\odot_{\Bbbk}$. However,$\mathcal{K}$-means algorithm is the direct cause of reduction of this measure. The main disadvantage of this approach is that it assumes global clusters. A modification is of d_knh as from [11] is obtained by simply calculating the average distance of each example $\varkappa_n$ from cluster $\odot_m$ to its $\mathcal{K}$ neighbors in each cluster $\odot_m$.

$$d_{knh}(n,\oplus) = \frac{1}{k}\sum_{i\in knh} \|\varkappa_n - \nu_{\Bbbk}\|^2 \tag{3}$$

C. Ranking Model

We have adopted the Mallows sampling model, which finds a central ranking among all the available label rankings using the maximum likelihood principle. For any distributions, the distance based probabilistic model proposed by Mallows yields the likelihood of any permutation $\eth$ of $\mathcal{L}$ labels is given in terms of a permutation distance $\lceil$ as follows

$$\mathbb{P}(\eth|\Theta,\amalg) = \frac{exp(-\Theta d(\amalg,\theta))}{z(\Theta,\eth)} \tag{4}$$

in which, $\eth \in \Re$ is reflected candidate form of permutation, $\amalg$ is central form of ranking, $\theta \in \Upsilon$ is a parameter for the measure of dispersion, $z(\theta, \amalg) = \sum_{\eth \in \Re} exp(-\Theta d(\eth, \amalg))$ is a normalization constant, $\lceil$ is assumed to be the $Kendalls$ tau distance d_τ. The maximum probability is assigned to the central ranking $\diamond$.

Several recent papers [8], [10] proposed to use decision Trees with binary splits for solving Label ranking problems. The proposal contains a recursive induction of decision tree by finding optimal splits that make the subsets as pure as possible regarding label ranking at each stage [8]. In our system, the construction of the optimized binary decision is formed by MPDF features of the regression tree. The tree uses variations of pixel difference as its comparison as a binary test in the internal nodes. Formally, given data subsample $\Re$, which iterates and splits into subsets by $\Re^+$ and $\Re^-$ by generalizing the sets trained on Mallows model and generating the ranks by formulating the variance in each subset. The results are the subset central ranking $\eth^+$ and $\eth^-$ proposed by Mallow model and the spread parameters θ^+ and θ^- that estimate the variance. Training data is a set $(\clubsuit_{\mathfrak{S}}, \Psi_{\mathfrak{S}}, \Delta_{\mathfrak{S}})$ in which $\mathfrak{S} = 1, 2, , \mathfrak{S}$ in which $\Psi_{\mathfrak{S}}$ is the ground truth value associated with image, $\clubsuit_{\mathfrak{S}}$ and the weight $\Delta_{\mathfrak{S}}$ is its importance factor (weight) calculated from the (3). Likewise, the binary classification of ground truth yields a value $+1$ and -1. The weights Δ_{st} enable us to assign different importance values to each different sample. The optimal split is the one that minimizes error and maximizes spread parameter obtained when the incoming training data is split by the test as in (5).

$$|\Re|^{-1}(\Re^+|\theta_{\Re^+}|\Re^-|\theta_{\Re^-}) \tag{5}$$

in which, $\Re^-$ and $\Re^+$ are the representative clusters of training instances in which binary check on an associated image were 0 and 1, respectively from S_m of cluster (4).

Recursively clustered the training data in this way happens until some termination condition is met. This is performed by minimizing the following quantity:

We measure the rank losses at each node $\Re$ as in (6) and prunes leaves of parent node with minimum value of losses

$$\sum_{n \in \Re} d_\tau(\amalg_n, \eth_\Re) - d_\tau(\amalg_n, \eth_\Re) + (\sum_{n \in \Re^-} d_\tau(\amalg_n, \eth_\Re^-)) \tag{6}$$

The disadvantage is that the final tree will have a fewer number of clusters-splits to adequately cluster the feature space if it would form a partial rank. Our algorithm starts by randomly selecting $\Bbbk$ ranks and growing a tree limited to the assigning one to the $\Bbbk$ ranks to the leaves set $\Re$ is iteratively split into two data subsets $\Re^+$ and$\Re^-$ by trying each of the $\Bbbk$ rankings for the subset central rankings $\eth^+$ and $\eth^-$ and selecting the best separation which reduces

$$\sum_{n \in \Re^+} d_\tau(\amalg_n, \eth_{\Re^+}) + (\sum_{n \in \Re^-} d_\tau(\amalg_n, \eth_\Re^-)) \tag{7}$$

and thus achieves the full rank. After the completion of the constructed tree, the $\Bbbk$ ranks are recalculated by finding a central ranking of examples assigned to each of the $\Bbbk$ clusters using the modified Borda count. The bound box of MPDF is purturbed by repeated sampling of two locations from a uniform distribution on a square $[-1, +1] \times [-1, +1]$.

A more generalized version of AdaBoost in the form of RealBoost [12], [14] is taken as a degenerative decision tree which is called a cascade inspired by the work [3], [10], [12], [14]. The earlier model adopts a boosted decision stump as a tree classifier which degenerates into two leaves constrained by the presence of threshold. However, higher order information curtails and less intractable feature dimensions are obvious problems. Each regressor modeled as an ensemble of trees which learns a greedy optimization of the weak learners to minimize the regressor loss function and to improve the reduction of the alignment error bounded by an optimal threshold. Each stage is obtained by confidence score of the soft output of the decision stump classifier of the previous stage. Thus multiple weak classifiers with reasonable accuracy are attained by rank based sampling of the outputs of the leaves of all classification stages in the cascade.

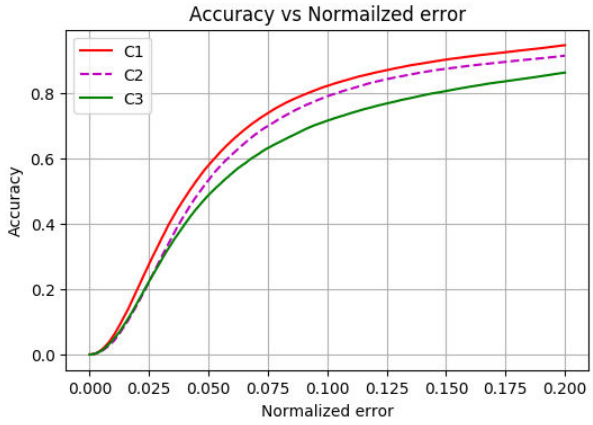
III. Dataset Description & Experimental set up

We have taken the most relevant face databases suitable for landmarking studies with Ground truth data. Ground truth data provides the manually landmarked spatial positions of the landmark points suitable for the referenced landmarking performance.

A. LFPW & LFW

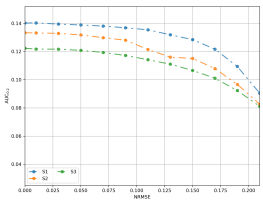
The Labeled Face Parts in-the-wild (LFPW) database was created in [2] contains 1,287 images downloaded from google.com, Flickr.com, and yahoo.com 1132 training images and 300 test images taken under unfavorable unconstrained conditions as the challenging task (in the wild) with significant variations in the pose, expression, illumination and with partial occlusions. From the initial dataset described in LFPW, we use only the 811 training images and the 224 test images provided by the ibug website Ground truth annotations of 68 facial points. We divide the available training samples into two sets: a validation set (135 samples) and a training set (676 samples). The LFW dataset is with 87 annotation was created by Huang et. al. [17] with 5,749 individuals from 13,233 images. Out 5,749 images, 4079 have distinct face images.

B. BIOID



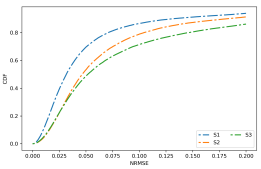
The BioID dataset is composed of grayscale face images with different sizes, illuminations, and backgrounds from 1521 approximate frontal faces was first proposed in Jesorsky et. al referred in [3], [15]. We used 17 of 20 facial landmarks manually annotated. We selected a subset of BioID that is of BioID-2 which consists of 1455 images, some of which include glasses, beards and blinking eyes; 790 images were used for training, 260 for validation, and 405 for evaluation.

Thus, we evaluate performance according to these four characteristics. Accuracy is evaluated according to the distance between the selected optimal landmark and the manually annotated landmarks as ground-truth. In both cases, we used



annotation in the dominant contours of faces, that is, in the locations of eyebrows, nose, upper and lower lip, mouth and eye corners.

C. Experimental result



In our experiments, the normalized root-mean-squared error (NRMSE) relative to the ground truth is adopted as the error measurement for the accuracy of the facial landmark detection. The NRMSE is given as a percentage, computed by dividing the root mean squared error by the distance between the two eye centers. The cumulative distribution function (CDF) is a typical cumulative error distribution (CDE) in which normalized error is represented by values in hte x-axis and proportion of test images are represented by values in the y-axis and thus, CDE of NRMSE is used to evaluate the performance of facial landmark detection algorithm.

(a) Accuracy Representation

(b) Face Shift VS AUC

(c) Face centre shift in CDF

Fig. 1. Graphs for Accuracy and Face Centre Shift

For the test set performance and overfitting minimization, Data augmentation happens with rotations, scale and translation and mirroring the imageset.

Each landmark point position estimation structure is learned independently in our framework. A progressive cascade constitutes of 6 stages with 18 trees having a depth equal to 9 yields a good results in practice. The bounding box estimates the position of a particular landmark point induced by supervised clustering tree in the ensembles. The learning of the landmark point is individually estimated. The local learning of each next stage is mapped on a training set with features generated by shrinking the bounding box by 0.7 and updating its center by moving it at the position output by the ensemble of the previous stage. In this way, invariance regarding scale and orientation are formed to scale the system robustness. times until The refining the predictions points are done in this way by several times of the process repetition.

First, we compare our system to the state-of-the-art methods based on a novel method using Boosted Regression coupled with Markov Networks [6] and local binary pattern applied [7]. The proposed method was observed to be performed significantly better than all previous methods in the below settings. We set the protocols from [3] to obtain the normalized errors for five facial landmarks with facial features like eye centers, mouth corners, and the tip of the nose as facial landmarks presents in the vicinity of the dominant contours around the facial features. The results are reported in the Fig. 1 in Fig. a. We can see that our method labelled as C1 outperforms the benchmark works in accurate landmark localization ($\varepsilon \approx 0.75$). One reason for this good performance is that the tree indexed learned to map in the leaf and provide exact image representation anticipating the ranked features in the leaf. Secondly, the regressor uses prior point information to localize the regression point very effectively in each state. Third very few features are required to mask the image.

Moreover, our method is approximately thousand times faster. It takes around 3.4 ms per image on a Pentium core $\rangle$ı with 3.5 GHz speed machine which is faster than OpenCV based systems on the same machine, in which it runs on nearly 16.4 ms and 17.8 ms for a detection of faces larger than 100100 windows of pixels in aspect around 640480 size image with 29 landmark detectors. It even outperform Belhumeur [2] as the system uses expensive local detectors (SIFT+ SVM) for consensus exemplars approach and it takes more than 10 seconds for 29 landmark detectors.

Fig. (b) in Fig. 1 shows that the maximum shift of bounding box from the ground truth is shrunk from about $\backsim$ .40 to .10. This is due to the small percentages $\backsim$ 1 to 2% of the ground truth rejection rate in each stage.

However, CDF is good for sensitivity analysis and AUC is a better choice according to literature for sensitivity analysis. Therefore, we provide Fig. 1 to have a good metrics for performance evaluation. $AUC_{0.2}$ is seen as the upper bound of the definite integration in the form $\int_0^{\upsilon} f(e)de$ in which $\upsilon = .2$. Fig. 1 shows the result in Fig. b and Fig. c respectively for face center shift for AUC and CDF.

The Later test is the nonparametric development of rank order label clustering taking the comparison with the experimental design in [16] in which, knn approximation methods are called in terms of F-measure over the dataset LFW in [17]. We induces a certain form of adjacency matrix with ground-truth 120 numbers of clusters taking the distance measure as in equation (4). The results are shown in Table I.

For k-Means the clustering algorithm defined in equation (4) produces clusters with ground truth number of clusters, where in ranked-order clustering labels depends on the distance threshold as defined in section II and in equation (7). Ranked order labeling induces more diverse discriminative

TABLE I
RANKED CLUSTERING IN THE LFW DATASET

Nonparametric development	Clusters	F-Measure
K-Means	*120*	.36
Our Method Rank order	*6000*	.83

features as fixed number of faces in large fraction of nearest neighbor lists and thus has to be evaluated at several effective values of clusters. The result of k-means algorithm shows poor clustering performance with lower value of F-measure, whereas, in rank-order clustering, the distance threshold which induces the cluster label with best overall F-measure close to the ground truth identity and thus scores significant F-Measure overall than K-Means.

IV. CONCLUSION

In this work, we have presented a clustering approach to learning local binary features for highly accurate and speedy face alignment for commercial perspective. The proposed approach helped to implement a sequence of estimators based on ensembles of regression trees. Individual estimators find the ranked result in the decision tree with better accuracy and sensitivity. Our method significantly performed better than the baseline methods for localization of landmarks accurately for the normalized root mean square and sensitivity analysis. Besides rank order clustering is effectively analyzed to score over the baseline algorithm. In the future, we will include more experimentation on effectiveness of ranked estimator which ultimately proves the commercial advantage of using this proposal.

***Abstract*— In developing countries, traditional access management systems ubiquitously use either keypad based password protection or radio frequency identification (RFID) card based protection. With the increased number of threats in recent years, these systems are becoming more vulnerable. If the password or the RFID card is somehow compromised, any unauthorized person can breach the system with ease. Considering and analyzing these issues, a cost-effective prototype of a vision based three-layer access management system with IoT connectivity was developed. In this paper, an access management system architecture is proposed based on the fusion of radio frequency identification, back propagation based face recognition and password protection. The system is also connected to a Node JS based web server. Whenever an access is granted or any unauthorized access is detected, an SMS and an email are sent to both the user and the system administrator. Data security is ensured by exploiting AES encryption on the system side and AES decryption on the server side. In case of face recognition, the access is granted if the achieved confidence level is over 80%.**

Keywords—AES encryption; back propagation; face recognition; Node JS; password; RFID;

I. INTRODUCTION

In today's world, significant priorities are being given to research and development of secure access management systems. As the level of security increases, the cost of systems increases accordingly. In developing countries like Bangladesh, it is quite overwhelming for small businesses and corporations to afford high-level and complex security systems. In most small businesses, access control systems are either based on password or radio frequency identification (RFID) cards or a combination of both. But it is seen that most of the time the access systems are quite vulnerable to potential threats. Unauthorized access is possible if the password or the RFID card or both are compromised somehow. To prevent such an inconvenience, a three-layer authentication based cost-efficient access control system integrating the internet of things (IoT) environment is developed. In section II literature review, section III system architecture, and section IV software architecture is described. Section V, VI and VII describe performance evaluation, comparative analysis and conclusion respectively.

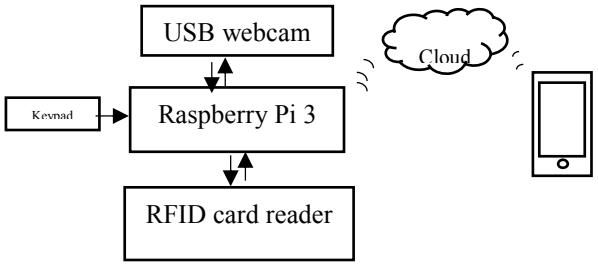
II. LITERATURE REVIEW

Face recognition and gait analysis based identification system for access control is shown in [1]. From a video, at first human detection is done then after background subtraction and human silhouette, the silhouette is normalized to analyze a gait. Both frequency representation and binary representation is shown in [1]. Research in [2] shows face, fingerprint and palm vein based biometric security systems for the internet of medical things (IoMT) platform. A noninvasive and continuous biometric signal collection, as well as authentication from wearable medical device for access control, are shown in research [3]. Smart card based control system where all system data is protected by cryptography is proposed in a research [4]. A near field communication (NFC) and digital signature based access control system is in literature [5]. Here the access is granted after the validation of NFC and digital signature. Electromagnetic lock and modified RFID based system was also shown in some research [6] where electromagnetic lock is interconnected with a system which will grant access for some specific RFID tag. An artificial neural network (ANN) controlled face recognition based access control system has been developed recently [7]. Local binary pattern based face recognition for access control is developed in [9] were after conversion to binary image, analysis of the pattern of the binary image is done for face recognition. An FNN and RFID based access system for internal use is shown in research [8]. A stereo face recognition system is proposed previously by some researchers [10] which can be implemented only in low light indoor environment. Principle component analysis based face recognition is shown in some access systems [11] where the captured image can be seen from a web browser and at same time, a GSM modem sends this information to the user and the administrator. The incorporation of password, fingerprint and RFID card for several stage authentications is implemented in one of the recent researches [12]. PCA and back propagation based face recognition is shown in some

research [14] which can be very useful in future access control system. Again, logistic regression based face image recognition can be a potential resource to use in accesses control systems. In [15], a smart phone application based smart lock system is introduced.

III. System Architecture

The proposed system hardware includes a raspberry Pi 3, an RFID reader, a USB webcam, and a 4X4 keypad. The system block diagram is given in the following Fig. 1.



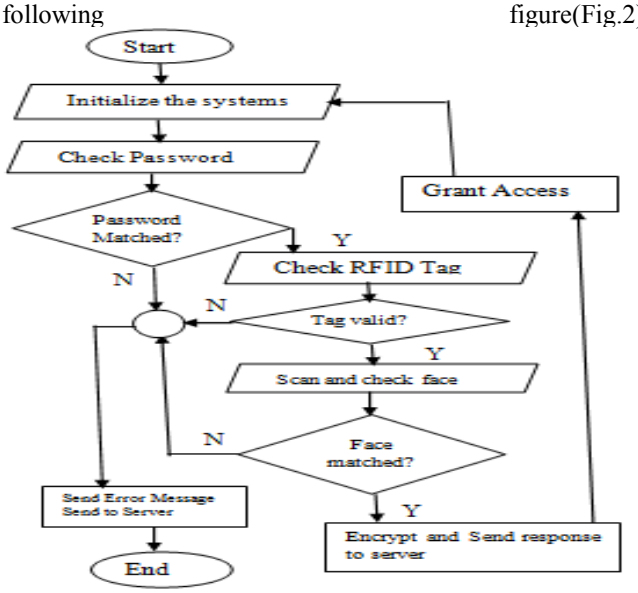


Fig. 1. System Architecture

The main processing part of authentication system is done in the Raspberry Pi 3, which is a single board computer with 1GB RAM, and the Linux operating system. To reduce power consumption, a 125kHz passive RFID tag is used and a low power RFID reader RDM600 [16] is connected with the Raspberry Pi 3 via serial communication, where the baud rate was 9600. The resolution of the USB web cam is 5M pixels, and the frame rate is 60fps. The focal length is manually adjustable from 3.5cm to 8cm. A lin-log CMOS image sensor is used in this camera.

If the user wants to access the facility, at first, the password has to be given via the keypad. After that, an RFID card has to be placed in front of the RFID reader. If the RFID card and the password are matched, then the face of the user will be scanned via the USB webcam. If all three of the systems are matched with the stored data, then the access is granted and an AES encrypted grant response is sent to the Node JS based cloud server. Upon receiving this message and decrypting it, the web server will send a verification SMS to the user and a notification SMS to the system administrator. The flow chart of the system is given in the following figure(Fig.2).

. Fig 2. Flow chart for access management

If any one of the step is mismatched, the system will send an error message to the web server which will be encrypted too. When the web server receives the error message, it will send an alert SMS to both the user and the administrator.

IV. Software Development

The software development can be divided into two main parts and they are system side software development and the server side software development. These two developments are described in the following two sub sections. The system side software was developed with python language and the server side software was developed in Node JS platform.

A. System Side Software Development

The main architecture of the software is based on the flow chart shown in the figure 2. The password verification, RFID match, and face recognition is employed via polling algorithm. The main section of the flow chart is the face recognition part. To recognize the face, back propagation based neural network is employed. At first, the image is captured and the face is detected. Then, the image is converted in to grayscale image. After that feed forward propagation is employed where each node of the network is characterized by sigmoid function denoted by,

$$g(x) = 1/(1+\exp(-z)) \quad (1)$$

Since sigmoid function is used, it has the probability to meet at the local minima so the modified cost function is defined as

$$J(\theta) = (1/m) * \{\Sigma\, y^{(i)} \log[g(x^{(i)})] + (1-y^{(i)}) \log[a-g(x^{(i)})]\} \quad (2)$$

The learning rate is chosen such that it is neither too small nor too large. If the learning rate is high, it has the risk to overshoot the minima. On the other hand, if the learning rate is too small then the it will cause prolonged convergence making the system impractical. To prevent oscillation, the momentum factor is chosen accordingly. The learning rate and momentum **f**actor took part in the modification of the weight.

The activation function of any layer is a_j^l and denoted by

$$a_j^{(l)} = g(\Theta^T.x) \quad (3)$$

Here Θ is the weight vector and Θ^T is the transpose of the weight vector.

If the error in jth node in layer l is denoted by

$$\delta_j^{(l)} = (\Theta^{l)\,T}\, \delta_j^{(l-1)}\ .\ *g^l(z^l) \quad (4)$$

Where $g^l(z^l) = a^{(l)}\ .*(1-a^{(l)})$.

After computing the error term, $\Delta_{i,j}^l$ will be modified as

$$\Delta_{i,j}^l := \Delta_{i,j}^l + a_j^{(l)}\, \delta(l\text{-}1) \quad (5)$$

Fig. 3.Face recognition dataset.

B. *Server Side Software Development*

The server side software development is more straight forward. In this development, a Node JS based IBM's server is used. In the subsequent two blocks after the decision taking block namely error response block in the flow chart in Fig. .4, Twilio's API is used for sending SMS to the user and the administrator. MongoDB API used for server side database development. It is realized by the following flow chart.

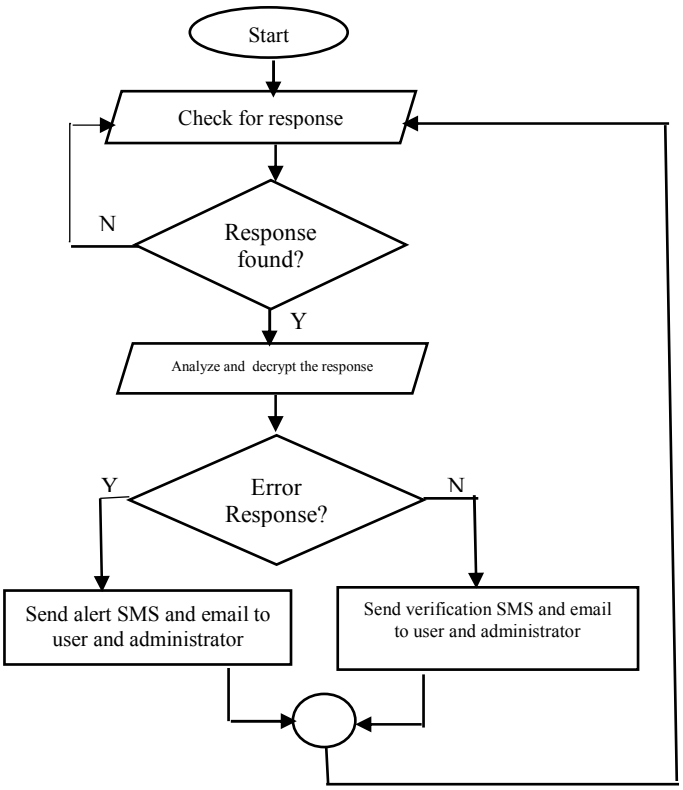

Fig. 4. Flow chart for web server side development

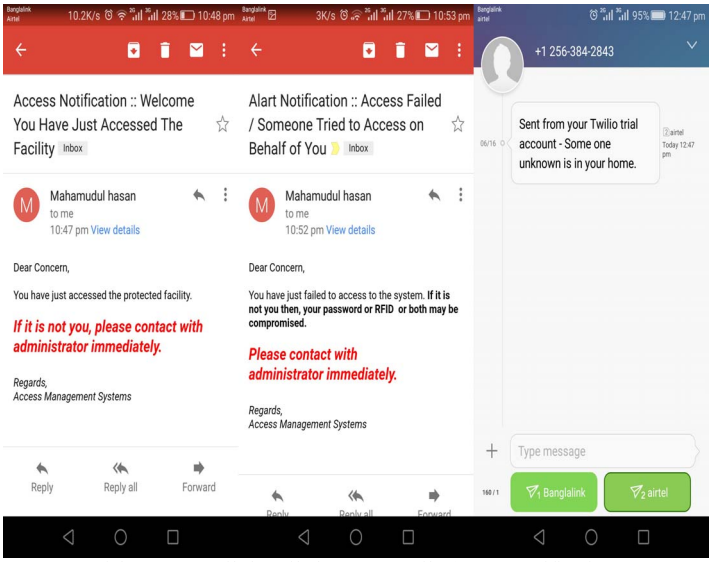
The practical implementation of the automated SMS and email in response to the defined situation is shown in the Fig. 5. The first two sub figures are email responses from the web server to the user about access notification and alert notification (Fig 5(a) and Fig 5(b)). The third sub figure is the SMS response to the user which notifies them about suspicious activity in their residence. (Fig 5c). Authorized face recognition and access management system hardware setup is shown in Fig. 6 and Fig. 7 respectively.

V. PERFORMANCE ANALYSIS



Performance analysis can be done in various ways. In this paper, performance is evaluated both qualitatively and quantitatively. These two analyses are described in the following subsections.

A. *Qualitative analysis:*

The qualitative analysis is done based on several parameters. These parameters are described in the following subsections.

a) Latency:

In real time embedded systems, latency is one of the key factors by which system's performance can be evaluated. The time interval between the application of input to the system and obtaining output from the system can be defined as system latency. There are three types of latencies in this system. They are Raspberry Pi 3 side system latency, IBM cloud server side latency and network side system latency. For simplicity, Raspberry Pi 3 side system latency and total system latency is measured since cloud side latency and network side latency are inconsistent over time. From the average of 50 instances, it is found that Raspberry Pi 3 side system latency is about 120ms in which the face recognition time is about 45ms as the total latency is about 3.5s.

(a) Successful access email (b)Failed access email (c) SMS notification

Fig. 5. E-mail and SMS based notification on mobile device

b) Data Security:

If the data of the system is stored properly and cannot be changed or altered, the security of the system is primarily ensured. The data is encrypted via AES 256 in system side and decrypted on server side. The key is being changed at a regular time interval to provide system integrity.

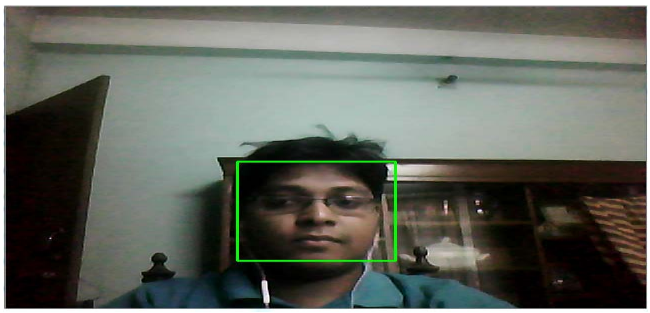


Fig. 6. Authorized face recognition

Fig. 7. Access management system

B. *Quantitaitve analysis:*

The quantitative analysis of the system is based on the performance of the back propagation of the neural network of the face recognition section. The following table shows the test data of three different samples. It is to be noted that each test is conducted 65 times. Every time true positive (TP), true negative (TN), false positive (FP) and false negative (FN) are calculated, and the recognition rate is denoted by the following equation.

$$RR = \frac{TP + TN}{TP + TN + FP + FN} \quad (6)$$

TABLE I. RECOGNITION RATE

	Test 1 $(\%RR)_{avg}$	*Test 2 $(\%RR)_{avg}$*	*Test 3 $(\%RR)_{avg}$*
Sample 1	83.31	81.32	85.11
Sample 2	85.32	82.71	87.31
Sample 3	84.74	81.57	89.74

For optimal performance of the face recognition system, the intensity of the light should be above 300 lux. All efficiencies (Test 1 and Test 2) of the table 1 are measured on 350 to 400 lux in daytime indoor condition. The system also recognizes the faces in day time outdoor environment(Test 3) where the light intensity is above 1000 lux.

Although it is tough to find homogeneous systems resembling the proposed system immaculately, the overall performance analysis of the access management system with some of the predecessor systems is shown in the following table.

TABLE II. PERFORMANCE ANALYSIS WITH RELEVENT SYSTEMS

The cloud connectivity and integration of three layers of authentication in cost effective platform is unprecedented in the previously developed systems. Due to cost effective hardware and multistage authentication, the overall system latency is comparatively larger.

VI. COMPARATIVE ANALYSIS

The comparative analysis is accomplished based on comparing the developed system to some of the previously developed systems. The comparative analysis is shown in the TABLE III .

In the proposed work, three layers namely, password, RFID and face recognition, based security system is developed and the IoT connectivity makes it easy for both the user and the administrator to verify the access. As the SMS and email are sent to user and administrator server, the access record is also preserved.

It is quite evident that most of the previously developed systems rarely concerned with more than two parameter access authentication and connectivity of those systems are seldom taken into consideration. Though some systems dealt with biosignals and zigbee based communication systems for ensuring systems data security, those systems showed seemingly complex method which will not only contribute to higher system latency but also will be prone to data taping if PAN ID of zigbee network is compromised or bio signal pattern is recognized via deep neural network. To prevent data tapping AES algorithm is employed in this work and the key is modified at a defined time interval which ensures data security.

In summary, few previously developed systems exploit three layers of hardware authentication, one layer of software based security for prevention of data tapping and three different connectivity schemes for access management system.

VII. CONCLUSION AND FUTURE WORKS

In this paper, three layer authentication based access management where data security is ensured via AES algorithm is developed. Implementation of three hidden layer back propagation based face recognition feature for both low light(indoor application) and day light(outdoor application) condition, which had recognition rate (RR) ranging from 81.32%(at low light) to 89.74%(at day light), improves the performance of the access management system. Incorporation of IoT environment for connectivity with AES algorithm for data security in software layer makes the system both flexible and secure simultaneously.

Presently, this system is using IBM's free IoT cloud server bluemix on trial basis which offers generic and limited development on their server. For dedicated smart

phone application stable api of the cloud server is required which is not available in this trial cloud platform. The free bluemix server also has limitations that prevent to employ good lossless data compression algorithm with fairly large blocks of code in server side. This free server also does not support over the air (OTA) update on remote devices. In future, when dedicated server for this access management system will be developed then, cloud connected smart phone application, exploitation of lossless data compression and OTA update on remote devices will be possible.

***Abstract*— Unwanted fire causes many disasters. Thus, fire detection has been an important phenomenon to save human life. In this paper, we proposed a hybrid model that incorporates computer vision and smoke sensor-based fire detection into a single system to devise a more accurate and smart fire detection system. Our vision-based fire detection model utilizes color and motion attributes of fire combustion. Rule-based color segmentation is performed for classifying fire color regions and a modified image difference technique is used for detecting the motion of fire regions in consecutive frames. The proposed dynamic threshold technique is used for mitigating the false positive rate of the vision-based model. After performing a vision-based analysis, the proposed algorithm uses the MQ-2 smoke sensor to detect environment smoke and gas caused by fire combustion. Our implemented system raises a fire alarm in the form of remote notification after analyzing vision and smoke sensor-based model data. Real life experimental data shows that our system can detect fire with 86.67% of accuracy. In addition, the proposed system can be incorporated in existing surveillance systems at an adequately low extra expense.**

Keywords—Fire flame detection, Fire color pixel segmentation, Fire region estimation, Dynamic threshold, Motion rate.

I. INTRODUCTION

Ensuring safety for the people and goods are one of the major challenges of 21st century. Among other causes one extremely dangerous cause that can ruin lives is fire. According to the National Fire Protection Association's (NFPA) report published on April 23, 2013 the United States fire department had to respond to an estimated annual average of 366,600 home structure fires from 2007-2011 [1]. And estimated 7 people died each day! One of the primary reasons for so many fire deaths is not immediately being aware of the fire hazard.

In the context of 21st century, surveillance cameras are extremely common. It is used in homes, offices, shops, industries and everywhere. Vision based fire detection that can be done with existing surveillance cameras can go a long way to reduce the amount of severe fire accidents. Even though only smoke based fire alarms are most popular but a lot of times they do not necessarily work the way they are intended. An integrated system that can check smoke as well as recognize the fire flame using existing surveillance cameras and immediately notify the authorized persons can reduce the fire loss immensely.

Fire has shown to have diverse, multispectral marks, a few of which have been used to devise diverse strategies for its detection. The vast majority of the techniques can be classified into smoke, heat, or radiation detection. According to Wikipedia "Fire detectors sense one or more of the products or phenomena resulting from fire, such as smoke, heat, infrared and/or ultraviolet light radiation, or gas" [2]. However, each of the fire detection technique is better suited for a distinct scenario and it is quite difficult to devise a solution which can detect all the phenomena caused by fire. Therefore we implemented a hybrid model which utilize computer vision as well as traditional smoke sensors for devising a more accurate and modern solution for fire detection in different environment. The objective of this work is to provide a fire detection model that utilize existing infrastructure but way more accurate and smarter than existing sensor based fire detection techniques.

The rest of the paper is organized as follows. The following section highlights some related works of sensor and computer vision based fire detection. Section III describes the proposed fire detection method as a whole. Section IV presents the architecture and the layout of our fire detector prototype. Section V describes the proposed vision based fire detection algorithm. It also discusses the methods in details. Section VI discuss about smoke sensor configuration in our prototype. Section VII shows the experimental data analysis in various real life environments and summarizes their result. Section VIII sheds light on why this system is beneficial for the detection of fire. Finally the last section IX concludes the paper.

II. RELATED WORK

Despite the growing interest in the field of automation, in the surveillance sector specially in fire detection, there is still not sufficient number of research conducted in the field of automated fire detection using real life scenarios. The authors [3] proposed a decent color analysis based fire detection method using HSI color space. They used image difference and color masking based approach for getting rid of spurious fire like region and also proposed a simple fire degree estimation technique. But the research only used color based distinctive feature of fire which is more error prone in real life scenarios.

Wireless sensor network based fire detection algorithm in video sequences is proposed by the authors [4]. They used motion and color feature of fire. For background extraction in image mixture of Gaussian is used and color based algorithm had been utilized for foreground extraction. The color detection algorithm is performed in RGB color space. Change map and blob's area of consecutive binary frames is computed for motion detection in fire region. But spurious fire color objects can also be detected as fire by the algorithm because the authors did not addresses the smoke based distinctive feature of fire.

A decent and architecturally complete fire alarm system is proposed by the authors [5] using raspberry pi, Arduino Uno and smoke sensors. The embedded system detects fire using presence of smoke in the air and generates a SMS notification with an image of surroundings. Thus it incorporates human intervention for confirming a notification to the fire fighters and mitigate false alarm. The shortcomings of this approach are it does not fully automate the fire alarm system and did not analyze the image captured by the system. A vision based model for analyzing surrounding image could be used for eliminating human intervention.

Therefore a complete fire detection system which incorporates vision and smoke sensor based fire detection in a single system is proposed for real life fire detection. This paper also provides a complete architectural design of a fire alarm system in great details.

III. Approach

Detection of fire using automated system is complex because fire has many distinctive features and all the feature cannot be detected using single type of fire detector. Therefore false positive rate of existing fire detection systems are very high.

Fire has many distinguishing features such as color, motion, shape, growth, heat, smoke and flame rays. In this paper we focused on features such as flame color, flame motion, generated smoke by fire and we hope to include additional features in our prototype in future work.

As mentioned earlier our algorithm is designed to work in static environment like CCTV surveillance areas therefore the first step of our algorithm is to dynamically define a threshold for the environment. After initializing the threshold the algorithm takes each frame from image source after T time and classifies fire like pixels using our color segmentation module.

In our prototype we have used IP camera as live image source and defined T = 2 sec. If the result of color segmentation find any fire like region then the algorithm proceed for motion detection of fire like region. After successful detection of motion in the fire like region the algorithm use the estimated amount of fire in the image and collect the data of smoke sensor for ensuring the presence of fire. If all the steps give positive result then our algorithm raise fire alarm in a form of remote notification.

IV. Architecture Of Fire Detector Prototype

"Fig 1" shows the components used in our prototype fire detector. "Fig 2" shows the architecture and full block diagram of the system. The structure of out fire detection

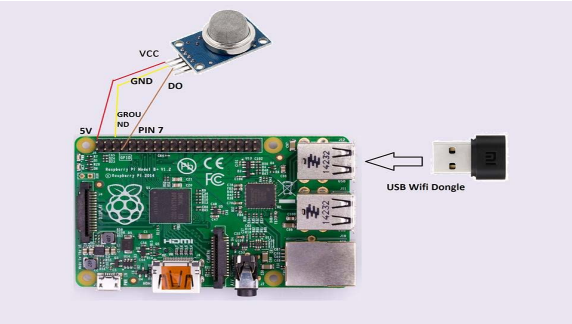

Fig. 1. Component diagram of the fire detector

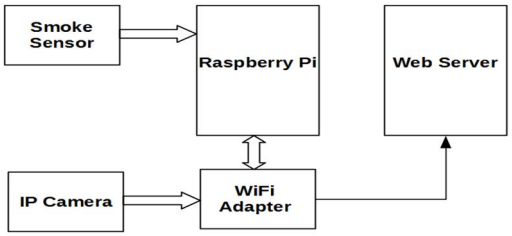

Fig. 2. Block diagram of the fire detector

system composed of five core components which are Raspberry Pi 2 Model B single board computer for data processing, MQ-2 smoke sensor for sensing gas or smoke, IP camera for capturing the image from the environment, WIFI adapter for accessing internet from Raspberry Pi and a web server for sending real time fire alarm. As a web server and backend API we have used IIS server and ASP.NET MVC as well.

V. Proposed Fire Flame Detection Method

The proposed fire flame detection method is based on RGB color space because the targeted hardware to run our algorithm is IOT boards like Raspberry PI or Arduino and for extracting fire colored pixels, RGB color space require less computation compared to other color space. The algorithm consists of three sub algorithms: fire like color pixels segmentation for extracting only fire color pixels from the image, fire like region estimation for estimating the amount of fire in the environment image and motion detection in fire like regions. But in real life scenarios we also need to define a threshold dynamically for each distinct environment for decreasing false positive rate. The following sections will describe the steps in more details

A. Fire like Color Pixels Segmentation

According to the literature review and based on our own experiments we noticed that fire has very distinctive color characteristics. It is a very powerful distinguishing feature of fire and almost every computer vision-based fire detection research used fire color feature extensively. The color of hydrocarbon flames which are the most common type of flame seen in nature belongs to red-yellow [6]. As mentioned earlier we used RGB color space for segmenting fire like color pixels from image. The authors [4, 7, 8, 9] also used RGB color space for aiding their fire color segmentation. For segmenting fire like pixels in RGB color space the two most commonly used rules shown in "(1)" and "(2)"

$$R(x,y) > R_{mean} \quad (1)$$

$$R(x,y) > G(x,y) > B(x,y) \quad (2)$$

Where x and y are the spatial coordinates of a frame at time *t*. In "(1)", *R(x, y)* is the intensity value of red channel at *x* and *y* location and R_{mean} "(1)" is the mean of red channel intensity values. In "(2)", *G(x, y)* and *B(x, y)* are the intensity values of green and blue channel at x and y location respectively. So, to classify a pixel as fire color pixel the value of red channel should be greater than the mean value of the red channel and the value of red channel supposed to be greater than the value

of green channel and the value of green channel supposed to be greater than the value of blue channel.

But in our color segmentation algorithm we modified the first rule "(1)" for decreasing false positive rate in the real-life environment. So, the modified version of Rule "(1)" shown in the following Rule "(3)".

$$R(x, y) > 200pt \quad (3)$$

Pixels that satisfy "(2): and "(3)" are considered to be fire like colored pixels in our color segmentation algorithm. The resulted image after performing the color segmentation can be represented as "(4)".

$$S(x, y) = \begin{cases} P(x, y), & if\ (2)\ and\ (3)\ is\ true \\ 0, & otherwise \end{cases} \quad (4)$$

Fig. 3. Fire image

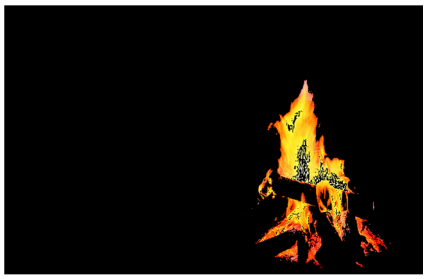

Fig. 4. Same fire image after color segmentation

Fig.. 5. Non fire image

Fig. 6. Same non fire image after color segmentation

As illustrated in "Fig. 3" and "Fig. 4", the fire areas are almost completely extracted. But only color segmentation is not sufficient for fire flame detection because "Fig. 3" and "Fig. 4" illustrates only the best-case scenario where there is no fire colored object in the background. Notice "Fig. 5" which is a non-fire image, but after color segmentation "Fig. 6" some areas are extracted because the pixels color belongs. to the range of hydrocarbon flame colors. So, the fire detection algorithms based on only color feature will be resulted in very high false positive rate.

B. Fire like Region Estimation

After color segmentation an approach is needed for estimating the burning degree of fire flames in the resulted image. A simple approach is proposed for roughly estimating the burning degree of fire flames which is similar to the approach of author [3]. In simple pseudo code, fire flame burning degree estimation can be expressed as,

```
counter = 0
for x = 0 to image.rows do
    for y = 0 to image.cols do
        if "(2)" and "(3)" equals true then
            counter++
        end if
    end for
end for
percentage = (counter / (image.rows * image.cols)) * 100
```

The percentage is used as the parameter of measuring the amount of fire in the image. Where 0 percentage means there is no fire found in the image and 100 percentage means the whole area is covered in fire.

C. Motion Detection

Motion detection algorithm runs on the result of color segmentation algorithm. The purpose of this sub algorithm is to remove static fire like colored object from the result and also gives a rough estimation of flame motion rate.

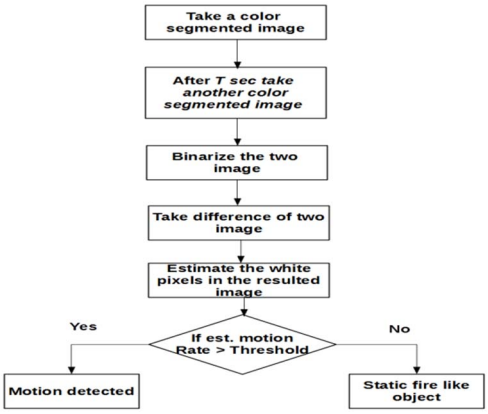

Fig. 7. Motion detection process

"Fig. 7" shows the motion detection algorithm takes two fire-color segmented images. The second frame should be taken after *T* sec of first frame. The next step is to binarize the images. The rule for binarization is if *P(x, y)* is greater than zero then the *P(x, y)* becomes white (255pt) otherwise the *P(x, y)* becomes black (0pt). After binarization the absolute

difference of two binarized frame is taken as resulted image. The result of motion detection algorithm is called motion rate which is nothing but the percentage of white pixels in the resulted image.

D. Dynamic Threshold

Despite of higher false positive rate of color-based fire detection algorithms, color-based approach is more popular because of its low false negative rate. Other vision-based fire detection algorithms that use color feature [3, 4, 7 - 13] also need to use other methods to decrease the higher false positive rate of color segmentation algorithm. Motion detection method can reduce the false positive rate of color segmentation but we also define a threshold at the very beginning of our fire flame detection algorithm. This method is also based on an assumption that when our algorithm first initializes the surrounding or the environment does not have any fire. On the basis of this assumption our algorithm takes a color segmented image of the environment and save its estimated fire pixel rate for using as threshold. So, whenever the algorithm estimates the fire pixel rate for any frame it deducts the threshold from its estimation. However, this technique is not applicable for dynamic environments where the background changes frequently. But this technique surprisingly decreases the false positive rate of the algorithm for static environment like surveillance camera's environment.

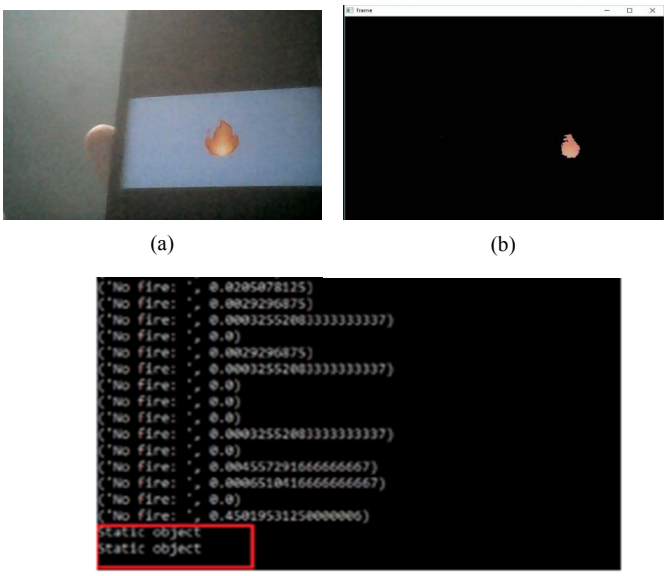
VI. SMOKE DETECTION

Smoke and gas are another important distinctive phenomenon caused by fire combustion. The gas produced during fire combustion highly dependent on combustion materials. Carbon monoxide is produced in quantity at most building fires because most organic materials contain carbon in their chemical structure. Materials that contain nitrogen, such as acrylic fiber, nylon, wool and urea-formaldehyde foam, could produce dangerous quantities of HCN in addition to CO [14]. Therefore, in our prototype we used MQ-2 smoke sensor which can sense smoke, LPG, Alcohol, Propane, Hydrogen, CO and even methane.

In our fire detection algorithm, the last step of verification of fire is smoke detection. After successful detection of fire flame by proposed fire flame detection algorithm, smoke detection take place. If smoke detection method gives positive result then our algorithm sends a strong fire alert to the web server otherwise it gives a mild fire alert because there is no smoke or gas in the air caused by fire combustion. The following section shows some experimental result of our fire detector in real life scenarios and a finally gives a verdict about its accuracy.

Fig. 8. MQ-2 smoke sensor

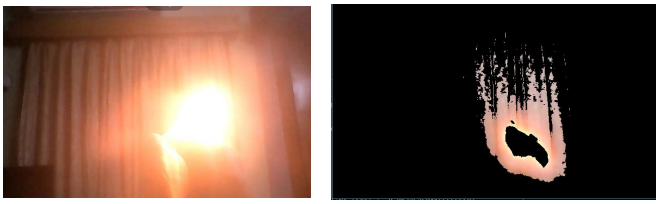
VII. EXPERIMENTAL RESULTS



The proposed fire detection method was tested 60 times in variety of environment including indoor and outdoor. Some of the distinct scenarios mentioned here.

(a) (b)

Fig. 9. Test scenario with fire and smoke



In "Fig. 9" (a) we have created some artificial fire and smoke. The fire detector successfully detected the flame area (b) and smoke and sent a strong fire alert to the web server.

(a) (b) (c)

Fig. 10. Static fire like object test

In "Fig. 10" (a) we tested our algorithm with static fire like object, at first it successfully segmented the fire color object as shown in (b) but due to absence of motion attribute of fire the fire detector classify it as a static fire like object.

(a) (b)

Fig. 11. Test scenario with fire

"Fig. 11" (a) shows an environment where we created artificial fire with match stick without artificial smoke. Our

fire detector successfully detected the fire as shown in (b) but due to absence of smoke in the environment the smoke detector does not sense any smoke therefore the fire detector sent a mild fire alert to our web server.

As mentioned earlier we conduct 60 tests in different environments and among 60 test cases 44 test cases contains actual fire and smoke and 16 test cases contains fake fire like objects without smoke. "Tab. I" shows the confusion matrix of experimental results where TP (true positive) means test cases where fire and smoke was present and algorithm detected it, FP (false positive) means test cases where fire wasn't supposed to be detected but the algorithm detected fire, FN (false negative) means test cases where fire was present but algorithm failed to detect it, and TN (true negative) means test cases where there was no fire and algorithm did not detect any.

TABLE I. CONFUSION MATRIX OF EXPERIMENTAL DATA

		Predicted Class	
		+	-
Actual class	+	41	3
	-	5	11

According to "Tab. I" the predictive accuracy of our proposed algorithm is about 86.67 %. The result is quite promising because all the test cases were done in real life environment. The author [4] achieved 92.8 % of correct classification result by their algorithm but all the test cases were on previously captured video sequences. Therefore, in real life scenarios 86.67 % of accuracy is quite sufficient in most of the cases.

VIII. ADVANTAGES OVER EXISTING SYSTEMS

The primary benefit of our proposed system over existing fire detection systems is the fact that whereas traditional fire detection system uses the smoke sensor to detect fire, our system not only detects the smoke but also can recognize fire combustion using computer vision. So, the detection is faster and more accurate than the traditional systems. The usability of our system is higher because of the real-time and two-step verification process. And the system is even more convenient since most offices and streets already have surveillance systems these days and our system can easily be integrated with those cameras that are already in place.

IX. CONCLUSION

In this paper, we proposed a hybrid fire detection system which incorporates computer vision and smoke sensor-based fire detection technique in a single system. Vision based algorithm use color and motion feature of fire combustion and MQ-2 smoke sensor detects smoke and gas produced by combustion. Our algorithm analyzes all the data produced by the vision and sensor-based model and raise alarm in form of remote Realtime notification. Our proposed system extends beyond fire detection and proposed a complete architectural reference of a fire alarm system. Our tests demonstrate that the proposed system distinguishes fire with high precision in real life CCTV surveillance environment. But the proposed system is not designed for the dynamic environment where the background changes frequently and the system is also not intelligent. So, in our future work we will endeavor to replace existing vision-based algorithm with deep learning based intelligent algorithm that will work equally in static and dynamic environment with better accuracy.

ACKNOWLEDGMENT

We would like to thank Mir Riyanul Islam, Faculty of Science and Information Technology, American International University Bangladesh for helping us optimizing our algorithm.

***Abstract*— This paper represents an implementation of Principal Component Analysis (PCA) on masked and non-masked face recognition. Security is an essential term in our today's life. In various Biometric technology, face recognition is widely used to secure any system because it is better than any other traditional techniques like PIN, password, fingerprint etc. and most reliable to identify or verify a person efficiently. In recent years, face recognition is a very challenging task because of different occlusion or masks like the existence of sunglasses, scarves, hats and different types of make-up or disguise ingredients. The accuracy rate of face recognition is influenced by these types of masks. Many algorithms have been developed recently for non-masked face recognition which are widely used and give better performance. Still in the field of masked face recognition, few contributions has been done. Therefore, in this work a statistical procedure has been selected which is applied in non-masked face recognition and also apply in the masked face recognition technique. PCA is more effective and successful statistical technique and widely used. For this reason in this work, PCA algorithm has been chosen. Finally, a comparative study also done here for a better understanding.**

Keywords—Face recognition, PCA algorithm, Eigen face, Eigen value, Masked face.

I. INTRODUCTION

Face recognition is one of the most promising field of computer vision. Recognize a face and verifying a person automatically from images, known as face recognition system [1]. Face recognition plays an important role in our regular life. In a passport checking, ATM, credit card, voter verification, smart door, criminal or terrorist investigation and many other purposes face recognition is widely used to authenticate a person automatically and accurately. For those reasons, face recognition is the most popular than any other Biometric techniques.

In all automated personal identification system, face recognition has gained much attention as a unique Biometric recognition technique. For protecting the assets of many industries in the world are now trying to implement this authentication technique in their organizations. Throughout the world, many of the governments also interested to secure the public places such as railway stations, airports and bus stations etc. by using face recognition system. However for poor recognition rate, in real time recognizing remain unsuccessful. Recognition rate depends on quality of image. Recognition rate decreases for noisy and low quality image. That's why pre-processing is needed for better recognition rate. Some pre-processing techniques like cropping, resizing, sharpening, de-noising, normalizing, enhancing are used in face recognition process [2]. Recently many algorithms have been developed for reliable face recognition. Different techniques depend on different methods and they have different recognition accuracy. All of these algorithms, Principal Component Analysis (PCA) gives a better accuracy rate in normal or non-masked face recognition [3]-[5].

In present days masked face recognition is more important. Mainly terrorists and criminals covered their face with mask for disguise. Besides this, sunglass, hat, color festoon etc. also act like mask. Using different types of masks or occlusions the key features to identify a person is decreasing. Lower numbers of face features in the masked face cause difficulties than other normal face recognition technique [6]. Consequently the accuracy rate of recognition is decreasing. That's why masked face is being one of the majors concerned factor in the field of face recognition. Figure 1 shows some of masked faces.

Fig. 1. Human faces with different types of masks.

For face recognition, at first we need to detect the face from image. After detecting face, we can recognize the person. It is easy for human to detect a face but harder for a system to detect face. For this reason at first we need to train the system for detect face portion from images. Here we use Viola-Jones algorithm to detect face from an image. Viola-Jones algorithm

detect face using machine learning approach from any digital image [7]. After detecting face from input image, then we use PCA algorithm for feature extraction from image, which are used for training.

This work also presents a statistical difference of accuracy between masked face recognition and non-masked face recognition using the most successful algorithm Principal Component Analysis. All the result are shown in both graphically and tabulated form.

The paper is organized as follows: Section 2 presents our face detection and face recognition methodology. Section 2 describes about face recognition process. Section 3 signifies dataset. Section 4 shows experimental results and section 5 draws conclusions.

II. METHODOLOGY

Figure 2 demonstrate our proposed method to the problem of robust face recognition under mask and non-mask conditions. For face recognition at first detect the face portion from an image, find out the face features and finally train a system for face recognition. During the training phase, for detecting face portion we used Viola-Jones algorithm in our work and then PCA is used to efficiently represent the gallery images. In this way we obtain a PCA feature space which is called Eigen faces or ghost face. In the test case, a target face image (which can be masked or not) is given to be recognized. At first its PCA representation is computed. As a result, potential facial components are identified. Then, the Eigen faces are selected and used for recognition. The recognition is carried out by comparing the selected features from the target image against selected features from the corresponding template images. The nearest neighbor (NN) classifier distance is taken for the recognition.

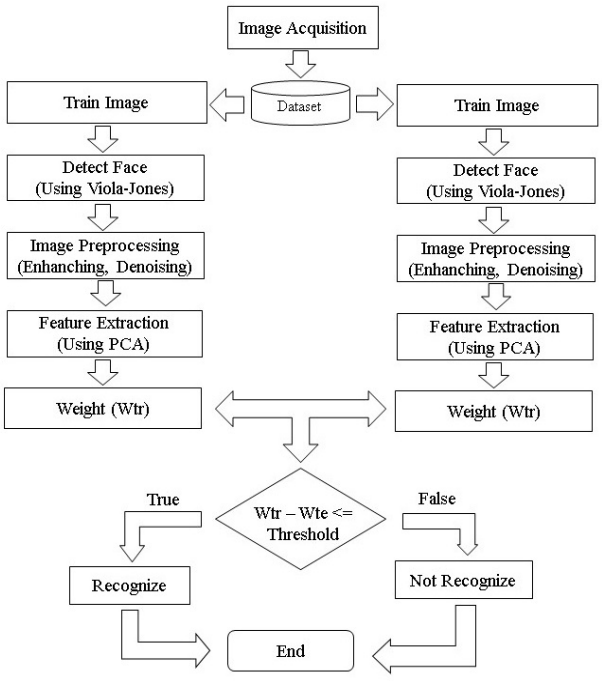

Fig. 2. Flow chart of face recognition process using PCA.

III. FACE RECOGNITION PROCESS

From a digital image or video sources identify or verify a person automatically by comparing facial features is called face recognition. Using various algorithms, features are extracted and then perform comparison between training image and test image for recognize a face.

A. Facial Image Acquisition

Image acquisition is the first stage of face recognition system. After obtaining the images, different methods of processing can be applied on the image. If the image has not been acquired correctly then the desired tasks are difficult to achieve. In this work we use faces from a database named ORL Database and some of our own captured images. We mix up our own masked and non-masked images to the database to enlarge the dataset so that our work is more reliable and efficient.

B. Detecting Face and Preprocessing

After acquiring the images, the first work is to segment out the face for further processing. We choose Viola-Jones face detection algorithm for detecting face region. Then implemented it in the MATLAB library to automatically segment the face region. Some of our face images quality are not much better as we needed. Up to expectation this face detector fails to detect face region in image. Faces which are heavily disguised or most of the important facial features are covered are subjects to fail detect face region. Every face image is normalized and apply image enhancement methods, so to achieve better results. This set of enhanced face images are therefore used to perform further experiments and evaluations.

C. Facial Feature Extraction using PCA

Principal Component Analysis (PCA) is an important statistical procedure and also defined as an orthogonal linear transformation. This algorithm emphasizes variation and brings out strong patterns in a dataset. It is used to minimize a big dataset to a small dataset still contains almost all the information as large dataset. PCA finds the data mean and principal components. It is popular as dimension reduction procedure. The technique is usually used for maximizing variance and seizing strong patterns of features in a dataset [8]. It was introduced by Karl Pearson in 1901. PCA is an effective statistical method.

For correlated data, Principal Component Analysis (PCA) works well. An image is also a highly correlated data. Hence extracting features from images, PCA performs better. Performing different operations on image matrix, it is transformed to a lower dimensional Eigen subspace. There after find out the covariance matrix from the lower dimension matrix. Relative variance between pixels in an image are represented by covariance matrix. Afterward Eigen vectors are calculated from this covariance matrix. Eigen vectors with the highest Eigen values are considered as the principal components.

Steps of Principal Component Analysis algorithm are mentioned below-

Step 1: Input data

Step 2: Calculate mean value of data

Step 3: Subtract the mean value from each input data

Step 4: Calculate Covariance matrix

Step 5: Calculate Eigen vectors and Eigen values

Step 6: Finding the greatest eigenvalue(s)

Step 7: Calculate Weight

D. Eigenvalue and Eigenvector

Eigenvalue and eigenvector comes from German word "Eigen" that means "Characteristic". In a square matrix eigenvalue is a scalar that represent by λ, which is a Greek letter. Eigenvector is represented by small letter *x* and it is a non-zero vector [9]. Here is an equation which is satisfied by all eigenvector and eigenvalue. Here, *S* is a given square matrix.

$$Sx = \lambda x \tag{1}$$

A huge calculation need in a large matrix and to solve this problem, eigenvalue and eigenvector method is used.

E. Eigen Face

Basically a set of eigenvector is called Eigen face which is used for face recognition of human. Eigen face extract the main feature from image and major Eigen face is selected for face recognition. In face recognition, Eigen face is used for represent the face image efficiently by principal component analysis. Images can be reconstructed as like as original image from a few number of weights and pictures [10]. Eigen face in a face recognition system must be less or equal to the total size of dataset. In figure 3 shows some of Eigen faces.

Fig. 3. Some Eigen faces.

F. Mathematical Analysis

For face recognition we need to train a dataset and then apply Principal Component Analysis on train dataset step by step. At first, we have to convert train dataset into face vector. Each 2D (*p* by *q*) train image is converted into 1D ($p \times q$ by 1) face vector. After converting all images, they are loaded which is called dataset. In this research work, total images K= 12 (face of our dataset). Here K depends on the number of train images and I is a variable which loads all images.

$$\mathrm{I} = \{\Gamma_1,\ \Gamma_2,\ \Gamma_3, \cdots\cdots\cdots, \Gamma_K\} \tag{2}$$

After load the dataset next procedure is to calculate average or mean face. Here average face is $\bar{X}$.

$$\bar{X} = \frac{1}{K}\sum_{n=1}^{n=K}\Gamma_K \tag{3}$$

Then, subtract the mean face from each image of the dataset which is called normalization. Here ϕ_n is a variable which stores the result of normalization. Then new matrix D is generated,

$$\phi_n = \Gamma_n - \bar{X}$$
$$\mathrm{D} = \{\phi_1,\ \phi_2,\ \phi_3, \cdots\cdots\cdots, \phi_K\} \tag{4}$$

After normalizing, we get a normalized face vector. Then we calculate covariance matrix of normalized vector.

$$C = DD^T\mathrm{s}$$
$$= \{D_{(p\times q)}D^T{}_{(q\times p)}\}_{(p\times p)} \tag{5}$$

Covariance matrix C is a large square matrix. For efficient and accurate calculation eigenvalue and eigenvector is calculated for reducing a huge face space vector. For recognition, we need to calculate weight which is compared with test image weight.

$$\omega_K = \mu^T(\Gamma_n - \bar{X}) \tag{6}$$

Here, ω = weight, μ = eigenvector, Γ = face and $\bar{X}$ = average face.

IV. DATASET AND EXPERIMENTAL ENVIRONMENT

In this work ORL face database [13] is used, which contains a set of faces taken between April 1992 and April 1994 at the Olivetti Research Laboratory in Cambridge, UK. This dataset contains 10 different images of 40 individuals. The files are in PGM format. Each image size is 92x112, 8-bit grey levels. For masked faces we created masked face images dataset using ORL face image and our own captured images. In this experiment, total 500 images used. 300 as a training image and 80-200 images used as test images on different test cases. Figure 4 shows some dataset images of our experiments. All the work done using MATLAB. Here use image processing toolbox of MATLAB 2017a version on windows platform.

V. EXPERIMENTAL RESULT

Proposed methodology is applied on our dataset images and found the resultant images. First step of face recognition is created a training dataset which contains pre-processed input images. After creating training set, average face is calculated for normalized training set. For normalize the dataset, subtracting an average face from each original face. Figure 5 shows the normalized faces of original face image. Then calculate the Eigen face which are shown in figure 6. Finally test some images for recognition. Here create some masked face images and also test them if it can be recognized

the person properly. Both masked and non-masked face testing images shown in figure 7.

Fig. 4. Some example images from training dataset.

Fig. 5. Some normalized faces

Fig. 6. Some Eigen faces

(a) (b)

Fig. 7. Testing (a) Masked face and (b) Non-Masked face

A statistical comparison between masked face recognition and non-masked face recognition using PCA algorithm shown in table-I. This table shows the recognition accuracy of both masked and non-masked face images. A graphical representation also shown in figure 8 for a better data visualization.

TABLE I. MASKED AND NON-MASKED FACE RECOGNITION ACCURACY

Test no.	Total train image	Total test image	Image types	Accuracy (%)
Test 01	300	80	Non-masked	96.25
	300	80	Masked	73.75
Test 02	300	120	Non-masked	95.83
	300	120	Masked	72.50
Test 03	300	160	Non-masked	95.05
	300	160	Masked	67.13
Test 04	300	200	Non-masked	95.62
	300	200	Masked	68.75

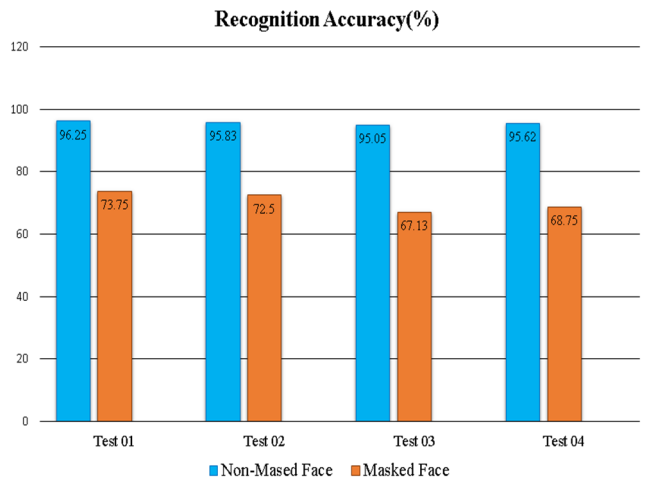

Fig. 8. Graphical representation of both masked and non-masked face recognition accuracy

From the above table, accuracy of masked face image recognition is on average 72% where non-masked face is on average 95%. So PCA gives poor recognition rate for masked face images rather than non-masked faces.

VI. CONCLUSION

This paper analyzed non-masked face recognition and masked face recognition accuracy using Principal Component Analysis (PCA) to recognize a person. It is proved that, a face without mask gives better recognition rate in PCA based face recognition system. But when a person is wearing mask, facial recognition gives poor recognition rate. It is found that extracting feature from a masked face is less than non-masked face. Because of missing features for wearing mask which decrease the recognition rate. Finally, we conclude that traditional statistical algorithm Principal Component Analysis (PCA) is better for normal face recognition but not for masked face recognition. So in the future, our concern to improve the accuracy of masked face recognition using other sophisticated machine learning methods.

Abstract— **Brain Tumor segmentation is one of the most crucial and arduous tasks in the terrain of medical image processing as a human-assisted manual classification can result in inaccurate prediction and diagnosis. Moreover, it is an aggravating task when there is a large amount of data present to be assisted. Brain tumors have high diversity in appearance and there is a similarity between tumor and normal tissues and thus the extraction of tumor regions from images becomes unyielding. In this paper, we proposed a method to extract brain tumor from 2D Magnetic Resonance brain Images (MRI) by Fuzzy C-Means clustering algorithm which was followed by traditional classifiers and convolutional neural network. The experimental study was carried on a real-time dataset with diverse tumor sizes, locations, shapes, and different image intensities. In traditional classifier part, we applied six traditional classifiers namely Support Vector Machine (SVM), K-Nearest Neighbor (KNN), Multilayer Perceptron (MLP), Logistic Regression, Naïve Bayes and Random Forest which was implemented in scikit-learn. Afterward, we moved on to Convolutional Neural Network (CNN) which is implemented using Keras and Tensorflow because it yields to a better performance than the traditional ones. In our work, CNN gained an accuracy of 97.87%, which is very compelling. The main aim of this paper is to distinguish between normal and abnormal pixels, based on texture based and statistical based features.**

Keywords— CNN, FCM, Medical Image, segmentation, SVM

I. INTRODUCTION

Medical imaging refers to a number of techniques that can be used as non-invasive methods of looking inside the body [1]. Medical image encompasses different image modalities and processes to image the human body for treatment and diagnostic purposes and hence plays a paramount and decisive role in taking actions for the betterment of the health of the people.

Image segmentation is a crucial and essential step in image processing which determines the success of a higher level of image processing [2]. The primary goal of image segmentation in medical image processing is mainly tumor or lesion detection, efficient machine vision and attaining satisfactory result for further diagnosis. Improving the sensitivity and specificity of tumor or lesion has become a core problem in medical images with the help of Computer Aided Diagnostic (CAD) systems.

According to [3], Brain and other nervous system cancer is the 10th leading cause of death, and the five-year survival rate for people with a cancerous brain is 34% for men and 36% for women. Moreover, the World Health Organization (WHO) states that around 400,000 people in the world are affected by the brain tumor and 120,000 people have died in the previous years [4]. Moreover, An estimated 86,970 new cases of primary malignant and non-malignant brain and other Central Nervous System (CNS) tumors are expected to be diagnosed in the United States in 2019 [5].

A brain tumor occurs when abnormal cells form within the brain [6]. There are two main types of tumors- Malignant and Benign. Malignant brain tumors originate in the brain, grows faster and aggressively invades the surrounding tissues. It can spread to other parts of the brain and affect the central nervous system. Cancerous tumors can be divided into primary tumors, which start within the brain, and secondary tumors, which have spread from elsewhere, are known as brain metastasis tumors. On the other hand, a benign brain tumor is a mass of cells that grow relatively slowly in the brain.

Hence, early detection of brain tumors can play an indispensable role in improving the treatment possibilities, and a higher gain of survival possibility can be accomplished. But manual segmentation of tumors or lesions is a time consuming, challenging and burdensome task as a large number of MRI images are generated in medical routine. MRI, also known as Magnetic Resonance Imaging is mostly used for a brain tumor or lesion detection. Brain tumor segmentation from MRI is one of the most crucial tasks in medical image processing as it generally involves a considerable amount of data. Moreover, the tumors can be ill-defined with soft tissue boundaries. So it is a very extensive task to obtain the accurate segmentation of tumors from the human brain.

In this paper, we proposed an efficient and skillful method which helps in the segmentation and detection of the brain tumor without any human assistance based on both traditional classifiers and Convolutional Neural Network.

II. LITERATURE REVIEW

One of the most challenging as well as demanding task is to segment the region of interest from an object and segmenting the tumor from an MRI Brain image is an ambitious one. Researchers around the world are working on this field to get the best-segmented ROI and various disparate approaches simulated from a distinct perspective. Nowadays Neural Network based segmentation gives prominent outcomes, and the flow of employing this model is augmenting day by day.

Devkota et al. [7] established the whole segmentation process based on Mathematical Morphological Operations and spatial FCM algorithm which improves the computation time, but the proposed solution has not been tested up to the evaluation stage and outcomes as- Detects cancer with 92%

and classifier has an accuracy of 86.6%. Yantao et al. [8] resembled Histogram based segmentation technique. Regarding the brain tumor segmentation task as a three-class (tumor including necrosis and tumor, edema and normal tissue) classification problem regarding two modalities FLAIR and T1. The abnormal regions were detected by using a region-based active contour model on FLAIR modality. The edema and tumor tissues were distinguished in the abnormal regions based on the contrast enhancement T1 modality by the k-means method and accomplished a Dice coefficient and sensitivity of 73.6% and 90.3% respectively.

Based on edge detection approaches, Badran et al. [9] adopted the canny edge detection model accumulated with Adaptive thresholding to extract the ROI. The dataset contained 102 images. Images were first preprocessed, then for two sets of a neural network, for the first set canny edge detection was applied, and for the second set, adaptive thresholding was applied. The segmented image is then represented by a level number and characteristics features are extracted by the Harris method. Then two neural network is employed, first for the detection of healthy or tumor containing the brain and the second one is for detecting tumor type. Depicting the outcomes and comparing these two models, the canny edge detection method showed better results in terms of accuracy. Pei et al. [10] proposed a technique which utilizes tumor growth patterns as novel features to improve texture based tumor segmentation in longitudinal MRI. Label maps are being used to obtain tumor growth modeling and predict cell density after extracting textures (e.g., fractal, and mBm) and intensity features. Performance of the model reflected as the Mean DSC with tumor cell density- LOO: 0.819302 and 3-Folder: 0.82122.

Dina et al. [11] introduced a model based on the Probabilistic Neural Network model related to Learning Vector Quantization. The model was evaluated on 64 MRI images, among which 18 MRI images were used as the test set, and the rest was used as a training set. The Gaussian filter smoothed the images. 79% of the processing time was reduced by the modified PNN method. A Probabilistic Neural Network based segmentation technique implemented by Othman et al. Principal Component Analysis (PCA) was used for feature extraction and also to reduce the large dimensionality of the data [12]. The MRI images are converted into matrices, and then Probabilistic Neural Network is used for classification. Finally, performance analysis is done. The training dataset contained 20 subjects, and the test dataset included 15 subjects. Based on the spread value, accuracy ranged from 73% to 100%.

Concentrating on Region based Fuzzy Clustering and deformable model, Rajendran et al. [13] accomplished 95.3% and 82.1% of ASM and Jaccard Index based on Enhanced Probabilistic Fuzzy C-Means model with some morphological operations. Zahra et al. [14] performed with LinkNet network for tumor segmentation. Initially, they used a single Linknet network and sent all training seven datasets to that network for segmentation. They did not consider the view angle of the images and introduced a method for CNN to automatically segment the most common types of a brain tumor which do not require preprocessing steps. Dice score of 0.73 is achieved for a single network, and 0.79 is obtained for multiple systems.

III. Proposed Methodology

In our proposed methodology, there are two distinct model for segmentation and detection of Brain tumor. First model segmented the tumor by FCM and classified by traditional machine learning algorithms and the second model focused on deep learning for tumor detection. Segmentation by FCM gives better result for noisy clustered data set [15]. Though it takes more execution time, it retains more information.

A. Proposed Methodology of Tumor Segmentation and Classification Using Traditional Classifiers

In our first prospective model, brain tumor segmentation and detection using machine learning algorithm had been done, and a comparison of the classifiers for our model is delineated. Our proposed Brain image segmentation system consists of seven stages: skull stripping, filtering and enhancement, segmentation by Fuzzy C Means algorithm, morphological operations, tumor contouring, feature extraction and classification by traditional classifiers. The results of our work accomplished satisfactory results. The main stages of our proposed model (Fig. 1) will be illustrated in the following sections.

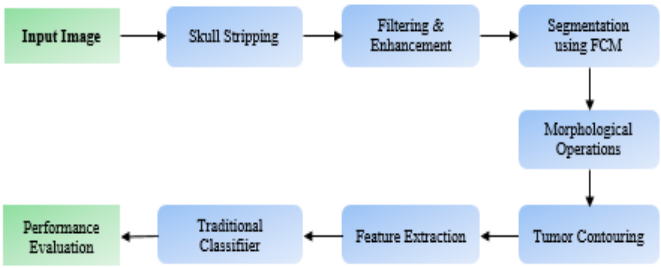

Fig. 1. Proposed methodology for classification using Traditional Classifiers

1) Skull Stripping: Skull stripping is a very important step in medical image processing because of the background of the MRI image not containing any useful information, and it only increases the processing time. In our work, we removed the skull portion from the MRI images in three steps. These three steps are:

a) Otsu Thresholding: For skull removal, at first we used Otsu's Thresholding method which automatically calculates the threshold value and segments the image into background and foreground. In this method, the threshold that is selected minimizes the intra-class variance, defined as a weighted sum of deviations of the two classes.

b) Connected Component Analysis: At the last stage of our skull stripping step, we used connected component analysis to extract only the brain region and as a consequence the skull part was removed.

2) Filtering and Enhancement: For better segmentation, we need to maximize the MRI image quality with minimized noise as brain MRI images are more sensitive to noise than any other medical image. Gaussian blur filter was used in our

work for Gaussian noise reduction existing in Brain MRI which prevailed the performance of the segmentation.

3) Segmentation using FCM: Fuzzy C-Means clustering algorithm was used for segmentation, which allows one piece of data to belong to two or more clusters. We got the fuzzy clustered segmented image at this stage, which ensured a better segmentation.

4) Morphological Operation: To segment the tumor, we only need the brain part rather than the skull part. For this, we applied morphological operations in our images. At first, erosion was done to separate weakly connected regions of the MRI image. After erosion, we will get multiple disconnected regions in our images. Dilation was applied afterwards.

5) Tumor Contouring: Tumor cluster extraction was done by an intensity based approach which is thresholding. The output of this image is the highlighted tumor area with a dark background.

6) Feature Extaction: Two types of features were extracted for classification. Texture-based features such as- Dissimilarity, Homogeneity, Energy, Correlation, ASM and Statistical based features including- Mean, Entropy, Centroid, Standard Deviation, Skewness, Kurtosis were extracted from the segmented MRI Images.

7) Traditional Classifiers: We used six traditional machine learning classifiers which are K-Nearest Neighbor, Logistic Regression, Multilayer Perceptron, Naïve Bayes, Random Forest, and Support Vector Machine to get the accuracy of tumor detection of our proposed model.

8) Evaluation Stage: Implementing other region-based segmentation methods and comparing it to our proposed segmentation technique, our model segments the ROI and segregates the tumor portion most accurately. An illustration of the whole process is depicted in Fig. 5. After segmentation and feature extraction from the tumor, we applied six classification techniques. Among them, we got the best result from SVM and obtained an accuracy of 92.42%.

B. Proposed Methodology Using CNN

Convolutional Neural Network is broadly used in the field of Medical image processing. Over the years lots of researchers tried to build a model which can detect the tumor more efficiently. We tried to come up with an exemplary which can accurately classify the tumor from 2D Brain MRI images. A fully-connected neural network can detect the tumor, but because of parameter sharing and sparsity of connection, we adopted CNN for our model.

A Five-Layer Convolutional Neural Network is introduced and implemented for tumor detection. The aggregated model consisting of seven stages including the hidden layers provides us with the most prominent result for the apprehension of the tumor. Following is the proposed methodology with a brief narration-

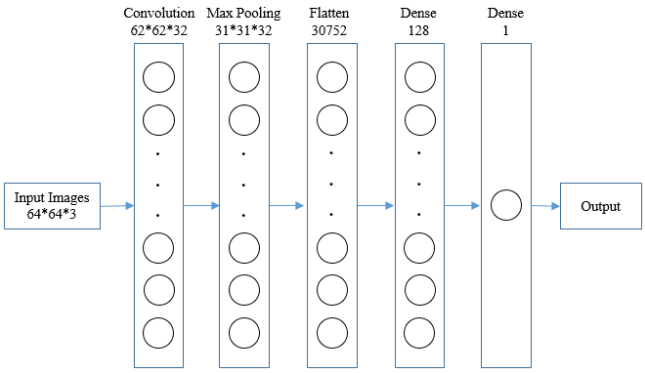

Fig. 2. Proposed Methodology for tumor detection using 5-Layer Convolutional Neural Network

Using convolutional layer as the beginner layer, an input shape of the MRI images is generated which is 64*64*3 converting all the images into a homogeneous dimension. After accumulating all the images in the same aspect, we created a convolutional kernel that is convoluted with the input layer — administering with 32 convolutional filters of size 3*3 each with the support of 3 channels tensors. ReLU is used as an activation function so that it's not corroborating with the output.

In this ConvNet architecture, progressively shorten the spatial size of the depiction for diminishing the chunk of parameters and computational time of the network. Working on the Brain MRI image can also cost the contamination of the overfitting and for this Max Pooling layer perfectly works for this perception. For spatial data which substantiate with our input image, we use MaxPooling2D for the model. This convolutional layer runs on 31*31*32 dimension. Because of divide the input images in both spatial dimensions, the pool size is (2, 2) which means a tuple of two integers by which to downscale by vertically and horizontally.

After the pooling layer, a pooled feature map is obtained. Flattening is one of the essential layers after the pooling because we've to transformed the whole matrix representing the input images into a single column vector and it's imperative for processing. It is then fed to the Neural Network for the processing.

Two fully connected layers were employed Dense-1 and Dense-2 represented the dense layer. The dense function is applied in Keras for the processing of the Neural Network, and the obtained vector is work as an input for this layer. There are 128 nodes in the hidden layer. Because the number of dimension or nodes proportional with the computing resources we need to fit our model we kept it as moderate as possible and for this perspective 128 nodes gives the most substantial result. ReLU is used as the activation function because of showing better convergence performance. After the first dense layer, the second fully connected layer was used as the final layer of the model. In this layer, we used sigmoid function as activation function where the total number of the node is one because we need to lower the uses of computing resources so that a more significant amount assuages the execution time. Though there is a chance of

hampering the learning in deep networks for using of the sigmoid as the activation function, we scale the sigmoid function, and the number of the nodes is much lesser and easy to handle for this deep network. In a summary, Fig. 3 shown the working flow of the proposed CNN model.

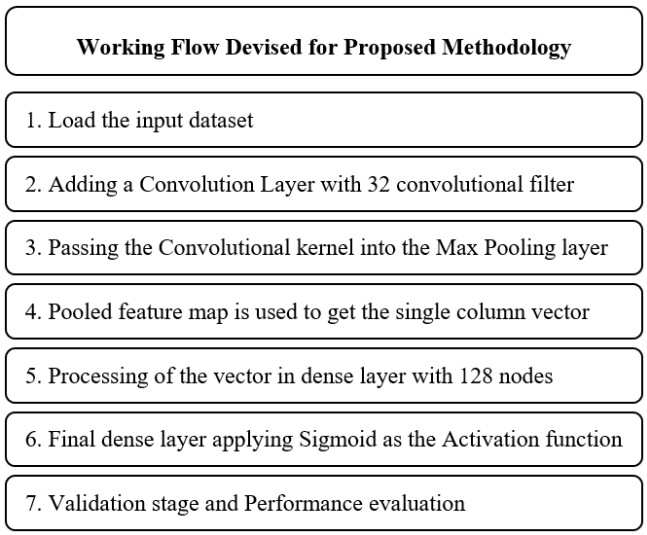

Fig. 3. Working flow of the proposed CNN Model.

Using Adam optimizer and binary cross-entropy as a loss function, we compiled the model and find the accuracy of detecting the tumor. An algorithm is depicted in Fig. 4 where we evaluated the performance of the model.

Algorithm 1: Evaluation process of CNN model

```
loadImage();
dataAugmentation();
splitData();
loadModel();
for each epoch in epochNumber do
    for each batch in batchSize do
        ŷ = model(features);
        loss = crossEntropy(y, ŷ);
        optimization(loss);
        accuracy();
        bestAccuracy = max(bestAccuracy, accuracy);
return
```

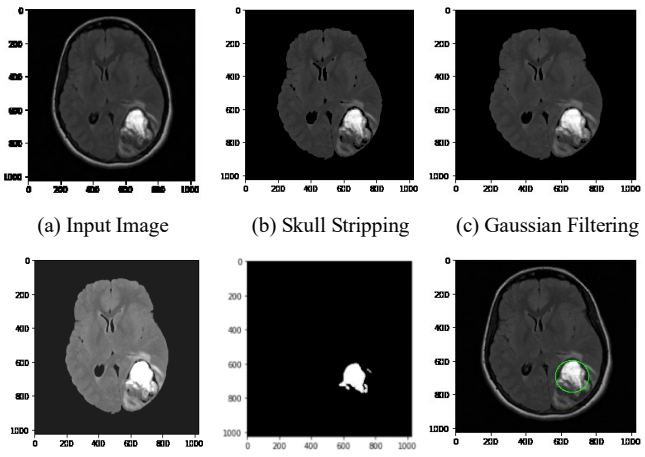
Fig. 4. Algorithm of the performance evaluation

All the hyper-parameters value are constituted in Table-I. Approximately 97.87% is achieved as the accuracy.

TABLE I. HYPERPARAMETER VALUE OF CNN MODEL

Stage	Hyper-parameter	Value
Initialization	bias	Zeros
	Weights	glorot_uniform
Training	Learning rate	0.001
	beta_1	0.9
	beta_2	0.999
	epsilon	None
	decay	0.0
	amsgrad	False
	epoch	10
	Batch_size	32
	steps_per_epoch	80

IV. EXPERIMENTAL RESULTS



To justify our proposed model, steps of segmenting the tumor from 2D Brain MRI is illustrated (Fig. 5) and a comparative analysis of our proposed models of classification using machine learning, and deep learning is shown. We got 92.42% of accuracy using SVM and 97.87% of accuracy is achieved using CNN.

A. Experimental Dataset

For Performance Evaluation of our proposed model, we used the benchmark dataset in the field of Brain Tumor Segmentation, and that is BRATS dataset [16], consisting two classes'— class-0 and class-1 represents the Non-Tumor and Tumor MRI images. 187 and 30 MRI Images containing tumor and non-tumor respectively classified as class-1 and class-0. All the images are MRI images from different modalities like- T1, T2, and FLAIR. For traditional machine learning classifiers, we obtained the superlative result splitting the dataset by 70 to 30 in terms of training to testing images, and for CNN, we divided the dataset in both 70 to 30 and 80 to 20 formation and compared the outcomes.

B. Segmentation using Image processing techniques

Based on our proposed methodology, we segmented the tumor without loss of any subtle information. We removed the skull because for tumor segmentation the role of skull is approximately null and ambiguous in this process.

(a) Input Image (b) Skull Stripping (c) Gaussian Filtering

(d) Image Enhancement (e) Segmentation (f) Tumor Contouring

Fig. 5. Segmentation processes of an MRI

From the dataset, a 2D MRI was taken as an input image, Skull stripping technique is performed on the input image (Fig. 1b) followed by image enhancement (Fig. 1c) for understanding the features of the MRI properly. After that, Gaussian filter (Fig. 1d) is used for noise removal and finally simulating the FCM segmentation technique (Fig. 1e) followed by tumor contouring (Fig. 1f) to find out the ROI which is the tumor for Brain MRI. After the segmentation of the tumor, we classified the tumor based on different traditional Machine learning Algorithms.

C. Classification Using Machine Learning

Texture and Statistical based features are more popular for detecting the Region of Interest (ROI). Based on these features we can segregate the tumorous and non-tumorous MRI. We used texture and statistical based features for classification. Texture-based features like- Dissimilarity, Homogeneity, Energy, Correlation, ASM and Statistical based features including- Mean, Entropy, Centroid, Standard Deviation, Skewness, Kurtosis were extracted from the segmented Brain tumor. Further, we extracted the Area, Convex Hull Area and Diameter of the tumor. Extrapolating these features from the segmented MRI, we classified the image as the existence of normal and abnormal tissue. Table-II depicts the values of the features of some of the segmented MRI. After feature extraction, classification had been done. We adopt six classifiers which are- KNN, Logistic Regression, Multilayer Perception, Naïve Bayes, Random Forest, and SVM and achieved the best accuracy as the performance from SVM. Confusion Metrics' along with the performance of the classifiers is characterized in Table-III. The following factor evaluates the performance-

$$Accuracy = \frac{TP+TN}{TP+FP+TN+FN} \quad (1)$$

$$Sensitivity(recall) = \frac{TP}{TP+FN} \quad (2)$$

$$Speficity = \frac{TN}{TN+FP} \quad (3)$$

$$Precision\ (PPV) = \frac{TP}{TP+FP} \quad (4)$$

TABLE II. EXTRACTED FEATURES FROM SEGMENTED TUMOR

Image No	Contrast	Dissimilarity	Homogeneity	Energy	Correlation	ASM	Label
1	281.18	1.37	0.97	0.90	0.97	0.81	1
2	97.36	0.53	0.98	0.98	0.94	0.96	1
3	337.39	1.68	0.98	0.97	0.82	0.95	1
4	357.59	2.34	0.94	0.92	0.90	0.86	1
5	149.37	0.82	0.98	0.96	0.96	0.93	0
6	357.59	2.34	0.95	0.93	0.90	0.86	0

TABLE III. CONFUSION METRICS' OF THE CLASSIFIERS

Classifiers	Accuracy	Recall	Specificity	Precision	Dice Score	Jaccard Index
K-Nearest Neighnout	89.39	0.949	0.428	0.933	0. 941	0.889
Logistic Regression	87.88	0.949	0.286	0.918	0.933	0.875
Multilayer Perception	89.39	**1.000**	0	0.894	0.944	0.894
Naïve Bayes	78.79	0.797	**0.714**	**0.959**	0.870	0.770
Random Forest	89.39	0.983	0.167	0.903	0.943	0.892
SVM	**92.42**	0.983	0.428	0.935	**0.959**	**0.921**

From Table-III, we characterized that, among the six traditional machine learning classifiers, SVM gives the most prominent result and it is 92.42% in terms of accuracy. Though in terms of Precision and Specificity, Naïve Bayes gave the prominent outcome but the discrepancy with SVM was very subtle and also negligible considering the other performance metrics. From other performance metrics', it's also concluded that from SVM we obtained the pre-eminent result in terms of Jaccard Index, Dice Score, Precision, recall etc.

D. Classification Using CNN

The five-layer proposed methodology gives us the commendable result for the detection of the tumor. Convolution, Max Pooling, Flatten, and two dense layers are the proposed five layer CNN model. Data augmentation had been done before fitting the model as CNN is translation invariance. We evaluate the performance in two ways based on splitting the dataset. We accomplish 92.98% of accuracy for 70:30 splitting ratio where the training accuracy is 99.01%. Then at the second iteration, 80% of the images assigned for training and the rest of the images accredited for testing where we concluded 97.87% of accuracy and 98.47% of training accuracy. So our proposed model gives the best result when the division is 80:20. Table-IV represents the performance of the proposed methodology based on CNN.

We got 97.87% as accuracy which is remarkable in terms of using five-layer CNN. We analyzed with a different number of layers but the divergent of the outcomes were not very significant in terms of using this five-layer CNN model. Some of the aspects that we obtained when we increase the number of layers is- computation time, the complexity of the method batch size and steps per was immensely high. Further, we used 0.2 as the dropout value but did not commensurate the model as the accuracy flattened. As a result, this model provides the best accuracy without using dropout.

TABLE IV. PERFORMANCE OF THE PROPOSED CNN MODEL

No	Training Image	Testing Image	Splitting Ratio	Accuracy (%)
1	152	65	70 : 30	92.98
2	174	43	80 : 20	**97.87**

Fig. 6 depicts the training and validation accuracy of our model. It was calculated by the keras callbacks function. Operating with the different number of epochs we observed

the training and validation accuracy. We found that after 9 epochs model has the maximum accuracy for both training and validation.

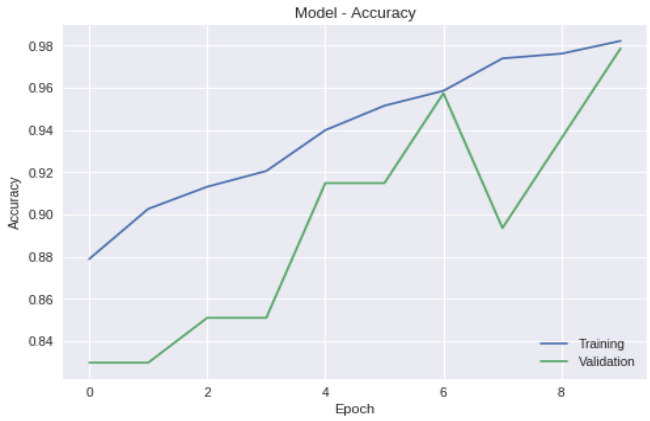


Fig. 6. Accuracy of the proposed CNN model.

E. Performance Comparison

Finally, we carried out a comparison between our proposed methodologies which are classification using traditional machine learning classifiers and CNN. We also compared our result with some other research articles which worked on the same dataset. In Seetha et al. [17], researchers got 83.0% accuracy using SVM based classification and 97.5% accuracy using CNN. Our proposed methodology provided an improved result for both machine learning and CNN based classification. Mariam et al. [18] got approximately 95% of dice co-efficient where we have 96% as the Dice score.

TABLE V. PERFORMANCE COMPARISON

Methodology	Accuracy (%)
Seetha et al [17]	97.5
Proposed CNN Model	**97.87**

CONCLUSION AND FUTURE WORK

Image segmentation plays a significant role in medical image processing as medical images have different diversities. For brain tumor segmentation, we used MRI and CT scan images. MRI is most vastly used for brain tumor segmentation and classification. In our work, we used Fuzzy C-Means clustering for tumor segmentation which can predict tumor cells accurately. The segmentation process was followed by classification using traditional classifiers and Convolutional Neural Network. In the traditional classifier part, we applied and compared the results of different traditional classifiers such as K-Nearest Neighbor, Logistic Regression, Multilayer Perceptron, Naïve Bayes, Random Forest, and Support Vector Machine. Among these traditional ones, SVM gave us the highest accuracy of 92.42%.

Further, for better results, we implemented CNN which brought in the accuracy 97.87% with a split ratio of 80:20 of 217 images, i.e. 80% of training images and 20% of testing images. In the future, we plan to work with 3D brain images, achieve more efficient brain tumor segmentation. Working with a larger dataset will be more challenging in this aspect, and we want to build a dataset emphasizing the abstract with respect to our country which will accelerate the scope of our work.

***Abstract*—One of the most interesting and visually appealing areas of image processing is image enhancement. In order to enhance the images, various methods have already been introduced. But, these existing enhancement methods are hardly able to enhance all types of images. To address this issue, Adaptive Gamma Correction (AGC) method has been introduced which classifies images into several classes based on the statistical information of the image and then applies an adaptive gamma correction method. However, AGC method can be affected by outlier pixels and fails to appropriately enhance the images. To solve this problem, we propose an improved version of Adaptive Gamma Correction (AGC) namely Bias-Free Adaptive Gamma Correction (BFAGC). The proposed BFAGC is rarely affected by the outlier pixels. The extensive experimental analysis has been performed to evaluate the efficacy of the proposed BFAGC method. Both the qualitative and quantitative evaluation metrics have shown that BFAGC produces comparatively better enhanced images than AGC and other existing state-of-the-art methods.**

***Keywords*—Contrast Enhancement, Image Classification, Image Enhancement, Adaptive, Gamma Correction.**

I. Introduction

Image enhancement is one of the well known issues in image processing field. Since, most of the images are affected by cloud, noise, low quality of the devices that capture images and the lack of operator expertise, image enhancement is needed to increase the visual quality and to remove unwanted noise of those images [1]. Besides this, image enhancement is necessary because of its expansive range of application in areas such as forensics [2], atmospheric sciences [3], astrophotography [4], oceanography [1], satellite image analysis [1], medical image processing [5], radar imaging [6], texture analysis and synthesis [1], remote sensing [7], person identification [8], face image analysis [9], machine learning [10], [11], [12], digital photography [13], surveillance and video processing applications [14].

In order to enhance the quality of an image, various contrast enhancement methods have been proposed. These methods involve Histogram Equalization (HE) [15], Brightness Preserving Bi-Histogram Equalization (BBHE) [16], Dualistic Sub-Image Histogram Equalization (DSIHE) [17], Recursively Separated and Weighted Histogram Equalization (RSWHE) [18], Contextual and Variational Contrast (CVC), Layered Difference Representation (LDR) [19], Gamma Correction with Weighting Distribution (AGCWD) [20] and Adaptive Gamma Correction (AGC) [21]. These methods are briefly described in the followings.

HE is one of the most fundamental image enhancement techniques because of its efficacy to give better contrast for all types of images [22]. It is a method that expanses the contrast by redistributing the gray level values equally [23]. Although HE improves the contrast and brightness of an image, it does not always give favorable result. It produces a significant amount of artifacts due to the mean-shift problem [23]. To reduce this problem, BBHE [16] and DSIHE [17] methods are introduced. BBHE [16] method solves the over-enhancement problem by dividing the input image into two sub-images based on the mean of the image. Then, HE is separately applied on both sides of the images. Afterward, two parts are merged to get the final output. For symmetric distribution of input image around its mean, BBHE provides better result. But it may fail for non-symmetric distribution [23]. Considering this issue, DSIHE [17] method is introduced which divides the histogram into two sub-images on the basis of median [17]. Then, each sub-image is equalized like BBHE. Though DSIHE method neglects the significant mean shift problem in some cases, it does not able to preserve mean brightness. It fails to improve some extents of image or to create artifacts on image [23]. Then, another method namely RSWHE [18] is introduced by combining BBHE [16] and DSIHE [17] methods, which improves the contrast and conserves the brightness of an image. It partitions the histogram into two parts and applies weights. At the last, it performs histogram equalization on each part of the weighted histograms. This method has the same time complexity but expands DSIHE by including multi-equalization to reduce the generation of artifacts.

Except these techniques, some other techniques have already been introduced. Among these, CVC [24] method uses inter pixel contextual information. This information is taken, and then enhancement is performed on its neighboring pixels which creates a 2D histogram [24]. For creating a better visual quality output image, this method is an effective one. But, the computational complexity of this method becomes higher. Another method, LDR [19] divides an image into multiple layers. Then, it derives a transformation function for each layer [19]. After performing those transformation functions, it merges all the layers to get final output. Another method, combining traditional gamma correction and histogram equalization methods are AGCWD [20]. This method first analyzes the histogram of the image then weighting distribution is used and then the Gamma Correction method is applied to the image to get the enhanced output image [20]. Although

AGCWD enhances the contrast, it may fail to provide desired output when an input image lacks bright pixels [23]. Since, the above methods rarely enhance the contrast of all types of images. To enhance both the contrast and brightness of an image, AGC method is introduced. This method classifies images into high contrast (Bright and Dark images) and low contrast (Bright and Dark images) class. Then, different transformation functions are applied for each class. Here, all the parameters are automatically set based on image information. But, sometimes this method is affected by outlier pixels and fails to enhance the image properly due to using arithmetic mean of the image. Therefore, in this paper we propose a modified adaptive gamma correction technique namely Bias-Free Adaptive Gamma Correction (BFAGC). The proposed BFAGC reduces the effect of outlier pixels using harmonic mean instead of arithmetic mean of the image. The novelties of this proposed method are as follows

- We introduce a modified adaptive gamma correction technique namely Bias-Free Adaptive Gamma Correction (BFAGC).
- We have used harmonic mean instead of arithmetic mean.
- We have performed extensive experimental analysis on various images.

The rest of the paper is organized as follows. Section II provides our proposed method. Experimental analysis is discussed in Section III. Finally, Section IV concludes the paper with future work.

II. Proposed Method

In this paper, we propose an improved version of Adaptive Gamma Correction (AGC) method. Here, we use harmonic mean instead of arithmetic mean to mitigate the problem faced by AGC method. The overall procedure of BFAGC is shown in Algorithm 1.

The proposed BFAGC enhances both gray and color images. In case of color images, direct RGB color processing cannot keep up the actual color. Therefore, it creates an unwanted effect on the output image. Due to this problem, we need to color space conversion. In image processing, available color spaces are HSV, HSI, Lab, YUV, Luma etc. In our method, we use HSV color space. It divides the color and brightness information of an image into hue (H), saturation (S), and value (V) channels. We use this model because it has the ability to separate color information from the brightness (or lightness) information and it has a good capability to represent a color for human perception. After transforming RGB image into HSV, V channel is considered to enhance the image as it contains the value of brightness.

At the beginning of the Bias-Free AGC (BFAGC) method images are classified into low contrast and high contrast class using Eq. (1).

$$g(I) = \begin{cases} \varrho_1, & \text{D}\leq 1/\tau \\ \varrho_2, & \text{otherwise} \end{cases} \tag{1}$$

where, D = diff((μ_h+2σ), (μ_h-2σ)) and τ is a parameter used for defining the contrast of an image. σ and μ_h are the standard deviation and harmonic mean of the image intensity respectively. The harmonic mean is calculated by Eq. (2).

$$\mu_h = \frac{n}{\sum_i \frac{1}{x_i}} \tag{2}$$

where, n and x_i represent the total number of pixels and each pixel intensity respectively. μ_h is the harmonic mean of the image.

The aforementioned two groups of images are enhanced using different transformation functions. These two transformation functions are illustrated in the following subsections.

Algorithm 1 : BFAGC Algorithm

Data: Input image, I_{in}
Result: Output image, I_{out}
1: **if** I_{in} is colored **then**
2: $I_{hsv} \leftarrow$ Convert I_{in} from RGB to HSV
$R \leftarrow$ V channel of I_{hsv}
3: **else**
4: $R \leftarrow I_{in}$
5: **end if**
6: **if** R_{in} is low contrast image **then**
7: Set γ using Eq. (4).
8: **else**
9: Set γ using Eq. (9).
10: **end if**
11: Define the value of c using Eq. (5).
12: Compute R_{out} using Eq. (3).
13: **if** I_{in} is colored **then**
14: $R_{out} \leftarrow$ Convert HSV to RGB image
15: **else**
16: $I_{out} \leftarrow R_{out}$
17: **end if**

A. Low-contrast image enhancement (ϱ_1)

For the transformation of image, we use traditional gamma correction where γ controls the slope of the transformation function. The equation of traditional gamma correction is given by Eq. (3).

$$I_{out} = cI_{in}^{\gamma} \tag{3}$$

In our method, for low-contrast images we choose the value of γ by using Eq. (4) which is same as AGC

$$\gamma = -\log_2(\sigma) \tag{4}$$

The value of σ is small for low contrast class that causes large γ value that result in better contrast. Generally, for illuminating or darkening the output image intensities c is used. But, on the basis of the qualities of the respective image this method uses several values of c for several images using Eq. (5).

$$c = \frac{1}{1 + Heaviside(0.5 - \mu_h) \times (k-1)} \tag{5}$$

Where, k is defined by Eq. (6).

$$k = I_{in}^{\gamma} + (1 - I_{in}^{\gamma}) \times \mu_h^{\gamma} \tag{6}$$

and the Heaviside function is defined by Eq. (7).

$$Heaviside(x) = \begin{cases} 0, & \text{x} \leq 0 \\ 1, & \text{x} > 0 \end{cases} \tag{7}$$

The reason behind using harmonic mean instead of arithmetic mean, arithmetic mean is always greater than harmonic mean [23]. So, in Eq. (6), arithmetic mean will generate large value of k which will decrease the value of c, causing lower brightness of an image. On the other side, the value of harmonic mean generates lower value of k and increase the value of c which causes higher brightness of an image.

Then, BFAGC method divides low contrast class into two parts dark images and bright images. The transformation function should exhibit the bright intensities over a wider range of darker intensities in order to increase the contrast of this type of images. BFAGC method achieved this by choosing the γ value that is greater than 1. For transformation of bright images in Eq. (3), c becomes 1 and the transformation function becomes

$$I_{out} = I_{in}^{\gamma} \tag{8}$$

For dark images the transformation function needs to be exhibited the dark intensities to the higher intensities in order to increase the contrast and brightness of this type of images. For enhancement of this type of images this method uses Eq. (3).
By the aforementioned way, our method is able to handle bright and dark images by choosing the values of γ and c in low contrast class.

B. High or moderate-contrast image enhancement (ϱ_2)

When the intensities of an image are scattered over the available dynamic range then the image falls into high contrast class. The more important concern of this type of images is brightness adjustment than contrast enhancement. In the case of high contrast class, I_{out} and c are calculated like Eqs. (3) and (5). γ is calculated using Eq. (9).

$$\gamma = e^{(1-(\mu_h-\sigma))/2} \tag{9}$$

For this class of images γ falls within a small range around 1. This method also divides the high contrast class into two types bright images and dark images. For dark images there is comparatively greater harmonic mean and not much changes in the intensities. And for enhancement of bright images I_{out}, c and γ are calculated using Eqs. (3), (5) and (9) respectively. Here, the main target is to preserve the image quality.

C. Why BFAGC is Bias Free?

An image is biased when there is inhomogeneous classification of the pixels. This make an image to show certain character and fails to provide better contrast enhanced image. Hence, a proper classification of images is necessary to enhance contrast without incurring artifacts. The main purpose of image classification in BFAGC is to categorize the image in such a way so that half of the pixels fall in one side and the remaining half is in another side for providing maximum contrast for an image [23]. AGC method fails to categorize the images effectively in some cases due to using arithmetic mean because it can be affected by outlier pixels. Therefore, BFAGC uses harmonic mean to classify images properly. The reason for choosing harmonic mean instead of arithmetic mean can be described based on TABLE I.

TABLE I: Pixel values based on arithmetic mean and harmonic mean

Image Name	Hill	Advertise	Boat	Girl
Arithmetic Mean	32.31	59.46	43.92	24.75
Pixels Above Arithmetic Mean	126646	87528	81251	84731
Pixels Below Arithmetic Mean	556354	295712	145899	128469
Harmonic Mean	0.69	5.84	23.46	6.96
Pixels Above Harmonic Mean	315540	101017	91422	88400
Pixels Below Harmonic Mean	367460	282223	135728	124800

In TABLE I, we have seen that Hill image has arithmetic mean 32.31. The pixels above arithmetic mean and the pixels below arithmetic mean are 126646 and 556354 respectively that means 18% pixels are stayed in one side and other 82% pixels fall in another side. For maximum contrast enhancement we needed 50% pixels in one side and the remaining is another side. But, using arithmetic mean it fails to provide the desired results and in some of the cases it is affected by outlier pixels. So, we use harmonic mean instead of arithmetic mean in order to mitigate the problem. As, for example in TABLE I for Hill image harmonic mean is 0.69. Hence, the pixels above harmonic mean and the pixels below harmonic mean are 315540, 367460 respectively that means 46% pixels are stayed in one side and 54% pixels in another side. Thus, BFAGC method able to classify images properly. Hence, this method becomes bias- free and gives a balanced output.

III. Experimental Analysis

In this section, we have chosen some standard images to appreciate the effectiveness of proposed method. The performance of this method compare with some of the other existing techniques such as HE [15], CVC [24], LDR [19], RSWHE [18], AGCWD [20] and AGC [21]. Here, the experimental section is divided into two parts qualitative and quantitative measurement. For the purpose of experiment, we have used MATLAB 2012, Windows 8.1 operating system.

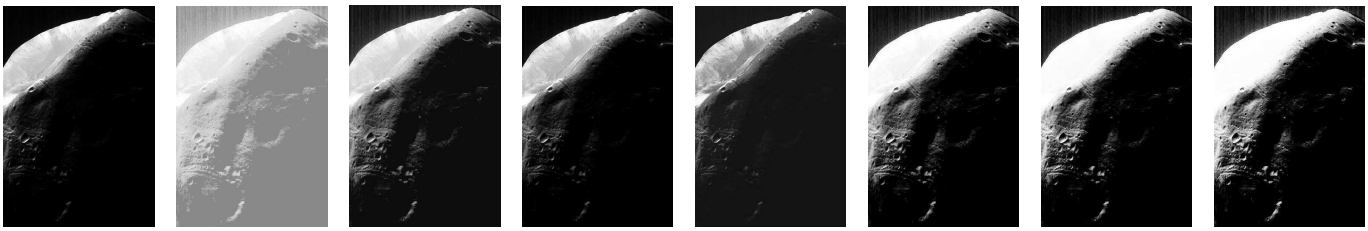
A. Qualitative Measurement

In this section, for qualitative measurement we took some images that were used in AGC method and some images from open source. After analyzing qualitative measurement, we found that BFAGC performs better result in most of the cases than other methods.

For "Advertise" image in Fig. 1, HE method over enhances the image by reducing natural look. HE transfers the original mean value from 59.46 to 130.08 which shows over enhancement problem. CVC and LDR are not able to enhance the images which can be seen from the Fig. 1. The mean value of CVC and LDR are 72.56 and 68.16.

(a) (b) (c) (d) (e) (f) (g) (h)

Fig. 1: "Advertise" image enhancement (a) Original (b) HE (c) CVC (d) LDR (e) RSWHE (f) AGCWD (g) AGC (h) Proposed



(a) (b) (c) (d) (e) (f) (g) (h)

Fig. 5: "Cave" image enhancement (a) Original (b) HE (c) CVC (d) LDR (e) RSWHE (f) AGCWD (g) AGC (h) Proposed

(a) (b) (c) (d) (e) (f) (g) (h)

Fig. 6: "Nature" image enhancement (a) Original (b) HE (c) CVC (d) LDR (e) RSWHE (f) AGCWD (g) AGC (h) Proposed

In RSWHE method the output is not satisfiable and the sky looks cloudy because the mean value reduced to 57.59. AGCWD unable to increase the overall brightness of this image. It transfers moderate bright pixels to the highest bright one. Although AGC method gives a better result than the aforementioned methods, our method gives brighter output with maximum identification of local details compared to other methods including AGC. Mean brightness of our proposed method for this image is 87.86 which shows overall brightness to the whole image.

For "Girl" and "Fountain" images in Figs. 2 and 3, we can see that HE method over enhances both images. The result produced by HE method does not look natural. It transfers most of the bright pixels to the highest bright region (original mean=24.73, 29.32 and transformed mean=136.30, 128.90) and causes over enhancement problem. CVC, LDR and RSWHE methods fail to improve the visual quality of these two images. We can see that AGCWD gives a comparatively better result than other existing methods but there is a lack of sufficient brightness. In the case of "Girl" image which is low contrast, it is needed to increase the brightness in such a way that the necklace can be easily identified. AGC method makes it possible to visualize the thin necklace but our method increases the brightness than AGC in such a way the necklace can be clearly identified and keeps the balance of the luminance of the hair region. The same thing is true for the Fountain image. Our proposed method brings out details of all object by increasing the brightness of the image (original mean=24.75, 29.32 and transformed mean= 96.55, 79.06).

"Hill" image in Fig. 4, is a dark low contrast image with mean brightness of 32.31. We can see that HE method over enhances the image by transferring the mean to 164.96. LDR fails to improve the result as there is not too much different between the original mean and the transformed mean (34.43). CVC method partially enhances the image. Unfortunately, RSWHE and AGCWD fail to improve the image quality properly and the output images are still dark because the enhancement of AGCWD depends on the maximum available intensity of the image and in this case the maximum intensity of the original image is small. AGC method enhances the image but there is a lack of proper brightness. The lower the value of k in Eq. (6), the higher the value of c in Eq. (5) is, causing an increase of brightness in Eq. (3). As the value of the harmonic mean is always less than the arithmetic mean. So, BFAGC increases the value of I_{out} from Eq. (3) giving overall brightness of the image. It gives mean brightness 58.76 which is balanced between dark and bright regions whereas the mean brightness value of AGC is 52.42.

"Cave" and "Nature" images in Figs. 5 and 6 are dark high contrast images where minimum pixels are 0, 2 and maximum pixels 255, 255 respectively. The mean value of these two images produced by HE is 125.48 and 125.69 which shows that most of the pixels are transferred to highest bright pixels incurring artifacts. CVC, LDR, and RSWHE methods are unable to improve the quality of the images. The result produced by AGCWD method provides limited brightness. Though AGC method enhances the image but our method gives a better result than other existing methods. The proposed method gives average brightness to all pixels (original mean=36.73, 122.42 and transformed mean of proposed method= 63.42 and 137.86).

TABLE II: Discrete Entropy (DE)

Image Name	Fountain	Nature	Advertise	Hill	Cave	Girl
Original	6.16	7.51	6.05	4.03	6.26	5.86
HE	6.85	7.84	7.15	3.66	6.88	6.65
CVC	6.92	7.48	6.82	3.92	0.82	6.86
LDR	6.94	7.59	6.64	4.01	7.06	6.78
RSWHE	5.93	7.31	5.67	3.64	6.20	5.60
AGCWD	7.15	7.39	6.76	3.74	6.79	6.64
AGC	7.23	7.49	6.43	3.64	6.74	7.06
Proposed	7.30	7.52	6.63	3.51	7.06	7.00

TABLE III: Root-Mean-Square (RMS)

Image Name	Fountain	Nature	Advertise	Hill	Cave	Girl

CVC	0.25	0.33	0.34	0.28	0.001	0.31
LDR	0.24	0.33	0.34	0.27	0.27	0.27
RSWHE	0.27	0.28	0.23	0.22	0.26	0.17
AGCWD	0.27	0.35	0.36	0.34	0.28	0.20
AGC	0.25	0.34	0.35	0.35	0.26	0.32
Proposed	0.26	0.35	0.35	0.36	0.27	0.33

B. Quantitative Measurement

We can not predict which method works well only considering the visual quality of an image. Hence, we need a mathematical evaluation to identify weather the quality of an image is enhanced or not. Here, we give a concrete evaluation of our method using three quality metrics Mean brightness, Discrete entropy and Root-Mean-Square (RMS). They are described in the followings.

1) **Discrete Entropy (DE):** Entropy can be defined by the measurement of the uncertainty of a random variable. If the random variable is more, an image has more entropy [21]. In image processing, large entropy means better-contrast of the image. Table II provides the Discrete entropy values performed by different methods. From the table, We observe that in most of the cases BFAGC creates larger entropy than other methods. For example, if we take a look at "Fountain",

TABLE IV: Mean Brightness Value

Image Name	Fountain	Nature	Advertise	Hill	Cave	Girl
Original	29.32	122.42	59.46	32.31	36.73	24.75
HE	128.90	125.69	131.08	164.96	125.48	136.30
CVC	50.00	142.11	72.56	55.53	61.42	73.17
LDR	50.14	126.42	68.16	34.43	62.69	65.49
RSWHE	51.93	123.21	57.59	44.05	51.23	40.25
AGCWD	86.39	159.49	92.45	52.60	61.26	53.82
AGC	71.64	114.48	78.87	52.42	58.84	93.65
Proposed	79.06	137.86	87.86	58.76	63.42	96.55

"Cave" and "Girl" images, we can see that our proposed method gives highest value such as 7.30, 7.06 and 7.00 than other methods. Hence, it can be concluded that BFAGC provides better result than other existing image enhancement methods.

2) **Root-Mean-Square (RMS):** RMS measure the standard deviation of pixel luminance of an image which is divided by the mean luminance of the whole image. The higher the value of the RMS the better the contrast of the image [19]. Table III provides the RMS values performed by different methods. From the table, We have seen that in some cases BFAGC creates same RMS value as AGC and in some cases it provides larger RMS value than other methods. Hence, it can be concluded that some of the cases BFAGC gives the same contrast as AGC and some of the cases it provides a better contrast than other methods.

3) **Mean Brightness Value:** Mean is the most basic of all statistical measure [25]. In image processing, a higher value of mean identifies, it improves the brightness of the image. Table IV provides the mean values of different methods. From the table, We also observe that in most of the cases BFAGC creates higher mean value than other methods. Finally, it concludes that BFAGC increases the brightness than other existing image enhancement methods.

IV. Conclusion

In this paper, an improved version of adaptive gamma correction technique has been proposed to enhance the contrast and brightness of the image. Here, we use harmonic mean instead of arithmetic mean. This method is able to classify the images appropriately and not incurred by outliers due to using harmonic mean. This method is also called BFAGC for this reason. From the experimental section, we have shown that our method provides better contrast and brightness than other existing methods. In the future, our method will be applied in various fields such as medical image processing, remote sensing, digital photography, etc.

Abstract— **Attendance taking is a tedious process and becomes much tougher with the increase in the number of students registered for the class. Many times, this may lead to the teacher skipping the whole process of attendance or they end up calling out only a few random names from the list to save their time. This is a bad system, as school/institute won't be able to maintain a proper student's record. But, marking attendance for a class may also waste a few minutes of the precious class time. To solve the above-mentioned problem, this paper presents an implementation of automatic attendance management system using a face recognition technique. The GUI is developed using MATLAB functionality. To develop this system, we have first developed a database consisting of the student's details of different age group, different texture like with a beard, without bread, veil etc. and then store the images of each student who has registered for that particular subject. By using the facial features of a person, the proposed system will be able to automatically mark the attendance. Hence, the proposed system is able to maintain a proper database of students and reduces the time wastage during the attendance marking. This research work has explored HOG (Histogram of Oriented Gradient) and PCA (Principal Component Analysis) techniques for face recognition and found HOG better.**

Keywords-Facial Recognition; Automatic Attendance; Image Recognition; Face Detection; Feature Extraction

I. INTRODUCTION

The recent years have witnessed a significant progress in various fields of technology. One such field is Computer Vision & facing Recognition [1]. The domain of computer vision has given numerous real time applications in the recent years as the ability to store large amount of data has boomed along with the increase in computational power of the machines especially with the use of GPUs. The huge amount of storage enabled us to learn the features more accurately and then use it for a variety of purposes including image classification or facial recognition. It can also be applied to object detection which too involves similar idea of computer vision and image processing. Computer vision provides the various techniques to detect the any object present in a digital frame. It will also lead the way to detect the human faces. Face detection, in which human faces are used to detect is the potential application of object class detection [2][3].

Earlier, University's professor used to take attendance using register given to them. But, it is a time-consuming process. It becomes much tougher with the increase in the number of students registered for the class. Many times this may lead to the teacher skipping the whole process of attendance or they end up calling out only a few random names from the list to save their time [4]. This is bad practice as the school/institute would not be able to maintain a proper record of the student's attendance. But, marking attendance for a class may also waste a few precious minutes of the class. It is also very difficult to verify students one by one in a large classroom, whether they are present or not [5].

The primary purpose of developing an attendance management system is to computerize the traditional way of marking attendance. Automated Attendance Management System performs the daily activity of attendance marking and analysis with reduced human intervention. During course registration, individual students face images are captured and stored in the database. The system consists of uploading of images of the students sitting in the classroom. This is followed by sending the image into the Face detection module where individual faces are detected in the image [6], and this is followed by recognition modules [7], which will recognize the student and then the attendance is marked on the database server. Here all the faces are detected from the input image and the algorithm compares them one by one with the face database. If any face is recognized, the attendance is marked on the server and stored in the database [8][9]. To ensure the presence of student, in class the image will be captured twice, once at the beginning and once at the end. Face database is the collection of images of student's faces. The attendance database contains the details about the students and it is also used to mark the attendance. In case, a student is present whose face is not recognized, the class teacher can update the system manually [10][11].

The remaining work is organized as follows: section II presents a description of face detection and extraction. Section III describes the database used and the attendance system. Further, section IV presents the results and discussion. At last, Section V concludes the paper.

II. FACE DETECTION AND EXTRACTION

Face Detection is the most important part in automatic attendance system. Face Detection is used to detect the faces of the students by detecting their faces automatically. And, its searches the student faces in the database. Thus it helps to reduce the burden of a teacher to mark manual attendance of the students. This section presents the process of face

detection and feature extraction of the stored images. Fig 1 shows the flowchart of the proposed system.

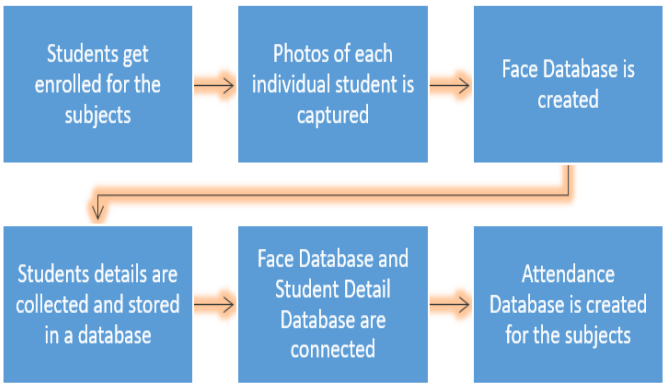

Fig.1. Flowchart of the proposed system.

Design of GUI Interface:

A. Making of GUI

A user interface is made with MATLAB built-in tools. It consists of two axes, one for the input image of the classroom and the other for output after it detects faces. Two push button was made for opening image and detect button. Table I represents the basic information about the functionality of developed GUI.

TABLE I. INFORMATION FOR GUI

Item	Type	Size	Colour
Load	Push Button	1 x 3	Grey
Detect	Push Button	1 x 3	Grey
Title	Static Text	1 x 10	Grey
Image Viewer	Axes	8 x 8	White
Face Viewer	Axes	8 x 8	White

B. Image Insertion

Images are inserted in the GUI file using the select button. The common file format of images which can be used is JPEG, BMP etc. In the case of unsupported file format insertion, the system will through the error/invalid selection messages. Fig. 2 shows the snapshot of the image acquisition interface of the developed GUI.

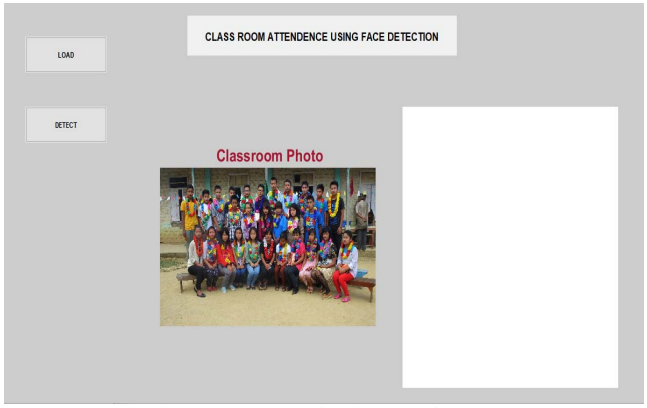

Fig.2. Image Insertion in a sample GUI.

Methodology

A. Face Detection & Recognition

Face Recognition is done using the Viola-Jones algorithm [12]. In this research work, the Viola-Jones algorithm is used for object detection. This algorithm works fast in face detection phase but the training phase is long. The algorithm is robust with a very high detection rate (true-positive), and a very low false-positive. In practical applications, at least two frames per second must be processed. The goal is to distinguish faces of familiar faces [13]. Fig. 3 shows the GUI interface of face detection.

B. Database

A database consists of the images of students faces taken during the class registration. The main folder consists of different folders for each of the students. In the subfolder of each student, eight photos of different shapes and angles are stored. So that a student face can be recognized from different angles and directions.

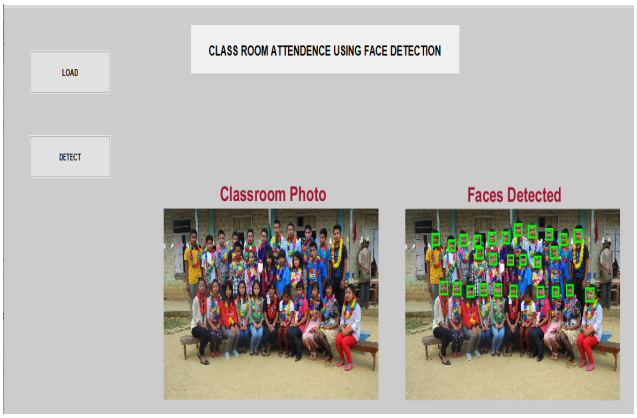

Fig.3. Detection of faces.

C. Face Extraction

The faces in the database are extracted using Histogram of Oriented Gradient algorithm (HOG). HOG is a popular technique to discover shapes within an image with a high detection rate. It works by sampling subregions of the image using a kernel. Then it checks the slope (Aka orientation gradient) and puts it in a bin. Then it samples another region until an entire image is been sampled. After the sampling, the algorithm searches the bin and tries to determine a consensus of slopes to determine the edge.

D. Comparison of Faces

During the comparison of faces, the feature of the individual faces is compared with 'person index' array. This is done to detect the faces. As the same faces will have a similar person index. This can be used to get the similar face from the database for the target face. Fig. 4 shows the query and recognized face.

III. FACE DATABASE AND ATTENDANCE SYSTEM

In this research work, a database of different texture, age group and orientation of faces has been created. So, each subject consisting of 8 different faces. The automatic attendance system will take an image as input from the classroom and detect the faces automatically and mark the

attendance. Fig. 5 presents the procedure to detect the face from a given image.

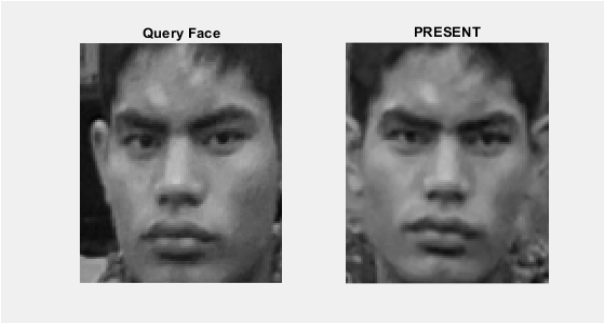

Fig.4. Attendance Procedure

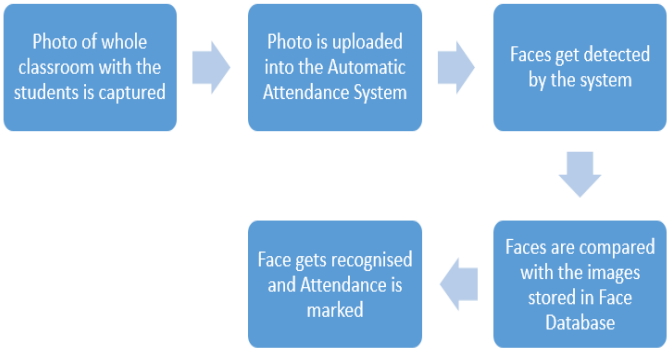

Fig.5. Recognition of Faces from Database

Fig. 6 shows the automatic attendance marked using automatic face recognition based system. An excel sheet is created from the developed GUI. The excel sheet consists of the name of students and roll numbers. Once, a student's face is detected she/he will be marked "Present" in the classroom.

	A	B	C	D
1	No.	RollNumber	29-Nov-18	
2	1	CS008	Present	
3	2	CS009	Present	
4	3	CS005	Present	
5	4	CS018	Present	
6	5	CS000	Present	
7	6	CS004	Present	
8	7	CS017	Present	
9	8	CS003	Present	
10	9	CS014	Present	
11	10	CS013	Present	
12	11	CS012	Present	
13	12	CS027	Present	
14	13	CS010	Present	
15	14	CS016	Present

IV. RESULTS & DISCUSSIONS

This section describes the results obtained from the proposed system. Fig. 7 shows the face detection accuracy curve using the proposed system up to 25 students. The proposed system achieves high accuracy except in case of low light and bad quality images. Table II shows the face detection rate under different sample size of students.

A. Accuracy of Face Detection Algorithm

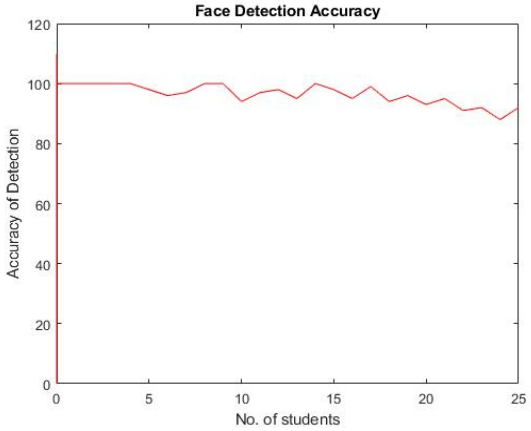

Fig.7. Accuracy of Face Detection.

TABLE II: FACE DETECTION RATE

No.	Students	Detected	Percentage
1.	4	4	100 %
2.	9	9	100 %
3.	14	13	93 %
4.	19	16	89 %
5.	25	22	88 %

B. Accuracy of Face Recognition

The proposed algorithm uses HOG and PCA for face recognition and it has been observed that HOG performing better than PCA. Therefore, this research work HOG has been applied. Table III shows the face recognition rate using the proposed system. Fig. 8 shows the face recognition accuracy curve using the proposed system up to 25 students.

TABLE III: FACE RECOGNITION RATE

No.	Faces	Recognized	Percentage
1.	4	4	100 %
2.	9	8	90 %
3.	14	12	86 %
4.	19	14	74 %
5.	25	19	78 %

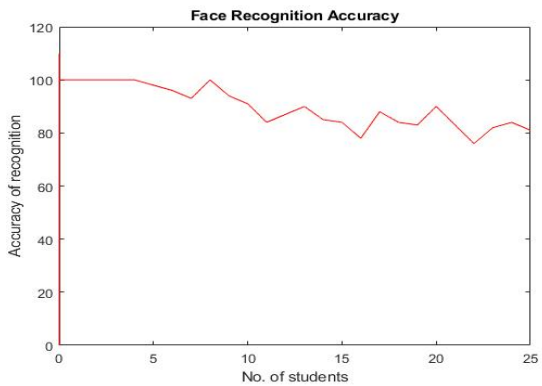

Fig.8. Accuracy of face recognition

C. Comparison with existing work

The proposed system is compared with the existing system [5] and the results show that the proposed system has better accuracy and detection rate. The accuracy table and plot are

represented in Table IV and Fig. 9 for existing and the proposed system.

TABLE IV: COMPARISON WITH THE EXISTING SYSTEM.

No.	Students	Recognized Faces		Accuracy	
		Existing	Current	Existing	Current
1.	4	4	4	100 %	100 %
2.	10	10	9	100 %	90 %
3.	14	11	12	79 %	86 %
4.	20	14	17	70 %	85 %

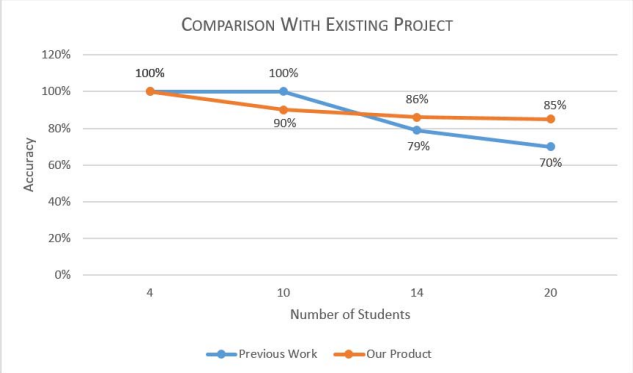

Fig.9. Accuracy comparison with the existing system.

V. CONCLUSION

This research work has presented an automatic attendance system based on face recognition. The proposed system has used the HOG and PCA based techniques to identify the student faces present in the class. A dataset has been created for the different texture, age group and orientation of faces. The results show an accuracy rate of 98% face detection using the proposed system. The proposed system is robust for different view and texture. In future, we plan to implement a gait based student identification system, which will detect the student walking through the front door of the class.

***Abstract*—Face Recognition refers to the identification of a human face from an image, first by finding the region of interest and then by processing the extracted facial part in the region of interest to get the most distinguishing facial features. Face recognition is considered to be the less intrusive and very fast biometric technology which does not require any physical interaction with the person being identified. Further, with the increase in security needs and the advancement in technology, extraction, and processing of information has become much simpler. In this paper, we have implemented and compared two different methods for face recognition. First, we used traditional Haar Cascade Classifier and second, we have used a pre-trained VGGNet to identify human-faces from the input video stream in real-time. Finally, the accuracy of the two methods is compared. In both the methods, the classifier is first trained on a suitable number of images and then it is tested with the input video stream in real-time. If a person is found, its name is displayed beside the face using OpenCV, otherwise, it is characterized as Unknown.**

***Index Terms*—Face Recognition, Face Detection, Transfer Learning, Haar Cascade, Biometric, CNN.**

I. Introduction

These days identification of a person has its application in a wide variety of fields ranging from social media tagging, phone unlocking, attendance in schools, to security purposes where access to a service is granted only to authorized people. Thus suitable measures can be taken in all cases if a person is recognized or some safety measures could be taken when the identity of a person is unknown i.e., the face labels with which the model is not trained. So there is a need to recognize a human face not only with good accuracy but also with the least computation time.

The domain of computer vision has given many real-time applications in the recent years as the ability to store large amount of data has boomed along with the increase in computational power of the machines especially with the use of GPUs. The huge amount of storage enabled us to learn the features more accurately and then use it for a variety of purposes including image classification or facial recognition. It can also be applied to object detection which too involves similar idea of computer vision and image processing. To detect an object in a digital frame, computer vision has various solutions and techniques. Computer vision is also leading the way in which the human faces can be detected. A potential application of object class detection is face detection. Face detection, is done first detecting the eye region and then used the HAAR algorithm to generates face regions for eyebrows, mouth, and other parts. As a final step, different features matching is performed which detects the face.

Face detection involves finding the exact locations of faces from the input frame captured i.e., location, size, position, orientation etc of different faces is determined. Face detection is the first step for facial recognition, whose results directly affect the processing of the human faces and as a result, the accuracy of face recognition model. There are various face detection approach such as Statistics-based, knowledge-based and integration approach. In statistics-based approach a face is detected by judging all possible areas of images by classifier. It means, to look for face region as a class of models, and use a large number of face and non-face training samples to construct the classifier. On the other hand, the knowledge-based approach is known to detect faces for complex background images to some extent. It also has high detection speed. But, in but knowledge-based approach more integration features are required to further enhance the adaptability [18].

The methods compared in this paper are robust with high classification accuracy. The first model i.e., the Haar Cascade Classifier relatively requires more images for training but it is computationally efficient and gives high classification accuracy, whereas the other model i.e, the pre-trained VGGNet requires very less images for training and gives far better accuracy than Haar Cascade Classifier on the test input video stream but it is computationally in-efficient. Though, the pre-trained VGGNet needs a lot of training and testing time, it has real-time detection capability along with high detection accuracy. The generated human face image is a representation of a two-dimensional image as a finite set of digital values, called pixels. Pixel values typically represent gray levels, colours, heights, opacitys etc. The digitization means that a digital image is an approximation of a real scene. The reason for wide use of VGGNet although being less computationally efficient is due to the tremendous growth in the field of computer vision and technology to process large amount of data efficiently is being utilized. An example of this could be the use of GPU for Computer Vision tasks.

Transfer learning is a machine learning method where a model developed for a task is reused as a starting point for a model on a second task. In other words, we use the knowledge acquired by learning from related tasks to do well on the target.

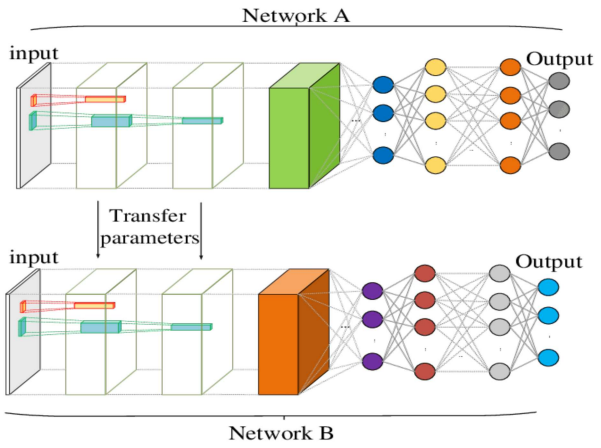

Fig. 1. Illustration of Transfer Learning Concept [19].

In deep learning, as the starting point on computer vision and natural language processing tasks pre-trained models are used. It is due to the vast compute and time resources required to develop neural network models on these problems and the huge jump in skill that they provide on related problems.

It is a popular approach in deep learning where pre-trained models are used as the starting point on computer vision and natural language processing tasks given the vast compute and time resources required to develop neural network models on these problems and from the huge jumps in skill that they provide on related problems.

The remainder of this paper is organized as follows: section II explains the experimental setup and tools used in the research work. Section III describes the implementation of the face recognition approaches. Section IV presents the results and discussion. At last, Section V concludes the paper.

II. Experimental Setup and Tools

This section explains the tools used to detect and track the face and the complete experimental setup.

A Laptop webcam is used to track images in real-time using OpenCV 3.4.1 for windows. the OpenCV module process it and captures the detected face parts. Then, the stored image is given to each of the model to recognizes the faces accordingly. The codes have been written using the Spyder IDE for windows.

A. OpenCV

OpenCV is an Open Source Computer Vision Library which consists of functions mainly useful for computer vision applications. It is free for use and is currently available in C, C++, Ruby, Python and Java. The use of OpenCV library for computer vision tasks reduces the lines of code significantly to perform all the major image processing tasks. It also takes care of small issues like memory leaks with certain programming languages like C and C++.

B. Spyder IDE

Spyder IDE is an environment used for writing and debugging Python codes. It offers a unique combination of the advanced editing, analysis, debugging, and profiling functionality of a comprehensive development tool with the data exploration, interactive execution, deep inspection, and beautiful visualization capabilities of a scientific package.

III. Implementation

The main objective of this research work is to perform detection and recognition of faces from real-time input video. The flow chart given below represents the proposed model:

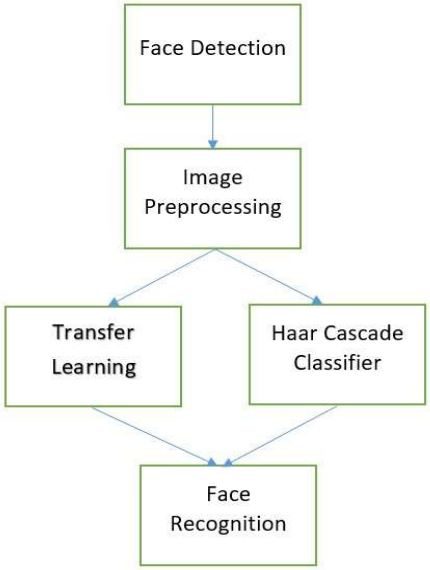

Fig. 2. A Flow Chart of Face Recognition Steps.

For training, 15-20 images have been taken and stored locally for training. After that the images are trained individually using Haar Cascade Classifier which implements Viola-Jones algorithm in its core and pre-trained VGGNet 16 which is a powerful Convolutional Neural Network technique for facial recognition. Although Haar Cascade requires sufficient amount of images for proper training, VGGNet gives really good accuracy with only one image due to the fact that its using pre-trained parameters. VGGNet utilizes 22 layers and 37 deep units. It takes input image of size 224 * 224 * 3 (RGB image). It uses 3*3 size Convolutional Layers, 2*2 size Max Pooling layers and then a fully connected layer at the end. The size of the pre-trained parameters which we used is 553MB. The image of VGGNet architecture is shown below :
Total Parameters Used : 138,357,544
Trainable Parameters : 138,357,544
Non-trainable Parameters : 0

$$softmax(z_i) = \frac{exp(z_i)}{\sum_{j=1}^{n} exp(z_j)} \quad (1)$$

The webcam is used for real-time video monitoring and face part is detected from the video continuously. Whenever a face is detected, its cropped and stored locally from where the classifier extracts it for recognizing. The stored image is accessed using OpenCV and bounding box is made around the face using the facial coordinates. The Image inside the bounding box is then cropped and processed. It is then compared with the images of the person with which the model is trained. The model is initially trained using 15 images of all three of the team members using Haar Cascade Classifier and with only 1 image using VGGNet.

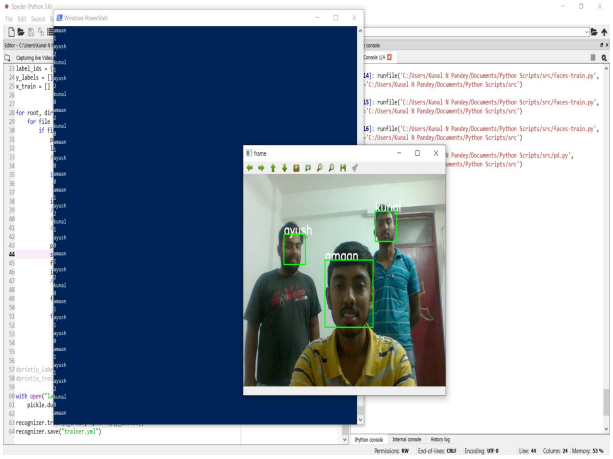

Fig. 3. Real-life Face Recognition.

VGGNet utilizes transfer learning which is widely used these days in Convolutional Neural Networks while dealing with images. We used VGGNet with 16 convolutional layers because of its uniform architecture for image classification and is found that it outperforms the traditional Haar cascade classifier significantly. Model is initially trained by feed forwarding the sensitivities with only one image using VGGNet and was able to classify the person with a very good accuracy.

A web interface has been developed where a user can signup with their name, email and password and can upload images directly on the website. These images are stored in the database and corresponding folder is created with the user's name. The number of images per user has been limited to 30 so that unnecessary overfitting is avoided for specific user. There is a also a button for a user to train the model after uploading their images so that the model can update itself. After training, a button has been provided in the website on clicking which a live window frame opens which captures the video in real-time and face is extracted continuously using infinite while loop and recognized in the same way as specified above. The developed website also has a documentation on how it can be used and a basic chat bot API to know users experience with the website. The is live and can be found on web [20].

We also implemented a module which finds the cosine similarity and euclidean distance between stored image and captures image.

$$cos\theta = \frac{A.B}{|A|.|B|} = \sum_{i=1}^{n} \frac{A_i.B_i}{\sqrt{\sum_{i=1}^{n} A_i^2}\sqrt{\sum_{i=1}^{n} B_i^2}} \quad (2)$$

If the cosine value is lesser than 0.45, then we say that the images are same. In case of euclidean distance comparison, if the distance between the images is less than 120, then we say that the images are same. In both the cases if the above conditions are not satisfied, then the images does not belong to the same person. Here we have represented images as vectors and found the similarity measures of two vectors. If both images are of same person, then measurement should be small. Otherwise, the measurement should be large if two images are of different person.

Fig. 4. Cosine & Euclidean based Comparison.

IV. RESULTS AND DISCUSSION

The deep learning model is trained using Haar Cascade Classifier and pre-trained VGGNet. In the training phase, a

certain number of images of 10 different person have been used. In the testing phase, the image is monitored using a real-time window frame continuously and the face part is detected and extracted using OpenCV by making a bounding box around the face which is then stored locally. In the same iteration, we take the stored image as input and gave it to the two face recognition models which we have used namely Haar Cascade Classifier and pre-trained VGGNet which utilizes transfer learning. This happens infinitely unless we terminate the browsing window. The captured image is fed to both of these networks and was found that VGGNet automatically extracts the best features for classification and outperforms traditional Haar Cascade classifier significantly.

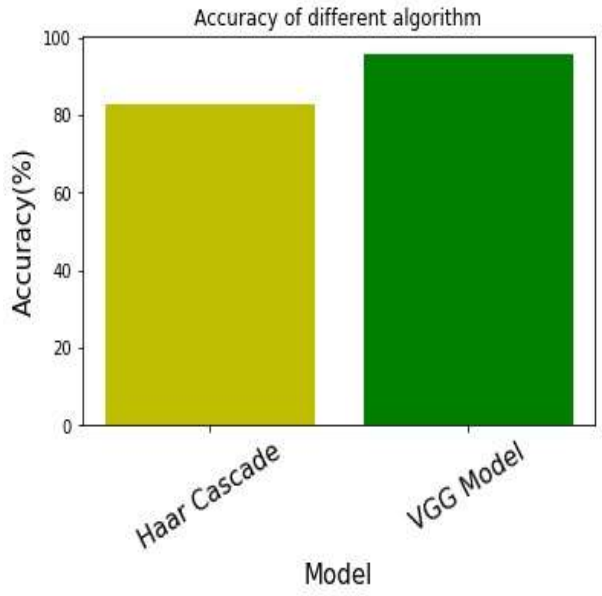

Fig. 5. Accuracy Comparison of Algorithms.

It has been found that the traditional Haar Cascade Classifier has an accuracy of approximately 83% whereas pre-trained VGGNet with transfer learning has an accuracy of approximately 92%. The only problem with VGGNet is that it is more computationally expensive than Haar Cascade Classifier because of its use of deep neural networks in its architecture as defined previously.

V. Conclusion

In this paper, We have implemented two deep learning techniques for facial recognition using Haar Cascade Classifier and pre-trained VGGNet with transfer learning. It has been found that VGGNet outperforms the traditional Haar Cascade Classifier significantly. Simultaneously, while capturing the images, our model displays the name of the person in the Video frame. Initially, we started with Haar Cascade Classifier but then we extended it to use more robust pre-trained VGGNet with transfer learning, a Deep Learning technique to extract best features automatically, resulting in the classification of images with even better accuracy at the cost of some extra computation. In this paper, only the detection of frontal human faces was considered. In the future we plan to extend this work to minimize the effect of rotation, side view, poses, expressions, disguises, and illumination difference while classifying an image. Also, we plan to incorporate the liveliness of image, or if it is a real image or a static picture.

***Abstract*— With the ever increasing population of the world, diseases and their possibilities are also increasing at an alarming rate. As time passes by, diagnosing diseases and providing appropriate treatment at the right time has become quite a challenge. Heart diseases have been a major cause of death worldwide. Therefore, this research has been focused on finding an efficient way to predict the chances of a heart failure and accordingly, recommend appropriate medicines to aid cardiologists in quicker decision making. The research includes finding the correlations or associations between the various medical profiles of the patients by utilizing the standard techniques of exploratory analysis and hence using the attributes suitably to predict the chances of a heart failure, as well as the medicine recommendations. A comparative study has also been included which shows the various attained accuracy rates of different machine learning algorithms including - Logistic Regression, Naïve Bayes, Decision Tree, Linear Support Vector Classifier, Random Forest, and Gradient Boosting Classifier. The Apache Spark framework has been used in order to make the system capable of handling big data.**

Keywords—Machine Learning, Exploratory Analysis, Heart Failure Prediction, Medicine Recommendation

I. INTRODUCTION

According to the data published by World Health Organization (WHO), in the year 2017, 14.31% of deaths in Bangladesh were caused by Coronary Heart Diseases [11]. In fact, the latest (2018) report provided by WHO has marked Heart Disease as one of the biggest causes of death all around the world [12]. With the growing population in countries like Bangladesh, it has become very difficult to provide proper treatment at the right time. This is mainly due to the reason that the medical test reports are usually manually analyzed by cardiologists before they can reach a reasonable conclusion. It is, undoubtedly, a time consuming process. Therefore, we intended on designing a system that would analyze the patient's medical test reports and provide cardiologists with the chances of a heart failure, and even suggest a medicine list that would be most suitable for the patient. The idea was to create a system that would facilitate cardiologists in taking quicker decisions so that more patients can receive treatments within a shorter period of time.

We have used an Austrian data set which originally contains 43 attributes, including information such as the patient's age, gender, existing diseases, smoking habits, and the prescribed medicines for each individual. A significant portion of the research had been invested on finding the correlations or associations between these attributes and selecting the attributes which would be a stronger candidate for aiding the predictions. Various techniques of exploratory analysis such as basic statistical graphs, heatmaps, etc. had been used for a better understanding of the data set. Once done with the exploratory analysis, the selected attributes were fed into various classification algorithms, which included: Logistic Regression, Naïve Bayes, Decision Tree, Random Forest, Linear Support Vector Machine Classifier (SVC), and Gradient Boosting Classifier. Therefore, our research focused on prototyping a model that would be able to provide valuable insights on the huge amount of patient data that is rapidly being generated all around the world.

This paper has been organized as follows: Section-II discusses the research work which were conducted on similar problems, Section-III contains the data set details and the Exploratory Data Analysis (EDA) techniques used, Section-IV demonstrates the methodologies and results, and Section-V concludes the paper.

II. RELATED WORK

Several researches have already been conducted on similar topics which provide rich guidelines on the basic idea of fusing Computer Science with Medical Science. Results of various surveys showed the impact of big data in the field of healthcare [5]. The research also included a comparison section of various tools and techniques including Hadoop, Storm, Spark, and High Performance Computer Cluster (HPCC), which provide solutions to the challenges imposed by big data.

Naïve Bayesian Classification technique was used to develop decision support in Heart Disease Prediction

System by Priyanga and Naveen [7]. With unknown input sample, Naïve Bayes Weighted Approach system classified into various sections and traced the risk of heart disease. The system was developed with 13 attributes provided by the user. The hidden knowledge could be extracted from related data.

Thomas and Princy proposed a system which predicted heart diseases using two modules: the classifier module and the prediction module. The classifier module used K-Nearest Neighbor (KNN) algorithm for classification and training, after which the second module found the risk rate using Iterative Dichotomiser 3 (ID3) algorithm. The mentioned data set consisted of 3 types of attributes: input, key, and prediction attributes [9].

While studying recent publications of emerging technologies which play a role in the healthcare sector, Miotto et al. discussed the latest applications of deep learning in the said sector which focused on biomedical data obtained from clinical imaging, genomes, etc. A tabular summary of the work done in this field using various deep learning architectures was also provided. They discussed the challenges faced, such as - data volume, temporality of the data, and the domain complexity; and scopes, such as - feature enhancement, federated inference, model privacy, incorporation of expert knowledge, and so on [4].

Soni, Ansari, Sharma, and Soni did a comparative study of data mining techniques proposed in recent years for heart disease prediction. The comparison conducted on the Cleveland data set using their Intelligent Heart Disease Prediction System showed that Decision Tree (89%) out-performed the other classification techniques, whereas Bayesian Classifier (86.53%) and Artificial Neural Networks (85.53%) also provided satisfactory results. They implemented Multilayer Perceptron Neural Network for comparison. Finally, their research showed that the results improve significantly with the use of genetic algorithm by reducing the data set to an optimal one [8].

Application of Hidden Naïve Bayes (HNB) classifier for the diagnosis of heart disease was used for testing its performance on the Statlog data set. Experimental results showed that HNB ensured comparatively better performance than other approaches. Proposed model exhibited data discretization and interquartile range filtering to enhance efficiency of HNB. The model recorded highest accuracy of 100% compared to Naïve Bayes classification model. HNB model assisted trustworthy and more authentic decision support system for automatic prediction of heart diseases [3].

The design and implementation of a worldwide medicine recommendation system framework that applies data mining technologies to the recommendation system had been proposed by Bao and Jiang [1]. The medicine recommendation system consisted of database system module, data preparation module, recommendation model module, model evaluation, and data visualization module. They researched medicine recommendation with Support Vector Machine (SVM), Back Propagation (BP) Neural Network and ID3 Decision Tree algorithm on the diagnosis data. Lastly, on the open data set, SVM recommendation model was chosen for the medicine recommendation system to get a better trade among model accuracy, efficiency, and scalability and to suggest an error checking process to ensure the accuracy and service quality.

Another study was based on an instance-based algorithm which permitted to explore big data sets by making pairwise relations between patients with metric-free method. Here each data set had ranks. By clumping these ranking orders, it was possible to conceptualize data based on each set, holding subsets of similar and correlated patients. The paper also demonstrated a visualizing tool for utilizing a database of diabetic patients. This module of a recommendation system applied the denoted algorithm to enhance data, structure patients, create relations between individuals and give recommendations [2].

III. Exploratory Analysis and Data Set

We have used the Austrian medical data set available from [6] for our research. The data set originally contained 45 attributes and 2300 rows. Table I shows some of these attributes and their classification category.

TABLE I. Some of the data set attributes and their classifitcations

Attribute	Classification	Attribute	Classification
age	numerical	pacemaker	yes/no
gender	male/female	crt-defib	yes/no
CAD-fam-history	yes/no	platelet-inhibitors	yes/no
hyperlipidemia	yes/no	oral-anticoagulants	yes/no
hypertension	yes/no	ace-at2	yes/no
NIDDM	yes/no	lipid-lowering	yes/no
smoking	yes/no/previous	diuretics	yes/no
CAD-year	numerical	beta-blockers	yes/no
chron-lung-disease	yes/no	calciumantagonists	yes/no

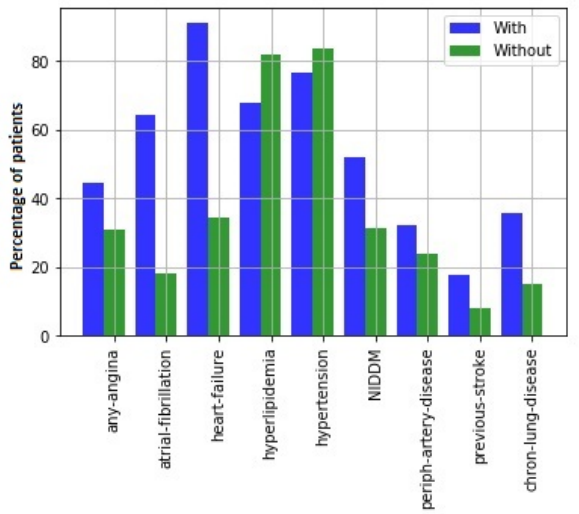
angina-episodes-week	numerical	antiarrhythm	yes/no
heart-failure	yes/no	ranolazin	yes/no
heart-rate	numerical	glycosides	yes/no
atrial-fibrillation	yes/no	long-acting-nitrates	yes/no

A. Understanding the Data Set

Exploratory Data Analysis (EDA) is a strategy for skimming data sets and seeing what information they contain. This is often done through data visualization techniques such as - statistical graphs and plots. It basically helps in summarizing the properties of the data set [10].

We plotted bar graphs to see the frequency distribution of each individual attribute with the other attributes which are supposed to have a high correlation with them. Figure 1 below shows one of these graphs which demonstrate the percentage of patients who have been prescribed glycoside. The blue bars represent the patients who have the said diseases or symptoms, while the green bars represent those who do not. From this figure we concluded that heart-failure and atrial-fibrillation seems to have a positive correlation with glycoside. According to our consultation with a cardiologist, glycosides are, in fact, used to treat congestive heart failure (CHF) and cardiac arrhythmias.

Thus we verified that our data set is consistent with actual medical definition of the said attributes.



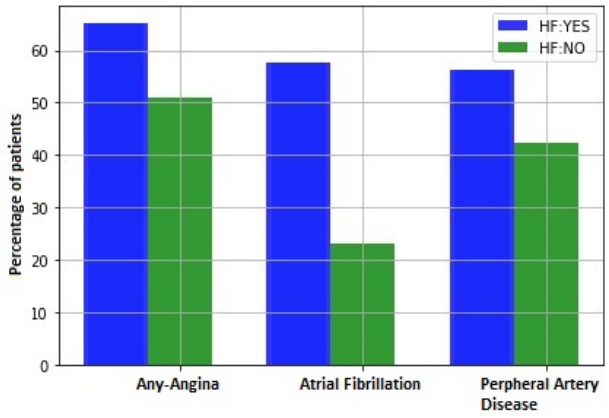


Fig. 1 Percentage of patients (who have been prescribed Glycoside) with and without the diseases and symptoms.

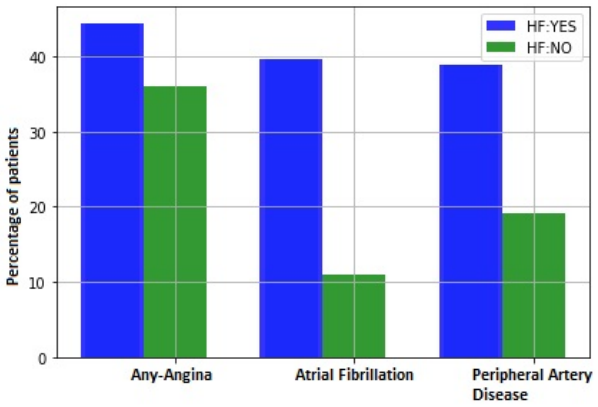
Some of the inferences made on the medicine columns on the basis of these bar graphs include:



- **Ace-At2** having a positive correlation with Hypertension, Heart-Failure, NIDDM (non-insulin-dependent diabetes mellitus), and Periph-Artery-Disease.
- **Beta-Blockers** having a positive correlation with Hyperlipidemia and Hypertension; and a negative correlation with Periph-Artery-Disease.
- **Calciumantagonists** having a positive correlation with Any-Angina, Hypertension, and NIDDM.
- **Diuretics** having a positive correlation with Heart-Failure, Atrial-Fibrillation, Periph-Artery-Disease, Previous-Stroke, Any-Angina, and NIDDM.
- **Glycosides** having a positive correlation with Atrial-Fibrillation, Heart-Failure, NIDDM, and Any-Angina; and a negative correlation with Hyperlipidemia.
- **Long-Acting-Nitrates** having a positive correlation with Any-Angina and NIDDM; and a negative correlation with Atrial-Fibrillation, Hyperlipidemia, and Heart-Failure.

Since Heart-Failure was our prime target attribute, we have plotted a different set of bar graphs for visualizing the relationship between Heart-Failure (HF) and other diseases and symptoms, separately for males and females. Figure 2 shows two of these graphs. Here, the blue bars represent the percentage of patients who have heart-failure and also have the labeled diseases, while the green bars represent the percentage of patients who do not have heart-failure but have the labeled diseases. Some of the inferences made on these graphs include:

- In case of both males and females, most of the patients who had a record of Heart-Failure also had Atrial-Fibrillation.

(a) Report for Male Patients

(b) Report for Female Patients

Fig. 2 Heart-failure correlation with respect to the three main attributes related to the heart.

- Most patients (male and female) with and without Heart-Failure report had Angina. So the correlation between Angina and Heart-Failure can be considered as weak, from these graphs.
- Whereas almost 50% of females with a Heart-Failure did not have Peripheral Artery Disease, the distinction is lower for male patients. Therefore, although we might infer that females with Peripheral Artery Disease are likely to have a Heart Failure, this cannot be said for the male patients.
- As for the other diseases, both male and female patient reports showed similar trends.
- Female patients had a higher frequency of depression than male patients.

B. Association Between Attributes

Although the graphs provided us with a primary insight on the data set, we still needed stronger evidences to confirm these hypotheses. For that we have applied various techniques to figure out which attributes are strongly associated with each other. Since most of the columns were categorical, the techniques used includes Pearson Correlation Coefficient and Spearman's Rank Correlation Coefficient.

Both Pearson-R and Spearman-R coefficients range from -1 to 1, to show negative linear correlation to positive linear correlation and a 0 to indicate zero-correlation. The problem with these methods is that they consider the attribute values as ordinal data. Since most of the attributes that we were concerned with were nominal, correlation was not quite the correct term that we were looking for. What we really wanted to see was how much the nominal attributes were associated with each other. The technique used for that purpose is Cramér's V. Figure 3 demonstrates the calculated Cramér's V coefficients for some of the attributes. In consideration of the values obtained, we decided on a threshold value of 20%.

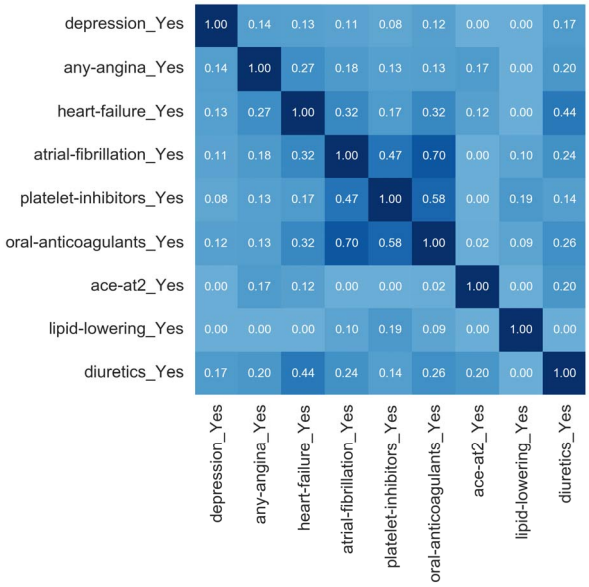


Fig. 3 Heatmap showing the Cramer's V coefficients of some of the attributes.

Some inferences based on the Cramér's V coefficients include:

- **Heart-Failure** has a strong association with Peripheral Artery Disease, Chronic Lung Disease, Angina, Atrial Fibrillation, Oral Anti-Coagulants, Diuretics and Glycosides.
- **Platelet Inhibitors** have a strong association with Atrial Fibrillation, Oral Anti-Coagulants and Glycosides.
- **Oral Anti-Coagulants** have a strong association with Gender, Heart-Failure, Atrial Fibrillation, Platelet Inhibitors, Diuretics and Glycosides.
- **Ace-At2** has a strong association with Hypertension and Diuretics.
- **Lipid Lowering** has a strong association with Hyperlipidemia

C. *Data Set Preprocessing*

From Table II, we can see that 23 of the selected attributes had at least 20% or more of the data missing. We could not directly eliminate these attributes since most of them were vital for the purpose of our research. The only columns dropped from this survey were: nitro-week, platelet-inhibitors-dual, CAD-year, beta-blockers-dosis, CAD-fam-history, angina-episodes-week, smoking, physical-activity, crt-defib, pacemaker and angina class.

For the rest of the attributes, we also could not just drop the missing rows since that would drastically decrease the size of our data. Therefore, we used Logistic Regression Classifier to predict the missing data using the 13 attributes with the least missing data rate. We used One-Hot Encoding before proceeding with the algorithm. Table III shows the iteration accuracy rates of each of these predicted attributes.

TABLE II. PERCENTAGE OF MISSING DATA FOR SOME ATTRIBUTES

Attribute	Percentage	Attribute	Percentage
calciumantagonists	0.000	hyperlipidemia	57.460
beta-blockers	0.000	crt-defib	57.503
age	0.695	ace-at2	57.721
heart-rate	1.304	physical-activity	57.721
hypertension	1.739	glycosides	57.808
NIDDM	2.001	molsidomin	58.025
nicorandil	3.392	oral-anticoagulants	58.199
chron-lung-disease	3.915	ranolazin	58.199
depression	4.393	previous-stroke	58.330
long-acting-nitrates	4.524	smoking	58.504
ivabradin	4.828	platelet-inhibitors-dual	58.504
periph-artery-disease	4.915	CAD-year	59.983
any-angina	14.702	heart-failure	60.244
angina-class	21.096	antiarrhythm	60.853
beta-blockers-dosis	30.187	diuretics	63.245
pacemaker	56.633	angina-episodes-week	70.987
lipid-lowering	56.633	CAD-fam-history	73.032
atrial-fibrillation	56.851	nitro-week	88.212
platelet-inhibitors	57.460		

TABLE III. ITERATION ACCURACIES OF PREDICTED ATTRIBUTES

Attribute	Iteration Accuracy
Heart-Failure	0.80
Lipid-Lowering	0.94
Atrial-Fibrillation	0.92
Platelet-Inhibitors	0.88
Ace-At2	0.94
Hyperlipidemia	0.94
Glycosides	0.88
Molsidomin	0.90
Oral-Anticoagulants	0.88
Ranolazin	1.00
Previous-Stroke	0.92
Diuretics	0.86
Antiarrhythm	1.00

After filling out the missing values, we dropped the columns - Antiarrhythm and Ranolazin because their unnaturally high accuracy rates were owing to the fact that most of their rows had a "No" classification.

After taking all these measures, our final processed dataset had a total of 25 attributes and 1614 rows (without any missing values). In order to check the reliability of this semi-synthesized dataset, we ran the Cramer's V on it. Comparing this new heatmap (figure 4) with the one obtained before, it was seen that although the values changed (due to an increase in data size), the relative association between the attributes remained very similar. Therefore, we concluded that this new dataset was in fact, consistent with the original dataset and thereafter, we proceeded with the machine learning algorithms.

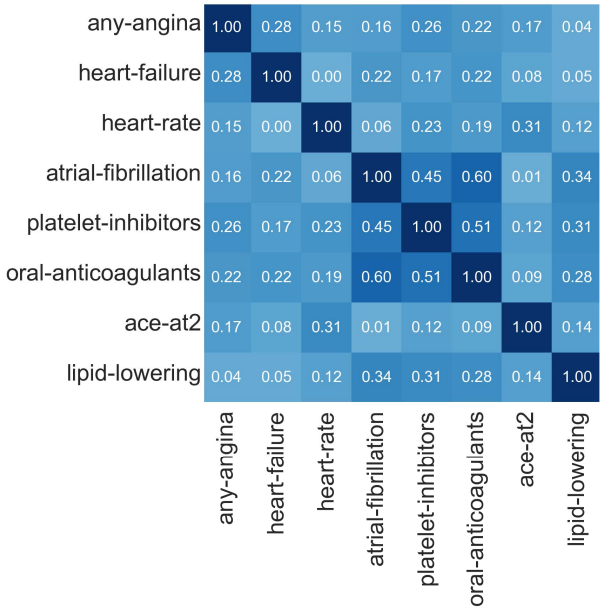

Fig. 4 The new Heatmap showing the Cramer's V coefficients of some of the attributes of the semi-synthesized dataset.

IV. Methodology and Results

A. Classifiers and Evaluation Techniques

We have used Logistic Regression (LR), Naïve Bayes (NB) (Bernoulli's Naïve Bayes to be more precise), Decision Tree (DT), Random Forest (RF), Linear Support Vector Classifier (SVC) and Gradient Boosting Classifier (GBC) for our comparative study.

The standard model evaluation criteria used includes: Accuracy, Precision, Recall, F1-Score, and Area under ROC (Receiver Operating Characteristic). Equations 1, 2 and 3 represent the equations for Precision, Recall and F1-score respectively, where TP, FP and FN stands for True-Positive, False-Positive and False-Negative, respectively.

$$\text{Precision} = \frac{TP}{TP+FP} \quad (1)$$

$$\text{Recall} = \frac{TP}{TP+FN} \quad (2)$$

$$F1 = \frac{2(\text{Recall} * \text{Precision})}{\text{Recall}+\text{Precision}} \quad (3)$$

B. Hyperparameter Tuning

Our data set was randomly divided into two parts: 80% for training and validating the model, and 20% for testing. The data separated for training and validation were then used to tune the models, to figure out the optimum parameters for each classifier. The validation parameters were set to 10 fold cross-validation, with a maximum of 50 iterations. After the best model was selected for each classifier, they were once again tested on the entire data set, with a cross-validation of 10 folds.

C. Results

Tables III and figure 5 demonstrates the obtained evaluation readings during the modelling and testing phase. The model accuracy is highest for Logistic Regression and Decision Tree, followed by Gradient Boosting Classifier. The difference between accuracy rates of model performance and test performance is the least for Gradient Boosting Classifier, whereas it is the highest for Decision Tree. Despite the fact that Random Forest is an upgradation of Decision Tree, the overall model performance turned out to be better for Decision Tree, than for Random Forest. Naïve Bayes and SVC, on the other hand, showed similar model performance. Their test scores were also quite close. The test performance usually signifies how well the model performs on unexplored data. In our case, however, since the data size was not that big, a small portion of the test data was unexplored. In any case, the best performer among the six algorithms turned out to be Logistic Regression, closely

TABLE III. Model Performance

Algorithms	Accuracy	Precision	Recall	F1-Score	AUC
LR	0.91	0.92	0.91	0.91	0.88
NB	0.83	0.83	0.84	0.83	0.74
DT	0.91	0.92	0.92	0.92	0.87
RF	0.89	0.89	0.89	0.89	0.89
SVC	0.83	0.83	0.84	0.83	0.78
GBC	0.90	0.90	0.90	0.90	0.86

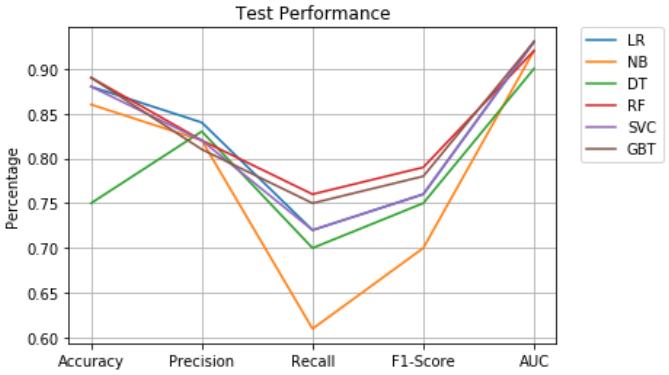

Fig. 5 Test Performance Comparison of the Algorithms.

followed by Gradient Boosting Classifier, Random Forest and SVC. Therefore, our system could predict the chances of a heart-failure and recommend medicines at the maximum model accuracy rate of 91% and test accuracy rate of 88% by using the Logistic Regression model.

D. Analysis

Logistic Regression applies logistic functions in order to map the predictions between the binary numbers 0 and 1. Since these models are still somewhat linear, they usually perform well when the data classes can be separated by a single decision barrier. Hence, it outperformed the other algorithms when run on this particular dataset. As for the classification trees, since they are designed to deal with non-linear decision boundaries, they force every variable in the tree to interact with every other variable. This can lead to poor predictions when the attributes are weakly correlated. The reason why SVC did not perform as well as Logistic Regression, could be that they are usually trickier to tune. In case of Naïve Bayes, on the other hand, it was no surprise that the other algorithms performed better. Since NB is far too "naive" or simple, other fine-tuned algorithms often get the upper hand.

V. CONCLUSION

With the aim to help Cardiologists take quicker decisions, we have tried to build a system that would predict the chances of a heart failure based on the patients' reports and also suggest a medicine list that would be most suitable for the patient. For our research we have used an Austrian medical data set which originally contained 45 attributes and 2300 rows. After completing Exploratory Data Analysis and data preprocessing, we were left with a total of 25 attributes, 1614 rows and a list of attributes that would be the best candidates for each predictive sub-system. Next, we used these features to predict our target attributes, namely - Heart Failure, Platelet Inhibitor, Oral Anticoagulant, Ace-At2, Lipid-Lowering, Diuretic, Beta-Blocker, Calciumantagonist, Ivabradin, Nicorandil, Molsidomin and Long Acting Nitrates. The algorithms used included Logistic Regression, Naïve Bayes, Decision Tree, Random Forest, Linear SVC and Gradient Boosting Classifier. Best model and test performance was attained by Logistic Regression, followed by Gradient Boosting Classifier and Decision Tree.

In order to make our model capable of handling big data, the final model was coded using the Apache Spark framework. It is an open source cluster computing framework which supports Hadoop Distributive File System (HDFS). The Python's API for Spark, known as PySpark, was used. It currently supports all the classifiers mentioned above.

***Abstract*—Consensus string is the most frequent common pattern in a set of string. Consensus string is an important feature of DNA sequence. Many algorithm have been introduced to discover consensus string. Among them, median string algorithm is the most popular one. Basically, that is a brute force algorithm.DNA sequence is composed of a series of four letter alphabet ∑={a,c,g,t}. If the size of the consensus string is l, then the algorithm generates all the 4^l number of l length strings called motifs or l-mer. Then try to fit the motifs one by one with the sequence. In this paper we have discovered a way to reduce the search space using chapman kolmogorov relation. We found that, the proposed system can find the same consensus string within a shorter period of time than the time taken by the median string algorithm. As the l-mer size increases, the proposed system takes much less time than the median string algorithm. For l-mer size 7, we found the proposed system is 47 times faster than the median string algorithm.**

Keywords—DNA,consensus, motif,chapman-kolmogorov

I. INTRODUCTION

Gene regulatory binding motifs are short DNA sequences that control gene expression. The length of these motifs, are 6-15 base pare long. These motifs do not contain any specific starting and end point. Gene regulatory binding motifs can start from anywhere within the DNA sequence. Since the starting point is unknown, the end point also is unknown. The only difference between regulatory motif and random sequence of an equivalent length is that, regulatory motifs occur more frequently than random sequence. The location of regulatory motif may vary from sample to sample. Frequency of these motifs, also vary from sequence to sequence. To discover such regulatory motif from a DNA sequence involves finding such a continuation of pattern [1]. This can be illustrated in Fig. 1.

Any DNA sequence is a sequence of four symbol like a, c, g, and t. Searching for a particular motif in a DNA sequence involves searching a short pattern over the alphabet ∑={a,c,g,t}. The main idea of motif search can be divided into two parts a) exploitation of appropriate model for representation of motif sequence b) formulation of algorithm for motif search. The most widely used motif models are position weight metrics[2] and consensus sequence[3].Position weight metric typically use statistical method, report in a short time but there is no guarantee about a global optimum[4,5,6]. Exact algorithms use consensus model.

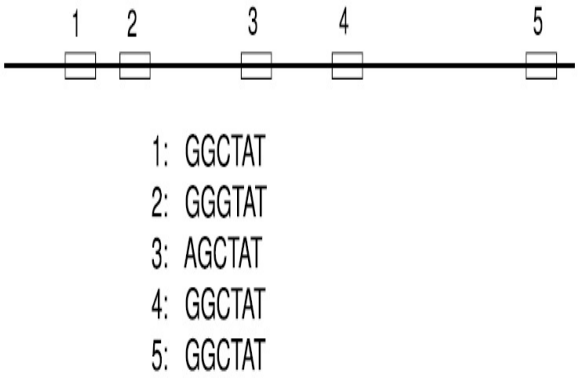

Fig. 1. Consensus string.

Most of the exact algorithms takes all string patterns of length l over alphabet ∑ as candidate motifs, and output the common pattern in all input sequences. In case exact algorithms, initially the search space is $O(|\Sigma|^l)$, that grows dramatically with the rise of $|\Sigma|$. As a result, most exact algorithms are developed for sequences where |∑|=4. But in case of protein data set where |∑|=20, these algorithms cannot find a low conserved motif within a reasonable time.

The idea of motif stem increased the potency of exact algorithms over large alphabet[7]. Consensus string (or closest string or center string) issues are to search out a representative string of a given set S of strings. The consensus issues are major issues in multiple string comparison and have been researched extensively [8,9,10,11,12,13,14,15] to unravel several issues arising in computational biology like motif finding, PCR primer style, and genetic probe style. Since most of the consensus issues are NP-complete, researchers even have designed fixed-parameter algorithms [10,16,17,18] approximation algorithms [13,17,19,20,21,22,23] and algorithms for a short range of strings [10,24,25].

II. MEDIAN STRING ALGORITHM FOR MOTIF SEARCH

Median string algorithm takes as input a set of t DNA sequences. It then generates all possible *l-mers* of length l. Since there are only 4 types of nucleotides in a DNA sequence, the number of all possible *l-mers* is 4^l. Then it starts from the start of each sequence, goes to the end by placing each *l-mer* and calculate distance. In this way for each *l-mer* ,

the minimum distance between the *l-mer* and each row is calculated. The sum of minimum distance of all the rows for a particular *l-mer* is the minimum distance of the *l-mer* with the DNA sample. In this way, the minimum distance for all the *l-mers* is calculated. The *l-mer* with lowest distance is the consensus string. The algorithm is listed below:

Median_string_search()

```
{inputs: DNA,t,n,l
 output: bestword
 procedure:
 MedianStringSearch (DNA, t, n, l)
        bestWord ←AAA…A
        bestDistance ←∞
           for each l-mer s from AAA…A to TTT…T
                 if TotalDistance(s, DNA) < bestDistance
                    bestDistance←TotalDistance(s, DNA)
                    bestWord ← s
          return bestWord
}
```

In median string algorithm, all the 4^l combination of *l-mers* need to be examined. When the length of *l* increases, the number of candidate *l-mers* increase according to 4^l the execution time also increases. But all the 4^l *l-mers* are not significant. A significant amount of the generated 4^l *l-mers,* will not be the consensus. Even some candidate motifs can be found in no sequence. Those motifs got generated as a result of permutation and combination. For those motifs too, median string still perform calculation and contribute to the time complexity. In this paper, we introduced chapman-kolmogorov relation to exclude insignificant candidate motifs and reduce the time complexity of median string algorithm.

III. Chapman-Kolmogorov Relation

A time series of random variables is said to be a markov chain if it has the following property:

$$P(X_t = x_t | X_0 = x_0, X_1 = x_1, \ldots\ldots\ldots, X_{t-1} = x_{t-1}) \qquad (1)$$

It is said to be homogeneous or stationary if it also satisfies

$$P(X_t = z | X_{t-1} = y) = P(X_{t+k} = z | X_{t+z-1} = y) \forall k \geq 0 \quad (2)$$

In other words, the time series of random variable is markovian if the future value of the random variable depend only on the value of random variable has at the present time. The value of the random variable in the future must be independent of the values that it had in the past. We showed that one time series of random variables have these property their behavior can be represented by a graph like the one shown in Fig. 2.:

The possible values that the random variables can have are shown in circles, so in this example the random variables can have the values A, B and C. Instead of talking about the values that the random variables can have though, we state the circles represents the states the system can be in.

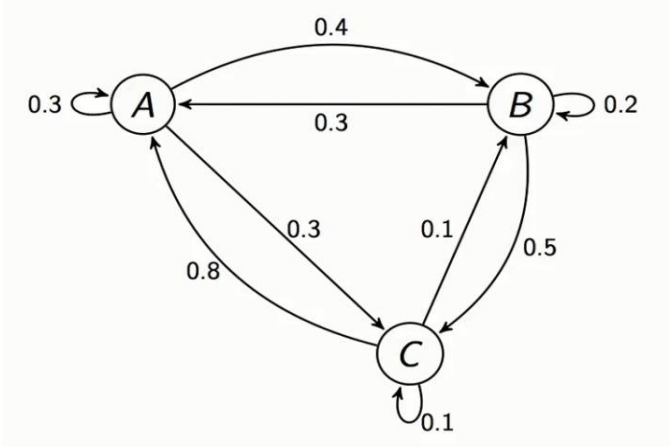

Fig. 2. Markov chain

The circles that represent states are connected by arrows and above these arrows numbers between 0 and 1 appear that represents the probability of moving between the states in a single time step. In this example the probability of moving from state c to state a is 0.8 in a single time step. Alternatively we might state the probability that a random variable has value c followed by a is equal to 0.8. From this markov chain, we can construct a transition probability matrix. We said that the rows in the matrix represent the initial states the system is in and the columns represents the states where the system moves at the next step. The position (a,b) in the matrix shows the probability of moving from state a to state b.

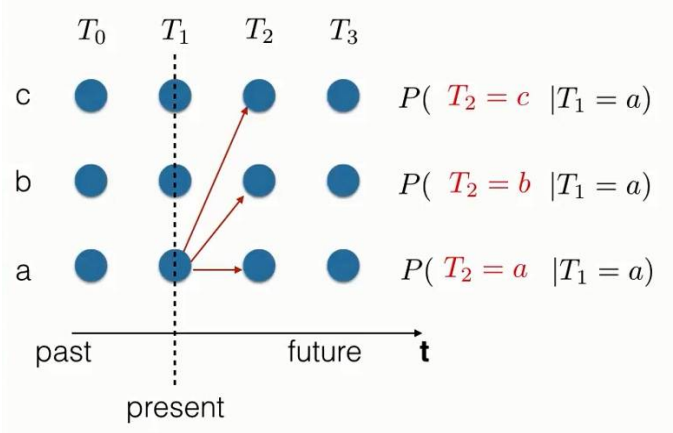

Fig. 3. One step transition

We now know how to obtain probability of T_2 being equal to a,b,c if T_1 =a. We can read this information either from the transition graph or from the one step transition probability matrix. What we would like now is to determine the conditional probability that T_3 takes on these three different values. In other words we would like to know, whether or not we can make prediction about the state of the system after two

or more time steps rather than after a single step. To see how, let us first consider the probability to the following happens in the future. We start with T_1=a, then move to T_2=c then again move to T_3=b. We know that we can get the probability of a single step from a to c from the transition matrix. Once we arrive in state c , i.e T_2=c, the system immediately forgets that T_1 was equal to a. The process is after all markovian and the state of the system was in the past do not affect the probability of the states in the future. Once we have moved from T_1=a to T_2=c, T_2=c becomes the present state of the system. As a consequence of this, we can also get the probability of the second transition T_2=c to T_3=b from the one step transition probability matrix. Because of the markov property, the event of moving from state T_1=a to T_2=c is independent of the event of moving from state T_2=c to T_3=b. The markov property ensures that the system immediately forget everything that happened in the past as soon as that is happened. Thus two adjacent transition are completely independent of each other. The only thing that affect the value of T_3 is the value of T_2. Now remember that we can obtain the probability that two independent event occur by multiplying the individual probability. Consequently for this particular problem, we can calculate the probability that the system will be moving from T_1=a to T_2=c then from T_2=c to T_3=b by multiplying the conditional probability T_3=b given T_2=c.

Let's now suppose, we want to calculate the probability for moving from state a to state b over two steps. There are three ways that can happen. We can go from state a to state c then on to state b. We can go from state a to state b then remain in state b. We can remain in state a for one step and then transfer to state b. The probability of each of the paths is shown in fig.

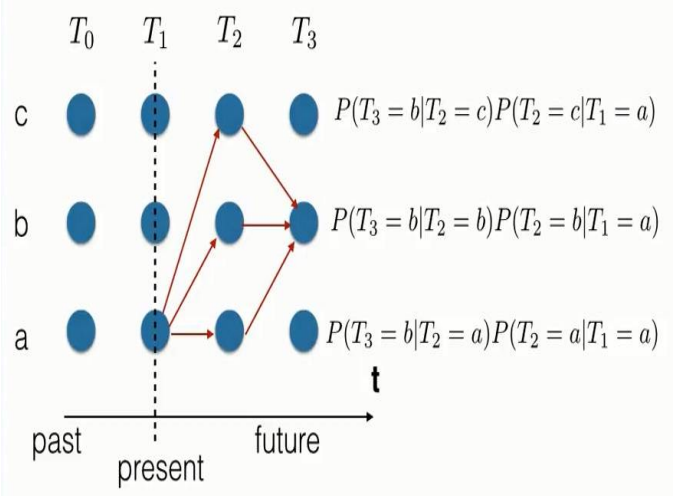

Fig. 4. Two step transition

Each of these pathway is mutually exclusive. As the random variable T_2 can only have one value, it cannot have two value simultaneously. We can thus obtain the total probability of moving from step a to step b over the course of two step by adding the probabilities of each of the paths. If we have only three steps, we can write everything explicitly. If we have more than three steps we can write that as a series notation like Eq

.

$$P(T_3 = b|T_1 = a) = \sum P(T_3 = b|T_2 = x_n)P(T_2 = x_n|T_1 = a) \quad (3)$$

This sum here rounds up all the possible value that the random variable T_2 can take. This sum of product is nothing more than the definition of the matrix product. Because the markov chain is homogeneous, the first matrix and second matrix are identical. We can thus obtain the two step probability matrix by multiplying the one step probability matrix by itself. In general,

$$A^{m+n} = A^m A^n \quad (4)$$

This is what is called chapman kolmogorov relation.

IV. Chapman Kolmogorov Relation Based Median String Algorithm

Consider a database with 10 data samples ($S1,S_2,\ldots\ldots,S_{10}$). Each sample is compose of 80 nucleotides.

TABLE I. DNA Data Set

SID	Sample
S_1	tagtggtcttttgagtgtagatctggagggaaagtatttccaccagttcggggtcacccagcaggcagggtgacttaat
S_2	cgcgactcggcgctcacagttatcgcacgtttagaccaaaacggagttggatccgaaactggagtttaatcggagtcctt
S_3	gttacttgtgagcctggttagacccgaaatataattgttggctgcatagcggagctgacatacgagtaggggaaatgcgt
S_4	aacatcaggctttgattaaacaatttaagcacgtaaatccgaattgacctggtgacaatacggaacatgccggctccggg
S_5	accaccggataggctggttattaggtccaaaaggtagtatcgtaataatggctcagccatgtcaatgtgcggcattccac
S_6	tagattcgaatcgatcgtgtttctccctctggtggttaacgaggggtccgaccttgctcgcatgtgccgaacttgtaccc
S_7	gaaatggttcggtgcgatatcaggccgttctcttaacttggcggtgcagatccgaacgtctctggaggggtcgtgcgcta
S_8	atgtatactagacattctaacgctcgcttattggcggagaccatttgctccactacaagaggctactggtgtgatccgta
S_9	ttcttacacccttctttagatccaaacctgttggcgccatcttcttttcgagtccttgtacctccatttgctctggtgac
S_{10}	ctacctatgtaaaacaacatctactaacgtagtccggtctttcctggtctgccctaacctacaggtcgatccgaaattcg

From this database we can construct a transition matrix like the following:

$$Transition = \begin{array}{c|cccc} & a & c & g & t \\ a & 49 & 39 & 46 & 50 \\ c & 48 & 46 & 39 & 56 \\ g & 40 & 48 & 58 & 53 \\ t & 48 & 55 & 56 & 59 \end{array}$$

Fig. 5. Transition matrix

The transition matrix contains the number of occurance of each of the sixteen possible digrams in the database. For

example Transistion(1,1)=49, that means there are 49 aa in the database. Similarly, Transition(4,4)=59, which means there are 59 tt in the data base. There are total 790 digrams in the database. Dividing all the elements of the matrix by sum of element, produces transition probability matrix like Fig. 6. A[i,j] represents the probability of transition from position *i* to position *j*.

```
A=      a           c           g           t
   a[0.06202532 0.06075949 0.05063291 0.06075949]
   c[0.04936709 0.05822785 0.06075949 0.06962025]
   g[0.05822785 0.04936709 0.07341772 0.07088608]
   t[0.06329114 0.07088608 0.06708861 0.07468354]
```

Fig. 6. Transition probability matrix

In this matrix A(1,1) indicates the probability of finding an a after a, A(2,3) indicates the probability of finding a g after c etc. If we multiply A by itself, we will have a matrix that indicates the probability of occurance of a particular nucleotide at the second step after a particular nucleotide. let us suppose, we are searching for 5 nucleotide sequence i.e our l-mer size is 5. In this case, if we multiply A by itself by 4 times, we will have a matrix like Fig. 7. This matrix contains the probability at fifth position.

```
A⁵=     a           c           g           t
   a[9.18004782e-07 8.28077016e-07 3.32785581e-07 8.28077016e-07]
   c[2.93215942e-07 6.69350669e-07 8.28077016e-07 1.63560335e-06]
   g[6.69350669e-07 2.93215942e-07 2.13306707e-06 1.78980072e-06]
   t[1.01558100e-06 1.78980072e-06 1.35907646e-06 2.32340330e-06]
```

Fig. 7. Transition probability matrix after five step.

This matrix indicates the probability of occurance of a particular nucleotide after 5 step of a particular nucleotide. For example, A(1,1) indicates the probability of occurance of an a after five step of an a. There are 16 elements in the matrix. Summing all the elements and then dividing that value by 16 we will get a threshold value. For the values that are greater than the threshold value, placing a 1 at that location and placing a 0 at other location we will have another matrix like Fig. 8. We can call this a significant matrix S. This matrix tells which transitions are significant and which transitions are not. The significant matrix contains 0's at some positions and 1's at some positions. 0's means insignificant, where as 1's mean significant.

```
S=     a  c  g  t
   a[0. 0. 0. 0.]
   c[0. 0. 0. 1.]
   g[0. 0. 1. 1.]
   t[0. 1. 1. 1.]
```

Fig. 8. Significant matrix

Having the significant matrix, we generate some rules acc ording to the significant matrix. For example, S(2,4)=1 means that the rule c→t is significant, S(3,4)=1 means rule g→t is sig nificant, S(2,3)=0 means rule c→c is insignificant etc. As per t he significant matrix, generated rules are listed in table II.

TABLE II. GENERATED RULES

First element (l_1)	Second element(l_2)	Count	Rule
c	t	56	c→t
g	g	58	g→g
g	t	53	g→t
t	c	55	t→c
t	g	56	t→g
t	t	59	t→t

From these rules, we can generate some motif of length 5. Any motif must start either from a or c or g or t. We will have four trees for motifs starting with four nucleotide. For exampl e one tree is depicted below in Fig. 9.

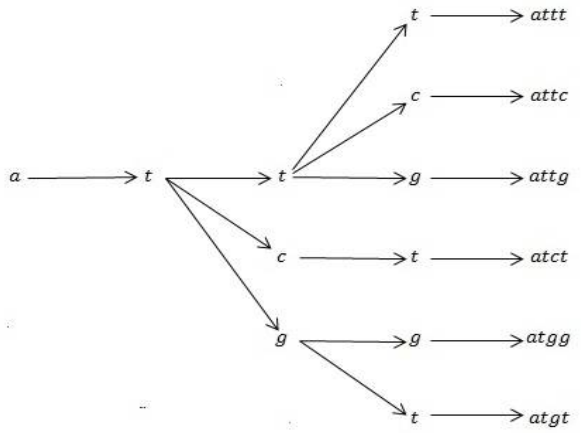

Fig. 9. Motif generation tree

From all the four trees, we will have a short list of motifs which is much shorter than 4^l. We will now use this short set of motifs as the search space of median string algorithm.

V. RESULT AND IMPLEMENTATION

To check the idea behind this concept, we have used Jupyter Notebook as Python programming language. The system configuration is:

- Processor: Intel core i7 CPU
- Clock rate:3.6 GHz
- HardDisk:1000GB
- RAM:8GB

Chapman Kolmogorov relation based median string algorithm accelerates the whole process easy and faster. We have compared the performance of Chapman Kolmogorov relation based median string algorithm with the performance of median string algorithm. In this demonstration we have compared the number of motifs generated by Chapman Kolmogorov relation based median string algorithm and median string algorithms for different *l-mer* size. Since our proposed system produces a only the significant motifs, for all l-mer size the number of motifs generated by the proposed system are found to be shorter than those produced by the

median string algorithms. The scenario is depicted in the table III.

TABLE III. NUMBER OF GENERATED MOTIFS

l-mer Size	Number of Motifs (Chapman Kolmogorov Relation Based)	Number of Motifs (Median String)
2	6	16
3	14	64
4	31	256
5	70	1024
6	157	4096
7	353	16784

The table narrates the results of both the methods used here. The results are the number of motifs generated by both the methods for different *l-mer* size. For *l-mer* size 2, Chapman Kolmogorov relation based system generates 6 motifs whereas Median string algorithm generates 16 motifs. So for *l-mer* size 2, Markov chain based system is (16-6)/6=1.66=166% better than Median string based system.

For *l-mer* size 3, Chapman Kolmogorov relation based system produces 14 motifs and Median string produces 64 motifs. Hence Chapman Kolmogorov relation based systems performance is (64-14)/14=3.57=357% better than median string performance. For *l-mer* size 5 , Chapman Kolmogorov relation produces 70 motifs and Median string produces 1024 motifs, as result Chapman Kolmogorov relation based system is (1024-70)/70=13.62=1362% better than Median string. For last data set the difference between two system reaches 4654%.So it is clear that, as the length of *l-mer* increases, Chapman Kolmogorov relation based system will produce comparatively more less number of motifs than the median string algorithm. The graphical analysis in Fig. 10. also reflects the same impact. The gray line is gradually in upward trend for Median String outcome and the blue line is the Chapman Kolmogorov relation based system outcome.

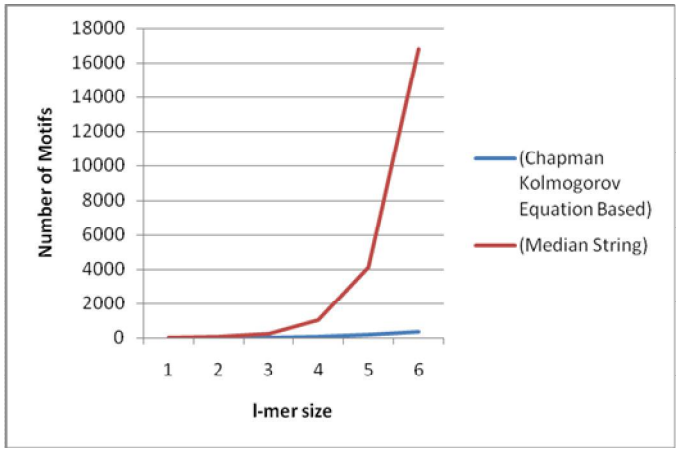

Fig. 10. Number of motifs generated

Same datasets have been imposed on core i7 computer with higher storage and RAM. In that case the processing time of Chapman Kolmogorov relation based system are also less than Median string based processing time.

We have checked every level time consumed by both methods. Median string method takes huge time for DNA consensus. Time consumed by these two methods convey their strengths

TABLE IV. TIME COMPARISION

l-mer Size	Chapman Kolmogorov relation Based Time(ms)	Median String Time(ms)
2	2.57	6.6
3	6.86	30.4
4	16.8	135
5	41.4	590
6	97.4	2590
7	236	11100

Every rows of the table IV demonstrates that Chapman Kolmogorov relation based Median string algorithm consumed less time than Median string orientation. For *l-mer* size 2, the time difference is (6.6-2.57)ms=4.03 ms. It is about 4.03/6.6=61% of the estimated time. That indicates that, Chapman Kolmogorov relation centric Median string finds DNA consensus faster than ordinary Median string algorithm. The time differences have been increased as the length of *l-mer* size increased. From the last row, Chapman Kolmogorov relation based analysis consumed 236 ms whereas ordinary median string algorithm consumed 11100 ms. There are 10864 ms difference for *l-mer* size 7. However it can be applicable for small *l-mer* size too. When *l-mer* size increases, we should consider Chapman Kolmogorov relation based system. In Fig. 11.we can see that, as the l-mer size increases, the time taken by the proposed system is much less than the time taken by the ordinary median string algorithm . Because the proposed system only produces significant motifs.

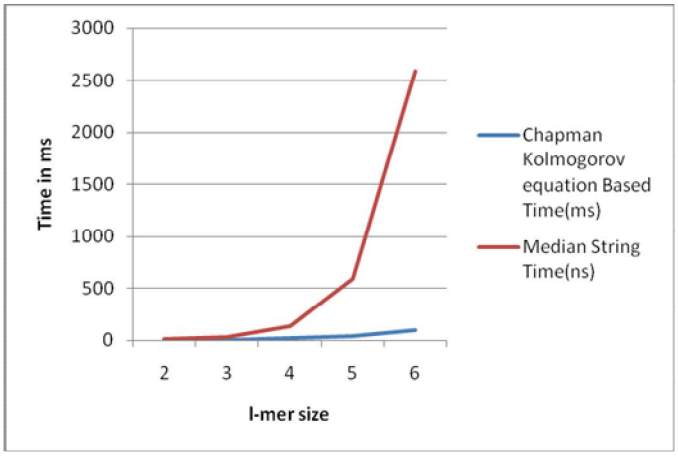

Fig. 11. Time comparision

VI. Conclusion

Median string algorithm generates all the 4^l number of l-mers, then fits each l-mer with the database and calculate the distance. In course of generating the l-mers, median string algorithm, generates significant and insignificant l-mers. Though this process takes much time but this is a certain process. Since we can generate a markov chain from the DNA data set, then also can find the chapman-kolmogorov relation. From this relation we generated a set of rules. Using that rules we produced a reduced set of significant motifs. Since the search space has been reduced, the proposed system takes much less time to find the consensus string. The way we have applied chapman-kolmogorov relation, there might be some other way of application. We believe that, further research may find some other way of application of chapman kolmogorov relation that may reduce the set of rules as well as number of generated motifs. We are working on that ground.

***Abstract*— Clustering is the identification of similar data from a rough or scaled or transformed data and grouping into clusters. Cluster shows symmetry and asymmetry of data and its relations. In this paper, comparisons of three fuzzy clustering algorithms and two conventional clustering algorithms are represented. The analysis is conducted on four datasets which include three gene expression datasets. Here, clustering performance is evaluated using both internal and external validation measurements and an attempt for searching the optimum number of the cluster has taken. This analysis provides an effective way of selecting a suitable algorithm for a particular dataset among different hardcore and soft-core clustering approaches.**

Keywords*— *Cluster analysis; Fuzzy C-Means; K-Means; K-Median; GG; GK;

I. INTRODUCTION

Clustering is the separation of the elements of a dataset in different groups by ensuring similarity in a group and dissimilarity between groups. For categorizing the data, firstly characterization and variation in their attributes are studied. This task is challenging for unknown datasets. Hard and soft clustering algorithms have been developed based on distance measurement techniques. Established algorithms for finding out the behaviour of the datasets, extracting meaningful information and to reveal the underlying hidden pattern are hierarchical clustering, partitioning clustering, clustering based on density and clustering based on grid etc. The challenge is in choosing a suitable algorithm for a given dataset for an optimal and feasible solution. Choosing the optimal number of clusters for a particular combination of algorithm and dataset is another challenge. The optimal number of cluster varies from the dataset to dataset and even a particular dataset may produce different results with a variety cluster numbers. So, there is a need to compare the performances of clustering techniques on various datasets to find out their behaviour.

In this paper, a comparative analysis of hard and soft clustering algorithms are presented. K-Means and K- Median are the representative of hardcore clustering and Fuzzy C-Means, Fuzzy K-Means, Gath- Geva clustering (GG) and Gustafson- Kessel algorithm (GK) are of soft or fuzzy clustering. Wisconsin Breast Cancer, Iris, Leukemia and Motor Cycle datasets have been used for performance evaluation. Structural nature of a dataset is revealed by accurate clustering. Cluster accuracy is ensured by minimizing the classification error rate, picking the optimum number of clusters and validated by validation measurement techniques. The following sections describe the comparative studies of selected clustering algorithms.

II. LITERATURE REVIEW

According to Daxin Jiang, Chun Tang, Aidong Zhang [1], the clustering process is useful for subtypes of cells, gene function, and gene regulations. The fuzzy clustering is used widely on the real-time dataset, multivariate dataset, gene expression dataset etc. [1]. For the analysis of Breast Cancer dataset, a comparative study between K- Means and Fuzzy C-Means was conducted by A Sathish and J Mohana Skundaram [2]. According to Anil K. Jain, clustering has a rich and long history in different scientific fields [3]. In spite of the fact that almost 50 years ago K-Means was proposed and since then, thousands of clustering algorithms have been published but K-Means is still in use [3]. This expresses the difficulty of designing a clustering algorithm whatever it is a general purpose or not and the ill-posed problem of clustering using Different distance measurements such as Mahalanobis distance based fuzzy clustering was established by Hsiang-Chuan Liu, Bai-Cheng Jeng, Jeng-Ming Yih, and Yen-Kuei Yu [4]. Ms Aparna K and Dr Mydhili K Nair [6] studied different partition clustering techniques which provide a glance at the recent problems. According to A. J. Patil, C. S. Patil, R. R. Karhe and M. A. Aher [7], K-Means and FCM, both are sensitive to the outliers and have higher noise ratio. Advancements in fuzzy clustering were done by introducing a mapping function in KFCM (Kernel Fuzzy C-Means). They compared the K-Means algorithm with the FCM algorithm. To overcome the limitations of FCM, they studied Kernel Fuzzy C-Means (KFCM) algorithm. Neha Soni and Amit Ganatra [8], also conducted a comparative study of clustering algorithms. V. Leela, K. Sakthi Priya and R. Manikandan [9], gives comparative studies based on Iris dataset. Shraddha K. Popat and Emmanuel M. [10], illustrated the various clustering and similarity measurement techniques and the types of clustering techniques. O. A. Mohamed Jafar and R. Sivakumar [11] also conducted a comparative study based on hard and fuzzy clustering algorithms with validity indices. The Fuzzy C-Means algorithm is a soft version of K-Means algorithms and Fuzzy K-Means is the modified version of K-Means. Besides, Gath-Geva clustering algorithm (GG) and Gustafson- Kessel clustering algorithm (GK) are also available. Jyotismita Goswami [12] found the suitability of the application of the K-Means algorithm. The K-Means algorithm falls in one of the partitioning methods [12]. The K-Medoids is another partitioning algorithm [12]. Others variations of K-Means and related algorithms are Minimum Spanning Tree Algorithm, Bond Energy Algorithm, GA based clustering etc. Few variations of the partitioning

algorithms are Genetic K-Means Algorithm (GKA), Fast Genetic K-Means Algorithm (FGKA), Incremental Genetic K-Means Algorithm (IGKA), Genetically Guided Algorithm (GGA), Hybrid Genetic-based clustering algorithm (HGA-clustering), Semi-Supervised clustering algorithm, K-Means Fast Learning Artificial Neural Network (KFLANN), Single Program Multiple Data (SPMD) and Genetic Weighted K-Means Algorithm (GWKMA). Nidhi Grover [13] illustrated various fuzzy clustering algorithms like Fuzzy C-Means Algorithms (FCM), Fuzzy Possibilistic C-Means Algorithms (FPCM) and Possibilistic C-Means Algorithm (PFCM) along with suitability of the methods. PCM enables noisy data clustering but it is very sensitive for initialization. To overcome the problems of Possibilistic C-Means, Fuzzy Possibilistic C-Means algorithms, Pal and Bezdek integrated features of PCM & FCM and FPCM, PFCM algorithms were proposed by pal [14]. Q. Huang, X. Huang, Z. Kong, X. Li and D. Tao[15], developed an evolutionary biclustering algorithm BP-EBA which consist of two phases where the first one is rows and columns evolution and the second one is bicluster evolution. Lu, H., Chen, J., Yan, K., Jin, Q., Xue, Y. and Gao, Z. [16], developed a hybrid algorithm by bringing together the Mutual Information Maximization (MIM) and the Adaptive Genetic Algorithm (AGA).

III. ALGORITHMS AND DATASETS

K- Means, K-Mediods, Fuzzy C-Means, Gustafson-Kessel and Gath-Geva clustering algorithms have been used for the analysis of Wisconsin Breast Cancer, Leukemia, Iris and Motor Cycle dataset[5]. The Principal Component Analysis is used for normalizations, visualization and reducing the dimensionality of the dataset. By applying PCA, the principal components of the dataset are extracted out.

IV. DATA PREPROCESSING
